Abstract: Dry age-related macular degeneration (AMD) is characterized by the accumulation of drusen and degeneration of photoreceptor cells and retinal pigment epithelial (RPE) cells in and around the macula. It has been proposed that phagocytic and lysosomal dysfunctions in RPE cells, which hinder the degradation of shed photoreceptor membranes, contribute to these pathological changes. According to our previous studies, raising intracellular zinc levels can restore lysosomal acidification in cases of arrested autophagy. Increasing intracellular and lysosomal zinc levels with a zinc ionophore clioquinol was highly effective in restoring lysosomal pH and degradation in chloroquine-induced arrest in autophagy. In addition, several studies have shown that raising cAMP levels are also effective in restoring lysosomal acidity and degradative function. With these findings as a backdrop, in the present study, we examined the effects of zinc and cAMP on lysosomal alkalization and dysfunction in a cell culture model of AMD. To induce lysosomal dysfunction in a human RPE cell line (ARPE19), we used A2E (lipofuscin derivative) and chloroquine (lysosomal alkalizing drug). Twenty four hours after the treatment with A2E, ARPE19 cells exhibited autofluorescence throughout the cell body, and eventually underwent cell death. On the other hand, as previously reported, chloroquine treatment induced vacuolar changes, lysosomal dysfunction, and cell death. Addition of zinc or dibutyryl cAMP reduced cell death in both cases. Moreover, zinc or dibutyryl cAMP decreased A2E autofluorescence in A2E-treated ARPE19 cells. In addition, we are currently examining the effects of zinc and cAMP on lysosomal parameters in A2E-treated ARPE19 cells. Present results support the possibility that adequate levels of zinc or cAMP may help overcome the cytotoxic effects of A2E or lysosomal alkalinizing agents, both of which may contribute to the pathogenesis of AMD.

Title: A psychophysical test of photophobia for blue and red light stimuli under binocular and monocular viewing conditions

Authors: M. ZIVCEVSKA[1], S. LEI[3], A. BLAKEMAN[3], *H. C. GOLTZ[5,2], A. M. WONG[4,2]

[5]Ophthalmology & Vision Sci., Hosp. for Sick Children, Toronto, ON, Canada

Abstract: Objective: Photophobia is a light hypersensitivity phenomenon defined by light-evoked painful sensations. Photophobia is thought to be mediated by the melanopsin-containing intrinsically photosensitive retinal ganglion cell (ipRCG) light-irradiance pathway, which is selectively sensitive to blue light. We have previously shown that the melanopsin response is a function of the retinal area stimulated. We developed a psychophysical test for photophobia and hypothesized that participants will be more sensitive to blue light than red light stimulation. Since binocular viewing stimulates greater retinal area, we also hypothesized that a binocular viewing condition will induce more discomfort than monocular viewing. **Methods:** Eleven visually-normal participants (5 females; mean age 25 years; range 22-31 years) were recruited. Participants received dilating drops (2.5% phenylephrine) prior to the experiment to maintain consistent pupil size and thus light exposure. Full-field stimulation using a Ganzfeld system presented 7 randomized intensities (1 s each) of either red (2, 25, 50, 75, 100, 200, 400 cd/m^2) or blue (2, 10, 20, 40, 60, 80, 100 cd/m^2) light, 20 times for each intensity, in four 70 trial blocks. Constant white-light stimuli (3 cd/m^2, 4 s duration) were interspersed between the chromatic trials. Participants rated the light as either “uncomfortably bright” or “not uncomfortably bright”. The experiment was done binocularly and monocularly in separate sessions, and the color/viewing sequence order was randomized across participants. The proportion of “uncomfortable” responses was used to generate a psychometric function and the 50% discomfort thresholds were calculated individually. **Results:** Light sensitivity was highest under blue light stimulation compared to red light stimulation, both during binocular ($t_{(10)}$=-3.55, p=0.005) and monocular viewing ($t_{(10)}$=-3.14, p=0.01). There was also a significant difference in sensitivity between viewing conditions (monocular vs. binocular) for blue light (p=0.004), but not for red light stimulation (p=0.21). On average, binocular viewing decreased discomfort thresholds (more discomfort) by 56% for blue light, while only 10% for red light. **Conclusion:** Melanopsin-activating blue light induces photophobia at lower thresholds compared to red light. Additionally, photophobia thresholds are lower in binocular viewing conditions for blue light only, suggesting that the perceptual experience of photophobia is integrative in nature. Collectively, this evidence supports the idea that photophobia is an ipRGC-mediated phenomenon.

Title: Identification and characterization of novel, conserved cone photoreceptor enriched factors

Authors: *A. SMITH[1,2], B. N. KENNEDY[2], A. SWAROOP[1]
[1]Natl. Eye Inst., Bethesda, MD; [2]Univ. Col. Dublin, Dublin, Ireland

Abstract: The inability of the retina to detect and/or transmit light-triggered signals is largely responsible for incurable blinding conditions such as age-related macular degeneration, and cone-rod dystrophy, due to dysfunction or death of photoreceptor cells. There remains a lack of understanding of genes involved in cone development, function and survival, hinting at the existence of cone specific or cone sensitive processes.
This research aimed to identify novel factors expressed in cone photoreceptors in zebrafish and mouse, and in the macula of humans, using sequencing technologies. 27 novel, evolutionarily conserved, cone-enriched genes were identified in zebrafish and mice, using microarray, and RNAseq analysis, respectively.
These factors were confirmed to be conserved in human, and enriched in the retina. FISH revealed that the gene clul1 was specifically expressed in the cone photoreceptors of adult, and developing larval zebrafish. Molecular characterization of clul1 in zebrafish and primate retina has elucidated its localization and expression pattern.
Conclusively, novel conserved cone photoreceptor enriched factors have been identified, and *in situ* hybridization and immunofluorescence have been employed to elucidated their expression patterns and subcellular localization. Functional investigation of this gene using CRISPR-Cas9 is now leading to insights into its role in visual function, and its role as a cone photoreceptor enriched factor.

Title: Rod photoreceptor morphogenesis: Role of Snta1 for form and function

Authors: *D. T. WHITAKER[1,2], H. FANN[1], P. HARGROVE[1], A. ALSUFYANI[1], M. J. BROOKS[1], S.-Y. KIM[1], A. SWAROOP[1]

Abstract: Structure and function are intimately connected within the nervous system. Neurons, from the brain to retina to spinal cord, have a diverse array of cellular morphologies that are unique and specific among the different functional populations. While much work has been done to uncover the exact physiological reasons why a cell or cell class has its defined shape, we are still more in the dark on the genetic factors that can help establish this structure. Using two closely related functional cell types, the light sensing rod and cone photoreceptors, that have similar but distinct morphologies, we sought to investigate those genes that could be playing a role in defining the morphological differences between the two. To accomplish our goal, we first characterized rod and cone (and cone-like) synaptic terminal structure. Then, we looked at the transcriptional landscape of developing rod and cone-like photoreceptors (similar to wild type S-cones) along with transcription factor binding profiles of key regulators of photoreceptor fate to identify a more workable list of candidates, 720 in total. From this, we selected and knocked down approximately 10% of these genes through *in vivo* electroporation of shRNAs and a rod-specific fluorescent reporter and assayed individual cells through quantitative analysis of the photoreceptor pre-synaptic terminal structure, specifically the depth within the connective layer between photoreceptors and interneurons and the size of the terminals. From these data, we have currently found 15 genes whereby knockdown in rod photoreceptors resulted in differential morphological features that are more similar to the cone than to the native rod. Confidence in these data is increased through knockdowns of the same genes with different shRNAs as well as rescue of some phenotypes. For one of our top targets, Snta1, we obtained the knockout mouse line. In this mutant, we see no gross alterations in retinal lamination or phototransduction, but we do see a large increase in the transmission of signal from rod photoreceptors to rod bipolar cells. This is exciting because it is the first example of such a result that we could find in the literature. These data show a direct correlation between neuron structure and function.

Title: Features of cone bipolar cell synaptic transmission onto retinal ganglion cells

Authors: *M. J. VAN HOOK
Ophthalmology & Visual Sci., Univ. of Nebraska Med. Ctr., Omaha, NE

Abstract: In the retina, approximately 12 classes of cone bipolar cells (CBCs) serve as intermediaries carrying rod- and cone-driven visual signals to retinal ganglion cells (RGCs). Despite CBCs' key roles in vision, most studies of mammalian bipolar cell synaptic function have relied on rod bipolar cells (RBCs), a specialized bipolar cell population specialized for dim light conditions. Thus, the basic properties of CBC synaptic transmission onto RGCs are unknown. The goal of this study is to characterize the Ca^{2+}-dependence, Ca^{2+} domain coupling, and short-term plasticity of CBC synapses onto RGCs. Whole-cell recordings were obtained from On- and Off- alpha-RGCs in flat-mounted mouse retinas and RGC identity confirmed with dye filling. CBC synaptic inputs were stimulated with current pulses delivered from an extracellular electrode positioned near bipolar cell somata. Extracellular [Ca^{2+}] was varied to assess the cooperativity of the CBC exocytotic Ca^{2+} sensor, while the L-type channel blocker nifedipine was applied to test for nano- vs micro-domain control of exocytosis. Paired pulse protocols and stimulus trains were used to assess synaptic vesicle release probability (Pr). Extracellular stimulation triggered excitatory glutamate receptor-mediated inputs onto recorded RGCs, as indicated by a reversal potential and pharmacology. Reducing excracellular [Ca^{2+}] reduced excitatory post-synaptic current (EPSC) amplitude and fits of the data showed that EPSC amplitude depended on extracellular [Ca^{2+}] with a Hill slope of ~5. The L-type Ca^{2+} channel blocker Nifedipine (1-30 μM) dose-dependently reduced type 6 CBC Ca^{2+} currents and RGC EPSCs. The relationship of EPSC amplitude and CBC Ca^{2+} currents was well fit with a Hill slope of ~1. In paired pulse experiments, inputs onto both On- and Off- RGCs were depressed with repeated stimulation, although On RGC inputs depressed more strongly. Train stimuli revealed that CBC inputs to On and Off RGCs have a Pr of ~0.9. The Ca^{2+}-dependence and nifedipine experiments suggest that CBC inputs onto alpha-RGCs operate with a conventional Ca^{2+} sensor with n = 5 and Ca^{2+} nanodomains, much like RBC inputs onto AII amacrine cells. Prominent short-term synaptic depression indicates that On and Off CBCs have a

high Pr. Differences between inputs to On and Off alpha-RGCs might have important implications for visual processing at CBC synapses.

Title: Crossing borders: A newly discovered, and unique subtype of bipolar cells provides excitatory input to both ON and OFF synaptic pathways in the retina

Authors: *B. K. YOUNG[1], C. RAMAKRISHNAN[3], P. WANG[2], K. DEISSEROTH[3], N. TIAN[2]
[1]Ophthalmology and Visual Sci., [2]Univ. of Utah, Salt Lake City, UT; [3]Bioengin & Psych, Stanford Univ. Dept. of Psychology, Stanford, CA

Abstract: In the retina, bipolar cells (BCs) process and transmit visual information from photoreceptors to retinal ganglion cells (RGCs) and amacrine cells (ACs). Traditionally, BCs have been divided into subtypes based on whether they receive their primary input from rod or cone photoreceptors, and where their primary synaptic output resides, either in the ON or OFF layer of the inner plexiform layer (IPL; Wassle et al., 2009). This classification produces 11 subtypes of cone BCs and 1 rod BC. Recently a new subtype of ON cone BCs has been discovered through the use of electron microscopy, implying the existence of more unidentified BCs (Helmstaedter et al., 2013). We utilize a novel transsynaptic technique with a Cre-dependent AAV2 WGA-Flpo:mCherry vector and a universal Flpo-dependent GFP transgenic mouse. Using this technique, we were able to identify a subtype of BC that has axonal terminals ramified in both the ON, and OFF layers of the IPL of the retina (see panels A and H1). We refer to this cell as an “Aii bipolar” cell (right cell in panel B) due to the similarity between the axonal processes of this cell to those of an Aii AC (left cell in panel B). However, immunohistochemistry analysis showed that Aii BCs contain ribbon synapses at their axonal terminal similar to other BCs, but unlike any AC (panel C). Ribbon synapses as well as vesicular glutamate transporter 1 (VGlut1) is expressed in the axonal terminals of the ON and OFF layer

ramifications (panels D-F). This indicates that they are excitatory neurons, unlike Aii ACs, and may release glutamate onto both ON and OFF RGCs, while all other cone bipolar cells synapse with RGCs either in the ON or OFF layer. Additionally, while Aii ACs express calretinin (panel G; Massey & Mills 1999), Aii BCs do not (panel H). The Orthodenticle Homeobox 2 gene (Otx2) has been used as a universal antibody marker for BCs (Park et al., 2017). However, Aii BCs do not express Otx2 (panel J). These results place Aii BCs in a singular position within the retina as the only subtype of BCs to have excitatory axonal projections that terminate in both the ON and OFF layers of the IPL.

Title: Connectivity and computations of horizontal cells in the mouse retina

Authors: *C. BEHRENS[1,2,3,4], Y. ZHANG[4], T. EULER[1,2,3], P. BERENS[1,2,3], T. SCHUBERT[1,2]
[1]Ctr. for Integrative Neurosci., [2]Inst. for Ophthalmic Res., [3]Bernstein Ctr. for Computat. Neurosci., [4]Grad. Training Ctr. of Neurosci., Univ. of Tübingen, Tübingen, Germany

Abstract: In the mouse retina, short and medium wavelength-sensitive cone photoreceptors (cones) provide input to 13 types of cone bipolar cell (CBC). Additionally, one horizontal cell (HC) type provides feedback and feedforward input to cones and BCs, respectively. Although this general connectivity was described decades ago, a quantitative description of HC connectivity is lacking. Moreover, the computational role of HCs in the outer retina is still unclear: Recent studies suggest that - in addition to providing lateral, global feedback - HCs may also act on a local scale.
We approach these questions by exploiting recent high resolution imaging data: We reconstructed the dendritic trees of three HCs in a serial block-face electron microscopy (EM) volume (Helmstaedter et al., 2013). For this dataset, reconstructions of BCs and cone axon terminals are available from prior work (Helmstaedter et al. 2013; Behrens et al., 2016). Having reconstructed all cell types involved in the outer retinal circuitry, we went on studying the connectivity of HCs quantitatively.
Using an automatic classification procedure, we identified potential synaptic contacts at the cone pedicle base and manually analyzed contact points outside the cone pedicle. In addition to the well-known HC contacts in the cone axon terminal, we find a second site of potential synaptic contacts: Along all HC dendrites we observed “swellings” (bulbs), short segments of increased dendritic diameter. Each bulb featured one or two contacts to either bulbs of other HCs or to BC dendrites. We then built a biophysically realistic model of a HC dendritic branch. Incorporating detailed morphology and connectivity from EM data, the model allowed us to study the prerequisites for local processing in HC dendrites and the role of the bulbs in visual processing.
Our study adds quantitative data on HCs towards completing the outer retinal connectome. The anatomical observations hint at a complex functional role of HCs in the processing of cone signals. We may have identified a second synaptic layer in HCs and preliminary simulations suggest that the distinct morphological structure of HCs could easily support local processing.

Title: GABA regulates presynaptic inhibition of mammalian cone photoreceptor Ca channels by modulating synaptic cleft pH

Authors: J. C. R. GROVE[1], A. A. HIRANO[1], N. C. BRECHA[1,2], *S. A. BARNES[3,1]
[1]Neurobio., UCLA, Los Angeles, CA; [2]VAGLAHS, Los Angeles, CA; [3]Dalhousie Univ., Halifax, NS, Canada

Abstract: The goal of this study was determine how GABA contributes to the modulation of Ca channel currents in mammalian cone photoreceptors, to add to our understanding of how horizontal cells inhibit photoreceptors. This feedback signaling regulates the gain of the photoreceptor output synapse and contributes to the properties of the center-surround receptive field properties of downstream neurons in the retina and visual pathway. Numerous prior studies have made clear that the input to this pathway, e.g. horizontal cell membrane potential, drives actions that modulate the activity of presynaptic Ca channels in photoreceptors, the dynamic output of inhibitory feedback to cone photoreceptors. Here we identify the cellular mechanisms that come in between. One line of evidence suggests that GABA is responsible but that it acts not at cones but rather on horizontal cells, the same cells that release it, producing extracellular pH shifts that modulate photoreceptor Ca channel activation. Here we test key steps underlying this multistep feedback pathway by patch clamping horizontal cells and photoreceptors in mouse, rat and guinea pig retinal slices, first affirming electrophysiologically that block of GABARs produces pH-dependent disinhibition of cone Ca channels. We show that GABARs in horizontal cells mediate this disinhibitory action and that GABA depolarizes horizontal cells. The requirement of GABA release by horizontal cells in this action is confirmed by its absence using the Cx57-VGAT KO mouse. The effects are voltage dependent in two ways: 1) depolarization of horizontal cells increases GABA release and autoreception, and 2) depolarization decreases the driving force on HCO_3^- efflux, allowing basal acidifying processes to dominate cleft pH. Finally we reproduce the autaptic site-specific actions of GABA on cone Ca channels by targeted expression in horizontal cells of engineered anion channels (PSAM-GlyRs), which, activated by their orthogonal ligand, mimic the role of GABARs. Taken together, the present investigations validate our model in which 1) horizontal cells release GABA in a voltage-dependent manner, 2) autoreception via GABARs increases horizontal cell HCO_3^- conductance, 3) HCO_3^- efflux, driven by the horizontal cell membrane potential, buffers the pH of the synaptic cleft, and 4) cone Ca channels are modulated by pH-induced shifts of the voltage dependence of their activation.

Title: Machine-learning-inspired approach to elucidate circuit dynamics and principles of parallel processing in the retina

Authors: *G. J. GUTIERREZ[1], F. M. RIEKE[2], E. T. SHEA-BROWN[2]
[1]Applied Math, [2]Univ. of Washington, Seattle, WA

Abstract: The retina is an adaptable neural circuit that processes an enormous range of inputs. Traditional models rely on static characterizations of retina circuit components, yet retinal ganglion cells are known to adapt not only their tuning but also the computations they perform [1-3]. Our goal is to understand how the retina optimally uses shared circuitry for different computations and to understand the circuit dynamics that underlie such changes in retinal processing. We've constructed a novel retina circuit model using an unconventional top-down approach that borrows from machine-learning [4]. A neural circuit is constructed from computational objectives rather than static circuit components to reveal the intrinsic neuron dynamics that generate flexible circuit computations. The model predicts functionally distinct currents that are needed to perform the simplest transformation of the circuit input. We then incorporate known biological features of the retina into the model, including a multi-dimensional structure that mirrors the parallel rod and cone pathways. Our ongoing work makes use of retina data to fit the model to conditions in which either rods or cones are activated alone. This will lead to more precise model predictions about the interaction between rod and cone pathways that produce retina-specific computations.

Title: Epoxyeicosatrienoic acid (EET)-mediated retinal functional hyperemia enhanced by inactivation of TRPV4 channels

Authors: *D. Y. TS'O[1], M. BEGUM[1], T. T. T. PHUONG[2], D. KRIZAJ[2]
[1]Dept of Neurosurg., SUNY - Upstate Med. Univ., Syracuse, NY; [2]OPHTHALMOLOGY & Visual Sci., Univ. of Utah Sch. of Med., Salt Lake Cty, UT

Abstract: Intrinsic signal optical imaging (ISOI) has considerable potential to non-invasively monitor retinal function in health and disease. The imaged response observed with ISOI has been shown to reflect the change in local blood flow due to light stimulation of rod photoreceptors, but the precise mechanisms underlying this chain of events remains unclear. Arachidonic acid (AA) metabolites including the EETs, 20HETE and prostaglandin having been shown as key mediators of neurovascular coupling but their contribution to light-evoked retinal hemodynamics *in vivo* is largely unexplored. Using ISOI in cat retina, we investigated the contributions of these AA metabolites on light-induced retinal hemodynamics via intravitreal injections of agents that specifically target these signaling pathways. We found that the inhibition of EET production via the agent PPOH (20uM) eliminated the stimulus-driven imaged response, indicating that EET is a critical intermediary in regulating light-activated retinal blood flow. One possible pathway of EET signaling is via its binding site on TRPV4, a shear flow-activated cationic channel. Immunocytochemistry showed TRPV4 expressed in human retinal microvascular endothelial cells and glial endfeet. The channel was activated by AA (10uM), 5'6-EET and 11'12-EET, and inhibited by antagonists of phospholipase A2. Intravitreal injection in cat of a selective TRPV4 agonist GSK1016790A (10nM) induced a marked vasodilation, (~25% reduction in retinal reflectance). In contrast, an injection of the antagonist HC067047 yielded a vasoconstriction (~10% increase in retinal reflectance). GSK1016790A also abolished the light-stimulated imaging signal, while HC067047 increased this signal. The action of GSK1016790A on the imaged signal is similar to other vasodilators (e.g. nifedipine) that reduce or abolish these signals by saturating the vasodilatory range of the vasculature. These results demonstrate the TRPV4 plays significant role in the control of retinal vascular tone. However, since TRPV4 inhibition increased the stimulus-driven retinal imaging signals, its role in the light-evoked signal is likely to be secondary. These studies help elucidate the underlying mechanisms of the ISOI technique in the retina and of retinal functional hyperemia.

Title: Long term visual restoration using optogenetic engineering of retinal ganglion cells with AAV2.7m8-ChrimsonR-td-Tomato

Authors: *G. GAUVAIN[1], H. AKOLKAR[1], A. CHAFFIOL[1], R. CAPLETTE[1], C. JAILLARD[2], E. BRAZHNIKOVA[2], M. DESROSIERS[2], D. PRUNEAU[3], J. DUEBEL[1], R. BENOSMAN[1], D. DALKARA[2], J. SAHEL[2], S. PICAUD[1]

Abstract: Retinitis Pigmentosa (RP) is a collection of inherited dystrophies with similar clinical features resulting in the progressive loss of photoreceptors leading to blindness. Although gene therapy is currently in clinical trial for hereditary dystrophies, the considerable genetic heterogeneity in RP preclude the rapid development of treatments for patients. In this pre-clinical study we are considering an alternative to classic gene therapy and propose to use viral vector to deliver a microbial opsin, ChrimsonR, to optically control surviving retinal ganglion cells. We previously selected AAV2.7m8-ChrimsonR-tdTomato as the most potent of our viral constructs. We investigated here in nonhuman primates the treatment efficacy after long term (6 month) expression of our transgene, for three viral doses. None of the injected primates developed significant immune response or sign of morphological alteration based on the fundus images. We performed ex-vivo retinal ganglion cells (RGCs) recordings on 256 electrode multielectrode arrays (MEA). We isolated the response of RGCs expressing our construct from natural light response using pharmacological blockers (L-AP4, CNQX, CPP). We stimulated retinas using a digital micro mirror device (DMD) with a light source centered at 600nm (+/-20nm) allowing for: 1) full field stimuli of various durations, and 2) patterned stimulation (small spots, moving bar and objects). We also used a variable wavelength source in order to determine spectral sensitivity. Our result indicates the highest viral does as optimal for best efficacy in term of transduction efficiency (evaluated through overall induced activity on the MEA, and post-fixation cell counting on confocal images) . We also demonstrate excellent spatio-temporal sensitivity of the reactivated retina (responses for spot as small as 50µm) as well as extremely short delay of responsiveness (~10msec for first evoked action potential). In combination of MEA recordings we did 2-photon guided single cell patch clamp experiments (whole cell and cell attached) to directly measure photocurrent induced by our opsin. These different

experiments demonstrate stable expression of ChrimonR-td-Tomato in non- human primates on a 6 month period post-infection, they also provide evidence for functional efficacy at doses, which could represent the therapeutic dose range for the future clinical trial.

Title: A high threshold, NMDA-dependent input drives retinal dopamine release in response to light

Authors: *J. W. MORLEY, V. PEREZ-FERNANDEZ, M. A. CAMERON
Med., Western Sydney Univ., Sydney, Australia

Abstract: Adaptation of the retina to the presenting light conditions relies considerably on modulation of retinal pathways by dopamine (DA). DA is released by a unique set of neurons known as dopaminergic amacrine cells (DACs). Cones, rods and intrinsically photoresponsive retinal ganglion cells (ipRGCs) have been shown to input DACs. However, measurement of dopamine release in the retina in response to light does not align with electrophysiological and/or immunohistochemical reports. The purpose of this study was to describe the photoreceptive origin of light-induced dopamine release using pharmacology and transgenic/mutant mouse models. We used UHPLC-MS/MS analysis to quantify DA released from the mouse retina in an *ex vivo* preparation in response to 4 light intensities (max 1.6 log W/m^2; ~10,000 lux). Wild-type, $Gnat2^{A517G}$ (cone-functionless), and *rd/rd* (lacking rods and cones) animals were light pulsed and pharmacological blockers applied. We found that light caused a significant increase in dopamine

release in the retinae of both wild-type and *Gnat2*^{A517G} mice but only at very bright light intensities (> 0.65 log W/m^2; ~1000 lux). In agreement with previous studies, no significant increase was obtained in response to light in *rd/rd* mice at any light intensity. The gap junction blocker MFA (1mM) caused a significant reduction in light induced DA release in both wild-type and *Gnat2*^{A517G} animals, but did not completely abolish the light-induced increase in comparison to dark conditions. While the glycine receptor blocker strychnine (10μM) did not affect dopamine release in either light or dark, the $GABA_{A/C}$ receptor blocker picrotoxin (100μM) caused a significant DA increase in both light and dark in wild-type mice. Surprisingly, the NMDA channel blocker AP5 (50μM) completely abolished light induced DA release in the wild-type mouse, suggesting a pivotal role for NMDA receptors in this response. While all our data thus far support the theory that rods are driving the light-induced release of DA, the threshold for this response is far (6 log units) above the rod threshold. We hypothesize that the NMDA input originates from ipRGC photoreceptors that are only effective when paired with inputs from the outer retina, allowing this input to be "gated" at such a high intensity. Thus both outer retinal (predominately rods) AND ipRGCs are required for light induced DA release.

Title: High spatial resolution recordings reveal the contribution of long-range horizontal inhibition in modulating light-evoked responses of ON and OFF retinal ganglion cells

Authors: *F. BOI[1], D. LONARDONI[2], S. DI MARCO[4], A. MACCIONE[3], L. BERDONDINI[5]
[1]NBT, NetS3 Lab., [2]Neurosci. and Brain Technologies, [3]Inst. Italiano Di Tecnologia, Genova, Italy; [4]Univ. of L'Aquila, L'Aquila, Italy; [5]Neurosci. and Brain Technologies, Fondazione Inst. Italiano Di Tecnologia, Genova, Italy

Abstract: The retina encodes visual sensory inputs into spike trains by processing information through five main layers where reside more than 60 different cell types. This processing is performed by parallel vertical circuits (from photoreceptors down to ganglion cells) that are modulated by horizontal inhibitory connections. However, the contribution of such long-range horizontal inputs remains not completely understood. High-resolution CMOS multielectrode arrays (4096 electrodes arranged in a 64x64 array, 42 μm electrode pitch) permit simultaneous spiking activity recording of more than 3'000 single retinal ganglion cells (RGCs) all over the

entire retina. By providing fine spatial and temporal sampling capabilities, these devices offer novel opportunities to investigate the effects of horizontal long-range network interactions (such as provided by wide-field amacrine cells) in modulating the spiking activity of RGCs during visual stimulation. Here, by combining these recording capabilities with a visual stimulator that enables micrometric and sub-millisecond spatiotemporal precision, we present results obtained by studying the effects induced by the spatial confinement of visual stimuli. The stimuli consisted in white/black flashes and moving bars of different spatial gratings (range of 0.026-0.75 cycle/deg), both presented at 1Hz stimulation frequency. We compared ON and OFF RGCs population responses of different retinas (n=4), both under full-field (FF, visual stimulus projected on the entire retina) and spatially confined "masked" stimuli (M, i.e. the same visual stimulus projected on an area of the retina). We found that flashes projected under the M condition gave rise to delayed ON and OFF RGCs responses (~30 ms) with respect to the FF stimulation condition. We further observed that OFF responses delay was strongly dependent to the stimulus contrast while the ON RGCs responses were always delayed regardless of the contrast. A similar trend was also observed by analyzing the spiking activity in response to moving bars presented under both M and FF conditions. Our results reveal that variations of the RGCs spiking activity dynamic in response to confined stimuli are most likely not only the result of vertical and local processing circuitries, but are also modulated by horizontal processing circuits carrying information from far regions of the retina. This observation was further confirmed by experiments showing that these differences in ON and OFF responses to visual stimuli under M and FF conditions disappeared under bicuculline, thus suggesting a potential role of wide-field amacrine cells in mediating the RGCs response delay.

Title: Optogenetic stimulation reveals type- and target-specific computations at genetically-identified amacrine cell synapses

Authors: *J. POTTACKAL[1,2], J. H. SINGER[3], J. B. DEMB[1]
[1]Dept. of Ophthalmology and Visual Sci., [2]Interdepartmental Neurosci. Program, Yale Univ., New Haven, CT; [3]Dept. of Biol., Univ. of Maryland, College Park, MD

Abstract: Recent work in the vertebrate retina has begun to provide insight into the receptive field properties, anatomical organization, and functional roles of the ~40 types of amacrine cells (ACs). However, while several AC types have been identified as critical sources of synaptic inhibition in specific retinal circuits, the precise computational and functional properties of AC synapses, and the extent to which these properties differ between AC types, remain largely unknown. Here, we develop an optogenetic approach to probe the synaptic properties of genetically-identified ACs in the wholemount mouse retina. To control presynaptic membrane potential (V_{pre}) of specific AC types, we conditionally expressed channelrhodopsin-2 (ChR2) using the Cre-Lox system. Current clamp recordings from ChR2-expressing CRH-1 ACs and starburst ACs (SACs) during optogenetic stimulation revealed fast, linear modulation of V_{pre}. Subsequent voltage clamp recordings from ON α ganglion cells (GCs) clamped at 0 mV during CRH-1 AC stimulation exhibited similarly linear inhibitory postsynaptic currents (IPSCs). By contrast, voltage clamp recordings from ON-OFF direction-selective GCs (ooDSGCs) clamped at 0 and -70 mV during SAC stimulation revealed strong rectification of both GABAergic IPSCs and cholinergic excitatory PSCs, respectively. To quantify differences in rectification and temporal filtering, we constructed linear-nonlinear (LN) models of PSCs recorded from GCs during optogenetic white-noise stimulation of presynaptic ACs. In addition to type-specific differences in PSC rectification, LN analysis also revealed distinct temporal filtering properties at each AC synapse: compared to SAC—ooDSGC synaptic filters, CRH-1 AC—ON α GC filters peak earlier and initially decay more rapidly. Surprisingly, we found that SAC—ooDSGC IPSCs exhibit stronger rectification and slower temporal filtering than SAC—SAC IPSCs, demonstrating that a single AC type can perform parallel synaptic computations in a target-specific manner. Finally, application of isradipine, a selective L-type voltage-gated calcium channel (VGCC) blocker, abolished ChR2-mediated IPSCs at CRH-1 AC—ON α GC synapses but not SAC—ooDSGC synapses, suggesting that distinct VGCC types mediate GABA release at these synapses. Taken together, these results show that AC synapses possess diverse computational properties that may be critical for shaping visual processing in retinal circuits.

Title: Satb1 regulates Contactin5 to construct a bistratified dendritic arbor in retina

Authors: *Y.-R. PENG[1], N. M. TRAN[1], A. KRISHNASWAMY[2], D. KOSTADINOV[3], E. M. MARTERSTECK[2], J. R. SANES[2]
[1]Mol. and Cell. Biol., [3]Mol. and cellular biology, [2]Harvard Univ., Cambridge, MA

Abstract: The size and shape of dendritic arbors are prime determinants of neuronal connectivity and function in the central nervous system. In the retina, for example, dendrites of different types of retinal ganglion cell (RGC) are confined to one or a few of ~10 strata within the inner plexiform layer, restricting the interneurons from which they receive inputs, and thus the visual features to which they respond. ON-OFF direction-selective RGCs (ooDSGCs) have bistratified dendrites, in which ON inputs that trigger responses to light-onset and OFF inputs that trigger responses to light-offset are segregated to inner and outer strata, respectively. Here, we describe a transcriptional program that controls assembly of the ON arbor. We found that the transcriptional regulator Satb1 is expressed by ooDSGCs but few other RGCs. In *Satb1* mutant mice, ooDSGCs become monostratified, lacking ON arbors but retaining OFF arbors. As a consequence, they lack ON responses, but there is no detectable effect on OFF visual responsiveness or direction selectivity, indicating that Satb1 specifies a discrete visual feature. To seek mediators of this effect, we compared transcriptomes of control and Satb1-deficient ooDSGCs. We found that Satb1 regulates expression of a homophilic adhesion molecule, Contactin 5 (*Cntn5*), and that *Cntn5* mutants partially phenocopy *Satb1* mutants. We then found that both Cntn5 and its co-receptor Caspr4 are expressed not only by ooDSGCs but also by ON starburst amacrine cells, an interneuronal type that form a scaffold on which ooDSGC ON dendrites fasciculate. Conditional knockdown of Cntn5 in either presynaptic interneurons or postsynaptic ooDSGCs leads to the same defect as constitutive Cntn5 loss, supporting the idea that Cntn5-mediated homophilic interactions of ooDSGCs with ON starburst amacrines are required for maturation or maintenance of ooDSGC ON dendrites. Thus, Satb1 acts in part through Cntn5 to direct formation of a specific portion of the ooDSGC dendritic arbor that enables these RGCs to respond to ON stimuli.

Title: Retinal electrophysiology in a mouse model of multiple system atrophy

Authors: *H. SEITTER[1], N. STEFANOVA[2], A. KOSCHAK[3]
[1]Pharmacol. & Toxicology, Leopold Franzens Univ. Für Innsbruck, Innsbruck, Austria; [2]Dept. of Neurol., Innsbruck Med. Univ., Innsbruck, Austria; [3]Pharmacol. and Toxicology, Inst. of Pharm., Univ. of Innsbruck, Innsbruck, Austria

Abstract: Multiple System Atrophy (MSA) is a neurodegenerative disease with proposed causal involvement of α-Synuclein (α-SYN) aggregate formation. In Parkinson's disease (PD), another α-Synucleinopathy, visual symptoms such as diminished contrast sensitivity are well described while for MSA visual manifestations have thus far not been prominent. In the clinical examination of patients, visual tests are an important tool to distinguish PD and MSA. Our experiments are aiming to determine the visual function of a MSA mouse model. In this mouse model of human α-SYN overexpression we detected strong aggregation of α-SYN in the retina. Therefore we set out to determine the effect of the α-SYN aggregation on retinal physiology and function.
We used transgenic mice, expressing human α-SYN under the proteolipid protein promotor (PLP-α-SYN) and corresponding wild type (WT) controls of two months of age. Mice were dark adapted and retinas were extracted under dim red light. Retinal ganglion cell spiking responses and retinal local field potentials ("in vitro ERG") were recorded using micro-electrode arrays (MultiChannel Systems MEA2100), while the retina was stimulated with a variety of visual stimuli designed to test contrast sensitivity. The stimuli included flashes, sinusoidal full field stimuli and drifting gratings, with different contrasts each. Visual stimulation was done at two distinct light levels achieved through the insertion of neutral density filters. The light levels corresponded to scotopic and photopic luminance ranges.
In vitro ERG responses to full field flashes of different contrasts showed no difference between WT and PLP-α-SYN retinas. However, we found significant changes in a frequency modulated sinusoidal stimulus which were light level-dependent. While the scotopic responses were comparable, the photopic responses of PLP-α-SYN retinas were significantly more delayed ($0.023 < p < 0.048$, Wilcoxon ranksum test; WT 81.5 ± 7.8 ms, PLP-α-SYN 114.1 ± 7.9 ms; means of 29 peaks ± std). Retinal ganglion cell responses in PLP-α-SYN mice on the other hand were comparable to WT both in frequency domain modulation as well as in ganglion cell contrast sensitivities.
The unchanged flash in vitro ERG highlights that outer retinal function of PLP-α-SYN animals is not severely impaired. The lack of a strong impact on ganglion cell responses conforms to the normal visual function in MSA patients. The changes in the in vitro ERG to frequency

modulation however revealed a so far unknown functional change that could be a potential diagnostic marker that might also be tested in human patients.

Title: Quantifying protein synthesis and axonal transport in the visual system and its response after optic nerve injury

Authors: *L. M. SCHIAPPARELLI[1,2], S. H. SHAH[4], Y. MA[3], J. YATES, III[3], H. T. CLINE[1], J. L. GOLDBERG[4]
[1]Neurosci., The Scripps Res. Inst., LA Jolla, CA; [2]Neurosci., [3]Mol. Med., The Scripps Res. Inst., La Jolla, CA; [4]Dept. of Ophthalmology, Stanford Univ., Palo Alto, CA

Abstract: How do protein synthesis and axon transport contribute to neuronal circuit development or to response to injury? To study this question in specific visual circuits and in response to pathological processes, we have developed new strategies for analyzing proteome translation in the retina and its axonal transport in the optic nerve (ON) to the lateral geniculate nucleus (LGN) or the superior colliculus (SC) (Schiapparelli et al 2014). We are using these methodologies to address two main questions: (a) as LGN and SC projections are involved in distinct visual functions, is the protein “transportome” to the LGN different from that to SC? And (b) how are protein synthesis and axonal transport affected in response to optic nerve injury? To address the developmental transportome, we labeled the retina in vivo with NHS-biotin, which tags pre-existing proteins. We found that the population of proteins transported to LGN or SC are highly overlapping, but some of these molecules are selectively sent to a specific target. Future experiments will uncover how differential targeting leads to differential downstream signaling in different neuronal circuits, determining specific function. To examine response to injury, we labeled newly synthetized proteins the retina with azidohomoalanine (AHA) following optic nerve crush (ONC) in adult rats, and identified ~30 proteins whose synthesis and subsequent transport to ON significantly changes 27 hours after ONC. To examine the transportome after injury, after NHS-biotin retinal labeling we identified ~300 proteins whose transport down the optic nerve decreased after ONC, and ~30 whose transport increased

after the 12 hours of ONC. Extending this methodology to glaucomatous injury will allow us to identify and quantify differentially translated and transported proteins in RGCs in the context of disease. We hypothesize that understanding whether specific proteins are synthetized and transported to an injury site will lead to new understanding of pathophysiology of injury and new approaches to promoting regeneration.

Title: Extracellular pH changes mediated by retinal Muller glia are shaped by two distinct molecular pathways

Authors: *M. A. KREITZER[1], B. K. TCHERNOOKOVA[2], D. SWYGART[1], C. HEER[1], M. GONGWER[1], L. SHEPHERD[1], H. CARINGAL[1], R. P. MALCHOW[2]
[1]Biol., Indiana Wesleyan Univ., Marion, IN; [2]Dept. Biol. Sci. & Ophthalmology, Univ. of Illinois at Chicago Dept. of Biol. Sci., Chicago, IL

Abstract: Alterations in extracellular H+ are correlated with significant changes in the release of neurotransmitter in the retina. This has led to a number of recent studies examining the role extracellular H+ dynamics play in shaping visual signals. However, few studies have directly measured H+ fluxes from individual identified cells. Self-referencing H+ selective microelectrodes have proven to be ideally suited for sensing extracellular pH changes from isolated cells. Two recent studies utilized self-referencing to measure H+ fluxes from retinal Müller glia, isolated from tiger salamander retina. These studies characterized two pathways by which Müller cells regulate extracellular pH. In the first pathway high KCl applied to Müller cells produces a large HCO_3^- dependent extracellular acidification at the endfoot. In the second

pathway application of extracellular ATP also induces a large HCO_3^- independent extracellular acidification. These studies, when coupled to a growing interest regarding the roles glial cells play in shaping synaptic transmission, bring an important focus on elucidating roles retinal glia play in shaping the pH of the extracellular environment. The present study directly examines overlap of the two previously reported regulatory pathways by measuring extracellular H+ fluxes using self-referencing H+ selective microelectrodes positioned adjacent to the endfoot of isolated Müller cells, while in a HCO_3^- buffered Ringer's solution. Externally applied 50 mM KCl induced an increase in H+ flux. 100 µM ATP led to a large additional H+ flux while the cell was bathed in high KCl. The H+ flux could be stepped back to control levels by first removing ATP followed by wash-off of the high KCl. The independence of these two pathways inducing acidification outside of the endfoot were further supported by Ca^{2+} imaging studies using the intracellular Ca^{2+} indicator Oregon Green BAPTA 1-AM. These trials demonstrated that high KCl induced an intracellular calcium rise that was dependent on extracellular calcium and not intracellular stores. ATP also induced an intracellular calcium rise but the rise occurred independent of the presence of extracellular Ca^{2+} and could be abolished when intracellular stores were emptied. Additionally, the increase in extracellular H+ mediated by ATP was calcium-dependent but the KCl-induced acidification was not. Collectively, these findings demonstrate that retinal Müller cells have two distinct pathways through which they regulate extracellular pH around the cell, and these findings also point toward a multifaceted ability of Müller cells to regulate pH and by extension shape synaptic transmission in the retina.

Title: Determining the role of pre-synaptic NMDA Receptors in retinofugal topographic map formation

Authors: *K. O. JOHNSON[1], J. TRIPLETT[2]
[1]Inst. of Biomed. Sci., The George Washington Univ., Washington, DC; [2]Ctr. for Neurosci. Res., Children's Natl. Med. Ctr., Washington, DC

Abstract: Efficient processing of sensory information is a critical function of the nervous system. Deficits in sensory processing and integration are commonly seen in

neurodevelopmental disorders such as autism and fragile X syndrome. In the visual system, neurons are organized topographically, such that neighboring neurons monitor adjacent regions of space. Retinal ganglion cells (RGCs) project topographically to the superior colliculus (SC) and dorsal lateral geniculate nucleus (dLGN). The establishment of topography in both the SC and the dLGN is dependent on spontaneous correlated activity. However, the mechanisms by which activity mediates topographic map formation remain unclear. Previous studies suggest that N-methyl-D-aspartate receptors (NMDARs) play a critical role in the establishment of topography by RGCs; however, it is unclear if they are required pre- or post-synaptically. To determine the role of pre-synaptic NMDARs in retinofugal topographic map formation, we used a conditional genetic strategy to specifically ablate NMDAR function in RGCs. We focally labeled RGCs and visualized the termination zone (TZ) of their projections in the SC and dLGN. Our preliminary data suggests that there was no change in TZ size in the SC, but TZs appeared to be larger in the dLGN. Bulk labeling of all RGCs in both eyes of these mice showed that eye-specific lamination was similar to controls, suggesting this activity-dependent process is unaffected in the absence of pre-synaptic NMDARs. Together, these data suggest that retinogeniculate topographic map formation may require pre-synaptic NMDAR activity, whereas retinocollicular map development may not. While our data do not suggest a role for pre-synaptic NMDARs in retinocollicular topography, we cannot rule out a role in the development of proper visual receptive fields. Thus, our future studies will explore visual function in the SC and dLGN to determine the role of pre-synaptic NMDARs visual circuit formation.

Title: Focal electroretinogram and visual evoked potential in rats

Authors: *A. GROSS, N. FARAH, Y. MANDEL
Fac. of Life Sciences/Optometry Track, Bar Ilan Univ., Ramat Gan, Israel

Abstract: Purpose: Measurements of focal retinal function is helpful in evaluation localized retinal malfunction and in assessing intervention efficiency in treatment modalities such as retinal prostheses, genetic therapy or stem cell transplantation. In this work we characterized the focal Electroretinogram (fERG) and Visual Evoked Potential (fVEP) in response to a photopic localized visual stimulus projected on pigmented rat retina.
Methods: fERGs and fVEPs signals were recorded in Long-Evans anesthetized rats in response to visual stimulus consisted of LED flashes relayed through circular apertures which are

incorporated into a fundus camera (Micron IV, Phoenix Research Lab) optical path. Stimuli with varying irradiances, repetition rates, and spot diameters ranging from 0.5 to 3.0 mm were investigated at various background illumination. VEP signals were recorded using screws electrodes implanted over the primary visual cortex and ERG signals were recorded using a corneal contact electrode.
Results: The fERG b-wave amplitude increased with light intensity reaching a plateau at $4*10^3 cds/m^2$, and decreased with increasing stimuli repetition rate and increasing background illumination. The fVEP amplitude (N1P2) demonstrated a similar trend, however, a plateau was observed at a lower stimuli luminance ($1*10^3 cds/m^2$) suggesting a smaller cortical dynamic range as compared to the retina. fERG and fVEP b-wave amplitude increased with stimuli spot size reaching a plateau at smaller spot size for high intensity illumination levels, suggesting a contribution of the scatter effect. The b-wave latency decreased with increasing stimuli luminance, reaching a minimum at luminance levels above $10cds/m^2$. The photopic stimuli elicited a robust photopic negative response (PhNR) with increasing amplitude and latency for increasing stimuli irradiance and spot size.
Conclusions: The effect of various retinal focal stimuli parameters on fERG and fVEP signals in normal pigmented rats show characteristic responses. A robust PhNR component was found and characterized. Evidences for a scatter effect were found at high irradiance stimuli, which could be reduced by addition of background illumination. In addition, our results demonstrate the larger retinal dynamic range as compared to the cortical dynamic range under photopic conditions. This study can serve as a basis for evaluating localized retinal function as an important research tool for investigating retinal diseases in rodents.

Title: Exploring synaptic and computational properties of starburst cells through altered neuronal morphology

Authors: *R. D. MORRIE[1], M. B. FELLER[1,2]
[1]Dept. of Mol. and Cell Biol., [2]Helen Wills Neurosci. Inst., Univ. of California, Berkeley, Berkeley, CA

Abstract: Direction selective ganglion cells in the mammalian retina fire action potentials maximally to objects moving in a preferred direction, but minimally to objects moving in the opposite, or null, direction. These directional responses are produced by an asymmetry in overall inhibitory conductance, such that object motion in the null direction elicits a greater amount of GABAergic inhibition onto direction selective cells. How does this asymmetry emerge? Starburst amacrine cells are axonless interneurons in the retina that are required for direction selectivity and are characterized by their radially symmetric dendritic arbors. The ends of these dendrites form GABAergic synapses onto direction selective cells, providing asymmetric GABAergic inhibition via two components: 1) directionally selective responses in starburst cell dendrites themselves, in which motion away from the starburst cell soma elicits a larger depolarization at GABA release sites than motion toward the starburst cell soma and 2) a selective wiring process between starburst cells and direction selective cells.
To determine how the “starburst” morphology of these cells enables and contributes to the mechanisms responsible for these directional responses, we utilized mice lacking the Sema6A signaling molecule, whose starburst cells no longer display radial symmetry (Sun et al., 2013), and whose ganglion cells have reduced direction selectivity. Using paired recordings and both subcellular and population level 2-photon Ca^{2+} imaging, I will present results describing how the morphological defects in these starburst cells impact the computation of direction selectivity at multiple levels within the retinal direction selective circuit.

Title: Disentangling multiple sources of variability in the responses of retinal ganglion cells

Authors: *A. I. WEBER[1], E. SHEA-BROWN[2,3,4], F. RIEKE[3]
[1]Grad. Program in Neurosci., [2]Applied Mathematics, [3]Physiol. & Biophysics, [4]UW Inst. for Neuroengineering, Univ. of Washington, Seattle, WA

Abstract: As our sensory systems encode information about the world around us, the relevant signals are corrupted by noise at several different stages.[1] Noise present in the stimulus itself, such as in stochastic photon arrival at the retina, corrupts the signal before it is encoded. Additional noise is added by a variety of biological processes, such as ion channel opening, vesicle release, and neurotransmitter diffusion. This noise not only places fundamental limits on the accuracy with which information can be encoded, but additionally dictates which processing strategies will be most effective in transmitting signal relative to noise.[2,3] Understanding the nature of noise in a neural circuit is therefore critical to interpreting its function.
Despite the many sources of noise present in biological circuits and the importance of understanding this noise, current models of neural responses typically assume a single source of variability, such as Poisson spike generation. Here, we present a framework to disentangle the contributions of multiple sources of variability in the responses of retinal ganglion cells. We record the spiking responses of ON alpha ganglion cells in the mouse retina to a flickering light stimulus under several different levels of ambient illumination. Then, using a flexible statistical model that incorporates multiple biologically feasible sources of noise, we determine the relative contributions of these noise sources using maximum likelihood estimation. Importantly, this work provides an approach to extend classical models, such as linear-nonlinear and generalized linear models, to include more biologically accurate sources of variability.
Using this new framework, we find that the relative contributions of different noise sources change with light level, suggesting that retinal ganglion cells ought to flexibly adapt their processing strategies in order to efficiently encode information under these different conditions.

Title: Dynamic modeling and functional analysis of *Drosophila* chromatic circuit

Authors: *T. BISWAS[1], C.-H. LEE[2], Y. LI[2]
[1]Physics, Loyola Univ., New Orleans, LA; [2]NIH, Washington, DC

Abstract: In Drosophila, UV (ultraviolet light) detection is mediated by UV-sensing R7 photoreceptors and their downstream amacrine neuron Dm8. Inactivation of R7s or Dm8 neurons abolished animals' innate preference to UV light over green light. Using calcium imaging to monitor neuronal activity, we found that UV illumination excited R7 photoreceptors but inhibited Dm8 neurons, consistent with our previous findings that Dm8 receives inhibitory histaminergic inputs from R7s. However, Dm8's responses exhibited additional properties: This includes OFF-excitation where after the UV stimulus is removed, the Dm8's do not directly relax to their normal state but rather become excited, and only slowly relax to their natural state thereafter. Also Dm8's exhibit center-surround antagonism, *i.e.* the Dm8's, that are "adjacent" to the Dm8 receiving inhibitory inputs from stimulated R7's, become excited. These features cannot be readily explained by known circuits. To gain more insight we take a "dynamical systems" approach involving first order differential rate equations to model the first few stages of the visual circuit. Based on our simulations and genetic manipulations, we suggest that Dm8's responses may be significantly shaped by a feedback inhibitory circuit.

Abstract: Purpose**:** To detect white matter (WM) damage and investigate the correlations between DTI parameters and retinal nerve fiber layer (RNFL) thickness in normal tension glaucoma (NTG) patients using diffusion tensor imaging (DTI).
Materials and Methods: 47 patients with NTG and 15 normal control (NC) subjects underwent DTI scanning and ophthalmological examination. Based on mean deviation scores (MDS) on visual field testing, the NTG patients were divided into three subgroups for comparison with the NC group: mild (mi-NTG, n = 18), moderate (mo-NTG, n = 14), and severe (se- NTG, n = 15) NTG. Atlas-based analysis (ABA) was performed on each subject to measure fractional anisotropy (FA) and mean diffusivity (MD). Association between DTI metrics and the severity of the disease (RNFL thickness) was studied using linear mixed regression analyses.
Results: Compared with NC subjects, significantly decreased FA and increased MD were observed in left anterior corona radiate (L.ACR), bilateral posterior thalamic radiation (B.PTR), bilateral sagittal stratum (B.SS), bilateral fornix/stria terminalis (B.FX/ST), bilateral tapetum (B.TAP), body of corpus callosum (BCC) and genu of corpus callosum (GCC) (all $p<0.05$). Further subgroup analyses revealed that the mi-NTG subgroup had significantly decreased FA and increased MD only in the B.PTR ($p<0.05$), the mo-NTG subgroup showed declined FA and increased MD in the B.PTR, BCC, GCC (all $p<0.05$); the se-AD subgroup exhibited lower FA and higher MD values in all these WM regions (all $p<0.05$). Furthermore, FA and MD values in these WM regions displayed good correlations with RNFL thickness ($p<0.05$), especially for the FA values in the B.PTR ($r=0.608$, $p<0.01$).
Conclusions: There are microstructural differences between different severity of NTG patients and normal controls in visual related WM regions, which could be used for the early diagnosis of NTG and monitoring disease progression.

Title: Functional characterisation of parvalbumin-expressing cells in the mouse retina

Authors: *E. SERNAGOR, G. HILGEN
Newcastle Univ., Newcastle Upon Tyne, United Kingdom

Abstract: It is well established that the Ca^{2+} binding protein parvalbumin (PV) is expressed in many retinal ganglion cells (RGCs) and amacrine cells (ACs). However, virtually nothing is known about their functional correlates. We have investigated the functional properties of PV-expressing cells in the mouse retina using pharmacogenetics, based on silencing (hyperpolarizing) PV neurons with Designer Receptors Exclusively Activated by Designer Drugs (DREADDs) in the presence of the DREADD agonist clozapine N-oxide (CNO). A high-density large-scale MEA (Biocam, 3Brain) featuring 4096 electrodes covering most of the mouse retina was used to study light-evoked responses from 100s-1,000s RGCs simultaneously. Various stimuli were used to characterize RGC receptive field organization and direction/orientation selectivity (DS, OS) in control conditions and in the presence of CNO (2μM). RGCs with >50% decrease in activity in CNO were classified as PV-RGCs and were compared to all other RGCs (non-PV RGCs). The role of PV-expressing ACs was established by comparing how non-PV RGCs respond to light without and with CNO. Overall, we found a high incidence of OFF transient cells (17.5%) amongst PV RGCs, whereas non-PV RGCs tend to have a higher incidence of ON transient responses (19.8%). We used the bias index (BI) to classify RGCs into ON (0.33<BI<1), OFF (-1<BI<-0.33) and ON-OFF cells (-0.33<BI<0.33). The BI for PV RGCs is close to 0 (-0.039) whereas in non-PV RGCs it is significantly skewed towards ON values (0.37). The duration of ON and OFF responses are both over 30% longer in PV RGCs. There was a massive increase in baseline activity in all non-PV RGCs in the presence of CNO. Their average BI increased to 0.67; ON and OFF responses became respectively 9.2 and 20.7% longer and the difference in duration between transient and sustained responses became less distinct. Both DS and OS (quantified by the DS and OS index) decreased by ~50% and the total number of spikes elicited by moving stimuli increased by ~50% in DS/OS cells. Interestingly, there was no change in motion elicited spike numbers in non-DS/OS RGCs. Finally, we found that oscillations induced in RGCs during specific visual tasks became much stronger in the presence of CNO. Our observations suggest that PV-RGCs tend to respond more to stimulus offset and their responses are relatively long. PV-expressing ACs mediate OFF responses and they gate both ON and OFF responses. They are strongly involved in establishing DS/OS, presumably by providing a robust direct or indirect asymmetric inhibitory input specifically onto DS/OS cells. Finally, they appear to control oscillatory activity between RGCs during specific visual tasks.

Title: Melanopsin sets the contrast detection threshold for M4 ipRGCs

Authors: *T. M. SCHMIDT, T. SONODA, S. LEE
Neurobio., Northwestern Univ., Evanston, IL

Abstract: Melanopsin-expressing, intrinsically photosensitive retinal ganglion cells (ipRGCs) have traditionally been associated with subconscious visual behaviors such as circadian photoentrainment and the pupillary light reflex. However, mounting evidence from *in vivo* electrophysiological recordings and behavioral experiments suggests that melanopsin phototransduction in ipRGCs also plays an important role in pattern vision. The cellular mechanisms underlying this influence have not been examined. Because melanopsin has been shown to be necessary for normal behavioral contrast sensitivity, even in the presence of fully functional rod and cone photoreceptors, we examined how melanopsin phototransduction influences the signaling properties of M4 ipRGCs. M4 ipRGCs are more commonly known as ON alpha RGCs, which are highly sensitive to contrast and project to image forming targets, making these cells good candidates for influencing behavioral contrast sensitivity. Consistent with a role for melanopsin in behavioral contrast sensitivity, when we directly measured the cellular contrast sensitivity of M4 ipRGCs we found that $Opn4^{-/-}$ M4 ipRGCs had significant deficits in contrast sensitivity at mean luminance levels ranging from scotopic (9 log quanta/cm^2/s) to photopic (12 log quanta/cm^2/s). These deficits were cell autonomous because we could acutely rescue contrast sensitivity deficits in $Opn4^{-/-}$ M4 cells that were virally infected with AAV2-hSyn-DIO-hM3D(Gq DREADD)-mCherry and exposed to bath application of 10 nM clozapine N-oxide (CNO) to activate the Gq pathway *in vitro*. Furthermore, we find that melanopsin phototransduction in M4 ipRGCs maintains a depolarized resting membrane potential at or above spike threshold for the cells and increases cellular excitability at all light levels tested. Combined, these influences of melanopsin phototransduction serve to optimize the response of M4 ipRGCs to the small, synaptic currents that would be associated with low

contrast stimuli, thereby enhancing the contrast sensitivity of M4 ipRGCs. These findings also allow us to link an observed behavioral influence of melanopsin phototransduction to a defined retinal cell population, the M4 ipRGCs.

Title: The role of Celsr3 in the development of retinal starburst amacrine cells

Authors: ***X. XIAO**, N. SHEN, Y. XU, L. ZHOU
Guangdong-Hong Kong-Mucau Inst. of CNS Regeneration, Jinan Univ., Guangzhou, China

Abstract: *Celsr3*, a core member of planar cell polarity (PCP) genes, encodes a seven transmembrane atypical cadherin and steers axonal projections in the different regions of the central nervous system during mouse brain development. In other species, *Celsr3* and its homologues (i.e. *Flamingo*) are required for visual development. For example, *Flamingo* regulated the organization of omatidium in *Drosophila*, and *Celsr3* mutation in zebrafish led to disrupted GABAergic signaling, which resulted in abnormal light response and visual function deficits. However, the role of *Celsr3* in mouse retinal development remains elusive. Here using *Celsr3-GFP* mice, we first found that *Celsr3* is expressed in some subtypes of amacrine cells and ganglion cells, as well as all horizontal, but not in photoreceptors or bipolar cells in adult retina. And during development, *Celsr3* keeps high expression in starburst amacrine cells (SACs) from P0 to P28. Then we conditionally inactivated *Celsr3* in SACs by crossing *Celsr3* "floxed" mice with *ChAT-Cre* mice. In *ChAT-Cre;Celsr3*$^{f/-}$ mice, mosaic spacing of ON- but not OFF-SACs is compromised. Moreover, ON- and OFF-SAC neurites fail to separate into two distinct bands in the inner plexiform layer with tangles and crosses in *ChAT-Cre;Celsr3*$^{f/-}$ retina, which emerges as early as P4. However, there are no significant defects in planar neurites arborization of SACs lacking *Celsr3*, implying that self-avoidance remains intact upon *Celsr3* knock-out. These results suggest that *Celsr3* shapes SAC development by regulating their planar soma distribution and neurites stratification, which provide a new insight into the role of *Celsr3* in neuronal circuits

assembly.

Title: Multiple synaptic mechanisms underlie global and object motion detection in the mammalian retina

Authors: X. HUANG[1], *W. WEI[2]
[1]Dept. of Neurobio., The Univ. of Chicago, Chicago, IL; [2]Univ. of Chicago, Chicago, IL

Abstract: In mammalian retina, the direction-selective ganglion cells (DSGCs) encode the direction of image motion. DSGCs receive glutamatergic excitatory inputs from bipolar cell terminals and cholinergic excitatory inputs from starburst amacrine cells (SACs). The inhibitory inputs onto DSGCs come from SACs, which are asymmetrically wired with DSGCs to provide directionally tuned inhibition. Previous studies using conventional motion stimuli including moving bars and drifting gratings have revealed a set of key mechanisms underlying direction selectivity of DSGCs. However, the synaptic circuitry that is engaged during more complex motion stimuli is not well understood. In this study, we aim to determine the synaptic components that are involved in computing direction selectivity during global and object motion in the mouse retina. Using two-photon targeted patch-clamp recording of GFP-positive neurons for light response, we find that different patterns of background motion evoke differential suppression effects on DSGC response to motion within the receptive field center. The suppression is strongest when uniform motion stimuli are presented to the background and the center (global motion). To address the mechanisms underlying the differential suppression effects, we applied two types of SAC-targeted genetic manipulations. The first one perturbed GABA release from the SAC by conditionally knocking out the vesicular GABA transporter

(Vgat) gene in SACs; the other one blocked all GABAergic inputs onto SACs by removing their GABA receptors. By comparing DSGC response in these conditional knock-out mice, we find that distinct sets of synaptic connections contribute to the spiking response of DSGCs during global and object motion.

Title: Lateral inhibition mediates excitation-inhibition covariation in retina direction selective circuit

Authors: *Q. CHEN, W. WEI
Univ. of Chicago, Chicago, IL

Abstract: Starburst Amacrine Cells (SACs) play an indispensable role in retinal motion computation by providing tuned excitatory and inhibitory inputs onto direction selective retinal ganglion cells (DSGCs). SACs receive GABA-A receptor-mediated inhibition from neighboring SACs and wide field amacrine cells. We have previously shown that this lateral inhibition is required for robust direction selectivity in noisy background for the On pathway. However, the mechanism underlying this function of lateral inhibition is not fully understood. Since the directional spiking pattern of DSGCs relies on the cancellation of excitation by inhibition in non-preferred directions, we hypothesize that the lateral inhibition onto SACs mediates the interaction of excitatory and inhibitory inputs onto DSGCs. To test this hypothesis, we performed voltage clamp recording of IPSCs and EPSCs in On-Off DSGCs both simultaneously and non-simutaneously, while stimulating the retina with a moving bar in the presence of random flickering noise. We then compared the difference of PSCs between control mice and mice that

lacks *Gabra2* (*Gabra2* KO) in SACs, a conditional knockout line previously developed to selectively remove lateral inhibition onto SACs. We find that disrupting lateral inhibition does not alter the directional tuning of IPSCs and EPSCs onto DSGCs, as measured by peak amplitude and charge transfer. However, in *Gabra2* KO mice, covariation between excitation and inhibition is significantly reduced in the null direction. This reduction of noise correlation in null direction is consistent with an increase in null-direction spiking in Gabra2 KO mice, revealed by loose patch recordings from DSGCs. Therefore, our results suggest that lateral inhibition onto SACs mediates the fine-scale balance of excitatory and inhibitory inputs onto On-Off DSGCs.

Title: Melanopsin-containing intrinsically photosensitive retinal ganglion cells are highly expressed in the noctural animal bat

Authors: M.-J. JEONG, H.-G. KIM, E.-B. PARK, *C.-J. JEON
Kyungpook Nat'l Univ., Daegu, Korea, Republic of

Abstract: Intrinsically photosensitive retinal ganglion cells (ipRGCs) respond to light and are involved in non-image forming vision such as circadian rhythms, pupil responses, regulation of sleep or image forming vision such as processing visual information and directing eye movements in response to visual clues. The purpose of this study was to identify the distribution, types and proportion of melanopsin-immunoreactive (IR) cells in nocturnal microbat retina. Three types of melanopsin-IR cells were found in the present study. M1 type had dendritic arbors extended into the OFF sublamina of the inner plexiform layer (IPL). M1 soma locations were observed either in the ganglion cell layer (GCL) (M1c; 21.00%) or the inner nuclear layer (INL) (M1d; 5.15%). M2 type had monostratified dendrites in the ON sublamina of the IPL and cell body in the GCL (M2; 5.79%). M3 type was bistratified cells with dendrites in both the ON and OFF sublaminas of the IPL and soma locations were either in the GCL (M3c; 26.66%) or the INL (M3d; 4.69%). In this study, some M3c (M3c-crv) had a curved dendrite heading up to the OFF sublamina of the IPL and heading down to the ON sublamina of the IPL (M3c-crv; 7.67%). Melanopsin-IR cells had small to medium soma size and medium dendritic fields. They had 2-5 primary dendrites and sparsely branched dendrites with varicosities. The total number of the

neurons in the GCL was 12,254.17 ± 660.39 (mean ± S.D.; n = 3) and that of the optic nerve axons was 5,179.04 ± 207.99 (mean ± S.D.; n = 3) in the bat retina. The density of melanopsin-IR cells was 227.12 ± 11.41 cells/mm^2 (mean ± S.D.; n = 4) and it was estimated that ipRGCs constituted about 15.83% of total RGC population. The study shows that the nocturnal bat has much higher density of melanopsin-IR cells than diurnal animals studied so far.

Title: Cholinergic neurons in the bat retina: Different dendritic stratification pattern as compared to other animals

Authors: *E.-B. PARK[1,2,3,4], J.-Y. JEON[1,2,3,4], G.-H. KIM[1,2,3,4], M.-J. KWON[1,2,3,4], E.-S. LEE[1,2,3,4], C.-J. JEON[1,2,3,4]
[1]Sch. of Life Sci., [2]BK21 Plus KNU Creative BioResearch Group, [3]Col. of Natural Sci., [4]Brain Sci. and Engin. Inst., Kyungpook Natl. Univ., Daegu, Korea, Republic of

Abstract: The purpose of this study was to localize the cholinergic amacrine cells, one of the key elements of a functional retina, in the retina of a microbat, *Rhinolophus ferrumequinum*. The presence and localization of choline acetyltransferase-immunoreactive (ChAT-IR) cells in the microbat retina were investigated using immunocytochemistry, confocal microscopy, and quantitative analysis. These ChAT-IR cells were present in the ganglion cell layer (GCL) and inner part of the inner nuclear layer (INL), as previously reported in various animals. However, the bat retina also contained some ChAT-IR cells in the outer part of the INL. The dendrites of these cells extended into the outer plexiform layer, and those of the cells in the inner INL

extended within the outer part of the inner plexiform layer (IPL). The dendrites of the ChAT-IR cells in the GCL extended into the middle of the IPL and some fibers ramified up to the outer IPL. The density of ChAT-IR cells was highest in the mid-ventral and mid-temporal retina. The average densities of ChAT-IR cells in the GCL, inner INL, and outer INL were 259 ± 31 cells/mm^2, 469 ± 48 cells/mm^2, and 59 ± 8 cells/mm^2, respectively. The average total density of the ChAT-IR cells was 788 ± 58 cells/mm^2 (mean ± S.D.; n = 3; 2,799 ± 182 cells/retina). We also found that the cholinergic amacrine cells in the bat retina contained calbindin, one of the calcium-binding proteins, but not calretinin or parvalbumin. As the cholinergic amacrine cells play key roles in the direction selectivity and optokinetic eye reflex in the other mammalian retinas, the present study might provide better information of the cytoarchitecture of bat retina and the basic sources for further physiological studies.

Title: Inhibition of Non-NMDA ionotropic glutamate receptors delays retinal degeneration in rd10 mice

Authors: Z. XIANG, J. ZHANG, *Y. XU
Jinan Univ., Guangdong, China

Abstract: Purpose: Retinitis pigmentosa is a progressive neurodegenerative disease that cause deterioration of rod and cone photoreceptors and is the leading cause of blindness in the world. The aim of this study is to understand the progress of the disease focusing in the glutamate pathway, and to seek effective way to protect the function of retinal neurons, hoping to provide a new strategy to treat retinitis pigmentosa in the clinic. **Methods:** In our study, we used rd10 mice, a well-established animal model of retinitis pigmentosa, to detect the changes of glutamate receptors expression during photoreceptor degeneration and the impact on the functions of retinal ganglion cells. We firstly checked the changes of ON signal cascade proteins (metabotropic

glutamate receptor 6, mGluR6 and TRPM1 proteins) and OFF signal cascade related ionotropic glutamate receptors(iGluRs)by immunostaining. Then we used multi-electrode-array (MEA) system to record the light response of ganglion cells and the effects of perfusing low dose of CNQX (non-NMDA iGluRs antagonist) on the functions of retinal ganglion cells. Lastly, we i.p. injected rd10 mice with CNQX for 2 weeks, and examined the changes of light response of ganglion cells and the morphology of retinal neurons, as well as the animal behavior. **Results:** mGluR6 and TRPM1 were down-regulated in the outer plexiform layer during photoreceptors degeneration. In contrast, iGluRs were up-regulated in the inner plexiform layer, and AMPA receptors formed abnormal clusters in the outer plexiform layer. During photoreceptors degeneration, the light response of ganglion cells in rd10 retina decreased while the spontaneous spiking increased abnormally. Both in vitro and in vivo application of low-dose CNQX inhibited the abnormal spontaneous spiking and increased the light evoked response of ganglion cells. Furthermore, in vivo application of CNQX increased the survival of photoreceptors, improved the morphology of bipolar cells as well as the behavioral performance. **Conclusion:** Our data indicate that blocking the ionotropic glutamate signal pathway by CNQX delays the functional decay of ganglion cells during photoreceptors degeneration, thus it might be an effective strategy to prolong the time window for the treatment of retinitis pigmentosa.

Title: Differential expression and sub cellular localization of copines in mouse retina

Authors: *M. GOEL, ***M. GOEL**, T. LI, T. C. BADEA
Natl. Eye Inst., NIH, Bethesda, MD

Abstract: Brn3 transcription factors are important for cell type specific arbor formation and dendrite stratification in the retina. Brn3b might be regulating several downstream genes that have a role in cell specific dendritic stratification and synapse formation in the inner retina. From the RNA sequencing done previously in our lab on wild -type and Brn3b $^{-/-}$ mouse retinas (Sajgo et al., 2017), we identified a family of proteins - Copines - which are regulated by the Brn3b transcription factor. There are nine Copines (1 to 9) present in the mammalian genome. Copines are intracellular, membrane bound proteins containing two C2 domains and an integrin-like von Willebrand A domain. Recently, Cpne6 has been shown to be important for synaptic plasticity and LTP formation in the hippocampus (Reinhard et al., 2016; Burk et al., 2017). Hence, the Copines might have a role in synapse formation in the Inner Plexiform Layer (IPL) in retina.

The aim of this study was to study the expression profile of the Copines in post-natal retina. We studied the expression of the Copine mRNAs in P0, P3, P7, P14 and adult retinas using in-situ hybridization. We also checked the expression of the Copine proteins using immunohistochemistry (IHC) in adult retina. To study the sub cellular distribution, HEK293 cells were transfected with the HA tagged Copines. Sub cellular distribution of Copines in the $Brn3b^+$ Retinal Ganglion Cells was also studied in virus infected retinas.
Copine proteins are expressed in the retina starting from early postnatal ages and have a dynamic expression through retinal development. The different copines have a differential expression pattern in the RGCs and amacrine cells. The HEK 293 cells transfected with Copines and Cre dependent expression of Copine in Brn3b RGCs indicated the expression of Copine in the nuclei, cell bodies as well as the dendrites of the cells. Moreover, a lot of the transfected HEK293 cells had 'neurite-like' processes.
The differential expression of different Copines suggests that they might be providing a combinatorial code for cell type specific dendritic stratification and synapse formation in the inner retina.

Title: Inner retinal contributions shape the b-wave of the electroretinogram (ERG) in adult zebrafish

Authors: A. HERRERA, *S. SASZIK
Psychology, Northeastern Illinois Univ., Chicago, IL

Abstract: Purpose: The electroretinogram (ERG) is mass retinal potential that can be recorded with an electrode on the cornea. Contributions from outer retinal neurons have been well described, however recent research has identified contributions from inner retinal neurons in some mammalian species. The purpose of the current experiments is to determine if contributions from ganglion cells can be identified in the light-adapted ERG in zebrafish.
Methods: To determine ganglion cell contributions to the ERG were recorded in control (CON) conditions and one week post optic nerve crush (ONC). Adult zebrafish were anesthetized and the eye rolled slightly to expose the optic nerve. The nerve was then crushed with forceps for 3 seconds. The fish was then placed into a 2.5 gallon tank and allowed to recover. After one week, fish were again anesthetized and electroretinograms (ERGs) recorded to a 50 ms flash of monochromatic light under light adapted conditions. Four wavelengths were tested (340 nm, 420

nm, 520 nm, and 620 nm). The amplitude of each response was measured at 180 ms. Intensity response function were plotted and comparisons of amplitude, time to peak, and threshold were measured.
Results: Examination of the ERG responses found no difference based on the wavelength of the light, thus data from the individual wavelengths was compiled and comparisons were made for CON and ONC. After ONC there was an increase in the time to peak (CON M=221.6 ms, SEM=1.9; ONC M=236.3 ms, SEM=6.9) and a decrease in the peak amplitude of the b-wave (CON M=1041.3 microvolt, SEM=98.1; ONC M=840.5 microvolt, SEM=102.6). Additionally, a ssignificant increase was found in the 50 microvolt threshold (CON M=6.3 log photons, SEM=0.1; ONC M=6.7 log photons, SEM=0.1). Further examination showed that in addition to a loss at 180 ms, a negative potential that has a time to peak around 300 ms was also removed.
Conclusion: After ONC several changes were seen in the ERG response that had an impact on the time course and amplitude of the b-wave suggesting the presence of a contribution reflecting the activity of ganglion cells. The loss of a negative potential after the b-wave is suggest that the zebrafish also has a photopic negative response. Together these results will provide some information about the cellular contributions to the ERG in zebrafish.

Title: Motion direction discrimination during neural aging

Authors: A. KARADUMAN[1,2], U. KAYA[1,5], E. T. KAROGLU[2,3], A. ERGUL-ARSLAN[2,3], M. M. ADAMS[2,3,4], *H. KAFALIGONUL[1,2]

Abstract: Understanding the principles underlying age-related changes in perception and cognition is paramount to improve the quality of life and health of elderly individuals. A number of studies have shown that the perception of visual motion is significantly altered throughout aging (Owsley, 2011). However, the neural mechanisms underlying the effect of aging on this aspect of vision, which is essential for survival in a dynamic world, are quite poorly understood.

The zebrafish have been commonly used as an aging model (Arslan-Ergul et al., 2013). Moreover, several studies have shown that zebrafish perceive first-order (Fourier) and second-order (non-Fourier) motions, suggesting that they have very similar motion systems as in humans (Orger et al., 2000). Using this animal model which offers a framework not only for aging but also for visual motion perception, we aimed to characterize contrast and spatial frequency dependency of direction discrimination for young (AB wild-type, 8-10 months) and old (AB wild-type, 24-30 months) groups. In our experiments, we used first-order and second-order drifting gratings, and relied on the averaged and normalized optomotor responses to these motion types. To generate the first-order motion, we used sine-wave gratings with varying contrasts (1-75 %) and spatial frequencies (0.01-0.8 c/deg). The second-order motion consisted of random dots and was flicker-frequency-modulated. The flicker frequency of the static random dots was modulated by a drifting square-wave (half-wave rectified, 50% duty cycle). We used the same spatial frequency values (0.01-0.8 c/deg) for the second-order motion. Our results showed that the optomotor responses were affected by the contrast and spatial frequency of first-order motion. However, these effects were distinct for each zebrafish group. Interestingly, compared to the young ones, the old zebrafish had larger optomotor response to the first-order motion with low contrast and spatial frequency, suggesting that they discriminate the direction of first-order motion better at the threshold level. On the other hand, the young group generated larger optomotor responses to second-order motion than the old group. Taken together, our findings here highlight distinct effects of aging on the first-order and second-order motion which are mostly believed to engage different motion systems. Characterizing these motion types for mutants in which the aging is accelerated or decelerated awaits further investigation.

Title: Neural mechanisms for integrating motion and form cues for the perception of heading during self-motion

Authors: *S. KUAI[1,2,3], Z.-X. XU[1,2], J. CHEN[3], J.-M. LI[1,2], D. T. FIELD[4], L. LI[3]
[1]The Sch. of Psychology and Cognitive Sci., East China Normal University, China; [2]Key Lab. of Brain Functional Genomics, Ministry of Education, Shanghai Key Lab. of Brain Functional Genomics, Inst. of Cognitive Neurosci., Shanghai, China; [3]NYU-ECNU Inst. of Brain and Cognitive Science, New York Univ., Shanghai, China; [4]Ctr. for Integrative Neuroscience. & Neurodynamics, Dept. of Psychology, University of Reading, United Kingdom

Abstract: When moving around in the world, the human visual system uses both form and motion information to estimate the direction of self-motion (i.e., heading). However, the neural mechanism responsible for integrating motion and form cues for heading perception remains unknown. In this study, we explored the brain areas that process form cues for heading perception and examined whether they overlap with the known brain areas that process motion cues for heading perception. We further investigated brain areas responsible for integrating motion and form cues for heading perception. Specifically, we used integrated glass patterns that had dot pairs oriented toward a locus on a screen (the form-defined focus of expansion (FOE)) but moved away from a different locus (the motion-defined FOE). The form- and the motion-defined FOEs were congruent or incongruent. In the congruent condition, the form- and the motion-defined FOEs were centered on the same location on the screen. In the incongruent condition, the form- and the motion-defined FOEs were on the opposite side relative to the center of the screen. Different stimulus conditions were presented in separate blocks in fMRI scans. Participants made a task-irrelevant (luminance discrimination) judgment during scanning. We compared BOLD response patterns across stimulus conditions using multiple voxel pattern analysis. We selected the 200 most active voxels in each ROI, trained a linear SVM to discriminate stimulus types, and then tested the classifier's prediction for each stimulus block. We found that early visual areas (V1 and V2) decoded both the form- and the motion-defined FOEs but could not discriminate the congruent and incongruent conditions, suggesting that these areas do not integrate form and motion cues for heading perception. The higher ventral areas (V4 and LO) decoded the form- but not the motion-defined FOE while the dorsal areas (MT and MST) decoded the motion- but not the form-defined FOE. In contrast, the higher dorsal areas (V3a, V3B and V7) and the parietal lobe (VIP and CSV) not only decoded both the form- and the motion-defined FOEs but also dissociated the congruent and incongruent conditions, suggesting that they contribute to the integration of form and motion cues for heading perception. Our findings provide the first empirical evidence suggesting that form and motion information are first processed along separate pathways and then integrated in the higher dorsal areas for the final estimation of heading during self-motion.

Title: Reverse-phi motion: Optomotor reflexes and visual cortex responses for a visual illusion of motion in mice

Authors: L. KIRKELS[1], J. DUIJNHOUWER[2], W. ZHANG[1], M. N. HAVENITH[1], J. GLENNON[1], P. H. TIESINGA[3], *R. VAN WEZEL[4]

Abstract: In reverse-phi motion, the contrast luminance of moving dots is reversed at each displacement step. Under those conditions their direction of motion is perceived as opposite to their veridical direction of displacement. In this study, we investigate whether mice also perceive a reverse-phi motion effect/illusion. In a virtual reality environment, mice were subjected to an immersive moving-dot stimulus that featured sudden changes in direction of regular motion (phi-motion) and reverse-phi motion. Mice were head-fixed and running on a floating-ball treadmill, surrounded by a projection dome covering 270 degrees of visual angle. For phi-motion, motion onsets to the left or right cause animals to reflexively compensate, adjusting their running direction towards the moving pattern. In contrast, for reverse-phi motion, mice compensate in the opposite direction, in accordance with the illusory motion that humans perceive for reverse-phi motion stimuli. We used two-photon calcium imaging to measure the neural responses of layer 2/3 primary visual cortex (V1) neurons of awake mice that passively viewed the moving dots on a screen. We find that only a small fraction of direction selective V1 neurons reverse their preferred direction for phi and reverse-phi motion, firing maximally at their null-direction. At the population level there was no statistically significant effect. The discrepancy between the clear behavioral impact of reverse-phi stimuli and their very moderate effect on V1 responses suggests that the illusion is processed via alternative visual pathways, e.g. superior colliculus, of which the individual cell responses during these stimuli were not measured in the current study.

Information Lab. @ CSUN, Sherman Oaks, CA

Abstract: Asthenopia is a condition characterized by significant visual discomfort symptoms including, but not limited to symptoms of blurred vision, double vision, and strained, sore, or tired eyes. In the past, self-report surveys have been used to assess the severity of asthenopic symptoms (e.g. the Visual Discomfort Survey, Conlon et al. 1999). In contrast to other works that have evaluated the effectiveness of such surveys, the present study aims to compare two different technologies used to obtain objective measures of oculomotor ability: a WAM-5500 autorefractor to evaluate accommodative posture, and Eyelink 1000 Plus eye-tracker to record multiple forms of oculomotor movements. Previous studies have examined similar phenomena using accommodative recordings to evaluate the effectiveness of surveys (i.e. Chase et al., 2009; Tosha et al., 2009). However, the present work aims to expound upon these findings through the use of two extended reading tasks on the computer; before and after each task, accommodative posture was evaluated via the autorefractor. The eye-tracker is likewise an additional tool that was used to collect data during one of the two reading task, and may be an indicator of convergence insufficiencies, which also have been shown to contribute to visual discomfort symptoms. Data from this preliminary study indicate multiple relationships observed between the accommodative postures, as recorded via the autorefractor, and oculomotor activity observed during eye-tracking. The use of objective laboratory techniques such as these, in conjunction with survey data, may help researchers with non-optometric evaluations of asthenopia. With the present dependency on computers in fields such as neuroscience, asthenopic symptoms induced by computer screens still need to be better understood before they can be mitigated.

Title: Light/dark asymmetries in motion perception

Authors: *A. W. FREEMAN, G. LUO-LI
Sch. of Med. Sci., Univ. of Sydney, Lidcombe, Australia

Abstract: Introduction. It is now well-established that responses to stationary light and dark stimuli of equal magnitude are asymmetric: psychophysical and neural responses to darks are larger and faster than responses to lights. We wondered whether this asymmetry might play a role in motion perception. We therefore measured the sensitivity of six human subjects to light and dark moving edges and bars. **Methods.** Stimuli were enveloped by a Gaussian spatial profile with a standard deviation of 0.3 deg, bar width was 0.1 deg and speed was 1, 3 or 10 deg/s. Movement was leftward or rightward, and the subject's task was to indicate motion direction. Stimulus contrast on each trial was sampled from a Gaussian probability density with zero mean, so that there was equal probability of a light or dark. We measured both the proportion of correct responses and reaction time. **Results.** We compiled psychometric and chronometric functions separately for light and dark stimuli: pooled psychometric data obtained with a bar moving at 3 deg/s are shown in the figure. Surprisingly, responses to light stimuli were stronger and faster than those to darks. At 3 deg/s the contrast sensitivity for lights (measured at the midpoint of the psychometric function) was 57% higher than for darks. At the same speed, reaction time for lights (measured at the midpoint of the chronometric function) was 32 ms less than for darks. The asymmetry was biggest at 1 deg/s and nearly absent at 10 deg/s. **Discussion.** Very high speeds will minimally stimulate motion-selective mechanisms and should appear to be stationary flashes. From previous work, we can therefore expect that responses to fast-moving dark stimuli will dominate those to lights; the trend we measured was in this direction. Why do lights dominate darks at low speeds? One possibility is the effect of surround suppression. Primary visual cortex is, in general, dark-dominated and a dark moving stimulus will generate more surround suppression that a light one. Perhaps, then, responses to dark moving stimuli are suppressed more that their light-evoked counterparts. We are testing this idea.

Title: Assessment of visual dysfunction of the optomotor response in APOE transgenic mice after TBI

Authors: *S. FERGUSON[1], T. SMITH[1], B. C. MOUZON[2], D. APONTE[1], M. J. MULLAN[1], F. C. CRAWFORD[1]
[1]Roskamp Inst., Sarasota, FL; [2]The Roskamp Inst., Sarasota, FL

Abstract: Our mouse model of repetitive mild TBI (r-mTBI) produces chronic optic nerve pathology and retinal degeneration. The APOE4 allele has previously been shown to be associated with poor outcome after head injury. In order to assess the visual function of APOE transgenic mice, we have optimized a mechanical assay to assess the optomotor response. The optomotor apparatus consisted of a rotating drum containing black and white stripes at varying angular resolutions at 2 rpm. Mice were acclimated to the apparatus for a period of 5 minutes in phototopic lighting. Optomotor testing at each resolution consisted of pairs of 2 minute trials with 1 trial in a clockwise rotation followed by 1 trial in a counter-clockwise rotation with an inter-trial time of 30 seconds. After the completion of all 4 trials the mouse was returned to the home cage and the next mouse was tested. All trials were recorded with Noldus Ethovision XT using both manual and automatic quantification. Optomotor testing and optimization revealed a quantifiable optokinetic response of the mice which decreased with decreasing stripe thickness,

and was significantly impaired in APOE4 transgenic mice after TBI. Ethovision XT based quantification of the head velocity failed to show a stripe-dependent decrease of the optomotor response, but more advanced pattern recognition algorithms may allow for more accurate automated detection of the optomotor response in the future. By varying the resolution of the stripes we were able to increase the difficulty of the task and determine the optimal conditions for discriminating subtle vision deficits. APOE4 transgenic mice show a significant vision impairment compared to sham controls, but current commonly used animal tracking software is insufficient for discriminating between the optomotor response and random head movements.

Title: Optic flow and visual self-motion information during real-world locomotion

Authors: *J. S. MATTHIS[1], K. S. MULLER[2], N. K. SCHNEIDER[3], K. BONNEN[1], M. M. HAYHOE[1]
[1]Ctr. for Perceptual Systems, Univ. of Texas at Austin, Austin, TX; [2]Ctr. for Perceptual Systems, Univ. of Texas at Austin, Austin, PR; [3]Mechanical Engin., Univ. of Texas at Austin, Austin, TX

Abstract: A large body of research has examined the way that patterns of motion on the retina might contribute to perception of self-movement through the world, but the actual visual motion stimulus generated by real-world locomotion has never been measured. We used computer vision techniques to estimate optic flow from a head-mounted video camera, recorded when subjects walked over various types of real-world terrain. Eye, head, and body movements were also recorded. We found that the optic flow experienced during locomotion reveals a pulsing pattern of visual motion that is coupled to the phasic acceleration patterns of the gait cycle, unlike the constant-velocity flow fields that are generally used to simulate self-motion. This difference between actual and simulated visual self-motion has a major effect on the behavior of the focus of expansion (FOE), a feature of optic flow that has been extensively studied as a locus of information about heading direction, but one that has not previously been recorded during natural behavior. Results show that the acceleration patterns of the head cause the FOE to follow a

complex path in the visual field, in contrast to simulated constant-velocity self-motion stimuli, where the FOE lies in a stable location in observer's environment. Thus its role in the control of heading must be more complex than previously imagined. Although the behavior of the FOE and the self-motion information experienced during locomotion are complex, their dynamics contain rich and potentially useful structure for the control of locomotion and posture.

Nijmegen, Nijmegen, Netherlands; [5]Radboud Univ. Nijmegen Med. Ctr., Nijmegen, Netherlands; [6]Radboud University, Donders Inst. For Brain, Cognition and Behaviour, Nijmegen, Netherlands

Abstract: A frequently used method to measure visual capabilities of mice is to observe reflexive head movements to moving patterns. In this study we introduce another technique that

also does not require training, but is more quantitative by recording traces of mice running head-fixed on an air-floated ball, while projecting large moving random dot patterns on the inside of a dome. Sudden onset of rightward or leftward moving patterns caused reflexive changes in the mouse running direction. We used these optomotor reflexes to quantify visual responses for different pattern speed, luminance contrast and dot size. The strongest reflexes are evoked with pattern speeds between 36 and 72 degrees per second, a luminance contrast of 0.2 and a dot size of 2 degrees, with an additional interaction effect between speed and luminance. Results revealed that changes in both contrast and dot size affect speed sensitivity . Furthermore, the obstruction of the left or right eye leads to stronger optomotor reflexes for leftward or rightward motion respectively. Our paradigm is a fast, consistent and a reliable test of optomotor response, with no adaptation effects within or across sessions. Most importantly, it does not require task training while at the same time testing more than purely reflexive visuo-motor responses. We conclude that this method is suitable for studies that need a fast and quantitative description of visually guided behavior in mice.

Title: TMS-induced disturbance of self-motion perception in humans

Authors: *C. SCHMITT[1], B.-R. BALTARETU[2], J. D. CRAWFORD[2], F. BREMMER[1]
[1]Philipps-Universität Marburg, Marburg, Germany; [2]York Univ., North York, ON, Canada

Abstract: Accurate perception of one’s direction of self-motion is of utmost importance during everyday life. Previous neurophysiological studies in the animal model (macaque monkey) and imaging studies in humans have provided clear evidence for an involvement of area MST in the encoding of self-motion. In a recent study combining monkey neurophysiology, human psychophysics and computational modeling we could show that saccadic eye movements modulate heading representation. The computational part of our study predicted a direction specific TMS-induced increase of response variance of heading perception. Here we wanted to investigate by means of neuronavigated transcranial magnetic stimulation (TMS) if (i) TMS can

mimic the effects of saccades on heading perception and if (ii) TMS indeed induces a greater variance of heading perception for simulated self-motion contraversive to the TMS stimulation site.
We presented an optic flow stimulus (random dot pattern) on a large projection screen 54 cm in front of the participants. In a given trial, the stimulus first was stationary, then moved for 50 ms, simulating forward self-motion across a ground plane in one of three directions separated by 30°, and was stationary again. Participants fixated a central target throughout the trial. After each trial, participants had to indicate perceived heading direction. In 57% of the trials three TMS pulses were applied, separated by 100 ms each, centered on self-motion onset. TMS-stimulation site was either right-hemisphere MST, which we identified using an fMRI localizer, or a control area 1.5 cm posterior to human MST.
TMS over MST increased response variance of perceived heading. Remarkably, and as predicted by our model, this result was strongest for simulated self-motion to the left (contraversive). This contraversive specificity was absent from the TMS control area. Different to saccades, which induce a compression of perceived heading, TMS pulses induced misperception towards both, more central and more peripheral, headings. Our results provide further evidence for a critical role of primate area MST for navigation.

Title: Short-latency ocular responses are strongly affected by the visual content during the initial fixation period

Authors: *B. M. SHELIGA, C. QUAIA, E. J. FITZGIBBON, B. G. CUMMING
Lab. Sensorimotor Res., Natl. Eye Inst., Bethesda, MD

Abstract: We recorded horizontal disparity-vergence responses (DVRs) to vertical 1D pink noise in two human subjects. The stimulus was preceded by 800-1100 ms of maintained fixation (on a visible cross), and we explored the effect of different stimuli (“fixation patterns”) presented during the fixation period. When the fixation pattern was a blank screen, the DVR usually had two well-defined peaks of acceleration—early and late. When the fixation pattern was a different sample of static zero-disparity noise, the early component was absent, resulting in weaker

responses with longer latency. When the fixation pattern was a dynamic noise stimulus at zero disparity the DVR latencies were even longer, and response magnitudes peaked at smaller disparities than those obtained with blank or static fixation patterns. When the dynamic noise stimuli were binocularly uncorrelated during the fixation period, we observed a still further drop (up to 60-70%) in the DVR amplitude. We found a different pattern using motion stimulus to drive short-latency ocular-following responses (OFRs). Blank and static fixation patterns produced similar responses. A flickering fixation pattern led to a massive drop in the OFR amplitude, very much like we observed with the DVRs when the fixation period images were uncorrelated in the two eyes. Thus, the visual context preceding the stimuli triggering the DVRs (as well as the OFRs) exerts a dramatic influence upon the characteristics of these short-latency ocular responses. These interactions can be explained by suggesting that transient and sustained visual inputs both contribute, but drive mechanisms with different disparity (or motion) responses. For example, the appearance of a stimulus following a blank screen activates transient channels. If these produce responses with shorter latency, it explains the changes in latency we observe. Some aspects of the measured response with blank fixation patterns may reflect the properties (e.g. spatial frequency tuning) of mechanisms driven by sudden contrast changes. For DVRs, only the dynamic fixation pattern isolates purely binocular processing - in this condition the appearance of the disparity driving the DVR is not associated with any monocular changes.

Title: Suppression and facilitation of neural responses in the human visual system

Authors: *M.-P. SCHALLMO, A. M. KALE, R. MILLIN, A. V. FLEVARIS, R. A. BERNIER, S. O. MURRAY
Univ. of Washington, Seattle, WA

Abstract: Neural suppression and facilitation regulate levels of activity within the brain, but how these effects are mediated remains poorly understood. Both reduced and enhanced neural

responses are well-known to emerge in the visual system via spatial context effects, and have a variety of perceptual consequences. For example, the perception of visual motion has been reliably shown to depend on the size and contrast of a stimulus. Specifically, more time is needed to discriminate the direction of motion of a large high contrast grating compared to one that is small. This seemingly paradoxical effect is referred to as spatial suppression, and has been suggested to reflect neural suppression from extra-classical receptive field surrounds. The effect of size on duration thresholds is reversed for a low contrast stimulus - less time is needed to discriminate motion direction for a large compared to small stimulus (spatial summation). Strong assumptions are often made about the neural processes underlying these seemingly complex interactions between size and contrast during motion perception. For example, it is often assumed that spatial suppression and summation reflect distinct neural mechanisms that rely on inhibitory and excitatory processes, respectively, within brain regions involved in visual motion processing (particularly area MT).
We tested these assumptions directly using a multi-modal approach that combined five different techniques: functional MRI (fMRI), magnetic resonance spectroscopy (MRS), pharmacology, quantitative behavioral analysis (psychophysics), and computational modeling. We show that: 1) spatial suppression and summation in fact naturally emerge from a single, well-established neural computation known to occur in visual cortex - divisive normalization; there is no need to posit separate mechanisms. 2) While neural responses in human MT complex (hMT+) indexed with fMRI provide better correspondence with the measured perceptual effect, there is substantial suppression in earlier visual areas. 3) Two separate methodologies - magnetic resonance spectroscopy (MRS) and pharmacological potentiation of $GABA_A$ receptors - demonstrate that spatial suppression is not directly linked to neural inhibition. While we find that inhibition plays a role in motion perception, increases in duration threshold as a function of stimulus size should not be taken as an index of inhibitory processing. In total, our results suggest that a single computational principle - divisive normalization - can account for spatial context effects, and that suppressive context effects are not driven by neural inhibition.

Title: A study of direction discrimination task using a touchscreen method in rats

Authors: *S. SAKATA[1], Y. IIO[2], Y. NAKAMURA[2]
[2]Dept. of Behavioral Sci., [1]Hiroshima Univ., Hiroshima, Japan

Abstract: Motion lines (MLs) are an effective technique for illustrating dynamic events such as fast movement of an object in a still picture. Perception of moving objects correlate with timing ability. This study explored whether MLs have the same effect for human and animals. First, we had a task to discriminate the motion direction of circles using touchscreen method in rats. Six male Long-Evans rats were food restricted and trained to perform moving visual tasks for food reinforcement. Animals were trained to perform two alternative left and right side operant choice visual discrimination of the direction of the motion. The discrimination moving stimuli were presented with five white circles background in dark display. All six rats showed good performance of direction discrimination over 80 % correct responses in forty training sessions. Then we tested with five kinds of MLs probe stimulus. These probe stimuli were 1) apparent movement five circles with MLs in low flame rate, 2) five circles with MLs at random position, 3) MLs with one side in a still picture, 4) MLs with both side in a still picture, 5) only five circles without movement. The results showed that its performance in MLs probe in a still picture were chance level. But in apparent movement probe showed good performance like motion direction discrimination. These results of this study suggest that rats could visual discriminate in apparent movement stimuli like human visual performance.

Title: Encoding multisensory information through distinct population activity in a premotor region

Authors: *C. J. GOLDSMITH, R. FOLLMANN, W. STEIN
Sch. of Biol. Sci., Illinois State Univ., Normal, IL

Abstract: Integrating information from multiple sensory modalities and producing appropriate motor outputs are vital functions of the nervous system, and the neural networks underlying these two functions are tightly linked. Most motor circuits produce a variety of distinct outputs in different sensory conditions (Li et al., *J Neurosci* 2016), yet it remains ambiguous how this is achieved by the nervous system. While traditionally not considered multisensory, premotor

circuits in both vertebrates and invertebrates are known to process information from several sensory modalities. In the crustacean stomatogastric nervous system, several neurons in the premotor region of the commissural ganglion are activated by multiple sensory pathways and modulate downstream motor circuits (CoGs; Stein, *J Comp Physiol A* 2009). Stimulation of individual premotor neurons can elicit distinct versions of the gastric mill motor pattern (Nusbaum & Beenhakker, *Nature* 2002), though it is likely that in conditions of natural behavior, several of these neurons are recruited simultaneously. We hypothesize that distinct combinations of neuronal recruitment in the CoG premotor region exist across different sensory conditions, i.e. multisensory information is processed via a combinatorial code.
We used selective stimulation of a chemosensory (inferior ventricular neurons, IV) and a mechanosensory (ventral cardiac neurons, VCN) pathway in combination with voltage-sensitive dye imaging to characterize the CoG neuronal network response under different sensory conditions. We show that both pathways activate the majority of imaged neurons, resulting in an overlapping (~80% multimodal neurons), yet consistently distinct (~20% unimodal neurons) network response between the two conditions (N=12 animals). In particular, VCN stimulation led to a higher proportion of excited neurons, while IV stimulation yielded a higher proportion of inhibited neurons in the premotor region. The specific neurons contributing to the network response were also distinct between inputs. Moreover, concurrent stimulation of IV and VCN pathways resulted in a network response that was not the additive result of the two unisensory conditions (N=6 animals). Our findings thus suggest that: (1) premotor neuronal networks distinctly encode different sensory inputs, and (2) there is an additional network reconfiguration in response to concurrent stimulation.

Title: Efficient coding of multisensory or multi-modality inputs by congruent and opposite neurons

Authors: *L. ZHAOPING
Univ. Col. London, London, United Kingdom

Abstract: Many medial superior temporal (MST) neurons are tuned to heading direction of self-motion based on optic flow or vestibular inputs. The preferred directions from different senses

within a single neuron can be congruent (matched) or opposite from each other (Gu, Angelaki, DeAngelis 2008). Similarly, neurons in middle temporal (MT) cortex are tuned to depth based on binocular disparity or motion parallax, and the preferred depths from different modalites can also be congruent or opposite (Nadler et al 2013). These are examples of neuron in the brain that respond to inputs from multiple sensory modalities, e.g., vision, audition, and touch, or from multiple unisensory cues. While the congruently tuned neurons appear natural for the functional role of cue integration, the oppositely tuned neurons appear somewhat puzzling. I propose that, together, congruent and opposite cells in a neural population achieve efficient coding given incomplete redundancy in the input sources (Barlow, 1961). Efficiency requires creating representations (also called bases) in which the inputs are decorrelated. For two sources, this implies two bases in which inputs that sample the features from the two sources are either (weighted and) added or (weighted and) subtracted; these are the genesis respectively of congruently and oppositely tuned cells. The opposite cells are needed because the two sources are typically only incompletely redundant, and their activities can encode input information not encoded by the congruent cells. The exact forms (i.e., relative weighting of the sources) of, and neural sensitivities to, individual bases should depend on, and adapt to, the statistical properties of the inputs (e.g., the correlation between the sources and the signal to noise ratios). Coding of visual-vestibular heading direction and stereoscopic-motion-parallax depth both become analogous to efficient stereo coding in the primary visual cortex (Li & Atick 1994), which represents inputs to the two eyes by the sum and difference of these inputs (which are then multiplexed in the responses of the neural population). Generalization to more than two senses or modalities is straightforward. For example, coding of inputs from three sources can be analogous to efficient color coding of inputs from three cone types (Atick, Li, Redlich 1992), so that there will be three decorrelated channels: a weighted sum and two weighted differences of the three input sources. I will illustrate with some examples and relate them with experimental data.

Title: Visual-proprioceptive integration and hand ownership in monkeys and humans

Authors: W. FANG[1,2], J. LI[3], *L. WANG[3]
[1]Inst. of Neuroscience, Key Lab. of Primate Neurobiology, CAS Ctr. for Excellence in Brain Sci. and Intelligence Technology, Chinese Acad. of Sci., shanghai, China; [2]Key laboratory of Brain Functional Genomics, Inst. of Cognitive Neuroscience, Sch. of Psychology and Cognitive Science, East China Normal Univ., Shanghai, China; [3]Inst. of Neuroscience, Chinese Acad. of Scie, Shanghai, China

Abstract: The ownership of body parts is a fundamental aspect of way we consciously experience our bodies, that is assumed to rely on the integration of sensory signals from multiple modalities. Although the sensory of ownership has been shown in both human and non-human primates, we still know little about how multisensory integration contributes to the feeling and controlling of own bodies. When moving hands to reach a target, subjects combine visual and proprioceptive signals to estimate arm's position. Here we used a virtual reality system and a reaching task to examine the proprioceptive drift, an objective and quantifiable behavioral correlate of the body ownership, in both monkeys and humans. We demonstrated that in both species, the self-location of an upper limb was spatially drifted when the spatial information of visual and proprioceptive signals was relatively matched, and such drift was disrupted when the multisensory conflicts significantly increased. The behavioral pattern of proprioceptive drift was well depicted by Bayesian Causal Inference model. Thus, the results suggest that the relative weighting of vision and proprioception during the integration may lead to the changes of body ownership in both monkeys and humans, which paves our way for further exploring neural mechanisms of bodily self-consciousness at the neural level in animals.

Title: Does sound pitch and location influence visual motion direction judgments?

Authors: *.. PRACHI[1], S. L. PRIME[2]
[1]Dept. of Psychology, [2]Psychology, Univ. of Saskatchewan, Saskatoon, SK, Canada

Abstract: Prior research has shown that auditory pitch can influence spatial and motion estimates of visual stimuli. Crossmodal correspondence between pitch and visual space show high pitch sounds are associated with upper space and low pitch sounds with lower space (Evans & Treisman, 2010). Ambiguous motion stimuli are perceived as moving upward when paired with ascending pitch sounds and downward with descending pitch sounds (Carnevale & Harris,

2016; Maeda, Kanai, & Shimojo, 2004). However, the extent to which pitch sounds influence unambiguous visual motion remains unclear. Also, how manipulating both a sound's pitch and spatial location (i.e., the pitch-space relationship) might influence visual motion perception has not been explored before. In this study we investigated how changes in pitch tones affect visual motion direction judgments while varying visual motion saliency and the pitch-spatial location relationship relative to the direction of a visual motion stimulus. Here, subjects were presented with high (1300Hz) or low (300Hz) pitch tones with a random dot kinematogram (RDK) stimulus displaying upward or downward motion. The saliency of visual motion was manipulated by systematically varying the level of coherent motion between 0, 4, 6, 8, and 10% coherence. In Experiment 1, the auditory stimuli were presented from both speakers placed horizontally, left and right of the RDK stimulus. In Experiment 2, the auditory stimuli were presented from either a speaker above or below the RDK stimulus. Subjects had to judge the direction of the coherent motion dots by a 2AFC response (up or down). Experiment 1 showed subjects were more likely to judge the direction of visual motion as going up with high pitch tones and down with low pitch tones. Our results also show this effect for pitch on direction judgments increased as coherence decreased. In Experiment 2, we found an interaction of sound location and pitch (e.g., low pitch tones from the bottom speaker yielded greater judgment bias than low pitch tones from the top speaker). These findings suggest that the extent pitch affects visual motion perception depends on the saliency of the visual motion signal and this pitch effect is sensitive to the pitch-space correspondence.

Title: A dynamic neural code may underlie multisensory integration and segregation in the primate superior colliculus

Authors: *J. T. MOHL, S. TOKDAR, J. M. GROH
Duke Univ., Durham, NC

Abstract: At the neural level, multisensory integration has typically been characterized in relation to either enhancement over the strongest component unisensory response (including linear summation of component responses), or as a weighted averaging computation between the unisensory responses (alternatively referred to as suppression, as it suppresses activity below the

best unisensory response). This averaging effect is particularly common in conditions of cue conflict, such as mismatched visual and vestibular cues or misaligned lights and sounds. However, these perspectives are incompatible with situations where multiple stimuli are represented simultaneously but separately, a prerequisite for perceiving multiple discrete sensory objects. One alternative possibility is that only one stimulus is encoded by each neuron or population at a given time, and that switching between these representations results in apparent averaging when activity is pooled across time or multiple experimental trials.
To probe this question, we required monkeys to localize either visual only, auditory only, or simultaneously presented visual and auditory stimuli at varying locations in space, while we recorded the activity of superior colliculus neurons. We analyzed this neural data using a novel statistical method capable of characterizing neural responses at the single trial level (Caruso et al., biorxiv 2017). We found that responses on combined modality trials often showed activity fluctuations across trials consistent with time-division multiplexing of the individual modalities, rather than averaging or summation of auditory and visual responses. This suggests the existence of a dynamic neural code that retains information about both components of multimodal stimuli.

Title: Multisensory enhancement during audiovisual looming responses in mice

Authors: *A. L. JUAVINETT[1], G. BEKHEET[1,2], A. K. CHURCHLAND[1]
[1]Cold Spring Harbor Lab., Cold Spring Harbor, NY; [2]Northeastern Univ., Boston, MA

Abstract: Multisensory integration is a fundamental computation that animals use to navigate their environment, avoid predators, and find prey. Despite a large body of work on multisensory behavior in humans, we do not have a clear map of the circuits and cell types that enable animals to effectively combine stimuli across sensory modalities. While the mouse model allows for targeted circuit interrogation, studying multisensory integration in mice using traditional psychophysical paradigms has proved difficult. We therefore characterized an innate behavior that will serve as a rich platform to investigate multisensory processing in rodents.
When approached overhead, prey either freeze to avoid being seen or escape to a safe place.

Remarkably, even simplified expanding discs commonly called “looming stimuli” reliably elicit freezing and escape responses in mice without prior stimulus exposure . Still, it is unknown whether mice demonstrate multisensory enhancement with the addition of a looming sound to the visual stimulus or which circuits underlie the integration of visual and auditory information--especially since a retinofugal pathway has been proposed as playing a major role in the behavior. To this end, we modified traditional visual looming stimuli to generate a novel multisensory paradigm. While the mouse was freely exploring an arena we presented visual or audiovisual stimuli: looming dots of varying contrasts sometimes paired with increasingly loud white noise. We optimized the speed of our stimulus to elicit robust escape responses to a nest. We measured the animal’s escape velocity, latency to return to the nest, and probability of returning to the nest, allowing us to make several observations: 1) High contrast stimuli elicit faster and more frequent escapes than low contrast stimuli. 2) Mice respond more strongly to looming than receding stimuli, which serve as a control. 3) Mice show a consistent multisensory enhancement, with faster and more frequent escapes in response to audiovisual stimuli.
Our work describes an innate behavior that will enable a mechanistic investigation of multisensory integration in an ecologically-valid context. Future experiments will investigate the neural underpinnings of this behavior using inactivation as well as electrophysiological recordings.

Title: Encoding of trial initiation in retrosplenial cortex during navigation in virtual reality

Authors: *L. FISCHER, M. T. HARNETT
MIT, Cambridge, MA

Abstract: Navigation through space requires the combination of knowledge about the surrounding environment with sensory and self-motion information to plan and execute specific trajectories. The retrosplenial cortex (RSC) is hypothesized to play an important role in this process by translating between allocentric and egocentric frames of reference during navigation. To do so, different streams of input, such as visual cues or motor information related to locomotion, need to be integrated. However, the mechanisms mediating this functionality have remained elusive. We have developed a spatial task in virtual reality that requires head-fixed mice to integrate visual, spatial, and self-motion information to locate a rewarded zone along a

linear corridor. Simultaneous 2-photon Ca^{2+} imaging of neurons in area A30 of the RSC allowed us to identify functional cell populations correlated with behavior. One striking response pattern were cells that robustly encoded the onset of a trial. These neurons were active whenever an animal initiated a new trial. However, depending on whether the rewarded zone was marked with a visual cue, or animals had to use self-motion information to locate the reward location, different ensemble dynamics emerged. A separate population of cells estimated the location of transition points between trials when no visual indication was available, but locked their activity to the transition point if there was. Interestingly, axonal boutons projecting into A30 from primary visual cortex showed similar sensitivity to transition points of trials. Two further A30 neuronal subpopulations were identified: cells robustly encoding or predicting rewards, and cells selectively active during traversal of the virtual corridor. Together these results describe the cell type(s) and spatial relationships between neurons in A30 of RSC for encoding multiple task-relevant variables. Encoding of trial onsets suggests a role in planning an upcoming trajectory through space, requiring the integration of spatial knowledge about the environment to translate it into a motor plan via an egocentric frame of reference.

Title: Multisensory spatial integration in a two-alternative forced choice task for head-fixed mice

Authors: *P. COEN, M. J. WELLS, M. CARANDINI, K. D. HARRIS
Univ. Col. London, London, United Kingdom

Abstract: The ability to combine information across different sensory modalities and better localize an object in space provides a critical survival advantage to many organisms, whether prey, predator, or pedestrian crossing the street. Most commonly, this process involves the combination of visual and auditory information into a single estimate of an object's location. The neural mechanisms underlying this form of audiovisual integration have been studied in several

species, primarily using detection and orienting tasks in freely moving animals. Such tasks have identified roles for cortical regions and subcortical structures. However, these effects have yet to be evaluated with modern recording techniques that allow comprehensive and reversible inactivation across cortex, as well as the opportunity to record from large neural populations. To probe the role of cortex in audiovisual spatial integration with two-photon calcium imaging and scanning optogenetic inhibition techniques, we have developed a two-alternative forced choice behavior for head-fixed mice. Our multisensory task builds on a previously established visual task (Burgess et al., bioRxiv, 2016), wherein the mouse must move a Gabor patch towards the center of its visual field by turning a wheel placed under its forepaws. We modified this task by adding an array of speakers, arranged radially with respect to the mouse's head, and presenting audiovisual stimuli—consisting of filtered pink noise and a visual Gabor, flashing synchronously at a rate of 5 Hz. Again, the mouse's goal was to move this stimulus to the center of its visual field, and both auditory and visual stimuli moved as the mouse turned the wheel. 5 of 6 mice learned this task within 5 days of training, and generalized to both individual sensory modalities without further training. When presented with a combination of unisensory and multisensory trials, mice perform above chance levels in all conditions, and exhibit enhanced performance and faster reaction times on coherent multisensory trials. We are currently exploring which strategy mice use to integrate information across these sensory modalities. Prior work in our lab has demonstrated that visual cortex is required for the visual version of this task (Zatka-Haas et al, SfN 2016). Thus, we anticipate that cortical regions will be critical for the multisensory enhancement we have observed. With this novel task design, we can now use scanning optogenetic inhibition to identify these regions, and calcium imaging to examine the corresponding neural activity.

Title: The action potential diversity of pit-viper's infrared neurons to different wavelength stimuli

Authors: *Q. CHEN, Y. LIU, L. DING, Y. TANG
Chengdu Inst. of Biology, Chinese Acad. of Sci., Sichuan, China

Abstract: The infrared sensor system of the pit-viper is a radiation receptor on broad spectrum. In the testing of neural activities on short-tailed pit-viper's tectum, we found that not only the warm object (such as human's hand, or hot water) could evoke the action potential of the infrared neurons, and the LED flashlight could affect the neural activity also. On the contrary, a LED light-compensating lamp for night-time shooting but cannot evoke the neural activity of infrared neuron. For this reason, the intensity of radiation was supposed to the key to the infrared neurons. Here we use three LED laser on different wavelength (405nm, 650nm, 830nm) as the stimuli for testing the neural activities of snake's tectum. The lenses in front of lasers could adjust the intensity for registering the aim temperature, and a shutter between the laser and snake could control the flash duration of stimuli. In this way, the neural activities would be tested in different wavelength and different temperature. The results showed that, the different color lasers evoked different performance of spike even in the same temperature level. And the patterns of neural activities might be changed among different heat effects. As a consequence, the function of the pit sensor may be the compound action of thermal and photochemical mechanisms.

Title: Multimodal sensory responses in neurons of the subesophageal ganglion

Authors: K. SUN, *M. A. STOPFER
NICHD, NIH, Bethesda, MD

Abstract: To generate useful neural representations of the world animals often need to integrate multiple forms of sensory input. To better understand the integration process we identified and characterized multimodal neurons in the brains of the moth *Manduca sexta*. The insect subesophageal ganglion (SEG) receives direct projections from the mouthparts, and is often regarded primarily as a gustatory center. Notably, we found that most neurons we tested throughout this brain area respond vigorously to other sensory modalities, primarily vision. We developed a new apparatus to deliver controlled patterns of taste, light, and odor stimuli to awake moths while making intracellular recordings with sharp electrodes from the SEG. In sequential recordings electrodes were placed blindly throughout the ganglion, usually into neural processes. We recorded from 175 neurons, filled 32 with dye for subsequent reconstruction, and, in five cases, immunostained to test for the inhibitory neurotransmitter GABA. All but two of the

filled neurons showed extensive branching within the SEG; most had somata near the mushroom body or antennal lobe.
Notably, about 86% of the 175 cells we tested showed clear excitatory or inhibitory responses to a 1s flash of light. SEG neurons in moths (N=4) from which either the left or right optic laminae had been removed responded to light, but SEG neurons in moths (N=5) with bilateral lesions did not. Thirteen filled cells extended processes directly to the eyes.
About 60% of tested neurons responded with excitation or inhibition to 1s puffs of odor (hexanol), but only about 38% of tested neurons responded to 1s pulses of tastant (1M sucrose or 1M NaCl). About 32% of tested neurons responded to separate presentations of light and tastant, and about 24% of tested neurons responded to separate presentations of odor and tastant. About 22% of tested neurons responded to all presented visual, taste, and odor stimuli. (We are presently testing additional stimuli alone and in combinations.) Of five multimodal neurons immunostained, none was positive for GABA.
Consistent with recent results from Drosophila larvae (Tastekin et al, 2015), our results suggest the subesophageal ganglion is a multimodal structure that integrates primary sensory inputs.

Title: Spatiotemporal coding of taste stimuli

Authors: *A. BORONAT-GARCÍA[1], S. REITER[2], K. SUN[1], M. A. STOPFER[1]
[1]NICHD/NIH, Bethesda, MD; [2]Max Planck Inst. for Brain Res., Frankfurt am Main, Germany

Abstract: To study how taste information is encoded by gustatory neurons, our laboratory has developed a set of techniques to deliver different tastants with precise temporal control while making *in vivo* electrophysiological recordings from multiple gustatory neurons before, during and after a stimulus is delivered. Using a relatively simple model organism, the moth *Manduca sexta*, we previously found that populations of gustatory receptor neurons (GRNs) use a spatiotemporal code to form unique representations of individual chemicals rather than taste categories such as sweet, sour, salty, bitter (Reiter et al, 2015). Information from the periphery travels to the sub-esophageal zone (SEZ), where GRNs synapse upon second order neurons (SONs). A given SON responds to more tastants than its pre-synaptic GRNs because SONs integrate, either directly or indirectly, input from multiple types of GRNs. Anatomical

reconstructions and immunostaining of SONs revealed different types of neurons in the SEZ: excitatory and inhibitory local neurons whose projections are restricted to the SEZ, and neurons that send projections either to the brain (ascending projection neurons, PNs) or to the body ganglia (descending PNs). In addition, local field potential recordings from the SEZ revealed tastant-elicited, picrotoxin-sensitive oscillatory synchronization of populations of neurons in the SEZ. However, much remains unknown about the connectivity in the SEZ between local neurons and PNs, how higher brain areas use the information from populations of ascending PN to represent tastant information, and what aspects of the information represented in PN neural activity are necessary for discriminating among tastants. Thus, to understand how gustatory information is transformed as it makes its way though higher brain areas, we are currently studying SEZ circuitry, and identifying and characterizing follower neurons by combining electrophysiological, anatomical and behavioral techniques.

Title: *In vivo* calcium imaging of CA3: Spatial pattern completion

Authors: *M. A. DUFOUR, R. TUIP, S. SUNDAR, R. ZEMLA, J. BASU
Neurosci., NYU, New York, NY

Abstract: The hippocampal CA3 sub-region, as an autoassociative network, has been proposed to support pattern completion. In particular, spatial representations in CA3 can present stability or undergo transformation in response to increase level of contextual manipulation.We have developed an in vivo head-fixed imaging paradigm to examine pattern separation and completion based population dynamics at cellular and sub-cellular resolution in CA3. In this task mice are exposed to a wide range of contexts where the differences in the multisensory stimuli between each context is gradually varied to different degrees. Under these conditions we are assessing dynamics between stability and remapping based plasticity of spatially tuned sequences of CA3 pyramidal neurons. In addition, we aim to anatomically and functionally map the long-range excitatory and inhibitory entorhinal cortex inputs.

Title: A new model of the superior colliculus and oculomotor cerebellum's interactions and functions provides one unified localization mechanism for visual, tactile, and auditory stimuli: Fitting together the forgotten pieces

Authors: *M. RIGGLE
Causal Aspects, Charlottesvle, VA

Abstract:

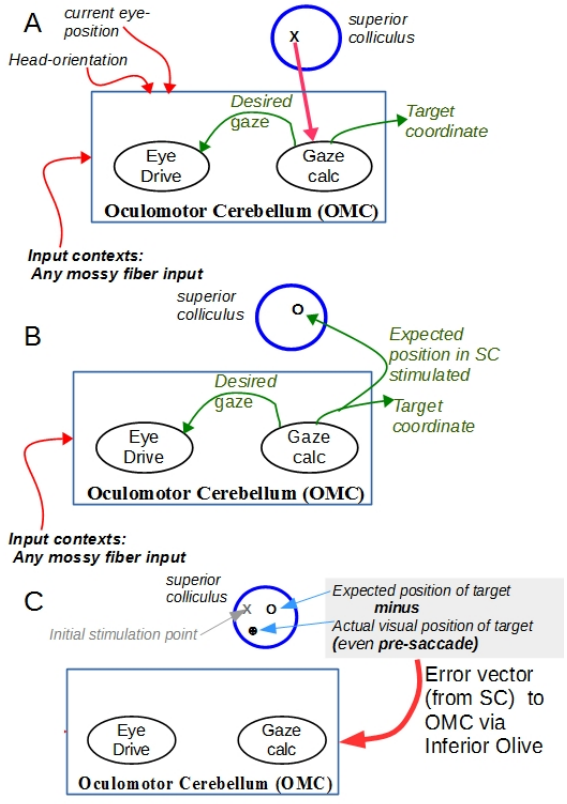

Fig: SC-OMC steps to learn localization.

Very early in fish, the accurate, adaptable visual saccade system evolved -- a system which pairs the superior colliculus(SC) with the oculomotor cerebellum(OMC). In this system, the SC only initiates a saccade, but, after that initiation, the OMC controls the saccade to the end-point. It is the OMC which makes the saccade both accurate and adaptable. Post-saccade, a saccade error is detected by the SC and passed to the OMC which then adjusts to correct the errors. In adaptation, the OMC can use different context inputs (such as eye-position, target velocity, or if you are wearing glasses) on mossy fibers to calculate different end-points for a saccade. This much is established; however, the role of the OMC is much larger. We show (with current supporting evidence) that when a visual target is attended to by the SC, the OMC must produce that target's world coordinate (and the coordinate becomes accurate via the error feedback). Producing correct error feedback from the SC requires the OMC to also calculate the expected position of the target in the SC and to stimulate that position; the SC then uses the difference between the expected position and the actual target to generate an error vector. [Some overlooked relevant OMC elements are: 1) The Head-Orientation-In-World vector is calculated in the OMC and allows the OMC to transform head-relative to/from world frames; 2) The cerebellum's architecture supports recurrent neural-networks].
This SC-OMC capability of using mossy fiber inputs to calculate (and learn) the actual location of visual targets is a reusable mechanism for both auditory and tactile stimuli. The steps to learn any localization (figure 1): A- using inputs, the OMC calculates the target’s world coordinate; B- OMC places expected target into SC; C- SC determines error vector and passes to OMC; last- OMC updates calculation. The steps are the same for visual localization, and tactile and auditory localization if the needed localization data is on mossy fibers - which we show they are.

Title: A fundamental circuit mechanism underlying sequences of behavioral actions in *Drosophila* courtship

Authors: *C. E. MCKELLAR[1], J. L. LILLVIS[1], D. E. BATH[1,2], J. G. CANNON[1,3], J. H. SIMPSON[1,4], B. J. DICKSON[1]

Abstract: Goal-directed animal behaviors are typically composed of sequences of motor actions, the precise order and timing of which can be critical for a successful outcome. Although much current work investigates neural mechanisms underlying complex behaviors, it is largely unknown how the brain assembles discrete actions into sequences for goal-directed behaviors. Here, we identify a recurring behavioral motif of three coordinated actions that male *Drosophila melanogaster* flies perform as they engage with a female during the late stages of courtship. The features of this motif suggest that it may be generated by a ramp-to-threshold mechanism, in which the increasing activity of a central coordinator elicits each action at successively higher activity thresholds. We describe a pair of descending neurons in the fly brain, aSP22, that act as such a central coordinator. Genetic ablation of aSP22 impairs all three actions of the engagement motif, whereas optogenetic activation of aSP22 elicits each action. Each action is triggered at a different activation threshold, with thresholds increasing in the order in which these actions occur within the engagement motif of natural courtship behavior. In biology, morphological patterns are often created through differing response thresholds to a single organizing activity that is spatially or temporally graded. Our findings reveal how an analogous mechanism is employed to assemble discrete motor actions into a recurring motif within a complex behavioral pattern.

Title: Early integration of temperature and humidity stimuli in the *Drosophila* brain

Authors: *D. D. FRANK, III[1], A. ENJIN[2], G. C. JOUANDET[1], E. E. ZAHARIEVA[1], A. PARA[1], M. C. STENSMYR[2], M. GALLIO[1]

Abstract: Many terrestrial organisms can only prosper within a specific range of air humidity. For example, small poikilotherms like *Drosophila melanogaster* risk desiccation (and death) when exposed to hot, dry conditions even for relatively short periods of time. Hence, a fly's

ability to detect and appropriately respond to humidity changes can be critical for survival. The Drosophila antenna is a hub for the senses, containing receptor neurons for mechanical, olfactory, thermal and humidity stimuli. Neurons expressing the ionotropic receptor IR40a have been recently implicated in the selection of an appropriate humidity range, but while previous work indicates that insect hygroreceptors may be made up by a 'triad' of neurons (with a dry- a cold- and a humid-air responding cell), IR40a expression included only cold- and dry-air cells. Here, we report the identification of the humid-responding neurons that complete the hygrosensory triad in the *Drosophila* antenna. Next, we follow the projections of hygrosensory neurons to the brain, and show that they form distinct glomeruli in the posterior antennal lobe. Here, a spatial map of neural activity represents related features of the external environment, with adjacent 'hot', 'cold', 'dry', and 'humid' glomeruli. This organization may allow for both unique and combinatorial sampling by central relay neurons, and we indeed find evidence for each. Our results further our understanding of humidity sensing in the *Drosophila* antenna, uncover neuronal substrates for the processing of temperature and humidity stimuli in the brain, and illustrate the logic of how ethologically relevant combinations of sensory cues can be processed together to produce adaptive behavioral responses.

Title: Projections of the diencephalospinal dopaminergic system to peripheral sense organs in larval zebrafish (Danio rerio)

Authors: *M. HAEHNEL[1], W. DRIEVER[1,2]
[1]Albert-Ludwigs-University Freiburg, Freiburg Im Breisgau, Germany; [2]BIOSS - Ctr. for Biol. Signaling Studies, Freiburg im Breisgau, Germany

Abstract: Diencephalic descending dopaminergic neurons in the zebrafish, which are located in the posterior tuberculum and hypothalamus, depend on the transcription factor Orthopedia and are homologues to the mammalian A11 dopaminergic group. Catecholaminergic projections in the central nervous system of larval zebrafish are characterized, and the A11 homologue groups were shown to send projections to the subpallium, endohypothalamic tract, rhombencephalon, and spinal cord. Although, there is evidence that the descending dopaminergic system of larval

zebrafish sends projections to peripheral sense organs, and particularly neurons with large cell bodies in the anterior part of the posterior tuberculum contact neuromasts of the posterior lateral line, a detailed anatomical analysis of dopaminergic projections to targets in the peripheral nervous system is yet missing.
We therefore investigated in detail peripheral catecholaminergic projections in larval zebrafish, adapting the recently developed tissue clearing method CLARITY for use in 3-8 days old zebrafish larval whole mounts to resolve the peripheral projections of the dopaminergic A11 system. To label dopaminergic projections, we used *Tg(th:Gal4-VP16)*^{m1233Tg} and *Tg(UAS:eGFP-CAAX)*^{m1230Tg} transgenic zebrafish to express membrane tagged GFP in dopaminergic neurons. We also combined the *th:Gal4* driver with *Tg(UAS:SypGFP, clmc2:EGFP)*^{m1238Tg} to label presynaptic dopaminergic structures. We focused on the lateral line but also consider connections to the auditory, vestibular and trigeminal system. Our data reveal extensive peripheral diencephalic DA projections to all lateral line organs. In the posterior lateral line, dopaminergic axons project along the posterior lateral line nerve. Single dopaminergic neurons project to multiple lateral line organs, but individual organs may also receive input from distinct dopaminergic neurons. Synaptophysin:GFP label suggests that dopaminergic neurons establish synapses with hair cells. Mapping of dopaminergic axons and synapses reveals that modulation of sensory information may not only occur at the sense organ, but also at the levels of lateral line ganglia and their projection fields in the rhombencephalon. Dopaminergic neurons therefore are likely to play an important role in efferent modulation of sensory systems. Together with recent work revealing lateral line sensory related activity of specific A11 type posterior tubercular dopaminergic groups in zebrafish (Reinig *et al.*, Current Biology 2017); our findings suggest that these dopaminergic neurons are potentially involved in some type of feedback regulation of the lateral line system.

Title: Frequency characteristics of thalamocortical pathways involved in affective pain: The mediodorsal/anterior cingulate cortex axis

Authors: A. F. PAQUETTE[1], *R. W. SIKES[2]
[1]Behavioral Neurosci., [2]Dept Physical Therapy, Northeastern Univ., Boston, MA

Abstract: This study focuses on thalamocortical transmission between the mediodorsal and parafascicular nuclei (MD/PF) and the anterior cingulate cortex (ACC). Strong reciprocal synaptic connections between these structures exist. Neurophysiological and behavioral studies have established this circuit as crucial in affective pain perception, learning, memory, reward, goal directed activity and attention. Additional studies explored the effect of frequency modulation in the theta range (4-8 Hz) on transmission in this circuit. Modulation of MD/PF activity into theta frequency range potentiates synaptic activation of ACC neurons, and these theta oscillations may allow engagement of functional subregions of ACC. Inflammatory pain can induce a decrease in functional connectivity in this circuit that is strongest in the theta range. The current study explores changes in simultaneously recorded activity of neurons in MD/PF and ACC measured before and during wide spectrum auditory stimulation.
Using 4 anesthetized Long-Evans male rats in the initial study (1.5% halothane), guide cannulas were surgically implanted over ACC and MD/PF. With stereotaxic control, extracellular recording electrodes (AM systems; 1-5 Mohms) were lowered into ACC and MD/PF. Spontaneous activity and a series of auditory evoked activity trials were recorded in both target structures simultaneously. Specifically, field potentials and multicellular action potentials were recorded using the Plexon Map data acquisition system. The action potentials were further resolved into single neuron activity using cluster cutting (Plexon Offline Sorter). Power spectrum and peristimulus histogram analysis were used to analyze the neural activity (Neuroexplorer software).
In initial data from 22 neurons (10 in ACC and 12 in MD/PF), significant responses to auditory stimulation were observed in 4 MD/PF neurons and 0 ACC neurons. Power spectral analysis of spontaneous field potentials in ACC and MD/PF showed more power in delta frequency range (0-4 Hz). During auditory testing the power spectra of ACC field potentials remained in delta range, but shifted to higher delta and theta frequencies in MD/PF. Thus, absence of ACC response may reflect a failure of thalamocortical transmission between these anatomically connected structures due to mismatch of their resonant frequencies. If true, this explanation concurs with previous findings, suggesting functional connectivity among MD/PF and ACC requires resonant frequencies between both structures to be in the theta range.
All experimental procedures were approved by Northeastern University Institutional Animal Care and Use Committee.

Title: Simultaneous intrinsic imaging of auditory and visual cortex releals cross-modal interactions

Authors: *M. TEICHERT[1], J. BOLZ[2]
[1]Inst. Für Allgemeine Zoologie Und Tierphysiologie, Jena, Germany; [2]Inst. für Allgemeine Zoologie und Tierphysiologie, Jena, Germany

Abstract: In their natural environment animals and humans simultaneously receive multimodal sensory inputs. The primary sensory cortices where these inputs are initially processed are anatomically separated. However, previous studies found intracortical connections between these early sensory cortices suggesting a multimodal interplay (Falchier et al., 2002; Cappe and Barone, 2005; Campi et al., 2010). For example, electrophysiological results obtained in rodents indicate that auditory stimulation can modulate visually evoked V1 responses and affect visual processing (Iurilli et al., 2012; Ibrahim et al., 2016). However, the consequences of an acute loss of one sensory modality on multisensory processing and, particularly on stimulus evoked processing in the spared senses, remain elusive. Here we investigated the early effects of acute hearing loss on visual processing in adult mice. To address this question at the functional and systemic level, we used intrinsic optical imaging which provides high resolution recording over a large field view. Thus, it reflects a population response of many neurons to external stimuli (Kalatsky and Stryker, 2003). First, we developed a method to simultaneously map the primary auditory (A1) and visual cortex (V1) using periodic intrinsic optical imaging. We found that reducing sound evoked A1 responsiveness due to the induction of conductive hearing loss (CHL) led to a concomitant increase of visually driven V1 activity. Accordingly, using the neuronal activity marker c-fos we found the number of stained pyramidal cells to be increased in V1 layer 2/3 after CHL. In contrast, numbers of c-fos positive parvalbumin (PV) and somatostatin (SOM) expressing inhibitory neurons were reduced after CHL. Finally, we adapted the periodic intrinsic imaging method to determine V1 contrast and spatial frequency tuning. Using this method we could show that cortical spatial resolution and contrast sensitivity were improved after immediately CHL. In addition, retrograde tracing experiments revealed direct anatomical projections from A1 to V1 which could potentially serve as a substrate for the observed effects. Taken together, our data suggest that an interplay of an intact auditory and visual sense controls evoked activity in V1. However, if the auditory input is deprived the brake of visually driven V1 activation is rapidly released suggesting a disinhibitory effect which leads to increased evoked V1 responses. We conclude that CHL rapidly disrupts the functional interplay between A1 and V1 leading to altered visually evoked V1 responses.

Title: Effect of vision of arm posture on a crossed hands illusion task in an amputee

Authors: *Y. SATO[1], T. KAWASE[1,2], K. TAKANO[1], K. KANSAKU[1,3]
[1]Sys. Neurosci. Sect., Dept. of Rehab. for Brain Funct., Res. Inst. of Natl. Rehabil. Ctr., Tokorozawa, Japan; [2]Biointerfaces Unit, Inst. of Innov Res., Tokyo Inst. of Tech., Yokohama, Japan; [3]Brain Sci. Inspir Life Supp Res. Cent, Univ. of Electro-Communications, Chofu, Japan

Abstract: When successive somatosensory stimuli are delivered one to each hand at moderately short intervals (< 300ms) with eyes closed, crossing the arms causes inverting of the temporal order (a crossed hands illusion task; Yamamoto and Kitazawa, 2001a). Similar stimuli were delivered to the tips of two drumsticks, one held in each hand, and the research group reported a similar illusion with the drumsticks crossed (Yamamoto and Kitazawa, 2001b). In our previous experiment, we applied the crossed hands illusion task to an amputee with a functional prosthetic arm, and found that the reversal illusion was significantly larger in an experimental condition with the prosthetic arm than in a control condition without the prosthetic arm (Sato et al., 2016). In this research, we investigated the effect of vision of arm posture on a crossed hands illusion task in an amputee participant. In an experimental condition, a left arm amputee wore a long prosthesis and judged temporal order of two successive tactile stimuli, one delivered to a socket of the prosthesis and the other to the third finger of the right hand. A dummy stimulator was placed at the tip of the prosthesis. When crossing the arms, the participant crossed the long left prosthetic arm on the right arm. In a control condition, the participant wore a short prosthesis and judged temporal order of two successive tactile stimuli, one delivered to the socket of the prosthesis and the other to the third finger of the right hand. A dummy stimulator was placed at the tip of the prosthesis. When crossing the arms, the position of his arms were same, but the short left prosthesis did not reach to the right arm.In both conditions, first, the participant was asked to perform the task with their arm uncrossed and crossed, with eyes closing. Then we asked the participant to open eyes to see the arm position, and again perform the task with

closing eyes. Degree of the reversal illusion was calculated as the differences between correct response rates of the arms crossed and those of the arms straight (Yamamoto and Kitazawa, 2001a). The degree of the reversal illusion with and without vision of the arm posture was evaluated, and the illusion induced by the vision was significantly larger in the experimental condition with the long prosthetic arm than in the control condition with the short prosthetic arm ($p < 0.05$). The results suggest the importance of vision of arm posture to the crossed hands illusion. Note that the tactile stimuli delivered and the arm posture were same in both conditions, but only vision of the prosthetic arm posture was different. The amputee may feel the tactile stimuli at the tip of the prostheses.

Title: Associations between sensory integration and sensory responsiveness in children with autism spectrum disorder

Authors: *J. I. FELDMAN[1], W. KUANG[1], D. M. SIMON[1], J. G. CONRAD[1], P. SANTAPURAM[1], A. TU[1], M. T. WALLACE[2], T. G. WOYNAROSKI[3]
[2]Hearing and Speech Sci., [1]Vanderbilt Univ., Nashville, TN; [3]Hearing and Speech Sci., Vanderbilt Univ. Med. Ctr., Thompsons Station, TN

Abstract: Children with autism spectrum disorder (ASD) differ in multisensory integration relative to typically developing (TD) peers. For example, in comparison to TD controls, children with ASD may show a reduced magnitude of integration for audiovisual speech, binding of audiovisual speech cues over an atypically wide window of time, and difficulty in perceiving speech in both visual only and matched audiovisual conditions. Children with ASD also show differences in their patterns of responses to sensory stimuli (i.e., sensory responsiveness) relative to TD peers. This study explored the extent to which multisensory speech perception and integration correlated with patterns of sensory responsiveness in children with ASD and TD children. Participants were 18, 8-17 year old children with ASD and 18 TD controls matched on chronological age, sex, and IQ. To assess multisensory speech perception and integration, we

utilized a psychophysical task, wherein participants were randomly presented with CV syllables (e.g., ba, ga) in auditory only, visual only, matched AV, and mismatched AV (visual ga + auditory ba; McGurk) conditions. To evaluate the effects of temporal asynchrony on binding of multisensory speech information, the timing of the mismatched auditory ba and visual ga stimuli was shifted so that the visual stimulus preceded the auditory stimulus by seven stimulus onset asynchronies (SOAs): 0 ms, 33, 66, 100, 166, 233, and 300 ms. Two parent report measures were used to measure sensory responsiveness. Several indices of multisensory speech perception/integration were associated with patterns of sensory responsiveness. Hyporesponsiveness (reduced responding to sensory stimuli) correlated with TBW size (r = .39), as well as accuracy in the auditory only (r = - .35), visual only (r = - .48), and matched AV (r = - .51) conditions. Hyperresponsiveness (exaggerated responding to sensory stimuli) correlated with accuracy in the visual only (r = - .52) and matched AV (r = - .36) conditions. Sensory seeking (fascination with/craving of certain sensory experiences) correlated with TBW size (r = .35) and accuracy in the auditory only (r = - .29), visual only (r = - .29), and matched AV (r = - .43) conditions. Regression analyses indicated that none of the aforementioned associations were moderated by group. is the first study to demonstrate that differences in multisensory speech perception and integration covary with atypical patterns of sensory responsiveness. Additional work is needed to determine whether differences in multisensory speech perception temporally precede, or are causally related to, differences in sensory responsiveness, or vice versa.

Title: Audiovisual stimulus correlation drives multisensory perceptual decisions

Authors: *A. R. NIDIFFER, R. RAMACHANDRAN, M. T. WALLACE
Hearing and Speech Sci., Vanderbilt Univ., Nashville, TN

Abstract: Sensory signals originating from the same event, such as the voice and mouth movements of a speaker, are often temporally correlated. It is hypothesized that the brain evaluates these correlations to facilitate feature integration and binding within and across sensory modalities. Previous studies have shown that correlation between unisensory signals facilitates several multisensory behaviors, whereas uncorrelated signals do not. In the current study, we sought to further illuminate the nature of this relationship, hypothesizing that multisensory

behavior will vary with the strength of correlation. To this end, we presented participants with sinusoidal amplitude modulated auditory and visual stimuli at modulation depth thresholds. Participants reported the presence or absence of modulation in either stimulus. On a trial, modulation was present in auditory, visual, both, or neither modality (10% of the total trials, catch trials). On audiovisual trials, visual modulation frequency and phase were constant while auditory modulation frequency and phase were varied to generate stimulus pairs with a range of temporal correlations. Accuracy and reaction time data were fit to a drift diffusion model in which non-decision time and drift rate could vary across conditions. The pattern of discriminability and drift rate across conditions was very similar to that of stimulus correlation, but with an apparent phase shift that reflected unique temporal processing of the unisensory stimuli across participants. After accounting for this phase shift, drift rate varied with stimulus correlation in every participant, suggesting that stronger stimulus correlations provide stronger sensory evidence. In two participants, non-decision time decreased with increased stimulus correlation indicating faster encoding of positively correlated stimuli. These results indicate that the degree of stimulus correlation strongly impacts multisensory perception. Further, they suggest that the process of binding could be stochastically dependent on correlation such that signals are more likely to be bound as their correlation approaches 1.

Title: Rapid recalibration to asynchronous audiovisual speech modulates the rate of evidence accumulation

Authors: *D. M. SIMON[1], A. R. NIDIFFER[2], M. T. WALLACE[2]
[2]Hearing and Speech Sci., [1]Vanderbilt Univ., Nashville, TN

Abstract: Asynchronous arrival of audiovisual information at the peripheral sensory organs is a ubiquitous property of signals in the natural environment due to differences in the propagation

time of light and sound. Rapid adaptation to these asynchronies is crucial for the appropriate integration of audiovisual cues, and consequently for the creation of a coherent perceptual representation of our dynamic world. We investigated the neural basis of rapid recalibration to asynchronous audiovisual speech using psychophysics, drift diffusion modeling, and electroencephalography (EEG). Consistent with previous reports of rapid audiovisual recalibration, we found that participant's perception of audiovisual temporal synchrony depends on the temporal structure of the previous trial. Drift diffusion modelling indicated that this temporal recalibration effect was well accounted for by trial order dependency in the rate of evidence accumulation (i.e. drift rate). Neural responses as measured via evoked potentials were likewise found to vary based on the temporal ordering of the previous trial. Furthermore, these neural signals displayed both response locking and a build to threshold structure that have previously been established as neural correlate of evidence accumulation. Within and across subject correlational analysis indicated that the observed changes in drift rate and the modulation of evoked potential magnitude were related. These findings indicate that trial-by-trial adaptation to asynchronous audiovisual speech occurs via rapid reweighting of sensory evidence.

Title: Head impulse saccades are affected differently without vision

Authors: *J. M. POGSON[1,3,4], L. MCGARVIE[2,3,4], R. L. TAYLOR[4], A. P. BRADSHAW[4], G. M. HALMAGYI[1,3,4], M. S. WELGAMPOLA[1,3,4]
[1]Sydney Med. Sch., [2]Psychology, Univ. of Sydney, Camperdown, Australia; [3]Neurol. Dept., Royal Prince Alfred Hosp., Camperdown, Australia; [4]Royal Prince Alfred Hosp., Inst. of Clin. Neurosciences, Camperdown, Australia

Abstract: The head impulse (HIMP) test reflects the relationship between the vestibulo-ocular reflex and the saccadic system. After peripheral vestibular loss, saccades can redirect gaze during HIMP while the head is still moving (covert saccades) or after the head stops (overt saccades)[1]. Generating covert saccades requires either vision or residual vestibular function[2]. When the head is still, the primary (initial) saccade affects the amplitude and latency of secondary (later) saccades, even without vision, indicating a non-visual map [3 4]. We examined if the same relationship exists between covert primary and overt secondary saccades in the HIMP.We tested

6 normal, 5 post-surgical unilateral vestibular deafferentation (UVD) and 5 bilateral vestibular loss (BVL) subjects. All subjects fixed on a target at a 160 cm. Passive horizontal HIMPs were captured first in light, then in complete darkness as subjects fixed on the imagined target. Head and eye movements were recorded by a video head impulse test system. Saccades occurring during and after the HIMP were classified as “covert” and “overt”. First and later saccades were named “primary” and “secondary”.In both UVD and BVL, mean prevalence of covert primary saccades did not differ between light and dark (UVD - light: 85±21%, dark: 90±11%; p=1, BVL - light: 58±42%; dark: 49±37; p=0.17), but BVL was significantly less than UVD in dark (UVD: 90±11%; BVL: 49±37%; p=0.02). In UVD, prevalence of overt secondary saccades was borderline less in light and dark (light: 89±13; dark: 61±31%; p=0.06), but BVL was significant less in dark (light: 76±21%; dark: 12±10%; p=0.02), also when compared to UVD in dark (UVD: 61±31%; BVL: 12±10%; p<0.01). In BVL, covert primary saccade onset latencies were shorter in dark than light (light: 132±35ms; dark: 120±26ms; p<0.001). UVD latencies were shorter in light (UVD: 123±28ms; BVL: 132±35ms; p=0.04). In UVD, overt secondary saccade onset latencies were shorter in light then dark (light: 355±100; dark: 378±104; p=0.02).In UVD and BVL, covert saccade prevalence is not affected by light but overt saccades are. This data demonstrates a non-visually triggered primary covert saccade, and points to a predominantly visual mechanism for triggering overt saccades. UVD and BVL subjects who can generate covert saccades during HIMPs do not rely on vision alone to redirect gaze. Paradoxically, the triggering of primary covert saccades in light in BVL is *delayed* but in UVD are *hastened*, supporting the multisensory nature of covert saccades. 1. Title: Distinct reference frames of visual and vestibular heading signals in macaque FEFsem and MSTd

Authors: *L. YANG[1], Y. GU[2]
[1]Syst. neuroscience, Inst. of Neurosci., Shanghai City, China; [2]Syst. Neuroscience, Inst. of Neurosci., Shanghai City, China

Abstract: Precise heading estimate requires integration of visual and vestibular information that originates from distinct spatial coordinates (visual: eye-centered; vestibular: head-centered). To explore whether the two heading signals may share a common reference frame along the hierarchy of cortical stages, we explored two multisensory areas: the pursuit area of the frontal eye field (FEFsem) which is closer to the motor side, and the dorsal portion of medial superior temporal area (MSTd) which is closer to the sensory side. In both areas, vestibular signals are head-centered. Compared to MSTd, visual optic flow signals are less eye-centered in FEFsem, yet still largely apart from the head-centered coordinate. Importantly, the visual reference frame is robust that is independent on: (1) smooth pursuit eye movement, (2) motion parallax, and (3) behavioral context for active heading estimation. Our results suggest that visual and vestibular heading signals may be coded in distinct reference frames in the brain.

Abstract: Cognitive neuroscience aims at understanding how dynamic interactions across neurons implement complex information processing in the brain. Yet, most current electrophysiology analysis methods require averaging over trials or long segments of data and are thus bound to miss the fast dynamics of neural activity. Here, we present an alternative way for studying sequences of cortical activations associated with the task. This approach is based on the hypothesis that when a cortical region starts to engage in a new process, there is a transient increase in neuronal activity lasting until the local inhibitory feedback quenches this activity burst. We report that precise spatio-temporal sequences can be detected in the human brain using noninvasive imaging techniques and relate these events to direct measurements of population

activity in non-human primates. Brain activity was recorded using MEG in subjects performing a sensorimotor synchronization task. The on-going magnetic fields were converted to current-dipoles from multiple points over the brain's hull. Brief activity undulations (BAUs) comprised of 20 msec deflections in the signal were automatically detected across all the current dipoles. Interestingly, the stereotypical shape of these events in the time domain closely resembles bursts of beta events described in previous studies. The times of these undulations were treated as point processes. We then searched for repeating spatio-temporal patterns of these BAUs. Many such repeating patterns were found ranging from repeating triplets of events to repeating patterns of 14 events. The null distribution of the number of repeating patterns was constructed by teetering the timing of the BAUs within ±1 samples resulting in a considerable reduction in the number of repeating patterns indicating the importance of the precise timing of these events. Using this technique, we showed that timing accuracy is better than 3 msec. Next, we asked if we could identify brief increases in local populations activity by direct neuronal recordings. We used linear array multielectrodes to record laminar profiles LFP (augmented by current source density or CSD) and multiunit activity (MUA) from both auditory cortical and frontal areas in behaving monkeys. This work is ongoing, but a potential analogue to the findings has already emerged; particularly in frontal and prefrontal areas, brief beta band, (20 Hz) oscillatory responses evident in both CSD and MUA profiles synchronize to the onset of the stimuli. Increased MUA around these events showed that it is reasonable to treat such transients as markers for the time at which a new wave of activity is elicited in the cortical patch.

Title: Aging impairs lag adaptation but not Bayesian temporal recalibration of sensory and motor stimuli

Authors: *A. N. SCURRY, A. NICHOLSON, M. A. WEBSTER, F. JIANG, T. VERCILLO
Psychology, Univ. of Nevada, Reno, Reno, NV

Abstract: Time perception is central to human experience and plays a crucial role in shaping behavior. Temporal perception is actively created by our own minds and like many other perceptual processes can be modulated by internal biological factors. For example, as we age time seems to speed up, as reported by the psychologist William James, and age differences in temporal perception can sometimes be attributed to deficits in other cognitive functions such as attention and working memory. As time perception is not a confined and singular mechanism but rather takes many forms and occurs at different levels of processing, it is difficult to isolate which aspects of time perception are impaired or altered by the aging process. Specifically, it is unclear whether aging has a broad influence on cognition, and therefore on time perception in general, or has a selective impact on distinctive and identifiable mechanisms underlying time perception. In the current study, we tested young and elderly adults in four temporal tasks, each measuring a different aspect of temporal sensitivity and adaptability. We designed three asynchrony tasks (unisensory, multisensory and sensorimotor) to measure temporal sensitivity as the ability to discern the temporal order of two stimuli (visual/visual, auditory/visual, visual/motor), and temporal recalibration as the ability to adjust these temporal judgments after adaptation to an asynchrony between the two stimuli. We also ran a duration task (visual), where we measured sensitivity for duration judgments and duration compression after speed adaptation. Temporal sensitivity decreased with age regardless of the task, suggesting a widespread effect of aging on time perception, most likely reflecting a general cognitive impairment. In contrast, the aging effects on temporal adaptability were task-specific. Temporal recalibration decayed with age for multisensory and sensorimotor, but not for unisensory stimuli. Most importantly, the effect of adaptation agreed with the Bayesian integration theory in the judgment of visual stimuli (unisensory temporal order, visual duration), whereas audiovisual and sensorimotor stimuli were recalibrated following a lag adaptation mechanism (Miyazaki, Yamamoto, Uchida & Kitazawa, 2006). Results from our study show that healthy aging selectively impairs the recalibration of temporal order between sensory modalities and between the sensory and the motor systems, and that a general loss in temporal sensitivity in elderly individuals might be related to an overall cognitive decline. Our results also revealed different mechanisms subserving the perception of time.

Title: Role of causal information in visual-haptic and visual-kinesthetic cue combination

Authors: *J. HEGDE
Brain and Behavior Discovery Inst., Augusta Univ., Augusta, GA

Abstract: The causal inference framework of multisensory perception (Körding *et al*., 2007) posits that the brain can infer the causal structure of sensory events from sensory information, and utilize this information during the cue combination process. We investigated the influence of the inferred causal structure during two different multisensory two-alternative force choice (2AFC) tasks. During the visual-kinesthetic task, human subjects freely moved a computer mouse (or joystick, depending on the experiment) and reported which of the two cursors simultaneously visible on a high-speed computer monitor was driven by the mouse. Note that the since the mouse was self-driven, the underlying causal information arises solely from reafferent sources in this case. We systematically varied the temporal parameters of the cursors, including their spatial and temporal jitter (*i.e*., variance), and the degree of synchrony between the mouse and either cursor. We found that when the variance of both cursors was relatively low (temporal jitter of < 4 Hz and/or spatial jitter of < 20 min arc on average), subjects performed well above chance levels ($d' > 2$, $p < 0.05$), as expected. However, with increasing cursor variance, subjects were increasingly likely to perceive the cursor with smaller variance as the one driven by the mouse. Indeed, sufficiently large cursor variance values could significantly override synchrony information ($d' < -2$, $p < 0.05$ at temporal jitter of > 8 Hz and/or spatial jitter of > 60 min arc). Similar results were obtained during a similar visual-haptic task in which the visual object was synchronized with the haptic object in real time using an embedded rotation/position sensor (Hegdé, 2016). Together, these results suggest that brain has an internal estimate of the reliability of its own reafferent information, and can override the inferred causal structure when it is inconsistent with other sensory information.

Title: Temporal probabilistic inference in three sensory modalities

Authors: *M. GRABENHORST[1], G. MICHALAREAS[1], L. T. MALONEY[2], D. POEPPEL[1,2]
[1]Neurosci., Max Planck Inst. (MPIEA), Frankfurt, Germany; [2]New York Univ., New York, NY

Abstract: Estimating the timing of event onset is fundamental for efficient interaction with the environment. Since fast ecologic cues happen on a short, continuous timescale, the brain has to model densely populated event horizons spanning intervals of several seconds. This temporal-probabilistic inference requires estimation of elapsed time as well as event probability over time. In this work, we study how the brain models these stochastic sources of information in three different sensory modalities, namely vision, audition and somatosensation. Recent work has demonstrated, using specific Probability Density Functions (PDF) of visual events, that reaction times (RT) and neuronal activity are correlated with the Hazard Rate function (HR) (Janssen and Shadlen, 2005), suggesting that this is one of the basic variables employed by the brain in order to model temporal probabilities. However it is unclear whether this relationship generalises beyond these specific PDFs and whether the PDFs themselves and/or their corresponding Cumulative Distribution Functions (CDFs) also contribute to this modeling process in the brain. Additionally it is not known if this process is similar across the different sensory modalities. To address the above standing issues, we extended previous work to different probabilistic structures, investigated each of three different sensory modalities and also performed inter-modal experiments in order to investigate the following questions: i) What variables (HR, PDF, CDF) are used by the brain to model temporal probability? ii) What are the differences in this modeling process between the different sensory modalities? We used several versions of a simple 'set' - 'go' trial structure that encoded different PDFs. We first show that the HR by itself does not accurately explain the observed patterns of RT. We then demonstrate that there are significant differences between modalities, indicating peripheral processing, but also a prevalent common pattern across the three modalities, suggesting shared central processing of temporal probability estimation. Ongoing magnetoencephalography recordings aim to identify the neural correlates of these mechanisms manifested in behaviour.

Title: Midbrain neurons show temporal retuning of intrinsic properties in response to patterned uni- and multisensory stimulation

Authors: *S. E. BUSCH, A. S. KHAKHALIN
Dept. of Biol., Bard Col., Annandale ON Hudson, NY

Abstract: To properly encode and process information within a functional network, neurons should have their intrinsic properties "tuned" according to their role in this network. For example, one can expect homeostatic plasticity to drive spiking thresholds up for neurons that receive stronger synaptic inputs. Similarly, it is conceivable that neurons involved in the temporal analysis of sensory stimuli could preferentially respond to either faster or slower patterns of synaptic activation. In this study, we use the dynamic clamp technique to explore changes in the intrinsic temporal tuning of midbrain sensory neurons in Xenopus tadpoles in response to sensory stimulation. We exposed animals to 3 hours of either visual, acoustic, or multisensory patterned stimulation that included light flashes, looming stimuli, and sound clicks. We then excited tectal neurons with simulated synaptic conductances of different temporal profiles in whole-cell patch-clamp mode, and measured their spike output. We asked whether, compared to controls, neurons in the tectum of tadpoles exposed to patterned stimulation retuned their temporal input-output functions, to potentially better adjust to this stimulation. We found that overall, the spiking in neurons from stimulated animals was homeostatically suppressed. When animals were exposed to looming stimuli, this suppression was weaker than for animals exposed to flashes, despite the fact that looming stimuli are known to induce stronger spiking in the tectum. Moreover, the temporal tuning of neurons in post-flash animals was strongly reshaped: while control and post-looming neurons spiked more in response to slower simulated synaptic conductances that mimicked looming stimuli, post-flash neurons preferred faster simulated inputs that mimicked full field flashes. This suggests that neurons became selective for the temporal stimuli to which they were exposed. We also checked whether acoustic stimulation alone, or a multisensory combination of visual and acoustic stimuli would change temporal tuning in tectal neurons. We found that although the tectum is typically thought of as a primarily visual area, repeated acoustic stimuli reduced tectal excitability, without reshaping temporal tuning. In multisensory experiments, unexpectedly, a combination of sound and visual flashes had a weaker effect on homeostatic suppression than visual flashes alone. The temporal tuning for multisensory stimuli also differed from unisensory, and depended on the delay between acoustic and visual stimuli during training. Finally, we report some of the cellular mechanisms behind these homeostatic changes.

Title: Cross-modal effects in speed judgments during virtual motorcycle riding

Authors: T. UEDA[1], T. MIYAGI[1], T. KURODA[2], J. WATANABE[3], T. SUEGAMI[4], H. DAIMOTO[5], *M. MIYAZAKI[2]
[1]Dept. of Informatics, Grad. Sch. of Integrated Sci. and Technol., [2]Dept. of Computer Science, Fac. of Informatics, Shizuoka Univ., Hamamatsu, Japan; [3]NTT Communication Sci. Labs., Atsugi, Japan; [4]Yamaha Motor Co., Ltd., Iwata, Japan; [5]Fac. of Human Sci., Tezukayama Gakuin Univ., Sakai, Japan

Abstract: During motorcycling, the rider's sense of speed is generated by multimodal information. For example, the sense of speed should be estimated based not only on the optical flow but also on the engine-drive sound and vibration. In what manner do such visual and audio-tactile information affect each other to generate the sense of speed? In the present study, we investigated cross-modal effects using a virtual motorcycle system. In previous studies using basic psychophysical tasks, two opposite types of cross-modal effects have been reported, namely the averaging effect (e.g., Ernst & Banks, 2002) and the contrast effect (e.g., Ho et al., 2014). We stated the two effects as alternative hypotheses. In our experiments, participants wore a head-mounted display (HMD) and earphones, and sat astride a motorcycle-type chassis. The HMD presented a moving scene during motorcycling from a first-person viewpoint. The earphones presented the engine-drive sound. An actuator under the seat of the chassis presented the engine-drive vibration. The sound and vibration were generated by using a common waveform signal for each trial. In Experiment 1, we tested the effect of the speed of the engine-drive sound and vibration on the speed judgment of the moving scene. When the speed of the engine-drive sound and vibration was higher relative to that of the moving scene, the participants (N = 16) judged the speed of the moving scene as higher than the actual speed. However, no effect was observed when the speed of the engine-drive sound and vibration was lower relative to that of the moving scene. In Experiment 2, conversely, we tested the effect of the speed of the moving scene on the speed judgment of the engine-drive sound and vibration. When the speed of the moving scene was lower relative to that of the engine-drive sound and vibration, the participants (N = 16) judged the speed of the engine-drive sound and vibration as lower than the actual speed. However, no effect was observed when the speed of the moving scene was higher relative to that of the engine-drive sound and vibration. Thus, the averaging effect was observed between the visual and audio-tactile modalities in speed judgment during virtual motorcycle riding. Moreover, our results suggest that the averaging effect operated only to accelerate the perceived speed when the visual modality influenced the audio-tactile modalities but only to decelerate perceived speed when the audio-tactile modalities influenced the visual modality.

Title: Complementary roles of spatial- and timing-based control during rhythmic arm movements

Authors: *R. W. NICKL[1,2], M. M. ANKARALI[4], N. J. COWAN[3]
[2]Dept. of Biomed. Engin., [3]Dept. of Mechanical Engin., [1]Johns Hopkins Univ., Baltimore, MD; [4]Dept. of Electrical & Electronics Engin., Middle East Tech. Univ., Ankara, Turkey

Abstract: In the study of online movement control, vision is assumed to dominate and timing is often taken for granted, amounting to an assumption that the brain executes "perfect-time" control [Lavalle & Egerstedt 2007, Lamperski & Cowan, 2016]. Paddle juggling (repeatedly bouncing a ball off a paddle) is a task that is considered predominantly spatially controlled [Siegler et al., 2013; Ronsse et al., 2010], despite the importance of arm movement timing [Schaal et al., 1996]. Moreover, stable paddle juggling behavior has characteristics that cannot be explained by vision alone: skillful juggling can be accomplished in the absence of vision [Sternad et al., 2001], and visuospatial accuracy can be enhanced by providing touch cues [Ankarali et al., 2014].

To study how non-spatial cues affect online control, we designed a virtual reality paddle-juggling task where human volunteers bounced a ball on a monitor using vertical movements of a haptic paddle [Ankarali et al., 2014]. The only explicit goal was spatial: to hit the ball to a peak height of 35 cm. Ball position was displayed visually for 221 ms (13 video frames), centered around the apex of the flight. Ball--paddle collisions were signaled using an audio beep and simultaneous force pulse delivered by the haptic paddle. All experiments were run on a custom hard-real-time platform (40-us precision).

Unbeknownst to participants (n=10 for each experiment), we imposed cycle-by-cycle perturbations of displayed ball peaks and collision cue timings, so that peaks were displayed higher or lower, or timing or cues were rendered earlier or later, than the simulated physics would dictate. Sinusoidal perturbations (+/-3 cm spatial and +/-30 ms timing amplitudes) were used to derive the frequency response of participants' visual and timing-based controllers. These frequency-response functions were fit with parametric models that were then used to predict responses to jump perturbations (+/-4 cm spatial and +/-30 ms temporal).

We found that visuospatial control was best fit by a proportional--integral model, consistent with

previous error correction models. We also uncovered a timing-related controller that, unlike the spatial controller, entrained to error rather than correcting it. Timing control exhibited higher bandwidth than spatial control. Further, frequency-domain spatial- and timing- control models accurately predicted responses to jump ("step") perturbations. These results suggest the brain not only controls movements to attain desired spatial goals, but also solves the temporal problem of synchronizing motor timing with event timing feedback.

Title: Representational similarity analysis of sound symbolic auditory-visual crossmodal correspondences

Authors: *S. M. LIST[1,2,3], S. A. LACEY[3], R. STILLA[3], L. C. NYGAARD[4], K. SATHIAN[3,4,5,6]
[2]Grad. Div. of Biol. and Biomed. Sciences, Program in Neurosci., [3]Dept. of Neurol., [4]Dept. of Psychology, [5]Dept. of Rehabil. Med., [1]Emory Univ., Atlanta, GA; [6]Ctr. for Visual and Neurocognitive Rehabil., Atlanta VAMC, Atlanta, GA

Abstract: Humans consistently indicate correspondences between the sounds in a word (e.g. 'loh-moh') and the visual physical shape of objects (e.g. blob). This phenomenon is an example of a sound symbolic cross-modal correspondence. Multiple other examples of cross-modal correspondences between auditory and visual features of objects exist (e.g. low pitch and large size vs. high pitch and small size). Others have investigated auditory-visual cross-modal correspondences and shown that modulating the physical dimensions that define them can influence multisensory integration. In previous investigations, our group and others examined sound symbolic cross-modal correspondences at the level of phonetic categories and found that specific phonetic segments of nonwords are more likely to be consistently rated as rounded or pointed. For example, sonorants like /l/ or /m/ tend to be rated as rounded. We have used the data-driven approach of representational similarity analysis (RSA) to extend these findings linking physical stimulus parameters and perceptual ratings for a range of rounded and pointed auditory nonwords and visual shapes. This approach minimizes the potential for categorization bias. RSA on perceptual ratings of auditory nonwords and visual shapes revealed that the perceptual continuum from pointed to rounded is nonlinear and is variable for some nonwords and shapes but not for others. For nonwords and shapes at or near the extremes of the continuum,

perceptual ratings are highly consistent and invariant regardless of the other stimuli of the same modality that are presented for judgment. For nonwords and shapes around the middle of the continuum, perceptual ratings are less consistent and judgments can be shifted depending on the range and number of the other stimuli presented. Our analysis further indicates that this nonlinear scale of rounded to pointed is evident in certain physical features of the auditory (e.g. speech envelope) and visual (e.g. curvature) stimuli. These connections between the perceptual and physical measurements are being used as models to inform functional magnetic resonance imaging experiments and may be reflected in participants' blood oxygenation level dependent response during presentation of these stimuli. This research provides insights into the fundamental nature of crossmodal correspondences and how they evoke specific interpretations of physical meaning in natural language at the physical, perceptual, and neural levels.

Title: Task selectivity as a comprehensive principle for brain organization

Authors: *A. AMEDI[1,2,3,4], S. HOFSTETTER[3,2], S. MAIDENBAUM[3,2], B. HEIMLER[3,2]
[1]Dept. of Develop. Med. Neurobio., Fac. of Med. Hebrew Univ. of Jerusalem, Jerusalem, Israel; [2]The Edmond and Lily Safra Ctr. for Brain Sci. (ELSC), The Hebrew Univ. of Jerusalem, Jerusalem, Israel; [3]The Inst. for Med. Res. Israel-Canada (IMRIC), The Hebrew Univ. of Jerusalem, Jerusalem, Israel; [4]Sorbonne Université, Univ. Pierre et Marie Curie (UPMC), Univ. Paris 06, Inst. de la Vision, Unité Mixte de Recherche en Santé (UMRS) 968, Paris, France

Abstract: What are the principles subtending the emergence of brain specializations in the human brain? In the last decades, convergent evidence from studies with sensory deprived populations such as blind and deaf adults showed that most of the known specialized regions in higher-order 'visual' and 'auditory' cortices maintained their anatomically consistent category-selective properties in the absence of visual/auditory experience when input was provided by other senses carrying category-specific information. In this talk I will review this evidence by comparing it with the predictions coming from a prominent theory in cognitive neuroscience, "neural recycling", from the Dehaene group, which postulates that the anatomical consistencies of brain specializations observed when learning new tasks stem from shared basic sensory physical similarities with the original task processed in that specific brain region. I will challenge the sensory-anchored assumption of the neural recycling theory and propose an integrated

framework regarding the principles subtending the sensory brain organization, ultimately supporting the notion of the brain as a task-machine rather than as a sensory machine as classically conceived. Next I will address the case of early sensory cortices as a model to unravel whether the whole brain is a task-machine or this notion explains only the organization of higher-order sensory cortices. I will present evidence suggesting that early sensory cortices re-organization following sensory deprivation and especially blindness, seems to suggest a negative answer to this question as the deprived V1 has been repeatedly shown to be activated by memory and language (task-switching plasticity). However, I will also present recent data challenging this negative conclusion and propose novel ways to conceptualize and test task-machine organization in those cortices. Finally, I will discuss the implications of our results for both basic research and for clinical rehabilitation settings.

Title: Handedness-related hemispheric dominance and spatial orientation constancy

Authors: *A. KHERADMAND[1], J. OTERO-MILLAN[2], A. WINNICK[2]
[1]JOHNS HOPKINS UNIVERSITY, Baltimore, MD; [2]JOHNS HOPKINS UNVIVERSITY, Baltimore, MD

Abstract: There is a significant lateralization in hemispheric contribution to perception of spatial orientation. This functional laterality is primarily localized to the vestibular cortical network with a handedness-related functional dominance in the non-dominant hemisphere (i.e., right hemisphere in right-handers and left hemisphere in left-handers). Here we studied the impact of such functional laterality on orientation constancy by measuring visual perception of upright with changes in lateral head position in 12 right handed and 12 left handed subjects. We used subjective visual vertical (SVV) to measure perception of upright before, during, and after prolonged lateral head tilts of 20° from upright position (~15min). Torsional eye position was also measured simultaneously using video oculography. The initial SVV error during the head

tilt was in the opposite direction of the head tilt (right handed mean: -2.6° right head tilt and 0.2° left head tilt; left handed mean: -5.0° right head tilt and 3.8° left head tilt), but there was a gradual drift in SVV responses in the direction of the head tilt (right handed mean: 0.2° right head tilt and -0.5° 1 left head tilt; left handed mean: 0.7° right head tilt and -0.5° left head tilt). After the head returned to upright position, there was also an SVV aftereffect in the direction of the previous head tilt (right handed mean: 2.6° right head tilt and -3.8° left head tilt; left handed mean: 1.6° right head tilt and -3.0° left head tilt). In both groups ocular torsion always drifted towards zero (the eye position during upright) by an average of about 4 degrees. These findings show the effects of hemispheric laterality and orientation constancy with respect to higher-order neural mechanisms that contribute to perception of upright and lower-order mechanisms that control torsional eye position.

Title: Rare variants in axonogenesis genes connect three families with sound-colour synaesthesia

Authors: *A. K. TILOT[1], K. KUCERA[1], A. VINO[1], J. E. ASHER[2], S. BARON-COHEN[2], S. E. FISHER[1,3]

Abstract: Synaesthesia is an intriguing non-pathological neurological phenomenon where stimulation of one sense provokes an automatic and consistent secondary perception. Although the molecular mechanisms underlying synaesthesia are not yet known, affected people show altered structural and functional neural connectivity. The trait also appears to be more common amongst people with autism spectrum disorder (ASD) and savant abilities. Previous linkage studies searching for shared loci of large effect size across multiple families have had limited success. In this study, we applied whole exome sequencing to 3 multiplex families with sound-colour (auditory-visual) synaesthesia. Combined, we identified 37 rare genetic variants that perfectly followed the synaesthesia phenotype within a family. No variants or genes matched

across families, consistent with the emerging consensus that synaesthesia is a multigenic trait, prompting us to look for unifying pathways. Gene ontology enrichment analysis revealed a set of 6 genes associated with axonogenesis and cell migration, with the corresponding variants encompassing all 3 families. These genes — S*LIT2*, *MYO10*, *ROBO3*, *ITGA2*, *COL4A1*, and *SLC9A6* — are expressed in the human auditory and visual cortices throughout development, including early childhood when synaesthetic associations are formed and refined. To test whether these genes reflect neurological processes applicable to other families with sound > colour synaesthesia, we next identified genes with correlated developmental expression patterns. Amongst the 109 coexpressed genes, 5 fell within putative synaesthesia linkage peaks, suggesting axonogenesis as a shared pathway implicated in a proportion of people with this form of synaesthesia. These results provide the first gene-level support for hyperconnectivity in the aetiology of synaesthesia, and identify an entry point for molecular approaches to the neurobiology that delineates our sensory experiences.

Title: The simple material discrimination task examined haptic evaluations of material objects in human and possibly nonhuman primate subjects

Authors: *M. ITO, A. TSUZURA, M. SASAKI, F. HAMANO, K. MITSUHASHI
Tokyo Med. and Dent. Univ., Tokyo, Japan

Abstract: Materials of surface provides a powerful clues to object recognition. Although such material perception is strongly dependent on perceiving both visual texture information and haptic information, material perception is not well understood in model animals for physiological studies. While we have trained two monkeys with a material discrimination task, we here examined human subjects by means of the similar task for comparison. Five human subjects (3 male and 2 females, age 21-57) reported four haptic-scores (rough/smooth, hard/soft, hot/cold or dry/wet) in five steps for a set of 109 material samples. They also reported five material-scores, indicating resemblance to each reference material (metal, wood, carpet, soft-gel-sheet, and urethane-foam). Relative scores were used for classifying sample materials into five material categories. They evaluated these scores by touching these samples under blind conditions or with

only visual inspection under room light. Order of sample presentation was randomized and each sample was presented once in a daily session. (1)The principle component analysis was applied to the haptic scores. In the two dimensional feature space of the first and second components (contribution rate; 50.0% and 32.6%), data were distributed over the wide area, indicating wide variety of the sample set. Top 20% samples for each haptic-score were well localized in this space. Similarly, samples with high material-scores (>4.0) were well localized in the same feature space. (2)Multiple regression analysis indicated that the four haptic-scores, especially those of hard/soft and hot/cold, were well predicted by the linear regression due to the material-scores ($p<0.01$). (3)To compare the results among individual subjects and experimental conditions, we modified the multidimensional scaling analysis, so that the four reference materials were presented at the fixed locations in two dimensional space. Individual difference was small enough to preserve the material categorization due the material-scores (three-way ANOVA, $p<0.01$). By visual inspection, scores tend to form a compact cluster for each material categories. However, the difference between materials was still preserved within each material category. Therefore, the relatively simple material discrimination task was sufficient for evaluating material perception within and between the material categories in a reliable manner. Since the material-scores can be acquired by a behavioral task, haptic perception might be evaluated even in primate subjects by using the similar material discrimination task.

Title: Synesthetes produce different language in creative writing tasks

Authors: *R. MORALES[1], S. LUNDQVIST[2], T. DOTY[2], D. LARRANAGA[2], R. B. ESQUENAZI[3], A. RUTCHICK[5], S. A. DREW[4]

Abstract: A condition known as synesthesia is commonly characterized by multiple sensory perceptions elicited by a single stimulus. These percepts can be intramodal (e.g. grapheme-color) or intermodal (e.g. lexical- gustatory). Aim: This exploratory research implements elements of both social and perceptual psychology to evaluate differences in synesthetes compared to controls in components of language production. In this study we observed trends in lexical

descriptors used by participants who experience synesthtetic perceptions compared to those who do not experience this condition. There appear to be multiple markers in which synesthetes significantly differ from controls. Method: Survey data of synesthetic perceptions and writing samples were collected. Writing tasks consisted of describing a picture, telling a story given three prompt words, describing a childhood memory, and recall of a recent or memorable dream. Results: Analysis of 180 participants' writing profiles was conducted using LIWC 2015 software (Pennebaker et al. 2015), an automated text analysis program that evaluates linguistic elements of writing samples. Findings indicate distinct differences between synesthetes and non-synesthetes, in the dimension of perceptual processing words (i.e. see, hear, feel, percept) with the strength of differences varying across tasks.

Title: Biophysically realistic neuronal model explains the inter-individual differences in the processing of multisensory speech

Authors: *V. G. KUMAR[1], S. DUTTA[1], D. ROY[2], A. BANERJEE[1]
[1]Natl. Brain Res. Ctr., Gurgaon, India; [2]Ctr. of Behavioural and Cognitive Sci., Allahabad, India

Abstract: In a predominantly used paradigm of speech perception (McGurk effect), participants perceive illusory speech sound (crossmodal) when presented with incongruent audio-visual (AV) stimuli. However, a large number of participants rarely perceive the illusion. Notably, existing studies in the field primarily accentuate the correlation between subjective behavior and cortical activations to reveal the neuronal mechanisms. Nonetheless, this approach does not provide mechanistic explanation of the inter-individual differences. In the present study, we explain our empirical observations of large-scale functional brain networks underlying crossmodal perception employing biophysically realistic neuronal models. Importantly, we propose how

coupling between the key neuronal systems can explain the observed changes in functional connectivity pattern dynamics between frequent and rare perceivers of McGurk effect.
EEG data was collected from 35 healthy volunteers who signed informed consents, approved by the Institutional Human Ethics Committee of National Brain Research Centre, India. The participants reported their percept while watching a set of incongruent and congruent AV stimuli. Based on their behavioral responses, the participants were categorized as frequent and rare perceivers of the McGurk illusion. Global coherence was computed from sensor-level EEG data to study the dynamics of the cortical network following crossmodal perception. Subsequently, a network of excitatory and inhibitory Hindmarsh-Rose neurons were used to represent a cortical area. Different time constants were used in the network to distinguish between auditory (fast), visual (slow) and multisensory (intermediate) areas. Subsequently, coherence spectras were computed from simulated large-scale network dynamics.
Frequent perceivers exhibited an enhanced gamma band coherence accompanied by decreased alpha and beta band coherence during crossmodal perception. For rare perceivers crossmodal perception was characterized with decreased alpha coherence. Our neuronal model could exhibit a coherence pattern similar to frequent perceivers when the direct coupling between the auditory and visual nodes was increased. Furthermore, an increase in the coupling between the auditory and the multisensory node could qualitatively generate the coherence pattern of the rare perceivers. Thus we predict the dynamic interplay between a fast temporal processing system (e.g. auditory) and slow temporal processing system (e.g. visual, multisensory) is the most crucial factor for crossmodal perception.

Title: Effects of audio and text messages on avoidance strategies while walking in healthy young adults

Authors: *W. H. DE SOUZA SILVA[1,2], J. FUNG[3,1], B. J. MCFADYEN[4], A. LAMONTAGNE[3,1]

[1]Sch. of Physical and Occup. Therapy, [2]Integrated Program in Neurosci., [3]McGill Univ., Montreal, QC, Canada; [4]Dept. of Rehabil., Laval Univ., Boul Hamel, QC, Canada

Abstract: Texting while walking poses a serious threat to safe locomotion, as multi-tasking can over-burden perceptual-cognitive resources that are essential for obstacle detection and avoidance. In this study, we tested the hypothesis that audio processing is less disruptive than visual processing for obstacle circumvention, as locomotion relies heavily on visual inputs. We expected audio messages to induce smaller alterations in avoidance strategies compared to visual (written) text messages. Healthy, right-handed adults (n = 7, 57% male, aged 25 ± 2 years (mean ±1SD)) were tested while walking over ground and viewing a virtual environment (VE) displayed in a helmet mounted display. The VE simulated a subway station with a target 11m straight ahead. Three non-reactive female avatars were positioned 7m ahead of the participant (±40° right/left and straight ahead at 0°). As the walking subject reached 0.5m of forward displacement, one of the 3 avatars would randomly approach while the others walked away. A collision would occur at 3.5m along the midline if the subject continued to walk straight with no avoidance. Message conditions that were tested included a visual text message, an audio message and no message. When present, messages were delivered at 0.5m of forward displacement (onset of avatar movement). The ability of the subjects to avoid the approaching avatar was characterized using the 3D position and orientation of the head recorded with a 12-camera Vicon system. Only two collisions occurred out of a total of 420 recorded trials, one for each message modality. For non-collision trials, when compared to the no message condition, visual text messages induced slower average and minimal walking speed and a wider deviation of the walking trajectory. In contrast, audio messages led to an increase in average and minimal walking speed but no significant change in maximal trajectory deviation. No consistent changes in the minimum distance maintained from the obstacle and the onset time of avoidance strategies were observed across tested conditions. We thus conclude that attending to phone messages while walking modifies obstacle avoidance strategies. As hypothesized, visual text messages cause greater dual-task interference compared with the auditory modality, as evidenced by the trend of reduced walking speeds and larger deviations in response to reading. While the use of larger trajectory deviations with visual text messages may reflect an underlying ‘safer’ avoidance strategy, it may pose further risk for possible collisions in the presence of multiple pedestrians. Audio messages may thus be considered as a safe alternative for on-the-go communication while walking.

Title: Cross-modal interactions in motion perception in blind adults

Authors: *M. M. BARRETT[1], J. P. RAUSCHECKER[2]
[1]Neurosci., Georgetown Univ., Washington, DC; [2]Dept. of Neurosci., Georgetown Univ. Med. Ctr., Washington, DC

Abstract: In sighted humans, there is evidence to support the notion of directional selectivity within the human middle temporal complex for visual motion information (Huk, Dougherty, & Heeger, 2002; Koyama et al., 2005; Morrone et al., 2000; Tootell, Mendola, Hadjikhani, Liu, & Dale, 1998). It has been shown that distinct regions within the motion-sensitive human middle temporal complex (hMT+) respond to radial and translational motion, suggesting a functional specialization within hMT+ for processing different types of motion information (Morrone et al., 2000). Furthermore, previous studies have found that the direction of moving sounds can be reliably decoded from fMRI activation patterns within putative hMT+ in blind adults (Dormal, Rezk, Yakobov, Lepore, & Collignon, 2016; Wolbers, Zahorik, & Giudice, 2011). The aim of this study is to elucidate the functional specialization of hMT+ in response to different auditory and tactile motion directions using fMRI. Moreover, this study will assess how combining auditory and tactile motion cues modulate BOLD responses in comparison to either tactile or auditory cues alone. Two groups are assessed, early blind and matched sighted controls. Auditory and tactile motion cues with different directions of motion are used to evaluate the functional specialization of the hMT+ region in both groups. In addition, the effect of combining tactile and auditory motion information using different levels of motion coherence is used to measure modulations in the BOLD response to multisensory motion inputs. These results not only elucidate the functional specialization of putative visual cortical areas in blind individuals, but also contribute to our understanding of how perception in the sensory-deprived brain may be enhanced via multisensory inputs.

Title: Impaired development of audiovisual integration in autism and the effects of modality switching

Authors: *M. J. CROSSE[1], J. J. FOXE[3], S. MOLHOLM[2]
[2]Neuroscience/Pediatrics, [1]Albert Einstein Col. of Med., Bronx, NY; [3]Pediatrics and Neurosci., Univ. of Rochester Sch. of Med., Rochester, NY

Abstract: Simultaneous presentation of information from different sensory modalities often leads to faster responses than presenting the same information separately. Response times for multisensory stimuli have been shown to exceed what would be predicted if the faster of the two unisensory responses were to win out (i.e., the race model; Miller, 1982), indicating integrated processing of the individual sensory streams. This ability to benefit from multisensory inputs increases across middle childhood and adolescence (Brandwein et al., 2011). However, the developmental course of the audiovisual (AV) facilitation that is observed in typically developing (TD) children is not seen in those with an autism spectrum disorder (ASD; Brandwein et al, 2012). Using the same audiovisual speeded reaction time (AVSRT) task, and data from nearly 300 participants ranging in age from 5 to 45, we demonstrate that this development is delayed until adolescence in ASD participants, but recovers considerably in adulthood. However, ongoing work has recently revealed that mixed presentation of unisensory and multisensory stimuli may give rise to the apparent redundant target effect because of a behavioral cost to switching modality during the unisensory trials, but not the multisensory trials. We therefore separated trials into those preceded by a different stimulus (switch trials) and those preceded by the same stimulus (repeat trials). Our analysis demonstrates that both TD and ASD participants show a "switching cost", but that only the TD participants show race model violation on the repeat trials. This violation may be due to a residual "mixing cost" because participants are still required to attend across modalities on a repeat trial. The fact that this mixing cost differentially affects behavior in TD and ASD participants suggests that it may in part reflect an underlying deficit in deployment of crossmodal attention. To further investigate these behavioral differences, we also examine neural responses to the switch and repeat trials recorded using high-density electrophysiology (EEG).

Title: Movement back projection during observation of an illusory embodied hand: Evidence by EEG mu-rhythm

Authors: *S. UNENAKA[1], *S. UNENAKA[1], S. SHIBUYA[1], T. ZAMA[2], S. SHIMADA[2], Y. OHKI[1]
[1]Kyorin Univ. Sch. Med., Tokyo, Japan; [2]Meiji Univ., Kanagawa, Japan

Abstract: We normally experience that our body is our own, and a coherent and unified entity separate from the external world. This sense of body ownership is fundamental to self-consciousness. However, people can also experience body ownership over a non-corporal object using a rubber hand illusion (RHI), wherein participants perceive a fake hand as their own by stroking their hidden real hand and the visible fake hand simultaneously (i.e., embodiment of the fake hand). Several RHI studies have reported that visual manipulation of the fake hand was back projected onto perception in the real hand (e.g., thermal or pain sensitivity). In this study, we examined whether motor manipulation of the embodied fake hand similarly back projected onto the observer's motor system by a combination of a novel RHI paradigm and electroencephalography (EEG). Eighteen healthy volunteers participated in the experiment. An experimenter stroked participants' and the false hands in synchrony (synchronous condition) or in asynchrony (asynchronous condition). Stroking was sometimes interrupted by unexpected movement of the false hand (i.e., finger spreading). Brain activities during the task were investigated using EEG. As a measure of motor system activation, we analyzed decrease of frequency power in a mu rhythm band (8-13 Hz; mu-suppression) during action observation. Subjective reports using a questionnaire indicated that participants perceived illusory body ownership of the false hand in the synchronous condition but not in the asynchronous one. Participants' fingers of the stroked hand moved spontaneously during action observation. The incidence of finger movements was significantly higher in the synchronous condition and also increased as a function of trials. EEG data showed greater and longer mu-suppression in the synchronous condition compared to the asynchronous one. Additionally, we found that the stronger the feeling of body ownership over the false hand, the greater the mu-suppression in the motor system. These findings provide strong behavioral and neurophysiological evidence of motor back projection, in which the movement of an illusory embodied 'body part' is inversely transferred to the sensorimotor system of the observer.

Title: Hearing loss modulates auditory cortex response to audio-visual speech

Authors: *S. ROSEMANN[1,2], C. M. THIEL[1,2]
[1]Univ. of Oldenburg, Oldenburg, Germany; [2]Cluster of Excellence "Hearing4all", Univ. of Oldenburg, Oldenburg, Germany

Abstract: Previous research provides compelling evidence for a cross-modal reorganization in the auditory cortex following auditory sensory deprivation, leading to increased neural responses to visual input. Recently, it was shown that these changes may already occur after a moderate hearing-impairment and not only after severe hearing-loss. By using functional magnetic resonance imaging, we investigated the influence of mild to moderate hearing-impairment on audio-visual speech processing.
We here measured 20 hearing-impaired participants (63.5 ± 5.4 years) with mild to moderate high-frequency hearing-loss who were not wearing a hearing-aid yet and 19 normal-hearing participants (63.2 ± 5 years). The fMRI paradigm consisted of an audio-visual speech detection task in which the participants had to indicate which word was included in the previous sentence. Sentences were presented either audio-visually congruent, audio-visually incongruent, only visually or only auditory. Loudness was individually adjusted to 80% speech intelligibility to enable equal performance in both groups. Outside the MRI, participants performed the McGurk illusion as a measure for audio-visual integration.
Our main aim was to relate high-frequency hearing loss to BOLD response amplitudes elicited by audiovisual speech processing. We observed a significant difference in BOLD response amplitudes for incongruent versus congruent input between hearing-impaired and normal-hearing subjects. Furthermore, the BOLD signal significantly correlated with hearing loss, with higher hearing-loss leading to an increased BOLD signal in the primary auditory cortex. Behaviorally we found a benefit of congruent audio-visual input and a distraction by incongruent audio-visual input, which was similar in both groups and did not correlate with hearing loss. Hearing loss, however, correlated with audio-visual integration in the McGurk task, with higher hearing-loss leading to stronger audio-visual integration.
Our data provide evidence for hearing-loss related changes in BOLD amplitudes in the auditory cortex. In line with previous research that hearing-impaired subjects tend to rely more on the visual input in challenging listening conditions, we here show a hearing-loss induced modulation of the BOLD response during incongruent audio-visual input. Behavioral measures showing an increased audio-visual integration with increasing hearing-loss complement our findings. These results suggest that cross-modal reorganization occurs early in the course of hearing loss and not only after severe hearing impairment, which may lead to an altered audio-visual speech processing.

Title: Systematic influence of the auditory system on human visual perception

Authors: *J. SONG[1,2], S.-B. PAIK[2]
[1]Information & Electronics Res. Inst., Daejeon, Korea, Republic of; [2]Dept. of Bio and Brain Engin., Korea Advanced Inst. of Sci. and Technol., Daejeon, Korea, Republic of

Abstract: Sensory information of different modalities is known to be merged in higher cortical regions (Beauchamp, et al., 2004), but little is known about how the different sensory systems affect each other's information processing. Interestingly, a recent fMRI study reported that the activity induced by different stimuli of one sensory modality is discernable in non-pertinent sensory systems in human (Liang, et al., 2013); However, how such influence between different sensory systems is organized in humans remains a question.
In the present study, we hypothesized that the auditory system systematically affects information processing in the visual system. To test our hypothesis, we conducted a set of psychophysical experiments: Human subjects were briefly shown a Gabor filter with various orientations on the monitor screen while keeping their eyes at the center. Shortly before a visual stimulus appeared, either no acoustic stimulus or a sound of various frequencies was introduced. Then, subjects were instructed to rotate the test Gabor probe and match its orientation as accurately as possible to that of the visual stimulus presented; the error—the angular difference between the appeared stimulus and subjects' response—was used as the performance measure.
As a result, we found that acoustic stimuli of different frequencies significantly changed subjects' performance error compared to that under no-sound condition. These effects were not uniform across the visual space: visual perception at different visual locations were specifically affected by sound frequencies within a given range, and such frequency bandwidth gradually shifted across the visual space.
Our results indicate that the auditory influence on visual perception is systematically organized. Because the information that the auditory and visual stimuli carry start to be processed in the very early stages of the sensory systems, we suggest that the systematic matching between the audio-visual systems originates from the early sensory cortices.

Abstract: The motor mirror system has been extensively studied, with fMRI and single-unit studies finding regions of cortex activated both when performing an action and also when observing someone else performing the same action. A complementary, but less thoroughly investigated system, is the sensory mirror system, where some regions of cortex are activated both when feeling a sensation of being touched and also when observing someone else being touched. Here we tested for the presence of a sensory mirror system within a 4 by 4 mm patch of anterior intraparietal area (AIP) of posterior parietal cortex (PPC) of a tetraplegic participant (NS) participating in a brain-machine interface clinical trial. We studied neural responses when NS either felt a touch on her face or shoulder (both sensations above the level of injury) or visually observed someone else's face or shoulder being touched. Sensory mirroring was observed at both the single-unit and population level. Activity for touching NS was observed regardless of whether NS's eyes were open or closed suggesting that the mirroring response was not purely visual in nature. Mirroring was also specific to body part. Comparing neural population level similarity measures, we found that the similarity between NS being touched on the face and observing someone else being touched on the face was significantly greater than the similarity between the face and shoulder. Likewise, similarity measures between when NS felt and observed touches of the shoulders were significantly greater than the similarity between the shoulder and face. Our results show for the first time at a single-unit and population level in humans that AIP contains a high level representation of the sensation of touch that is activated both when feeling a touch and observing someone else being touched.

Title: Divisively normalized integration of visual and proprioceptive information for motor adaptation

Authors: *Y. KATO[1], T. HAYASHI[2], D. NOZAKI[3]
[1]department of health and education, The Univ. of Tokyo, Tokyo, Japan; [2]The Univ. of Tokyo, Grad Sch. Educ, Tokyo, Japan; [3]Grad School, Univ. of Tokyo, Tokyo, Japan

Abstract: When we experience an error during a movement, the motor system corrects the motor command according to the difference between predicted and actual sensory information. Although previous studies have investigated the contribution of visual and proprioceptive errors for the motor adaptation (Wei & Kording JNP 2009; Marko et al., JNP 2012), it has not been fully elucidated how the errors in the two distinct sensory modalities are integrated. Here, we aimed to clarify the way of integration by examining single-trial motor adaptation during a reaching task when various combinations of visual and proprioceptive errors were systematically imposed. Fourteen participants moved a cursor toward a front target with their unseen hand. We interleaved one of 35 types of perturbations: the combinations of directional errors of the cursor (±45°, ±30°, ±15°, 0°) (visual error: VE) and the hand (±30°, ±15°, 0°) (proprioceptive error: PE) around a start position with the error-clamped methods. In the subsequent reaching trial to the same front target, we measured lateral force to the channel as an index of the motor adaptation (aftereffect). The aftereffects were suppressed when the errors were imposed in the opposite direction (e.g., +30° VE and -15° PE), but they were not increased even when the error was added to another sensory modality (e.g., +15° PE did not increase the aftereffect to +30° VE). Thus, simple summation of the aftereffects obtained separately for each VE and PE could not predict the size of the aftereffect observed when both types of errors were simultaneously imposed. The idea of “relevance of error” (Wei & Kording, JNP 2009) or Bayesian integration model (Ernst & Banks, Nature 2002) could not explain our results: For example, even when the size of the error was increased with the relevance of error maintained (e.g., from +15° VE and PE to +30° VE and PE), the aftereffect did not increase. Alternatively, we assumed that the aftereffect is determined as a response to divisively normalized error information (Carandini & Heeger, Nat Rev Neurosci, 2012) and that this mechanism works as a way of integrating multisensory information (Oshiro et al, Nat Neurosci 2011). We found that this simple

mechanism could nicely reproduce the complicated pattern of aftereffects to combination of VE and PE. This result suggests that divisive normalization that is known to be a canonical neural computation is likely to work in the motor learning system.

Title: Oscillatory activity underlying attentional modulation of crossmodal matching in a trimodal sensory paradigm

Authors: *J. MISSELHORN[1], U. FRIESE[2], A. K. ENGEL[1]
[1]Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]Inst. of Cognitive Sci., Osnabrück, Germany

Abstract: Crossmodal matching is a key mechanism underlying perceptual interaction in complex multisensory environments. That is, signals from distinct modalities can be integrated more effectively if they coincide in time and space, but also if structural or semantic features can be matched. When more than two modalities are involved, highly ambiguous situations can arise where attention is needed to resolve conflicts. Here, we used a novel multisensory paradigm featuring audio-visuo-tactile stimuli to investigate crossmodal matching of stimulus amplitude changes. In this paradigm, subjects had to focus on either visuo-tactile or audio-visual components of the trimodal stimulus for which crossmodal congruence of brief intensity changes had to be evaluated. The respective third component of the trimodal stimulus served as a task irrelevant distractor. Both stimulus-driven effects of crossmodal congruence and cognitive effects of selectively attending or ignoring stimulus components were evaluated. Behaviorally, visuo-tactile matching was faster than audio-visual matching. Moreover, crossmodal congruence led to faster reactions. While the latter corresponds to well documented findings on multisensory enhancement, the former indicates differences with respect to attentional aspects of crossmodal matching. In a source level analysis of EEG data, we found neither significant modulation of oscillatory power within nor coherence between early sensory regions involved in the task. In a whole-brain analysis of oscillatory power we observed that right central and frontal alpha power was decreased for visuo-tactile matching. Attended crossmodal congruence induced higher theta

power in cingulate and lower alpha power in parietal and frontal cortex. These preliminary results suggest that crossmodal matching and its modulation by attention do not occur at early sensory processing stages. Rather, both stimulus-driven (i.e., multisensory enhancement) and cognitive effects are reflected in modulation of higher cortical areas and, thus, suggest that crossmodal interaction in our task takes place rather late in the processing hierarchy. In an ongoing analysis of functional connectivity of the same dataset, we investigate changes in corticocortical coupling underlying crossmodal matching.

Title: Alpha and beta oscillations in the language network, motor and visual cortex index semantic congruency between speech and gestures in clear and degraded speech

Authors: *L. DRIJVERS[1,2], A. OZYUREK[1,3], O. JENSEN[4]
[1]Radboud Univ., Nijmegen, Netherlands; [2]Donders Inst., Nijmegen, Netherlands; [3]Max Planck Inst. for Psycholinguistics, Nijmegen, Netherlands; [4]Sch. of Psychology, Univ. of Birmingham, Birmingham, United Kingdom

Abstract: Oscillatory dynamics are thought to subserve the integration of information from multiple modalities. This is particularly relevant during face-to-face communication, which integrates auditory (e.g., speech) and visual inputs (e.g., gestures). Under adverse listening conditions, speech comprehension can be improved by the semantic information conveyed by these gestures. However, when gestures mismatch speech, audiovisual integration might be hindered, especially when speech is degraded and the semantic information from gestures cannot aid to resolve the remaining auditory cues. Here, we used MEG to investigate how oscillatory dynamics support the semantic integration of speech and iconic gestures in clear and degraded speech. Participants were presented with videos of an actress uttering an action verb, accompanied by a matching (e.g., a mixing gesture + 'mixing') or a mismatching gesture (e.g., a drinking gesture + 'walking'). Speech in the videos was presented clear or degraded by using 6-band noise-vocoding. Semantic congruency and speech degradation modulated oscillatory activity in the alpha (8-12 Hz) and beta (15-25 Hz) band. Source analyses revealed larger alpha and beta power suppression in LIFG and visual cortex when speech was accompanied by a mismatching as compared to a matching gesture, but only when speech was clear. This indicates

that the visual system is more engaged to allocate attention to mismatching than matching gestures when speech is clear. The observed congruency effects in the LIFG are likely to reflect an increased semantic processing load to resolve the conflict. This conflict reduced when speech is degraded, due to the lack of auditory cues. In clear, but not degraded speech, beta power was more suppressed in (pre)motor cortex when a gesture mismatched than matched the speech signal, suggesting that a listener might simulate the mismatching gesture to re-evaluate its fit to speech. Beta power was more suppressed in MTG/STG, MTL and AG when speech was degraded and gestures mismatched as compared to matched speech. This suggests that listeners try to resolve the speech signal, but that semantic audiovisual integration might be hindered when the mismatching gesture fails to aid retrieval of the degraded input. Our results provide novel insight by revealing how low-frequency oscillations support semantic audiovisual integration in clear and degraded speech: when gestures mismatch and speech is clear, listeners engage the extended language network to process the mismatching gesture. In degraded speech, the extended language network is less engaged, possibly reflecting the hindered coupling of gestures and the degraded signal.

Title: Neural practice effect during cross-modal selective attention: General and modality-specific effects

Authors: X. JING, N. LIU, *Q. CHEN
South China Normal Univ., Guangdong, China

Abstract: Practice and experiences gradually modify the central nervous system, from the synaptic level to large-scale neural networks. However, the supra-modal and modality-specific effects of practice during cross-modal selective attention remain unknown. In two fMRI studies, we adopted a cross-modal interference paradigm in conjunction with the hybrid fMRI design. In alternating task blocks, participants attended to either the visual or the auditory component of

simultaneously presented audiovisual stimuli and ignored information from the unattended modality. The temporal position of each and every trial in a given block was included as a covariate to calculate how neural activity changed as a function of the time of practice. Results from the two fMRI studies consistently showed that with the progress of practice, neural activity linearly decreased in the frontoparietal central executive network (CEN) while increased in the default-mode network (DMN). Critically, the practice effect in CEN and DMN occurred independently of the modality attended, indicating the general mechanisms of selective attention. On the other hand, increasing extent of functional decoupling between the auditory and the visual systems was observed with the progress of practice and varied as a function of the modality attended. During auditory attention, the auditory system was functionally decoupled with both the dorsal and ventral visual stream with the practice; during visual attention, the auditory system was decoupled only with the ventral visual stream. Taken together, both supra-modal mechanisms in CEN and DMN and modality-specific mechanisms in the sensory systems associated with practice were revealed during cross-modal selective attention.

Title: Temporal facilitation of audiovisual speech processing in young children with and without autism spectrum disorder

Authors: *T. G. WOYNAROSKI[1], D. M. SIMON[2], J. I. FELDMAN[2], S. EDMUNDS[4], A. TU[2], W. KUANG[2], J. G. CONRAD[2], P. SANTAPURAM[2], M. T. WALLACE[3]
[1]Hearing and Speech Sci., Vanderbilt Univ. Med. Ctr., Thompsons Station, TN; [3]Hearing and Speech Sci., [2]Vanderbilt Univ., Nashville, TN; [4]Univ. of Washington, Seattle, WA

Abstract: Explaining individual differences in language understanding and use of young children with autism spectrum disorder (ASD) is a top priority of research because language has been repeatedly linked with long-term outcomes in this population. Temporal facilitation (the gain in speech processing speed that is associated with having access to visual speech cues) may account for variability in language understanding and use across children with ASD. Previous work indicates that older, relatively high functioning children with ASD are highly variable in

their ability to perceive visual speech cues. Children with ASD who do not use visual speech cues may process speech more slowly, and slow speech processing may underlie impairments in understanding language, leading to delays in using language. This project will evaluate the theoretical association between temporal facilitation and language in a sample of children with ASD who are younger and who represent a broader range of cognitive and functioning levels than have previously been studied. Our task is a direct neural measure that is low in demand, but that has the temporal resolution needed to capture the speed of the neural response to rapid audiovisual speech input - event-related potentials (ERPs). We hypothesize that young children with ASD will show less temporal facilitation on average relative to their typically developing peers, but that there will be a wide range of individual differences in the extent to which visual cues "speed up" speech processing across children with ASD. We anticipate that the degree of temporal facilitation experienced (a) may be explained by gaze patterns to audiovisual speech and (b) will positively correlate with measures of language understanding and use. IMPACT: If our hypotheses are born out, this work will have identified an impediment to language development in children with ASD that independent evidence suggests is malleable and therefore potentially remediable.

Title: Audio-visual cross-modal processing in individuals with cortical/cerebral visual impairment

Authors: *E. BAILIN[1], C. R. BENNETT[2], M. REZK[3], O. COLLIGNON[3], L. MERABET[4], C. M. BAUER[1]
[1]Mass. Eye and Ear -- Harvard Med. Sch., Boston, MA; [2]Mass. Eye and Ear -- Harvard Med. Sch., Somerville, MA; [3]Univ. of Louvain, Louvain, Belgium; [4]MEEI-Harvard Med. Sch., Boston, MA

Abstract: Cortical/Cerebral Visual Impairment (CVI) is caused by early developmental brain damage and is the leading cause of pediatric visual impairment in developed countries (Good et al. 2001 and Dutton 2013). Despite its prevalence and breadth of associated visual dysfunctions, very little is known regarding multi-modal processing in children with CVI. To this end, the current study utilized functional MRI (fMRI) to determine how adolescents with CVI process auditory and visual cross-modal motion.

A cohort of individuals with CVI (ages 14-24, mean= 18.4) and normally-sighted and developed controls (ages 15-25, mean 19.75) underwent our neuroimaging protocol on a 3T Philips Achieva system using a 32-channel phased array head coil. A T1w structural scan, a field map, and two fMRI experiments (totaling 6 runs) were acquired for each subject. During the first experiment, blocks of horizontal visual movement, horizontal auditory noise, static images, and random auditory noise were interspersed with rest blocks. During the second experiment, subjects were presented with blocks of auditory and visual motion that were either moving in the same (congruent) or in opposite (incongruent) directions, which were interspersed with blocks of static stimuli and rest. The primary contrast of interest was congruent vs. incongruent motion in areas V1, A1, and hMT+, which were functionally defined from experiment one. Functional data were preprocessed in FSL using standard processing pipelines including brain extraction, MNI registration, and motion correction. A GLM using FLAME 1+2 was used to assess cluster-wise significance between groups, focusing on A1, V1, and hMT+. Significance was set at z 2.3, $p < 0.05$.

Compared to controls, the CVI group showed significant bilateral decreases in activation in areas V1 and hMT+, and in the left A1, with significant increases in activation in right A1 during both visual and auditory uni-modal motion, as well as congruent and incongruent cross-modal conditions compared to rest. Compared to controls, the CVI group also showed bilateral increases in A1, V1, and hMT+ when comparing congruent and incongruent conditions, however these were stronger in the right hemisphere.

Together, these results indicate that individuals with CVI show significantly different patterns of activation compared to controls during both uni- and cross-modal processing of auditory and visual motion stimuli. Thus suggests that individuals with CVI may require greater amounts of neural resources to process visual and auditory motion and that visual motion may be particularly affected

Title: The Ganzfeld experience: Characterizing multimodal integration failure using resting-state fMRI

Authors: N. JAGANNATHAN[1], M. LJUBLJANAC[1], T. NIERHAUS[2], *T. SCHMIDT[1,2]
[1]Inst. of Cognitive Sci., Univ. Osnabrück, Osnabrück, Germany; [2]Neurocomputation and Neuroimaging Unit, Freie Univ. Berlin, Berlin, Germany

Abstract: The Bayesian brain hypothesis posits that interactions between top-down predictions and bottom-up sensory signals modulate perception, such that disruptions in the balance between the two processing streams can result in multimodal integration failure. This phenomenon can be tested using multimodal Ganzfeld (MMGF), a sensory homogenization technique in which the visual and auditory systems are exposed to totally unstructured stimulation (i.e. homogenized visual input and auditory white noise). Sustained exposure to MMGF can cause alterations in consciousness that are characterized by pseudo-hallucinatory experiences. We used resting-state fMRI to identify how changes in functional connectivity between the thalamus, sensory, and higher-order brain networks characterize these integration failures. Data from N=19 subjects were acquired in a 25min MMGF functional scan, preceded and succeeded by 7min control scans. The phenomenology of the MMGF-induced altered state of consciousness was retrospectively assessed using the Altered States of Consciousness Rating Scale and Phenomenology of Consciousness Inventory. The psychometric assessments demonstrated that the homogenization of sensory inputs used in MMGF induces substantial deviation from the normal wakeful state. A comparison of the MMGF condition to the pre- and post- control sessions revealed increased Eigenvector centrality for the precuneus during the Ganzfeld experience. Furthermore, a progressive decoupling of sensory regions from the thalamus was observed under sustained exposure to MMGF. In line with the predictive coding framework, the increased Eigenvector centrality in the precuneus may reflect increased top-down influences. Additionally, the reduction in functional connectivity between the thalamus and lower-order sensory regions is indicative of disturbed bottom-up signaling. This imbalance of top-down and bottom-up processing reflects multimodal integration failure, which in turn gives rise to the alterations in consciousness characteristic of the Ganzfeld experience.

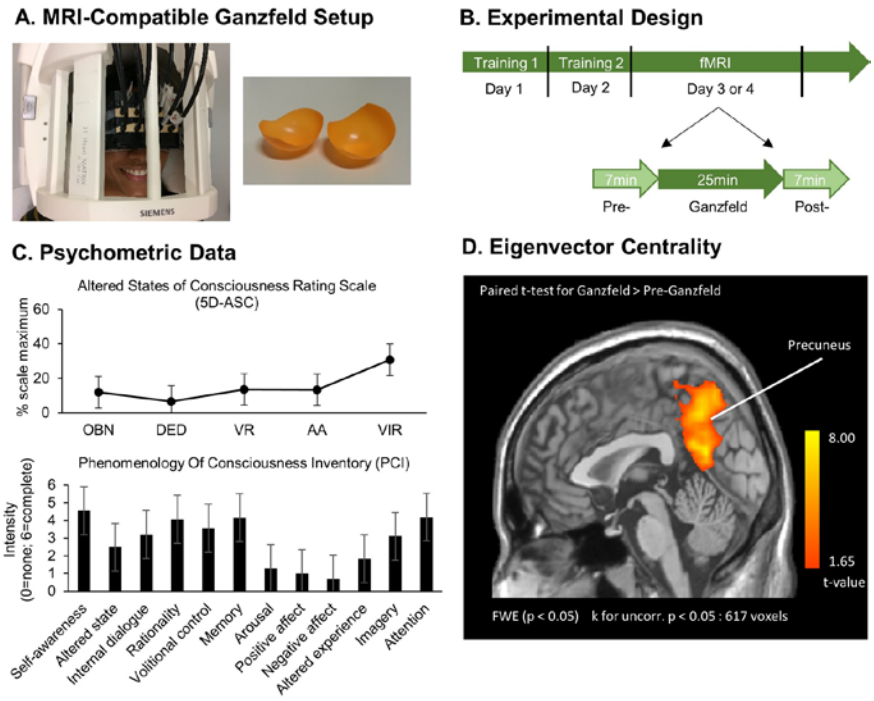

Figure 1. Experimental paradigm and results. **A. MMGF setup:** anatomically-cut ping pong balls (right) and customized goggles with fiber optic cables (left) were used to provide homogenized visual input during the MMGF. **B. MMGF sessions:** subjects completed two training sessions prior to participating in the pre-, Ganzfeld, and post- resting-state scans. **C. Questionnaires:** average ratings across subjects are displayed for the 5D-ASC (OBN: Oceanic Boundlessness, DED: Dread of Ego Dissolution, VR: Visual Restructuralization, AA: Auditory Alterations, VIR: Vigilance Reduction) and PCI. **D. Eigenvector centrality:** increased centrality during the MMGF condition was observed for the precuneus, a core aspect of the default mode network.

Title: Visual and auditory cues can enhance subliminal tactile sensitivity but interfere with suprathreshold performance

Authors: *M. F. WESNER, E. LO, K. D. MACLAM, V. B. K. JOHNSON
Psychology, Lakehead Univ., Thunder Bay, ON, Canada

Abstract: Although cortical parcellation demonstrates localized functionality, there can be extensive underlying neural circuits that interconnect throughout associative and subcortical brain. Sometimes these interconnections can be preserved after neurological damage allowing patients to use intact, multisensory circuits for rehabilitation. Hierarchical integrative

efficiencies, however, are not well understood. Typically in multisensory research, response times (RTs) are measured while presenting coincidental stimuli across modalities. The problem is that RTs are based on high-threshold theoretical principles and do not account for integrative phenomena specific to hierarchical processing.
We psychophysically measured percent correct (%C) right-hand finger responses to haptic toe stimulations on the left foot. Fifty-seven participants (n=36 female, age 18 to 35) were screened for confounding medical conditions, and all had normal, or corrected-to-normal near acuity and auditory functioning. Using six von Frey monofilaments of varying target buckling forces (0.008 to 300 gm; log iterations), we presented the monofilaments to the tops of the second or fourth toe in a two-alternative forced choice experiment. Two experiments were conducted in which either a visual icon or a single frequency tone was presented simultaneously with the haptic presentations. Within each experiment, three conditions were used: (1) Control condition where the von Frey hairs were applied alone, (2) 100-percent cue condition where the cues correctly identified which of two toes were being tactually stimulated, and (3) 60-percent cue condition where the cues were only 60 percent valid. Cues were delivered for 350ms within the averaged 1.5 s haptic-delivery trial. Plotting %C as a function of log target force, we found a significant interaction ($p<.001$) between the Control and 60-percent cue validity measures, where detectability for subthreshold forces increased with the cues, but decreased at suprathreshold levels. For the 100-percent valid condition, all intensities showed near perfect detection, better than even the most intense tactile stimulus, indicating that participants disregarded all tactile presentations and used only the attention cues.
This systematic investigation reveals an important dependency on intensity and cue validity when it comes to integration and demonstrates how individuals may make selective multimodal, top-down decisions to optimize their volitional responses. Understanding these effects can play a prominent role in the development of more effective therapeutic training techniques for the neurologically impaired.

Title: Synesthesia and creativity: Looking at association with writing and word tasks

Authors: *T. DOTY[1], R. B. ESQUENAZI[2], D. L. LARRANAGA[3], A. RUTCHICK[4], S. A. DREW[5]

[1]Cal State Northridge, Northridge, CA; [2]California State Univ. Northridge, Northridge, CA; [3]Psychology, VISN Lab. At California State University, Northridg, Altadena, CA; [4]Dept. of Psychology, Cal State, Northridge, CA; [5]California State University, Northridge, Northridge, CA

Abstract: Synesthesia is a condition in which individuals experience an additional sensory stimulation automatically when exposed to particular stimuli. Research has shown that those with synesthesia tend to exhibit more creativity through art, music, and verbal tasks (Ward et al., 2008; Domino, 2009; Sitton & Pierce, 2004). Little research exists however examining quantitative examination of creativity and synesthetic percepts. This study examined the potential relationship between synesthesia and creativity, specifically in word and writing tasks. The participants completed a survey administered through MTURK, consisting of synesthesia screening questions, two implicit Remote Association Test (RAT) writing tasks, fifteen explicit RATs, and the same synesthesia screening questions to solidify consistency. The RATs consisted of word triads where one key word would fit with the three words individually. For example, the triad “cheese, baby, and moon” would be solved with the word “blue” to create the word pairs “blue cheese”, “baby blue”, and “blue moon”. In the implicit writing tasks, the instructions were to create a story using the triad words provided. To correctly “solve” the task, the participant must have used the answer word in their story. These stories were also assessed for creativity, such as figurative language. Figurative language was operationalized as language that is not interpreted in the literal sense, such as metaphors and hyperboles. The explicit RATs consisted of a word triad where the participants must supply the key word directly. No significant relationship was observed between synesthesia and either the implicit or explicit RATs. However, there was a significant association between the use of figurative language and synesthesia, providing quantitative support for a relationship between synesthesia and creativity.

Title: Relief from intractable phantom pain by combining psilocybin and mirror visual feedback (MVF)

Authors: *V. S. RAMACHANDRAN[1], C. CHUNHARAS[1,2], Z. J. MARCUS[1]
[1]UCSD, La Jolla, CA; [2]Med., King Chulalongkorn Mem. Hospital, Chulalongkorn Univ., Bangkok, Thailand

Abstract: Patient AL sustained a compound fracture of the right tibia and 3 nails were inserted into the foot and tibia to stabilize them, promote healing, and avoid amputation. Four weeks later, his right leg amputated below the knee, and he was seen by us 2 weeks after amputation - with phantom pain (PLP) as the presenting complaint. From simple tests done on a lower-limb amputee, AL, we were able to demonstrate several new principles of brain organization, especially pertaining to the plasticity of connections and inter-modular interactions. We observed: 1) First we replicated our own previous finding that when an amputee watches someone else limb being touched stroked or tapped - he will experience these sensations as emerging from corresponding locations on the phantom. This inter-subject synesthesia results from activation of mirror neurons, leading to “I-her” confusion and misattribution of quale` from others to oneself. Viewing a leg massage applied to the volunteer V resulted in a massage being felting the phantom-sometimes relieving phantom pain. 2) Mirror visual feedback (MVF) produced some relief from pain as did, “phantom massage”, merely watching his friend massaging her own leg. 3) Intriguingly, when small doses of psilocybin were combined with the mirror he noticed a strong synergistic effect and after 2 weeks there was a complete elimination of PLP and reduction in paroxysmal episodes, so he was able to substantially reduce the dose of psilocybin. A dose response curve was obtained informally, and it was found that the relief was proportionate to the drug dose, suggesting a specific pharmacological effect. 4) Touching the precise location in the volunteer's leg, where the three nails were originally placed evoked a highly specific nail-like sensation boring through the leg even though neither leg nor nail existed. Using a joke shop “telescoping” nail, we created the visual illusion of a nail being pulled out - and AL reported corresponding pain relief. 5) Phantom fire from a Halloween shop - when lit in the vicinity of the phantom - produced warmth in the phantom. “It feels wonderful on my cramp”... “like lying next to a fireplace”, he cried. Taken collectively, these observations entail a radical revision. Brain modules are in a state of dynamic equilibrium with sensory inputs (vision modulates pain), the skin and bones (as in RSD/CRPS2), and even with other brains - so that someone else's massage is felt in your hand.

Title: Two different phase coding mechanisms for integrating audio-visual information via slow neural oscillation

Authors: *H. MIZUHARA, T. KUMAGAI, A. OOZONO
Kyoto Univ., Kyoto-shi, Japan

Abstract: Our sensory modalities simultaneously process a variety of information (e.g., visual and auditory information) throughout daily life. Our brain must appropriately bind relevant information into a coherent whole to segregate one object from others. How does the brain choose and bind relevant information from many inputs? Neural oscillation is a possible underlying mechanism that can answer this question. Namely, phase coding—where information can be integrated when arriving simultaneously at the same phase of neural oscillation—might be a functional role of neural oscillation. Two neural mechanisms (phase shift and amplitude suppression of neural oscillation) were considered as candidates to achieve phase coding via neural oscillation (Jensen et al., Trends Neurosci 2014). To test whether multimodal information is integrated by the phase coding via neural oscillation, we measured human scalp EEG during two audio-visual integration tasks: a ventriloquism task and a McGurk task. In the ventriloquism task, participants (4 females and 10 males) were required to judge sound location, with visual cues appearing prior to a sound stimulus to suggest/fake the sound location to which participants paid attention (Kumagai & Mizuhara, NeuroReport 2016). The visual cue used two conditions to induce bottom-up attention or top-down attention. The results showed that the bottom-up visual cue shifted theta oscillation phase, while the top-down cue suppressed alpha oscillation amplitude at electrode positions in the contralateral hemifield to which attention was paid. To confirm whether the phase shift manipulated the timing of neural excitability for the audio-visual integration, we measured EEG from 37 participants (10 females) during a McGurk task (Oozono & Mizuhara, in prep.). By changing presentation intervals between visual and auditory stimuli, we tested whether the phase shift of neural oscillation appeared in association with visual/auditory input. The frequencies of neural oscillation corresponded well with the behavioral results of the McGurk effect, confirming that the audio-visual information was integrated at an ideal phase of neural oscillation. Taken together, the phase shift and amplitude suppression caused by anticipatory input would result in enhancing neural excitability when following visual/auditory input. Our results demonstrated that there are two different mechanisms of phase coding involved in the integration of multimodal information: phase shift and amplitude suppression of slow neural oscillation.

Title: Differential contribution of striatal pathways activity to action selection after reward and aversive learning

Authors: *M. LANGE, H. KAKINUMA, B.-W. CHERNG, T. SHIRAKI, T. ISLAM, H. HAMA, A. MIYAWAKI, H. OKAMOTO
Brain Sci. Inst., RIKEN, Wako-Shi, Saitama, Japan

Abstract: Action selection among several choices to adapt animal behavior is a fundamental cognitive process, well conserved in animal kingdom. It is well documented that neuronal circuits of the corticobasal ganglia are critical for decision-making in mammalian. Particularly, it has been classically hypothesized that two basal ganglia pathways mediate generation of action via opposing role: the direct pathway by *approach* (Go behavior) and the indirect by *avoidance* (NoGo behavior). We have elucidated that zebrafish *Danio rerio*, has partially the equivalent structure as the mammalian corticobasal ganglia circuitry, and that zebrafish telencephalon contains the direct- and indirect-like neuronal populations essential in action selection during reward and aversion reinforcement.
By combining transgenic animal, Rabies-virus tracing system and Scale tissue clearing technology we generate brain wide maps of neurons sending projection to the striatal direct or indirect pathway. We discovered that the majority of the inputs of the striatal pathway arise from the zebrafish dorsal pallial neurons (functionally equivalent to the mammalian cortex). Overall, our results determine that the corticobasal ganglia circuitry is conserved throughout vertebrates - from Zebrafish to Primates.
Then, using the genetically encoded calcium indicator GCaMP7, we recorded the brain activity in the striatal pathway in trained zebrafish for either positive (i.e. food) or aversive (i.e. electric shock) reinforcement learning, during behavioral cue presentation. Using a cranial window implementation and two-photon imaging we record at single cell resolution the striatal pathways activities. We observed that the striatal activity, mediating Go or NoGo behavior, is dependent of the conditioning reinforcers (negative or positive) after learning. Our results reconsider the classical view of corticobasal ganglia function mediating opposite effects, and support a cooperative model depending on the behavioral valence of the situation.

Title: Direct functional innervation of dorsolateral striatum spiny projection neurons by the amygdala

Authors: C. CUNHA, R. SUDDLE, C. GAZZOLA, A. VIJENDRAN, *J. L. PLOTKIN
Neurobio. and Behavior, Stony Brook Univ. Dept. of Neurol., Stony Brook, NY

Abstract: The striatum is loosely organized in a somatotopic fashion, with striatal subregions preferentially receiving similar types of excitatory inputs. For example, the dorsolateral striatum is robustly innervated by the somatosensory cortex and thalamus, whereas the ventral striatum receives inputs from more limbic-associated brain regions. Recent anatomical work has highlighted that while striatal spiny projection neurons (SPNs) in the dorsal striatum predominantly receive sensory and motor related inputs, a small number of limbic-related inputs also converge on the same SPNs (Wall et al., 2013). While such convergence would suggest a potential mechanism by which dorsal striatum-mediated action selection and habit learning can be directly influenced by limbic-associated cues, direct functional evidence of such synaptic connections is scant. Here we use a combination of electrophysiology, 2-photon calcium imaging and optogenetics to demonstrate that both direct and indirect pathway SPNs in the dorsolateral striatum are functionally innervated by the basal and lateral nuclei of the amygdala (BLA). Channelrhodopsin 2 (ChR2) was stereotaxically expressed in the BLA of drd2-eGFP and drd1-tdTomato transgenic mice, SPNs voltage clamped in acute brain slices and synaptic contacts visualized by marching a blue laser (approximately 10 micrometers in diameter) along the dendrite and measuring the location of NMDA receptor-mediated calcium transients. Using this technique we observed that functional BLA inputs are a) disperse, with typically no more than 5 contacts per 100 micrometer stretch of dendrite, b) distributed similarly across proximal and distal dendrites and c) preferentially target dendritic shafts as opposed to spines. Synchronized activation of BLA inputs with the blue laser targeted to a distal dendrite in current clamp mode was capable of evoking somatic action potentials. Action potentials were followed by a prolonged depolarization lasting tens of milliseconds, similar to that evoked by optogenetic activation of cortical terminals, but significantly scaled down in both amplitude and duration. The implications of BLA synaptic inputs on corticostriatal synaptic integration are currently being investigated.

Title: Pharmacological targeting of the striatal indirect basal ganglia pathway neurons improves subthalamic nucleus dysfunction and treats repetitive and compulsive behaviors in mice

Authors: *A. M. MUEHLMANN[1], K. BOSWELL[2], M. A. KING[3], M. H. LEWIS[4]
[1]Psychiatry, [2]Univ. of Florida, Gainesville, FL; [3]Univ. Florida, Gainesville, FL; [4]Psychiatry, UF Col. of Med., Gainesville, FL

Abstract: Repetitive, restricted, and compulsive behaviors are common phenotypic traits of neurodevelopmental, neurological, and psychiatric disorders. Although antidepressant medications have been used with some success in individuals with obsessive compulsive disorder (OCD), they're not effective for all OCD patients and have not been FDA approved for treatment of repetitive behaviors in other disorders. Based on our findings of lower indirect basal ganglia pathway function in mouse models of repetitive behavior, we have designed a drug cocktail that targets the relevant cell type in striatum to boost pathway function. This drug cocktail is made up of a dopamine D2 receptor antagonist, an adenosine A2A receptor agonist, and a glutamate mGluR5 positive allosteric modulator. We found this drug cocktail significantly reduces repetitive behavior in two mouse models (deer mice and C58 mice) and dramatically lessens the incidence of excessive grooming-induced tissue trauma in an OCD mouse model (*Sapap3* knockout mouse). These improvements in behavior are associated with altered gene expression profiles and increased dendritic spine density in the subthalamic nucleus, an important driver of indirect basal ganglia pathway output. These data suggest that repetitive and compulsive behaviors share neuropathological features and that a drug cocktail that targets dopamine, adenosine, and glutamate receptor heteromeric complexes may offer pharmacotherapeutic benefit to many neurodevelopmental, neurological, and psychiatric disorders.

Title: Distinct roles of substantia nigra projection neurons in controlling orienting movements

Authors: *E. A. STUBBLEFIELD[1], G. FELSEN[2], J. T. DUDMAN[1]
[1]Janelia Res. Campus, Ashburn, VA; [2]Dept. of Physiol. and Biophysics, U. of Colorado Sch. of Med., Aurora, CO

Abstract: Purposive behavior requires making appropriate responses to salient stimuli. The appropriate response to a stimulus involves accurate execution of the response (sensorimotor mapping) and inferring, from prior experience, stimuli that are informative about future outcomes (rewards). The superior colliculus (SC) is a critical node in controlling orienting responses to salient stimuli. The inhibitory projection from the output nucleus of the basal ganglia, substantia nigra pars reticulata (SNr), to the deep layers of the SC (SNr^{SC} neurons) is thought to be a permissive gate that determines when orienting movements will be driven by SC output. SNr activity reflects features of reinforced behaviors including reward expectations, and thus the SNr^{SC} projection may allow reinforcement history to influence the control of orienting movements. However, the specificity of information conveyed by the SNr^{SC} projection relative to the population activity of SNr remains poorly described. In addition, it is unclear whether SNr^{SC} neurons modulate orienting responses selectively when reward history is informative.
We developed a novel head-fixed orienting task to tease apart the potentially distinct roles of SNr^{SC} and $SNr^{non\text{-}SC}$ neurons mediating visual discrimination, reinforcement-based decisions, and motor output. Mice are trained to rotate a wheel left or right with their forelimbs to bring an eccentric visual stimulus to the center of their visual field to obtain reward. We use two versions of this task: 1. A blocked trial structure in which trial-side is determined by a Markov process with a fixed transition rate, and 2. A randomized trial-side structure. In blocked trials, reward history is informative of current choice, and average performance quickly reaches 89% correct. In randomized trials, reward history is not informative, and mice require more training to perform better than chance, ultimately reaching an average performance of 77%
In behaving transgenic mice expressing ChR2 in SNr neurons, SNr^{SC} neurons were antidromically isolated via optical "tagging," allowing us to compare task-related activity between SNr^{SC} neurons (tagged) and putative $SNr^{non\text{-}SC}$ neurons (untagged). Both neuron types exhibit activity changes related to stimulus presentation, movement, and reward. This cell-type specific recording approach will allow us to assess whether and how the contribution of SNr^{SC} neurons, as well as putative $SNr^{non\text{-}SC}$ neurons, differs when reward history is and is not predictive of the rewarded movement.

Title: Effects of globus pallidus or substantia nigra pars reticulata inactivation in startle reflex and locomotor behavior

Authors: S. RODRIGUES, *T. L. FERREIRA
Unversidade Federal ABC, Sao Bernardo Do Campo, Brazil

Abstract: The capability to stop an action in course is important for living animals and might occur for many reasons in a way to reach a goal or survive. Basal ganglia (BG) are considered to be the one of the main neural substrate, at least in mammals, that allows initiate and stop a behavior. Consistently, BG dysfunction terminates in loss of behavioral arrest. Prepulse Inhibition (PPI) is an example of this type of behavioral modulation. During PPI, the animals have to inhibit the startle response to a suddenly sensorial stimulus. Accordingly, patients with BG deficits (e.g. Schizophrenia, Parkinson, TOC) also share low indices of PPI. Classically, BG contains two dopaminergic-mediated pathways that are distinguished by function. The direct pathway is excitatory and promotes the movement. The indirect pathway otherwise, is inhibitory and block the motor programs. Therefore, the objective of this study was to verify the contribution of direct and indirect pathways on PPI and locomotion by inhibiting their target regions. Muscimol infusions into the entopeduncular nucleus (named in primates, globus pallidus internal segment, GPi) or substantia nigra reticulata (SNr) - direct pathway targets - induced PPI deficit by increasing startle, despite a decreasing in animals exploratory behavior. Conversely, indirect pathway inhibition - after muscimol infusion into globus pallidus (external segment, GPe) - has no effect on PPI and startle, but tends to increase the locomotor activity in open field test. Recently, studies using optogenetics techniques showed that the control of these two dopaminergic pathways over behavior can be more complex than previously believed: both pathways can be active during an ongoing action. Together, these results can contribute to elucidate the role of BG in inhibitory outcomes and to develop more effective therapeutics to treat BG related diseases.

Title: The descending diencephalic dopamine system is tuned to sensory stimuli

Authors: *W. DRIEVER[1], S. REINIG[1], A. ARRENBERG[1,2]
[1]Fac. of Biol., Albert-Ludwigs-University Freiburg, Freiburg, Germany; [2]Werner Reichardt Ctr. for Integrative Neurosci., Eberhard-Karls-University Tübingen, Tübingen, Germany

Abstract: The vertebrate diencephalospinal dopaminergic system (A11 in mammals) provides the sole dopaminergic innervation of hindbrain and spinal cord, and has been implicated in modulation of locomotion and sensory processes. However, exact contributions of sensory stimuli and motor behavior to A11 dopaminergic activity remain unclear. We recorded cellular calcium activity in four anatomically distinct posterior tubercular A11-type dopaminergic subgroups, and in two adjacent hypothalamic dopaminergic groups, using *th:Gal4* and *UAS:GCaMP7a*-transgenic, semi-restrained zebrafish larvae. Correlation of calcium activity to motor behavior and specific sensory stimuli revealed the contributions of different sensory modalities and motor states to dopaminergic activity. Each posterior tubercular and hypothalamic subgroup showed distinct activity patterns, while activity was synchronous within individual subgroups. Caudal and dorsomedial hypothalamic dopaminergic neurons are activated following vigorous tail movements, and stay active for about 10 seconds, revealing predominantly post-motor activity. In contrast, posterior tubercular dopaminergic neurons are predominantly sensory driven, with subgroups differentially responding to different tactile or visual sensory modalities. In the most rostral posterior tubercular dopaminergic subgroup, neuronal response magnitudes are tuned to tactile stimulus intensities, revealing features similar to sensory systems. We identify the lateral line system as source for this tactile tuning. In contrast, caudal posterior tubercular dopaminergic neurons are responsive to distinct moving visual stimuli. Specifically, translational forward stimuli, which may indicate insufficient rheotaxis and drift, induce dopaminergic activity, but backward or rotational stimuli not. The activation of posterior tubercular dopaminergic neurons by sensory stimuli, and their projections onto peripheral mechanosensory systems, suggest a participation of A11-type neurons in the feedback regulation of sensory systems. Together with the adjacent hypothalamic neurons they may serve to set basic behavioral states.

Title: The hyperdirect pathway in cynomolgus monkeys: A single-axon tracing study

Authors: *D. COUDÉ[1,2], A. PARENT[1,2], M. PARENT[1,2]
[1]CERVO Res. Ctr., Quebec, QC, Canada; [2]Psychiatry and Neurosci., Univ. Laval, Quebec City, QC, Canada

Abstract: This study provides the first detailed description of individual axons that form the hyperdirect pathway in monkeys. These axons, which arise from the motor cortex and provide a major glutamate-mediated excitatory input to the subthalamic nucleus (STN), were studied individually in cynomolgus monkeys (*Macaca fascicularis*) following microiontophoretic injections of biotinylated dextran amine in layer V of the forelimb area of the primary motor cortex (M1). Singly-labeled axons were reconstructed in 3D from serial sections using a computerized image analysis system. The innervation of the STN arising from M1 derives essentially from collaterals of long-ranged corticofugal axons en route to the brainstem. Typically, after leaving M1, these large caliber axons (1.7-3.7 µm) enter the internal capsule and travel between the caudate nucleus and putamen without providing any collaterals to the striatum. More ventrally, they emit a thin collateral (0.2-1.6 µm) that runs lateromedially within the dorsal region of the STN, providing boutons en passant in the sensorimotor functional territory of the nucleus. Occasionally, the lateromedially coursing collateral breaks out into thinner and varicose branches that plunge ventrally into the STN. In some cases, its medial tip invades the lenticular fasciculus dorsally and yields a few beaded axonal branches in the zona incerta, whereas in other cases, the collateral runs caudally and innervates the ventrolateral region of the red nucleus in which large axon varicosities are observed, many displaying a perisomatic arrangement. One axon was seen to yield thin collaterals that departed form the internal capsule to arborize in the reticular thalamic nucleus before reaching the STN. Only one neuron had an axon that reached the STN without continuing its route to the brainstem. It remains thin as it travels in the internal capsule, exhibiting small-sized axon varicosities in this

major fiber bundle as well as in the zona incerta. Altogether, our findings indicate that the so-called hyperdirect pathway is in fact largely indirect, as it derives essentially from collaterals of long-ranged corticofugal axons en route to the brainstem. Furthermore, these collaterals are not solely devoted to the STN, as they also innervate the red nucleus and/or the zona incerta. Such detailed knowledge of the primate hyperdirect pathway is essential to reach a better understanding of the anatomical and functional organization of the primate basal ganglia. It is likely to help unraveling the poorly known mechanisms that underlie the therapeutic effect of deep brain stimulation (DBS) often used to alleviate motor symptoms of Parkinson's disease.

Title: One critic, two actors

Authors: *T. BORAUD[1], D. KASE[2], M. TOPALIDOU[3], N. ROUGIER[4]
[1]CNRS - Univ. Bx2, Bordeaux, France; [2]Dept. of Neurobio., Univ. of Pittsburgh, Pittsburgh, PA; [3]IMN, Bordeaux, France; [4]INRIA, Bordeaux, France

Abstract: We propose a new hypothesis concerning the dissociated role of the basal ganglia in the selection and the evaluation of action that has been formulated using a theoretical model and confirmed experimentally in monkeys. To do so, prior to learning, we inactivated the internal part of the Globus Pallidus (GPi, the main output structure of the BG) with injections of muscimol and we tested monkeys on a variant of a two-armed bandit task where two stimuli are associated with two distinct reward probabilities (0.25 and 0.75 respectively). Unsurprisingly, performance in such condition are at the chance level because the output of basal ganglia is suppressed and they cannot influence behaviour. However, the theoretical model predicts that in the meantime, values of the stimuli are nonetheless covertly evaluated and learned. This has been tested and confirmed on the next day, when muscimol has been replaced by a saline solution: monkeys instantly showed significantly improved performances (above chance level), hence demonstrating they have covertly learned the relative value of the two stimuli. This tends to suggest a competition takes place in the Cortex-BG loop between two actors, one of whom being sensitive to criticism and the other not. Ultimately, the actual choice is valuated, independently of the origin of the decision.

Title: Integrated basal ganglia pathway activity controls execution during reaching and freely moving behavior

Authors: *E. A. YTTRI[1], B. PANIGRAHI[2], J. T. DUDMAN[3]
[1]Neurobio., Carnegie Mellon, Pittsburgh, PA; [2]Janelia Res. Campus, Ashburn, VA; [3]HHMI, Ashburn, VA

Abstract: The prevailing theory of action selection suggests that the opposing pathways of the basal ganglia (BG), an evolutionarily conserved subcortical area, promote or suppress action, respectively. However, diseases afflicting the BG - such as Parkinson's disease - are characterized by an impairment of *how* actions are executed rather than an inability to select the actions themselves. We found that biasing BG activity does not promote or suppress movement, but instead, bidirectionally selects and reinforces execution parameters in a dopamine-dependent manner (Yttri and Dudman, *Nature* 2016).
Our current work further distinguished between putative BG functions of action gating and performance control. We employed brief optogenetic stimulation to either the direct or indirect pathway whenever a freely moving animal paused locomotion. Gating models predict that direct pathway stimulation should induce locomotion, while indirect pathway stimulation should prolong stopping. However, our selective stimulation produced the opposite: direct pathway activation prolongs pausing while indirect pathway stimulation shortens pausing. The converse held true when selective stimulation was applied during locomotion.These data are consistent with our stimulation in closed-loop with reach velocity but stand in sharp contrast to previous studies using prolonged, indiscriminate stimulation. We then proceeded to explore the range of execution parameters for which closed-loop stimulation can sculpt performance and how biasing BG activity interacts in the context of dopamine release and Parkinson's disease.
Finally, we investigated how the striatum might accomplish this execution control, and particularly how striatal neuronal ensembles function as dynamical systems. We discovered that the striatum encodes not only the start and stop of a reach, but also other control parameters such as velocity, amplitude and duration – a profoundly greater level of detail than previously thought. Then, utilizing a simple decoder, we were able to predict the full path and velocity of a individual reaching movement over 140 milliseconds before it is performed, positioning the BG to actively drive changes in the kinematics of movements. This fundamental shift in the

paradigm of BG function has important implications for our understanding of action selection and human disease that will be pursued in the newly started Yttri Lab.

Title: Chemogenetic inhibition of direct-pathway neurons in dorsomedial striatum reduces locomotor activity in mice supporting the role of the direct pathway in promoting movement

Authors: *M. RICKHAG, C. CIRIACHI, A. BAY-KØNIG, U. GETHER
Mol. Neuropharm Lab, Ctr. For Neuroscience,, Kobenhavn N, Denmark

Abstract: The striatum is the main input structure of the basal ganglia, a series of subcortical nuclei that play a key role in motor control. Two distinct basal ganglia circuits, the direct and the indirect pathways, originate from the striatal projection neurons and are canonically believed to respectively facilitate and oppose motor behavior. Ablation studies have revealed that distinct striatal compartments have different functions in the regulation of movement, yet their role is still unclear. In order to get a deeper understanding of striatal compartmentalization and to validate the contextual function of the basal ganglia circuits, we aimed at selectively modulate the activity of direct pathway-medium spiny neurons (dMSNs) in the dorsomedial striatum (DMS). This specificity was achieved by viral-genetic tools combining the Cre-driver mouse lines (D1R-Cre) and chemogenetic tools, the *Designer Receptors Exclusively Activated by Designer Drugs* (DREADDs). This approach allowed us to remotely control signal transduction in selective neurons and, therefore, to modulate specific neuronal pathways in a limited time window. Here, we show that activation of inhibitory (Gαi-associated) DREADD in DMS-dMSNs significantly decreased locomotor activity in the open field test. DREADD-mediated inhibition was also able to reduce locomotor activity following acute cocaine administration. To validate the involvement of Gi- protein signaling pathway upon DREADDs activation, we analyzed downstream effectors via immunohistochemistry and immunoblotting techniques. Moreover, we confirmed that DREADDs expression in the striatum was restricted to the dorsomedial region and showed both somatic and axonal/dendritic localization. Overall, our

results provide further evidence supporting the role of the direct-pathway in promoting movement.

Title: Effect of correlations and sensory responses in the basal ganglia on the transmission of motor signals to the thalamus

Authors: *M. MOHAGHEGHI NEJAD[1,3], S. ROTTER[1,2], R. SCHMIDT[4]
[1]Bernstein Ctr. Freiburg, Univ. of Freiburg, Freiburg Im Breisgau, Germany; [2]BrainLinks-BrainTools, Univ. of Freiburg, Freiburg im Breisgau, Germany; [3]Sch. of Computer Sci. and Communication, Royal Inst. of Technol., Stockholm, Sweden; [4]Dept. of Psychology, Univ. of Sheffield, Sheffield, United Kingdom

Abstract: One prominent feature of Parkinson's disease is the emergence of correlated activity in basal ganglia output neurons. In contrast, in healthy animals, the activity in basal ganglia output regions is usually uncorrelated, potentially due to active decorrelation (Wilson, 2013). However, the functional role of active decorrelation on the transmission of motor signals from the basal ganglia to the downstream regions including ventral thalamus is unknown. Basal ganglia output neurons (e.g. in the substantia nigra pars reticulata; SNr) may transmit motor signals by decreasing their firing rate during movement initiation. Such decreases in SNr firing rate can lead to post-inhibitory rebound spikes in downstream thalamic neurons (Goldberg et al., 2013).
To study potential functional roles of active decorrelation, we investigated the effect of correlations among SNr neurons on rebound spikes in a Hodgkin-Huxley model of a thalamocortical neuron (Rubin et al., 2004). We found that uncorrelated SNr inputs lead to rebound spikes briefly after the movement-related decrease in firing rate. In addition, despite

stochastic inputs, the latency from the decrease to the onset of the rebound spike showed small trial-to-trial variability. In contrast, correlated SNr inputs lead to rebound spikes not only after the movement-related decrease, but also at random times. This is because the correlated input spike trains are more likely to contain brief pauses without spikes, which trigger a "random" rebound spike. Furthermore, the latency of the movement-related rebound spikes became variable over trials.
In addition to movement-related decreases, SNr neurons briefly increase their firing rate in response to sensory stimuli such as "Go" and "Stop" cues in a stop-signal task (Schmidt et al., 2013). We studied the effect of such sensory responses in SNr on the transmission of motor signals. We found that sensory responses up to 30 milliseconds before the movement-related decrease facilitated the generation of movement-related rebound spikes. In contrast, SNr firing rate increases after the onset of the movement-related decrease suppressed rebound spikes. Therefore, the timing of the sensory responses determined whether they promoted or suppressed movement, indicating an important functional contribution in sensorimotor integration.
In conclusion, active decorrelation in basal ganglia output may promote the transmission of motor signals via rebound spikes. Pathological correlations impair this transmission by increasing the trial-to-trial variability and the number of movement-unrelated rebound spikes, which may be related to motor symptoms in Parkinson's disease.

Title: Electrophysiology of rat motor thalamus reveals unique patterns of firing during movement

Authors: *M. GAIDICA[1], C. CYR[2], A. HURST[2], *A. KAMATH[3], D. K. LEVENTHAL[3,1,2]
[1]Neurosci. Grad. Dept., [2]Neurol., [3]Biomed. Engin., Univ. of Michigan, Ann Arbor, MI

Abstract: The thalamus is commonly regarded as a relay nucleus, but it is increasingly appreciated that it is a critical node in shaping normal and pathological motor behaviors. It remains unclear how its primary inputs from the basal ganglia, cerebellum, and cortex differentially contribute to the cortical-bound output of the "motor thalamus". To determine behavioral correlates of neuronal activity in the rat motor thalamus we performed electrophysiology during a cued choice reaction time task. We found task-specific firing rate modulations for all behavioral events based on single unit neuronal classifications. This included neurons that rapidly increased their firing rate in response to sensory cues, neurons that showed

tonically sustained firing during all movements, and neurons that showed rhythmic increases in firing rate precisely at movement onset. We performed a detailed investigation of neuronal activity specifically associated with the movement onset population as it has specific implications to movement disorders characterized by the inability to initiate movements (e.g. Parkinson's disease). These neurons' firing rates are depressed during a hold period prior to cued movement initiation. This is consistent with standard thalamocortical firing rate models which suggest GABAergic afferents from the basal ganglia regulate movement through disinhibition. Secondly, the burst frequency across these neurons was highly regular and consistently in the theta band (4-8 Hz). Finally, many of these neurons fired more strongly for contralateral movements. Ongoing work is directed at determining whether these functional classifications are correlated with distinct anatomic or physiologic features (e.g., cerebellar vs basal ganglia afferents), and how these activity patterns are generated.

Title: Movement-related encoding in the ventral pallidum

Authors: *J. D. LEDERMAN[1], S. LARDEUX[2], S. M. NICOLA[3]
[1]Dominick P. Purpura Dept. of Neurosci., [2]Albert Einstein Col. of Med., Bronx, NY; [3]Dept. Psychiatry, Albert Einstein Coll Med., Bronx, NY

Abstract: The ventral pallidum (VP) is the main output nucleus of the nucleus accumbens (NAc) and essential for translating limbic sensory, value and motivation signals into motor output, but how it does so is unknown. To assess what role the VP plays in motivated behaviors, particularly in regards to locomotion, we recorded from the VP of food-restricted rats performing a discriminative stimulus (DS) task. The DS was an auditory cue, presented at variable intervals, which directed the rat to approach and press a lever to obtain 10% sucrose reward. A lever press during the 10 s DS resulted in reward delivery and cue termination. Trained animals were implanted with microelectrode arrays in the VP. Video tracking of head-mounted LEDs enabled detection and measurement of locomotion. Our results show that approximately half of the

neurons in the VP were excited by DS presentation, while a small proportion (~15%) were inhibited. Moreover, after DS presentation, neural firing rates were positively correlated with movement initiation latency. In a largely different population of VP neurons, changes in activity were highly correlated with initiation and cessation of spontaneous locomotor movements (i.e., movements during the inter-trial interval that were typically not directed towards the lever). Typically, neurons that showed inhibition during movement onset were excited during movement cessation, and vice versa. These results suggest that the ventral pallidum is involved in, and may be necessary for, initiation and cessation of movement, and the translation of emotionally salient sensory stimuli into motor action.

Syst. and Univ. of Michigan, Ann Arbor, MI; [5]Dept. of Neurol. and Kavli Inst. for Fundamental Neurosci., Univ. of California San Francisco, San Francisco, CA

Abstract: Basal ganglia circuits are involved in motor control, including the initiation and cancellation of movements. While movement-related firing rate changes of single neurons have been described in different basal ganglia subregions and cell types, the underlying population code remains unclear. Here we apply advanced data analysis techniques to a large data set of electrophysiological recordings in rats performing a stop-signal task to study such coding schemes.
Firstly, we describe the population coding schemes in terms of their sparseness and heterogeneity. Here we consider sparseness as the fraction of neurons changing their firing rate during an event (e.g. movement initiation). We derived a novel sparseness measure from the components of the eigenvectors of the covariance matrix taken as the neuron's contribution to overlapping patterns. This measure is more informative, compared to other measures, when

different patterns of activation are multiplexed in the population. Heterogeneity describes the diversity in the firing patterns. Using coding theory we define heterogeneity as the average "codeword length" of a particular prefix code computed from the population and relate it to minimum redundancy codes represented by Huffman trees. We provide an algorithm for constructing one of such trees. We find that the coding scheme in the population of striatal medium spiny neurons is sparse and heterogeneous. In contrast, the code in the substantia nigra pars reticulata is distributed and homogeneous. This points to the input and output stages of the basal ganglia having opposite coding strategies.
Secondly, we use dimensionality reduction techniques to generate low-dimensional trajectories that characterize diverse firing patterns during movement initiation. To do so, we provide means of mapping population parameters to the geometry of the trajectory. We also suggest ways of comparing trajectories (e.g. from long and short reaction times) and studying the effect of preprocessing steps (e.g. smoothing the firing rate) in distorting the trajectory shape. We find that basal ganglia subregions and cell types have distinct population trajectory shapes. In particular the output region of the basal ganglia (substantia nigra pars reticulata) shows an almost linear evolution around movement initiation. In contrast, other basal ganglia subregions show more curved trajectories during movement initiation.
Our results indicate that different basal ganglia subregions employ different population coding schemes during movement and this might reflect different functional contributions to the processing of motor signals.

Title: Homeostatic motor adaptation: Cerebellum's failure emboldens basal ganglia

Authors: *R. A. CAPPS, D. TODOROV, W. BARNETT, Y. MOLKOV
Mathematics & Statistics, Georgia State Univ., Atlanta, GA

Abstract: The cerebellum and basal ganglia (BG) are both vital for motor adaptation. The cerebellum is believed to be responsible for error-based (supervised) learning, comparing visual input with an internal representation of the environment. The BG are thought to be responsible for non-error based (reinforcement) learning. Although their roles have been investigated

independently, the interplay between BG and cerebellum remains unclear. Some studies suggest that when visual input is unreliable, the cerebellum stops influencing movements. To investigate this phenomenon, we designed a network model with the cerebellum implemented as a phenomenological node, and the BG implemented as a firing-rate model. Our model describes a homeostatic mechanism by which motor control shifts from the cerebellum to the BG when a perception perturbation is too strong for the error-based learning mechanism to be effective. We used the model to simulate behavioral experiments by Gutierrez-Garralda et al. (2013) in which subjects throw a ball at a target with their vision perturbed by a prism reflecting about a vertical axis. Such a visual perturbation causes error-based motor adaptation to correct the movement in the opposite direction thus having an adverse effect on the performance. This occurs because cerebellar correction relies on vector error, which if reflected, also reflects the correction. To avoid mal-adaptation, we suggest that cerebellum contains an adaptive critic mechanism, which compares the current error to a previously observed error. If the error decreases predictably, the adaptive critic facilitates cerebellum to further correct the movement. Otherwise, the adaptive critic suppresses cerebellar learning. In the above experiments the subjects could still improve throwing accuracy in a non-error-based manner, supposedly by reinforcement learning mechanisms. The non-error-based correction in the model is provided by BG via reinforcement learning. The reward for each movement depends on proximity to the target. The BG learn to reinforce/block actions based on reward-prediction error (RPE), which is calculated as the difference between the expected/previous reward and current reward values. If visual perturbation does not alter the subject's perception of the vector error, the cerebellum mediated adaptation leads to gradual improvement in movement accuracy, thus generating a positive RPE, which reinforces the action chosen by BG. Thus in these conditions, motor adaptation is exclusively guided by cerebellum. In contrast, perturbations that lead to cerebellar mal-adaptation result in a negative RPE stimulating the BG to search for more rewarding actions.

Title: Patch compartment lesions reduce habitual sucrose consumption

Authors: *K. A. HORNER, J. B. LOGUE, T. A. JENRETTE
Div. Basic Med. Sci., Mercer Univ. Sch. of Med., Macon, GA

Abstract: The striatum mediates habit formation and reward association. The striatum can be divided into the patch and matrix compartment, which are two neurochemically and anatomically distinct regions that may sub-serve different aspects of behavior. For example, the patch compartment may mediate reward-related behaviors, while the matrix compartment may mediate adaptive motor functions. Furthermore, previous studies have shown that enhanced relative activation of the patch versus matrix compartment is associated with inflexible behaviors, such as stereotypy. Habitual behaviors are also inflexible in nature, but whether enhanced activation of the patch compartment contributes to habitual behavior is not known. The goal of the current study was to examine the role of patch compartment neurons in the development of habit formation. We used dermorphin-saporin to specifically ablate neurons of the patch compartment prior to training animals to self-administer sucrose on a random interval schedule of reinforcement, which has been shown to foster habit formation. Our data showed that destruction of the neurons of the patch compartment prevented the reinstatement of sucrose self-administration after sucrose devaluation, indicating that absence of the patch compartment interrupted the development of habitual behavior. Our data also indicate that c-Fos levels were decreased in the dorsolateral striatum (DLS) and sensorimotor cortex (SMC), but increased in dorsomedial striatum (DMS) and prefrontal cortex (PFC) in patch-lesioned animals that did not develop habitual behavior, indicating that diminished habit formation is associated with decreased activation of regions that participate in habitual behavior, and increased in regions associated with goal-directed behaviors. Together, these data indicate that the patch compartment participates in habit formation by altering the flow of information through basal ganglia circuits.

Title: Anatomical and functional characterization of parvalbumin-expressing neurons in the mouse external globus pallidus

Authors: *V. LILASCHAROEN[1], E. H. WANG[2], A. N. TRAN[1], X.-Y. WANG[1], B. LIM[1]
[1]Biol. Sci., [2]Biomed. Sci., UCSD, La Jolla, CA

Abstract: The external globus pallidus (GPe) is one of the major nuclei of the basal ganglia, a group of subcortical nuclei that are critically involved in voluntary movements and is therefore

strongly implicated in movement disorders such as Parkinson's disease. According to the classical model of basal ganglia circuitry, the GPe is considered to be a homogeneous structure that functions as a relay station in the indirect pathway receiving afferents from the striatum and sending GABAergic efferent to the subthalamic nucleus (STN). However, classifying the GPe circuit organization is complicated by the fact that a single GPe neuron can send axonal collaterals to multiple brain structures, suggesting a more complex model of circuit architecture and information processing in the basal ganglia. By using a novel viral-genetic approach, we have identified two distinct populations of parvalbumin-expressing neurons in the GPe (GPe-PV) based on their projections to either the parafascicular thalamic nucleus (PF) or the substantia nigra pars reticulata (SNr). We will further apply a combination of electrophysiological, viral-genetic approaches, and *in vivo* imaging to provide a comprehensive framework on anatomical and functional organization of the GPe-PV neurons and to demonstrate how different GPe-PV populations undergo changes in animal models of Parkinson's disease.

Title: Tardive dyskinesia induced by prolonged antipsychotic treatment in monkeys is associated with Akt pathway activity in dopamine D3 receptor expressing cells of the putamen

Authors: G. HERNANDEZ[1], S. MAHMOUDI[1], M. CYR[2], J. DIAZ[3], P. J. BLANCHET[4], *D. LEVESQUE[1]
[1]Univ. of Montreal, Fac. of Pharm., Montreal, QC, Canada; [2]U. Quebec a Trois-Rivieres, Trois-Rivieres, QC, Canada; [3]Lab. de Neurobiologie et Pharmacologie Moléculaire (UMRs INSERM), Univ. Paris Descartes, Paris, France; [4]Stomatology, Univ. of Montreal, Fac. of dentistry, Montreal, QC, Canada

Abstract: The pathophysiology of tardive dyskinesia (TD) remains elusive. This delayed and potentially irreversible motor complication arises after chronic exposure to centrally acting dopamine $D_{2/3}$ receptor antagonists such as antipsychotic drugs. Antipsychotics modulate

multiple kinase pathways, but their involvement in TD is not well understood. To investigate the neurochemical basis of TD, we exposed capuchin monkeys to prolonged haloperidol (N = 11) or clozapine (N = 6) treatments. Six untreated animals were used as controls. Five haloperidol-treated animals developed TD similar to that found in humans. No TD was observed in the clozapine group. Using Western blots, we measured total and phosphorylated protein kinase levels (normalized over GAPDH or tubulin protein levels) previously associated with dopamine $D_{2/3}$ receptor signaling cascades in the putamen. While haloperidol enhanced phospho[Thr202/Tyr204]-p44/42 (pERK1/2) levels by 3.4 fold, no difference was observed between dyskinetic and non-dyskinetic monkeys. On the other hand, phospho[Th34]-DARPP-32 levels were induced by 1.7 fold only in dyskinetic animals. Interestingly, haloperidol specifically reduced putamen GRK6 (64%), β-arrestin2 (57%) and phospho[Ser9]-GSK-3β (pGSK-3β) (69%) levels in haloperidol-treated animals which developed TD, whereas phospho[Ser473]-Akt (pAkt) levels were upregulated in this subgroup (183%), and positively correlated ($r^2 = 0.590$, p value = 0.0022) with TD scores. Levels of phosphorylated protein kinases observed in the clozapine group were generally similar to controls and non dyskinetic animals treated with haloperidol. But, GRK6 protein levels were upregulated 1.7 fold by clozapine. Total protein kinase levels were not altered by any treatment. Previous results in our laboratory correlated an upregulation of striatal D_3 (not D_2) receptors with TD. Using double immunohistochemistry, we observed an increase of pAkt/D_3 colocalization (140%) in the putamen of dyskinetic monkeys, as compared to non TD animals. Our results suggest that upregulation of D_3 receptors and alterations in the GRK6/β-arrestin2/Akt/GSK-3β molecular cascade are associated with the development of TD in this non human primate model.

Title: Event-related stimulation of subthalamic nucleus alters conflict-related control in a time period overlapping with low-frequency activities

Authors: *A. GHAHREMANI[1,2,3], K. UDUPA[3], U. SAHA[3], D. REDDY[3], S. K. KALIA[3,4], M. HODAIE[3,4], A. M. LOZANO[3,4], A. R. ARON[6], R. CHEN[3,5]

Abstract: The subthalamic nucleus (STN) of the basal ganglia is implicated in controlling responses during conflict. Several human deep brain recording studies have shown that conflicting responses are related to increased STN power in low frequencies (delta-theta, 2-8Hz). Yet, whether the STN and/or its associated circuitry is critical in implementing conflict-related control, and the temporal dynamics of this putative critical effect are unknown. Using a novel event-related deep brain stimulation paradigm, we transiently disrupted the STN and/or its related circuits during a Stroop task. The subjects were required to name the font color and ignore the word meaning, yielding non-conflict (word meaning and color matched) and conflict (no match, word-meaning caused a bias) conditions. In a double-blinded design, we delivered short bursts of stimulation at three time points: at the beginning of trial when a cue signaled subject to get ready; and early close to word cues and late close to responses. Stimulation had no significant effect on RT of non-conflict trials, but on conflict trials, it made subjects respond relatively faster ($F(3,30)=3.379$, $P=0.03$). Further, stimulation generally made subjects *less* accurate when applied selectively early in the response period ($P=0.01$). This time period corresponded with increased low frequency power for the contrast of conflict and non-conflict. These results provide causal evidence in humans that the STN and/or its associated circuitry is critical for processing response conflict, and that the period of LFO power increase is associated with suppressing errors. Our results provide temporal information about the dynamics of when such control occurs.

Abstract: Synaptic plasticity requires *de novo* genes expression and protein synthesis for long lasting synaptic modificationsand behavioral changes. Previously, it has been indicated that a low glutathione content can impair short and long term synaptic plasticity mechanisms;

however,this topic remains poorly explored. The aim of the present work is to evaluate the effect of GSH depletion on synaptic plasticity of the nigrostriatalpathway. L-buthioninesulfoximineor NaClwas injected in the *substantianigracompacta* of Male Sprague Dawley rats. Arc, bdnf and D2 mRNA expression were determinedby RT-PCR at 24 hours and 7 days after BSO injection. In addition, rats were evaluated in object exploration test and TH-positive cells were counted at 7 days. Results showed lower exploration in BSO rats as well as loss of dopaminergic cells in the SNpccomparing to controls. No modifications in bdnf or arc mRNA expression were found in the SNpc but both genes increased their expression in the striatum. Moreover, the expression of D2 receptor was decreased in the SNpc and increased in the striatum. Taken together, these results suggest that transient GSH depletion is related to impairment of exploratory behavior by means of nigral degeneration and nigrostriatal plasticity modifications.

Title: Calcium-dependent potassium currents can promote or inhibit burst firing depending upon their temporal dynamics

Authors: *C. J. KNOWLTON, C. C. CANAVIER
Cell Biol. and Anat., Louisiana State Univ. Hlth. Sci. Ctr., New Orleans, LA

Abstract: Midbrain dopamine neurons are implicated in the many known disorders of dopamine signaling including addiction, schizophrenia and Parkinson's disease. In vivo, they exhibit two primary activity patterns, tonic (single spike) firing and phasic bursting. These firing patterns, and the transitions between them, are essential for driving release of dopamine, and thus for controlling signal processing and behavioral functions of cortico-striatal circuits. Two potassium currents, the small conductance (SK) calcium-activated potassium current and the ATP-mediated potassium (K-ATP) current have been shown to have opposite effect on bursting in nigral dopamine neurons. Blocking the SK current de-regularizes firing and increases bursting (Drion et al. PLoS Comput Biol. 7:e1002050 2011), whereas silencing K-ATP channels, using virally mediated gene transfer, greatly reduces burst firing in a medial subpopulation of these neurons (Schiemann et al. Nature Neuroscience 15:1272, 2012). This result seems paradoxical in light of

the putative indirect Ca^{2+}-dependence of the K-ATP channel (Knowlton et al. SFN abstract 246.03, 2016): why would two calcium-dependent potassium currents have diametrically opposed effects on bursting? In order to address this question, we used a separation of time scales approach. Our simple one-compartment model has a fast subsystem for spiking, comprised of a voltage-dependent Na^+ current and a delayed rectifier K^+ current. It also includes a low threshold voltage-dependent Ca^{2+} current and a calcium balance that provided two slow variables: the free Ca^{2+} concentration which activates the SK channel, and a delayed version of the Ca^{2+} signal implemented with a first order differential equation. This delayed version is an analog for the ADP/ATP metabolism that activates the K-ATP channels. Experimental studies to date have not been designed to study the effects of SK and K-ATP block on bursting in the same neuron. We demonstrate that both effects could theoretically be observed in the same neuron; when a random barrage of EPSPs with an NMDA component was incorporated, the model was able to mimic both the increase in bursting due to SK block and the decrease in bursting due to K-ATP block. In a deterministic version of the model, 1) both types of bursting are initiated by a fold bifurcation, 2) bursting mediated by SK reduction is terminated by a flip bifurcation, whereas 3) K-ATP mediated bursting is terminated by a homoclinic bifurcation. These results resolve the paradoxical effects of these currents and suggest that burst signaling in nigral dopaminergic neurons is heterogeneous.

Title: Axon initial segment morphology can account for variability in the intra and extracellularly recorded action potentials in nigral dopamine neurons

Authors: *L. F. LOPEZ JURY[1], R. MEZA[1], C. C. CANAVIER[2], P. HENNY[1]
[1]Dept. de Anatomía, Univ. Católica, Santiago, Chile; [2]Cell Biol. and Anat., Louisiana State Univ. Hlth. Sci. Ctr., New Orleans, LA

Abstract: For over three decades, action potentials (APs) in nigral dopamine neurons have been thought to have two separate components, reflecting initiation in the axon initial segment (AIS)

and subsequent somatic dendritic (SD) spike. This is evidenced as a notch in the extracellular waveform and in the derivative of the intracellular waveform recorded in the soma (Grace AA and Bunney BS, 1983). The two components are often visible in the phase plane in which the membrane potential is plotted versus its first temporal derivative (Bean BP, 2007). However, the two separate components are not observed in all recordings from these neurons (Lerner et al, 2015). Here, we use a morphologically realistic model of a pacemaking nigral dopamine neuron to dissect the contribution of these two components to both the intra and extracellularly recorded waveforms. It is known that spontaneous firing rate of dopaminergic neurons depends on the relative size of their AIS (Meza, López-Jury, Canavier and Henny, in revision) and we wanted to know if this morphological variable also affects the AP waveform. Decreasing the length of the AIS makes the AIS component in the phase plane less prominent, to the point where it can disappear. Location, on the other hand, does not seem to affect the prominence of the AIS component. Electrophysiology studies shows that the shape of the extracellular waveforms is well correlated with the first differential of the intracellular waveforms on dopaminergic neurons (Ungless MA and Grace AA, 2012). In our model, for an active soma indistinguishable from the dendrites, no notch appears in the extracellularly recorded AP, despite it does in the intracellular AP. However, if the axial currents overwhelm the intrinsic somatic currents, then separate AIS and dendritic components are visible in the extracellularly recorded AP and the notch appears. In this case, the extracellular AP is proportional the derivative of the intracellularly recorded AP. We also tested, for this case, the effects of AIS length on extracellular AP shape. The notch increases its amplitude with increasing AIS length. Thus these results explain how the morphology of the AIS can explain much of the observed variability in intracellular and extracellular AP waveforms.

Title: Conditional knockdown of Slitrk-1 gene in striatal cholinergic interneurons impairs sensorimotor function in mice mimicking Tourette syndrome

Authors: *J.-C. DU[1,2], L.-W. TUNG[2], H.-J. LEE[3], L.-C. CHIOU[4,5]
[1]Taipei City Hosp., Taipei, Taiwan; [2]Grad. Inst. of Pharmacology, Col. of Medicine, Natl. Taiwan Univ., Taipei, Taiwan; [3]Natl. Taiwan Univ., Taipei, Taiwan; [4]Dept Pharmacol, Col. Med. Natl. Taiwan Univ., Taipei, Taiwan; [5]Grad. Inst. of Brain and Mind Sciences, Col. of Medicine, Natl. Taiwan Univ., Taipei, Taiwan

Abstract: The Slitrk-1 (*Slit and NTrk-like family 1*) gene is one of vulnerable risk genes in Tourette syndrome (TS), a chronic neuropsychiatric disorder with multiple motor and phonic tics regarded as stereotyped behaviors. In the striatum of mammals, Slitrk-1 is highly expressed in early childhood but gradually disappeared in adulthood except cholinergic interneurons, which are the only striatal neurons with persistent expression of Slitrk-1 into adult stage. A postmortem study had shown that adult TS patients had less cholinergic interneurons in the striatum than normal subjects, suggesting the contribution of Slitrk-1 in maintaining normal function of striatal cholinergic interneurons in adults. We, therefore, hypothesized that silencing Slitrk-1 in the striatum of adult mice can be an animal model of TS by impairing the function of striatal cholinergic interneurons specifically, leading to certain stereotyped behaviors. Slitrk-1 siRNA or non-targeting scramble siRNA (*Accell siRNA*) was bilaterally injected (0.5 μg in 0.5 μl) into the dorso-medial striatum (A:-0.74mm, L:±1.6 mm, D: 3.5 mm) of C57Bl/ 6J mice (8-10 weeks). A serial analysis of mice behaviors and prepulse inhibition (PPI), a TS endophenotype, was performed after injection of siRNA for 72 hours. Mice with Slitrk-1 siRNA injection (Slitrk-1-KD, n=6) showed significantly more stereotyped behaviors, compared to those with scramble siRNA (n=6), and these stereotyped behaviors were suppressed significantly by haloperidol (0.3mg/kg, *i.p.*), an effective anti-tic agent by blocking D2 receptors (n=4). The Slitrk-1-KD group had obviously impaired PPI (n=3), as compared with the scramble group (n=3). Adhesive removal test, another test for evaluation of sensori-motor function, was also performed by measuring the latency to remove the adhesive patch on forepaws. The Slitrk-1-KD group (n=6) showed longer latency than the scramble group (n=5) (119.0±33.3 v.s. 36.4±6.2 sec, p=0.04), which means the Slitrk-1-KD group had sensori-motor impairment. Electrophysiological characteristics of the Slitrk-1 KD cholinergic (ChAT) interneurons were also examined. Slitrk-1 KD ChAT interneurons seemed to have the trend showing higher action potential threshold and decreased firing rate under step stimulations, implying the function of ChAT interneurons may be impaired. These results revealed selective knockdown Slitrk-1 gene in the striatal ChAT interneurons of adult mice, inducing haloperidol-sensitive excessive stereotypy behaviors, impaired PPI, longer adhesive removal time and altered electrophysiological characteristics of ChAT interneurons, could be regarded as an animal model of TS.

Title: Investigation of subpallial neural circuits in larval zebrafish

Authors: *T. THIELE[1], H. CHASIOTIS[2], M. MARTIN[2], V. AGUDA[2], N. GUILBEAULT[2]
[1]Univ. of Toronto Scarborough, Univ. of Toronto Scarborough, Scarborough, ON, Canada;
[2]Univ. of Toronto Scarborough, Toronto, ON, Canada

Abstract: Neural circuits in the basal ganglia play a central role in determining what actions we perform, however, much remains unknown concerning the circuit mechanisms within these structures that underlie behavioral decisions. Remarkably, it has recently been shown that the majority of the components and connections of the mammalian basal ganglia are present in the ancient jawless lamprey, indicating that they are also likely to be present in teleosts. If these circuits exist, the reduction in complexity and unparalleled optical access in larval zebrafish, when compared to the attributes of rodent models of basal ganglia function, should make relationships between basal ganglia activity and behavioral control more salient. To address the function of basal ganglia circuits in zebrafish, we are utilizing Gal4 lines that target the fish's putative direct and indirect pathways which have been shown in mammals to promote or inhibit movement respectively. To gain genetic control of the indirect pathway, we are using a BAC transgenic line which stably expresses Gal4 in neurons that express the dopamine receptor gene drd2a (generated in a Baier Lab BAC screen). For the direct pathway, we are targeting Gal4 to the drd1a locus using CRISPR/Cas9 integration and are currently screening for stable lines. Following anatomical characterization of the drd2a and drd1a Gal4 lines, we will examine the function of labeled circuits using a combination of population calcium imaging, pharmacology, optogenetics and behavioral analyses. By taking this multifaceted approach, we should be able to identify the logic of cellular activity patterns throughout the direct and indirect pathways of larval fish and hopefully provide new insights into general circuit mechanisms controlling action selection across species.

Title: Globus pallidus activity during short-term adjustments of the speed-accuracy trade-off in a reach selection task

Authors: *D. THURA, P. CISEK
Dept Neurosci., Univ. Montreal, Montreal, QC, Canada

Abstract: The basal ganglia (BG) have long been implicated in many aspects of cognition and motor control. Previous theoretical and experimental work suggests that they play a role in the adjustment of the speed-accuracy trade-off (SAT) of decisions between conditions favoring either hasty or accurate decisions. Our previous results (SFN 2015, 2016) are consistent with that proposal, suggesting that SAT adjustment occurs through modulations of a context-dependent urgency signal originating from the BG to regulate decision-related activity in cortical structures. However, in addition to adjustments between different contexts, humans and animals also exhibit SAT adjustments on a shorter time-scale, within each context, depending on the outcome of previous trials. Here, we investigate whether the BG are involved in such short-term SAT adjustments.

To investigate this question, we recorded pallidal activity in two monkeys trained to perform a probabilistic decision task in which sensory evidence guiding the decision continuously evolves during the time course of trials. Animals were free to report their choices by moving a cursor whenever they felt confident enough to commit. We first compared neural activity in trials following a correct choice versus those following an error. We found that in the globus pallidus externus (GPe) and internus (GPi), very few cells varied their baseline activity depending on the previous trial outcome. This contrasts with our findings in dorsal premotor and primary motor cortex (Thura et al. 2017 J Neurophysiol), in which roughly half of the population showed either higher or lower activity depending on previous trial outcome. Next, we computed the outcome history in sequences of 10 trials and investigated if more vs. less successful sequences affected GP responses in the next trial. Here again, we found only a small minority of cells showing modulation of baseline activity depending on performance history. Finally, we compared the baseline activity of BG cells averaged across 5-10 trials and compared it against the animal's success probability and decision timing averaged across the same trials. We found that baseline activity of 30-50% GP cells significantly co-varied with the monkey's decision duration and/or success probability. These results suggest that BG activity reflects the speed-accuracy trade-off of decisions before the influence of sensory evidence, and that this fluctuates on a time scale of a few trials as well as between different behavioral contexts.

Title: Specific gene deletion in the efferent striatal pathways confer electrophysiological, neuronal morphological and behavioural characteristics of ASD in mice

Authors: *D. RIAL[1], E. PUIGHERMANAL[2], E. VALJENT[2], S. N. SCHIFFMANN[1], A. D. D'EXAERDE[1]
[1]Neurophysiol., Univ. Libre De Bruxelles, Brussels, Belgium; [2]Genómique Fonctionnelle, Ctr. Natl. de la Recherche Scientifique (CNRS), UMR-5203, Inst. de Génomique Fonctionnelle, Montpellier, France, Montpellier, France

Abstract: Keywords: Striatum, cell-type-specific gene, striatonigral pathway.
The striatum is a critical brain structure for motor programming, attention, motivation, action selection and cognitive flexibility. The striatum is mainly composed by neurons denominated MSNs (medium spiny neurons) driven by cortico-thalamic projections that based on their function and neurochemical phenotype are traditionally divided into two distinct populations, namely the striatonigral and the striatopallidal pathways; these populations give rise to the direct (expressing dopamine D_1 receptors, D_1R) and indirect pathways (expressing adenosine A_{2A} receptors, $A_{2A}R$). Still the striatum can be divided in subregions namely the dorso-medial, dorso-lateral and ventral striatum (DMS, DLS and VS respectively). Each of these subregions is accounted for different functions receiving input from distinct brain regions. A clear overlap between striatal functions and correlated symptoms of ASD, such as stereotyped routines, rigid thinking and abnormal social approach would involve dysfunctions of the DMS, DLS and VS respectively (Fuccillo, 2016). The involvement of the striatum as a whole indicates a rationale role for the intertwinned cell-selective disruption in the physiological functions within the striatum. Comparative analysis in rodents provides a unique opportunity to leverage growing genetic association data to reveal whose dysfunction directly contributes to aspects of ASD symptomatology. Here we intent to identify and functionally characterize genes expressed in both pathways that could mimic ASD-like symptoms in electrophysiological, behavioral and neuronal morphological aspects in mice. Using flox mice we generated knockout models for these genes. We are now assessing the effect of gene deletion using a multi technique approach,

combining 3D reconstruction, electrophysiology and behavioral tests.

Title: Correlated activity in globus pallidus neurons of a macaque monkey during hand reaching movements

Authors: *W. WONGMASSANG, S. CHIKEN, T. HASEGAWA, A. NAMBU
Div. of Syst. Neurophysiol., Natl. Inst. For Physiological Sci., Aichi, Japan

Abstract: The basal ganglia (BG) are a group of subcortical nuclei, which play a crucial role in control of voluntary movements. There are many reports on movement-related activity in the external (GPe) and internal (GPi) segments of the globus pallidus; the former sends inhibitory signals to multiple BG nuclei and may control the whole BG activity, whereas the latter sends inhibitory BG outputs to the thalamo-cortical and brainstem motor systems. The correlated GPe/GPi activity may converge in the target nuclei and induce large inhibitory effects and post-inhibitory rebounds, however previous studies have reported no correlation of GPe/GPi activity at rest without tasks. In this study, we examined correlation of GPe/GPi activity during hand reaching task. A female Japanese macaque monkey (*Macaca fuscata*) was trained to perform a reaching task with its hand to the left or right target, which was indicated by LED. The activity of GPe/GPi neurons was simultaneously recorded during task performance using a multi-channel electrode with 16 equally spaced contacts by 150 μm. The bipolar stimulating electrodes were also inserted chronically into the hand area of the primary motor cortex (MI) and supplementary motor area (SMA). MI/SMA stimulation induced a triphaisc response composed of early excitation, inhibition and late excitation, suggesting that GPe/GPi neurons were located in the hand motor area. Many GPe/GPi neurons changed their activity in relation to task events, such as hand-release from the home position, reaching movements, touching the target, and reward delivery. Some GPe-GPe and GPi-GPi pairs showed short-duration but significant correlated activity at specific event timings, although most pairs showed weak or no correlation. Our findings have demonstrated that while the majority of GPe/GPi activities are functionally

independent, a fraction of them transfer neuronal information to their target nuclei by correlated activity.

Title: Behavioral and neuronal correlates of hyperactivity in the nucleus accumbens disinhibition rat model

Authors: *D. YAEL, I. BAR-GAD
Bar-Ilan Univ., Ramat Gan, Israel

Abstract: Attention deficit/hyperactivity disorder (ADHD) is a common neuropsychiatric disorder affecting roughly 5% of children with persistence of 30-50% in adulthood. While the pathophysiology leading to ADHD is unknown; multiple lines of evidence suggest the involvement of the cortico-basal ganglia pathway, and particularly fronto-striatal networks. In this study, we present a novel rodent model in which hyperactivity is elicited by disinhibition of the nucleus accumbens (NAc). Following injections of a GABA-A antagonist (bicuculline) into the NAc, the animals developed hyperkinetic symptoms expressed as increased locomotion lasting for 30-45 minutes. The neuronal activity of the behaving rat's dorsal and ventral striatum was continuously recorded during naïve and hyperactive states and their behavior was monitored. The behavior of the animals was offline analyzed, and their movement was automatically tracked. Kinematic properties were extracted from the data and synchronized with the recorded neuronal activity. Comparison between the naïve and disinhibited states reveals qualitative and quantitative changes in the neuronal activity in both the macro (local field potential) and micro (single neurons) scales. In addition, comparison of the bicuculline injections into the NAc to those performed into the dorsal striatum, which elicit motor tics, reveals common changes in the neuronal encoding in the limbic and sensorimotor territories. Our data provides new insights into the involvement of the limbic basal ganglia in the expression of hyperactivity and normal motor behavior.

Title: Rostral thalamic intralaminar nuclei modulation of striatal microcircuitry and action

Authors: *K. K. COVER[1], U. GYAWALI[1], A. E. MARQUARDT[1], C. MU[1], M. H. PATTON[1], M. G. WHITE[1], B. M. ROBERTS[2], B. N. MATHUR[1]

Abstract: Survival in a rapidly-changing environment requires attention to sensory stimuli in order to optimize action for reward acquisition. How specific neural circuits subserve this complex function is unclear. The thalamic intralaminar nuclei (ILN) are positioned to receive salient sensory stimuli and to directly modulate actions through a direct projection to the dorsal striatum, a critical node for action selection. The rodent ILN are distributed in caudal and rostral groupings: the caudal ILN consists of the parafascicular (Pf) nucleus, whereas the rostral ILN (rILN) includes the centromedial (CM), paracentral (PCN), and centrolateral nuclei (CL) nuclei. While the Pf has been functionally examined for its role in sensory-cued action encoding, the rostral ILN has been largely ignored. Using optogenetics and fast scan cyclic voltammetry in mice, we have identified a unique microcircuit by which the rILN innervate the dorsal striatum to elicit dopamine release. How the rILN encode sensory stimuli and cognate action selection is explored using an all-optical approach. Our results provide novel insight into how the thalamus may contribute to salience-informed action selection, which has implications for several disorders of action including Parkinson's disease and addiction.

Title: Regulation of locomotion by nucleus accumbens core activity

Authors: *Q. YAN, H. YIN
Dept. of Psychology and Neurosci., Duke Univ., Durham, NC

Abstract: Despite an extensive literature on the neural basis of locomotion in many species, the role of the brain in regulating locomotion remains poorly understood. Previous studies have indicated a critical role of the nucleus accumbens core (NAcc) in locomotion and approach behavior. Here we used optogenetics and continuous 3D motion capture to quantify the contributions of NAcc to locomotion in freely moving mice. We implanted bilateral optical fibers in the NAcc in mice that selectively expressed channelrhodopsin and halorhodopsin in the direct pathway projection neurons to manipulate NAcc output, and continuously recorded movements during both free locomotion and moving target pursuit. Our results suggest that the NAcc output may determine the initiation and termination of locomotion.

Title: Stationary corticostriatal networks promote compression of automatic action in aging

Authors: *J. BERTRAN-GONZALEZ[1], Z. SKRBIS[2], M. R. BAILEY[3], P. D. BALSAM[4], B. W. BALLEINE[1], J. GOETZ[2], M. MATAMALES[1]

Abstract: The acquisition of motor skills involves implementing action sequences that increase task efficiency while reducing cognitive loads. This learning capacity depends on specific

cortico-basal ganglia circuits that are affected by normal aging. Here, combining a series of novel behavioral tasks with extensive neuronal mapping and targeted cell manipulations in mice, we explored how aging of cortico-basal ganglia networks alters the microstructure of action throughout sequence learning. We found that, after extended training, aged mice displayed squeezed automatic behaviors characterized by ultrafast oligomeric action chunks that correlated with deficient reorganization of corticostriatal activity. Pharmacogenetic disruption of the D1-striatonigral subcircuit in dorsolateral striatum in young mice reproduced most age-related action features, and the introduction of an action-related feedback cue restored normal sequence structure in aged mice. Our results reveal static properties of aged cortico-basal ganglia networks that promote deficits in action automatization, something that can compromise procedural learning in aging.

Title: Distinct roles for cortico- and thalamostriatal projections in motor skill learning and execution

Authors: *S. B. WOLFF, A. K. DHAWALE, R. KO, B. P. OLVECZKY
Harvard Univ., Cambridge, MA

Abstract: The remarkable capacity of the brain to acquire and execute motor skills depends on a distributed motor network. While many individual components have been identified, less is known about their specific roles and how they interact during learning and execution of motor skills. To address this, we train rats in a lever-pressing task which results in spatiotemporally precise movement patterns. Our previous finding that motor cortex is necessary for learning, but not for execution of this motor skill, suggests that motor cortex may act as a tutor for subcortical motor circuits during learning. A main candidate to receive this tutoring is the dorsolateral part of striatum, a major target of motor cortical projection neurons. In line with this hypothesis, we show that the striatum is indeed necessary both for the acquisition and execution of the motor skills we train. Furthermore, chronic and selective silencing of motor cortex's direct projections to the striatum, by viral and molecular strategies, prevented animals from learning the motor skill. In line with our previous lesion experiments, the same silencing did not affect skill execution when it was done after learning. We next tested the contribution to skill execution of striatum's other main input, that from thalamus. We found that chronic silencing of

thalamostriatal projections disrupted both skill execution and learning. These findings identify the striatum as a central player and suggest distinct roles for its cortical and thalamic inputs during motor skill acquisition and execution. To further dissect the interplay between these areas, we are combining transient and chronic activity manipulations with long-term electrophysiological recordings to study their activity, their mutual influence on each other and the network changes that accompany motor learning.

Title: Recruitment of prefrontal-striatal circuit during skilled motor challenge

Authors: *S. PRATHAP[1], Z. WANG[2], Y. GUO[2], D. P. HOLSCHNEIDER[2]
[1]Neurosci. Grad. Program, [2]Psychiatry & the Behavioral Sci., USC, Los Angeles, CA

Abstract: BACKGROUND: Exercise, including treadmill running, dancing, Tai-Chi, bicycling and others, have been shown to improve cognition, particularly executive function in aging individuals, as well as delaying the onset of dementia in the cognitively impaired. These different exercise types differ in the extent of motor skill and aerobic challenge required for their execution. Prefrontal cortex (PFC) is well known to play a central role in cognition, and especially in executive function. Its importance in guiding motor learning—both during healthy aging, as well as during the neurorehabilitation of brain disorders—is less well understood. Our aim was to use functional brain mapping to compare the ability of two motor tasks to acutely engage the prefrontal-striatal circuit (PFC-Str). The two motor tasks--walking in a complex running wheel with irregularly spaced rungs or walking in a running wheel with a smooth internal surface--differed only in the extent of skill required for their execution.
METHODS: Adult rats received jugular vein catheters, and were habituated to a running wheel. Cerebral perfusion was mapped by injection of [14C]-iodoantipyrine during acute walking (6 m/min) in either the complex wheel or in the simple wheel. Regional cerebral blood flow (rCBF) was quantified by whole-brain autoradiography and analyzed in 3-D reconstructed brains by statistical parametric mapping and seed-based functional connectivity.
RESULTS: Correlation analysis with a medial PFC (mPFC, prelimbic area) seed showed significant correlations of the mPFC with the dorsomedial striatum during walking in the complex wheel that was not seen during walking in the simple wheel.

CONCLUSION: The level of skill involved in a motor training task determines the extent of functional recruitment of the prefrontal corticostriatal circuit. Our results are consistent with our earlier work that showed that 4 weeks of skilled wheel running improves functional recruitment of the PFC during horizontal treadmill walking, as well as discrete motor outcomes in a rat model of striatal dopaminergic deafferentation (Neurobiology of Disease, 2015, 77:71-87). These findings support the notion that the basal ganglia are significantly influenced by inputs from PFC, which may provide a top-down control signal for guiding the resolution of response competition that amplifies one response command and suppresses competing commands.

Title: High fat diet blocks the effect of the antipsychotic haloperidol and enriched environments reverses the effect in rats

Authors: *I. C. SUMAYA, S. VILLARREAL, N. RAMIREZ, A. HUSSAIN, M. CHAUNDHRY
Psychology - 24 DDH, California State Univ. Bakersfield, Bakersfield, CA

Abstract: Antipsychotics are very effective in ameliorating the positive symptoms of schizophrenia, however, a high percentage of those treated with antipsychotics suffer from the serious motor-related extrapyramidal side effects. Specifically, these drugs show high affinity for the D_2 dopaminergic receptors in the striatum serving to block the transmission of dopamine (Seeman & Lee, 1975). Relevant to the current research are the recent finding that high-fat serves to deplete dopamine in the substantia nigra and the striatum (Morris et al., 2010), the major players in voluntary motor responses. Based on these findings, the purpose of the current investigation was to investigate the behavioral motor effects of high fat and low fat on the dopamine system during treatment with a D_2 antagonist that is used in clinical populations in the treatment of schizophrenia. Also, based on previous work done in our lab finding that enriched environments served to counteract the negative effects of high fat in cognitive domains (Suter et

al., 2016; Sumaya et al., 2015), we were also interested in investigating the possible effects of environmental enrichment on motor domains after treatment with a D_2 antagonist. We placed rats in either enriched environments (n=20) or standard cages (n=20) and fed rats either a low fat diet (10% fat) or a high fat diet (45% fat) for a month then injected rats with the dopamine antagonist, haloperidol (1 mg/kg, i.p). We then tested rats in the bartest measuring hypokinesia. Our controls, the low fat group housed in regular cages, experienced high levels of hypokinesia staying on the bar for an average of 18 minutes (1090 $\pm$238.50 sec). However, their counterparts fed a high fat diet experienced little to no hypokinesia only staying on the bar for an average of 17 seconds (17.10$\pm$4.37 sec) thus showing high fat to counteract the effect of haloperidol. Paradoxically, rats in the enriched environments fed a high fat diet experienced high levels of hypokinesia (587.40$\pm$203.82). Similar to the groups in the regular cages, the low fat groups in the enriched environments also showed high levels of hypokinesia (928.20$\pm$255.06 sec). In regards to weight, as expected, rats fed the high fat diet gained more weight as compared to the low fat group and regardless of diet, rats in enriched environments gained the least amount of weight. In summary, the high fat diet served to counteract the effects of haloperidol and enriched environments served to reverse the effect. These results provide first time behavioral data showing high fat diets to interfere with the effects of antipsychotics and that the environment may play a role in these effects.

Title: Short term plasticity shapes information transmission in the indirect pathway of the rat basal ganglia

Authors: *H. LAVIAN[1], A. KORNGREEN[1,2]
[1]Bar-Ilan University, Gonda Brain Res. Ctr., Ramat Gan, Israel; [2]The Mina and Everard Goodman Fac. of Life Sci., Bar-Ilan Univ., Ramat-Gan, Israel

Abstract: The basal ganglia have long been implicated in motor control and action selection. During movement, cortical information flows through the basal ganglia via the direct, indirect and hyper-direct pathways, and converges to the entopeduncular nucleus (EP), one of the basal ganglia output nuclei. In the indirect pathway of the basal ganglia, globus pallidus (GP) neurons form inhibitory depressing synapses in the EP. GP neurons are spontaneously active and show transient decreases or increases in firing rate during movement. Inputs from the indirect pathway

continuously modulate the firing of EP neurons, yet the link between these synaptic inputs to neuronal firing in the EP is unclear. To investigate this input-output transformation we used numerical modeling and whole cell recordings from single neurons in rat brain slices. First we constructed a model of an EP neuron that receives input from a constantly active inhibitory depressing synapse. We used this model to predict the change in EP membrane potential induced by transient changes in firing rate of the presynaptic neuron. Our simulations show that the change in EP membrane potential, and subsequent firing rate, depends greatly on the initial activation frequency of the synapse. We further performed whole cell recordings from single neurons in the EP and recorded the response to stimulation of the GP at different frequencies. These recordings yielded similar results to those of the simulations, showing that integration of GP evoked inhibitory post synaptic potentials depends both on the present and past firing rate of the presynaptic neuron. Our results thus show that the inhibitory effect of GP input on EP activity is highly dependent on the baseline frequency of the pallidal neurons, and demonstrate how short term synaptic plasticity shapes information transmission through the indirect pathway of the basal ganglia.

Title: Differences in globus palllidus asymmetry in patients with cervical and generalized dystonia

Authors: *A. SEDOV[1], S. USOVA[1], U. SEMENOVA[1], V. POPOV[2], R. MEDVEDNIK[1], A. TOMSKIY[2], A. G. SHAIKH[3]
[1]Lab. of human cell neurophysiology, Semenov Inst. of Chem. Physics, Russian Aca, Moskva, Russian Federation; [2]Functional Neurosurg., Burdenko Res. Ctr. of Neurosurg., Moscow, Russian Federation; [3]Neurol., Case Western Reserve, Moreland Hills, OH

Abstract: Dystonia is a movement disorder defined by sustained muscle contractions, causing twisting and repetitive movements and abnormal postures. The pathophysiology of dystonia is incompletely understood, but it is thought to involve the loop circuit from sensorimotor cortices (SMC) through parts of the basal ganglia and ventrolateral thalamus and back to cortex. The globus pallidus internus (GPi) occupies a critical position in this circuit, being the major output structure of the basal ganglia “motor” territory. Decreases and increases in discharge of the

GABAergic neurons of GPi are believed to facilitate and suppress, respectively, the activity of recipient thalamocortical circuits and, eventually, muscle activity. Asymmetric pallidal neuronal activity was shown in patients with cervical dystonia.We used microelectrode recording (MER) and local field potentials (LFP) to analyze the differences of pallidal asymmetry in patients with cervical and generalized dystonia. The data was obtained during microelectrode-guided basal ganglia stereotaxic DBS surgeries. We used burst index to separate tonic and burst cells and calculate mean firing rate. We also perform spectral analysis of LFP and estimate oscillations scores (OS) for each band: delta, theta, alpha, beta and gamma. We found that discharge rate of GPi tonic cells was significantly higher in ipsilateral to the side of head turning or tilt in CD patients. In GD patients we found just few tonics cells. At the same time, GPi burst cells have the same discharge rate for both side in CD and GD patients. LFP analysis has shown the asymmetry in gamma range oscillation scores in CD and no asymmetry in GD patients. It is worth noting the absence of any interhemispheric differences in GPe activity for all patients. Imbalance in GPi tonic cells activity could influence on the level of thalamic activity and thus results in imbalance in neck muscle activity. Our data confirm the hypothesis that CD is associated with an asymmetric pallidal outflow and imbalance in direct pathway. We propose that GPi asymmetry could be results from disturbance of proprioceptive feedback or cerebellar motor efference copy.

Title: Parkinson's disease risk genetic polymorphisms are associated with imaging markers of the putamen and substantia nigra in healthy adults

Authors: *D. E. VAILLANCOURT[1], R. G. BURCIU[2], P. SHUKLA[3], M. NALLS[5], A. SINGLETON[5], M. OKUN[4], R. D. SEIDLER[6]
[1]Applied Physiol. and Kinesiology, [2]Dept. of Applied Physiol. and Kinesiology, [4]Neurol., [3]Univ. of Florida, Gainesville, FL; [5]Natl. Inst. of Aging, Bethesda, MD; [6]Univ. of Michigan, Ann Arbor, MI

Abstract: Great efforts are being made towards developing new approaches to assess which people are at greater risk for developing Parkinson's disease (PD). While genetics and neuroimaging offer distinct possibilities for determining those at risk for developing PD, a combined approach may offer even greater insight. In this study, we used a neurogenetics approach to explore two neuroimaging biomarkers for PD in a group of healthy adults that carry risk variants for developing PD. A total of 31 individuals with no motor and cognitive symptoms (mean age: 62.1 ± 9.3; 14 males) participated in the study. Functional magnetic resonance imaging (fMRI) during a force production task and diffusion magnetic resonance imaging (dMRI) with 64 directions were performed on a 3T Philips Achieva scanner equipped with 32-channel headcoil. The primary outcome measures were percent signal change in the putamen and free-water in the substantia nigra. We also collected clinical data using the following tests: motor section of the Movement Disorder Society Unified Parkinson's Disease Rating Scale, Purdue Pegboard Test, Dynamic Gait Index, 6-Minute Walking Test, Montreal Cognitive Assessment, and Beck Depression Inventory. Participants were genotyped using the NeuroX platform and and two commonly cited single nucleotide polymorphisms that have been associated with increased odds risk of PD were examined: rs356219 and rs76904798 that relate to the SNCA and LRRK2 genes, respectively. In our analysis we summed across the two variants and ended with a value between 0-2 for each control subject, with 2 representing the highest value indicating a person is a carrier of both risk variants. Results showed that the number of "at-risk" genotypes was significantly associated with reduced fMRI signal in the putamen, and elevated free-water in the anterior substantia nigra. There was no association between the number of "at-risk" genotypes and clinical measures. Together, results suggest that healthy individuals who carry multiple risk variants for PD have impaired nigrostriatal function and structure. Task-fMRI and dMRI markers represent brain endophenotypes for carriers of PD risk genotype loci, which could open the door for a neurogenetics approach in prodromal PD.

Title: Electrophysiological and behavioral characterization of a mutant mouse lacking Rem2 protein in striatal medium spiny neurons

Authors: *D. J. LIPUT[1], H. L. PUHL, III[3], S. R. IKEDA[2]
[1]Lab. of Mol. Physiol., [2]Lab. Molec Physiol., NIH/NIAAA, Rockville, MD; [3]NIH, Rockville, MD

Abstract: Rem2 is a small GTPase of the Ras-related RGK family and is primarily expressed in the nervous system, including the striatum. Previous studies have shown that Rem2 inhibits high-voltage-activated Ca^{2+} channels and instructs dendritogenesis and synaptogenesis. To evaluate the role of Rem2 in the striatum, we generated a Rem2 conditional knockout mouse line and bred these animals to a RGS9cre driver line to generate mice with a deletion of Rem2 in striatal medium spiny neurons (MSN-Rem2KO mice). For some experiments, a tdTomato transgene, under the control of the dopamine D1 receptor promoter, was bred onto the MSN-Rem2KO line. To examine the effect of Rem2 knockout on synaptic input to MSNs and intrinsic excitability, acute brain slices containing striatum were prepared (> P25). Spontaneous EPSCs were recorded from MSNs in the dorsal striatum. Rem2 knockout decreased sEPSC frequency (median: 2.6 vs 1.7 Hz) and increased corresponding sEPSC interevent intervals (median: 395.4 vs 580.2 ms), but had no effect on sEPSC amplitude. Intrinsic excitability was assessed by delivering 500 ms hyperpolarizing and depolarizing current steps (-200 pA to +780 pA) and recording voltage output. Consistent with previous reports, striatopallidal MSNs were more excitable then striatonigral MSNs evidenced by lower rheobase and a leftward shift in the action potential frequency (F-I) curve. However, excitability of $MSN^{LoxP/LoxP}$ and MSNRem2-KO neurons was indistinguishable. Whole-cell calcium currents were recorded from acutely dissociated MSNs. I-V curves recorded from $MSN^{LoxP/LoxP}$ and MSN-Rem2KO neurons were similar over the entire voltage range examined (-80 mV to +75 mV). Normalized peak current density was larger in MSN-Rem2KO neurons (median: -65.2 vs -92.1 pA/pF), which was attributed to a decrease in capacitance (median: 6.8 vs 5.6 pF). The effect or Rem2 knockout on striatum dependent behavioral output was also assessed. Adult $MSN^{LoxP/LoxP}$ and MSN-Rem2KO mice had similar performance on an accelerating rotarod task and displayed equivalent locomotor activity in a novel environment. $MSN^{LoxP/LoxP}$ and MSN-Rem2KO mice learned a fixed ratio operant

conditioning task at similar rates. However, in preliminary progressive ratio experiments, MSN-Rem2KO mice (n = 6) displayed elevated lever press responses and achieved higher breakpoints compared to $MSN^{LoxP/LoxP}$ mice (n = 5). These results may be related to changes in effort as extinction was similar between genotypes in a separate cohort of mice. The results presented are consistent with the hypothesis that Rem2 is involved in striatal synaptogenesis and has a role in some domains of striatum dependent behavioral output.

Title: The thalamic posteromedial nucleus activates the direct pathway

Authors: *K. D. ALLOWAY[1], G. D. WATSON[2]
[1]Ctr. for Neural Engin., Penn State Univ., University Park, PA; [2]Psychology and Neurosci., Duke Univ., Durham, NC

Abstract: Clinical studies indicate that deep brain stimulation in the zona incerta (ZI) reduces the symptoms of Parkinson's disease (PD). This is significant because ZI inhibits the medial part of the posterior (POm) thalamic nucleus, which innervates only the dorsolateral part of the striatum (DLS), a basal ganglia structure that is essential for the expression of repetitive sensorimotor habits. To assess the potential influence of POm on the basal ganglia, we first used neuronal tracing combined with unbiased stereology to assess the relative strength of the projections from the dorsomedial and dorsolateral striatal regions to the external globus pallidus (GPe) and the substantia nigra pars reticulata (SNR), which are the respective targets of the Indirect and Direct pathways. Subsequently, we used optogenetic stimulation combined with extracellular recording techniques to determine whether activation of POm alters neuronal activity in the substantia nigra reticulata (SNr), which is a major output nucleus of the basal ganglia.
Consistent with previous studies, we found that anterograde tracer deposits in the dorsomedial striatum revealed equal innervation of the external globus pallidus (GPe) and SNr. By contrast, tracer deposits in the DLS indicate that its neurons project preferentially to SNr. Consistent with these anatomical results, short pulses of optical stimulation in POm caused brief activation of neuronal activity in DLS that is immediately followed by longer-lasting inhibition of neurons recorded in the lateral part of SNr. Although many neurons in SNr did not respond to POm

stimulation, we never observed POm-induced excitation in SNr. These results suggest that POm preferentially activates the direct pathway of the basal ganglia. To examine how ZI deep brain stimulation might mediate its therapeutic effects in PD, we are currently characterizing the effects of ZI electrical stimulation on neuronal activity in POm, DLS, and SNr.

Title: Corticostriatal inputs from somatosensory and motor cortex have distinct effects on behavior through differential actions on striatal neurons

Authors: *C. R. LEE[1], J. M. TEPPER[2], D. J. MARGOLIS[1]
[1]Cell Biol. and Neurosci., Rutgers The State Univ. of New Jersey, Piscataway, NJ; [2]Ctr. for Mol. and Behavioral Neurosci., Rutgers The State Univ. of New Jersey, Newark, NJ

Abstract: The striatum is the main input nucleus of the basal ganglia and receives excitatory afferents from wide areas of neocortex as well as the thalamus. It is largely unknown, however, whether 1) afferent input from sensory and motor cortical areas has different effects on behavior and 2) how distinct areas of cortex influence striatal projection neurons and interneurons. Here, we explored the roles of primary somatosensory cortex (S1) and primary motor cortex (M1) in controlling behavior and the cellular mechanisms that might underlie those functions. Specifically, we tested the hypothesis that corticostriatal input from S1 induces sensory-driven behavioral response inhibition while input from M1 promotes behavioral response activation. Channelrhodopsin-2 (AAV1.CamKIIa.hChR2(H134R)-eYFP.WPRE.hGH) was expressed in either S1 or M1 and mice were trained to perform a tactile Go/No-Go decision making task using their whiskers to discriminate between two textures for a water reward. Preliminary results indicate that activation of S1 inputs to striatum increased the number of trials without a response (correct reject and miss) while activation of M1 inputs to striatum increased trials with a response (hit and false alarm).
We investigated the possible cellular mechanisms underlying these behavioral effects using ex vivo whole cell recordings of identified D1 and D2 receptor-expressing medium spiny neurons

as well as parvalbumin (PV)-expressing fast spiking interneurons and optogenetic activation of corticostriatal afferents from S1 or M1. These experiments revealed marked differences in the amplitude of excitatory postsynaptic potentials (EPSPs) recorded in each of the neuron types from the two cortical areas. Optogenetically activated inputs from S1 to striatum induced an approximately 7-fold larger EPSP in PV-expressing interneurons when compared to either D1 or D2 receptor-expressing medium spiny neurons. In contrast, optogenetic activation of M1 corticostriatal inputs produced an an EPSP of similar amplitude in D1 and D2 medium spiny neurons as well as PV-expressing interneurons.
Our results suggest that corticostriatal input from S1 and M1 induces behavioral inhibition and activation respectively, that is likely mediated through distinct activation of striatal circuitry by these cortical regions.

Title: Corticostriatal projections map the organization of inter-area corticocortical connectivity

Authors: *A. E. PAPALE[1], R. PALETZKI[2], M. FEROZE[1], C. R. GERFEN[2], B. M. HOOKS[1]

Abstract: A long standing model of corticostriatal organization is that interconnected cortical areas form the basis of parallel functional circuits through the basal ganglia. This model accounts for both the topographic organization of corticostriatal projections as well as the patterns within the striatum from different cortical areas. An emerging view ascribes distinct functions in motor behavior to dorsolateral, dorsomedial and ventral striatal regions. To better understand how the information responsible for these distinct functions is organized, we analyzed the projections of layer-specific subtypes of cortical projection neurons in primary somatosensory, primary motor and secondary motor cortical areas. Mice with Cre-expression selective for intratelencephalic layer 5A (IT), pyramidal tract layer 5B (PT), and corticothalamic layer 6A (CT) were injected with 3 different Cre-dependent reporter viral vectors in different cortical areas. After sectioning and imaging of brains, images were aligned to a reference brain using BrainMaker software (MBF Bioscience). For each Cre-driver line, up to 90 injection sites were analyzed. Long-range axonal projections in specific target regions were then assessed. Correlation coefficients of voxel fluorescence in striatum were computed across injection sites. A hierarchical clustering algorithm was applied to the correlations, revealing distinct clusters that were well-matched to

injection sites. In striatum, primary motor and sensory areas clustered together, as did medial and lateral frontal cortical areas. Analysis of correlations along different anatomical dimensions suggested a distinct anterior/medial region of striatum where all areas of the sensorimotor system converge. Comparison of topography for IT- and PT-projections to striatum revealed differences in the degree of topographic precision. K-means clustering analysis of striatum suggested subdivision of striatum that corresponded well with expected regions given known striatal connectivity. In conclusion, we find that subcortical projections from sensorimotor areas are coarsely topographic, allowing for integration from multiple regions in basal ganglia-thalamus-cortex loops.

Title: Significance of striatal feedforward inhibition in propagation of cortical oscillations

Authors: *J. BELIC, A. KUMAR, J. HELLGREN KOTALESKI
KTH Royal Inst. of Technol., Stockholm, Sweden

Abstract: The basal ganglia (BG) comprise the largest subcortical system in the brain and play a crucial role in motor control and cognitive processes. The striatum is the largest and main input nucleus of the BG, receiving glutamatergic inputs from all cortical areas and thalamus. About 95% of neurons in the striatum are medium spiny neurons (MSNs) that form the only output from the striatum. Two of the most examined sources of GABAergic inhibition into MSNs are the feedback inhibition from the axon collaterals of the MSNs themselves, and the feedforward inhibition via the small population (1-2% of striatal neurons) of fast-spiking interneurons (FSIs). Feedforward inhibition is a common property of neuronal networks throughout the brain and plays a crucial role in neural computations. For instance, feedforward inhibition sets the window of temporal integration and spiking and thereby contributes to the control of firing rate and correlations. In the striatum despite their high firing rates, FSIs do not seem to play a major role

in controlling the firing of MSNs and so far, it has not been possible to attribute a functional role to FSIs in the striatum. Here, we propose that FSIs can perform an important role in transferring cortical oscillations to the striatum.
Recently, high frequency oscillations have been observed at the level of individual MSNs firing and local field potential in the striatum of both awake and anaesthetized animals. It is quite likely that the experimentally observed oscillations in the striatum are in fact cortical oscillations transmitted by the cortico-striatal projections because recurrent connectivity within the striatum is not strong enough to generate local oscillations. However, there is limited knowledge about the exact nature of this routing process and here we use a spiking neuron network model of the striatum to isolate the mechanisms underlying the transmission of cortical oscillations to not only the MSNs that receive direct cortical inputs but also to the other unstimulated MSNs. We show that the selective activation of striatal FSIs via oscillatory inputs could successfully entrain the MSN population to oscillate at the input driving frequency. Strong and divergent connectivity of FSIs implies that even weak oscillations in FSI population activity can be spread to the MSN population. Overall, our results support the idea of the precise orchestration of FSI activity that plays a key role in determining the pattern of the firing of MSNs, which might provide optimal integration of external inputs into striatal network.

Title: Correlation between song acoustics and neural activity in the song-related basal-ganglia-thalamo-cortical circuit in songbirds

Authors: *A. LEBLOIS[1], W. E. WOOD[1], R. DARSHAN[2], D. HANSEL[1]
[1]CNRS / Univ. Paris Descartes, Paris, France; [2]ELSC, the Hebrew Univ., Jerusalem, Israel

Abstract: The ability to generate variable movements is essential for learning and adjusting complex behaviors. This variability has been linked to the temporal irregularity of neuronal activity in the central nervous system. However, how this neuronal irregularity actually translates into behavioral variability is unclear. We combine modeling, electrophysiological and behavioral studies to address this issue. A model circuit comprising topographically organized and strongly

recurrent neural networks can autonomously generate irregular motor behaviors, as recently published by our group. Accordingly, simultaneous recordings of neurons in singing finches that reveals an increase in neural correlations across the circuit driving song variability, in agreement with the model predictions. Going beyond neural correlation predicted by our modeling study, we have investigated correlations between neural activity and behavior along this pathway. Interestingly, the singing-related activity of single neurons in the premotor nucleus (Lateral Magnocellular Anterior Nucleus, LMAN) displays relatively little correlation to the acoustic features of the song syllables (pitch, spectral entropy and amplitude). In contrast, we confirm the mild but reliable level of correlation between the activity of motor neurons in the robust nucleus of the arcopallium (RA) and these acoustic features. These differences in correlation with behavior can be well explained in our network model. However, these results may challenge the recently proposed framework for the implementation of reinforcement learning in the song-related BG-thalamo-cortical loop.

Title: Distribution of interneurons associated with perineuronal nets in the mouse neocortex

Authors: R. SULTANA, *C. C. LEE
Comparative Biomed. Sci., Louisiana State Univ. Sch. of Vet. Med., Baton Rouge, LA

Abstract: Perineuronal nets (PNNs) are lattice-like accumulations of extracellular matrix components surrounding the neuronal cell body, dendrites and axons, but sparing the synapse. Whereas the association of PNNs with neurons has been described for various regions of the brain, the comparative occurrence of PNNs around interneurons throughout the brain has received less attention. In the present study, we examined the distribution of PNN-associated interneurons throughout the mouse neocortex, as well as systematically and comparatively analyzed the relationship between the location and function of the differential presence of these extracellular structures. We utilized a transgenic VGAT-Venus mouse strain to identify interneurons associated with Wisteria Floribunda Agglutinin (WFA)-stained PNNs. Our study

revealed that WFA stained-PNNs were associated more commonly with interneurons in layers II/III and V/VI of mouse neocortex. However, their density was considerably different between various cortical areas, greatest in the visual cortex and fewest in the secondary motor cortices. Further analysis indicated that the neuron associated matrix sheaths around interneurons are denser in certain cortical as compared to others. Subfields of cortical areas also differed with respect to the occurrence of PNN-associated interneurons, and the subtlety of cortical representations correlated with the density of PNNs around interneurons in the primary somatosensory, motor or secondary association areas. Thus, the functional heterogeneity of different cell population in different areas of brain is reflected in the density of PNN-associated neurons.

Title: Xylazine acts at excitatory presynaptic terminals of rat prefrontal cortex pyramidal neurons

Authors: J. QUIÑONES[1], J. ORTIZ[2], K. COLON[1], R. VAZQUEZ-TORRES[3], C. A. JIMENEZ-RIVERA[3], *P. SANABRIA-RAMIREZ[1]
[1]Physiol., Univ. Central Del Caribe, Bayamon, PR; [2]Biol., Univ. of Puerto Rico, Rio Piedras, PR; [3]Physiol., Univ. of Puerto Rico, Physiol. Dept., San Juan, PR

Abstract: The role of xylazine, a veterinary non-opiate sedative, in neuronal circuits associated with addiction is not well characterized. It has been recognized that this veterinary drug has been used as an adulterant in recreational drugs such as heroin and cocaine. Our previous in vitro electrophysiology studies have shown that 5 min perfusion of rat medial prefrontal (mPFC) cortex coronal slices with xylazine at 10 and 100 µM altered the firing pattern of layer V pyramidal cells. Here we examined whether xylazine modulates spontaneous excitatory synaptic transmission in mPFC. The preliminary data show that application of xylazine (100 µM) to whole cell patched mPFC pyramidal cells decreased the frequency (control 2.33 ± 0.55, xylazine 1.02 ± 0.55, n=4, p = 0.0124, paired t-test) of spontaneous excitatory postsynaptic currents

(sEPSCs) but not its amplitude (control, 25.01 ±1.36 pA, xylazine, 23.21 ± 2.12 pA, n =4, p=0.208, paired t-test). No changes were observed in either rise time (control, 1.76±0.30 ms, xylazine 1.67± 0.23 ms, n=4; p = 0.56) or decay time (control 3.70 ±1.20 ms, xylazine 2.58 ±0.54 ms, n=4; p = 0.28). These results are consistent with our previous observation that 100 µM xylazine significantly decreases mPFC pyramidal cell's firing (control- 8.45 ± 1.80 spikes, xylazine- 4.20 ± 1.128 spikes, n =5; p= 0.011, paired t-test). Pharmacologically, xylazine, is an alpha2-adrenergic agonist. Light and electron microscopy have shown that α2A-adrenergic receptors are distributed in axon terminals and somatodendritic processes in layer V of the mPFC. Therefore, these results suggest that xylazine might be acting at pre-synaptic terminals inhibiting glutamate release. We have also evaluated xylazine's effects in fast afterhyperpolarization potential (fAHP) since it has been shown that conductance responsible for fAHP contributes to firing properties of many cortical neurons. Xylazine, either at 10 or 100 µM had no effect on fAHP suggesting that its modulation of pyramidal cell activity is not mediated through the regulation of calcium activated voltage dependent potassium channels. These results constitute the first efforts to understand the effect of this drug of abuse adulterant at the level of the neuronal circuits involved in addiction.

Title: Differences in the structure of variability in movements of individual fingers and group of fingers

Authors: *V. SHANKAR, V. SKM
Indian Inst. of Technol., Chennai, India

Abstract: A task in biomechanics is usually produced by a system of elemental variables like variation in displacement of fingers, change in joint angles. While performing a simple task, the joint angles change and this leads to change in a required output variable.
Variance in a multidimensional space of elemental variables can be divided into two components. First one – [V_{UCM}] does not affect the performance variable and this lies within the Uncontrolled Manifold Space [*Scholz & Schöner, et al. 1999*]. Second component [V_{ORT}] lies in the orthogonal space and it affects the performance variable. Many studies have studied the

nature of these components of variance in multi-element tasks such as fingertip force production, aiming and pointing etc. In this study we attempt to document the changes in these components of variance in a kinematic learning task.
In our study, 10 right handed subjects (2 females) participated. Subjects viewed a template of a tube with a middle line and acceptable error ranges on the monitor. The Subjects were randomly divided into two groups – One Finger and Two Finger Group. One finger group practised with only *Index or Middle* finger and two finger group practised with *Index & Middle* fingers respectively. We mounted POLHEMUS - 2 micro + 1 standard sensors (2 on the tip of Index and Middle finger respectively + 1 Reference wrist sensor) to collect kinematic information. A customized LABVIEW Code was written for user interface and data was collected at 100 Hz. Subjects exerted maximum displacement of Index and Middle fingers separately, both in the flexion and extension directions. Subjects were required to move the fingers in such a way that the dot representing the vertical coordinate of their finger(s) moved over the tube as accurately as possible using either Index/Middle or both the fingers. Prior to practise all the groups had to perform similar Pre-test and Post-test using two fingers. Two performance scores, RMS(error) and Tout (total time outside the tube) were computed and provided as feedback to the subject. Both the groups showed a significant improvement in the performance indices with practise. Normalized good and bad variances (VUCM & VORT) were computed in the displacement space, averaged across subjects. Both the groups showed greater VUCM than VORT signifying stabilizing synergy. For the 2 finger group, a significant reduction in VUCM was observed with practise. But VORT decreased only for the one finger group but not for the two finger group. Our results are not consistent with similar experiments in kinetic domain. Further studies are needed to clarify the seemingly contradictory results from kinematics and kinetics of finger function.

Title: Dissociating improvements in speed and task performance in a novel motor sequence learning task

Authors: *D. R[1], R. RANGANATHAN[2], V. SKM[1]
[1]Applied Mechanics, Indian Inst. of Technology, Madras, Chennai, India; [2]Dept of Kinesiology, Michigan State Univ., East Lansing, MI

Abstract: The central phenomenon of motor learning is change in behavior in the course of time with practice. This improvement in behavior of a sequence learning task can be reflected as general improvements in speed and specific improvements related to sequence/keymap (task) being practiced. In our present study, we focused on segregating speed and keymap related components in a novel motor sequence learning task (glove based typing task) where we could manipulate the "keymap" – i.e the layout of the keyboard. 7 males and 1 female subject participated in the current study. Subjects typed words shown on the screen using a touch based glove that converted touches to ASCII code and sent it to computer via USB. Polhemus liberty standard sensors were used to collect the kinematic information of the thumb and wrist. Key press and key release time were collected in sync with the kinematic data at 100Hz in LAB VIEW. The temporal features such as completion time (time taken to complete a word correctly), dwell time (time stayed on an alphabet), errors in typing were calculated from the timing data. Movement time was computed from kinematic data. Key map (arrangement of alphabets on the glove) remained same for the first 6 days and from the 6th day subjects were asked to practice the keymap 2. Transfer blocks (T1 to T3) were tested during 1st, 3rd and 6th day of practice for key map 1 and 6th, 8th and 11th day of practice for key map 2. We observed that the performance of the variables improved with practice from day1 to day6 and once the key map was changed on day6 there was reduction in performance. However, we observed that performance in new keymap 2 was much better compared to day1 practice of key map 1. But this performance was not as good as day6 performance of key map 1. We performed one way repeated measures ANOVA for all the outcome variables with Transfer block as a factor (6 levels) and our results showed significant differences between T1 of the key map1 and T1 of key map2 ($P<0.05$) as well as between T3 of key map1 and T1 of key map2 ($P<0.05$). This suggests that there exists not only overall improvements in speed but also keymap-specific learning. We identified speed related learning as the improvement in performance between first practice of the two keymaps. Changing keymaps brings an interference in learning that is reflected in a reduction in performance from T3 transfer block to T1 transfer block. We hypothesize that this reduction in performance after changing the keymaps can be identified as key map related learning. Further studies can be performed to understand how exactly the variant and invariant features of a task can be used as a tool to enhance the motor performance in the kinematic domain.

Title: Interdependence of finger movements during flexion extension and neutral position of wrist

Authors: *N. C S, V. SKM
Indian Inst. of Technol. Madras, Chennai, India

Abstract: A task involving movement of one finger accompanies involuntary movement of neighbouring fingers of a human hand. This phenomenon is termed as Kinematic Enslavement(KE). KE is caused due to neural and mechanical connections of the fingers with muscles. Studies have shown that the movement of non instructed fingers is uniquely interdependent on the active instructed finger. When the wrist is flexed or extended, the tendons connecting the fingers are in tension or relaxation. In this study, we investigated the changes in finger interdependence, over various hand postures. 4 male and 2 female subjects, with no neuro-muscular disorders, participated in this experiment. The task was to perform cyclic flexion-extension of Index, middle, ring and little fingers one at a time for three different wrist positions - flexion 30^0, neutral 0^0 and extension 30^0. The kinematic data of all the phalanges of these four fingers were collected using 16 sensor Polhemus Liberty data acquisition system, at 100Hz, with the help of a LabVIEW GUI. The first part of the task involved measurement of the maximum flexion - extension of each finger, at three different postures. The second part involved 3 trials of cyclic flexion - extension for 30s each, in synchronous to a 1.5Hz metronome beep (movement of 0.75Hz) within the range of 65% - 85% of the maximum. Subjects were occasionally instructed to concentrate on only the active finger and ignore any movement of the non instructed fingers. Individual movement cycles were filtered at 5Hz and segregated based on the amplitude and frequency matching. Enslavement matrix was computed by averaging the slopes between finger position data, for three different hand postures. Individuation Index (II) was derived for the three different postures and was compared. Statistical analysis showed that there was a consistent drop in Individuation Index of the middle finger in the case of flexion and extension of the wrist as compared to the neutral case. And also, the decrease of Individuation Index in the flexion case was more than that of extension. Changes in Individuation Index were observed for the other fingers but were subject specific.

Title: A behavioural model for a visuomotor adaptation task using index and little finger forces

Authors: *S. SALAM[1], S. VARADHAN[2]
[1]Indian Inst. of Technol., Chennai, India; [2]Indian Inst. of Technol. Madras, Chennai, India

Abstract: Background:
To our knowledge, the 'models' available in kinematics space such as reaching, or grasping isn't as limited as what is understood for the kinetics space. While further explicitly designed experiments are inevitable, we used a dataset that was earlier obtained from a study on effects of various sensory modalities on motor performance. System identification techniques were used to study the underlying motor control mechanism that leads to the observed structure of motor variability.
Methods:
12 healthy right handed subjects (6 males; age: 25.25 ± 3.05 years) participated in the study. A cursor on the visual feedback screen was controlled by the index and little finger forces (along horizontal and vertical axes respectively) using two force sensors (Nano-17, ATI) sampled at 200 Hz through an environment designed in LabVIEW. After sufficient training to 'move properly' in the perceived space for the novel visuomotor task, the subjects were instructed to "reach the target about any of the ideal path" accurately. The subjects performed 15 trials each for 4 experimental blocks for 4 mechanical effort biasing (MEB) ratio of 1:1 (15 - 15), 1.5:1 (15 - 10), 2:1 (15 - 7.5) and 3:1 (15 - 5) (as percentage of maximum voluntary contraction force of index (I) and little (L) finger force respectively).
Correlation (auto/cross) function were computed for the task parameters of a trial: the I and L finger forces, and their rate of change, the joint vector and its rate of change, and the deviation*. Effects across blocks (of MEB ratio) were checked on performance indexes of a trial performance which include precision* in both visual and force space, correction ratio* and completion time. (*Specific methods not included here.)
Results and discussion:
Within a trial, the performance variables is affected by decreasing weights of its most recent performance. The weights for different task parameters decay at different rates reflecting their corresponding relevance (or irrelevance) in successfully executing such a goal oriented task. Across trials, even though the degree of control (formally the correction/adaptation factor) varies as an individual's ability, the ACF coefficients for small lags were consistently ordered. The small coefficients that decays sharply implies minimal learning effects across trials.

In sum, such similar features of planning as well as execution in both kinetics and kinematics reflects the behavioural property of the human control system which follows the same hierarchy of constraints, regardless of the observation (or performance) space.

Title: Hand dominance and grip force variability in a dynamic bimanual manipulation task

Authors: *R. BANUVATHY, S. ANNAMALAI, V. SKM
Indian Inst. of Technology, Madras, Chennai, India

Abstract: In everyday life, most of the activities demand the use of both hands to perform a task. Proper coordination of fingertip forces of both hands is essential for the better performance of a bimanual task. According to dynamic dominance hypothesis (Sainburg RL, 2002), dominant hand is effective and consistent for performing dynamic tasks and the non-dominant hand for static tasks, in kinematic space. The objective of this experiment is to understand the role of hand dominance in kinetic space while performing a dynamic bimanual task. We hypothesized that the variability in the grip force of the right hand when it is involved in cyclic movement is lesser when compared to the variability in grip force when left hand is moving. Our experiment involved a dynamic bimanual manipulation task. The task involves lifting a manipulandum having two handles of height 25cm separated by acrylic hollow tube of length 40cm fitted with two Polhemus standard position sensors and four, 6 axis ATI Nano 17 force sensors on either handles. This customized manipulandum was utilized to record grip and load forces produced by the index finger and thumb of the two hands of the participants. Five male and four female subjects were instructed to lift the handles with both the hands to a height of 5cm above the table through precision pinch grip with their upper arm positioned vertically and elbow flexed 90° and then they were asked to make cyclic up and down movements with the instructed hand. The subjects were provided with visual feedback of instructed hand through its position data on the monitor and requested to time their movements in such a way that they are either at peak or trough during the metronome beep (1.33Hz) which acted as a cue for speed. Force and position data were sampled at 100Hz and collected while the participants performing the task. Difference in variance of right hand thumb and index fingertip grip forces is lesser than the left hand thumb and index fingertip grip forces both during the moving and static state. From the preliminary

analysis of the data, we were able to understand that the dominant hand shows lesser variation in grip force for both dynamic and static task in kinetic space. Further study of the tangential forces and coordination between tangential and grip forces can help us corroborate the results with the results in kinematics domain on dynamic dominance.

Title: Force planning depends on experiencing object weight during lift but not holding

Authors: *V. VAN POLANEN[1], M. DAVARE[1,2]
[1]Fac. of Kinesiology and Rehabil. Sci., KU Leuven, Heverlee, Belgium; [2]Inst. of Neurol., Univ. Col. London, London, United Kingdom

Abstract: Skilled object manipulation requires the planning of a motor command appropriate to the object properties. For instance, to lift an object, fingertip forces must be scaled according to object weight. To ensure a smooth lifting motion, the brain plans these forces before lift onset and, if necessary, adjusts the force output based on rapid sensory feedback loops during the lifting phase. When lifting a series of different objects, the planning of fingertip forces are influenced by the weight of the previous object, an effect often referred to as sensorimotor memory. In this study, we investigated whether force planning is based on a sensorimotor memory of the previous object weight that can be experienced either during the dynamic lifting phase or during the static holding phase. We used a virtual reality environment to manipulate object weight after lifting had commenced. Participants (N=9) lifted a semi-randomized series of objects that could decrease or increase in weight during the holding phase. For instance, a light object lift could be followed by a heavy object holding or, conversely, a heavy object lift could be followed by a light object holding. We analysed the effect of object weight changes on fingertip force rates applied on the next object lift as a way to quantify motor planning and compared them to control trials in which object weight was not altered. This allowed us to test whether sensorimotor memories used for force planning rely more on the dynamic lifting phase or the static holding phase. We found that force planning was based on the previous object weight experienced during the lifting phase ($p=0.009$), but not during the holding phase

(p=0.37). This indicates that sensorimotor memory is generated by collecting information about weight over a transient period. We suggest the lifting phase is a key time period for mediating sensorimotor memory. The comparison between expected and actual sensory inputs that take place within this time period could be more critical than information acquired during static holding for building up an object representation that can be used for the planning of future interactions with objects.

Title: Differences in alpha and beta ERD patterns during various grasping movements

Authors: *Y. INAMURA[1], S. SHIMADA[2]
[1]Meiji Univ., Kawasaki Kanagawa, Japan; [2]Meiji Univ., Kawasaki, Japan

Abstract: The hands are primary interface for us to interact with the world. The hand motions to interact with objects can be roughly divided into reaching and grasping. To identify neurophysiological representation of these motions is important to construct brain-machine interface system which, for example, can control prosthetic hands. Event related desynchronizations (ERDs) in alpha (8-12Hz) and beta (18-24Hz) band in electroencepharogram (EEG) are the common phenomena that reflect sensorimotor brain activity. We investigated the difference in ERD patterns during various grasping movements. One right-handed subject (male, aged 24) was participated in our experiment. The subject was instructed to reach and grasp 6 daily-use objects at his own timing. These objects corresponded 6 grasping forms according to Kamakura's classification of human grasping. Each form can be categorized into 3 classes : power grip (Pwr), intermediate grip (Itm) and precision grip (Prc). EEG signals were sampled at 1200Hz from 30ch electrodes selected from the extended international 10/20 system, and major finger joints were sampled at 64Hz from 18ch bend sensor by using a data glove. The subject usually performed reaching and grasping movements within 2.5 s. The reaching movement peaked at around 1s after the task onset, the subject grasped and held the object for 1.5 s. The intertrial interval was 1s. For ERD analysis, EEG data were transformed into time-frequency data by using Wavelet transform and standardized by the mean power between -1 to -0.5 s before the task onset. We applied t-test ($p < 0.5$) to alpha and beta bands of the EEG data which was segmented into 250 ms time bins sliding by 50 ms with overlap. The result showed that there

were significant ERDs at C3, but the alpha and beta ERD patterns were different among grasping forms. Around the task onset (-0.2 to 0.4 s), alpha and beta ERDs were commonly observed in all movements. In holding duration (1 to 1.5s), beta ERD was commonly disappeared. However ERD were intermittently observed in Pwr and Prc movements, but not in Itm. After holding duration (1.5 to 2.5 s), alpha and beta ERDs were similarly observed in Itm and Prc, but not in Pwr. These result suggest that ERD patterns in the motor cortex during grasping movements are different depending on its grasping forms.

Title: Effects of observing correct or incorrect motor plans on predictive force control during object lifting

Authors: *G. RENS[1], M. DAVARE[1,2]
[1]Dept. of Kinesiology, KU Leuven, Heverlee, Belgium; [2]Sobell Dept. of Motor Neurosci. and Movement Disorders, Inst. of Neurol., London, United Kingdom

Abstract: Recent studies have established that, when two individuals have to lift the same object sequentially, observation of lifting errors mediates perceptual weight judgement and enables the observer to update his internal object representation without actual sensorimotor experience. For example, observing an actor overestimate the force needed to lift an object allows the observer to subsequently downscale his fingertip forces to lift the object in a single and smooth motion. However, it is still unknown whether the observation of an accurately planned lift is also able to update these internal sensorimotor representations. Here, we tested this hypothesis by asking participants to perform a dyadic interaction task. Thirteen healthy volunteers were recruited to grasp and lift a manipulandum in alternation with an actor. Every 3rd to 6th trial performed by the actor the object weight changed unpredictably between either 2 or 6N. Participants were informed that (1) they would always lift the same weight as the actor did in the preceding trial and, (2) based on the task condition, the actor would perform either a skilful lift (accurately estimating object weight) or lifting errors (over- or underestimating object weight). Subjects were always required to lift objects as accurately as possible. First, when visuomotor cues were absent (task performed without actor), subjects made typical force overestimation or underestimation errors (both $p<0.001$) when object weight unpredictably switched from heavy to

light or light to heavy, respectively. Second, and in line with current literature, when observing the actor making these typical lifting force errors, subjects could accurately plan their fingertip forces according to the actual object weight (both $p<0.001$). Third, our results show that participants were also able to predict the actual object weight after observing accurately planned lifts but only for heavy ($p<0.001$) and not light objects (ns.). This highlights that predictive scaling of lifting forces is strongly mediated by observing sensorimotor errors but can also be driven by more subtle differences in observed visuomotor information. Altogether our results add to the current knowledge about the relative contribution of different visuomotor cues to predicting object weight for the control of skilled hand-object interactions.

Title: Force illusions caused by muscle vibration

Authors: C. CUADRA[1,2], S. RESCHECHTKO[1], *M. L. LATASH[1]
[1]Dept. of Kinesiology, Pennsylvania State Univ., University Park, PA; [2]Escuela Kinesiología, Facultad de Ciencias de la Rehabilitación, Univ. Andres Bello, Vina del Mar, Chile

Abstract: We used the hypothesis that the neural control of movement can be adequately described as the specifications of time patterns for spatial referent coordinates (RCs) of the effector, and that abundant afferent signals report on deviations of the effector from its RC. Within this hypothesis, perceptions of force and position are interrelated, so muscle vibration is expected to cause illusions of both position of and force produced by an effector. Vibration-induced position illusions have been well documented, but force illusions have not been reported; observing such illusions was the main goal of the study. To explore the generality of such illusions, we studied force matching by both dominant and non-dominant hand during accurate force production under visual feedback and also during unintentional force drifts caused by turning the visual feedback off. Subjects pressed with all four fingers of either hand on individual force sensors and used visual feedback to produce accurate steady force level with one hand. When visual feedback was turned off, the subjects were asked to continue producing the same force and to match the perceived force by pressing for a few seconds with the other hand. Vibration at 80 Hz was applied to extensor muscles in either or both forearms. Turning visual feedback off led to a slow decrease in force production. Vibration of the extensors reduced the

magnitude of the force drift. There was no time drift in the matching hand performance even as the force produced by the other hand decreased. Vibrating the forearm involved in the continuous task led to higher matching hand forces, while vibrating the forearm that performed the matching task led to lower matching hand forces. These effects suggest that force produced by the hand under vibration was consistently overestimated by the central nervous system. Taken together, our observations suggest that muscle vibration leads to changes not only in the sensory component of kinesthetic perception but also in the RC component: vibration of the extensors effectively pushed RC values into the direction of flexion. These observations support the scheme for kinesthetic perception based on the RC concept. They suggest that the force drift originates not at a hierarchically high task level (e.g., as a result of a drift in working memory), but at an intermediate level which is responsible for interactions between the hypothetical control variables (time-varying RCs) and feedback signals on current effector configuration.

Title: Cognitive agency in hand grasp performance - implications for rehabilitation

Authors: *R. NATARAJ
Biomed. Engin., Stevens Inst. of Technol., Hoboken, NJ

Abstract: Improving hand grasp function impaired by neuromuscular pathology is a critical objective in rehabilitating performance of activities of daily living. Standard rehabilitation protocols rely on the repetitive practice of grasp to better learn operation of an assistive device or re-formulate neuromotor connections. Virtual reality (VR) environments that heighten patient engagement have been utilized to accelerate training progress. But adapting a person's cognitive perception of the training to improve functional performance has not been thoroughly examined. Our objective is to develop a VR platform that investigates the role of cognitive agency in hand grasp performance. We hypothesize that improved grasp performance will be achieved with a greater sense of *agency*, the perception of being the "true author" of one's hand movements. Our methodology aims to systematically vary a subject's perception of agency over a computer hand and to observe the correlation with performance of grasp force and motion tasks. Demonstrating how individuals perform with greater agency will potentially provide a powerful basis for creating rehabilitation protocols that are more intuitive and more efficient. If the functional

connection between agency and performance is established, agency can be a highly viable criterion to optimize rehabilitation protocols that rely on repetitive task execution. Across repetitions, operational parameters of assistive devices or therapies such as non-invasive brain stimulation may be better adapted with the expressed purpose of maximizing agency-dependent performance. Such a test-bed can then be extended as a concept platform for more efficient movement rehabilitation following neuromuscular pathologies such as spinal cord injury, stroke, or upper-limb amputation. Related findings may facilitate more optimal parameters for controllers, generate greater motor gains with fewer practice repetitions, and better incorporate the user in device operation. Foundational methods could be employed towards improved development of exoskeletons, approaches using functional electrical stimulation, and sensory-feedback prostheses.

Title: Hierarchical organization of force and moment stabilizing synergies in the space of theoretical control variables

Authors: *S. RESCHECHTKO, M. L. LATASH
Dept. of Kinesiology, Pennsylvania State Univ., University Park, PA

Abstract: We used the theory of control with referent coordinates (RCs; Feldman 2015) and the framework of the uncontrolled manifold (UCM) hypothesis (Scholz and Schöner 1999) to study force- and moment-stabilizing synergies in the space of hypothetical control variables. These theoretical control variables were associated with referent coordinate (RC) and apparent stiffness (k) of the effector. We analyzed inter-trial co-variation of those variables during isometric multi-finger pressing tasks and drifts in such co-variation after visual feedback was turned off. Subjects performed isometric pressing tasks with the four fingers of the dominant hand during which they produced a precise combination of total force and supination moment. For the first 8 s of each trial, subjects received visual feedback on total force and moment. After the first 8 s, one of the following feedback schemes was imposed for the remaining 13 s of the trial: (1) no feedback was displayed; (2) only force feedback was displayed; (3) only moment feedback was displayed. RC

and k of each finger were recorded twice per trial by changing the location (AC) of all four fingertips using the “inverse piano” device (Martin et al. 2011) and measuring the resultant changes in force production (cf. Ambike et al. 2016). RC and k were recorded once during visual feedback (5 s after trial initiation) and once close to the end of the trial after visual feedback was manipulated. When feedback was removed, subjects displayed drifts in the variable(s) with missing feedback. Without feedback, total force decreased and total moment drifted into pronation values. UCM-based analysis of finger force variance showed that synergies stabilizing total force or total moment of force were strong under visual feedback but disappeared over the course of drifts in performance. Pairs of RC and k measured in different trials were matched via random permutation and the force values computed from these pairs yielded much more variable total force and moment than was observed in experimental conditions, even after performance drifts. The difference between inter-trial variability in force produced by permuted and actual {RC k} pairs was smaller, however, after such performance drifts. These results indicate that the CNS stabilizes performance by organizing synergies in the {RC k} space at the hand level as well as at the individual finger level. This stabilization is most effective under visual feedback, but it persists at the level of control variables even without visual feedback.

Title: Complexity of movements in humans with 6 fingered hands

Authors: *H. CHOI[1], M. BLÜHER[1], L. BASHFORD[1], A.-S. BUSCHHOFF[1], A. SERINO[2], M. AKSELROD[2], O. BLANKE[3], M. MACE[4], E. BURDET[4], C. MEHRING[1]
[1]Bernstein Ctr. Freiburg and Fac. of Biol., Albert Ludwigs Univ. of Freiburg, Freiburg Im Breisgau, Germany; [2]Dept. of Clin. Neuroscience, Lausanne Univ. Hosp. and Lab. of Cognitive Neurosthetics, Ctr. for Neuroprosthetics, Lausanne, Switzerland; [3]Lab. of Cognitive Neuroscience, Brain Mind Institute, Ctr. for Neuroprosthetics Sch. of Life Sci., EPFL, Lausanne and Univ. of Geneva, Geneva, Switzerland; [4]Dept. of Bioengineering, Imperial Col. of Science, Technol. and Med., London, United Kingdom

Abstract: Brains control body parts with many degrees of freedom (d.o.f.) to produce complex movements. How brains control multiple d.o.f. and can make use of the complexity of the effector space for movement is barely understood. Here we address the following questions:If the number of d.o.f. of the effector increases, can the human motor system use this additional complexity for purposeful movements? Or will the complexity of movement be limited due to

finite neural resources or limited complexity of neuronal computations?
As a case study to address this question, we compared the complexity of movement between 13 normal five-fingered subjects and 2 subjects with six-fingered hands, who had fully functional supernumerary fingers between thumb and index finger on both hands and fully functional regular fingers. Electromagnetic motion-capture sensors (12 and 14 for five and six fingered) were attached to their right hand and captured the hand movements during haptic exploration tasks and different real-world task (tying shoe laces, flipping book pages, origami and rolling a towel). In the haptic exploration task subjects were blindfolded and they were asked to explore one of 50 objects with diverse size and shape, to guess what it was.
Principal component analysis was performed and the number of components to explain 90% of the variance in the data was calculated. This value can be considered as an estimate of the effective d.o.f of the movements. Six-fingered hands required a significantly higher number of components (12 and 12 from 39 dimension of captured data), compared to five fingered subjects (8.4~10.5 from 33 dimensions 95% confidence interval).
We discretized the finger movements into 243 ($=3^5$, five fingered subjects) or 729($=3^6$, six fingered subjects) different action states where the movement of each finger was classified as either folding, unfolding or not moving. This enabled us to analyze the complexity of movements using information entropy. The joint entropy of six fingers (8.52 and 8.26 bits) was significantly larger than that of five fingered subjects (6.84±0.04 bits). Interestingly, the joint entropies were only 9.3%, 11.8% and 11.3% smaller than the sum of the independent entropy of the fingers (9.39, 9.36 and 7.71±0.02 bits).
Our results suggest that six-fingered individuals can produce more complex hand movements with more effective d.o.f. than five fingered individuals. This supports the idea that the human motor system can exploit the additional d.o.f. of six-fingered hands to increase the complexity of hand movements.

Title: Partial-gravity as an extended insight on the adaptive and learning mechanisms of the CNS during rhythmic arm movements

Authors: *L. OPSOMER[1], V. THÉATE[3], P. LEFEVRE[4], J.-L. THONNARD[2]
[1]Inst. of Neurosci., Univ. Catholique De Louvain, Bruxelles, Belgium; [2]Univ. Catholique De Louvain, Brussels, Belgium; [3]WOW Technol., Namur, Belgium; [4]ICTEAM and Inst. of Neuroscience, Univ. catholique de Louvain, Louvain-la-Neuve, Belgium

Abstract: Several studies have investigated the kinematics and dynamics of precision grip during cyclic movements of the arm in normal (1 g), micro- (0 g) and hyper- (1.8 g) gravity fields. These studies have highlighted the ability of the central nervous system (CNS) to adapt its internal predictive models to new environments (Augurelle et al., 2003; White et al., 2005) and the ability of subcortical central pattern generators (CPGs) to adapt the frequency of rhythmic movements to a new gravitational context (White et al., 2008). The objective of the present study was to extend these results by investigating the same movements when performed in partial-gravity environments during two partial-g parabolic flight campaigns. Fourteen subjects participated in the experiment. Six subjects were experienced with respect to exposure to micro-gravity whereas eight were not. Participants performed vertical oscillations of the extended arm with a manipulandum held in precision grip while being exposed to five different gravitational conditions: normal (1 g), micro- (0 g), Lunar (0.16 g), Martian (0.38 g) and hyper- (1.8 g) gravity. Two LEDs constrained the amplitude of the movements and the subjects chose the frequency that they considered most comfortable. Results showed that for most subjects, movement frequency increased as the gravity level increased, but that microgravity was a singular point, supporting previous results (White et al., 2008). For most of the subjects, the frequency remained stable within conditions from the first trials, suggesting that a low-level mechanism such as a subcortical CPG drives the movement frequency. We also investigated the evolution of the grip force (GF) according to the load force (LF) variations within each parabola and across parabolas. The analysis of the dynamics thereby provides a more comprehensive insight on the adaptive and learning mechanisms of the CNS when exposed to completely novel environment dynamics.

Title: Effects of a cognitive task on the grip force control in two manipulative tasks

Authors: *G. V. GOMES[1], P. B. FREITAS, Jr[2], B. CUNHA[3], S. M. FREITAS[4]
[1]Moviment Analysis Lab., Univ. Cidade De São Paulo, São Paulo, Brazil; [2]Univ. Cruzeiro do Sul, São Paulo, Brazil; [3]Cruzeiro Do Sul Univ., São Paulo, Brazil; [4]Univ. Cidade De Sao Paulo, Sao Paulo, Brazil

Abstract: In many everyday situations, we hold and/or carry an object while performing other motor or cognitive activities. The magnitude of grip force (GF), responsible for avoiding object slippage caused by a load force (LF), increased during simultaneous execution of a cognitive and a lifting and holding task. However, it is unknown whether there is influence of the cognitive task in GF and LF control and coordination during a cyclical manipulation task, with a higher level of automatization. To evaluate whether the execution of a cognitive task influences the GF and LF control and coordination during the execution of manipulation tasks involving sequential or cyclic movements. Fifteen right-handed, young and healthy adults performed two motor tasks consisting of i) grasping, lifting, and holding a 214 g instrumented object for 15 seconds; and ii) holding the object and moving it up and down continuously for about 20 centimeters at their preferred frequencies for 15 seconds. The tasks were performed in isolation or simultaneously to a cognitive task (dual task). The cognitive task was performed in isolation to verify whether performing a motor task simultaneously affects the performance on the cognitive task. The cognitive task was to recall the number of images of houses (5 per trial) in which either a ladder and garage, or a ladder and a car could be identified and to report the response verbally at the end of each trial. The results revealed that during the dual task the peak of GF during lifting and the averaged GF during holding were greater than when only the motor task was performed. Individuals were more conservative by increasing the GF magnitude in a predictive way when performing the sequential motor task simultaneously to a cognitive task. The results also revealed that the coefficient of cross-correlation between GF and LF was higher during the dual task condition in a cyclical manipulation task. Also, the errors in the cognitive task were higher when it was associated with the sequential manipulation task, but not during the cyclical manipulation task. These findings indicate that the cyclical manipulation task, unlike the sequential task, does not require attentional resources for its performance.

Title: Differential preparatory activity for reaching and grasping movements in area V6A of the macaque monkey

Authors: *P. FATTORI, E. SANTANDREA, R. BREVEGLIERI, A. BOSCO, C. GALLETTI
Univ. of Bologna, Bologna, Italy

Abstract: Over the years, electrophysiological recordings in macaque monkeys performing visuomotor tasks brought about accumulating evidence for the expression of several neuronal properties in the posterior parietal area V6A, including selectivity in the visuospatial and somatosensory domains, and encoding of visual affordances and motor cues. Altogether, these properties build an ideal neural substrate for allowing control of prehension. Moreover, pre-movement population activity in monkey V6A has been recently shown to convey grip-related information for upcoming grasping actions. Here we directly tested whether macaque V6A neurons encode preparatory signals specifically related to the arm/hand action to be performed, thus differentiating between dissimilar actions before movement onset. The activity of 85 V6A neurons was recorded from 2 monkeys (*Macaca fascicularis*) during the execution of two visuomotor tasks sharing the same spatio-temporal structure, in which the animals were instructed to perform either reaching or grasping movements. To control for any influence of visual information on pre-movement activity, tasks were carried out both in darkness and in light. In most V6A neurons, a selective task-related activity was expressed in anticipation of action execution, effectively differentiating between arm/hand movements aimed at reaching a specific location and arm/hand movements aimed at grasping a handle at the exact same location with appropriate wrist orientation and grip execution. Such action-specific pre-movement activity was expressed in more than half of V6A neurons in our dataset, either alone (*Task cells*, 26/85, 31%) or in combination with sensitivity for visual feedback (*Task/Background cells*, 21/85, 25%). Stronger pre-movement activity was observed more often in the grasping vs. reaching task (*Task cells*: 69% vs. 31%; *Task/Background cells*: 67% vs. 33%). Most importantly, we found striking consistency in neural discharges measured during pre-movement and movement epochs, suggesting that the former is a preparatory activity implementing suitable motor programs which support subsequent action execution. In sum, our findings support a role of V6A in planning and execution of prehensile actions (notably grasping), and strengthen the emerging view that areas in the dorsomedial and dorsolateral visual stream act as cooperating routes for controlling the whole act of prehension.

Title: Enhancement of force steadiness induced by synusoidal vibrotactile stimulation depends on contraction intensity

Authors: *C. M. GERMER, L. S. MOREIRA, L. A. ELIAS
Neural Engin. Res. Lab, DEB-FEE, UNICAMP, Campinas, Brazil

Abstract: Motor control studies have shown that an optimal level of additive noise on cutaneous mechanoreceptors improves motor performance and electrophysiological recordings in humans. The phenomenon behind these improvements seems to be the so-called stochastic resonance. As far as we know, the effects of contraction intensity on the improvement of force control induced by vibrotactile stimulation was not yet explored. The aim was to evaluate whether supra-threshold sinusoidal vibration applied to the skin improves motor performance during a force control task. Additionally, we aimed at investigating if contraction intensity affects this enhancement. Healthy young subjects (N=6, 4 males, 29±4 yr) performed a visually guided force-matching task, which consisted of an abduction of the non-dominant index finger. A mechanical vibration was delivered by a linear resonant actuator (f=175Hz) positioned at the proximal phalanx of the index finger. Subjects were asked to perform isometric contractions with the first dorsal interosseous muscle at three target levels: 5%, 10% and 15% of maximal voluntary contraction (MVC). Five trials of 30s were performed at each contraction intensity. In order to evaluate the effects of mechanical vibration, a random sequence of five supra-threshold stimuli (amplitude 0.05G to 1.5G) was applied at each trial and a control condition (i.e. no vibration, Ctrl) was also considered. Each vibration intensity lasted 4s. Force variability and precision were assessed by the coefficient of variation (CV) and root mean squared error from the target (RMSE), respectively. The vibration level at which the best performance was achieved was considered as the optimal stimulation (OS). The force CV decreased from 0.030±0.005 at 5%MVC to 0.018±0.002 ($p=0.0001$) and 0.019±0.003 ($p=0.0004$) at 10% and 15%MVC, respectively. Similarly, the RMSE was significantly smaller in 5%MVC (0.0022±0.0004) as compared with 10%MVC (0.0030±0.0003, $p=0.014$) and 15%MVC (0.0038±0.0004, $p<0.0001$). There was a significant difference between Ctrl and OS for the CV (0.025±0.005 vs.

0.020±0.003, p=0.01) as well as for the RMSE (0.0033±0.0005 vs. 0.0027±0.0004, p=0.02). At 5%MVC OS enhanced force CV by 29±10%, which was significantly higher than at 10%MVC (8±8%, p=0.02) but not than at 15%MVC (17±11%, p=0.2). However, albeit OS improved RMSE by ~15%, there was no statistical difference among the contraction intensities. These results suggest that supra-threshold sinusoidal vibrotactile stimulation with an appropriate level (different from zero) improves isometric force control, but the enhancement is higher during low-intensity contractions.

Title: Spatiotemporal profiles of neuromagnetic oscillatory changes related to the movement imitation

Authors: *H. SUGATA[1,2], M. HIRATA[2,3], Y. TAMURA[4], T. ARAKI[4], H. ONISHI[5], S. YORIFUJI[4]
[1]Fac. of Welfare and Hlth. Sci., Oita Univ., Oita, Japan; [2]Dept. of Neurosurg., [3]Dept. of Clin. Neuroengineering, [4]Div. of Functional Diagnos. Sci., Osaka Univ., Suita, Japan; [5]Dept. of Occup. Therapy, Osaka Prefecture Univ., Osaka, Japan

Abstract: Imitation is a higher-order processing of cognitive and motor functions organized by the central nervous system. This process requires an observation-execution matching system that transforms an observed action into an identical movement performed by the observer. Recent studies have demonstrated the involvement of oscillatory neural activities during imitation in low-frequency components such as the alpha and beta bands. Although the low-gamma band is thought to reflect higher cognitive processes, no studies have focused on it. In the present study, we used magnetoencephalography (MEG) to examine the frequency-dependent neural oscillatory changes not only in the alpha and beta bands but also in the low-gamma band during imitation. Twelve healthy, right-handed participants performed a finger task consisting of 4 conditions

(imitation, execution, observation, and rest). Under imitation and execution conditions, significant attenuations of oscillatory power [termed as event-related desynchronizations (ERDs)] were observed at the left frontal, central, and parietal MEG sensors in the alpha, beta, and low-gamma bands. Functional connectivity analysis using imaginary coherence exhibited an imitation-specific network in the front-central regions in the low-gamma band. Furthermore, synthetic aperture magnetometry (SAM) analysis showed significant ERDs in the low-gamma band at the left sensorimotor area and middle frontal gyrus (MFG) during the imitation condition as compared with those in other conditions. Our results suggest that the oscillatory neural activities of the low-gamma band at the sensorimotor area and MFG play an important role in the observation-execution matching system related to imitation.

Title: Perceptual and visuomotor tasks respectively adhere to and violate Weber's law in response to functionally graspable target objects

Authors: *J. MANZONE[1], M. PECORA[1], M. KHAN[1], S. DAVARPANAH JAZI[2,4], M. HEATH[1,3]
[1]Sch. of Kinesiology, [2]Dept. of Med. Biophysics, [3]Grad. Dept. in Neurosci., Western Univ., London, ON, Canada; [4]Lawson Hlth. Res. Inst., London, ON, Canada

Abstract: Within-participant variability of peak grip aperture provides a measure of just-noticeable-difference (JND) values that are used to address whether responses adhere to or violate the relative psychophysical properties of Weber's law. Evidence from our group indicate that open-loop grasping and perceptual size estimates (i.e., manual estimation) respectively violate and adhere to Weber's law - an indication of visual processing mediated via the dorsal and ventral visual stream. However, recent work has questioned the utility of Weber's law in concluding the neural correlates of actions when responding to objects that approach the biomechanical limits of our grip aperture. Specifically, Bruno et al. (2016: Neuropsychologia) reported that both visuomotor (i.e., open loop grasping) and perception based tasks (i.e., manual estimations) adhere to Weber's law at 'small' (5-20mm width), but violate the law at 'large' objects (40-120mm width) with the latter finding being attributing to the reduced biomechanical

freedom associated with aperture opening. It is important to note that the larger objects used may have exceeded the functionally graspable range of participants' grip aperture leading to artificial constraints on the associated JND values. Thus, in the present investigation participants performed a visuomotor (i.e., open-loop grasping) and two perceptual size estimation tasks on objects with widths that matched decile increments (i.e., 10-80%) of their specific maximal aperture separation. The open-loop grasping task required participants to reach-to-grasp objects while the perceptual size estimates required participants to match the long-axis of an object by either separating the distance between their thumb and forefinger (i.e., manual estimation task) or by adjusting the width of a computer-generated object on a screen (i.e., method of adjustment task). All tasks were completed without vision of the target object (i.e., in visual open loop conditions). Results showed that the visuomotor task produced a null scaling of JNDs to object size (i.e., violation of Weber's law) and perceptual size estimates produced JND/object size scaling (i.e., adherence to Weber's law) - a set of results incompatible with the biomechanical constraint hypothesis. Alternatively, our findings support the utility of Weber's law through the entire functional range of grip aperture separation and demonstrate absolute and relative processing of visuomotor and perceptual tasks, respectively.

Title: Self-reported sensory perception is related to precision grip force in healthy young adults

Authors: *J. TUCKER[1], A. MERIDA[1], C. R. DAHM[2], A. J. GROFF[2], P. WANG[2], N. M. ETTER[3], K. A. NEELY[2]
[1]Biomed. Engin., [2]Kinesiology, [3]Communication Sci. and Disorders, Pennsylvania State Univ. Univ. Park, University Park, PA

Abstract: Understanding the perception-action relationship is particularly relevant for the study of neurodevelopmental disorders. Our recent work reports subtle differences in grip force output in adults with and without ADHD (Neely et al., 2016, 2017). However, it is unknown whether

somatosensory deficits contributed to these differences. Thus, we sought to determine the relationship between grip force, tactile threshold estimates, and a trait measure of sensory processing in healthy young adults (N=20). In the motor task, participants produced force for 4 s separated by 2 s of rest, for a total of 5 trials in one 30-second block. Blocks were repeated 4 times and separated by 12 s of rest, for a total of 20 trials. Participants completed 7 target conditions from 5% to 50% of their maximum voluntary contraction. In the somatosensory task, tactile detection and discrimination threshold estimates were obtained for the right index finger, thumb, and hypothenar muscle region of the palm. Participants completed the Adolescent/Adult Sensory Profile (AASP), a trait measure of sensory processing comprised of self-report items related to everyday sensory experiences. The AASP is divided into four subscales based on Dunn's Model of Sensory Processing (1997): low registration, sensation seeking, sensory sensitivity, and sensation avoiding. We hypothesized force output would be related to somatosensory measures, but not AASP. To test this hypothesis, we conducted bivariate correlations between force output, tactile threshold estimates, and quadrant scores on the AASP. Force output variables included root mean square error, coefficient of variation, and rate of change from baseline to the target (rate-on) and from target to baseline (rate-off). Counter to our hypothesis, force output was not consistently correlated with somatosensory assessments, but was correlated with the AASP. Rate-on was correlated with sensation seeking, such that individuals with high sensation seeking scores were slower to reach the target on 5 of 7 conditions. Sensation seeking reflects characteristics such as the pursuit of sensory stimuli. Rate-off was correlated with low registration, such that individuals with low sensory registration scores elicited slower rates of change on all 7 conditions. Low registration scores relate to behaviors such as missing or responding slowly to stimuli. Our findings suggest these clinical somatosensory measures may not be sensitive enough to detect subtle differences in healthy young adults. High-precision methods are needed to identify subclinical traits associated with tactile feedback and grip force production in healthy young adults.

Title: Is learning encoded in the resting brain?

Authors: *A. HOOYMAN, J. KUTCH, S. BABIKIAN, C. WINSTEIN
USC, Los Angeles, CA

Abstract: Why do some people acquire a novel motor skill with relative ease and efficiency, while others struggle and eventually fail? There are reports of individuals who are unable to learn even after extensive practice (Brooks et al. 1995). Our long-term goal is to discover a simple, accurate and reliable brain biomarker of motor learning capability; this would promote development of personalized training programs to foster motor learning in athletic and rehabilitation settings. Our primary aim in this study is to determine if resting-state electroencephalography (rs-EEG) can be used to predict motor learning capability in non-disabled individuals. **Methods:** Nineteen non-disabled adults (8 females, mean age 25.7 +/- 2.8 yrs) participated. We used a discovery learning task to discriminate if participants can discover the movement strategy that governed task success. We adapted the Brooks' (1995) task--the objective is to use a thumb joystick to move a cursor from a start box to a stop box in $\leq$ 3 sec. Unknown to the participants, the coupling of joystick to cursor movement is determined through rate control, not typical position control. This required participants to search the environment for the right movement pattern. We measured their level of search by calculating the variance of the cursor movement during early performance. Participants practiced 200 trials of the task on Day 1 of the experiment and 50 retention trials on Day 2 (24 hours later). Prior to practice on Day 1, 5 min of rs-EEG were acquired using a 64 lead EEG cap. We used a support vector machine to determine which intercortical connectivity measures-previously recorded during pre-practice rs-EEG--were most predictive of early search. **Results:** Participants had a wide range of performance capabilities with some individuals capable of many successful trials and others with few to zero. However, the amount of search during early practice predicted the accuracy with which each participant could execute the task rule during late performance on Day 1 and retention on Day 2. Finally, the support vector machine demonstrated that connectivity between the contralateral dorsal prefrontal cortex and the contralateral orbitofrontal cortex were most predictive of early search. **Conclusion:** Together, these results demonstrate that rs-EEG can predict specific motor learning capability in young non-disabled adults.

Title: A direct effect of perception on action when grasping a cup

Authors: E. ROUNIS[1], V. VAN POLANEN[2], *M. DAVARE[4,3]
[1]Oxford Univ., Oxford, United Kingdom; [2]Fac. of Kinesiology and Rehabil. Sci., [3]KU Leuven, Leuven, Belgium; [4]Inst. of Neurol., London, United Kingdom

Abstract: Affordances represent features of an object that trigger specific actions. Here we tested whether the presence and orientation of a handle on a cup could bias grasping movements towards it in conditions where subjects were explicitly told to ignore the handle. We quantified the grip aperture profile of twelve healthy participants instructed to grasp a cup from its body while it either had no handle, a handle pointing towards, or away from the grasping hand (3 'move' conditions, with large grip aperture). To ensure the smaller grip aperture afforded by the handle was implicitly processed, we also interspersed trials in which participants had to grasp the cup from its handle or a handle not attached to a cup with a pinch grip. We found that grip aperture was modulated based on both the presence and orientation of the handle in the 'move' conditions. Specifically, grip aperture was smaller when the handle was present, and in particular when it was pointing towards the grasping hand compared to away from it. This suggests that the specific action elicited by an object's attribute can affect movement performance in a sustained manner throughout movement execution.

Title: Prior information triggers differential mirror activity in primary motor cortex of observers even in the absence of kinematic cues

Authors: *A. CRETU, K. RUDDY, M. GERMANN, N. WENDEROTH
Health, Sci. and Technol., Neural Control of Movement Lab., Zürich, Switzerland

Abstract: Observers are able to infer the action intentions of other people in a seemingly effortless way. Studies using transcranial magnetic stimulation (TMS) demonstrated that the observer's primary motor cortex (M1) becomes facilitated in a muscle-specific manner and that excitability changes are time-locked to the observed kinematics as movements unfold. However, when informative cues are available before an actor initiates the movement, anticipatory motor activity can be decoded from the observer's M1 even before grasping kinematics are visible. Here, we explored whether the muscle-specific modulations occurring in corticospinal activity depend on the type of cue appearing prior to action observation. Furthermore, we were interested in comparing the changes in corticospinal activity elicited when actions are preceded by colored

cues but movement kinematics are not shown at all. To investigate this question, we applied single-pulse TMS to M1 and measured motor-evoked potentials (MEPs) in the index (FDI) and little finger (ADM). Participants observed either whole-hand (WHG) or precision grasping (PG) action videos which were either fully visible or where grasp-specific kinematics were covered. Furthermore, each movement was preceded by an informative cue, which was associated with a certain grasp and which could be used for predicting the upcoming action, or a non-informative cue, which was neutral and could not be associated with any grasp type. To assess the grip-specific modulation present in M1, we compared the change in MEP amplitude across the two muscles, separately for each cue, video type and phase of movement. Our preliminary results show that changes in MEP amplitude are grip-specific when the observed movement kinematics are fully visible confirming previous results. Interestingly, when the grasping kinematics are covered, grip-specific modulation seems to be dependent on the cue type. This suggests that cortico-motor excitability measured in the observer's M1 exhibits grip specific modulation depending on the type of prior information participants receive about the upcoming grip type.

Title: Changes in brain activation patterns as a result of bilateral transfer of learning of a visuo-motor task

Authors: K. M. KIRBY[1,2], O. T. CARMICHAEL[2], *A. W. VAN GEMMERT[1]
[1]Kinesiology, Louisiana State Univ., Baton Rouge, LA; [2]Biomed. Imaging Ctr., Pennington Biomed. Res. Ctr., Baton Rouge, LA

Abstract: Previous research has shown that training a visuo-motor task with one limb results in performance improvements of the untrained contra-lateral limb (Pan & Van Gemmert, 2013). The performance improvements have been shown to be often asymmetrical, i.e., a greater amount of transfer from one limb to the other limb occurs than vice versa. Although some research has shown some changes in brain activation patterns as result of learning and bilateral transfer of learning, research into brain activation pattern changes as a result of the acquisition of fine motor tasks due to bilateral transfer has been sparse. The current study was designed to add to the limited amount of studies conducted to gain a better understanding of the neural and behavioral correlates of bilateral transfer of learning of a fine motor task. The experiment

required participants to learn a multidirectional point-to-point visually rotated movement task performed with one hand using a joystick. Baseline, acquisition, retention, and transfer tests of the task were all performed in a magnetic resonance imaging (MRI) machine while functional MRI (fMRI) data was acquired. As expected, the behavioral data showed that performance of both the trained and the untrained hand improved over the course of training. Preliminary imaging data showed that brain activation decreased in the frontal lobe over the course of training, while activation increased over the course of training in the occipital lobe. A similar pattern of brain activation changes was found when comparing data from the trained hand before and after training, and when comparing data from the untrained hand before and after training. Although these results are based on a limited amount of individuals and a thus a limited amount of scans, the findings suggest that performance improvements of a visuo-motor task are driven by similar brain activation patterns, no matter whether the improvement is the result of physical practice or not. Future analyses and research will be aimed at determining whether asymmetric transfer of learning performance coincides with asymmetric brain activation patterns.

Title: Visuomotor rotation to quantify the impact of vision on grip force control

Authors: *S. TOMA, M. SANTELLO
Sch. of Biol. and Hlth. Systems Engin., Arizona State Univ. - Tempe Campus, Tempe, AZ

Abstract: To prevent object from slipping during object lift, grip force is adjusted in synchrony to the load changes induced by hand motion. Due to unavoidable delays in detecting load force changes by the fingertips, the timing of grip force adjustments need to be planned ahead by the central nervous system with respect to a prediction of when peak load force will occur. This prediction depends on sensorimotor memory built through previously-experienced hand-object interactions. It has been proposed that vision is used before contact to estimate object dynamic, whereas somatosensory signals are used for task-related grip force modulation once the object starts to be manipulated. However, how these modalities might be integrated after contact is not well understood. Here we tested the hypothesis that the contribution of vision for grasp force control can extend beyond contact, and thus influence manipulation performance.
We asked participants to produce ballistic upward (UU) and downward (DD) movements with a

hand-held object while providing a 180°-rotated visual feedback of object motion. This was done to quantify the extent to which grip force would reflect visually- vs. haptically-based predictions of object motion. For the UU condition where the hand moves upward and visual feedback shows downward object motion (UD), we expected peak load force to occur either at the beginning or end of movement based on somatosensory or visual feedback, respectively, and the opposite for DD movements with visual feedback showing an upward object motion (DU). Time to peak grip force during the UD condition occurred later than in UU condition (0.43 ± 0.18 and 0.37 ± 0.12 movement time, respectively; $p < 0.05$) and earlier in DU than DD conditions (0.69 ± 0.13 and 0.76 ± 0.15 movement time, respectively; $p < 0.05$). By removing the effect of rotated feedback on arm kinematics and load force, we found that visual feedback of object motion caused significant changes in peak grip force timing (15% and 10% for UD and DU, respectively). We then quantified the relative weighting of visual and haptic feedback contributions by hypothesizing that changes in peak grip force timing result from a weighted linear combination of the time to peak load force inferred by visual and somatosensory feedback. Surprisingly, we found that the relative weight of vision was sensitive to the direction of visual feedback (0.20 and 0.15 for UD and DU, respectively). Taken together, our findings suggest that the role of vision for grip force control is not limited to the early stages of grasping. Moreover, the observed asymmetry in the influence of vision on grip force control suggests sensitivity to the task context.

Title: Transcutaneous multi-electrode array nerve stimulation for delayed hand fatigue

Authors: *H. SHIN[1,2], C. DAI[1,2], X. HU[1,2]
[1]Univ. of North Carolina At Chapel Hill, Chapel Hill, NC; [2]North Carolina State Univ., Raleigh, NC

Abstract: Loss of strength and control in the peripheral limbs is a common result of a neurological incident such as a stroke or spinal cord injury. Hand function is especially important for activities of daily living, and restoring hand function is an important focus in rehabilitation engineering. Functional electrical stimulation (FES) is a common technique used to restore the loss of function in paralyzed muscles, but it often leads to quick fatigue of the stimulated muscles. In this study, we examined the force sustainability of a transcutaneous multi-electrode nerve stimulation technique compared to that of a traditional FES technique. Individual load-

cells were attached to the four fingers to record the flexion force of each individual digit. An electrode array was applied on the skin over the ulnar and median nerves underneath the short head of the biceps brachii. Pairs of electrodes that resulted in finger motions were stimulated continuously for 10 minutes to record the change in force level over time. Peak finger force levels were matched with stimulation of the motor point directly over the corresponding finger flexor muscle. The force sustainability was calculated as the mean time it took to reduce to 50% of the original peak force level. Our results showed a prolonged delay in the decrease of the flexion force with the proximal nerve stimulation compared to the distal muscle belly stimulation. This technique has the potential for extending the usability of therapeutic and assistive rehabilitation devices, as well as resulting in decreased comfort.

Title: Postnatal motor cortex stroke alters development of the rubrospinal system and proprioceptive afferents

Authors: *P. T. WILLIAMS[1], J. R. BRANDENBURG[1], J. H. MARTIN[1,2]
[1]CUNY Sch. of Med., New York, NY; [2]Grad. Center, City Univ. of New York, New York, NY

Abstract: Cerebral palsy (CP) is a common developmental disorder caused by perinatal stroke. In unilateral CP the corticospinal system (CS) from the damaged cortex fails to develop strong contralateral spinal connections, and the CS from the less affected hemisphere develops bilateral spinal connections and leads to motor map impairments, behavioral deficits, and spasticity. The CS and the rubrospinal system (RS) are two key pathways for skilled limb control, and proprioceptive afferents (PA) provide feedback control. It is unknown if CS miswiring after stroke enhances or corrupts development of the RS or PAs. We addressed two questions: (1) Does motor cortex (M1) stroke alter development of the red nucleus (RN) motor map and pattern of rubrospinal tract (RST) terminations in the cervical spinal cord? (2) Does M1 stroke alter rate-dependent depression (RDD) of the H-reflex and cervical PA axon density. We studied these questions in cats, a species for which we have detailed information about the timing of development of the corticospinal tract, RST, and PAs. Our hypothesis is that M1 stroke produces adaptive augmented growth of the RST and expansion of the RN motor map on the ipsilesional side and maladaptive outgrowth of PAs, leading to hyperreflexia. To model CP, a unilateral

photothrombotic stroke (rose Bengal; 15 min 530 nm illumination) was induced in the forelimb region of M1 at postnatal week 5, a key period of CS and RS development in cats. We examined RST terminations in C8-T1 bilaterally. In terminal experiments at weeks 7-8, the RN motor maps on the ipsilesional and contralesional sides were examined and we assessed RDD of the flexor digiti quinti H-reflex. PAs were labeled with CTB, injected into wrist extensor compartments bilaterally. There was low lesion size variability. All animals showed a contralateral forelimb placing impairment, consistent with M1 lesion. The ipsilesional RN map was larger compared to controls. Surprisingly, the contralesional map was abnormally small with elevated thresholds compared with the ipsilesional side. We found dysregulation of the H-reflex on the contralesional side and an associated increase in PA density. These are the first results to show that CS lesion alters development of the RS and PAs and their functions. The diminished contralesional RS suggests the intact CS out competes the RS for access to spinal motor circuits. The outgrowth of PAs on the contralesional side suggest a maladaptive response leading to dysregulation of the H-reflex. The results highlight the challenge in developing therapeutic strategies for CP, that it is necessary to balance axonal outgrowth and strength across multiple motor and sensory systems.

Title: Age-related differences in white matter integrity and its association with measurements of grasping

Authors: *T. R. VANGBERG[1], O. VASYLENKO[2], S. A. CASTRO-CHAVIRA[2], M. M. GORECKA[2], K. WATERLOO[2], C. RODRIGUEZ-ARANDA[2]
[1]Univ. Hosp. of North Norway, Tromsø, Norway; [2]Dept. of Psychology, Univ. of Tromsø, Tromsø, Norway

Abstract: Background: Older subjects have difficulties in fine motor control of hand dexterity. Degeneration in the neuromuscular system combined with cognitive decline cause movements to become less efficient and slower on both hands during aging. Age-related changes in the CNS may be implicated in these declines. The aim of this study was to investigate the association between the microstructure of cerebral white matter and grasping parameters bilaterally in healthy young and older adults.
Materials: Healthy younger subjects (N=25, 14 males, age 23.0 y), and healthy elderly (N=52, 29 males, age 70.9 y) were tested with the Purdue Pegboard test and video recorded using Vicon

Motus to calculate movement times (MT) and kinematic parameters of grasping. Kinematics included path length, angle and linear and angular velocities. All subjects were right handed. Group differences were found in path length, mean angle and mean MT for grasping. These measurements were selected for each hand (6 in total) and used in the correlation with DTI indices. DTI scans were acquired on a 3T MR scanner. FA and MD maps were processed using tract based spatial statistics. Permutation based statistics were used to assess the association between DTI indices (FA and MD) and each of the kinematic variables, using age and gender as covariates.

Main findings:

• Association between mean path length and mean MT of left hand with FA and MD in left and right corticospinal tract (CST) (Figure).

• Interaction between group and mean time of left hand grasp and FA in the right anterior part of corpus callosum.

Discussion: Only left hand grasp parameters were associated with white matter diffusion indices, which suggests that longer travelled distance and slower movements performed with non-dominant hand are more dependent on age-related changes in the CST than well-learned movements performed with the dominant hand. Data suggest that old subjects primarily influence the association with DTI indices. The significant interaction is found in a region with crossing fibers and may be related to selective degeneration of specific tracts.

Title: Prolonged time to close the hand during fine grasping after spinal cord injury

Authors: *M. A. PEREZ[1,2], L. YUMING[1,2]
[1]Dept. of Neurolog. Surgery, The Miami Project to Cure Paralysis, Univ. of Miami, Miami, FL; [2]Bruce W. Carter Dept. of Veterans Affairs Med. Ctr., Miami, FL

Abstract: Most of our daily tasks involve reach-to-grasp movements with the arms. The extent to which reaching and grasping actions are affected in humans with chronic incomplete cervical spinal cord injury (SCI) remains poorly understood. Using kinematic analysis we measured arm acceleration (time between movement onset and peak arm velocity), hand opening (time between hand opening onset and maximum aperture size between the index finger and thumb) and closing (time between the maximum aperture size and grasp) and movement duration (time between reaction time and grasp) during unilateral self-paced reach-to-grasp movement to a small cylinder in individuals with SCI and age-matched controls. Asymmetries were found in muscle force between the arms of SCI participants, therefore, we refer to the stronger and weaker arm. We found that movement duration of each arm of SCI subjects was prolonged (stronger arm=1.2±1.9 s, weaker arm=1.3±2.6 s) compared with controls (1.0±0.8 s). Although all phases of the reach-to-grasp movement were prolonged in SCI participants compared with controls the increases in movement time were not equally distributed across the arms. Movement time remained similar between arms during arm acceleration (stronger arm=0.4±0.9 s, weaker arm=0.4±0.1 s) and hand opening (stronger arm=0.6±0.1 s, weaker arm=0.6±0.2 s) but it was largely increased during hand closing in the weaker (0.4±0.2 s) compared with the stronger (0.3±0.1 s) arm. Our findings indicate that the ability to grasp a small object is mostly altered at the time to close the hand and contact the object. Hand closing might represent a crucial time for the recovery of grasping following SCI.

Title: Neural information processing in motor control during aging

Authors: *S. DAUN[1,2], N. ROSJAT[2], S. POPOVYCH[1], L. LIU[1], B. WANG[2], T. TOTH[1], C. GREFKES[3,2], G. FINK[3,2]
[1]Univ. of Cologne, Koeln, Germany; [2]Forschungszentrum Juelich, Juelich, Germany; [3]Uniklinik Koeln, Koeln, Germany

Abstract: The interest in ageing-related changes of motor performance and the neural basis thereof are governed by the quest for more detailed insights into the possible reorganization of the key phases of an action. For this reason, it is apt and timely to study ageing-dependent effects on the neural organization of motor performance in more detail. The crucial point of such investigations is the study of both, amplitude and phase synchronization, key mechanisms underlying the coordination of distinct neural populations in shaping complex motor tasks.
In earlier EEG-studies on young and older adults, we found that when generating simple finger movements, *local* oscillations in the δ-θ frequencies over the primary motor (M1), the supplementary motor (SMA) and the pre-motor area (PM) exhibited robust phase locking prior to and during the movement. This phase locking represents a trigger of movement preparation and initiation and has no influence on motor performance. We further observed a decrease in post-movement β amplitude synchronization (PMBS) in the medial pre-frontal cortex (mPFC) of older subjects, which may affect the cognitive control of stimulus-induced motor tasks and thereby motor performance.
To further investigate the neural processes underlying age-related dependence of motor performance, we employed *inter-regional* phase-locking analysis by calculating the phase-locking values (PLVs) as well as dynamic causal modeling (DCM) from the EEG records of the two data sets mentioned above. Our analysis revealed significant PLV in both age groups in the δ-θ frequencies around movement onset. Invariant sub-networks were established by strong PLV between brain areas involved in the motor act, which were different in the two groups. Data suggest that older subjects compensate for the diminished contralateral M1 - SMA - ipsilateral PM connectivity during movement preparation and execution by establishing additional intra- and inter-hemispheric connections. The DCM analysis revealed a stronger negative coupling between the β amplitudes of the pre-frontal cortex (PFC) and the mPFC indicating that the strong over-activation of the PFC generally observed in older subjects might be causal for the decreased PMBS in the mPFC.
Based on the above findings, we built a mathematical model consisting of phase oscillators representing main regions of the motor network. This simple model is capable of reproducing the

effects of increased PLI and, independently of this, the effect of increased PLV between both regions.

Title: The influence of cerebellar transcranial direct stimulation on motor skill acquisition in a complex visuomotor task in parkinson's disease

Authors: *L. LIMA DE ALBUQUERQUE[1], K. M. FISCHER[1], S. JALENE[1], M. R. LANDERS[1], Z. A. RILEY[2], B. POSTON[1]
[1]Dept. of Kinesiology & Nutr. Sci., Univ. of Nevada, Las Vegas, Las Vegas, NV; [2]Indiana Univ. Purdue Univ. at Indianapolis, Indianapolis, IN

Abstract: Cerebellar transcranial direct current stimulation (c-tDCS) is a non-invasive brain stimulation technique that can improve motor performance in hand and arm tasks in young and old adults. However, the ability of c-tDCS to enhance motor performance in Parkinson’s disease (PD) is unknown. Therefore, the purpose was to determine the influence of c-tDCS on motor skill acquisition in a complex visuomotor tracking task in PD. The study was a double-blind, sham-controlled, between-subjects experimental design. Twenty individuals with PD were allocated to either a c-tDCS group or a SHAM stimulation group and each subject completed a single one hour experimental session. Subjects performed a maximal voluntary isometric (MVC) precision grip task and a submaximal visuomotor precision grip task (PGT; practice task) with their most affected hand while on their medications. The PGT involved matching a target sine wave (1 Hz; target force range: 5-35% of MVC) for trials lasting 30 seconds. For the PGT, a baseline block of 5 trials was performed followed by a practice block of 10 trials. The 10 trials were completed over a time course of 25 minutes, which corresponded to the c-tDCS or SHAM stimulation application periods. Anodal c-tDCS or SHAM stimulation was applied over the cerebellum ipsilateral to the primarily affected hand using stimulation parameters that have been proven effective in healthy populations (anode 3 cm to the right of the inion, cathode over the ipsilateral buccinator muscle, 2 mA current strength, 25 minutes stimulation duration) during the PGT practice trials. SHAM stimulation was applied in the same manner according to well-established blinding procedures in which the current was ramped up and down over a 60 second

period. The primary dependent measure of interest was the average force error, which was calculated as the difference in the force produced relative to the target force for each trial and trial block. The force error was similar in the baseline block (P = 0.836) and in the practice block (P = 0.868) for the two groups. The findings indicate that a single application of c-tDCS does not elicit greater improvements in motor skill acquisition compared to practice alone in a complex visuomotor tracking task in PD.

Title: Effects of aging on postural adjustments to visual perturbations during fast pointing

Authors: *Y. ZHANG[1,2], E. BRENNER[1], J. DUYSENS[2], S. VERSCHUEREN[2], J. B. J. SMEETS[1]
[1]Fac. of Behavioural and Movement Sci., Vrije Univ. Amsterdam, Amsterdam, Netherlands; [2]Fac. of Kinesiology and Rehabil. Sci., KU Leuven, Leuven, Belgium

Abstract: People can quickly adjust their goal-directed hand movement to an unexpected visual perturbation (a target displacement or background motion). An age-related decline in the ability to make the appropriate compensatory postural adjustments might make the manual adjustments of the elderly weaker than those of the young. A decreased resolution of vestibular and proprioceptive information might make their postural adjustments to visual perturbations stronger by making them give more weight to visual information. We therefore examined how aging would affect early manual adjustments and responses of the head and trunk to both types of perturbations, in terms of timing (response latencies) as well as intensity (lateral velocity). Sixteen young (28.3 ± 3.0 yrs) and sixteen elderly (73.9 ± 3.9 yrs) adults participated in our experiment. They were instructed to hit a target as accurately and fast as possible by moving their hand in the sagittal direction on a horizontal screen while standing. In some trials, the target jumped or the background moved in the lateral direction when the hand started to move. We found a similar pattern of manual responses for the young and the elderly, but for the elderly the latencies of the hand were 11 ms longer for both types of visual perturbations. For the elderly, the finger responded 121 ms after the target jump and 133 ms after the onset of background

motion. The response was about 40% smaller than the young for target jumps. The longer latencies for both types of perturbations were also observed for the upper and lower trunk. For the head, we found that neither groups responded to target jumps, but only to background motion. The response magnitude was much larger for the elderly. These results indicate that aging can delay hand responses, and can increase head responses to background motion.

Title: Changes in muscle activity secondary to a six-week hand training program using a novel concept rehabilitation device

Authors: A. PEPE[1], D. VASILIU[2], B. VOLLEBREGT[3], A. JAIN[4], K. REINIKKA[5], J. LAWRENCE-DEWAR[6], *V. B. JOHNSON[3]
[1]Carleton Univ., Ottawa, ON, Canada; [2]Independent Consultant, Thunder Bay, ON, Canada; [3]Lakehead Univ., Thunder Bay, ON, Canada; [4]SJCG, Thunder Bay, ON, Canada; [5]NOSM, Thunder Bay, ON, Canada; [6]TBRRI, Thunder Bay, ON, Canada

Abstract: Background & Purpose: Stroke significantly compromises independent finger function. As a result, muscle contraction pattern is altered, with finger and wrist extensor muscle activity inhibited by spasticity, in addition to tightness in the distal flexor muscles. Consequently, ability to perform activities of daily living is compromised. In recent years, the use of robotic devices for hand rehabilitation has garnered interest in the research and clinical community however costs limit their accessibility to patients. This study examined the efficacy of an innovative, low-cost, passive hand rehabilitation device and a custom-structured hand training program designed to improve muscle function in stroke survivors.
Methods: Eight participants (three females) who were at least five months' post-stroke underwent a six-week training program consisting of 18, one-hour classes with a novel hand rehabilitation device. Force, range of motion, speed of contraction and coordination were randomly altered throughout the training process; while visual observation of the on-going task

was prevented to enhance proprioceptive inputs to the cerebellum and cortex. EMG was collected both pre- and post-training from eight muscles, while participants grasped the device to a pre-set resistance, isometrically, for a duration of 30 seconds. The root mean square (RMS) values of the period of muscle contraction were measured. A mixed-groups factorial ANOVA using the LSD procedure (alpha = .05) was used to determine differences between the pre- and post-training program assessments.
Results: A main effect was observed for both muscle ($F_7 = 48.345$, $p < .000$) and time ($F1 = 5.932$, $p = .015$). An interaction effect was observed for the muscle by time factor ($F7 = 2.769$, $p < .008$). This indicated that there was a net decrease in EMG-RMS values over time between pre- and post-training. Pairwise comparisons revealed significant decrease in RMS values for the first dorsal interossei and flexor policis brevis ($p < .05$).
Conclusions: These results suggest that the six-week hand training program resulted in an altered muscle contraction pattern, as observed by a decrease in EMG-RMS values in muscles essential to performing grasp function, accompanied by decreases in proximal muscles that were non-essential to performing grasp function, thereby altering patterns that control hand function. This pilot study provides promising results for the newly designed passive device and the hand function training program. However, results require further testing in a larger population in order to generalize these results.

Title: The effects of daily activity on the age-related decline in finger motor function

Authors: *T. AOKI
Prefectural Uni of Kumamoto, Kumamoto-city, Japan

Abstract: Purpose: The purpose of the present study was to compare the finger motor function between elderly who were determined to be active for the use of hands in their daily lives (ex. playing musical instruments) (“active elderly subjects”) and who were determined to be inactive in hand use. Methods: Eight active elderly and 9 inactive elderly subjects performed maximum frequency tapping by the index, middle, ring or little finger (single-finger tapping) and with alternate movements of the index-middle, middle-ring or ring-little finger-pair (double-finger tapping). The maximum flexion or extension force by each finger, tactile sensitivity of each fingertip, and time taken to complete a pegboard test were also measured. Results: Compared with the inactive elderly subjects, the active elderly subjects had significantly faster tapping rates in the ring finger in the single-finger tapping and the middle-ring finger-pair in the double-finger tapping. There was no significant group difference in the maximum flexion and extension forces of all fingers, the tactile sensitivities of all fingers and in the pegboard test. Conclusion: Maximum rate of finger tapping was faster in the active elderly subjects compared to the inactive elderly subjects. Thus, the daily activity in elderly adults can be effective in preventing aging in finger motor function evaluated by the tapping test.

Title: Cortical motor control of reeler mice

Authors: *M. NISHIBE[1], T. YAMASHITA[2]
[1]Osaka University,, Osaka, Japan; [2]Osaka Univ., Osaka, Japan

Abstract: The *reeler* homozygous mutants inherently exhibit disorderly positioned corticospinal neurons compared to layered cortical descending projections in a typically developed mouse. The present study investigated the consequence of such a developmentally disrupted cortical lamination on the forelimb motor control in the reeler model, using the neurophysiological, histological and quantitative measures. Using intracortical microstimulation (ICMS), we found evident consequence of the disordered lamina in the mutants, requiring a higher electrical current

to evoke skeletal muscle movements. The current threshold was yielded to be 66.17±8.86μA and 276±73.67μA for the WT and mutants, respectively. No cortical layer-dependency of the threshold alternation may be reported statistically. Upon using different stimulation upper-limits for each group, resulting body representation organization and areal measures were similar. Quantitatively, no significance was detected in the area representing elbow and wrist movements of the reeler (1.37±0.198 mm^2) from that of the WT (1.0±0.09mm^2). Meanwhile no morphological abnormality was observed in the neuromuscular junction (i.e. structure of the acetylcholine receptor) when examined by the immunohistochemistry. Nor the level of choline acetyltransferase was altered when quantified by the western blot. Thus, the functional level of reeler peripheral motor system was comparable to that of the control. Our findings suggest that the mammalian lamina formation represents necessity for proper cortical descending transmission even when the peripheral motor function may be preserved.

Title: A novel method for the prediction of decreased motor performances in the elderly using handwriting characteristics

Authors: *Y. HOSOKAWA[1], K. WATANABE[2], T. WATANABE[2], E. TANAKA[2], T. ANME[2], H. KAWAGUCHI[1]
[1]Toyo Univ., Gunma, Japan; [2]Univ. of Tsukuba, Ibaraki, Japan

Abstract: We aimed to establish a simple quantitative method for the prediction of decreased motor performances in the elderly by analyzing their handwriting characteristics using a digital pen. This device, which digitizes handwriting with resolutions of 0.3 mm and 13 ms, can easily and simultaneously acquire data from many users. Therefore, the digital pen is suitable to screen for the decrease in the motor performances in the elderly.
In total, 138 elderly people (age: 55–92 years; 10 men and 128 women) were recruited for a follow-up cohort study conducted over 4 years (2013, 2014, and 2016) as a part of the Joso project (Elderly People Health Empowerment Project in Joso city, Ibaraki Prefecture, Japan). This project was conducted in cooperation with Joso city, the University of Tsukuba, and Toyo University. The participants were required to complete three questionnaires: lifestyle, basic checklist, and motor fitness scale. These questionnaires included both drawing a figure and the "risk of fall" subscale. The participant's physical and motor functions were also reviewed using parameters such as height, weight, muscle mass, fat mass, blood pressure, abdominal girth, and

grasping power and the one-leg stand test and timed up and go (TUG) test results. Several handwriting characteristics, including writing speed, acceleration of writing speed, stroke range, and writing pressure, were analyzed.
A significant correlation was observed between the acceleration of writing speed and the grip strength in young–old people (age < 74 years, $r = 0.44$, $p < 0.05$). However, a negative correlation was observed between the writing speed and the TUG test result in old–old people (age > 75 years, $r = -0.54$, $p < 0.10$). This implied that people with a higher writing speed exhibited a shorter time in the TUG test result, i.e., they were good at performing complex exercises. Because a significant correlation was observed between the writing speed and the systolic blood pressure in young–old people ($r = 0.35$, $p = 0.10$), we analyzed the systolic blood pressure using binomial logistic analysis. We observed that the writing speed in the first year was significantly associated with the increase in the systolic blood pressure in the fourth year ($p < 0.01$). Some reports have suggested that there is a relationship between an increase in the systolic blood pressure and a decrease in the muscle mass. Therefore, the analysis of writing speed can be useful in the prediction of decreased muscle mass in the elderly. These evaluations might be efficient in maintaining the quality of life in the elderly.
The protocols used in this study were approved by the Ethics Committee of the University of Tsukuba.

Title: Abnormal electroencephalographic oscillations in β and low γ bands in patients with writer's cramp

Authors: *G. CISOTTO[1], K. KITA[2], K. UEHARA[3], K. YOSHINAGA[4], Y. HASHIMOTO[6], T. SAKAMOTO[5], J. USHIBA[7], T. HANAKAWA[8]
[1]Univ. of Padua, Padova, Italy; [2]Chiba Univ., Chiba, Japan; [3]Neural Control of Movement laboratory, Sch. of Biol. and Hlth. Systems, Arizona State Univ., Tempe, AZ; [4]Natl. Ctr. of Neurol. and Psychiatry, Kodaira-Shi, Japan; [5]Natl. Ctr. of Neurol. and Psychiatry, Kodaira, Japan; [6]Kitami Inst. of Technol., Hokkaido, Japan; [7]Keio Univ., Kanagawa, Japan; [8]Natl. Ctr. Neurol & Psych, Kodaira, Japan

Abstract: Writer's cramp is a task-specific focal hand dystonia causing involuntary twitching of muscles preventing patients from writing. Electrophysiological and imaging studies have

identified manifold pathophysiology, including loss of inhibition, exaggerated excitability and deficient sensorimotor integration. As a biomarker of altered sensorimotor processing, abnormal oscillations in electroencephalography (EEG) have been observed during several kinds of tasks. However, recent studies suggested a relevant role of EEG oscillations in other frequency bands, e.g. θ and γ, in the pathophysiology of the disease. The aim of the present study was to explore abnormal EEG oscillations in all frequency bands during the accomplishment of a pen-holding task in writer's cramp. Movement-related EEG (de)synchronization was computed in the 5-45 Hz range in a group of eight patients compared with a group of eight healthy subjects. Between-group comparison of reaction times revealed no significant differences either for movement onset or offset. A robust cluster-based statistical procedure allowed us to identify a few time-frequency bins of EEG oscillations that showed significant between-group differences. First, patients produced smaller and delayed 23-28 Hz desynchronization at the pre-movement period. Second, reduced 13-34 Hz synchronization was seen at the termination of the task in patients. Finally, we for the first time identified 28-45 Hz (low γ band) desynchronization in patients during the execution of movement where healthy subjects showed clear synchronization. As β-band (around 20 Hz) oscillations have been associated with the information flow from the brain to the periphery (i.e. the muscles), impairment at this frequency band has been explained by pathological processes in the cortico-spinal tract, as suggested by previous transcranial magnetic stimulation studies on focal hand dystonia. On the contrary, low γ band has been shown to mainly carry sensory information - locally - within the sensorimotor circuit; consequently, abnormalities of this frequency band can relate to the impaired sensorimotor integration in patients, as previously suggested by means of other electrophysiological techniques. Overall, we provided a revised view about abnormal patterns of EEG oscillations in writer's cramp. Patients with writer's cramp showed abnormal EEG oscillations of both β band (around 20 Hz) and low γ band (30-45 Hz), which appeared at different timings relative to the movement onset and offset. These complex time-frequency EEG abnormal patterns could be further exploited in the future for the design of a new intervention for writer's cramp patients.

Title: Common neural substrates support visually guided force control and working memory in healthy older adults

Authors: *K. A. NEELY[1], K. A. KURKELA[2], J. T. GOODMAN[2], S. SAMIMY[1], S. L. BLOUCH[1], A. CHENNAVASIN[3], M. T. DIAZ[2], N. A. DENNIS[2]

Abstract: Advancing age is accompanied by deficits in motor control and cognition that may compromise activities of daily living such as driving, social interaction, and maintaining a daily schedule. Recent work from our group suggests that force control may rely on working memory (Neely et al., 2016, in press). In this study, we sought to determine the overlap in neural activation supporting visually guided force control and working memory in healthy older adults. Further, we aimed to determine whether these tasks elicit similar patterns of increasing neural activity as a function of increasing task demands. To test whether functional activity was domain-specific, a verbal fluency task was included to control for age-related increases in activation associated with task difficulty. Participants (N = 27, ages 60-85) completed three levels of difficulty in each of three tasks (motor, memory, verbal fluency) in one neuroimaging session. In the visually guided force task, difficulty was operationalized by level of target amplitude predictability. In the easy, "static" task, participants produced constant force for 30s to a predictable target. In the medium, "dynamic-same" task, participants produced 2s force pulses separated by 1s of rest to a predictable target. In the difficult, "dynamic-different" task, participants produced 2s force pulses separated by 1s of rest to an unpredictable target. In the working memory task, difficulty was operationalized by a standard n-back task with three conditions: 0-back, 1-back, and 2-back. In the verbal fluency task, difficultly was operationalized by increasing the lexical frequency of the visual stimuli to give rise to three conditions: high, medium, and low lexical frequency. Task difficulty was nested in a blocked-design paradigm consisting of alternating task and rest intervals. A task versus baseline contrast demonstrated that task-relevant brain regions were active during each task. Linear trends related to increasing task difficulty were obtained by modeling each task block using a linear parametric analysis. Subsequently, we employed a conjunction analysis to identify voxels that linearly increased in activity with increasing task difficulty across tasks. The results revealed that no voxels linearly increased as a function of difficulty across all three tasks. However, several areas of overlap were revealed for the motor and memory tasks, including activation in bilateral premotor cortex, right dorsolateral prefrontal cortex, and left supramarginal gyrus. Overlapping activation across the motor and memory tasks supports our hypothesis that both tasks rely on similar neural substrates in healthy older adults.

Title: Grip force control during different manipulative tasks in individuals with diabetic peripheral neuropathy

Authors: *K. C. LIMA[1], G. O. C. SANTOS[3], S. S. V. DONATO[3], P. B. DE FREITAS, JR[2]
[1]Univ. Cruzeiro Do Sul, São Paulo, Brazil; [2]Univ. Cruzeiro Do Sul, Sao Paulo, Brazil; [3]Univ. Cruzeiro do Sul, Sao Paulo, Brazil

Abstract: The diabetic peripheral neuropathy (DPN) impairs function mainly due to the reduction of sensory input from the feet and especially of the hands. During manipulative tasks, the control system based on somatosensory memory and afferent information from skin receptors (i.e., faster and lower adaptation mechanoreceptors), sets relatively high grip force (GF) than the minimum required to hold the object (safety margin - SM). Recently, our studies showed that DPN reduced the SM compared to healthy individuals during a simple holding task. Whereas we expect the same reduced SM in others more complex tasks (e.g., lifting and oscillation), it is still unknown if other phases that precede or compete with the hold phase the same reduced SM will be seen in DPN individuals. To test this hypothesis, we selected 12 individuals with DPN and compared to 12 healthy individuals (65±1.3 YO) to participate in this study. Firstly, we evaluated cutaneous sensitivity of the five fingers from the dominant hand using the Semmes-Weinstein monofilaments. Next, participants were asked (1) to hold a 6.39 N heavy handle covered with sandpaper (320 grit), using multi-digit grasp, during 10 s and release the handle by slowly opening their digits until slippage; (2) hold and lifting the same object ~5 cm above the table during 22 s; (3) hold and shaking (oscillation task) the same object during 15 s at 1Hz of the frequency. In the first task, the GF mean (GFh) from the holding phase and, the minimum amount of GF needed to hold the object (GFmin) and the relative SM (SMrel) from the slippage phase were calculated [SMrel=100*((GFh-GFmin)/GFmin)]. After, the same equation was used to calculated the SMrel during the lifting and oscillation task. As expected, DPN individuals presented moderate sensory loss in the tip of the digits. Regarding the manipulative tasks, the DPN individuals showed lower SMrel than healthy individuals (91±50% and 181±53% of GFmin, respectively) only during the holding task, showing similar performance in the lifting (224±112% and 287±156%) and oscillation tasks (242±21% and 232±25%), respectively. These results lead us to reject the hypothesis that DPN individuals would set lower SM than controls in more complex manipulative tasks. Apparently, the moderate sensory loss is sufficient to drive the system to an error of GF estimation needed to hold an object, only when the peripheral stimulus is lower and stable (e.g., holding task). When peripheral information is large enough

(i.e., lifting and oscillation tasks), the control system is able to obtain the information and adopt similar strategies of the GF control, maintaining a stable and similar SMrel between DPN and healthy individuals.

Title: Carpal Tunnel Syndrome intervened with the sensorimotor learning process in unconstrained grip tasks

Authors: *W. ZHANG[1], B. SCHMITT[1,2], M. SANTELLO[3]
[1]Dept. of Physical Therapy, City Univ. of New York / CSI, Staten Island, NY; [2]Dept. of Biol. Engin. Compiègne Univ. of Technol., Sorbonne Univ., Compiègne, France; [3]Sch. of Biol. and Hlth. Systems Engin., Arizona State Univ., Tempe, AZ

Abstract: Carpal tunnel syndrome (CTS) is a compression neuropathy of the median nerve leading to sensory deficits in the affected digits (thumb, index, middle, and the radial half of the ring finger). Our previous work has also revealed motor deficits during manual tasks in CTS patients including excessive large grip force production in whole-hand grasping (Zhang et. al., 2011), reduced ability to modulate digit forces to object mass and mass distribution (Zhang et. al., 2012), and deficits in coordination of CTS-affected and nonaffected digits when engaged in different grip types (Zhang et. al., 2013). The present study was designed to investigate the effect of CTS on anticipatory force control by using a grip device that does not constrain digit position on the object. Ten CTS patients and ten age and gendermatched healthy controls were instructed to grasp, lift, hold and replace a grip device as straight as possible by using either thumb and index finger (2D grip) or all digits (2D and 5D grip, respectively). A hidden weight (200 g) inserted underneath the grip device was used to shift the object center of mass (CM) towards the thumb or finger side (TCM and FCM), respectively. Subjects performed 10 consecutive lifts in each CM condition per grip type (40 trials total). We measured digit forces exerted by the thumb and fingers, as well as object kinematics. Experimental variables were extracted at the time of object lift onset to quantify trial-to-trial learning of anticipatory multi-digit force control. We

found that CTS patients exhibited deficits in multidigit modulation compared with healthy controls, but only early in the early learning stage (trials 23). Moreover, these deficits were found only for grip types that combined CTS-affected and non-affected digits. Specifically, CTS patients exhibited similar grip force to controls, but smaller compensatory moments in 5D at Trial 3 ($P<0.01$) and larger antagonist moment in 5D at Trial 23 ($P<0.05$). These findings suggest that (a) somatosensory deficits induced by CTS may delay sensorimotor learning of hand-object interactions; (b) multi-digit grasping at unconstrained contacts may allow CTS patients to reduce excessive grip force production during manipulations in activities of daily living; and (c) previously reported deficits using CTS-affected and non-affected digits may be due to the greater muscle co contraction than grips using CTS-affected digits only, two or three-digit grips.

Title: Recovered hand function in chronic stroke is related to task based contralesional M1 activity independent of the integrity of lesioned M1 and CST

Authors: *K. P. REVILL[1], J. J. FREEMAN[1], G. M. KOWALSKI[1], M. PIFER[2], M. W. HAUT[2], S. R. BELAGAJE[1], C. M. BUETEFISCH[1]
[1]Emory Univ., Atlanta, GA; [2]West Virginia Univ., Morgantown, WV

Abstract: Stroke often impacts the integrity of primary motor cortex (M1) and its corticospinal projections, resulting in incomplete recovery of hand function. The neuronal substrate supporting hand function in the chronic phase of stroke is not well understood. Abnormally increased activity of contralesional M1 (cM1) is consistently reported in task based fMRI studies of stroke patients moving their affected hand, but its relationship to recovered hand function is still unclear. Here we test the hypothesis that recovered hand function is related to cM1 activity depending on the integrity of ipsilesional M1 (iM1) and CST. Twenty patients (9M, age = 61.7 ± 11.4 years, months since stroke = 31.7 ± 33.0) with partially recovered hand function following stroke involving either M1 or its corticospinal projections completed two runs of cued wrist

extension movements with the affected hand during functional scanning. A single run of eyes-open resting state data was also collected from 19 of the patients. Recovered hand function was assessed with the Jebsen Taylor Test (JTT) and by measuring the peak acceleration of wrist extension movements. Ipsilesional M1 thickness and corticospinal tract (CST) fractional anisotropy (FA) were measured to assess their structural integrity. ROIs were created using the Juelich atlas of motor areas, intersected with the subject's lesion mask where appropriate. Percent signal change (PSC) in the wrist extension task relative to rest was extracted for each ROI. Both measures of hand function (JTT, peak acceleration) were significantly correlated with task activation in cM1. Higher PSC in cM1 was associated with slower peak wrist acceleration and poorer performance on the JTT, even when age was included as a covariate, but iM1 thickness and CST FA did not contribute significantly when included as regressors. We also explored whether task based cM1 activity was related to resting state connectivity between iM1 and cM1. The iM1 seed was created by intersecting the atlas-based iM1 mask with the task based functional activation mask. The amount of correlation between iM1 and cM1 was marginally related to cM1 activity, where patients with a higher iM1-cM1 correlation at rest had more cM1 activity (higher PSC) during the wrist extension task. Our results indicate that in the chronic phase of stroke with injury to M1 or its corticospinal projections, the extent of cM1 activity correlates inversely with recovered hand function independently of the structural integrity of M1 or CST as measured by MRI of the lesioned hemisphere.

Cidade de São Paulo, São Paulo, Brazil; [5]Univ. Cidade de São Paulo, São PAulo, Brazil; [6]Univ. Cidade De Sao Paulo, Sao Paulo, Brazil

Abstract: Individuals with Parkinson's disease (PD) present several motor impairments that can negatively affect the performance of hand function during daily tasks. The Jebsen and Taylor

hand function test (JTHFT), a clinical test used to characterize the global hand function. Archimedes spiral drawing (ASD) task is generally used to assess the tremor of PD individuals, but if this task could also be used to examine other characteristics of the hand function is still unknown. Therefore, the aim of the present study was to examine the relationship between the performances in the ASD task and the JTHFT of individuals with PD. Twenty-eight subjects, 14 with PD and 14 healthy individuals, right-handed individuals were evaluated. The subjects with PD performed the evaluation under the 'ON' medication and were Hoehn and Yahr stage I and III. Participants performed three trials of ASD task over a digitalizing tablet and one trial of each task of the JTHFT. The order of applied tests was randomized and half of the participants started the tasks with the right hand (dominant) and the other with the left hand. The times to complete the JTHFT tasks and the ASD were recorded. For ASD analysis were also assessed the total displacement (TD) and the displacement and velocity for the anterior-posterior (respectively, Dap and Vap) and medial lateral (respectively, Dml and Vml) directions. Analyzes of variance (ANOVA) were carried for comparison between groups and hands. Pearson's correlations were also carried. The significance value was maintained at 0.05. The time to perform the JTHFT differed between hands and groups and the ASD differed between groups. Interaction was also observed for the variable speed in the ASD. Relation between the JTHFT and ASD was not observed. These findings suggested that although there is no relationship between JTHFT and ASD, both tests are useful for assessing and describing the impairment of the hand function of PD individuals. However, the JTHFT could be a better option as it is more practical for clinical.

Title: Dynamic neural oscillations in the primary motor cortex during retention of motor adaptation

Authors: *F. MAWASE, S. UEHARA, K. CHERRY-ALLEN, P. CELNIK
Physical Med. and Rehabil., Johns Hopkins Sch. of Med., Baltimore, MD

Abstract: Long-term retention is one of the critical processes of motor learning. Indeed, retention plays an important role in preserving the practiced skill. Neurophysiological and brain imaging evidence suggests that the primary motor cortex (M1) is involved in the formation and

retention of motor memories. We, however, know little about the neural oscillatory and the temporal neural dynamics associated with long-term motor retention. Here, we utilized the high temporal resolution of human electroencephalography (EEG) to investigate the oscillatory dynamics in M1 during retention of recently learned adaptation task. We recorded EEG from M1 in 19 healthy human participants during different learning phases of a visuomotor adaptation task, over two consecutive days. On the first day, participants performed three blocks. In the first block (Rest 1), we recorded brain activity while participants rested for 1 minute. In the second block (Baseline), participants performed rapid reaching movements toward visual targets with full feedback of the cursor. In the third block (Adaptation), participants adapted to a visuomotor perturbation in which the visual curser was shifted 30° relative to their hand. On the second day, which took place 24 hours later, participants performed four additional blocks. In the first block (Rest 2), we recorded brain activity during a minute of rest. In the second block (Retention), participants performed reaching movement with no curser feedback. The absence of feedback allowed us to probe the magnitude of retention per se. In the third block (Washout), participants performed reaching movement with full feedback of the unperturbed cursor. In the last block (Re-adaptation), participants re-adapted to the same visuomotor perturbation as in the first day. For analysis, movements were divided into pre-movement (a time window of 250 ms before movement onset to movement onset) and execution phases (a time window of 250 ms after movement onset). In the temporal domain, we measured event-related potentiation (ERP) locked to movement onset. In the frequency domain, we focused on the power of β [12-30 Hz] and γ [31-85 Hz] oscillations as they have been shown to correlate with voluntary movements and learning processes.We observed increased pre-movement β and γ power during the Retention block compared to Baseline. During movement execution, we observed reduced β activity. We also observed increase in motor event-related responses associated with pre-movement. These data suggest that change in M1 beta and gamma oscillations during retention might be related to retrieval or recall of recently acquired motor memory.

Title: Individual differences in adaptation learning are linked to dynamic changes in functional brain states

Authors: *J. Y. NASHED[1], D. STANDAGE[2], J. FLANAGAN[2], J. P. GALLIVAN[2]
[1]Ctr. for Neurosci. Studies, [2]Queen's Univ., Kingston, ON, Canada

Abstract: Learning a new motor skill frequently involves a progression from an initial adaptation stage, which is often error-riddled and highly cognitively demanding, to a less effortful stage marked by an increase in task success. These changes in motor performance are presumed to be mediated by complex interactions between various brain regions and circuits that are continuously changing over multiple time scales. However, our current understanding of the temporal evolution of brain networks over the course of learning and how these relate to behavioural performance remains sparse. Here, using functional MRI (fMRI), we investigated dynamic changes in coupling strength between brain areas and the expression of discrete brain configurations while subjects learned a visuomotor task, from its initial adaptation stages through to plateaus in performance. In accordance with prior work on sequence-based learning (Bassett et al., 2014), we predicted that the recruitment and organization of functional brain networks will change during task performance and that particular features of these dynamics will be correlated to subjects' learning parameters. Twenty-seven subjects, during one continuous fMRI acquisition, performed a visuomotor task that required movement of a cursor from a center target to one of eight possible peripheral targets using a small joystick. After 120 trials, a 45 degree visuomotor rotation--where feedback of the hand cursor was rotated with respect to the hand--was introduced and maintained for another 320 trials. Learning rates for each subject were determined by fitting their movement errors over time with an exponential function. Our analysis of the corresponding fMRI data revealed that although the repertoire of functional brain states was largely preserved across subjects, state-specific temporal features, such as the frequency of expression and number of transitions into particular states, were strongly correlated with task performance. In particular, we found that faster learning rates during initial exposure to the visuomotor rotation were associated with greater connection strengths between visual and sensorimotor areas. Similarly, the frequency of other functional network configurations were also found to be correlated with better initial learning in participants. Together, these results show that individual differences in motor learning is related to dynamic changes in brain network organization and suggest that visuomotor adaptation involves modification of functional coupling strengths between widely distributed brain regions.

Title: Reduction in motor evoked potentials following somatosensory perceptual training

Authors: *M. DARAINY, T. F. MANNING, D. J. OSTRY
McGill Univ., Montreal, QC, Canada

Abstract: It has been recently shown that perceptual training—passive arm movement in conjunction with a perceptual discrimination task with feedback, results in an improvement in both the rate and extent of a subsequent sensorimotor adaptation task (Darainy et al. 2013). In a related experiment, a resting state brain connectivity analysis identified functional changes to both sensory and motor area of brain that were associated with perceptual training (Vahdat et al. 2014). We have seen that perceptual training results in changes to motor area of the brain and these changes in motor areas cannot be accounted for by changes, which occur in somatosensory areas. Here we have further investigated the effect of perceptual training on motor function. We used transracial magnetic stimulation (TMS) of brain to measure motor evoked potentials (MEP), a measure of brain motor area excitability. Twenty subjects participated in the experiment and biceps and triceps MEPs were recorded before and after perceptual training. In each case we recorded a block of 30 MEPs using a stimulation magnitude in the middle of each participant's baseline input output curve. Each participant underwent two perceptual training procedures. In the first, the participant's arm was moved passively by a robotic arm to the right or left of the body midline. No response or judgment was required. This was followed by a block of 30 MEPs and then a second perceptual training task. In the second task, the robot again moved subjects' arm passively to one of 10 randomly selected targets that were distributed evenly to the right and left of body midline. In these blocks subjects need to make a judgment as to whether robot moved their arm to the right or left and verbal feedback indicating the accuracy was provided. This second perceptual training task was followed by recording of 30 additional MEPs. As we expected we found no changes to MEP amplitudes following passive movements. In contrast, we found a reduction in biceps MEP following the perceptual training block in which subjects made judgments and were provided feedback. Changes to triceps MEP magnitude did not reach significance but had a negative trend like biceps. A separate group of control subjects did no experimental perceptual manipulation whatsoever. For these subjects we recorded the three blocks of 30 MEPs each. Between blocks subject rested for the duration that experimental group used to do the task. No changes in MEP were found between these three blocks. Our results indicate that passive perceptual training may result in decreases in motor cortical excitability.

Title: An acute bout of exercise performed immediately after motor learning alters Beta-band oscillations in the motor cortex

Authors: F. DAL MASO, B. DESORMEAU, A. GHOSH, M. ROIG, *M.-H. BOUDRIAS
Sch. of Physical and Occup. Therapy, McGill Univ., Montreal, QC, Canada

Abstract: Introduction: Performed immediately after motor skill practice, an acute bout of cardiovascular exercise is thought to maximize memory consolidation. This type of exercise has been shown to increase corticospinal excitability, which is associated with motor improvements. Our objective was to use electroencephalography (EEG) to assess how a single bout of exercise modulates corticomotor network neuroplasticity during the initial stages of motor memory consolidation. We hypothesized that a bout of exercise would alter power spectrum of motor cortex (M1) oscillations. Methods: Twenty-six participants were fitted with an EEG cap (BrainVision, 64 electrodes). Data were collected at rest, during the hand-grips as well as during a visuomotor accuracy-tracking learning (AT) task. Then, subjects were taken to the cycle ergometer. The EXE group (n=13) performed a 3*3 min blocks of exercise at 90% of their maximum aerobic power. The CON group (n=13) rested on the bike. Then, resting-state and hand-grip task were repeated at +30 min, +60 min, and +90 min post exercise. The AT task was repeated at +8h and +24h post exercise. Analysis: In this study, we were interested in assessing the effect of group on motor performance gains and the cortical oscillations power spectrum associated with it. Results: All participants improved their motor scores during the practice of the AT task. The EXE participants had greater retention scores at +24h (P=0.021). During the resting-state, beta-band power spectrum density increased in both groups over all scalp areas. This increase was significantly greater in the right M1 for the EXE group (P values ranged between 0.002 and 0.040). During the hand-grip task, Beta-band event-related desynchronization significantly decreased in the left M1 for the EXE group (P values ranged between 0.011 and 0.034). Conclusion: Modulations of M1 beta-band power spectrum suggest that exercise may have altered the level of GABAergic inhibition within both M1. These results suggest that a single bout of intense cardiovascular exercise performed immediately after motor learning triggers neuroplasticity in corticomotor networks of both hemispheres. This observed neuroplasticity may make part of the mechanisms underlying enhancement of motor memory consolidation.

Title: Aging does not affect practice-induced increases in beta modulation during a motor task

Authors: R. MEHRARAM[1], S. RICCI[1], A. B. NELSON[1], E. TATTI[1], P. PANDAY[1], H. CHEN[1], B. O. THOMSON[1], M. BOSSINI-BAROGGI[1,2], M. KAMEL[1], *M. F. GHILARDI[3,1]
[1]CUNY Med. Sch., New York, NY; [2]Dept. of Informatics, Bioengineering, Robotics and Syst. Engin., Univ. of Genoa, Genoa, Italy; [3]CUNY, New York, NY

Abstract: Movement planning and execution are accompanied by EEG power modulation in the beta range (15-30 Hz) over the sensorimotor area contralaterally to the moving limb: beta power decreases during planning, reaches a minimum during the movement itself and rebounds with a maximum at the movement end. We have shown that in elderly subjects such movement-related modulation increases during one-hour practice block and returns to baseline values when tested 24 hours later (Moisello et al, 2015; Nelson et al, 2017). These practice-dependent increases might represent excitability and plasticity changes of the sensorimotor cortex, which might change with aging.
Here we determine whether: such practice-dependent increases similarly occur in young subjects; beta modulation further increases during several practice blocks; periods of quiet rest re-establish beta modulation to the baseline values; EEG rest activity recorded with eyes opened after each block shows increases in low frequency range.
Therefore, we recorded EEG signal (EGI, 256 electrodes) during one-hour blocks of choice reaction task with reaching movements of the right arm on a digitizing tablet and after each block (2-min eyes-opened resting state) in 26 normal subjects. For each movement, we computed several parameters and movement-related beta modulation over the left sensorimotor area. In a first experiment, young (13, age 22±2.8 yrs) and elderly (13, age 57.5±8.2 yrs) subjects performed the task for one block. While young subjects had a better motor performance ($p<0.01$), both groups showed practice-related increase of movement-related beta modulation ($p<0.001$) without group differences ($p>0.9$). In a successive experiment in 13 young subjects, we found that movement-related beta modulation increased within and across blocks, reaching a plateau by the third block. There were not significant performance changes across blocks. Movement-related beta modulation returned to baseline values after 90 minutes of quiet rest

when tested in a fourth block. Spontaneous EEG recorded with eyes opened after each block showed a progressive specific increase in the low frequency range (<8 Hz) over the left sensorimotor area where movement-related beta modulation was maximal.
We conclude that beta modulation may reflect saturation of cortical excitability and plasticity-related phenomena, as it reached a plateau after 2-hour practice, is not linked to on-line behavioral improvement, left a trace in the spontaneous EEG and re-set after prolonged rest. Also, as beta modulation increases did not depend on age, it is likely that excitability of sensorimotor cortex might not change in the age range we tested.

Title: EEG Beta-band modulations in implicit and explicit motor adaption processes

Authors: *N. MALFAIT[1], A. JAHANI[2], J. ALAYRANGUES[2], F. TORRECILLOS[2]
[1]CNRS / INT, Marseille, France; [2]AMU / Inst. des Neurosciences de la Timone, Marseille, France

Abstract: Modulation of human EEG β-band (15-30Hz) oscillations has been originally described in relation to voluntary movement, but since then it has also been extensively described in cognitive tasks requiring sensorimotor interaction, and has received increasing interest in different domains like perception, attention and memory. However, surprisingly β-band activity has been only recently investigated in relation to movement-error processing and motor learning. Tan et al. (2014) demonstrated for the first time that the β-rebound, an increase in β-power at the end of movement, is modulated by kinematic errors. In a previous study (Torrecillos et al. 2015) we found that pre- and post-movement β-activities both are sensitive to kinematic errors, but exhibit different patterns of modulation revealing functional differences. In the present study, our aim is to tease apart the β-band modulations related to implicit adaptation processes from those reflecting the processing of explicit mismatch/surprise, performance feedback and/or reward. We recorded EEG while participants performed a ballistic reaching task in which a visual rotation was unexpectedly introduced in some trials. Participants were

previously trained to use a strategy to compensate for the visual rotation. An explicit reward was provided when the target was hit. First, focusing on the error-related oscillatory responses observed during the foreperiod phase, we contrast two types of trials. On one side, 'after-effect' reaches following directly movements executed under visual rotation, in which the motor command update is automatically triggered. On the other side, trials in which the motor-command update is guided by an explicit instruction, a performance feedback or a reward. Second, focusing on the post-movement period, we compare error-related β-power modulation for reaches in which movement-execution error is induced by an unexpected visual perturbation with trials in which the sensory-prediction error is expected and dissociated for the goal achievement. Third, in the light of previous studies examining β-oscillatory correlates of feedback processing in the context of reward-learning tasks, we examine β-band response to positive reinforcement.

Title: Neurochemical basis for learning novel sensorimotor maps

Authors: ***F. T. VAN VUGT**[1], T. HENNESSY[2,3], J. NEAR[3,2], J. DOYON[4,5,6], D. J. OSTRY[1,7]

Abstract: One of the puzzles of learning to talk or play a musical instrument is how we learn which movement produces a particular sound: an audiomotor map. Existing research typically uses mappings that are well-learned at the outset such as using a computer mouse to control the movement of a cursor on a screen. Here, we study acquisition of novel sensorimotor maps by having participants learn center-out arm movements to auditory targets. The sounds were not physically localised in space but consisted of oscillators whose frequencies depended in a non-

trivial fashion on the end position of the movement. We previously showed that this mapping can be learned, but the neurochemical bases of this learning are unclear. Here, we acquired functional magnetic spectroscopy (fMRS) over the primary motor cortex hand area while human subjects learned a sensorimotor map. LCModel analysis of MRS data was performed to obtain time resolved measures of various metabolites during sensorimotor learning, including glutamate, glutamine, lactate, N-acetylaspartate (NAA), creatine, choline, myo-inositol, aspartate, and glutathione. Before and after learning, we also obtained resting state functional magnetic resonance imaging (fMRI) scans. In order to assess learning performance, testing blocks were administered before and after learning where participants made reaching movements without receiving auditory feedback to a fixed set of targets, each of which repeated two times in random order. Behaviourally, prior to learning, we found that pairs of participants' movements to the same targets were equally different as pairs of movements to different targets, indicating that they came to this task without prior knowledge. They then showed a marked reduction in reaching error over the course of training indicating that they learned the novel sensorimotor mapping. FMRS revealed increases in lactate and decreases in aspartate concentration during learning, while glutamate showed no significant change. Interestingly, the change in aspartate concentration was significantly correlated with the amount of learning on a subject-level basis, suggesting a possible role of aspartate metabolism in sensorimotor learning. We also assessed changes in functional connectivity at rest between primary motor cortex and other motor and sensory structures that are correlated with the amount of learning. We relate these changes in functional connectivity with metabolic changes obtained using spectroscopy. The present works is a first step towards uncovering the neurochemical basis of changes in brain connectivity in the context of learning novel sensorimotor maps.

Title: Cerebellum drives motor skill acquisition through online learning and early consolidation

Authors: *N. F. BERNARDI[1], F. T. VAN VUGT[1], R. VALLE-MENA[2], S. VAHDAT[3], D. J. OSTRY[1,2]

Abstract: The acquisition of skills such as painting or handwriting requires fine control of movement trajectory. However, the neural bases that allow us to learn these skills have been little investigated. Furthermore, studies on the neural basis of motor learning typically focus on either online task performance or on the changes in brain function observable at rest, once learning is complete, but it remains unclear how these two facets of brain plasticity relate to each other. Here we used fMRI to characterize the changes in brain networks that occur as human participants learn to use wrist and finger movements to trace a narrow semicircular path at a prescribed speed. Functional scans were collected during motor learning as well as at rest, immediately before and after learning. We show that in the active phase of learning, motor skill acquisition is accompanied by cerebellar, primary motor as well as prefrontal brain activity and connectivity. Immediately following the task we observed learning-related changes in the spontaneous activity of the brain, involving the connections between the cerebellum, premotor areas and sensory areas, both visual and somatosensory. Our findings provide an account of the changes in brain function throughout the early stages of acquiring a motor skill, suggesting that the cerebellum functions as a hub tying together motor performance, motor learning and early consolidation.

Title: Individual differences in cortical beta oscillations associated with motor learning

Authors: *S. ESPENHAHN[1], B. C. M. VAN WIJK[2,3], H. E. ROSSITER[4], A. O. DE BERKER[1,2], N. D. REDMAN[1], J. DIEDRICHSEN[5], N. S. WARD[1]

Imaging Ctr., Sch. of Psychology, Cardiff Univ., Cardiff, United Kingdom; [5]Brain and Mind Inst., Univ. of Western Ontario, London, ON, Canada

Abstract: People vary in their capacity to learn and retain new motor skills. Although the relationship between neuronal oscillations in the beta frequency range (15-30 Hz) and motor behaviour is well established, the functional relevance of resting and movement-related beta-band activity for motor learning and retention in humans is incompletely understood.
Here, we investigated the neurophysiological mechanisms underlying inter-individual variability in short-term motor learning behaviour. Since alterations in beta oscillations have been seen with ageing (Rossiter et al. 2014; Heinrichs-Graham & Wilson 2016; Gaetz et al. 2010), and previous studies have suggested an age-related reduction in the potential for plasticity (Tecchio et al. 2008; Fathi et al. 2010; Todd et al. 2010; Chollet 2013), we used the ageing motor system as a model for variations in the balance between inhibition and excitation to examine its behavioural relevance.
Twenty young (18-30 years) and twenty elderly (62-77 years) healthy adults were trained on a motor sequence tracking task and subsequently tested for early (45-60 min) and late (24 hours) retention. Scalp electroencephalography (EEG) during a separate simple motor task was recorded before each training and retention session.
Crucially, we found that pre-training levels of resting beta power from contralateral sensorimotor cortex were correlated with early motor sequence retention ($r = -0.35$, $p = 0.031$), such that subjects with less beta activity prior to training retained more sequence-specific motor skill. Additionally, post-training movement-related beta power from contralateral sensorimotor cortex was associated with early retention of general motor skills, such that subjects with smaller MRBD ($r = 0.29$, $p = 0.073$) and greater PMBR ($r = 0.34$, $p = 0.038$) immediately after training exhibited greater retention. These findings contribute to our understanding of the neurophysiological mechanisms underlying motor learning, and suggest that beta oscillations as potential markers of the net inhibitory and excitatory mechanisms in human sensorimotor cortex are linked to individual differences in the capacity to retain learned motor skills. In the context of disease, beta oscillations may offer novel targets for therapeutic interventions designed to promote rehabilitative outcomes after brain injury.

Title: The effect of concussion on the learning of a novel visuomotor task in elite athletes

Authors: N. GURUPARAN[1], J. HURTUBISE[2], D. J. GORBET[3], *L. E. SERGIO[4]
[1]Sch. of Kinesiology and Hlth. Sci., York Univ., Toronto, ON, Canada; [2]Kinesiology & Hlth. Sci., [3]Ctr. for Vision Res., York Univ., North York, ON, Canada; [4]Sch. Kinesiol & Hlth. Sci., York Univ., Toronto, ON, Canada

Abstract: Elite athletes are distinct in their ability to learn and perform skilled tasks with greater speed, consistency, and agility relative to non-elite athletes. Previously we have characterized the ways in which elite athletes' learning of a complex eye-hand coordination skill were superior to non-elite athletes (all with no concussion history, CH-), and the sex-related differences in this learning[1] . An issue of increasing concern is the effects of concussion history on skilled performance and motor learning, particularly in asymptomatic young athletes competing at or hoping to compete at elite levels. Recently we have shown that skilled performance can be affected in asymptomatic youth and young adults with a concussion history (CH+) months after deemed recovered by current standards[2-4]. Here we combine and extend these studies by comparing motor learning in an eye-hand coordination task in elite athletes with concussion history (deemed recovered), without concussion history, and CH- non-elite athletes. We characterized the initial and change in kinematics of 69 young athletes (23 CH+ elite, 23 CH- elite, 23 CH- non-elite; 7 females each group; ages 17-28) over multiple trials of learning to navigate a virtual force environment (Phantom™ 3.0 haptic 6D robotic arm) designed as a standard slalom task where the pylons would shift slightly as they were approached[1] . As expected there was a main effect of group on improvement in slalom course movement time ($p<0.05$), mean velocity ($p<0.05$), and mean jerk ($p<0.01$), as well as significantly different variance for these variables between groups. Surprisingly, however, post-hoc analyses revealed no movement time, jerk, or velocity improvement between CH- and control athletes. This was due to an initial worse performance by CH+ athletes. Lastly, mean jerk improvement was lower for CH+ elite athletes. These data show that there are subtle differences in the ability to learn complex skills in young elite athletes with a concussion history, despite being deemed recovered by current standards. 1:McCullough et al.2006, Appl physiol nutr metab,31,S57;2:Hurtubise et al.2016, Concussion1(3) DOI 10.2217/cnc-2016-0006;3:Dalecki et al.2016,Concussion1(3) DOI 10.2217/cnc-2016-0001;4:Brown et al.2015, Oct 19;7:25.

Title: Adaptations to novel visuomotor rotations after stroke

Authors: *R. T. MOORE[1], S. P. DUKELOW[2,3,4,5], T. CLUFF[1,3]
[1]Fac. of Kinesiology, [2]Clin. Neurosciences, [3]Hotchkiss Brain Inst., [4]Div. of Physical Med. and Rehabil., [5]Cummings Sch. of Med., Univ. of Calgary, Calgary, AB, Canada

Abstract: Stroke is a leading cause of disability in Canada, where many of the 405,000 adult stroke survivors have long-term disability. Most stroke survivors access neurorehabilitation to improve sensory and motor function. However, little is known about how stroke influences basic mechanisms of sensorimotor learning, and understanding these mechanisms may help improve rehabilitation outcomes. Here we examine motor learning patterns in a task that required stroke survivors and healthy adults to adapt their reaching movements to a novel visuomotor rotation. Experiments were performed with a KINARM exoskeleton robot. Subjects (5 stroke survivors; 21 healthy adults) interacted with a virtual reality system through the movement of their arms. The position of their fingertip was displayed in real time using a white cursor (0.8 cm diameter). We asked subjects to reach back-and-forth between two circular targets (2cm diameter) positioned 10-cm apart. Subjects first completed 25 movements with true feedback of their hand position. We then introduced a 30□counter-clockwise rotation onto the hand feedback cursor to examine how subjects adapted their movements. We unexpectedly removed this rotation after subjects completed 125 movements. Subjects then performed another 25 movements with true hand feedback to examine how they de-adapted their movements. For each trial, we calculated the angular deviation of the hand's path from a straight trajectory between the targets at 150 ms after the onset of movement. Each subject's angular hand path deviations were fit to mathematical models to determine the rate and extent of learning, as well as how this learning was retained from one movement to the next. Group comparisons were conducted using Mann-Whitney U tests. Preliminary analysis revealed marked differences in the learning patterns of stroke subjects and healthy adults. Although the overall extent of learning was similar across groups, stroke subjects required more trials to adapt (>90 trials) their movements to the same visuomotor rotation as healthy adults (<40 trials). Our analysis suggests a reduction in trial-by-trial retention of learning may contribute to the slower learning rates displayed by stroke survivors ($U_{(25)} = 2.35$; $p = 0.0096$). Collectively, our results suggest stroke survivors can indeed adapt their movements to the same overall extent as healthy, age-matched adults. However, this learning is achieved at a slower rate due to a reduction in the amount of learning that is retained from movement to movement. Thus, stroke subjects need to perform many more movement repetitions than healthy adults to adapt to the same visuomotor rotation.

Title: Application of POrtable Motor learning LABoratory (PoMLab): Cross-syndrome comparison of implicit visuomotor adaptation among patients with stroke and Parkinson's disease

Authors: *M. SHINYA[1], K. TAKIYAMA[2], T. SAKURADA[3], S. MURAMATSU[4], H. OGIHARA[5], T. SATO[5], T. KOMATSU[6]
[1]Hiroshima Univ., Higashi-Hiroshima, Hiroshima, Japan; [2]Dept. of Engin., Tokyo Univ. of Agr. and Technol., Koganei-Shi, Japan; [3]Functional Brain Sci. Lab., [4]Div. of Neurol., Jichi Med. Univ., Tochigi, Japan; [5]Dept. of Physical Therapy, Kakeyu Hosp., Ueda, Japan; [6]Col. of Sports Sci., Nihon Univ., Tokyo, Japan

Abstract: BACKGROUND AND AIM: How to characterize motor dysfunction of patients with neurological disorders is a central question in clinical neuroscience. To measure behavioral data from many patients anytime and everywhere without a huge experimental setup, we have developed a smart device application PoMLab where a cursor on a screen can be controlled by tilting a tablet device (Takiyama and Shinya, PLOS One, 2016). In this study, we compared an implicit adaptation to gradual visuomotor perturbation among patients with stroke and Parkinson's disease (PD). METHODS: Fourteen patients with stroke, 12 patients with PD, 11 elderly control, and 11 healthy young university students are recruited. The patients with PD were in Hoehn and Yahr stages 1 to 4, as evaluated during the on state of their medication cycle. The visuomotor rotation was added by the cursor being rotated with respect to the direction of actual tilt of the device. In our experiment, the visuomotor rotation was gradually increased to 15 degrees, and it gradually decreased to zero so that the participants could not be aware of the perturbation. The adaptation to the perturbation was quantified by calculating a slope of the learning curve. RESULTS: The implicit visuomotor adaptation tested in this experiment was similar among patients with stroke, healthy control elderly participants, and young university students. In contrast, patients with PD showed worse implicit adaptation ability: slower and smaller adaptation comparing with the other groups. CONCLUSIONS: Implicit motor learning mechanisms were intact among young students, elderly control, and patients with stroke. In

contrast, the patients with PD showed worse implicit motor learning than those populations. Although slower adaptation in the patients with PD sounds contradictive to a previous study using an abruptly introduced perturbation (Semrau et al. 2014), our results demonstrate not explicit but implicit components are significantly different in patients with PD. Our results might be consistent with previous findings that patients with PD lack consolidation of the motor memory (Marinelli et al. 2009). These results may be indicative for developing an effective rehabilitation.

Title: Fast and slow motor learning processes in Alzheimer's dementia

Authors: *K. SUTTER[1], L. OOSTWOUD WIJDENES[1], J. A. CLAASSEN[1,2,3], R. P. C. KESSELS[1,4,3], W. P. MEDENDORP[1]
[1]Donders Inst. For Brain, Cognition and Behaviour, Radboud Univ., Nijmegen, Netherlands; [2]Dept. of Geriatric Med., [3]Radboudumc Alzheimer Ctr., [4]Dept. of Med. Psychology, Radboud Univ. Med. Ctr., Nijmegen, Netherlands

Abstract: Motor learning is governed by multiple interactive processes, each with different time constants and sensitivity to errors. Evidence for this is based on a paradigm that evokes spontaneous recovery after learning a visuomotor rotation. The recovery allows inferring a fast process that learns and decays quickly, and a slow process that responds weakly to error but decays slowly. Alzheimer's dementia (AD) is characterized by a decline in declarative memory. While AD patients are still able to learn new motor skills, it is not clear how this learning is achieved. Recently, it has been suggested that the fast motor learning process shares resources with declarative memory processes. Hence, a deficiency in declarative memory should affect the fast, but not the slow process in motor learning. To test this hypothesis, we used a spontaneous recovery paradigm to examine the role of fast and slow learning processes in the acquisition of new motor skills in AD patients (age range 55-80). Participants performed reaching movements to a target while holding the handle of a robotic manipulandum. Visual feedback of hand position (cursor) and target position was provided in the plane of movement. Learning was measured using error clamps and indexed as an adaptation index (AI) representing the fraction of ideal

force compensation. We fitted a two-state adaptation model to capture the time course of the AI. Our first results in healthy age-matched controls are in line with previous observations in the literature, showing evidence for a fast process, which learns and decays quickly, and a slow process, which learns and decays slowly. Experiments and analyses are currently under way to examine how AD patients differ from this behavior.

Title: Impaired representation of limb dynamics after stroke

Authors: R. L. HARDESTY, JR[1], V. RAJASEKARAN[2], C. L. ROSEN[2], *V. GRITSENKO[2]
[1]Neurosci., [2]West Virginia Univ., Morgantown, WV

Abstract: Cerebral infarct, or stroke, is the leading cause of physical disability in the United States. Post-stroke neural damage can result in contralateral paralysis or hemiparesis. While physical and occupational rehabilitation can promote recovery of motor function, long-term residual deficits are common. Even when motion deficits a relatively minor, the muscle activation patterns often differ from age-matched healthy individuals. This may make the impaired movements less efficient and requiring more effort. Therefore, understanding how changes in the neural motor system after stoke alter the muscle activation patterns that lead to movement deficits will help identify interventions that would reduce these deficits. We assessed post-stroke changes in the descending motor pathways using single-pulse transcranial magnetic stimulation of the primary motor cortex (M1). Stroke survivors and age-matched controls reached and pinched visual targets in a virtual reality environment. Targets were located to elicit movements with varying dynamical loads on the limb, i.e. increasing or decreasing gravitational load and assistive or resistive interaction torques between shoulder and elbow. At random times during movement, the M1 was stimulated through a figure-of-eight coil under motion-capture guidance. Motor evoked potentials (MEPs) recorded with electromyography were collected for 15 muscles spanning the shoulder, elbow, wrist, and hand. MEP amplitudes at different times

during movement were used to reconstruct a temporal profile of corticospinal excitability. The temporal modulation of corticospinal excitability was obtained by normalizing MEP amplitudes to the motoneuron recruitment using a linear regression model of static MEPs obtained at different postures. Temporal modulation profiles across muscles were compared using a regression analysis and hierarchical clustering of correlation matrices. Stroke survivors showed decreased temporal modulation of corticospinal excitability compared to age-matched controls, particularly in tasks with resistive interaction torques and increasing gravitational load. These results suggest that altered muscle activation patterns leading to residual motor deficits after stroke may be the result of dysfunctional representation of limb dynamics in the impaired descending motor pathways.

Title: Use of a EMG-controlled game as a therapeutic tool to retain hand muscle activation patterns following stroke

Authors: M. GHASSEMI[1], A. BARRY[2], K. TRIANDAFILOU[2], M. STOYKOV[2], *D. G. KAMPER[3], E. ROTH[2]
[1]Joint Biomed. Engin. Dept., UNC & NC State, Raleigh, NC; [2]Shirley Ryan Ability Lab., Chicago, IL; [3]Biomed Engin., North Carolina State University/ Univ. of Nor, Raleigh, NC

Abstract: Aberrant muscle activation patterns constitute one of the primary mechanisms of hand impairment following stroke. Individuals with chronic hemiparesis typically exhibit an inability to fully activate a desired muscle, to deactivate the muscle once excitation begins, and to modulate muscle activation patterns with task. The region of the activation workspace which they can voluntarily attain is often quite limited. To encourage exploration and expansion of the activation workspace, we developed a custom computer game that is electromyographically (EMG) controlled. Specifically, principal components (PCs) describing the accessible activation workspace are mapped to the axes of the computer screen, with one PC representing the vertical direction and one PC representing the horizontal direction. The user must create scaled combinations of these patterns to move the cursor in order to reveal pictures, traverse through mazes, or gather coins to play a game based on Asteroids. This system is being used as part of an

ongoing longitudinal intervention study for stroke survivors with severe hand impairment, as rated Stage 2-3 on the Stage of Hand section of the Chedoke-McMaster Stroke Assessment scale. One cohort of the study participants focuses on training activation patterns, by alternating between use of the EMG-controlled game and an EMG-controlled active hand orthosis. So far, 8 individuals from this cohort have completed the treatment, which includes 9 sessions (45 minutes each) with the EMG-driven game over 6 weeks. For each subject, PCs from the unimpaired hand were introduced as the target PCs for the impaired hand over the 9 sessions and difficultly was gradually increased by expanding the required range of the desired PC. Preliminary results showed a 4.8 ± 7.6 min decrease, equal to 25% of the total value across subjects in average time to complete the task from the second day to the ninth day of training. These findings demonstrate that stroke survivors with even chronic, severe impairment can learn to improve control of muscle activation patterns. Assessment of translation to functional hand use is ongoing.

Title: Age-Related differences in controlling a robot arm

Authors: *M. R. PADMANABHAN
Kinesiology, Michigan State Univ., East Lansing, MI

Abstract: A fundamental question in motor development examines whether or not children and adults learn motor skills differently, especially when learning a novel motor task. In previous studies, we found age-related differences in movement performance and coordination in a 2-dimensional cursor-control task. In this study, we further investigated the generality of these age-related learning differences by changing the task in two ways (i) controlling a robot arm, instead of a cursor, in 2-dimensions, and (ii) using velocity-control instead of position-control. Participants' shoulder movements were measured using 4 inertial measurement units (IMU) and these movements were mapped to the velocities of a robot end-effector. Participants learned to control the robot arm by reaching to distal targets that were placed equidistant from a center target. Both children and adults practiced for a total of 72 trials reaching toward 4 targets in the cardinal directions. To examine the generalization, we also included three tests (pre, during and post-practice), where participants reached toward 4 additional targets in the diagonal directions. Principal Component Analysis (PCA) was used to perform the dimensionality reduction. Results showed that age-related differences in learning continue to exist in this framework.

While 96% of adults and 67% of 12-year-olds were able to complete the task, only 27% of 9-year olds completed the task. Adults and the 12-year-olds did not have significantly different movement times and path straightness to the targets, which differs from previous results. Additionally, we examined movement exploration by running a PCA of the sensor signal data and comparing the percent variance explained by the first two principal components. The adults showed a decrease in movement exploration throughout the task while the 12-year-olds exhibited similar exploration throughout the duration of the task. These results suggest that there may be age-related differences in the way a novel task is learned. These results have implications for structuring practice schedules in children, especially pediatric rehabilitation.

Title: Understanding the relationship between exploratory variability and learning ability by dissociating the effects of persistence versus task relevance for motor variability

Authors: *T. RANJAN[1], M. A. SMITH[2]
[1]Sch. of Engin. and Applied Sci., [2]Sch. Engin., Harvard Univ., Cambridge, MA

Abstract: Variability in the motor system has been found to predict motor learning ability across individual subjects and tasks (Wu et. al, Nat. Neurosci. 2014). However, this result is still controversial (He et. al, PLoS Comp Bio 2016) and variability is not monotonic, so that specific components of variability may underlie the relationship between motor variability and motor learning. One way to parse variability is into variability that occurs in task relevant vs task irrelevant (i.e. redundant) dimensions. A second way to parse variability is based on accumulating versus non-accumulating components. Accumulating variability displays persistence and will thus act like a drifting random walk process in that current variability builds upon previous variability, resulting in a strongly positive autocorrelation. In contrast, non-accumulating does not persist and will thus act like a white noise process in that current variability is independent of previous variability, resulting in near-zero autocorrelation. A recent study (Singh et. al, PNAS 2016) suggested that baseline variability only in the task-irrelevant dimension is predictive of the learning rate of the task. However, it is known that task-irrelevant variability displays large positive autocorrelations corresponding to a drifting, random-walk-like behavior, like that observed in cortical areas that control movement. In contrast, task relevant

variability does not display these high autocorrelations, because feedback in task relevant dimensions allows motor adaptation to compensate for these drifts to reduce errors. Thus, task relevant feedback in the baseline period can obscure the ability to measure the random-walk-like accumulating variability that would occur without feedback-driven motor adaptation in task relevant dimensions, and which may correspond to the centrally driven component of task relevant motor variability. We thus devised an experiment to allow us to determine whether motor learning ability is predicted better by sources that drive random-walk-like accumulating variability versus sources that drive variability in task relevant dimensions per se. We thus simultaneously measured, in a baseline period without feedback, both non-accumulating (white noise) and accumulating (random-walk-like) components of motor variability in dimensions that would be irrelevant to subsequent motor learning versus in dimensions that would be task-relevant to motor learning. This enables us to dissect the relationship between motor variability and motor learning ability based on both task-relevant vs irrelevant dimensions and accumulating vs non-accumulating variability sources.

Title: The relation of proprioceptive working memory to human motor learning

Authors: ***A. SIDARTA**, F. T. VAN VUGT, N. F. BERNARDI, D. J. OSTRY
McGill Univ., Montreal, QC, Canada

Abstract: The capacity to maintain in working memory previously performed movements, and their success or failure, presumably plays a substantial role in motor learning. Indirect evidence to this idea come from a recent study in which we found that motor learning correlates with changes in functional connectivity between second somatosensory cortex (SII) and BA 9/46v (lateral prefrontal cortex), the latter being known to contribute to somatosensory working memory (sWM). In the current study, we directly tested the hypothesis that there would be a correlation between proprioceptive sWM and human motor learning. We designed a behavioral task which is a variant of an N-back procedure to assess such working memory. On each trial a robotic device displaced the participants arm in a number of different directions (memory set),

and was followed by a test displacement that was used assess working memory. On half of the trials, the test direction was one of the items in the memory set, and in the other half it was not. Participants had to indicate whether or not the test movement was from the memory set. We expected that response accuracy would decay for items in the memory set being presented longer ago and that this decay measured sWM capacity. A memory curve was computed as the proportion of Hits minus False Alarms as a function of number of movements separating the test item and to-be-remembered item (lag). On a separate day, the same subjects performed a motor learning task in which they made reaching movements to hidden targets and received positive reinforcement when they were successful. Overall, we found that subjects that had better sWM learned more in the motor learning task ($r = 0.51$, $p < 0.05$), suggesting the involvement of sWM in motor learning. The correlation is the strongest for lag-1 ($r = 0.53$, $p < 0.01$). The findings suggest a contribution of proprioceptive working memory to human motor learning. This knowledge enhances our understanding on the role of somatosensory information in the initial stages of motor learning.

Title: Proprioceptive changes following complex motor skill learning

Authors: *J. L. MIRDAMADI[1], H. J. BLOCK[1,2]
[1]Dept. of Kinesiology, [2]Program in Neurosci., Indiana Univ., Bloomington, IN

Abstract: Motor skill learning entails changes in behavior through practice. It is well established that this process involves plasticity in motor regions, including primary motor cortex and the cerebellum. However, recent literature suggests that multiple types of motor learning influence sensory processing and are associated with plasticity in somatosensory cortex. For example, trial-and-error motor adaptation shifted hand position sense or proprioception (Ostry et al., J. Neurosci., 2010), and center-out reaching practice enhanced proprioceptive acuity (Wong et al., J. Neurophysiol, 2011). Whether such changes occur when learning a novel complex motor skill is unclear. In contrast with motor adaptation, motor skill learning involves acquisition of new movement patterns in the absence of a perturbation and an overall enhancement in movement quality. Here we asked whether proprioception improves in association with motor skill learning

in the upper limb. The motor skill was a track-tracing task that involved navigating a cursor using a robotic manipulandum handle (McGrath & Kantak, Hum Mov Sci, 2016). Subjects were instructed to move the cursor through an irregular-shaped track as accurately as possible within a prescribed movement time range. Total length of the track was 20 cm, and visual feedback was provided to encourage subjects to prioritize movement speed. Participants practiced the motor skill on two consecutive days. Performance was assessed through changes in accuracy (percentage of the subject's movement path that was within the track). On the third day, there was a retention test where learning was assessed through a shift in the speed-accuracy function relative to baseline performance. On each day, we quantified proprioception in the hand relative to a visual reference using an adaptive staircase algorithm. Preliminary data (n = 4) suggest that practice improved motor performance during training and enhanced the speed-accuracy tradeoff function at retention. Furthermore, proprioceptive bias and sensitivity were improved following a single session of training. However, these proprioceptive changes did not persist at retention. These findings have important implications for the role of proprioception in motor control and learning. Specifically, improvements in proprioception may be important for complex motor skill learning.

Title: An experimental investigation of the role of spatial working memory in age-related declines in working memory

Authors: *L. RAJESH KUMAR[1], K. M. TREWARTHA[2]
[1]Cognitive and Learning Sci., [2]Michigan Technological Univ., Houghton, MI

Abstract: Motor learning is supported by the combined influence of a fast process that allows for rapid improvements in performance, and a slow process that allows more gradual improvements. Research has shown that age-related declines in working memory are associated with impairments in the fast component of motor learning. However, the precise nature of the working memory mechanisms underlying age-related changes in the fast process for motor learning is unclear. The current project was designed to investigate whether spatial working memory resources in particular, underlie age-related declines in the fast component by manipulating spatial working memory load during a motor learning task. A group of older adults (60 to 85 years old), and a group of younger adults (18 to 30 years old) gradually learned to adapt their arm reaching movements to a clockwise or counterclockwise curl-field applied by a

robotic device (KINARM, BKIN Technologies). Participants from each age group were randomly assigned to a high or low working memory load condition and made center-out reaching movements to four visual targets. In the high load condition the order in which the targets were presented was randomized, whereas in the low load condition the targets appeared in a repeating four-target sequence. Participants also performed a cognitive battery that allowed us to evaluate the correlations between the fast process for motor learning and spatial working memory, associative working memory, and implicit memory resources in younger and older adults. The first aim of this project was to determine whether younger and older adults were differentially affected by the manipulation of spatial working memory load during the motor learning task. We tested the hypothesis that older adults would benefit less from the reduced working memory load condition compared to younger adults. The second aim was to test the hypothesis that the fast process for motor learning is more related to spatial than associative working memory in the older adults. Combined, the current data contribute to our understanding of the memory mechanisms underlying motor learning, and the nature of age-related changes in those memory processes in later adulthood.

Title: Mental workload and motor performance assessment during practice of reaching movements under various task demands

Authors: *I. SHUGGI[1], H. OH[2], P. A. SHEWOKIS[3], R. J. GENTILI[1]
[1]Univ. of Maryland, Col. Park, College Park, MD; [2]Univ. of Maryland, College Park, MD; [3]Drexel Univ., Philadelphia, PA

Abstract: Numerous studies have focused on assessing mental workload to inform how attentional resources are allocated during task performance, which is critical for understanding the underpinning mechanisms of human cognitive-motor behavior. Although a large body of work has examined mental workload in a context of motor performance, a limited number of studies have investigated mental workload during motor practice/learning. Specifically, no prior work has examined the relationships between mental workload and the rate of motor improvement during practice while also considering individual differences. Therefore, the aim of this study was to assess the concomitant variations in mental workload and motor performance resulting from practicing novel reaching movements by manipulating the level of task difficulty. Through a human-machine interface, individuals had to learn to control a virtual robotic arm to

reach targets that were randomly located in a 2D workspace. Participants were assigned to one of two groups, where they performed the task at either a low or high level of nominal difficulty. Nominal difficulty level was determined by the robotic effector's velocity. Surveys and arm kinematic data were analyzed to assess cognitive workload and motor performance, respectively. Mental workload, motor performance and motor improvement dynamics were analyzed by employing a traditional group-level analysis complemented by a cluster analysis to detect specific individual patterns of cognitive-motor responses. Both group-level and cluster-level analyses revealed that performance improved during practice and that an elevation of mental workload resulted in performance deterioration accompanied by slower motor improvement. Considering the optimal challenge point theory, this work suggests that the functional task difficulty: i) partially depends on the nominal difficulty level as well as on the individual's information processing capabilities, and ii) could be assessed via the level of mental workload, which when excessive can lead to performance degradation as well as a deceleration of motor improvements. Currently this work is being extended through the use of EEG to assess the attentional reserve and cortical effort, which can collectively index the cognitive workload during motor practice and learning. Overall, this work can inform human cognitive-motor processes as well as assist in the design and practice parameters associated with assistive technologies and prostheses.

Title: Older adults benefit less from explicit instruction, but show a larger change in perceived but not predicted estimate of hand position following visuomotor training

Authors: *C. M. VACHON[1], S. MODCHALINGAM[2], B. M. T'HART[3], D. Y. HENRIQUES[4]
[1]Psychology, [2]Kinesiology and Hlth. Sci., York Univ., North York, ON, Canada; [3]Psychology, York Univ., Toronto, ON, Canada; [4]Dept Kinesiol & Hlth. Sci., York Univ., North York, ON, Canada

Abstract: Our brains are very successful at adapting our motor movements to a wide array of changes, including bodily changes due to senescence. Such adaptation of skilled movements to

changes is thought to rely on sensory estimates of errors. Despite decreased sensory capacity with aging, some studies have shown intact motor learning in older adults compared to younger adults. It is unclear how older adults maintain task performance on some motor tasks and not others. Two possible explanations are that older adults compensate for sensory decline by relying more on (1) efference based estimates of hand movement, and/or (2) explicit, cognitive strategies. In the current study we compared how older (n=17) and younger (n=43) adults responded to instruction (provided to half of each group) on how to compensate for a 30º visuomotor rotation during training and afterwards when reaching without a cursor. We also compared training-induced changes in proprioceptive and predicted estimates between these two age groups. We did this by having all four groups, both before and after visuomotor adaptation, estimate the location of the unseen hand when the hand was moved out by the robot (passive localization) and when the hand was moved by the participant themselves (active localization). The difference between these two estimates roughly reflects changes in predicted or efferent-based estimates, whereas the passive localization should reflect mostly proprioception. Older adults benefitted less from instructions during initial training with the rotated cursor. Following visuomotor adaptation, older adults showed larger visually-driven changes in their passive or proprioceptive - but not their efference-based or predicted - estimates of hand position. This indicates that older adults appear to visually recalibrate felt hand position more than younger adults. Our preliminary results suggest that rehabilitation for older adults should focus less on explicit instructions, but rather on training that emphasizes visual feedback.

Title: Is proprioceptive recalibration explained by a multi-rate model?

Authors: *J. E. RUTTLE, B. ’T HART, D. HENRIQUES
York Univ., North York, ON, Canada

Abstract: A powerful model for motor learning combines a fast and slow learning process (Smith et al., 2006). It can be extended to visuomotor adaptation, with explicit and implicit learning representing the fast and slow process, respectively (McDougle et al., 2015). After adaptation to a visuomotor rotation we also observe a shift in felt hand location; 'proprioceptive recalibration'. Here we investigate if a multi-rate learning model can explain proprioceptive recalibration, specifically, if recalibration maps onto the slow or fast process in reach adaptation. We test this with two visuomotor adaptation paradigms, with the same four phases using varying visual feedback of the hand, modelled after earlier experiments: 1) aligned training, 2) prolonged rotation training, 3) brief opposite rotation training, and 4) error-clamp training. During error-clamp trials the cursor moves straight to the target, regardless of actual reach direction, removing movement error signals. In this phase, reach output should rebound to what the slow process has retained from the prolonged training phase. One of our paradigms includes a localization trial after each reach training trial, to measure proprioceptive recalibration on a trial-by-trial basis. In localization trials, a robot moves the unseen, trained right hand to a location close to the previous training target. Participants then indicate the felt location of their right hand on a touchscreen, using their visible, untrained, left hand. A visual arc demarcates the correct distance from the start position. In the second paradigm, localization is replaced with a pause. A two-rate model predicts reach directions fairly well (RMSE=2.88°, R^2=.837), including the rebound in the error-clamp phase. The trial-by-trial data suggest that proprioception recalibrates extremely fast. AIC analysis shows that this does not follow the time course of either the slow or fast process of the reach model (both $p<.0008$). Modelling localization change as a proportion of the visuomotor rotation from the preceding reach trial gives the best fit, but this is indistinguishable from a single-process ($p=.393$) or two-process ($p=.052$) model of localization. When comparing reaches across paradigms (localization vs. pause) the time course of learning and values for each parameter were similar with localizations only reducing the fast retention rate ($p_{fdr}=0.15$). It remains unclear how to model proprioceptive recalibration and its effects on reach adaptation. It is clear that proprioceptive recalibration does not merely reflect an aspect of motor changes, and should be considered an independent process in motor learning.

Title: Explicit awareness of a perturbation during training does not affect predicted and perceived sensory consequences of hand motion

Authors: *S. MODCHALINGAM[1], C. M. VACHON[2], B. M. 'T HART[3], D. Y. HENRIQUES[4]
[1]Hlth., York Univ., Toronto, ON, Canada; [2]Psychology, York Univ., North York, ON, Canada; [3]Ctr. for Vision Res., York Univ., Toronto, ON, Canada; [4]Dept Kinesiol & Hlth. Sci., York Univ., North York, ON, Canada

Abstract: Explicit awareness of a task is often evoked during rehabilitation and sports training with the intention of accelerating learning and improving performance. However, the effects of awareness of perturbations on the resulting sensory and motor changes produced during motor learning are not well understood. Here, we use explicit instructions as well as large rotation sizes to generate awareness of the perturbation during a visuomotor rotation task and test the resulting changes in both perceived and predicted sensory consequences as well as implicit motor changes. We split participants into 4 groups which differ in both magnitude of the rotation (either 30° or 60°) during training, and whether they receive a strategy to counter the rotation or not. The effect of explicit instruction seems limited to an initial error-reduction advantage of ~20°, regardless of the size of the perturbationWe show that with instructions, and also with large perturbations, participants are aware of how they counter the rotation. This allows them to apply a strategy at will in open loop reaching tasks following training. However, when asked to exclude the strategy, none of the four groups can entirely exclude learning, implying a base amount of implicit learning (~15°) which is present in all groups, regardless of strategy use or rotation magnitude.Also following visuomotor adaptation, participants estimate the location of the unseen hand when it is moved by the robot (passive localization) and when they generate their own movement (active localization). By comparing the differences between these hand estimates after passive (only proprioception) and active (both proprioception and efferent-based prediction) movements, we are able to tease out a measure of predicted sensory consequences following visuomotor adaptation. These estimates of felt hand position and predicted sensory consequences change to a similar extent independent of whether participants receive instructions or not. Our results indicate that although some aspects of motor learning are affected, not all processes

benefit from an explicit awareness of the task. Particularly, proprioceptive recalibration and the updating of predicted sensory consequences are largely implicit processes.

Title: Motivational state influences motor adaptation

Authors: *J. GALARO[1], A. DIZENZO[2], D. MCNAMEE[3], V. S. CHIB[1]
[1]Biomed. Engin., Johns Hopkins Sch. of Med., Baltimore, MD; [2]Kennedy Krieger Inst., Baltimore, MD; [3]Computat. and Biol. Learning Lab., Univ. of Cambridge, Cambridge, United Kingdom

Abstract: We have the remarkable ability to learn a myriad of motor behaviors in a variety of contexts. From skipping down the street to swinging a golf club, we are able to learn to control our movements to perform complex actions - but how does our motivation impact motor learning? Current theories regarding motor learning posit that reduction of motor error drives motor adaptation; recent work has indicated that other variables, such as action-contingent rewards/punishments modulate the learning process. In this study we tested whether a person's internal motivational state influences the manner in which they learn to control their movements by applying a well-established classical conditioning paradigm to a motor control task. More specifically, we examined how motor learning of a novel dynamical environment (a force-field perturbation) is influenced by the concurrent presentation of Pavlovian conditioned stimuli (CS). These stimuli were fractal images that had been previously presented in association with either

high ($30, CS+) or low ($10, CS-) monetary rewards. Participants then performed a force-field learning task during which the conditioned stimuli were presented on screen. The motor learning task involved making center-out movements while grasping the handle of a planar manipulandum rendering a velocity-dependent curl field. Each of the conditioned stimuli (CS+ and CS-) were presented on 50% of the trials, pseudo-randomly interleaved. Critically, rewards were only delivered during the Pavlovian association phase and no rewards were contingent on the action being performed. This allowed us to examine how motivational state, independent of and uncorrupted by the effects of reward, influences motor adaptation. We found that learning was significantly faster in the higher motivational state CS+ condition compared to the CS- condition. This manifested in larger decreases in maximum perpendicular error and increases in mean performance rate. Control conditions in which the Pavlovian rewards were matched in magnitude resulted in no significant differences in motor adaptation. Furthermore, we analyzed our data using a hierarchical mixed effects model in order to observe how prediction error and kinematic update measures interact to result in enhanced learning. Applying a reward prediction error model gated on the motivational state condition showed that participants had an increased update weight for trials performed in the CS+ condition as compared to the CS- condition. Our results indicate that an enhanced motivational state increases the degree to which individuals update their motor plans, and that these invigorated updates amplify motor learning.

Title: Selective suppression of adaptation to motor errors irrelevant to task success

Authors: N. RAO[1,2], *N. KUMAR[3], P. K. MUTHA[4]
[1]Hlth. and Human Performance, Univ. of Houston, Houston, TX; [2]Cognitive Sci., [3]Indian Inst. of Technol. Gandhinagar, Gandhinagar, India; [4]Indian Inst. of Technol. Gandhinagar, Palaj, India

Abstract: Human arm movements appear to be planned as vectors with independent specification of direction and extent. According to this framework, errors in direction and extent must be differentially processed when adapting our movements to varied task conditions. We tested this hypothesis and predicted that if these two errors are processed independently, subjects should selectively suppress adaptation to one of them if it is irrelevant to task success. Seven groups of subjects adapted to three perturbations: rotation alone, gain alone or rotation+gain. The rotation and gain induced direction and extent errors respectively. Error relevance was manipulated by having subjects reach to an arc or a bar; direction errors were irrelevant for the arc but not the bar and vice versa for extent errors. Adaptation was assessed via catch trials requiring reaches to a point target. Rotation and gain adaptation was evident during reaches to the bar and the arc. Thus, error relevance did not matter in the rotation alone or gain alone conditions. Remarkably however, in the rotation+gain condition, we observed a striking double dissociation. Subjects showed no rotation adaptation when reaching to the arc, and no gain adaptation when reaching to the bar. That is, adaptation to a perturbation that was irrelevant to task success was selectively suppressed when it was presented simultaneous with another that was relevant to task success. Control conditions confirmed that the observed suppression was not due to an inability to adapt to two simultaneously imposed perturbations. These results thus strongly support the idea that movement direction and extent are independently processed in the brain.

Title: Influence of switching rule on motor learning

Authors: *K. TAKIYAMA, K. ISHII, T. HAYASHI
Dept. of Engin., Tokyo Univ. of Agr. and Technol., Koganei-Shi, Japan

Abstract: Humans can flexibly generate different behaviors for an identical sensory stimulus, e.g., we kick a soccer ball towards a friend who belongs to our team but we kick the soccer ball far away from the friend who belongs to an opposing team. This relation between sensory stimuli and responses is referred to as Stimulus-Response map (S-R map). The abovementioned example indicates our ability to flexibly switch between congruent S-R map (movement direction is towards a visual stimulus (i.e., a friend)) and incongruent S-R map (movement direction is far

away from a visual stimulus). In other words, we can flexibly switch a rule to generate appropriate motor commands.
Conventional motor learning theories depend on goal-directed reaching movements, or the congruent S-R map (Thoroughman & Shadmehr, 2000, Nature, Donchin et al., 2003, JNS). Those theories indicate that planned movement is a principal factor to affect motor learning. Although the same movement can be planned in different rules, e.g., kicking the ball towards rightward direction when a friend in our (opposing) team is in the rightward (leftward) direction, it is unclear whether we can show the same motor learning effect when the planned movements are the same but the rule is switched.
Here, we investigated how switching rule affected motor learning based on pro- and anti-reaching tasks (Riehle et al., 1994, Neuro Rep, Klaes et al., 2011, Neuron). In the pro-reaching task, subjects were instructed to reach towards a visual target. In contrast, subjects were instructed to reach towards opposite direction of a visual target in the anti-reaching task. First, our findings indicated that switching rule affects motor learning even when planned movements are the same; transfer of learning effects from pro- to anti-reaching movements was 75% when the planned movements were the same. Second, we proposed several candidates of computational models to explain this result: 1) a model in which aimed movement directions in anti-reaching show fluctuation in each trial, 2) a model in which neural activities in anti-reaching movements are smaller than those in pro-reaching movements, and 3) a model in which the height of tuning curve is different between pro- and anti-reaching. Third, for dissociating the predictions of those models, we investigated the transfer of learning effects from anti- to pro-reaching movements. The transfer was also 75%, supporting the predictions of 3) tuning-height modulation model.
We thus conclude that the switching rule affects height of tuning curve and partially diminishes motor learning effects even under the same planned movements.

Abstract: We examined error-based motor adaptation during practice of goal-directed reaching against unpredictable spring-like loads to quantify the impact of explicit recall of performance memories on implicit learning. Twenty human subjects sat in a high-backed chair and grasped the handle of a horizontal planar robot. An opaque horizontal screen occluded vision of the arm served as a display surface upon which visual stimuli were projected. All subjects participated in an initial "Performance Self-Assessment" testing session. Five subjects completed a secondary control session (the "Sensory Feedback Contrast" session). During the Self-Assessment session, subjects performed 3 blocks of 120 quick “out-and-back” reversal movements to capture a visual target mid-movement. The stiffness of the robot’s physical spring constant changed pseudorandomly from trial-to-trial. One of 3 conditions was tested per block, (*Proprioceptive Assessment (P), Visual Assessment (V), and* the *Control Condition(C)).* During *C*, all subjects completed the reach task without self-assessment. During the *P* trial block, subjects indicated their perceived reach extent by moving the robot handle - without load - to that location. During the *V* block, subjects indicated their perceived reach extent using a visual cursor controlled by a button box manipulated with the non-moving hand. During the Sensory Feedback session, five subjects returned to complete a block of *P trials* as well as a block of *VP* trials wherein the subjects had visual feedback via a visual cursor that tracked the hand faithfully. *Test Trials* included no visual feedback except during the *VP* block. In the Feedback Session, we found a significant influence of feedback condition such that ongoing visual feedback allowed for a reduced impact of past performance errors on future performances. Across conditions in the Assessment session, we found no difference in performance across conditions and no difference in how memories of past performances were used to update subsequent motor commands. Interposing explicit self-assessments between each trial had minimal impact on kinematic performance and error-based motor adaptation during reaching, despite the P trial block requiring active movement of the unloaded test arm in-between successive trials. Self-assessment of task performance does not appear to interfere with how the goal-directed reach was learned and performed; These two phases of the assessment trials may be interpreted by the CNS as distinct tasks. Support: Marquette University Strategic Innovation Fund.

Title: The extent of overlap between explicit and implicit visuomotor learning

Authors: S. BAO[1], G. TAYS[2], *J. WANG[3]
[1]Univ. of Wisconsin Milwaukee, Milwaukee, WI; [2]Univ. of Wisconsin - Milwaukee, Milwaukee, WI; [3]Dept Kinesiology, Univ. of Wisconsin, Milwaukee, WI

Abstract: Adapting to a novel visuomotor condition during targeted reaching movements, a type of motor learning, has been traditionally thought to mainly involve implicit, as opposed to explicit, processes. This view was challenged by recent findings, which suggest that explicit processes may play a more significant role than previously thought. The objective of this study was to determine the extent to which visuomotor adaptation involves implicit and explicit processes, by investigating the pattern of transfer between two experimental conditions: one in which subjects dealt with a rotated visual display by relying on a cognitive strategy (explicit learning) and the other in which subjects dealt with the rotated display without being aware of it (implicit learning). It was hypothesized that if the typical visuomotor adaptation involved both explicit and implicit processes, substantial transfer would be observed between the two conditions. Healthy, right-handed young adults were separated into 2 groups: Implicit-to-Explicit, or Explicit-to-Implicit. Subjects in the former group experienced familiarization, implicit learning, and explicit learning sessions; and those in the latter group experienced familiarization, explicit learning, and implicit learning sessions. All subjects used the right arm in all sessions. During the explicit session, subjects were told to reach toward a position that was rotated 30º CW relative to one of 6 targets presented in a random order; and veridical visual feedback of a cursor indicating the hand position was provided throughout the movement. During the implicit session, subjects were told to reach toward one of 6 targets presented; and visual feedback of the cursor was rotated 30º CCW about the start position. Our results indicate that initial explicit learning did not facilitate subsequent implicit learning; and initial implicit learning did not facilitate subsequent explicit learning either. These results suggest that the extent of overlap between the cognitive and/or neural processes underlying implicit and explicit learning conditions is minimal, which in turn suggests that explicit processes may not play a very significant role in typical visuomotor adaptation.

Title: Implicit visuomotor adaptation has temporally stable and labile components, but explicit adaptation is entirely stable

Authors: *J. R. MOREHEAD[1], M. A. SMITH[2]
[1]Sch. of Engin. and Applied Sci., [2]Sch. Engin., Harvard Univ., Cambridge, MA

Abstract: Memories acquired through sensorimotor adaptation show partial decay over short intervals of time, from seconds to minutes (Sing et al., 2009). Recent work suggests that this is decay of an implicit memory, rather than an explicit strategy, but this observation was limited by experimental conditions that were not specifically designed to assess the time course of the memory decay (Miyamoto et al., 2014). Here we carefully measured the temporal decay curve of a visuomotor memory at multiple time points for both implicit and strategic learning (n=17). Participants were first trained to asymptotic performance with a 30° visuomotor rotation over 200 trials, while reaching to a single target. After this initial learning phase, we exposed participants to 7 different inter-trial time delays ranging from 3s to 90s in a randomized order. Each time delay was tested 8 times, with 9 readaptation trials between each exposure, allowing full asymptotic adaptation to be recovered before the next delay was imposed. Over this set of inter-trial delays, we observed a decay of the adapted state which rapidly increased in magnitude over short intervals of 3-10 seconds, before settling to a similar sized decrease for delays of 30-90 seconds. This change in behavior was consistent with an exponential decay of the adapted state with a time constant of approximately 13 seconds. The longest inter-trial interval we tested, 90 seconds, resulted in a decay of approximately 19% [95% CIs, -27%, -12%] of the asymptotic adapted state. We observed no change [95% CIs, -6%, 3%] in explicit aiming over any of the delay intervals, indicating that the temporally labile component of adaptation is implicit in nature. Moreover, upon repeating this experiment with a smaller 15° rotation (n=13), we measured a similar 16% [95% CIs, -26%, -6%] decay of the adapted state at the maximal inter-trial interval of 90 seconds, also with no change in explicit aim [95% CIs, -5%, 2%]. Our results suggest that for visuomotor rotation learning, approximately 15-20% of implicit adaptation decays over time. This is in contrast to explicit learning, which shows no appreciable decay over this time scale. Our findings show that explicit strategies are temporally stable, whereas implicit sensorimotor adaptation has both temporally-labile and temporally-stable components. Thus the temporally-labile component of motor adaptation is implicit in origin, whereas temporally-stable learning can arise from either implicit or explicit sources.

Title: Sensitivity of implicit motor adaptation and explicit aiming

Authors: *S. A. HUTTER, J. A. TAYLOR
Psychology, Princeton Univ., Princeton, NJ

Abstract: It has become increasingly clear that learning in visuomotor rotation tasks, which induce an angular mismatch between movements of the hand and visual feedback, largely results from the combined effort of two distinct processes: implicit motor adaptation and explicit aiming. However, it remains unclear how these two processes work together to produce trial-by-trial learning. Previous work has found that implicit motor adaptation is only sensitive to small errors and operates automatically, regardless of task relevancy and the actual effect of adaptation on performance. In contrast, little is known about the sensitivity of explicit aiming to visual errors and how it is affected by task relevancy. Here we sought to characterize the sensitivity function of these two processes and how they work together to facilitate performance in a visuomotor rotation task.

To test the sensitivity of implicit adaptation and explicit aiming to visual error, participants made reaching movements while experiencing pseudo-random perturbations of visual feedback. The relevancy of these errors to learning was manipulated by varying the number of trials in a row in which the same visual error (i.e., rotation direction and magnitude) and training location (i.e., target location) were experienced. Intended aiming direction was recorded via a touch screen before every movement and implicit adaptation was inferred by subtracting the aiming direction from the hand location.

We found that overall learning, as measured by hand angle relative to target, scales proportionally to the size of the visual perturbation. Implicit adaptation also scales relative to the visual error, but only for small perturbations (replicating Wei & Kording 2009). In contrast, explicit aiming does not play a role until visual errors are relatively large and/or implicit adaptation saturates. Furthermore, participants choose not to aim when the visual errors are task irrelevant, while implicit adaptation occurs even when visual errors are irrelevant to task performance. Although overall learning is proportional when errors are task relevant, this proportionality is accomplished through the combined effects of two separate and non-proportional components.

Title: CXCR4 but not CCR5 antagonism reduce the rewarding effects of the 'bath salt' 3,4-methylenedioxy-N-methylcathinone (MDPV)

Authors: *C. F. OLIVER[1], J. K. KIM[3], S. U. NAYAK[2], S. M. RAWLS[2]
[1]Psychology, [2]Temple Univ., Philadelphia, PA; [3]McLean Hosp., Belmont, MA

Abstract: Psychostimulant abuse is a major public health concern, yet there are no FDA-approved therapies available. 3,4-methylenedioxy-N-methylcathinone (MDPV) is a type of ‘bath salt’ that is ten times more potent but mechanistically similar to cocaine. This psychostimulant has powerful reinforcing effects that manifest as escalating self-administration and relapse following abstinence. Chemokines, leukocyte attractant inflammatory proteins, are dysregulated in cocaine users. Specifically, the receptor-ligand pairs CCR5-CCL5 and CXCR4-CXCL12 have been linked to cocaine use in humans and animals. We have found that AMD3100, a CXCR4 antagonist, decreased cocaine and MDPV-induced hyperlocomotion, self-administration, and conditioned place preference. We also found that maraviroc, a CCR5 antagonist, decreased MDPV-induced hyperlocomotion but not MDPV-induced conditioned place preference. Therefore the rewarding effects of MDPV and cocaine appear to be driven by a CXCR4-dependent mechanism. The results of these studies suggest that the FDA-approved chemokine antagonist AMD3100 but not maraviroc can attenuate the rewarding effects of MDPV and cocaine, making it an ideal candidate therapeutic for addiction to MDPV and other psychostimulants.

Title: Profiling the neuroimmune response to poly I:C: sex differences, sickness behaviors, and memory

Authors: *C. K. POSILLICO, N. C. TRONSON
Psychology, Univ. of Michigan, Ann Arbor, MI

Abstract: Aberrant neuroinflammation disrupts normal neural processes including learning and memory. Memory-related disorders such as Alzheimer's Disease and post-traumatic stress disorder have been linked with increased inflammation and have a higher prevalence in women compared with men. The bacterial endotoxin lipopolysaccharide (LPS) has been widely used to elicit robust immune activation via binding to toll-like receptor (TLR) 4 expressed on microglia. We have previously shown significant sex differences in acute hippocampal cytokine response to systemic LPS. However, it is important to consider how other physiologically relevant stimuli affect the neuroimmune system, particularly with respect to sex differences in the disruption of memory processes, as many immune responses involve mechanisms outside of the TLR 4 pathway. Thus, our study aimed to characterize the effects of acute polyinosinic:polycytidylic acid (poly I:C) on sickness behaviors, hippocampal-dependent memory tasks, and the neuroimmune profile of cytokines in male and female mice. Poly I:C is a viral mimic of double-stranded RNA that binds to toll-like receptor 3 expressed on astrocytes, microglia, and neurons, making it a useful tool to study the effects of broad-based inflammation on neuroimmune function and behavior. We administered an acute, intraperitoneal injection of poly I:C (6mg/kg and 12mg/kg), or its vehicle PBS, to both sexes to determine a time course and dose-response curve of sickness behaviors and fever response following peripheral immune activation. Next, we profiled the acute cytokine response of the hippocampus in response to peripheral poly I:C to determine how systemic immune activation affects a brain region crucial for memory formation. Finally, we examined the consequences of poly I:C on the induction and consolidation of distinct memories using contextual fear conditioning, novel object recognition and novel object location tasks. These findings will provide a broader understanding of the effects of a peripheral immune challenge on acute neuroimmune activation and its impact on memory, which will better inform research on memory disorders linked with a history of inflammation.

Title: The effects of a ketogenic diet on two-way active avoidance learning during an immune challenge in mice

Authors: E. GUENDNER, M. E. GIEDRAITIS, *R. A. KOHMAN
Psychology, Univ. of North Carolina Wilmington, Wilmington, NC

Abstract: Administration of the bacterial endotoxin lipopolysaccharide (LPS) leads to an inflammatory response that has been shown to disrupt learning and memory processes. One factor that can be utilized to potentially reduce inflammation is diet. The ketogenic diet (KD) is a high fat low carbohydrate diet that has shown some utility in reducing inflammation. Though the findings are mixed, there is also some indication that consuming a KD may have beneficial effects on cognitive function. Whether KD can attenuate inflammation-induced deficits in cognitive function has yet to be directly tested. Therefore the current experiment examined the effect of KD on the cognition of subjects exposed to LPS and tested in the associative learning task two-way active avoidance conditioning. In this task, subjects can learn to avoid or escape the presentation of an aversive stimulus. Previous research indicates that LPS given prior to training impairs performance in the task. The present experiment found modest deficits in avoidance learning in the LPS-treated mice as shown by reductions in response efficiency during later days of testing. The behavioral alterations induced by LPS administration were similar in mice fed the KD or control diet (CD). Additional work is currently in progress to determine whether KD modulates LPS-induced increases in cytokine levels. The KD mice showed improved performed compared to the CD mice in the two-way active avoidance task. While the results found no indication that KD attenuates LPS-induced behavioral deficits, they illustrate that KD itself may have beneficial effects on associative learning.

Title: Maternal high fructose diet and neonatal immune challenge alters offspring anxiety-like behavior across the lifespan

Authors: S. H. F. BUKHARI[1], O. E. CLARK[1], *L. L. WILLIAMSON[2]
[1]Neurosci. Program, [2]Psychology Dept, Williams Col., Williamstown, MA

Abstract: Maternal diet has a profound impact on fetal and neonatal development, especially as obesity rates are on the rise worldwide. Specific macronutrient overabundance has been explored in some models of gestational diabetes, but the role of high fructose in the maternal diet

combined with a neonatal immune challenge remains unexplored in animal models. To test the interactions between *in utero* inflammation caused by maternal diet and neonatal inflammation caused by lipopolysaccharide (LPS), we bred 2 cohorts of dams, half fed with high fructose diet (60% fructose as carbohydrate source by weight) and half with normal chow (Teklad Diets). In the first cohort, each pup in a litter was injected subcutaneously on postnatal (P) 3 and P5 with either endotoxin-free 0.9% saline or 50ug/kg LPS. All pups in a litter were treated identically. On P7, 1 male and 1 female from each litter were tested for ultrasonic vocalizations (USVs) after a 10 min separation from the dam, as a measure of anxiety-like behavior. Subsequently, brain tissue was harvested and post-fixed in 4% formaldehyde. The remaining littermates were allowed to grow undisturbed until weaning and then undisturbed into adulthood. The adult offspring (P150-P200) were tested on the elevated zero maze (EZM) for anxiety-like behavior and in a context-object discrimination (COD) task for context memory. In a second cohort, neonates were treated with saline or LPS on P3 and P5 and all pups were weaned on P25. On P26, they were tested on the EZM and tested on the COD task on P32-34 prior to tissue harvest. While USVs showed no differences between maternal diet groups, neonatal treatment or sex, maternal diet and neonatal treatment had significant effects on juvenile (P26) behavior on the EZM. Offspring exposed to maternal high fructose diet spent significantly more time in the closed arms of the apparatus and offspring injected with saline spent significantly more time in the closed arms, with both effects likely driven by the offspring exposed to maternal high fructose and saline. In adults, offspring exposed to maternal high fructose diet spent significantly less time in the closed arms compared to offspring exposed to maternal normal diet. Surprisingly, neonatal LPS has an anxiolytic effect on the EZM in juveniles. However in adulthood, high fructose exposure also has an anxiolytic effect. Ongoing work will assess the results of COD testing and the cellular and molecular effects of maternal high fructose diet and its potential interactions with neonatal inflammation on the developing nervous system.

Title: Effects of intrauterine inflammation on cognition and motivation in male and female mice

Authors: *T. M. REYES[1], K. R. LLOYD[2], R. A. MAKINSON[2], H. LUNDE[2], S. K. YAGHOUBI[2]
[1]Psychiatry and Behavioral Neurosci., [2]Univ. of Cincinnati, Cincinnati, OH

Abstract: Chorioamnionitis, or intrauterine inflammation (IUI), occurs in approximately 10-15% of term births and is associated with developmental and psychiatric disorders including ADHD, autism, and anxiety disorders. We previously found that IUI in mice leads to white matter damage and increased novelty-seeking behavior in adulthood. Here, we hypothesize that IUI exposure will impair executive function. C57BL6/J female mice were bred to DBA males and then injected with lipopolysaccharide, a bacterial mimic, to induce a uterine-specific inflammatory response at embryonic day 15. The dams then delivered at term. Offspring were trained on operant behavior using an automated touchscreen apparatus beginning at 12 weeks of age, with males and females housed and tested in separate rooms. IUI offspring display hyperactivity during Pavlovian Conditioned Approach, with no changes to sign or goal tracking behavior. In a progressive ratio task, there was no effect of IUI on motivation in males, but female IUI mice were motivated to work for food reward than controls. Both sexes and treatment groups were able to learn a Fixed Ratio 1 (FR1) task, with prolonged training increasing the responses made by IUI females. There was no effect of sex or IUI status on performance in the 5 Choice Serial Reaction Time Task. The data suggest that IUI offspring display hyperactivity but maintain normal executive function abilities. In a related study, we found that male mice make comparable numbers of FR1 responses when housed in male-only or co-ed rooms, but females make more responses when housed in co-ed rooms. We hypothesize that the females, in response to male odor, are more motivated to work for food reward to acquire extra calories to support a potential pregnancy. These data highlight the importance of housing conditions during operant behavioral testing.

Title: Assessment of associative learning in toll-like receptor-4 deficient mice

Authors: *O. V. POTTER[1,2], M. E. GIEDRAITIS[2], R. A. KOHMAN[2]
[1]psychology, Univ. of North Carolina At Wilmington, Beulaville, NC; [2]Psychology, Univ. of North Carolina Wilmington, Wilmington, NC

Abstract: Toll-like receptor-4 (TLR-4) is a pattern recognition receptor that stimulates a proinflammatory innate immune response following detection of Gram-negative bacteria. Prior

research has established that stimulation of TLR-4 and the resulting inflammatory response produces transient cognitive deficits in a number of behavioral paradigms. Even in the absence of a TLR-4 agonist, TLR-4 has been shown to interfere with adult hippocampal neurogenesis and memory. However, the basal effects of TLR-4 on cognitive function are mixed; as TLR-4 deficient mice show enhanced spatial memory, impaired contextual and cued fear conditioning, and no differences in passive avoidance conditioning. To clarify these differential results, the current study compared TLR-4 deficient mice to control mice with functional TLR-4 receptors in an associative learning task. Adult male and female B6.B10ScN-Tlr4lps-del/JthJ (TLR-4-/-) and control C57BL/6J (TLR-4+/+) mice were assessed for alterations in locomotor behavior and anxiety-like behavior in the novel object exploration and open field tests. Subsequently, mice were evaluated in two variants of the two-way active avoidance conditioning task that differed in the time between trial presentation (i.e., inter-trial interval). Results showed that no differences in locomotor behavior or anxiety-like behavior exist between the TLR-4 deficient and control mice. Further, TLR-4 deficient mice showed comparable acquisition of the associative learning task relative to controls. Enhanced learning occurred in both strains with longer inter-trial intervals. Assessment of long-term retention of the avoidance task is currently in progress. Initial results indicate that the absence of TLR-4 has no negative effects on associative learning.

Title: Examination into the effects of a second pregnancy on postpartum anhedonia and neuroimmune function

Authors: *J. GOMEZ[1], J. M. SCHWARZ[2]
[1]Dept. of Psychological and Brain Sci., Newark, DE; [2]Psychological and Brain Sci., Univ. of Delaware, Newark, DE

Abstract: We have previously found that pregnancy (in first time mothers) produces significant anhedonia or depressive-like behavior immediately postpartum (Posilico and Schwarz, 2016). This anhedonia, as determined by a decrease in sucrose preference, is identical to that seen in female rats that are stressed for 1 week. We have also found that first time mothers have a striking increase in the pro-inflammatory cytokine IL-6 within both the medial prefrontal cortex

and the hippocampus, as well as a significant increase in Brain Derived Neurotrophic Factor (BDNF) within the medial prefrontal cortex all on the day of birth. These two brain regions are important for modulating mood and behavior, and have been implicated in many mood disorders, including depression. Similarly, elevated levels of circulating IL-6 have been associated with clinical depression in humans (Rich et al., 2017). This would suggest one of two things: either rats experience a short-lived postpartum anhedonia (resembling the "baby blues" described in humans) that is driven by an increase in IL-6 within the medial prefrontal cortex or the hippocampus; or the stress of a first-time pregnancy may be the cause of increased IL-6 within the brain and the associated postpartum anhedonia. We have begun to examine these hypotheses by studying postpartum sucrose preference and cytokine expression to see whether second pregnancies are also associated with these changes in neuroimmune function and mood. This research was supported by a NARSAD Young Investigator Grant from the Brain & Behavior Research Foundation to JMS.

Title: CCR6 mediates Th17 cells pathogenicity in depressive-like behavior in mice

Authors: *J. LOWELL, E. BEUREL
Psychiatry and Behavioral Sci., Univ. of Miami Miller Sch. of Med., Miami, FL

Abstract: $CD4^+$ T-cells actively survey the brain and differentiate into effector T-helper (Th) cells in response to changes in the inflammatory milieu. Proinflammatory cytokines including interleukin (IL)-1β, TNFα, and IL-6 promote the differentiation of Th17 cells and have been found to be elevated in depressed patients. We previously found that Th17 cells promote susceptibility to depressive-like behaviors in mice, and accumulate in the brain of mice exhibiting depressive-like behavior. Furthermore, $ROR\gamma T^{+/GFP}$ mice that have impaired Th17 production show resilience to depressive-like behaviors. Together these indicate that Th17 cells have a pro-depressant effect. Here we show after transfer, Th17 cells infiltrate the hippocampal parenchyma in mice subjected to learned helplessness and identified the hippocampus and prefrontal cortex as two regions of accumulation. Unexpectedly, the majority of the Th17 cells

found in the hippocampus after transfer originated from the donor rather than the host, whereas $CD4^+$ T-cell transfer led to hippocampal accumulation of host $CD4^+$ T-cells. Furthermore, transfer of Th17 cells into $ROR\gamma T^{+/GFP}$ mice restored sensitivity to learned helplessness and led to increased GFP induction in the hippocampus. Together these findings suggest donor Th17 cells cooperate with the host immune system. To characterize Th17 cells infiltrating the hippocampus after learned helplessness, we analyzed 2 pathogenic surface markers, CCR6 and IL-23R and a T-follicular helper (T_{FH}), CXCR5. Th17 cells found in the hippocampus of learned helpless mice, compared to non-learned helpless mice, exhibit significantly increased expression of CXCR5, CCR6, and IL-23R, identifying T_{FH}17-like cells as potential arbiters of depressive-like behaviors. To assess the requirement of CCR6 in the pro-depressant action of Th17 cells, we transferred CCR6-deficient Th17 cells into wild-type mice and found CCR6-deficient Th17 cells unable to promote susceptibility to learned helplessness in contrast to wild-type Th17 cells. This revealed that CCR6 is required to induce Th17-dependent depressive-like behavior. Altogether, we have uncovered a subpopulation of Th17 cells that is associated with learned helplessness, which might provide a potential new avenue for characterizing biomarkers for depression.

Title: Behavioral effects of maternal immune activation in mice

Authors: M. E. CRONIN[1], K. T. PRESTI[1], *A. C. BASU[2]
[2]Psychology, [1]Col. of the Holy Cross, Worcester, MA

Abstract: Epidemiological studies in humans have revealed associations between maternal immune activation during pregnancy and increased risk of schizophrenia in offspring. We sought to investigate the biological basis for this association by treating pregnant mice on gestational day 18 with the viral mimic polyinosinic:polycytidylic acid (poly I:C) and then assessing sensory gating, social behavior, and spatial cognition in adult male and female offspring. This study was

conducted in C57BL/6J mice (13 male and 11 female control offspring, 20 male and 11 female poly I:C exposed offspring). Data were analyzed using ANOVA, including treatment and sex as between-subjects variables, and an additional within-subjects variable as appropriate for repeated measures. Prepulse inhibition (PPI) of the acoustic startle response, a sensory gating phenomenon, was not affected by treatment or sex. The expected dependence of PPI on prepulse intensity was observed. There was a significant interaction between treatment and within-session trial block in our analysis of startle reactivity, suggestive of elevated initial startle response in female offspring of poly I:C treated dams. In the sociability assay, offspring of poly I:C treated dams were more sociable and demonstrated higher preference for social novelty than offspring of control (vehicle-injected) dams. Using a standard Morris water maze test of spatial learning and spatial reference memory, we found no significant effects of treatment or sex on path length, velocity or escape latency. We are currently conducting an analysis of spatial search strategies to further investigate the water maze results.

Title: Impact of minocycline administration on neuroimmune outcomes following prenatal alcohol exposure

Authors: *T. S. BODNAR, J. WEINBERG
Cell. and Physiological Sci., The Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Prenatal alcohol exposure (PAE) has a significant impact on immune function, resulting in an increased risk of infections, alterations in immune organ development, and disturbances to immune cell populations. Importantly, altered immune function can impact both physical and mental health. Specifically, the neuroimmune system is involved in brain development, with perturbations linked to cognitive deficits and mental health disorders. We have shown previously that following PAE, cytokine levels are increased in the brain during the

early postnatal period, a critical window for both brain and immune system development. Based on these findings, here it was hypothesized that administration of an anti-inflammatory agent during early-life could have a beneficial impact on the neuroimmune system following PAE. To test this hypothesis, pregnant Sprague-Dawley rat dams were assigned to: PAE – *ad libitum* access to liquid ethanol diet; or Control (C) – *ad libitum* access to control diet. Next, male and female offspring were administered minocycline, an antibiotic that targets microglia. Minocycline was administered during either lactation [postnatal (P) days 1–15] or during adolescence (P33–43). Immune organs and brain tissue were collected during and following minocycline administration to assess cytokine levels. In adulthood, the response to lipopolysaccharide (LPS) challenge was assessed and, due to the modulatory role of the neuroimmune system on cognition and learning and memory, adult were tested in the Barnes Maze, an assessment of spatial learning/memory.
Results indicate that PAE increases thymus weight at birth and ongoing work is assessing whether this is associated with alteration in cytokine levels, as well as to assess the impact of minocycline administration. Immediately following lactational minocycline, levels of key immune cell were examined to confirm that minocycline does not have a suppressive effect on the developing peripheral immune system. Differences in lymphocyte, monocyte, basophil, and eosinophil levels were not detected following minocycline administration and thus minocycline does not appear to be negatively affecting the peripheral system. Ongoing work is evaluating whether minocycline administration impacts the response to LPS challenge as well as spatial learning/memory in the Barnes Maze.
Taken together, as altered immune function/neuroimmune signaling may underlie some of the long-term effects of PAE, findings from this ongoing study may have implications for understanding the long-lasting deficits associated with FASD and support further investment into immune-based intervention strategies.

Title: The effects of alcohol on memory function and microglial cells in rat

Authors: *S.-Y. CHEN[1], C.-H. YANG[2], S.-N. YANG[2], J. WANG[1]
[1]HungKuang Univ., Shalu, Taiwan; [2]Departments of Pediatrics and Med. Research, E-DA Hospital, Col. of Medicine, I-Shou Univ., Kaohsiung, Taiwan

Abstract: Alcohol is the most widely consumed recreational drug. There are about 2 billion people as the regular consumers of alcohol in the world. It is known that alcohol is harmful to central nervous system (CNS). Evidence indicated that acute alcohol treatment induced marked functional impairments in learning and memory. Adult human reveal deficits in cognitive function such as working memory following consumption of alcohol. In normal condition, microglial cells are at a resting state in the brain. But alcohol as a neurotoxic factor that can activate microglial cells to release inflammatory mediators to induce further neuronal damage. However, the relationship between alcohol consumption and microglial dysfunction is not clear. In this study, we wanted to estimate the behavioral changes and the influence of microglia following alcohol exposure. Male SD rats fed with various concentration of alcohol for 1 week (Day 1 and 2: 1 %; Day 3 and 4: 5 %; Day 5, 6 and 7: 10 % alcohol). The diet of rats was restricted in order to decrease 20 % body weight. Then we started operating the behavioral experiment and estimated the memory functions by 8 arm maze. Rats were sacrificed after about 1 month. Our data indicated that the latency time of alcohol group was longer than control group. The memory task (total time) was significantly increased in alcohol group at Day 2, 3, 4 and 6 (291 ± 66 vs 791 ± 60; 465 ± 140 vs 852 ± 38; 409 ± 129 vs 724 ± 74; 376 ± 88 vs 791 ± 82 sec). The total working memory error (WME) and working reference error (WRE) were increased in alcohol group, too. The results of immunocytosatining of brain revealed that the activation of microglial cells increased significantly in prefrontal cortex and hippocampus (CA1). We suggested that alcohol will impair the normal memory function and induced the microglial cells activation.

Title: The influence of social hierarchy on immune responsiveness

Authors: *D. AMADO RUIZ[1], T. LODDER[1], M. TOEBES[3], A. KALSBEEK[2], H. HU[4], T. N. SCHUMACHER[3], H. W. KESSELS[1]

Abstract: Social status has been identified as one of the strongest predictors for human health. We used robust behavioral assays to measure the social hierarchy in groups of socially housed mice for which the hierarchy is established and stable, and violent acts of domination are largely absent. We found that the social status significantly correlated with the adaptive immune response in the periphery: mice with a high social status showed improved T-cell expansion upon antigenic stimulation. However, the brain regions that translate social status into improved immune responsiveness are unknown. The medial prefrontal cortex (mPFC) is known to play a central role in the control of social hierarchical behavior. To assess whether the mPFC also regulates immune function in the periphery, we manipulated synapse strength selectively at mPFC synapses by increasing or lowering AMPA-receptor levels at excitatory mPFC neurons. Our experiments demonstrate that enhancing AMPA-receptor levels at mPFC synapses is sufficient to improve antigen-specific T-cell responses. These experiments reveal a causal link between synapse strength in the mPFC, a brain area involved in higher order cognition, and the efficacy of the peripheral immune system.

Title: Astrocyte specific mediation of heroin-conditioned immune suppression

Authors: *J. E. PANICCIA, C. L. LEBONVILLE, M. E. JONES, D. T. LYSLE
Dept. of Psychology and Neurosci., Univ. of North Carolina-Chapel Hill, Chapel Hill, NC

Abstract: Exposure to both heroin and previously heroin-paired stimuli suppress peripheral indices of nitric oxide (NO) production, such as splenic inducible nitric oxide synthase (iNOS) and plasma nitrate/nitrite. Our laboratory has established the critical importance of interleukin-1β (IL-1β) signaling in the dorsal hippocampus (DH) for the expression of heroin-conditioned suppression of iNOS and nitrate/nitrite following re-exposure to the conditioned stimulus (CS). However, the cellular mechanisms of IL-1β remain unknown. The current set of experiments

investigated cell type specific expression of IL-1β during CS re-exposure, and manipulated cell type specific signaling *in vivo* in two different heroin-conditioning paradigms. In experiment 1, male rats underwent five conditioning sessions where heroin (1 mg/kg s.c) was paired with a distinct context for 1 hour every other day. Six days following the last session, animals were re-exposed to the CS, or remained in home cage as controls. Tissue was collected at three different time points: 30, 60, or 120 min following CS onset. Astrocytes were revealed as the cell type predominantly expressing IL-1β in our model. Thus, experiment 2 manipulated astrocytes *in vivo* using designer receptors exclusively activated by designer drugs (DREADDs) during CS re-exposure to disrupt heroin-conditioned immune suppression. We bilaterally infused GFAP-hM4Di-mCherry, a G_i-coupled DREADD under a GFAP promoter, into the DH of male rats. Following virus incubation, rats underwent heroin conditioning as outlined above. Six days later, animals were tested for the expression of heroin-conditioned immune suppression, and were either re-exposed to the CS, or remained in home cage. Clozapine-*N*-oxide (CNO; 3 mg/kg), or vehicle, was given 30 min prior to CS to activate the glial DREADDs. Immediately following CS, animals were given lipopolysaccharide (LPS; 1 mg/kg) to induce an immune response, and tissue was collected 6 hours later. Activation of GFAP-hM4Di-mCherry significantly attenuated heroin-conditioned suppression of plasma nitrate/nitrite and splenic iNOS mRNA expression. Experiment 3 investigated if the effect of GFAP-hM4Di-mCherry also disrupted heroin-reward associated memories. We bilaterally infused the construct into the DH of male rats prior to training in heroin-conditioned place preference (CPP). CNO administration 30 min prior to testing for the expression of heroin-CPP did not alter preference for the heroin-paired chamber. This suggests a specific role for G_i signaling in astrocytes to disrupt heroin-conditioned immune suppression, but not heroin-conditioned reward associations.

Title: Role of ventral hippocampus in context-heroin conditioned immunosuppression

Authors: *C. LEBONVILLE[1], M. E. JONES[1], J. E. PANICCIA[1], R. A. FUCHS[2], D. T. LYSLE[1]
[1]Psychology and Neurosci., Univ. of North Carolina At Chapel Hill, Chapel Hill, NC; [2]Integrative Physiol. and Neurosci., Washington State Univ., Pullman, WA

Abstract: Similar to heroin itself, exposure to environmental contexts associated with the prior effects of heroin can produce immunosuppression through Pavlovian associative conditioning. Our laboratory has demonstrated that the functional integrity of the basolateral amygdala (BLA), nucleus accumbens shell (NAcS), and dorsal hippocampus (DH) is necessary for the expression of this conditioned immune response. However, it is unknown whether the ventral hippocampus (VH) plays a role in this phenomenon. We tested the hypothesis that the VH plays a role in heroin conditioned immunosuppression based on its connectivity with the BLA and NAcS and based on evidence that projections from the VH to the NAcS may play a role in drug-related behavior. To test this hypothesis, we bilaterally infused an adeno-associated viral vector carrying the sequence for the G_i-coupled designer receptor exclusively activated by a designer drug (DREADD), HM4Di, under a CAMKIIα promotor (AAV5-CAMKIIα-HA-HM4Di-IRES-mCitrine) into the VH of male rats. Two weeks later, heroin (1 mg/kg) was repeatedly paired with access to a distinct context. After training (30 min before the test session), rats received systemic injections of the DREADD agonist, clozapine-*N*-oxide (CNO; 3 mg/kg), or vehicle. At test, rats were then re-exposed to the heroin-paired context for 1 h (to induce conditioned immunosuppression) or remained in their home cages (control). Rats then received a systemic injection of lipopolysaccharide (LPS; 1 mg/kg) to trigger the expression of proinflammatory mediators. VH inactivation failed to alter the heroin-conditioned suppression of splenic iNOS and plasma nitrate/nitrite levels assessed 6 h later. Together with our previous findings, these results indicate a role for the DH, and not the VH, in heroin-conditioned immunomodulation in the spleen.

Title: Neuroimmune signaling in stress-enhanced fear learning, an animal model of post-traumatic stress disorder

Authors: *M. E. JONES[1], J. E. PANICCIA[2], C. LEBONVILLE[1], D. T. LYSLE[3]
[1]Psychology and Neurosci., Univ. of North Carolina At Chapel Hill, Chapel Hill, NC; [2]Dept. of Psychology and Neurosci., Univ. of North Carolina-Chapel Hill, Chapel Hill, NC; [3]Univ. of North Carolina at Chapel Hill, Chapel Hill, NC

Abstract: Neuroimmune signaling is important in learning and memory processes. Further, converging evidence suggests that neural immune interactions, including astrocyte activity, are altered following stress exposure. For example, our laboratory has shown that the severe stressor in stress-enhanced fear learning (SEFL), an animal model of PTSD, induces a time-dependent increase in interleukin-1β (IL-1β) protein and mRNA and that blocking IL-1 signaling prevents the development of SEFL. Here, we employed triple labeling fluorescence immunohistochemistry to determine the cellular source of IL-1β and recent advances in chemogenetic technology to begin to explore the role of astrocytes, a key immune cell type in the central nervous system, in stress-enhanced fear learning. We used glial DREADDs (designer receptors exclusively activated by designer drugs) to test whether Gq and/or G_i signaling specifically in hippocampal astrocytes influences the development of SEFL. In Experiment 1, rats were exposed to Context A of the typical SEFL paradigm (15 2mA scrambled foot shocks over 90 minutes on a 6 minute variable interval schedule) and sacrificed via transcardial perfusion 48 hours later. Brains were extracted and tissue was processed for immunohistochemistry with primary antibodies against IL-1β and cell type specific markers for astrocytes, GFAP, neurons, NeuN, and microglia, Iba-1. Alexa fluor -conjugated secondary antibodies were used for visualization. Confocal microscopy and Bitplane Imaris colocalization analyses revealed that 92% of hippocampal IL-1β is expressed by astrocytes, while only 3% and 5% of hippocampal IL-1β is expressed in microglia and neurons, respectively. In Experiment 2, rats were infused with *AAV8-GFAP-hm4di-mcherry* or *AAV5-GFAP-hm3dq-IRES*-mCitrine directly into the dorsal hippocampus (DH) and allowed three weeks to recover from surgery and for the virus to express. Rats were then exposed to the typical SEFL paradigm and administered Clozapine-n-oxide (CNO) (3 mg/kg, s.c.) immediately, 24h and 48h after removal from Context A. Interestingly, while activating astroglial G_i signaling significantly attenuated the development of SEFL, activating astroglial G_q signaling did not influence SEFL. In summary, Experiment 1 quantitatively showed that astrocytes are the predominant cellular source of stress-induced IL-1β in the DH. Strikingly, our preliminary data in Experiment 2 showed that activating astroglial Gi signaling, but not astroglial G_q signaling attenuated SEFL, a PTSD-like phenotype. Further studies in our laboratory are testing whether any effects of glial GPCR signaling occur through an IL-1β-dependent mechanism.

Title: Effects of adolescent exposure to the short-chain fatty acid, propionic acid, and lipopolysaccharide on adolescent and adult rat anxiety and sensorimotor gating

Authors: *D. WAH, M. KAVALIERS, K.-P. OSSENKOPP
Psychology, Univ. of Western Ontario, London, ON, Canada

Abstract: Alterations in the gut-brain axis have been implicated in the development of Autism Spectrum Disorders (ASD). Children with ASD show elevated levels of *Firmicutes* and *Desulfovibrio* bacteria in their stool. These bacteria produce short-chain fatty acids, such as propionic acid (PPA) and lipopolysaccharide (LPS) that affect anxiety-like behaviours and sensorimotor gating. The present study examined how an early adolescent exposure to LPS interacts with acute exposure to PPA in adolescence and adulthood on a measure of anxiety and sensorimotor gating. Adolescent male Long-Evans rats were administered 200 μg/kg LPS or vehicle intraperitoneally (i.p.) on postnatal days (P) 28, 30, 32, and 34. Rats were then injected with 500 mg/kg PPA or vehicle i.p. on P40 and tested on a Light-Dark (LD) task as an indicator for anxiety-like behaviour and locomotion. On P43, rats were again injected with 500 mg/kg PPA or vehicle i.p. and tested on Acoustic Startle Response (ASR) as an indicator of sensorimotor gating. In adulthood, rats were injected with PPA or vehicle and tested on P74 using the LD task and P77 using ASR. The results suggest that LPS interacted with PPA to decrease the number of light-dark transitions on the LD task in comparison to controls in adolescent rats. Finally, there were no differences in percent prepulse inhibition among treatments. Findings from this study will guide future research using an animal model of ASD through exposure to an immune insult and gut metabolite.

Naval de Alta Especialidad, Secretaria de Marina, México, Mexico

Abstract: Major Depression Disorder (MDD) is a global health emergency with 350 million people and 2-5.6% are adolescents; despite this, research on adolescents is limited. Regarding MDD, it has been reported that inflammatory response contributes to the onset of depression. In adults MDD patients, it has been described a link between the chemokine levels and the symptoms severity. We evaluated the serum levels of MCP-1(CCL2), MIP-1α(CCL3), MIP-1β(CCL4), IL-8(CXCL8), IP-10(CXCL10) and eotaxin(CCL11) in adolescents with MDD and their clinical psychiatric evolution by HDRS score. 18 healthy volunteers (HV) and 22 adolescents with MDD were evaluated along eight weeks (W) of clinical follow-up. In all cases, significant differences were detected in circulating chemokine levels between patients before treatment and HV ($P<0.0001$). Then, all chemokines evaluated showed a trend to decrease at

W4; however, only MCP-1 and IL-8 presented significant differences (P<0.05) between W0 vs W4. In adolescents with MDD, all chemokines rose to their initial concentrations (W0 vs. W8), but only IP-10 presented a significant (P<0.05) increase (W0 vs W8). All patients showed a significant decrease in their HDRS score at W4, (P<0.0001) and W8, (P<0.0001) compared to W0. Regarding the effect of fluoxetine on chemokine levels, our results showed a significant elevation of chemokines in adolescent with MDD despite the consumption of fluoxetine and improvement in HDRS scores. The high levels of eotaxin, IP-10 and IL-8 may partially explain some features of MDD as cognition, memory, and learning. Further studies are necessary to explore these findings and its implication in therapeutic approach.

Title: Elucidating adaptive roles for microglia in chronically stressed mice

Authors: *M. L. LEHMANN[1], T. K. WEIGEL[1], H. A. COOPER[2], S. L. KIGAR[1], M. A. HERKENHAM[1]
[1]Natl. Inst. of Mental Hlth., NIH, Bethesda, MD; [2]Temple Univ., Philadelphia, PA

Abstract: We hypothesized that chronic psychosocial stress can directly precipitate an immune reaction in the brain through activation of resident microglia and that the degrees and kinds of reaction are dependent on the psychological status of the animal. To model psychosocial stress in rodents, we used a chronic social defeat (CSD) paradigm. Mice susceptible to CSD (CSD-S) showed enduring deleterious behavioral consequences; however, a subset of resilient (CSD-R) animals avoided this outcome. We first performed a microarray analysis on microglia isolated from CSD-S and CSD-R mice to understand how these immune cells differentially respond to and perhaps contribute to stress adaptability. Gene expression profiles revealed that microglia from CSD-S relative to CSD-R mice might be phagocytically active and might promote a permeable blood brain barrier (BBB) that could support entry of peripheral monocytes into the brain. A series of *ex-vivo* and *in-vivo* experiments was performed to test the array results. First, microglia from CSD-S and CSD-R brains were isolated, placed in culture, exposed to fluorescently labeled apoptotic cells, and assayed for phagocytic activity. We found that

microglia from CSD-S mice compared to CSD-R mice contained higher levels of labeled debris and therefore were significantly more phagocytic. Second, BBB permeability was quantified in brains of CSD-S and CSD-R mice using i.v.-injected sodium fluorescein and, in addition, histochemically visualized using i.v.-injected fixable FITC-dextran. We found that CSD-S brains had substantially increased BBB permeability compared to brains from CSD-R and non-stressed mice. Third, we tested monocyte extravasation by injecting mice previously exposed to two weeks of CSD with peripheral blood mononuclear cells (PBMC) isolated from ubiquitously expressed GFP (Ubc-GFP) reporter mice. Brains and spleen were examined for GFP-positive cells three days after Ubc-GFP transfer. Although spleens from all groups showed colonization of GFP-positive cells, neither flow cytometry nor immunohistochemistry showed the presence of GFP-positive cells in brain in any condition, suggesting that CSD does not cause extravasation of PBMCs into brain. Together these results demonstrate that CSD-S microglia are more phagocytic and secrete molecules that break down the BBB, though at the time point examined, peripheral cells do not enter the brain. We hypothesize that these collective activities represent a CNS-centric inflammatory state that contributes to the susceptible phenotype. Causal relationships between microglia phenotype and behavioral phenotype are under current investigation.

Title: T cells are necessary for resolution of inflammation-induced depression-like behavior via an IL-10 dependent pathway

Authors: *A. KAVELAARS, G. LAUMET, J. D. EDRALIN, R. DANTZER, C. J. J. HEIJNEN
Neuroimmunology Lab., Univ. of Texas MD Anderson Cancer Ctr., Houston, TX

Abstract: Major depressive disorder (MDD) is one of the most common mental disorders worldwide. Accumulating evidence indicates a role of the innate immune system in the onset of depression. In patients with MDD have increased level of circulating inflammatory cytokines and blood T cell count and proliferative responses to mitogens are reduced in depressed patients compared to mentally healthy individuals. On the basis of rodent studies of inflammation-induced depression-like behavioral it is known that IDO1 activity is necessary for depression-

like behavior (O'Connor et al, Mol Psy, 2009; Kim et al, JCI, 2012). *Ido1* expression is upregulated by proinflammatory cytokines such as IFNγ, TNFα and IL-1β (O'Connor et al, J Neurosci 2009). T cells are key regulators of the immune response and recent evidence has shown that T cells are also essential for maintaining central nervous system homeostasis (Ellwardt, Trends Immunology, 2016). However, little is known about the role of T cells in inflammation-induced depression. In order to investigate the role of T cells in inflammation-induced depression, we compared C57Bl/6 WT and T cell-deficient ($Rag1^{-/-}$ and $Rag2^{-/-}$) mice. Inflammation-induced depression-like behavior was measured as increased immobility time in the forced swim test in response to lipopolysaccharide (LPS) or Complete Freund's adjuvant (CFA). In both models, the onset of depression was similar between WT and T cell deficient mice, but depression-like behavior was drastically prolonged in T cell deficient mice. This was associated with prolonged upregulation of *Ido1* in the brain. Reconstitution of T cell-deficient mice with CD3+ T cells normalized resolution of depression-like behavior and expression of brain *Ido1*. During the resolution, T cells accumulated in the meninges but did not penetrate the brain parenchyma. In the brain, the inflammation-induced increase in pro-inflammatory cytokines such as *Ifng*, *Tnf* and *Il1b* was T cell independent. In contrast, T cells were required for induction of IL-10 in the brain. Nasal administration of neutralizing anti-IL-10 antibody prolonged depression-like behavior, indicating that brain IL-10 signaling is required for resolution of depression-like behavior. Transfer of IL-10-deficient T cells to T cell deficient mice was sufficient to induce resolution of depression-like behavior, indicating that T cells were not the source of IL-10. In conclusion, we show for the first time that T cells are required for resolution of inflammation-induced depression-like behavior and to silence *Ido1* expression in the brain via an IL-10-dependent pathway.

Abstract: (R, S) ketamine (KET) is recognized for its rapid-acting antidepressant properties in humans, as well as rodent models. Recent studies have shown that (2R, 6R) hydroxynorketamine (HNK), a metabolite of KET, reverses stress-induced anhedonia and behavioral despair. It has also been reported that pre-treatment with low-dose KET in an inflammation model blocks the typical manifestation of these behaviors after sickness symptoms have subsided, approximately 24 h after an immune challenge. Given the known anti-inflammatory properties of KET, the goal of this study was to compare the effects of KET and HNK on lipopolysaccharide (LPS)-induced sickness behaviors and consummatory anhedonia. C57Bl/6J male mice (9 weeks of age; 8 mice/group) were administered either KET, HNK (20 mg/kg, i.p.) or vehicle followed 1 h later by either LPS (1 mg/kg, i.p.) or vehicle. Weight, temperature and sickness scores were recorded 2, 6 and 24 hours post injection. Twenty-four hours after LPS administration all groups underwent a sucrose preference test. KET, but not HNK, significantly attenuated sickness behavior 2 h post injection; however, neither KET nor HNK had significant impacts on LPS-induced changes in weight or temperature. In contrast, LPS-induced anhedonia in the sucrose preference test was completely blocked by HNK, but only partially by KET. This study suggests that, at the dose utilized, KET has anti-inflammatory effects that occur independently of its metabolite HNK. Moreover, our results show that HNK can prevent inflammation-induced anhedonia. Future studies will be required to elucidate the antidepressant and anti-inflammatory mechanisms of KET, and the mechanism by which HNK prevents anhedonia.

Title: An inflammatory pathway links dietary antioxidant levels and human gray matter morphology: Moderation by cardiorespiratory fitness

Authors: *R. L. LECKIE[1], D. C.-H. KUAN[2], P. J. GIANAROS[3]
[1]psychiatry, [2]Univ. of Pittsburgh, Pittsburgh, PA; [3]Univ. Pittsburgh, Pittsburgh, PA

Abstract: Several health behaviors can predict brain atrophy and cognitive decline, including diet and physical activity (PA). Specifically, greater dietary consumption of antioxidants (derived from fruits, nuts, and vegetables) and greater PA and cardiorespiratory fitness (CRF) are associated with larger GM volumes, even in midlife. Similarly, both antioxidant-rich diets and high CRF levels are associated with lower systemic inflammation. In fact, evidence suggests that systemic inflammation may play a role in effects of diet and PA on tissue morphology. Yet, it is unknown if the associations of diet and CRF with GM volume are independent or if they interact to predict brain volume via systemic inflammation. Accordingly, we tested whether GM volume in healthy middle-aged adults was associated with circulating antioxidant levels, and whether this association was accounted for by inflammation and moderated by CRF. Participants were 137 midlife adults (49%male, aged 30-50 years, mean age 40.7(6.15)). Blood samples were assayed for antioxidants (beta-carotene, alpha-tocopherol, gamma-tocopherol, beta-cryptoxanthin, retinol) and systemic inflammation (interleukin-6, C-reactive protein). CRF was estimated by resting heart rate, sex, height, and weight, and self-reported physical activity from the Paffenbarger Inventory. T1 MRI images were segmented for values of GM volume for the whole brain, four lobes, and select subcortical structures. Using residuals from intracranial volume, greater inflammation was associated with lower GM volume, while greater CRF moderated the association of antioxidant levels and GM volume in the frontal and occipital lobes. The dietary influences of antioxidant consumption may depend on PA, which has implications for age-related brain tissue losses and possibly cognitive decline.

Title: Mating and reward system activation increases the expression of CCR5 on T cells

Authors: *T. BEN-SHAANAN, M. SCHILLER, N. BOSHNAK, B. KORIN, H. AZULAY-DEBBY, A. ROLLS
Immunol., Technion Fac. of Med., Haifa, Israel

Abstract: Mating is a major driving force in evolution. From an immunological perspective, mating is considered risky because of the potential exposure to sexually-transmitted pathogens. Although connections between mating and immunity are expected, they are still largely unknown. Here we show that mating elevates the expression of the chemokine receptor CCR5 on blood circulating CD4 and CD8 T cells. CCR5 is especially relevant for sexually transmitted diseases as it is the main cellular entry mechanism of the HIV virus. We demonstrate that

exposing male mice to mating-associated cues, or direct activation of the brain's reward system, associated with mating behavior, were sufficient to induce the increase in CCR5 levels. This increase in CCR5 expression was mediated by noradrenaline and peripheral opioids activity. Taken together, these results demonstrate a connection between, mating, activation of the reward circuitry, and CCR5 expression on T cells. Given the central role of CCR5 in HIV infection, our data suggests a possible mechanism whereby mating-associated immune reactions play a role in the evolutionary host-pathogen arms race.

Title: Isoforms of HMGB1 modulate pain response in animals and activate neuronal cells

Authors: *H. YANG, Q. ZENG, M. ADDORISIO, M. K. GUNASEKARAN, S. S. CHAVAN, K. J. TRACEY
Feinstein Inst., Manhasset, NY

Abstract: Secreted by activated cells or passively released by damaged cells, extracellular high mobility group box 1 (HMGB1) is an inflammatory mediator in both sterile injury and infection. Emerging evidence revealed that the release of HMGB1 following nerve injury plays a central role in the pathogenesis of neuropathic pain (Calvo M, et al, Lancet Neurol 2012, Karatas H et al, Science 2013). HMGB1 can directly act on nociceptors to induce pain as well as priming enhanced pain. HMGB1 expresses three cysteine residues and their redox states determine the biological function of HMGB1. All three cysteine reduced (fully reduced) HMGB1 induces chemotactic responses; mild oxidation (disulfide) HMGB1 is cytokine-inducing and pro-inflammatory; and oxidation of all cysteine residues (sulfonyl) HMGB1 has no known immune function (Yang H et al, Mol Med 2015). But it is not clear on the role of these isoforms of HMGB1 in neuropathic pain. Here we aimed to elucidate the effects of isoforms of HMGB1 in neuropathic pain and neuronal activation. Mechanical nociceptive threshold response in hind paw was determined in rats subjected to injection of isoforms of HMGB1. Compared to vehicle (PBS) -injected controls, intraplantar administration of disulfide HMGB1 (at 0, 2, 12 or 20 μg per paw) evoked mechanical hyperalgesia in female Sprague-Dawley rats in a dose-dependent manner [threshold response (gm) of vehicle = 4.1 $\pm$ 0.4, 0.2 μg/paw = 3.8 $\pm$ 0.6; 12 μg/paw =

2.3* ± 0.2, 20 µg/paw = 1.9* ± 0.2, N=6 or 12 per group, *: P<0.05 *vs.* vehicle group]. In comparison, fully reduced HMGB1 had similar effects whereas sulfonyl HMGB1 did not (data not shown). Systemic administration of neutralizing anti-HMGB1 monoclonal antibodies (mAb) ameliorates these hyperalgesia effects induced by disulfide HMGB1 in rats [threshold response (gm) of normal = 4.9 ± 1, HMGB1 alone = 1.9 ± 0.3, HMGB1 + mAb = 3.3* ± 0.3. *: P<0.05 *vs.* HMGB1 alone). In sensory neuron-like F11 cells, administration of disulfide HMGB1 significantly increased intracellular calcium influx (3.7 ± 0.3-fold increase over basal) whereas sulfonyl HMGB1 did not. Similar findings were observed using primary rat dosal root ganglions, indicating that disulfide HMGB1 activates neuronal cells *in vitro.* Exposure to albumin did not activate calcium influx, and the addition of neutralizing anti-HMGB1 mAb inhibited these effects; showing the specificity of the responses. Taken together, these results suggest that the redox state of HMGB1 is a critical determinant in neuropathic pain and in neuronal sensory neuron activation, with significant implications for developing experimental strategies targeting HMGB1-dependent neuronal-inflammatory diseases.

Title: Characterization of hedgehog-responsive cells in the adult mouse spinal cord

Authors: M. S. RALLO, *M. P. MATISE
Rutgers-RWJMS, Piscataway, NJ

Abstract: Introduction: Sonic hedgehog (Shh) signaling plays an important role in both neural development and adult CNS function. The mechanism of signaling involves binding of Shh to the Ptch1 receptor, thus relieving the inhibition on Smo and allowing for differential activation of Gli transcription factors (Gli1-3) which mediate target gene expression. Notably, *Gli1* itself is a positively regulated target of Shh signaling. In the adult CNS, Shh is critical for maintaining pools of neural stem cells in the subventricular and subgranular zones of the brain as well as astrocytes within discrete regions of the forebrain. However, the distribution and properties of Shh-responsive cells in the adult spinal cord is yet to be elucidated.
Materials/Methods: To characterize $Gli1^{+}$ cells in the adult spinal cord we used two mouse lines: (1) a tamoxifen-inducible *Gli1:CreERT2;Rosa26:eYFP* line which permits lineage tracing

of cells expressing Gli1 indicating that they have received Shh signaling, and (2) a *Gli1:lacZ* line in which cells actively receiving Shh signaling express β-galactosidase. Spinal cord sections from the *Gli1:CreERT2;Rosa26:eYFP* animals were analyzed by IHC using neuronal- and glial-specific antibodies and RNA-seq to establish the molecular profile of these cells. The morphology and localization of $Gli1^+$ cells were also examined. *Gli1:lacZ* animals were fed BrdU in their drinking water for four weeks before collection to label slowly-proliferating cells within the adult spinal cord.
Results: Cells expressing Gli1 ($Gli1^+$ cells) were found distributed throughout the grey matter of the spinal cord 7 days following tamoxifen administration. No $Gli1^+$ cells were found in the white matter or ependymal zone. $Gli1^+$ cells co-labeled with glial markers Sox9, GFAP, Olig2 but not with the neuronal marker NeuN or the oligodendrocyte-lineage markers NG2, APC-CC1, MBP, or the microglia marker IBA-1. The molecular profile of $Gli1^+$ cells remained the same 1 year following tamoxifen administration. In addition, the cells displayed a highly branched morphology and were found in apposition to PECAM-stained blood vessels. The results of the proliferation analysis showed no incorporation of BrdU into $Gli1^+$ cells.
Conclusion: Our data indicate that $Gli1^+$ cells in the adult spinal cord represent a molecularly distinct subset of protoplasmic astrocytes in the adult CNS, suggesting a unique function. Based on the juxtavascular localization of the cells it is likely that these astrocytes are important components of the neurovascular unit. Future experimentation will assess the functional role of these cells in the lesioned spinal cord.

Title: Isoflurane mitigates Evans blue dye extravasation caused by carbogen inhalation in mice and rats

Authors: K. LIAO[1,3], K.-S. POON[1,3], Y.-L. PAN[1], H.-L. WANG[1], K.-B. CHEN[1,3], Y.-C. LIU[1,3], *T. W. LAI[2,1,4]

Abstract: Isoflurane protects the blood-brain barrier (BBB) against cerebral extravasation of the Evans blue dye (EBD), a commonly used serum protein tracer, in animals subjected to BBB disruption. As such, it has been implicated as a therapeutic agent that can prevent brain edema and damage caused by a number of brain insults, including focal ischemia and intracerebral hemorrhage. In a recent study, we reported that isoflurane protects against cerebral extravasation of EBD following ischemic stroke in large through induction of hypothermia (Liu *et al*., 2017 PLoS One). This finding raised the possibility that isoflurane protected against other causes of BBB disruption also through hypothermia. To test this hypothesis, we subjected mice and rats to carbogen inhalation, an inducer of BBB disruption, in the presence or absence of isoflurane whilst measuring their rectal temperature. In mice, carbogen inhalation on its own caused marked hypothermia, and under this condition, isoflurane had no additional effect on rectal temperature. Nevertheless, isoflurane strongly protected against carbogen-induced cerebral extravasation of EBD. In addition, when temperature was maintained at 37^{o}C by means of an automated heating pad, isoflurane remained protective against cerebral extravasation of EBD. In rats, isoflurane mildly exacerbated carbogen-induced hypothermia, but also protected against cerebral extravasation of EBD. In conclusion, isoflurane strongly protected against cerebral extravasation of EBD caused by carbogen inhalation in mice and rats, but unlike isoflurane-mediated protection against ischemic BBB disruption, the effect here could not be explained by anesthesia-induced hypothermia.

Abstract: Although lymph vessels were recently discovered in the meninges, it is still widely debated how waste products are removed from the brain. It has been proposed that brain waste clearance occurs by bulk flow of interstitial fluid through neuropil as well as along blood vessels (the “glymphatic” concept [1,2]). A prerequisite for such an advection is a reasonably high hydraulic permeability. If the gaps between brain cells are too narrow, the neuropil permeability will be low and bulk flow will not be permitted for physiological pressure gradients.
Estimates of the neuropil permeability based on fluid injections and pressure recordings have several caveats, and the reported values for permeability of neuropil in the literature has a wide range, typically from 720 nm^2 to 4000 nm^2. Here we estimate the permeability based on a computer simulation of flow in electron microscopic (EM) reconstructions with realistic extracellular volume fractions.
We simulated bulk flow in geometries from Kinney et al. [3]. The extracellular space was divided into sheets and tunnels. Sheets were defined as the extracellular space between two parallel membranes (typically 10 to 40 nm wide), whereas tunnels were defined as the extracellular space where three or more membranes meet (typically 40 to 80 nm wide). For two different geometries with the same extracellular volume fraction we found that the geometry with the largest tunnel volume fraction had a 36% higher permeability. However, even for larger extracellular volume fractions than what is reported for sleep and for geometries with a high tunnel volume fraction, the permeability was too small to allow for any substantial bulk flow at physiological hydrostatic pressure gradients.
We also found that the permeability was about two orders of magnitudes lower (~10 nm^2) than what is typically reported in the literature. Our simulation results suggest that even large molecule solutes are more easily cleared from the brain interstitium by diffusion than by advection. Thus, we conclude that diffusion within the interstitial space combined with advection along vessels is likely to substitute for the convection-based lymphatic drainage system in other organs.

Title: Mixture theory based analysis of the glymphatic system

Authors: *P. A. PATKI[1], B. J. GLUCKMAN[3], P. J. DREW[4], F. COSTANZO[2]
[1]Mechanical and Nuclear Engin., The Pennsylvania State Univ., State College, PA; [2]Ctr. for Neural Engineering, Engin. Sci. and Mechanics, The Pennsylvania State Univ., University Park, PA; [3]Ctr. for Neural Engin., Penn State Univ., University Pk, PA; [4]Dept. Engin. Sci. and Mechanics, Pennsylvania State Univ., University Park, PA

Abstract: It is well known that the lymphatic system, which is involved in the removal of toxins throughout the body, is absent in the brain. Thus the solute clearance mechanism of the brain remains an active area of research. In this context, a 'glymphatic system' was proposed by Iliff, Nedergaard and co-workers[1]. They observed exchange of metabolites from extracelluar space to the main cerebrospinal fluid (CSF) compartment. The observed rates indicated a prominent convective component to the flow of metabolites. To explain this, they proposed a pathway (glymphatic system) by which CSF is drawn into paravascular space of penetrating arteries and finds its way into parenchymal extracellular space primarily through AQP4 channels on the endfeet of astrocytic projections surrounding blood vessels. The interstitial fluid (ISF) is collected into the para-venous spaces. The flow was claimed to be driven mainly by arterial pulsations. The advection is said to be strong enough to carry macromolecules, thus leading to brain-wide solute clearance. We consider realistically inspired models of brain parenchyma to investigate if such a solute clearance mechanism can actually exist from a physical point of view. Previous numerical studies have assumed brain tissue to be a rigid solid with CSF flow through the inter-cellular spaces. We model the brain as a poro- elastic material and consider flow of CSF and passive transport of solutes. The Mixture Theory based Finite Element formulation developed by Costanzo and Miller[2] was used for numerical modelling of Fluid-Structure Interactions in the tissue. Here we discuss a relatively simple thought experiment: We check

whether a peristaltic wave traveling along arteries induces a significant convective flow of ISF in the surrounding tissue. This calculation is meant to ascertain whether or not pulsation alone in the absence of pressure gradients can in fact drive ISF convective flow. Our primary results show that such a scenario does not generate appreciable convective flow. Thus, if pulsation is the main driving element of the glymphatic system, it can only occur if mechanisms other than mere peristalsis are dominant.

Title: Treatment frequency of focused ultrasound mediated blood-brain barrier opening treatment for Alzheimer's disease

Authors: *C. POON[1], K. SHAH[2], R. TSE[1], K. KIM[1], S. MOONEY[1], K. HYNYNEN[1]
[1]Physical Sci., Sunnybrook Hlth. Sci. Ctr., Toronto, ON, Canada; [2]Univ. of Toronto, Toronto, ON, Canada

Abstract: Background: Focused ultrasound (FUS)-mediated blood-brain barrier opening (BBBO) is a noninvasive method to enhance drug delivery to targeted regions of the brain. FUS BBBO has been used to deliver a variety of agents to the brain (e.g. chemotherapeutics, natural killer cells) and results in an increased rate of neurogenesis. Using FUS-mediated BBBO, antibodies directed against amyloid-β (Aβ) have been successfully delivered to the brain parenchyma of the TgCRND8 mouse model of AD. A follow-up study showed that three weekly treatments of FUS-mediated BBBO targeted to the bilateral hippocampus (without therapeutics) significantly decreased Aβ plaque load and improved spatial memory performance in AD mice to the levels of non-transgenic controls.

Objective: The objective of this study is to determine if five biweekly (once every two weeks) FUS-mediated BBBO treatments reduces Aβ plaque burden and improves cognitive functions in the TgCRND8 mouse model of AD, and to compare this with the results from the three weekly FUS treatments study [Burgess *et al.*, Radiology 2014].
Methods: Seven-month old TgCRND8 mice were given FUS-mediated BBBO treatments targeted to the bilateral hippocampi once every two weeks for a total of ten weeks. FUS treatments were conducted by mechanically scanning a spherically curved transducer (1.68 MHz, 10 ms bursts, 1 Hz burst repetition frequency, 120 s duration) in conjunction with a bolus injection of Definity microbubbles (20 μl/kg) under magnetic resonance imaging (MRI) guidance at 7T. Hippocampus-dependent memory was assessed using the Novel Arm Y-Maze test one week after the last FUS treatment. Bromodeoxyuridine (BrdU) was injected 2 hours before sacrifice. Aβ plaques were stained using immunohistochemistry, and quantified using stereology.
Results: Biweekly FUS treatments were well-tolerated by TgCRND8 mice. After five biweekly FUS treatments, plaque burden decreased significantly in AD FUS mice compared to AD control mice (413.7 ± 16.1 compared to 298.6 ± 24.1, mean ± SEM, n=5-8). Results were comparable to the three weekly FUS treatments regime [Burgess *et al.*, Radiology 2014].
Significance: Although FUS-mediated BBBO will likely be used as a means to deliver AD therapeutics in order to maximize treatment efficiency, the effects of the FUS itself on AD symptoms should be determined. The frequency of FUS treatments delivered to AD patients must be clinically feasible and result in maximal treatment benefits.

Abstract: Cerebrospinal fluid (CSF) is thought to be transported into and out of the brain via the glymphatic system. Decreased turnover of CSF in the brain plays a role in aging and in neurodegenerative disorders. However, the anatomical pathways by which CSF and interstitial fluid (ISF) leave the brain are poorly understood, and elucidating these pathways is important as they will play a role in controlling CSF turnover. There is evidence that the CSF exits into the nasal epithelium via the cribriform plate, the perforated bone through which olfactory sensory neurons enter the brain. To better understand the anatomical substrate at the microscopic and mesoscopic scale, we used microCT imaging and histological reconstructions of the nasal turbinates, cribriform plate and olfactory bulbs in mice. CT imaging revealed the cribriform plate was highly porous, with four major foramina located laterally from the crista galli, the ridge of bone along the midline of the plate. Multiple, smaller foramina, lined with Aquaporin-1, concentrated mostly along the crista galli were also observed. Blood vessels were observed traversing foramina of the plate. Using cell-type specific labeling in transgenic mice, the relationship of the dura and lymphatic vessels along the olfactory nerves was investigated. We are currently examining the microscopic anatomy of the outflow pathway (interstitial space between nerves, blood vessels, and lymphatics) with injections of FITC-albumin. Our results show that the cribriform plate is an important CSF outflow pathway in mice.

Title: Exploring the angiogenic response of hippocampal vasculature to focused ultrasound-mediated increases in blood-brain barrier permeability

Authors: *D. MCMAHON[1,2], K. HYNYNEN[2,1]
[1]Sunnybrook Res. Inst., Toronto, ON, Canada; [2]Med. Biophysics, Univ. of Toronto, Toronto, ON, Canada

Abstract: Therapeutic treatment options for central nervous system diseases are greatly limited by the blood brain barrier (BBB). Focused ultrasound (FUS), in conjunction with circulating microbubbles, can be used to induce a targeted and transient increase in BBB permeability, providing a unique approach for the delivery of drugs from the systemic circulation into the brain. While preclinical research has demonstrated the utility of FUS, there remains a gap in our knowledge regarding the long term response of brain vasculature. This work stems from a study demonstrating transcriptional changes in hippocampal rat microvessels in the acute stages following sonication. Microarray analysis of microvessels was performed at 6 and 24 hrs post-FUS and suggest that FUS may initiate angiogenic processes. Preliminary results suggest that these changes in gene expression manifest as increased perfused vessel density in CA1 at 9 days following sonication. The time course of this angiogenic response, from 7 days to 21 days, was also investigated with BrdU and GLUT1 colocalization and demonstrates increases in vessels density and newborn vascular endothelial cells in the sonicated regions. While further work is necessary, these results open up intriguing possibilities for novel FUS applications in neurological disorders in which vascular density is negatively affected.

Title: Nuclear functional kinin-B2 receptors in the human hCMEC/D3 blood brain barrier cell model

Authors: *M. N. GONZALEZ VEGA[1], Y. FERRER ACOSTA[2], W. TORRES[3], A. H. MARTINS[4]
[2]Neurosci., [1]Univ. Central Del Caribe, Bayamon, PR; [3]Biologia, Univ. del Este, Carolina, PR; [4]Pharmacol. and Toxicology, Univ. of Puerto Rico Med. Sci. Campus, San Juan, PR

Abstract: Bradykinin (BK) is a nonapeptide which is generated by kininogen. BK acts through the kinin-B2 receptor (B2BKR), a G-coupled protein receptor that belongs to the kallikrein-kinin system and it is expressed in blood brain barrier (BBB) forming cells. The activation of the B2BKR increases the permeability of the BBB. There are cell models that mimic the BBB,

however the immortalized human cerebral microvascular endothelial cell line (hCMEC/D3) is well known since the cell line can form the BBB without the presence of other cells. Even though the role of B2BKR is important in the BBB, the expression or activity is yet unknown in hCMEC/D3. The role of this project was to determine the expression and effect of B2BKR on hCMEC/D3. Hence, the expression of B2BKR was assessed by western blot and the cellular localization by immunofluorescence followed by z-stack analysis. The functionality of B2BKR was measured by calcium imaging and patch-clamp recordings. Whole cell lysate demonstrated the presence of B2BKR on hCMEC/D3, however extracellular stimulation with bradykinin did not induce any change in intracellular calcium release. The localization of B2BKR was detected in the nucleus of hCMEC/D3 cells using immunofluorescence with anti-B2BKR and a z-stack analysis. To determine if the intracellular B2BKR was functional, the activity was observed using patch-clamp recordings. Measurements of the inward calcium currents made before and after intracellular administration of the peptide to the pipette solution, revealed a decline of inward calcium current supporting the view that BK has an intracrine effect in hCMEC/D3 cells. The findings demonstrated that hCMEC/D3 cells express functional B2BKR in the nucleus, providing new mechanistic insights into B2BKR functioning in these cells highly used to mimic the BBB.

Title: Aberrant Cdk5 activation induces blood-brain barrier modifications in CK-p25 mice, an inducible model of neurodegeneration

Authors: *C. TACCOLA[1], S. CARTOT-COTTON[2], D. VALENTE[3], P. BARNEOUD[4], M. LOCHUS[1], X. DECLÈVES[1], F. BOURASSET[1]
[1]Lab. de Pharmacocinétique, Faculté De Pharmacie, Inserm UMR-S 1144, Paris, France; [2]Pharmacokinetics, Dynamics and Metabolism, [3]Drug Metabolism and Pharmacokinetics, Res. Platform, [4]Neurosci. Therapeut. Area, Sanofi, Paris, France

Abstract: Drugs aimed at treating central nervous system disorders need to cross the cerebral endothelium, also known as the blood-brain barrier (BBB). The BBB is a dynamic interface modulating exchanges of compounds between the brain and blood and plays a crucial role in

maintaining brain homeostasis. Modifications of the BBB have been shown in Alzheimer's disease (AD) patients and in various AD mouse models. Prolonged and aberrant p25-dependant Cdk5 activation has been linked to neurotoxicity and several neurodegenerative disorders including AD. CK-p25 is a transgenic mouse model of neurodegeneration (ND) that inducibly overexpress the human p25 protein. To date, little is known on the BBB integrity of these mice. We used the *in situ* brain perfusion method to investigate the implications of Cdk5 aberrant activation on the physical and functional integrity of the BBB of these mice on early (3 weeks) and advance (6 weeks) stage of p25-induced ND. We first confirmed that p25 induction was accompanied by significant brain atrophy with a decrease in brain weight of 15 to 30% at early and advanced stage of ND respectively. The cerebrovascular volume of distribution of sucrose, a vascular space marker, was significantly increased in p25-induced mice from early stage of ND, suggesting an impaired BBB permeability, but without significant changes observed in the expression of tight junction proteins. The expression and function of cerebral essential nutriments and amino-acid transporters such as Glut-1 and LAT-1 were significantly increased on advanced stage of ND suggesting an adaptive compensatory mechanism for p25-induced neurotoxic insults. Most ABC-family efflux transporters were significantly increased on advanced stage of ND, probably in response to cerebral neurotoxic compounds accumulation. Finally, we showed that influx and efflux transporters of cholesterol and amyloid-β (Aβ) peptide, two compounds that play a critical role in AD pathology, were greatly modulated. In conclusion, CK-p25 mouse model is a valuable and fast model that could be of great interest in ND new therapy development. We showed that CK-p25 mice display an increased BBB permeability and profound functional modifications, some of which interestingly differ from those described in other AD or neurodegeneration mouse models. BBB damages could drastically impair cerebral homeostasis and thus neuronal and glial function. Many studies have already suggested that AD and cerebrovascular abnormalities are closely linked but it remains to be investigated if BBB dysfunctions are a cause or a consequence of the neurodegeneration.

Title: Establishing multiple cell culture model of the blood-brain barrier

Authors: *M.-H. JO, N. B. ABID, M.-W. KIM, A. KHAN, M. KHAN, M.-O. KIM
Gyeongsang Natl. Univ., Jin-ju, Korea, Republic of

Abstract: Blood brain barrier a neurovascular complex which acts as a selective semi-permeable membrane separating circulating blood from brain extracellular fluids. BBB not only controls trafficking of material in and out of CNS but also regulates homeostasis of brain. For last decade BBB research have not only been highlighted to understand mechanisms of drug delivery but also to elaborate correlations between neurodegenerative diseases and BBB disruption. To attain detailed mechanisms at molecular level a comprehensive *in vitro* model is required which is capable enough to mimic physiological environment under control experimental conditions. In present study we established a multiple cells *in vitro* model of BBB comprises of brain endothelial cells (BEndo.3), astrocytes (astrocytes clone Type I) and neuronal cells (HT22). Model in present study is not only capable to provide structural and physiological details of neurovascular complex to study drug delivery but also addresses role of BBB integrity in neurological disorders (Alzheimer's disease, Parkinson's disease, etc.) and traumatic conditions (Traumatic brain injury, Ischemia etc.). Present study is a comprehensive mechanistic approach which covers *in vitro* and *in vivo* disease models. It will provide better understanding of neurological disorders and will provide an insight to design futuristic therapeutic strategies. (supported by NRF)

Abstract: Diffuse white matter disease has been observed in many neurodegenerative diseases including small vessel disease and dementia. Pericytes are vascular mural cells embedded in the wall of the smallest blood vessels. In the brain, they control blood-brain barrier (BBB) integrity and cerebral blood flow (CBF) and they participate in clearance of toxins. Mice with global pericyte degeneration, caused by platelet-derived growth factor receptor-β (*Pdgfrβ*) deficiency in pericytes ($Pdgfr\beta^{F7/F7}$), have been shown to develop aberrant CBF responses and chronic BBB breakdown associated with brain accumulation of serum proteins in grey matter regions (e.g., cortical mantles and hippocampus). However, whether white matter is affected by pericyte loss, and whether pericytes are necessary for healthy white matter, remain unknown to date. Using $Pdgfr\beta^{F7/F7}$ pericyte-deficient mice, magnetic resonance imaging, viral-based tract-tracing, behavior and tissue analysis, we show that pericyte degeneration leads to early deposition of blood-derived neurotoxic products and blood flow reductions in the white matter causing diffuse white matter degeneration and loss of myelin, axons and oligodendrocytes. This disrupts brain circuits leading to white matter functional deficits long before neuronal loss occurs. Overall, our data suggest that pericytes are critical for proper white matter structure and functional connectivity, which has implications for the pathogenesis and treatment of human white matter disease and small vessel disease.

Title: Evaluating the size of focused ultrasound-induced blood-brain barrier opening in cats using 7 Tesla magnetic resonance imaging

Authors: *H.-Y. LAI[1], X. FENG[1], C.-T. WANG[1], T. HE[1], W. XIONG[1], C.-H. TSAI[2], B. XU[1], H.-L. LIU[1,2]

Abstract: Focused ultrasound with the presence of microbubbles has been shown to transiently open the blood-brain barrier (BBB) and brings new opportunity in delivering molecules into the brain. Our previous study demonstrated that 0.55-mechanical index (MI) FUS intensity is the safe range of exposure to induce BBB opening in rats. However, the optimum acoustic pressure of FUS-induced BBB opening may be different in large animals due to the skull. The purpose of this study is to evaluate safety and size of the BBB opening in cats using 7 Tesla Magnetic Resonance Imaging (MRI, Siemens 7T Magnetom) and Evans Blue (EB) dye at distinct acoustic pressures and exposure periods. We systematically presented 0.9- and 1.2-MI FUS with the intravenous injection of microbubbles for 15, 30, 60 and 120 s exposures in the cat brain. The T1-weighted images were recorded to assess the size of BBB opening before FUS, and 0.5, 1.5, 2.5, 3.5, 4.5, 5.5 and 6.5-h post-FUS. To localize the spatial distribution of BBB opening, EB dye (1 ml/kg) was injected intravenously immediately following FUS. To Noninvasively monitor the dynamic changes of the spatial distribution of FUS-induced BBB-opening, the whole brain 3D dynamic contrast-enhanced (3D-DCE) images were recorded for 5 min after each MRI

contrast-agent, Gadolinium-DTPA (Gd-DTPA, 0.3mmol/kg), IV injection at 0.5, 3.5, 6.5 h and 1 day post-FUS. After finish of all MRI recordings, all animals were deeply anesthetized with chloral hydrate (350 mg/kg) and sacrificed to get EB-stained brains. T1-weighted images showed that BBB could be disrupted by using 1.2-MI FUS for 30, 60, and 120 s, as well as 0.9-MI FUS for 60 and 120 s. The 3D-DCE images showed that BBB closed after 3.5 h and there is no BBB opening after 1 day post-FUS. The size of BBB opening is related to both acoustic pressures and exposure periods. The EB-stained brains showed the leakage region which was correlated with the results of 3D-DCE images. As compared with the rat, the safe acoustic pressure of FUS-induced BBB opening is higher because of the thickness and microstructure of skull. These results demonstrated that FUS-induced BBB-opening can be used successfully in cats, and it might potentially apply to the nonhuman primate and further clinical applications.

Title: Intranasal delivery of antibodies achieves significantly higher CNS to blood ratios than systemic delivery - an investigation of distribution, pharmacokinetics, dose-response, and mechanism of transport

Authors: *N. KUMAR[1], J. J. LOCHHEAD[1], M. E. PIZZO[1], D. J. WOLAK[1], G. NEHRA[1], S. BOROUMAND[1], E. BRUNETTE[5], D. STANIMIROVIC[5], R. G. THORNE[1,2,3,4]

Univ. of Wisconsin - Madison, Madison, WI; [5]Inst. for Biol. Sci., Natl. Res. Council of Canada, Ottawa, ON, Canada

Abstract: Intranasal delivery is a non-invasive strategy that can potentially bypass the blood-brain barrier (BBB) and blood-cerebrospinal fluid barriers (BCSFBs) to rapidly target biologics to the CNS via extracellular pathways (Thorne et al. *Neuroscience* 2004 & 2008; Lochhead et al. *J. Cereb. Blood Flow & Metab.* 2015). Here, we provide a detailed comparison of antibody delivery to the CNS following intranasal (IN) versus intra-arterial (IA) administration. Anesthetized rats were administered either radiolabeled or fluorophore-labeled antibodies. To investigate dose response following IN delivery, we compared a tracer dose (50 µg), a middle dose (1000 µg), and a high dose (2500 µg) of radiolabeled IgG in separate experiments. Higher IN doses resulted in greater CNS exposure, suggesting access to extracellular pathways to the CNS that are not easily saturated. Dose-response following IA delivery was first investigated for IgG doses that resulted in blood exposure similar to the IN doses at the experimental end-point (30 minutes following administration). IA delivery resulted in significantly lower CNS IgG levels compared to IN delivery for each matched dose. Next, we examined dose-response following IA delivery for IgG doses equal to the IN doses. IA delivery resulted in significantly higher blood exposure than IN delivery at 30 minutes following administration. However IgG delivery to the CNS did not scale up as dramatically following equal dose IA compared to IN delivery. Furthermore, we observed that following IA delivery of fluorophore-labeled IgG at a dose equal to IN delivery, the fluorescent signal was largely restricted to the endothelial compartment. Our studies involving IN delivery of fluorophore-labeled IgG provide the first evidence for a three step nose-to-brain delivery process for antibodies that bypasses the BBB via transport: 1) Across the nasal epithelium; 2) Along the perineural compartments of the olfactory and trigeminal nerves; 3) Within the brain along the perivascular space (PVS) of cerebral blood vessels. The PVS is a fluid-filled compartment; bulk flow and transport in this compartment is likely to scale with brain size across different species (Wolak & Thorne. Mol. Pharma. 2013). The ability of IN delivered IgG to access the PVS compartment is therefore highly relevant for potential clinical translation. Finally, we have recently reported relatively low vascularity and vascular permeability in the nasal olfactory region, suggesting IN targeting of drugs to that area may favor brain delivery due to reduced clearance to the systemic circulation (Kumar et al. *Sci. Rep.* 2016).

Title: NG291 a stable B2 kinin receptor agonist increase the permeability in normal blood brain barrier- possible role in organophosphate poisoning

Authors: S. R. MASSO[1], S. MARTINEZ[2], V. A. ETEROVIC[3], P. A. FERCHMIN[4], *A. H. MARTINS[1]
[1]Univ. of Puerto Rico, San Juan, PR; [2]Neurosci., [3]Biochem., Univ. Central Del Caribe, Bayamon, PR; [4]Neuroprotection For Life, San Juan, PR

Abstract: Organophosphates are phosphorus-containing compounds that inhibit the acetylcholinesterase generating a cholinergic crisis that is fatal if not treated. The classical antidote atropine and pralidoxime are able to protect peripherally, but cannot protect the central nervous system. Pralidoxime is the only FDA approved drug that re-activates the inhibited acetylcholinesterase by organophosphate. Pralidoxime has limited neuroprotective potential because it is not able to cross the blood brain barrier (BBB) effectively. In order to increase this potential, our group is using a stable B2 kinin agonist NG291. This peptide can transiently open the BBB and increase the pralidoxime delivery to the brain after organophosphate poisoning. Sprague-Dawley rats were subjected to NG291 treatment (50µg/Kg) via intravenous (IV) route followed by 2% Evans Blue dye injection. 24 hours after the peptide injection the animals were perfused and the amount of albumin-Evans blue was qualitative analyzed. To verify whether the transient opening of the BBB increased brain water content, 11 controls (saline) and 12 rats injected with the peptide NG291 were euthanized 24 hours after the peptide injection, and the percentage of water content was measured. To assure that the transient opening of BBB does not cause brain damage, control and NG291 injected rodents were stained with Fluoro-Jade C to verify the presence of dead neurons and glial fibrillary acidic protein (GFAP) was used to evaluate astrocyte activation 72 hours after the injection of 50µg/Kg of NG291. NG291-treated animals have shown infiltration of Evans Blue to the brain parenchyma and accumulation in the ventricles showing an increase of BBB permeation 24 hours after the injection. The water content of the brain did not increase with NG291 treatment. 72 hours after the treatment the histology using Fluoro-Jade and GFAP did not show significant changes when compared to controls. Normal BBB permeability can be increased using NG291. In future studies, this peptide will be used to facilitate the delivery of pralidoxime into the brain and therefore increase the overall effect of this drug.

Title: Impact of western versus omega-3 diets on mfsd2a expression

Authors: K. E. SANDOVAL[1], J. S. WOOTEN[2], M. L. SCHALLER[2], M. P. HARRIS[2], *K. A. WITT[3]
[1]Pharmaceut. Sci., Southern Illinois Univ., Edwardsville, IL; [2]Applied Hlth., [3]Pharmaceut. Sci., Southern Illinois Univ. Edwardsville, Edwardsville, IL

Abstract: Major facilitator super family domain containing 2a (mfsd2a) transports the omega-3 fatty acid, docosahexaenoic acid (DHA), and other long-chain fatty acids in the form of lysophosphatidylcholine across the blood-brain barrier. While Mfsd2a alterations have been shown to be important in the formation and integrity of the blood brain barrier, it remains unclear how diets with different types and percentages of fatty acids may impact its expression in adult animals. To examine this association, C57BL/6 mice were treated with diets of: 10% lard, 10% fish oil, 41% lard or 41% fish oil for 32 weeks starting at eight weeks of age. Cerebral cortex and subcortical (hippocampus, amygdala, thalamus, caudate) tissues were respectively assessed and evaluated for changes in protein (Western Blot; n=6/group) and mRNA (RT-PCR; n=12/group) expression relative to the 10% lard diet.
Diet significantly impacted the change in weight over the course of the study ($p<0.05$) and glucose tolerance at 31 weeks ($p<0.05$). The type of diet was a significant predictor of cortical mfsd2a protein expression ($p<0.05$). Cortical Mfsd2a protein expression was significantly higher in mice receiving 10% fish oil ($p<0.05$), 41% fish oil ($p<0.05$) or 41% lard ($p<0.05$) when compared to mice receiving a 10% lard based diet. The type of diet was found to be a significant predictor of subcortical mfsd2a protein expression ($p<0.05$). Subcortical Mfsd2a protein expression was significantly higher in mice receiving the 41% fish oil diet ($p<0.05$) or 41% lard diet ($p<0.05$) when compared to mice receiving the 10% lard diet. No significant differences were identified as to mfsd2a mRNA expression. This study shows that fish oil based diets and high-fat lard diets increase protein expression of Mfsd2a compared to 10% lard based diet.

Title: Intrathecal administration of antisense oligonucleotides: CNS distribution and implications for neurodegenerative disease treatment

Authors: *B. WILKEN-RESMAN[1], M. E. PIZZO[1,2], E. BRUNETTE[7], N. KUMAR[1], K. VANG[3], G. GREENE[1], D. B. STANIMIROVIC[7], R. G. THORNE[1,2,4,5,6]
[1]Div. of Pharmaceut. Sci., [2]Clin. Neuroengineering Training Program, [3]Neurobio., [4]Inst. for Clin. & Translational Res., [5]The Ctr. for Neurosci. and Neurosci. Training Program, [6]Cell. and Mol. Pathology Grad. Program, Univ. of Wisconsin-Madison, Madison, WI; [7]Inst. for Biol. Sciences, Natl. Res. Council of Canada, Ottawa, ON, Canada

Abstract: Clinical trials are ongoing for several intrathecally-administered macromolecule therapeutics, including antisense oligonucleotide (ASO) therapies in patients with neurodegenerative diseases such as Huntington's Disease, familial amyotrophic lateral sclerosis (ALS), and spinal muscular atrophy. ASOs are typically ~7 kDa single-stranded DNA oligomers and are particularly attractive therapeutic candidates for diseases caused by known genetic abnormalities because they can specifically manipulate target mRNA to enable or restore normal protein synthesis. ASOs must be administered centrally because of limited-to-nonexistent blood-brain barrier (BBB) penetration. However, despite the common use of the intrathecal route for most ASO studies to date, the CNS distribution of ASOs after intrathecal administration has not been well described. There are thought to be two primary transport mechanisms governing the distribution of macromolecules in the brain: diffusion in the extracellular spaces and convective flow in perivascular spaces surrounding the cerebral vasculature. Here, we investigated the diffusion and CNS distribution of 19-mer phosphorothioate-modified ASOs covalently attached to either DyLight488 or AlexaFluor488 fluorophores. ASO hydrodynamic properties were first characterized by measuring free diffusion in agarose using integrative optical imaging (IOI),

yielding free diffusion coefficients of 1.53 ± 0.05 x 10^{-6} cm^2/s (mean ± sem; *n*=26) and 1.88 ± 0.03 x 10^{-6} cm^2/s (mean ± sem; *n*=29) for DL488-ASO and AF488-ASO, respectively, and hydrodynamic diameters of approximately 4 nm for each. Intrathecal administration of each ASO was performed in rats and the distributions were visualized using *ex vivo* fluorescence imaging and confocal microscopy. ASO distribution to perivascular spaces was markedly less than that of a protein macromolecule of similar hydrodynamic diameter, regardless of the fluorophore used, suggesting ASOs experience additional sources of hindrance aside from their size that limit their distribution in the brain (e.g., electrostatic interactions). Co-infusion with a hyperosmolar solution has been shown to be an effective method to enhance perivascular access from the CSF, a strategy that may also be effective in improving the brain delivery of ASOs to additional regions and deeper areas. Our data provides key guidance for understanding the potential/limitations of central ASO delivery strategies and the resulting distribution to be expected with intrathecal infusion. It may also lead to new methods to enhance the CNS delivery of ASOs for the treatment of a variety of neurodegenerative diseases.

Abstract: Neurocysticercosis (NCC) is the main brain infectious disease affecting people in developing countries and the study of this pathology is scarce. Common lesions reported in NCC patients include the presence of reactive gliosis, inflammatory infiltrates and vascular changes. NCC pathology varies depending on cyst location and viability. Since clinical manifestation of this infection generally occur when the parasite starts degenerating, the progression of NCC is not well understood and animal models have been used to explore NCCpathology. There is a link between vascular changes and blood-brain barrier (BBB) alteration in many neurological disorders. To explore vascular abnormalities presented in NCC we used an animal model for NCC. Holtzman rats (12-15 days old) were injected intracranially with T.solium activated oncospheres (n=18) and saline for controls (n=8). After 3 months of infection 13 rats developed viable cysts. Animals were euthanized and the pathology was studied using immunohistochemistry. We found vascular abnormalities in the tissue surrounding the cyst. Alterations include dilated vessels and fibrotic vessels detected by Masson trichrome staining. These fibrotic vessels showed a reaction to fibrinogen protein. Additionally, different cells presented strong reaction to desmin, alpha-smooth muscle actin, and platelet-derived growth factor receptor beta. Interestingly, dilatated vessels presented low expression of the endothelial brain barrier antigen reflecting BBB compromise. Together this data shows that vascular changes in NCC include an increase in vascular caliber and changes in its structure were endothelial cells, pericytes, and smooth muscle cells could be affected resulting in the possible alteration of the BBB. Whether this vascular changes could contribute to NCC pathology or could be exacerbated in degenerated cyst has to be addressed in future studies.

Title: Impact of western versus omega-3 based diets on glut-1 expression

Authors: K. A. WITT[1], J. S. WOOTEN[2], M. L. SCHALLER[2], M. P. HARRIS[2], *K. E. SANDOVAL[3]
[1]Pharmaceut. Sci., Southern Illinois Univ. Edwardsville, Edwardsville, IL; [2]Applied Hlth., [3]Pharmaceut. Sci., Southern Illinois Univ., Edwardsville, IL

Abstract: The glucose transporter-1 (glut-1) regulates glucose across the blood-brain barrier, serving as a key regulator of brain energy. This study assesses how diets with different types and percentages of fatty acids may impact glut-1 expression in adult animals. To examine the association between diet, glucose tolerance and expression of glut-1, C57BL/6 mice were treated with either a 10% lard, 10% fish oil, 41% lard or 41% fish oil diet for 32 weeks starting at eight weeks of age. Cerebral cortex and subcortical (hippocampus, amygdala, thalamus, caudate) tissues were respectively assessed and evaluated for changes in protein (Western Blot; n=6/group) and mRNA (RT-PCR; n=12/group) expression relative to the 10% lard diet. Poorer glucose tolerance at 31 weeks was observed in mice receiving the 41% lard based diet compared to mice receiving 41% fish oil ($p<0.05$) or 10% fish oil ($p<0.05$). However, neither glucose tolerance or weight change were predictors of cortical or subcortical glut-1 protein expression. Cortical glut-1 protein expression was higher in mice receiving the 41% fish oil diet ($p<0.05$) and the 41% lard diet ($p<0.05$), compared to 10% lard based diet. Subcortical glut-1 protein expression was significantly higher in mice receiving the 10% fish oil diet ($p<0.05$), 41% fish oil diet ($p<0.05$) and 41% lard diet ($p<0.05$), compared to 10% lard based diet. No significant differences were identified as to glut-1 mRNA expression. This study shows that 41% lard and 41% fish oil diets in the cortical and subcortical, and 10% fish oil in the subcortical, increase glut-1 protein expression compared to 10% lard diet.

Title: Modelling the diseased blood-brain barrier using patient-derived stem cells: Making a case about Batten’s disease and Familial form of Alzheimer’s disease

Authors: *R. PATEL, A. ALAHMAD
Pharmaceut. Sci., Texastech Univ. Hlth. Sci. Ctr., Amarillo, TX

Abstract: ***Background:*** The blood-brain barrier (BBB) constitutes physical and chemical barrier formed by specialized brain endothelial cells (BMECs) surrounded by astrocytes, pericytes and neurons. Such barrier plays an essential role in the maintenance of the brain homeostasis. More recently, several studies highlighted the contribution of a dysfunctional BBB in several neurological disorders, particularly in neurodegenerative disorders such as Alzheimer's disease or Huntington's disease. Yet, the impact of genetic factors involved in certain neurodegenerative disorders on the BBB function remains unclear. In this study, we demonstrated the impact of such genetic factors on the BBB function using an isogenic model of the BBB based on induced pluripotent stem cells (iPSCs) ***Methods:*** We used iPSC derived from patients suffering from Batten's disease (BD, CLN3 mutation) and from an early onset familial form of Alzheimer's disease (eFAD, PSEN1 mutation). We differentiated all iPSCs to astrocytes, BMECs and neurons using differentiation protocols established in our lab. We characterized each differentiated cell types using cell-specific markers and for the presence of biological features associated with such disorders (e.g. lipofuscin accumulation for BD patients). In addition, we investigated changes in barrier properties (using TEER and fluorescein permeability) and transporters activity (e.g. Amyloid β (Aβ) peptide clearance across BMECs) ***Results:*** Preliminary data obtained from BD patients suggest the presence of a dysfunctional barrier as we noted lower barrier tightness in CLN3-derived BMECs compared to IMR90-derived BMECs (asymptomatic control) monolayers. CLN3-derived BMECs showed the presence of lipofuscin inclusion bodies. In the other hand, iPSC-derived BMECs showed the presence of an active diffusion of Aβ 1-40 across IMR90-derived BMECs, such diffusion occurred through a transcellular manner. ***Discussion:*** In this study, we demonstrated the ability to differentiate a BBB model from patients suffering from neurodegenerative diseases. Our preliminary data suggest that such mutations also impact non-neuronal cells, in particular cell types present at the BBB (BMECs and astrocytes). Our future direction is focused on using such model to demonstrate the impact of such mutations on astrocytes function by providing side-by-side comparisons in barrier induction in astrocytes/BMECs co-cultures in both BD and eFAD cells, as well as understanding the impact of PSEN1 mutation on Aβ peptides clearance.

Title: Modeling ischemic stroke injury at the human blood-brain barrier *In vitro* using patient derived stem cells

Authors: *A. ALAHMAD, S. PAGE
Pharm Sci., Texas Tech. Univ. Hlth. Sci. Ctr., Amarillo, TX

Abstract: *Background:* Stroke constitutes the fifth cause of death and a leading cause of disability in the United States. Most of stroke events are categorized as “ischemic stroke, resulting in an hypoperfusion and hypoxic/ischemic onset. The blood-brain barrier (BBB, a component of the neurovascular unit formed by specialized brain microvascular endothelial cells (BMECs) surrounded by astrocytes, neurons and pericytes) constitutes the first line of cells sensing such stressor. Its disruption constitutes a crucial event in the pathophysiology of stroke injury, yet the mechanism leading to such disruption at the human BBB and the presence of a sexual dimorphism in such disruption remains unclear. In this study, we investigated the cellular response of the human BBB following ischemia/reoxygenation *in vitro*. *Methods:* We used patient-derived induced pluripotent stem cells (iPSCs) derived from males and females asymptomatic control patients. We differentiated such cells into BMECs, astrocytes and neurons following established differentiation protocols. Cells were exposed to oxygen glucose deprivation stress (OGD; 1% O2 and glucose-free medium) for 6 or 24 hours, followed by reoxygenation (Reox). Hypoxia induced factor-1alpha (HIF-1alpha) and VEGF protein levels were assessed by ELISA, cell metabolic activity was assessed by MTT assay. Barrier function was assessed using TEER, fluorescein permeability and immunofluorescence. 10µM CAY105586 or YC1 were used as HIF-1 inhibitors. *Results:* All cells showed a detrimental response to prolonged (24 hours) OGD stress by loss in barrier integrity, decreased cell metabolic activity, loss of neurites (neurons) and increased VEGF secretion. Following OGD/Reox stress, we noted differences in HIF-1alpha protein levels between male and female iPSC lines. Furthermore, such dimorphism was reflected on the barrier recovery during Reox. We noted differences in VEGF secretion between iPSC lines and differences in neurite outgrowth in iPSC-derived neurons. Both CAY or YC1 failed to block HIF1-alpha protein stabilization and showed only minimal effect on the BBB. *Discussion:* Our data suggest a possible sexual dimorphism between male and female cells following response to OGD/reoxygenation stress. OGD-induced barrier disruption appears driven through a HIF-1/VEGF axis, such axis appears to show some differences between sex and individuals. We are currently investigating such differences in terms of changes in cell respiratory metabolism and response to HIF-1 inhibitors.

Title: Pericytes in the neurovascular unit of a sexually dimorphic nucleus in rats

Authors: *Z. HE, S. A. FERGUSON, M. PAULE
Div. of Neurotoxicology, Natl. Ctr. For Toxicology Res., Jefferson, AR

Abstract: A working module of a neurovascular unit (NVU) in the sexually dimorphic nucleus of the preoptic area (SDN-POA) was proposed (SFN 2016). However, one of the key components, pericytes existing along capillaries and veinules, has not been thoroughly investigated. In this report, male and female weanling rats (n=4-5/sex) were used to define these cells within the SDN-POA. **Methods.** Calbindin D28K (CB28)-immunoreactivity was used to delineate the SDN-POA in which pericytes were tagged with CD13- or alpha-smooth muscle actin (αSMA)-immunoreactivities (irs), two pericyte biomarkers, using two adjacent brain sections (90 micron intervals). Densities of CD13- and αSMA-irs along with SDN-POA volume were compared between males and females after averaging bilateral SDN-POA structures. **Results.** Male SDN-POA was $5.0\pm0.3x10^{-3}$ mm^3 in volume, which was significantly larger than the female ($1.7\pm0.3x10^{-3}$ mm^3, $p<0.05$). Within the SDN-POA, the CD13-irs were characterized as dots, densely packed and net-like in distribution, while the aSMA-irs, excluding pipe-like or circular structures, appeared as short rod-like structures that were relatively sparsely distributed. The short rod-like aSMA-irs counts were $353\pm57/mm^2$ in males and $124\pm46/mm^2$ in females ($p<0.05$). On the other hand, densities of the dot-like CD13-irs were $4009\pm301/mm^2$ in males and $4018\pm414/ mm^2$ in females (not significant at $p>0.05$). Accordingly, we propose that a subset of capillary pericytes is aSMA-positive and likely functions (dependent upon their aSMA-associated structure and physiology) to control the local blood-brain barrier. Since the majority of pericytes within the SDN-POA were aSMA-negative, they likely function differently. Future studies using larger group sizes are warranted to verify whether pericytes that selectively express aSMA do so in a sex-dependent fashion in the SDN-POA.

Title: Zona incerta as a substrate for orchestration of adaptive responding - variation on a theme by John Mitrofanis (Neuroscience 130:1-15, 2005)

Authors: *D. S. ZAHM[1,2], M. T. DESTA[2], S. SUBRAMANIAN[2], Y. TAN[3], K. P. PARSLEY[1]
[1]Pharmacol. and Physiological Sci., [2]Pharmacol. and Physiol., St. Louis Univ. Sch. of Med., Saint Louis, MO; [3]Dept. of Surgery, St Louis Univ. Sch. Med., Saint Louis, MO

Abstract: Motivation arises due to innate (e.g., hoard, nest, mate) and homeostatic (e.g., eat, drink, relocate) imperatives, and cues signaling threat or reward (usually related to such imperatives). The medial forebrain bundle (mfb) is the common pathway for outputs subserving motivation. Signals descending in the mfb directly modulate adaptive responses like, e.g., locomotion and acoustic startle, but, due to not reaching to spinal motor networks, having relatively weak projections to brainstem effector sites and targeting (via thalamus) mainly cortical association rather than motor/premotor areas, mfb cannot orchestrate complex adaptive behavior. Zona incerta (ZI), in contrast, has strong connections with brainstem and spinal motor sites and is strongly and reciprocally connected with sensorimotor cortex, rendering it suitable to enlist movements, which stimulating ZI actually does. Inactivating ZI blocks movement caused by stimulating the mfb. We have undertaken to provide a better characterization of input to ZI from motivation-related structures (i.e., that project via the mfb). Using new and archived cases and some reports published by others, anterogradely transported Phaseolus vulgaris-leucoagglutinin (PHA-L) and, in a few cases, biotinylated dextran amine (BDA) were mapped in the subthalamic region of rats following injections into motivation-related brain structures. Injection sites were selected from maps of retrograde labeling produced by injection of cholera toxin β subunit into the rostral (r) subdivision of the ZI (SfN Abstr 708.02, 2015). ZIr was distinguished from the underlying dorsolateral (dl) lateral hypothalamus (LH) with antibodies against tyrosine hydroxylase. LHdl received dense projections from many evaluated structures, including the prefrontal cortex, lateral septum, ventral pallidum, bed nucleus of stria terminalis, sublenticular extended amygdala and central amygdala, of which all sent additional sparse projections into rZI. However, tracer injections into the lateral preoptic area and LH, particularly LHdl, produced moderate ZIr labeling and yet more robust ZIr labeling was generated by tracer injections along the descent of the mfb, particularly in the retrorubral area, lateral, ventrolateral and precommissural periaqueductal gray and the pedunculopontine, laterodorsal tegmental and

parabrachial nuclei. Projections from widespread motivation-related structures thus may converge at several nodes, which, collectively, provide a robust input to the ZIr. Insofar as all parts of the ZI are robustly interconnected, activity throughout the entire ZI may be modulated by motivation-related signals.

Title: Elucidating the role of the supramammillary nucleus in motivational processes

Authors: *A. KESNER[1], S. IKEMOTO[2]
[1]Natl. Inst. On Drug Abuse, Baltimore, MD; [2]Behav Neurosci Br., Natl. Inst. on Drug Abuse, Baltimore, MD

Abstract: Motivational capacity to interact with the environment is fundamental for everyday healthy living. Motivated behaviors ultimately manifest through reward and aversion processes, where animals must approach positive 'rewarding' stimuli and avoid negative 'aversive' stimuli to survive. The supramammillary nucleus (SuM), is a small posterior hypothalamic nucleus that provides dense projections throughout the cerebrum. Past research on SuM has focused on its role in arousal, learning, and memory. Our lab previously found that pharmacological stimulation of SuM neurons can reinforce behavior, leading us to further investigate the role the SuM and its related circuitry plays in reward and motivation. We first confirmed stimulation of SuM neurons is rewarding using a self-stimulation procedure with optogenetics involving *channelrhodopsin-2* (ChR2) in wild-type (C57/BL6) mice. Mice with ChR2 and optic fibers in SuM quickly learned to respond on a lever reinforced by photostimulation and switch responding when lever assignments are reversed. Mice do not reliably self-stimulate when optic fibers are placed in areas adjacent to SuM, ie. in the mammillary bodies or ventral tegmental area. Next, using a Cre-dependent ChR2 and vGlut2-Cre, vGat-Cre or Th-Cre mice, we show this rewarding effect of SuM neuron stimulation is likely mediated by glutamatergic neurons, but not dopaminergic or GABAergic neurons. Then, using optogenetic terminal-stimulation we dissect which glutamatergic projections from the SuM mediate self-stimulation behavior. Mice learned to respond for the stimulation of SuM glutamatergic neurons terminating in the septal area, but not terminals in the paraventricular thalamic nucleus (PVT), ventral subiculum, or diagonal band

of Broca. In addition, mice show real-time place preference for activation of the SuM to septum circuit, and real-time place aversion for activation of the SuM to PVT circuit, indicating bivalent affective processes driven by SuM circuitry. To investigate the role of SuM neurons in food taking and seeking behaviors, we conducted single-unit in-vivo electrophysiology experiments in mice seeking sucrose, a natural reward. Most SuM neurons change their firing rates as a function of sucrose seeking, taking, or both. Our results implicate the SuM and its downstream targets in motivational processes. As this circuitry is somewhat non-canonical in terms of classical reward circuits, we feel it warrants future research into its role in psychiatric disorders such as depression and addiction.

Title: Coordinated gamma oscillations in the lateral septum and the lateral hypothalamus drive food seeking

Authors: *M. CARUS-CADAVIECO[1], M. GORBATI[1], L. YE[2], F. BENDER[1], S. VAN DER VELDT[1], N. DENISOVA[1], F. RAMM[1], K. DEISSEROTH[2], A. PONOMARENKO[1], T. KOROTKOVA[1]
[1]FMP Berlin, Berlin, Germany; [2]Bioengin & Psych, Stanford Univ. Dept. of Psychology, Stanford, CA

Abstract: Cortical cognitive processing involves gamma oscillations, which support memory, attention and behavioral flexibility. These functions crucially contribute to feeding behavior, however, the underlying neural mechanisms are unknown. Lateral hypothalamus (LH) is crucial for regulation of feeding, yet little is known about the regulation of LH by top-down inputs from cognitive control regions. Top-down forebrain innervation of LH is provided, to a large extent, by inhibitory inputs from the lateral septum (LS), a key region for governing innate behaviors according to environmental context; LS is connected, in turn, with cortical networks. Here we

combined optogenetics and electrophysiological high-density recordings in mice during spontaneous behavior in a free-access feeding paradigm. We found that LS and LH displayed prominent gamma oscillations (30-90 Hz) which entrained neuronal activity within and across the two regions (Carus-Cadavieco et al., Nature, 2017). When mice engaged in approach to the food zone, the power of gamma oscillations in LS and LH matched the time required to reach the food zone, but not the drinking zone. Optogenetic gamma-frequency stimulation of somatostatin-positive (LS-SST) projections to LH facilitated food-seeking, i.e. shortened latency to reach the food zone but not the drinking zone or a control zone. It also increased probability of entering the food zone prior to food-free zones, located in other corners of the enclosure. Optogenetic inhibition of the LS-SST-LH pathway during food approach reduced food seeking. LS inhibitory input enabled separate signaling by LH neurons according to their feeding-related activity, making them fire at distinct phases of the gamma oscillation. In contrast to increased food intake during optogenetic stimulation of LH Vgat cells, food intake during gamma-rhythmic LS-LH stimulation was not changed. Accordingly, we identified that LS-LH gamma-rhythmic input regulate activity of function-selective subgroups of LH cells in a different way than activation of LH Vgat neurons. Upstream, we identified medial prefrontal cortex projections providing gamma-rhythmic inputs to LS, leading to improved performance in a food-rewarded learning task. Overall, our work identifies a novel top-down pathway, which utilizes gamma synchronization to guide activity of subcortical networks and to regulate feeding behavior by dynamic reorganization of functional cell groups in hypothalamus. Abstract: Goal - directed behaviors are thought to involve top-down representations of cognitive and emotional information to subcortical regions. Projections from the lateral septum (LS) to midbrain and lateral hypothalamus support drug- and food-seeking (Luo et al., Science, 2011, Carus-Cadavieco et al., Nature, 2017), with the latter utilizing gamma oscillations (30-90 Hz). Gamma oscillations enable synchronization and communication between neuronal populations and play an important role in memory, attention and sensory responses. To study circuitry providing gamma-rhythmic signaling to LS we combined optogenetics, local field potential (LFP) and multisite unitary electrophysiological recordings in freely behaving mice, CLARITY and computational modeling. A biophysical network model of LS demonstrated locally generated gamma rhythm which was further stabilized by external, weakly oscillating at gamma frequency, input. LS and its prominent excitatory input, hippocampus, were weakly coherent at gamma frequencies. Conversely, we found co-occurrence of gamma LFP epochs in LS and mPFC and increased gamma coherence of current flow density in the LS with LFP in mPFC. CLARITY revealed prominent fibers of CaMKIIa-expressing mPFC neurons terminating in the LS. The firing of LS cells during gamma oscillations was preceded by an increased discharge of mPFC neurons, the precision of co-firing between LS and mPFC predicted phase lags between concurrent LFP gamma cycles in these regions. Recordings from mPFC and LS as the animals performed a food-rewarded learning task in the T-maze revealed that correct choices were associated with an increased count of fast (60-90 Hz) and slow (30-60 Hz) gamma oscillation episodes in mPFC and LS selectively during the choice phase of the task but not in the start arm of the T-maze. Optogenetic stimulation of mPFC-LS projections at gamma frequency led to an increase of the number of correct trials in the T-maze and improved temporal stability of the performance, increasing fraction of repeated correct trials compared to repeated incorrect trials. The inhibition of mPFC-LS projections led to an opposite effect, decreasing the performance in the T-maze. These results suggest that signaling from the mPFC to the LS is coordinated by gamma oscillations, which regulate goal-directed behavior in a food-rewarded task. Title: Role of theta rhythmic signaling from hippocampus to lateral septum during exploratory behaviour

Authors: *F. BENDER[1], M. GORBATI[2], M. CARUS-CADAVIECO[2], N. DENISOVA[2], X. GAO[2], C. HOLMAN[2], T. KOROTKOVA[2,3], A. PONOMARENKO[2]
[1]Leibniz-Institut Für Molekulare Pharmakologie, (FMP), Berlin, Germany; [2]Leibniz-Institut Für Molekulare Pharmakologie (FMP), Berlin, Germany; [3]Max Planck Inst. for Metabolism Res., Cologne, Germany

Abstract: During locomotion, frequency of hippocampal theta oscillations (5-12 Hz) changes with running speed. However, the relationship between theta synchronization and motor output is complex. Hippocampal theta rhythm is modulated via the medial septum, which is considered the fundamental theta pacemaker. It receives ascending inputs from several brainstem areas and forwards sensory signals to the hippocampus. Medial septal parvalbumin-positive GABAergic cells synapse onto interneurons in the hippocampus CA1 and can thus rhythmically release pyramidal cells from inhibition. The entrainment of various neuronal types during theta oscillations is highly coordinated within and across hippocampal lamina and coherent across hemispheres. The lateral septum is the main subcortical output region of the hippocampus, receiving massive excitatory inputs from hippocampal pyramidal cells. Yet, little is known about the interactions between these regions. The lateral septum is a key element in circuits governing expression of innate behaviours according to environmental context, possibly by regulating communication from cortical to subcortical structures. A major efferent of the lateral septum, the lateral hypothalamus, comprises the diencephalic locomotion region, that provides downstream motor circuits with direct commands for movement. Combining optogenetic control of hippocampal theta oscillations with electrophysiological recordings in mice, we found that hippocampal theta oscillations regulate locomotion. Higher theta regularity caused more stable and slower running speeds during exploration and was accompanied by more regular theta-rhythmic spiking output of hippocampal pyramidal cells. Theta oscillations were coordinated between the hippocampus and the lateral septum. Both chemo- (DREADDs) and optogenetic

inhibition of this pathway revealed its necessity for the hippocampal regulation of running speed. Moreover, theta-rhythmic stimulation of lateral septum projections to the lateral hypothalamus replicated the reduction of running speed. These results suggest that changes in hippocampal theta synchronization are translated into rapid adjustment of running speed via the lateral septum.

Title: Diffusion-imaging derived cell density in the nucleus accumbens core predicts delay discounting in humans

Authors: *J. J. CASTRELLON[1], K. H. KARLSGODT[2,3]
[2]Psychology, [3]Psychiatry and Biobehavioral Sci., [1]UCLA, Los Angeles, CA

Abstract: Structural brain imaging studies of impulsivity in humans have largely implicated the nucleus accumbens (NAc). However, most such studies lack the spatial resolution or tissue modelling to distinguish the complex cellular composition of the NAc. The core (NAcc) and denser shell (NAcs) subregions present dissociable relationships with delay discounting (DD)—a feature of impulsivity—in rodents that received either NAcc or NAcs lesions. Specifically, while the core is critical to DD, the shell serves other functions. Given the dissociable roles in rodents, it may be speculated that similar specific associations might drive impulsivity in humans. We therefore used high-resolution multi-shell diffusion-weighted imaging (DWI), spatial modelling, and data-driven source estimation of human brains *in vivo* to derive spatial components of NAc cell density. Further, we tested associations between DD and NAc cell density in identified subregions. High-quality minimally-preprocessed DWI data for 80 healthy unrelated adult participants were examined from the Human Connectome Project dataset. Participants also completed a DD task for hypothetical monetary rewards. Voxelwise maps of neurite orientation and dispersion density (NODDI) were calculated for each participant. From these NODDI maps, a histologically-validated tissue model was fit to derive compartment estimates representing cellular density. Cell density maps were submitted to an independent component analysis (ICA) to derive subregional spatial maps within *a priori* masks of the left and right NAc. Component

maps were compared with known histological features of the NAc. Linear regressions were run on participant loading scores for components of interest with age and sex as covariates to predict DD. An intensity gradient that delineates the NAcc and NAcs emerged from cell density maps. Consistent with past findings, better DD was positively correlated with a cell density component in the right NAcc but not the NAcs. The findings present a promising role for DWI in translational models of cellular microstructure. The positive correlation with DD seen specifically in the NAcc highlights the importance of considering the heterogeneous composition of the NAc when investigating its role in governing impulsive choices.

Title: Effects of inhibiting the lateral preoptic area and ventral pallidum on psychostimulant induced and basal locomotion

Authors: *R. A. REICHARD, S. SUBRAMANIAN, K. P. PARSLEY, D. S. ZAHM
Pharmacol. and Physiological Sci., St. Louis Univ. Med. Sch., Saint Louis, MO

Abstract: The lateral preoptic area (LPO) and ventral pallidum (VP) are output structures serving mainly the septal-preoptic and ventral striatopallidal sectors of the basal forebrain. We showed earlier that locomotor activation is much more robustly increased by disinhibition of the LPO than VP. Further, disinhibition of the VP, but not LPO, is accompanied by dyskinesia and compulsive ingestion. We here extend the comparison to the locomotor effects of inhibiting LPO and VP. Guide cannulae targeting the VP or LPO were implanted into groups of Sprague Dawley rats. After a week of recovery, the rats received subcutaneous injections of D-amphetamine (1.0mg/kg) ten minutes prior to testing in activity monitors. Locomotion was recorded for 12 minutes before the GABA(A) receptor agonist, muscimol (74ng/0.25µl/min), or an equivalent volume of saline was infused bilaterally into the VP or unilaterally into the LPO. They were then tested for thirty minutes more. High locomotor counts (4542 ± 487[mean ± SEM]) were maintained following saline infusions. LPO muscimol infusions significantly reduced locomotor counts [2294 ± 526; $t(22)=3.37$, $p=0.006$ compared to pooled saline infusions], whereas VP muscimol infusions almost completely suppressed locomotion [112 ± 34; $t(22)=6.65$, $p<0.001$ compared to pooled saline; $t(22)=2.87$, $p=0.009$ compared to LPO muscimol]. Additional experiments produced similar effects following bilateral LPO and unilateral VP infusions of

muscimol. To determine the effects on basal locomotion, separate experiments were conducted. During the second hour of the dark cycle, when basal activity is maximal, bilateral infusions of muscimol into either structure nearly abolished locomotion [VP: 243 ± 51; LPO: 260 ± 59; pooled saline: 243 ± 51; pooled saline vs VP: $t(11)=4.52$, $p=0.003$; pooled saline vs LPO: $t(11)=4.05$, $p=0.004$]. Thus, like disinhibition, inhibiting VP and LPO distinguishes these two important forebrain structures, which the data indicate have contrasting roles in the inhibition of locomotion elicited by D-amphetamine but, not basal locomotion. Whether the differences reflect distinct connectivity with dopamine neurons vs. downstream behavioral effectors requires further investigation. However, we can surmise that the LPO and VP activation and inhibition data, together with the failure of VP activation to alter ventral tegmental area dopamine neuron activity (Floresco et al., 2003, Nat Neurosci 6:968-73), support a model in which activation of the LPO, but not VP, facilitates dopamine release in the accumbens (Acb) and the locomotor activating property of Acb dopamine release is conveyed to behavioral effectors through the VP but not LPO.

Title: Animals can use optogenetic-induced brain activations of the prefrontal cortex or the nucleus accumbens shell, as a predictive cue to avoid punishment and to obtain rewards

Authors: *J. LUIS[1], B. DURAN-SOSA[2], G. B. FLORAN[2], R. GUTIERREZ[2]
[1]Farmacologia, [2]CINVESTAV, Mexico, Mexico

Abstract: Several brain manipulations (either electrical or optogenetic) have been used to perturb the brain activity in order to evaluate their sufficiency -or necessity- of a particular behavior. Nevertheless, these brain perturbations can generate interoceptive cues that can be used to guide behavior. The majority of studies have focus in the somatosensory cortex (S1), however we reason that any brain region will be able to generate such interoceptive states. We hypothesize that pairing an arbitrary optogenetic stimulation, regardless of the brain region, with

a relevant behavioral event, will induced plasticity on brain circuits normally associated to that event, such as now the optogenetic activation will be able to drive behavior. To test this idea, we used the Thy1-ChR2 mice to photoactivate either cortical pyramidal neurons from layer V (in prefrontal cortex, PFC) or its fibers inputs to the nucleus accumbens shell (NAcSh). Thy1-ChR2 mice were trained in a two sipper sucrose alternating task, where -in order to receive two drops of sucrose- they had to alternate between two opposite left and right sippers (Phase 1). Additional licks in the rewarded sipper will no longer release more sucrose, until mice licked the opposite sipper. In half of trials, when the subject heads halfway toward the opposite port, a 1 s train of photostimulation (20Hz) + a tone were delivered, mice uses these cues to change its direction and return to the previously rewarded port to be rewarded again with sucrose. If they continued and lick the opposite sipper, mice were punish (with 2 airpuffs). After learning, the tone was removed and phase 2 begins: the subjects had to predict punishment only using photostimulation. We found that transgenic mice can avoid punishment, by only using the photostimulation cue (tone off). Photoactivations of PFC and NAcSh induced the same performance, and transgenic mice learned Phase 1 -30 sessions- faster than wild-type mice, suggesting that the photostimulation was better cue than the tone itself. Thus, optogenetic stimulation can be a predictive signal of an outcome, regardless of its original function. Finally, we tested if subjects can learn different rules by discriminating between 2 photostimulation frequencies (e.g., 20 Hz indicates continue and 1 Hz return). We found that subjects can discriminate between the 2 frequencies. In summary, we demonstrate that arbitrary optogenetic evoked brain activations can be interoceptive cues, and animals can use specific frequencies to generate different behaviors. This work paves the way to investigate how artificial network's activations are associated via pavlovian learning to avoid punishment or to obtain rewards.

Title: Optogenetic stimulation of lateral hypothalamus GABAergic neurons in a closed-loop open-field task elicits place preference and increases consumption of the nearest most salient stimuli

Authors: *A. I. HERNANDEZ-COSS[1], J. LUIS-ISLAS[2], A. GARCÍA-GUTIÉRREZ[2,3], L. PURÓN-SIERRA[2], D. ELÍAS-VIÑAS[1], R. GUTIERREZ[2]
[1]Dept. of Electrical Engin., [2]Dept. of Pharmacol., CINVESTAV, México, Mexico; [3]Inst. de Fisiología Celular, México, Mexico

Abstract: Although many studies have linked the Lateral Hypothalamus (LH) with feeding and reward, the specific mechanisms through which the LH controls reward, appetitive and consummatory behaviors is not yet clear. When presented with different food stimuli, electrical stimulation of the LH increases consumption of a preferred stimulus, this led to the idea that electrical stimulation in the LH induces a "stimulus bound" and that it depends on the subject's latent preference. However, it is not known how LH GABAergic neurons participate when several food stimuli are simultaneously presented and the mice self-stimulate these neurons. We addressed this by using Vgat-ChR2 mice to photoactivate LH GABAergic neurons and by designing a novel closed-loop open-field task, where several food stimuli are present simultaneously in a circular arena. Sated mice were placed in the center of the arena, equidistant to three different stimuli plates containing cork, food chow, chocolate pellets and a sipper with 10% sucrose solution. For 30 minutes an online computer vision program tracks the position of the subject and when it enters an area at the center of the arena it triggers a train of blue light pulses (473 nm, 50 Hz, 15 mW, 2 s on 4 s off). We found that all mice robustly self-stimulate by crossing and/or staying at the center spot of the arena, and although the consumption of food increased it varies between subjects, with some animals preferring chow, others sucrose, in a non-consistent pattern. When the area that triggers the optogenetic stimulation was relocated from the center to a different place of the arena (e.g., to the area around the pellet) we observed that the subjects remained for a longer time on the new stimulation area, even when paired to a food that was previously uninteresting to them, as was the case with the chocolate pellet (the most novel stimuli) until it was paired with the optogenetic stimulation. We also observed an increase of the spill and consumption of the food stimuli nearest to the optogenetic stimulation sites. In summary, our results indicate that our closed-loop optogenetic activation of LH GABAergic neurons in LH induces a robust place preference and increases food intake of the nearest food item, regardless of the subject's previous preference. The closed-loop open-field stimulation task is robust enough to override stimulus-bound behaviors previously observed in open-loop stimulation tasks. Thus, our data indicates that activation of LH GABAergic neurons is rewarding and it can dynamically re-shape the saliency of the nearest food stimuli.

Title: Activation of the lateral hypothalamus GABAergic neurons that promote consummatory behavior depends on the proximity and palatability of the stimulus

Authors: *D. A. GARCÍA[1,2], J. LUIS-ISLAS[2], A.-I. HERNANDEZ-COSS[2], L. PURON-SIERRA[2], R. GUTIERREZ[2]
[1]UNAM, Distrito Federal, Mexico; [2]Dept. of Pharmacol., CINVESTAV, Mexico, Mexico

Abstract: Recently, it was found that optogenetic stimulation of LH GABAergic neurons produce appetitive and consummatory behaviors, regardless of nutritional value and activation of these neurons induced approach behavior to the closest salient stimulus. We reasoned that these behaviors can be influenced by the palatability (or attractiveness) of the stimulus. To test this idea, satiated Vgat-ChR2 transgenic mice, which express ChR2 in LH GABAergic neurons, were trained in a novel open loop task that consisted in an operant box with three ports. The left port contains 3% sucrose, the central port -water-, and the right lateral port -18% sucrose-. Taste solutions were available all times. We found that transgenic mice increased consumption of 18% sucrose in 5 min laser on blocks compared to 5 min off blocks. These results can be explained because the mice spent more time near the most palatable stimulus (18% sucrose) and thus during optogenetic stimulation (2s on 4s off) they consume more 18% sucrose. We then asked whether activation of LH GABAergic neurons promote the consumption of the more palatable stimulus or the nearest although less palatable stimuli. To test this idea we designed a closed loop task, in the same behavioral box described above, but this time the laser was activated when the mice made a head entry in the central port (where water is available). We observed two different behaviors, one group of transgenic mice (n=6) increased their consumption of water (in the central port) over sucrose (lateral port), and another group (n=4) self-stimulate by doing a head entry in the central port, but they do not lick for water instead they move to consumed 18% sucrose, these inter-subjects variability shows that activation of LH GABAergic neurons may modulate two components: proximity and palatability of stimulus. Finally, we replaced water of the central port to either putting: 1) a dry sipper, transgenic mice increased the number of head entries in central port and kept licking the dry sipper; 2) when quinine 3) or airpuffs were given in the central sipper, mice decreased the number of licks, but they maintain a high number of head entries to self-stimulate. 4) However, when we changed the rule to turn on the laser from head entry to lick once the central sipper (i.e., the airpuffs now were inescapable), we found that now mice totally stopped self-stimulation, thus an aversive stimuli is stronger than LH GABAergic neurons activation. Finally; we put 18% sucrose in the central sipper and transgenic mice greatly overconsume sucrose. We concluded that activation of LH GABAergic neurons drives consummatory behavior by an interaction between the proximity and the hedonic value of the stimulus.

Title: The pallido-subthalamic projection and indirect cortical integration in the subthalamic nucleus

Authors: *C. A. BISHOP, S. R. HEILBRONNER, S. N. HABER
Univ. of Rochester Med. Ctr., Rochester, NY

Abstract: The cortico-basal ganglia network conveys information through direct, indirect, and hyperdirect pathways consisting of open, integrative loops from functionally distinct areas of the cortex. Through such connections, this network is involved in a wide range of psychiatric and neurological disorders, including obsessive-compulsive disorder, addiction, and Parkinson's disease. The subthalamic nucleus (STN) is part of both the indirect and hyperdirect cortico-basal ganglia pathways. The organization of the hyperdirect frontal cortico-STN projection was recently identified as generally topographic, though with convergence along the functional boundaries (Haynes and Haber 2013). The indirect circuity of the BG, on the other hand, has yet been thoroughly charted to the STN. Through this pathway, cortical projections are routed through the striatum and external segment of the pallidum (GPe) and ventral pallidum (VP) before the STN. In this study, our goals were to 1) identify specific pallidal projections to the STN, 2) identify cortical representation within the STN through the indirect cortico-basal ganglia pathway, and 3) compare the indirect and hyperdirect projections within the STN. We used nine cases in which anterograde/bidirectional neural tract tracers were injected into the GPe and VP of macaques. Our database of frontal cortical and striatal injections allowed us to determine the indirect cortical representation in the STN. Results demonstrate a clear pallidal topography within the STN: VP and rostral GPe project medioventrally in the rostral STN, caudal-lateral portions of the GPe project laterally and dorsally within the STN, and caudal-ventral portions of the GPe project centrally within the STN. There is also convergence within this topography such that non-overlapping pallidal injections produce overlapping terminal fields in the STN. Moreover, largely due to such extensive cortical integration within the striatum, cortical divisions of the STN are not as clear through the indirect pathway as compared to the hyperdirect pathway. These results demonstrate the convergent nature of the cortico-basal ganglia circuit. Additionally, they help to identify the distinct functions of the hyperdirect versus indirect

pathways and provide maps of STN afferents that can be used in deep brain stimulation treatment of neurological and psychiatric disorders.

Title: Function dissection of neural circuitry in paraventricular hypothalamus

Authors: *S. XU, H. YANG, F. HENRY, S. M. STERNSON
Janelia Res. Campus, HHMI, Ashburn, VA

Abstract: The paraventricular hypothalamus (PVH) has a major role in controlling behavioral states associated with animal survival functions. It plays important roles in feeding, osmoregulation, stress, grooming, social approach, sexual behavior and regulation of the autonomic nervous system. However, little is known about the integration of functional dynamics of neuronal ensembles in PVH because of the technique challenges caused by its deep-brain location and the intermingled distribution of molecularly defined cell types. To overcome these challenges, here, we report a functional imaging platform that can simultaneously investigate neuronal ensemble dynamics of multiple molecularly defined cell types in a deep-brain structure. GCaMP was pan-neuronally expressed in the PVH. PVH neuron calcium activity was recorded through a GRIN lens by two photon volumetric imaging in awake behaving animals under multiple behavioral states. After in vivo imaging, the brain was sectioned and cell type molecular identity was determined by multiplexed fluorescence in situ hybridization. This platform links traditional system neuroscience ensemble activity measurements with detailed molecular identity of individual neurons in the ensemble, thus it bridges the gap from gene expression to neural dynamics and behavior. Moreover, because this platform does not require genome modification, it's applicable to a large variety of organisms.

Ctr., [6]Dept. of Pharmacol., Univ. of North Carolina, Chapel Hill, NC; [7]Dept. of Neurosci., Med. Univ. of South Carolina, Charleston, SC

Abstract: Nociceptin/Orphanin FQ Opioid Receptor (NOPR) and its endogenous ligand, nociceptin (NOC) are widely distributed throughout the brain and have been demonstrated to have a role in mediating pain, stress, anxiety, feeding, and reward behaviors. In particular, systemic NOPR stimulation has been shown to inhibit dopamine neuron firing and reduce drug-reward behavior. However, the endogenous sources and natural role of nociceptinergic circuits within these reward behaviors are not understood. Using a novel knockin prepronociceptin (PNOC)-Cre mouse driver line and retrograde tracing techniques, we discovered a population of prepronociceptin neurons located within the paranigral and paraintrafascicular nuclei of the ventral tegmental area (peri-VTA). We found that these prepronociceptin neurons have monosynaptic projections onto dopamine cells and selective ablation of these cells enhanced sucrose seeking under fixed ratio three and progressive ratio operant tasks. In addition, we found that chemogenetic stimulation of peri-VTA nociceptin cells and optogenetic photo-stimulation of peri-VTA prepronociceptin terminals reduced operant responding in the progressive ratio task as well as caused conditioned place aversion. These findings identify a previously unknown population of nociceptin-containing neurons that are positioned to tonically suppress reward motivation via dopamine cell inhibition. To assess the functional activity of this prepronociceptin cell population during fixed and progressive ratio operant tasks, we used fiber photometry to record activity of prepronociceptin neurons during operant behavior. Understanding how this discrete nucleus regulates motivation and reward seeking behaviors could provide critical insight into behaviors dysregulated during motivational states such as depression and addiction.

Title: Nucleus accumbens mu-opioid receptors are necessary for the enhancement of motivated behaviors

Authors: ***D. C. CASTRO**, A. GUGLIN, T. ONYEADOR, M. R. BRUCHAS
Anesthesiol., Washington Univ. in St Louis, Saint Louis, MO

Abstract: Mu opioid receptors (MORs) are involved in motivation for natural and drug rewards. One site for MOR action is nucleus accumbens medial shell (NAc mShell). MOR stimulation in this mesocorticolimbic hub enhances appetitive behaviors such as food intake and social interactions. By contrast, disruption of MOR signaling has yielded ambiguous results. Here, we sought to determine when mu opioid receptors are recruited to mediate motivated behaviors by disrupting MOR signaling during baseline or enhanced motivated states (i.e., ad libitum versus food deprived, social versus isolated housing). To disrupt MOR signaling, we used constitutive $MOR^{-/-}$ knockout (KO), conditional knockout ($Oprm1^{fl/fl}$), and pharmacological approaches. KOs showed normal baseline behaviors compared to wildtype controls, but failed to show enhanced motivation after food deprivation or social isolation. Targeted viral deletion of MORs in NAc mShell of $Oprm1^{fl/fl}$ mice showed a similar pattern, suggesting that MORs are recruited to enhance, not generate motivated behaviors. Next, to determine whether MORs are dynamically recruited, we microinjected CTAP (MOR antagonist) into NAc mShell. MOR blockade only reduced motivated behaviors when animals were in heightened motivated states. Finally, to pinpoint which neuronal populations are important in NAc mShell for MOR-mediated enhancements, we crossed $Oprm1^{fl/fl}$ mice with dynorphin- or enkephalin-cre mice to delete MORs from those neuronal populations. Results suggest that MORs act primarily via D1/dynorphin neurons, but not D2/enkephalin neurons. Future work will further define the mechanisms mediating MOR control over motivation by testing MOR sufficiency in receptor rescue experiments, by quantifying changes in neural ensemble activity via *in vivo* calcium imaging, and by optically stimulating photosensitive MOR chimeras during discrete,

behaviorally relevant events. These results will show where, how, and when MOR signals act to enhance motivated behaviors.

Title: DREADD-activation of the mesolimbic circuit alters cue-induced behavior

Authors: *L. FERGUSON[1], L. G. LONGYEAR[2], A. M. AHRENS[2], J. ALDRIDGE[2]
[1]Psychology, [2]Univ. of Michigan, Ann Arbor, MI

Abstract: Rats express differences in their motivation to approach and interact with learned reward-paired cues. Pavlovian conditioning in which an approachable cue (a lever) precedes a reward by a few seconds will expose these individual differences. As rats learn the association of a cue and a paired reward, they diverge into different groups. Some rats approach and interact with the Pavlovian cue when its presented (sign-trackers, STs) while other individuals respond to the cue by moving to and engaging the reward delivery apparatus (goal-trackers, GTs). To investigate neural circuit differences between these individuals, the impact of the ventral pallidal (VP) influence on the ventral tegmental area (VTA) was examined. We have previously shown that firing patterns of ventral tegmental dopamine neurons are more active in STs than GTs to presentation of incentive cues. The VP acts to regulate populations of active VTA dopaminergic neurons and as a result may alter tonic dopamine release in the nucleus accumbens (Floresco et al., 2003). This study utilizes designer receptors exclusively activated by designer drugs (DREADDs) to selectively target neurons projecting from the VP to the VTA and the consequent effects of DREADD-activation on behaviors directed towards Pavlovian cues. By inhibiting the rostral VP during Pavlovian conditioning we expect that incentive salience of reward-paired cues will increase producing more sign-tracking behavior. Animals (n=14) received inhibitory DREADDs targeting VP neurons projecting to the VTA. After a 2-week incubation period, animals were trained in Pavlovian conditioned approach paradigm (PCA) and then tested in the Pavlovian task for an additional 2 weeks with injection of either CNO to activate DREADDs or saline for controls. Immediate behavioral effects due to DREADD activation with CNO were seen only in STs on day 1 of testing, expressed as increasing lever contacts. In contrast, DREADD activation showed changes in goal-trackers over the 5 days of testing. Specifically,

GTs demonstrated increased probability to contact lever, decreased latency to approach lever, increased latency to enter magazine, decreased probability of a magazine entry, and overall fewer magazine entries. In short, GTs exhibited more sign-tracking-like behavior with DREADD evoked activation disinhibiting the VP to VTA circuit and increasing dopamine with concomitant enhancement of incentive salience. A ceiling effect on sign-tracking behavior in STs, on the other hand, may limit changes in that phenotype. Future work will explore correlates of these behavioral shifts to neural firing pattern changes in dopamine and non-dopamine neurons in the VTA.

Title: Motivational regulation by dopamine D2 receptor downstream signaling pathways

Authors: *T. RAHBEK-CLEMMENSEN, E. GALLO, P. DONTHAMSETTI, J. JAVITCH, C. KELLENDONK
Dept. of Psychiatry, Columbia Univ., New York, NY

Abstract: Deficits in motivation are core negative symptoms in several psychiatric disorders. In schizophrenia dopamine D2R receptor (D2R) occupancy in the Nucleus Accumbens (NAc) is inversely correlated with negative symptoms. Using a mouse model with specific, viral-mediated upregulation of D2R in the indirect pathway of NAc core (D2R-OE_{IndAc} mice), we observed increased motivation in a progressive ratio task and locomotor activity as well as increased excitability and decreased excitatory input and output of indirect medium spiny neurons. With the development of two novel D2R mutants that either signal specifically via Gi/o/z or arrestin signaling pathways, we have a unique opportunity to determine which downstream pathways are important for regulating directional and activational components of motivation. Using in vivo studies, we are investigating how the signaling-bias in the medium spiny neurons of the indirect pathway affects the motivated behavior and locomotor activity. In parallel, we examine the effect on the physiological properties and circuitry of these medium spiny neurons to characterize the effect of either of these two mutants on the neuronal excitability and changes in neuronal circuitry and as well as the relationship to our behavioral data. Overall, the project could provide a potential path towards new therapeutic strategies for psychiatric disorders.

Title: Nucleus accumbens activity during acquisition, maintenance, and extinction of sign-tracking and goal-tracking behavior

Authors: *Z. S. GILLIS, S. E. MORRISON
Dept. of Neurosci., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Drug-related cues may acquire incentive value, precipitating relapse by making an addict more likely to interact with them. However, there is broad variation among individuals in the power of such reward-predictive cues to control behavior. This variation may be modeled in rodents using a Pavlovian conditioned approach assay in which some subjects tend to interact with the conditioned stimulus (CS) - a behavior known as “sign tracking” - while others tend to approach the site of reward, a behavior known as “goal tracking.” Sign tracking has been found to be more resistant than goal tracking to both reward devaluation (Morrison et al., 2015) and extinction learning (Ahrens et al., 2015). These behavioral differences are paralleled by neurochemical differences in the mesocorticolimbic reward pathway: in sign-trackers, cue-evoked dopamine (DA) release in the nucleus accumbens (NAc) is higher than in goal-trackers, while DA release evoked by the reward becomes lower over the course of training (Flagel et al., 2011). However, the impact of these differences on the signaling of individual neurons in the NAc remains unclear. Therefore, we recorded the activity of single cells in the NAc core in both sign-tracking and goal-tracking individuals during the acquisition, maintenance, and extinction of conditioned approach. Surprisingly, after acquisition, we found little difference in cue-evoked firing between the two behavioral response profiles, and the magnitude of cue-evoked excitations had a strong inverse relationship with latency to perform either action. Moreover, in both sign trackers and goal trackers, we observed firing patterns consistent with negative reward prediction errors at the time of omitted reward. In contrast to these similarities, we found that sign-tracking subjects retained higher cue-evoked firing rates in the NAc during extinction learning, consistent with their behavioral resistance to extinction. Finally, systemic administration of quinpirole, a D2 receptor agonist, reduced baseline activity, cue-evoked excitation, and behavioral responses to the cue in both sign trackers and goal trackers. Future experiments will focus on refining our

understanding of the relationships among DA release, sign-tracking and goal-tracking behavior, and the activity of individual neurons in the NAc.

Title: Cortical-amygdala circuits for value-based decision making

Authors: *M. MALVAEZ[1], C. SHIEH[1], M. MURPHY[1], V. Y. GREENFIELD[1], H. G. MONBOUQUETTE[2], K. M. WASSUM[1]
[1]Psychology, [2]Chem. & Biomolecular Engin., UCLA, Los Angeles, CA

Abstract: The value of an anticipated reward is a major contributing factor in the decision to engage in actions towards its pursuit. Such value is dynamic, fluctuating based on one's current need state, and must be learned through relevant state experience (e.g., consumption of a food item while hungry). The basolateral amygdala (BLA) is required for this incentive learning process, but little is known about how it achieves this function within the broader reward-seeking circuitry and whether it also participates in the online use of reward value during decision making. Because the BLA is densely innervated by cortical glutamatergic projections, we hypothesized that glutamate released into the BLA would track changes in reward value important for value-guided reward seeking. To test this, we used electroenzymatic biosensors to make near-real time measurements of BLA glutamate concentration changes during incentive learning (experience with a food reward in novel hungry state) and a subsequent reward-seeking test. Transient elevations in BLA glutamate concentration were detected that tracked the incentive learning process. No such changes were detected in the absence of incentive learning when the food was experienced in a familiar state. BLA glutamate elevations were also detected immediately preceding bouts of subsequent reward-seeking activity, but only if rats had access to the current value of the food reward. Supporting these correlational data, inactivation of BLA NMDA glutamate receptors prevented incentive learning, while inactivation of either BLA AMPA or NMDA receptors attenuated the normal increase in reward seeking that would occur following a positive incentive learning opportunity. We next used designer receptor-mediated

inactivation of specific glutamatergic cortical projections to the BLA to determine the afferent contributors to these input signals. Projections from the lateral orbitofrontal cortex (OFC) were found to be necessary for encoding a positive change in reward value, but not for later retrieval of this information for online decision making. Conversely, projections from the medial OFC were not required for incentive learning, but their inactivation did disrupt online reward-seeking activity. These data demonstrate that the BLA participates in both the encoding and retrieval reward value via input signals from the lateral and medial OFC, respectively.

Title: The role of basolateral amygdala output pathways in reward expectation-guided behavior

Authors: ***N. T. LICHTENBERG**[1], Z. T. PENNINGTON[1], V. Y. GREENFIELD[1], K. M. WASSUM[1,2]
[1]Psychology, UCLA, Los Angeles, CA; [2]Brain Res. Institute, UCLA, Los Angeles, CA

Abstract: Reward-related decisions are heavily influenced by expectations about future potential rewards. These expectations are generated by using information in the environment (e.g. stimuli or available actions) to retrieve detailed memories of associated rewards. The basolateral amygdala (BLA) is a key node in the circuitry supporting expectation-guided behaviors, but little is known about how specific BLA outputs contribute to this function. The BLA sends excitatory projections to several cortical and striatal regions, including the orbitofrontal cortex (OFC) and dorsomedial striatum (DMS), which are independently implicated in reward expectation-guided behaviors. We used designer receptor-mediated inactivation of specific BLA output pathways to evaluate their contributions to expectation-guided behaviors. Pathway-specific chemogenetic inactivation of monosynaptic BLA to OFC projections disrupted the motivating influence of cue-triggered reward expectations over action selection and conditioned goal-approach responding as

assayed by outcome-specific Pavlovian-to-instrumental transfer (PIT) and Pavlovian devaluation, respectively. These projections were not necessary when actions were guided by reward expectations generated based on learned action-reward contingencies, or when rewards were physically present to direct responding. These data suggest that bottom-up projections from the BLA to the OFC enable cue-triggered expectations to guide adaptive conditioned responding and decision making. Ongoing experiments are evaluating the contribution of BLA to DMS projections in reward expectation-guided conditioned responding and action selection.

Title: A novel viral approach for genetically targeting ventral tegmental area GABA projection neurons in wildtype rats reveal heterogeneous terminal fields throughout the cortex, subcortical and mesolimbic regions

Authors: ***M. FEJA**[1], A. SHIELDS[1], K. T. WAKABAYASHI[1,2], A. VENNER[3], P. M. FULLER[4], C. E. BASS[1]
[1]Univ. At Buffalo SUNY, Buffalo, NY; [2]Res. Inst. On Addictions / Univ. At Buffalo, Buffalo, NY; [3]Dept. of Neurol., [4]Harvard Med. Sch., Boston, MA

Abstract: Genetic manipulation techniques have been useful in elucidating the function of defined neuronal subtypes. However, their lack of specificity in non-murine models limits their translational applicability, particularly in behavioral models that primarily use rats. We have recently developed a dual adeno-associated virus (AAV) targeting system to restrict expression of transgenes to dopamine neurons in both wildtype rats and mice. In this system, one AAV delivers Cre recombinase under the control of subtype specific promoter (e.g. tyrosine hydroxylase), while another virus delivers a Cre dependent construct (e.g. DIO, FLEX cassettes) under a strong generalized promoter (e.g. EF1α, or hSyn). Only in neurons where these two constructs overlap does expression occur. Recently, we have developed a new Cre virus under the control of the gamma-amino decarboxylase 1 (GAD1) promoter. By co-infusing GAD1-Cre-AAV2/10 with EF1α-DIO-hM3D-mCherry-AAV2/10 into the ventral tegmental area (VTA), we have been able to target hM3D, the activating designer receptor exclusively activated by designer drugs (DREADD), to GABA neurons in this region. In addition to the strong mCherry expression in the VTA, there were distinct and intense terminal fields throughout the brain. Most GABA neurons in the VTA are interneurons, but ~1 in 5 are GABA projection neurons (GPNs)

that send efferents to multiple brain regions. We observed extensive projections to the striatum, in both dorsal and ventral subregions. In particular, there was a distinct dorsolateral to dorsomedial gradient. In the ventral striatum, there was intense terminals in the olfactory tubercle and nucleus accumbens (NAc), with the core receiving more dense projections relative to the shell. We also observed moderate expression of VTA GABA terminals in the ventral pallidum and medial prefrontal cortex (mPFC), particularly in the anterior cingulate and prelimbic cortex, among other regions. To target the VTA GPNs to the NAc we infused GAD1-Cre-AAV2/6 into this region, and the EF1α-DIO-hM3D-mCherry-AAV2/10 into the VTA. AAV2/10 transduces cells bodies at the injection site, while AAV2/6 is also retrogradely transported, allowing us to transduce only those GAD1+ neurons in the VTA that project to the NAc. We observed extensive mCherry+ cell bodies within the VTA and terminals primarily within the NAc core and to a lesser extent in the shell. Intriguingly, GABAergic signals were also found in several other regions, including the dorsomedial striatum, prefrontal cortex, and olfactory tubercle, suggesting the existence of GPN collaterals arising from the VTA to NAc projections.

Title: White-matter tract connecting amygdala and nucleus accumbens is associated with probabilistic reward learning

Authors: ***J. K. LEONG**[1], G. R. SAMANEZ-LARKIN[2], B. KNUTSON[1]
[1]Stanford Univ., Stanford, CA; [2]Duke Univ., Durham, NC

Abstract: Amygdala and nucleus accumbens (NAcc) circuits may contribute to dissociable aspects of reward seeking. While previous research has shown that NAcc activity can precede and predict reward seeking, recent work suggests that glutamatergic projections from the basolateral amygdala to the NAcc can also promote reward seeking behaviors. However, less research has examined the white-matter tracts that connect these circuits. White-matter tracts

conduct neural signals between circuits, and thus may mediate the effect of one circuit on the other. To study the potential relevance of a putative amygdala-NAcc tract to probabilistic reward learning in humans, we conducted an experiment in which individuals first performed a monetary incentive learning task, followed by a diffusion-weighted MRI scan. In the learning task, individuals chose between pairs of fractal cues and learned to select the better cue to maximize earnings. Individuals selected between cue pairs in gain, loss, and neutral conditions. In the gain cue pair, one cue represented a higher probability of monetary gain (66% +$1.00 / 33% +$0.00 versus 33% +$1.00 / 66% +$0.00). In the loss cue pair, one cue represented a higher probability of avoiding loss (66% -$0.00 / 33% -$1.00 versus 33% -$0.00 / 66% -$1.00). In the neutral cue pair, both cues represented no monetary outcome (100% $0.00). Behaviorally, learning performance for gain acquisition and loss avoidance were uncorrelated ($r = -0.31$, $t(17) = -1.32$, $p = 0.20$). In the same sample, we additionally performed probabilistic tractography on diffusion-weighted MRI data to trace tracts connecting the amygdala and the NAcc. Tractography results revealed the amygdala-NAcc tract follows the ventral amygdalofugal pathway, leaving the temporal lobe with the uncinate fasciculus but then diverging medially to terminate in the posterior NAcc. Coherence of this tract was then estimated by calculating fractional anistropy along the tract and averaging across the middle 50% of the tract. Individual differences in coherence of the amgydala-NAcc tract was positively associated with successful probabilistic reward learning in both gain acquisition and loss avoidance domains, however the effect was driven by gain learning (both: $r = 0.52$, $t(17) = 2.50$, $p = 0.02$; gain: $r = 0.46$, $t(17) = 2.11$, $p = 0.05$; loss, $r = 0.10$, $t(17) = 0.41$, $p = 0.69$). Our results extend previous research suggesting that white-matter tracts projecting to the NAcc can facilitate probabilistic reward learning, and implicate input from amygdala to NAcc in forming associations between novel cues and reward outcomes.

Title: Effects of optogenetic stimulation of DRN 5-HT neurons and 5-HT input to the mesolimbic DA system on operant responding for a primary reinforcer

Authors: *C. J. BROWNE[1,3], X. JI[3], Z. LI[3], P. J. FLETCHER[3,1,2]
[1]Psychology, [2]Psychiatry, Univ. of Toronto, Toronto, ON, Canada; [3]Biopsychology, Ctr. for Addiction and Mental Hlth., Toronto, ON, Canada

Abstract: Serotonin (5-hydroxytryptamine; 5-HT) neurons originating in the midbrain raphe nuclei innervate virtually the entire brain and are implicated in the control of many behavioural processes. Several lines of evidence suggest that serotonin exerts an inhibitory influence over motivated behaviour, but it is uncertain what 5-HT pathways mediate this effect. Serotonin neurons originating in the dorsal raphe nucleus (DRN) have been implicated in reward processing and reward-related behaviour. These neurons also heavily innervate the mesolimbic dopamine (DA) system – a critical neural substrate for motivation. The DRN sends particularly dense input to the ventral tegmental area (VTA), which could enable 5-HT to regulate mesolimbic DA output. In these experiments, we used an optogenetic approach to identify the role of the DRN-VTA pathway in modulating incentive motivation. The optogenetic construct was developed by crossing mice from the serotonergic cre-driver line ePet-Cre with Ai32 mice, which bear a ubiquitous conditional ChR2-EYFP allele downstream of a loxP-flanked STOP cassette. The progeny of this cross express ChR2 exclusively in 5-HT neurons. Mice received stereotaxic implantation of an optical fiber targeting either the DRN or VTA. First, we tested whether optogenetic stimulation of DRN 5-HT neurons altered lever pressing for the primary reinforcer saccharin (0.2%, 0.02 ml) on a RR4 schedule of reinforcement. Photostimulation (10 mW, 10 ms pulses) of the DRN had no effect on responding for saccharin at a range of frequencies (1, 5, 10, 20 Hz). However, when DRN photostimulation (2.5 Hz) was coupled with the selective 5-HT reuptake inhibitor citalopram (5 mg/kg), a synergistic reduction in responding for saccharin was observed. Analysis of within-session responding found that combining DRN photostimulation with citalopram dramatically reduces responding early in testing. Next, we examined the effects of optogenetic stimulation of 5-HT input to the VTA on responding for saccharin. Photostimulation (5 mW, 10 ms pulses) of 5-HT terminals in the VTA alone had no effect on responding for saccharin, but combining photostimulation with citalopram treatment (5 mg/kg) greatly reduced responding, particularly early in the test session. Together, these results support an inhibitory function of DRN 5-HT neurons in modulating motivation and suggest that this may be mediated in part by 5-HT input to the VTA. Further, the ability of 5-HT to alter incentive motivation in this pathway appears to depend critically on the regulation of extracellular 5-HT by the serotonin transporter.

Title: Amygdalar neural ensembles that encode the aversive quality of pain experience

Authors: *G. F. CORDER[1], B. AHANONU[2], B. GREWE[5], M. SCHNITZER[3], G. SCHERRER[4]
[2]CNC Program, [3]Howard Hughes Med. Inst., [4]Anesthesiology, Perioperative, and Pain Med., [1]Stanford Univ., Palo Alto, CA; [5]Inst. of Neuroinformatics, ETH Zurich, Zurich, Switzerland

Abstract: The experience of pain leads to motivated behaviors that limit exposure to noxious stimuli. However, it remains unknown how the brain's affective neural circuits generate the aversive quality of pain. To identify a neural basis for pain aversion, we used chemogenetic and in vivo calcium imaging methods to study nociceptive neural ensembles in the basal and lateral amygdala (BLA) of mice. By using a head-mounted miniature microscope to track the dynamics of these cells in freely behaving mice, we identified BLA neural populations that represent different types of painful stimuli via a combinatorial coding scheme. Chemogenetic silencing of nociceptive cell ensembles selectively alleviated pain affective-motivational behaviors, but without affecting detection of noxious stimuli, withdrawal reflexes, anxiety levels or reward seeking. After induction of a neuropathic pain state, innocuous stimuli prompted heightened activation of the nociceptive cell ensembles. Remarkably, silencing neuropathic cell ensembles blocked the pathological affective dysfunctions that characterize chronic pain. Collectively, these results indicate there is a neural representation of nociception in the amygdala that is functionally required for the innate, negative quality of painful experiences.

Title: A new monosynaptic craniofacial affective pain neural circuit drives robust aversive behaviors

Authors: *E. RODRIGUEZ[1], K. SAKURAI[1], J. XU[1], D. RYU[1], S. ZHAO[1], K. TODA[2], H. H. YIN[2], B. HAN[1], F. WANG[1]
[1]Neurobio., [2]Psychology and Neurosci., Duke Univ., Durham, NC

Abstract: Humans often rank craniofacial pain as more severe than body pain. Evidence suggests that a stimulus of the same intensity induces more pain in the face than the body. However, the underlying neural circuitry for the differential processing of facial versus body pain remains unknown. Interestingly, the lateral parabrachial nucleus (PB_L), a critical node in the affective pain circuit, is activated more strongly by noxious stimulation of the face than the hind paw. Using a novel activity-dependent technology called CANE developed in our lab, we identified and selectively labeled pain-activated PB_L neurons, and performed comprehensive anatomical input-output mapping. Surprisingly, a hitherto uncharacterized monosynaptic connection specifically between cranial sensory neurons and the PB_L-pain neurons was discovered. Optogenetic activation of this monosynaptic craniofacial-to-PB_L projection induced robust escape/avoidance behaviors and stress calls. The new circuit route revealed here thus provides a neural substrate for heightened craniofacial affective pain.

Title: Distinct time course of the limbic activation between spinal and trigeminal inflammatory pain models as revealed with manganese enhanced MRI in the mouse

Authors: *F. KATO[1], D. ARIMURA[1], Y. TAKAHASHI[1], K. SHINOHARA[2], T. TSURUGIZAWA[3], T. TOKITA[1], R. IKEDA[2], K. MARUMO[2]

[1]Dept Neurosci, Jikei Univ., Tokyo, Japan; [2]Dept. Orthop., Jikei Univ. Sch. Med., Tokyo, Japan; [3]Neurospin/I2BM/DSV/CEA, Gif Sur Yvette, France

Abstract: Recent functional brain imaging studies in human subjects indicate that a shift of brain regions that are spontaneously activated characterizes the process from acute-to-chronic pain transition. In particular, the activation of the limbic system is proposed to be a hallmark of the establishment of chronic pain. In agreement with this notion, synaptic activation and phosphorylated ERK expression appearing after the acute pain in the central amygdala have been documented in the rodent model of early inflammatory pain (Carrasquillo & Gereau, 2007; Miyazawa et al., 2014). However, it remains entirely unknown whether such shift of spontaneous pain-associated brain regions also occurs in the animal model of chronic pain. To address this issue, we used manganese (Mn^{2+}) enhanced MRI (MEMRI) with ultra-high field scanner and cryodetectors (9.4T; Bruker Biospec) to visualize the neuronal excitation history in the animals spent under spontaneous behaviors after formalin injection, a model recently shown to show a rapid shift in symptoms from acute pain-like to chronic pain-like. In particular, as the nociception in the areas with spinal and trigeminal innervations is sent to the brain via distinct pathways, effects of the inflammation site on the brain activation pattern were examined by administering formalin to the left upper lip (trigeminal inflammation group; TI) or the plantar (spinal inflammation group; SI) of the left hind paw of the mice at 2 h (scanning after the acute phase; “acute scanning”) or 6 h (that after the acute and post-acute phases; “post-acute scanning”) before the MRI scanning and we compared the accumulation of Mn2+ between groups and treatments. $MnCl_2$ injection and scanning were done at a 22-h interval under isoflurane anesthesia. Except for these and formalin/saline injection, the mice were kept in the home cage and allowed to move freely to ensure spontaneously pain sensation. All mice showed typical acute nocifensive behaviors that faded within <60 min. In post-acute scanning in SI group, and in acute scanning in TI group, a significantly larger accumulation of Mn^{2+} in limbic areas such as the central amygdala was observed. A significant Mn2+ accumulation in the sensory cortex was observed in acute scanning in both groups with distinct somatotopy-dependent patterns. These results indicate a dynamic shift in brain areas presumably associated with spontaneous pain sensation in the acute-to-chronic transition in a manner temporally dependent on the site of inflammation.

Title: Ketamine attenuates the aversive effects of chronic pain

Authors: *H. ZHOU, K. LIU, J. WANG
NYU Sch. of Med., New York, NY

Abstract: It is well understood that chronic pain can induce a generalized enhancement in the aversive response to nociceptive inputs, as demonstrated by our previous studies in rodents as well as conditions such as fibromyalgia and persistent postoperative pain. However, effective treatment of these types of conditions has traditionally been difficult, and new therapeutic modalities are urgently needed. In the current study, we ask the following question: Can any pharmacological treatments attenuate this generalized enhancement of pain aversion? We hypothesize that Ketamine, which has recently been shown to provide enduring anti-depressant and anxiolytic properties, may attenuate these aversive effects in the chronic inflammatory pain model.
Complete Freund's Adjuvant (CFA) was injected into the plantar aspect of one hindpaw to induce chronic inflammatory pain. Two days after CFA injection, ketamine (10mg/kg) (or saline control) was administered systemically via intraperitoneal injections. A brief two-chamber conditioned place aversion test (CPA) was performed to quantify the aversive effect of painful stimuli (pin prick). A higher CPA score corresponds to greater aversion of pain-associated chamber. Mechanical allodynia and traditional Hargreaves test were used to measure mechanical and thermal hypersensitivity as an assessment of the sensory component of pain.
Our results show that in the chronic inflammatory pain model, Ketamine is able to significantly attenuate the aversive effects of nociceptive inputs up to five days after treatment. Interestingly, this decrease in aversion is not associated with any change to the sensory component of pain. Our experiments show that Ketamine may represent a novel treatment option for the affective symptoms of chronic pain.

Title: Aversive emotional circuits are impaired in the MeCP2^{Tg} mouse

Authors: *B. YU[1], L. HE[2], T. CHENG[1], B. YUAN[1], R. ZHANG[1], Z. QIU[1]
[1]Inst. of Neuroscience, CAS, Shanghai City, China; [2]Baylor college of medicine, Houston, TX

Abstract: MeCP2 is a DNA binding protein encoded by a gene located on chromosome Xq28 in humans, and is a protein that is evolutionarily conserved both in structure and in function. Large amount of studies have showed that MeCP2 expression level is extremely important for normal function of central nervous system. A loss of function of MeCP2 gene is the main cause of most cases of Rett syndrome, a severe neurodevelopmental disorder. And a gain of function of MeCP2 will cause MeCP2 duplication syndrome, another neurological developmental disease. Both of these syndromes show typical autistic symptoms. In contrast to Rett syndrome, research on MeCP2 duplication syndrome is relatively fewer. Especially, how MeCP2 affects neural circuits in the whole brain is largely unknown. In this study, we used neurotropic viruses tracing method, optogenetic and electrophysiological strategies to target social and anxiety relevant neural circuits in the MeCP2 duplication mouse. We found that BLA-mPFC circuit which is one of the most widely studied aversive emotional circuits is impaired in the MeCP2Tg mice.

Abstract: Anxiety behaviors form a part of the natural repertoire of animal behavior, with their disorders being a prevalent psychiatric condition. However, the specific neural signaling patterns underlying anxiety remain unclear. Several elements of the corticolimbic circuit, including the amygdala, are strongly implicated in regulating anxiety. Here, using calcium imaging, we record the activity of neurons within the basolateral amygdala over time in mice engaged in anxiety-like

behaviors, and characterize the underlying neural encoding patterns. Results will shed important light on the neural information processing during expression of anxiety-like behavior.

Title: Differential activation of arginine-vasopressin receptor subtypes in the amygdaloid modulation of anxiety in the rat by arginine-vasopressin

Authors: *O. R. HERNANDEZ PEREZ[1], M. CRESPO-RAMIREZ[1], M. PEREZ DE LA MORA[1], K. FUXE[2]
[1]Cognitive Neurosci., Inst. de Fisiologia Celular, UNAM, México city, Mexico; [2]Dept. of neuroscience, Karolinska Institutet, Stockholm, Sweden

Abstract: The amygdala plays a paramount role in the modulation of anxiety and social behaviours. A relationship between arginine vasopressin (AVP), anxiety and aggression has now been suggested. And that both behaviors have as substrate to the amygdala. Numerous studies have shown AVP elicits anxiogenic effects following either its systemic or septal administration. The aim of this study was to evaluated the involvement of vasopressinergic neurotransmission in the amygdaloid modulation of unconditioned anxiety and to ascertain whether or not AVP receptor subtypes may have a differential role in this modulation and if this relationship is involmented in social behaviours. Anxiety behavior was evaluated both in Shock-Probe Burying Test and Light-Dark Box and social behaviour in social interaction test following the bilateral micro-infusion of AVP alone or AVP together with either AVP 1a or AVP 1b receptor antagonists into the central amygdala (CeA) and the social behaviour was evaluated in the social interaction test. AVP micro-infusion elicited at low (1ng/side) but not at high doses (10 ng/side) anxiogenic-like responses in the Shock-Probe Burying Test but not in the Light-Dark Box. SSR149415, an AVP 1b antagonist unlike Manning compound, an AVP 1a antagonist fully prevented AVP effects in the Shock-Probe Burying Test when it was administered together with AVP. No effects of any AVP antagonist by itself were observed in both anxiety paradigms. Moreover, AVP micro-infusion (1ng/side) decreased social behaviors and increased aggression.

Our results indicate that AVP 1b receptor contribute to the amygdaloid modulation of anxiety and social behaviours. It remains to the future to ascertain whether AVP receptor subtypes have indeed differential actions in the modulation of specific features of unconditioned anxiety.

Title: Anxiety cells in a hippocampal-hypothalamic circuit

Authors: *J. C. JIMENEZ[1], K. SU[2], A. GOLDBERG[2], V. LUNA[2], P. ZHOU[2], G. ORDEK[3], S. ONG[2], L. ZWEIFEL[5], L. PANINSKI[2], R. HEN[4], M. KHEIRBEK[6]

Abstract: The ventral hippocampus (vHPC) may modulate anxiety-related behaviors by connecting cognitive association regions with subcortical structures that can directly impact mood. However, what stimuli are encoded within vHPC circuits and how those representations are used to guide behavior remains unknown. To understand this, we used cell-type specific calcium imaging to investigate how innately anxiogenic contexts are represented in ventral CA1 (vCA1) pyramidal neurons. We found that vCA1, but not dorsal CA1 activity increased during exploration of innately anxiogenic environments. Moreover, the magnitude of this activity increase was tightly correlated with the anxiety state of individual animals. Using a closed-loop

optogenetic design, we found that silencing vCA1 during exploration of anxiogenic environments significantly reduced avoidance behavior, suggesting that vCA1 anxiogenic representations were causally modulating anxiety behavior. We next determined through which vCA1 output streams these effects could be mediated. We focused on vCA1 projections to two subcortical nuclei implicated in anxiety, fear, and behavioral responses to stress, the Basal Amygdala (BA) and Lateral Hypothalamus (LHA). Retrograde tracing studies revealed that vCA1 outputs to the LHA and BA are segregated into two largely non-overlapping cell populations within vCA1. Using optogenetic techniques to control these two vCA1 outputs, we found that modulation of vCA1-LHA, but not vCA1-BA terminals impacts innate anxiety and aversion, while vCA1-BA but not vCA1-LHA terminal modulation impacts contextual fear memory. Finally, we conducted projection-specific calcium imaging to visualize the activity of vCA1-BA and vCA1-LHA neurons during exploration of anxiogenic environments, and found that vCA1-LHA projecting neurons were highly enriched in anxiety-responsive neurons relative to vCA1-BA neurons. This study provides a functional map of the cell-types and long-range circuits that underlie the vHPC contribution to innate anxiety-related behavior, and suggests that the vCA1-LHA pathway may serve as a direct route by which vCA1 can modulate innate avoidance behavior.

Title: Opposite effects produced by N-methyl-D-aspartate (NMDA) receptor activation within the left or right medial prefrontal cortex on anxiety in mice

Authors: *R. L. NUNES-DE-SOUZA[1,2], N. S. COSTA[1,2], B. S. CARDOSO[1]
[1]Univ. Estadual Paulista, UNESP, Araraquara, Brazil; [2]Joint Grad. Program in Physiological Sci. (PIPGCF), Araraquara, Brazil

Abstract: The medial Prefrontal Cortex (mPFC) is densely populated by glutamatergic neurons, which, in turn, play a role in the modulation of anxiety via NMDA receptor activation. Besides, recent findings have shown that chemical manipulations of the Right (R) or Left (L) mPFC provoke distinct effects on anxiety of mice exposed to the elevated plus maze (EPM). Here, we investigated the effects of NMDA activation in the L or R mPFC on anxiety-like responses of mice exposed to the EPM. Methods: Male Swiss mice (n=5-7) received intra-mPFC injection of saline or NMDA (Right: 0.02 or 0.04 nmol/0.2 µL; Left: 0.04 nmol/0.2 µL). Ten minutes later, each mouse was exposed to the EPM to record the conventional measures of anxiety (percentage of open-arm entries and percentage of open-arm time: %OE and %OT), locomotor activity (frequency of closed-arm entries: CE), risk-assessment behaviors [protected (p) and unprotected (u) stretched attend posture: SAP] and frequency of rearing for a period of 5 minutes. Results: Statistical analysis (R: One-way ANOVA; L: Non-parametric Mann-Whitney test) showed that NMDA differently alter behavior when injected into the R or L mPFC. Intra-RmPFC NMDA injections provoked an anxiogenic-like effect [%OE: $F(2,13)= 4.14$; %OT: $F(2,13)= 13.94$; $p<0.05$] without changing CE [$F(2,13)= 0.37$; $p>0.05$]. In contrast, intra-LmPFC NMDA injection provoked a borderline anxiolytic-like effect, increasing open-arm exploration (%OE: $Z=1.70$; $p=0.08$; %OT: $Z=1.86$ $p=0.06$) without changing locomotor activity [CE: $Z=0.89$; $p=0.3$]. Also, Left-NMDA treatment tended to reduce the pSAP ($Z=1.70$; $p=0.08$) without changing the uSAP ($Z=-0.81$; $p=0.41$), whilst activation of the RmPFC did not alter the pSAP [$F(2,13)=0.52$; $p=0.6$] but reduced the uSAP [$F(2,13)=3.09$; $p=0.04$ at 0.02 nmol dose]. Neither R nor L treatment alter frequency of rearing [L: $Z=-0.56$; $p=0.56$; R: $F(2,13)=4.03$; $p>0.13$], suggesting NMDA effects were selectively on anxiety-related behaviors. Conclusion: These results are suggestive that glutamate NMDA receptors located within the RmPFC and LmPFC play an anxiogenic- and anxiolytic-like role in the modulation of anxiety in mice exposed to the EPM.

Title: Carbon monoxide promoted anxiolytic-like effect and increasing expression of heme-oxigenase in locus coeruleus

Authors: *C. R. LEITE-PANISSI[1], R. A. CAZUZA[2]
[1]Ribeirao Preto Dent. Sch. - USP, Ribeirao Preto, Brazil; [2]Dept. de Psicologia, Faculdade de Filosofia, Ciências e Letras de Ribeirão Preto, Ribeirão Preto, Brazil

Abstract: Previous study suggested that the carbon monoxyde (CO) acting on locus coeruleus (LC) play role on emotional behavior modulation. Again, the LC has high expression of the heme-oxygenase (HO) enzyme, responsible for the production of CO. The CO in LC can modulate the activity of the local neurons, however, the mechanism by which the HO-CO pathway of LC participates in the modulation of emotional responses needs to be elucidated. Here, we investigate whether the systemic treatment (ip) acute (3h before) or chronic (10 days/2 times a day) with a carbon monoxide releaser (CORM-2) or an inducer of heme enzyme oxygenase (CoPP), is able to alter the behavioral responses in the elevated plus maze (EPM) and in the light-dark box test (LDB), and the expression of the HO-1 or HO-2 enzymes into LC cells in rats. Male Wistar rats (200g, n=50, CEUA 2015.1.531.58.4) were divided into distinct groups that received acute or chronic treatment with CORM-2 (5mg/kg, i.p.), CoPP (2.5 mg/kg, i.p.) or vehicle (DMSO) and were submitted to EPM and LDB for 5 min each test. Two-way ANOVA was used for the analysis followed by the Tukey test ($P<0.05$). The results showed that the CO induced by acute or chronic administration of CORM-2 or CoPP increased the number of entries into the open arms and the percentage of time spent in the open arms in the EPM when compared to control group ($P<0.05$). In the LDB test, chronic treatment with both drugs increased the time spent in the light compartment compared to control group ($P<0.05$). The treatment with CORM-2 or CoPP (acute and chronic) promoted an increase HO-1 enzyme expression in cells located in the LC without altering the immunoreactivity of HO-2 enzyme. These results shown that the CO promoted anxiolytic-like effect and increasing expression of HO-1 enzymes in LC cells.

Title: Control of anxiety-like behavior by serotonergic circuits innervating the interpeduncular nucleus

Authors: *I.-J. YOU[1], L. LIU[1], A. SACINO[1], M. UCHIGASHIMA[1,2], K. FUTAI[1], A. R. TAPPER[1]
[1]Brudnick Neuropsychiatric Res. Institute, Dept. of Psychiatry, Univ. of Massachusetts Med. Sch., Worcester, MA; [2]Med. Dept. of Anat., Hokkaido Univ., Sapporo, Japan

Abstract: Recently, the interpeduncular nucleus (IPN) has been implicated as a critical neuroanatomical substrate for modulating fear and anxiety-like behavior. However, functional IPN afferent and efferent circuitry that contributes to these behaviors is largely unknown. Interestingly, viral tracing studies indicate that the IPN receives projections from the medial raphe nucleus (MRN), although serotonergic signaling in the IPN and the functional relevance of this MRN→IPN input has not been elucidated. Molecular and biophysical analysis of 5-HT receptors in the IPN indicated robust functional expression of 5-HT1, but not 5-HT5 receptors. Double fluorescent in situ hybridization experiments revealed co-localization of 5-HT1A receptor and glutamic acid decarboxylase 67 transcripts suggesting serotonergic IPN inputs innervate GABAergic neurons in the rostral sub-nuclei of the IPN. To test the hypothesis that MRN→IPN serotonergic inputs modulate anxiety-like behavior, we expressed channelrhodopsin in MRN serotonergic neurons that project to the IPN using retrograde viral delivery in FEV-Cre mice. Optical stimulation of serotonergic terminals in the IPN increased anxiety-like behavior in the elevated plus maze and open field test. In contrast, stimulation of MRN→IPN inputs did not significantly affect locomotor activity, depression-like behavior, or reward. These results reveal a novel role for a serotonergic MRN→IPN circuit in modulating anxiety-like behavior.

Title: Molecular mechanism of circadian regulation of mouse anxiety-like behavior

Authors: *K. SHIMIZU, J. NAKANO, Y. FUKADA
Dept. Biol. Sciences, The Univ. of Tokyo, Tokyo, Japan

Abstract: Circadian regulation of physiology extends to higher brain functions including cognition and memory, such that time-of-day-dependent variations in cognitive performance and

memory formation have been described in various species. Disturbances in human activity rhythms such as those arising from rotating shift work or jet lag increase the risk for mood disorders. In rodents, perturbations of the circadian clock by means of surgical, genetic, pharmacological or light-induced manipulations lead to a spectrum of abnormalities in emotionality-related behaviors, including elevated or attenuated anxiety-like behaviors. While these lines of evidence show that disruption of the circadian clock triggers a spectrum of affective abnormalities, how the clock regulates mammalian emotionality remains unclear. We sought to unravel the mechanisms governing mammalian anxiety regulation and characterized temporal regulation of mouse anxiety-like behaviors by the circadian clock. We show that anxiety-like behaviors are expressed in a circadian manner in mice and demonstrate that the clock machinery in the dorsal telencephalon is required for the time-of-day-dependent regulation of anxiety-like behaviors. We identify SCOP/PHLPP1β (suprachiasmatic nucleus circadian oscillatory protein) as an essential intracellular signaling molecule mediating this temporal regulation downstream of the clock. SCOP is a signaling molecule originally identified as a gene product whose expression oscillates in a circadian manner in the rat SCN (Shimizu *et al*. FEBS Lett 1999). SCOP protein is predominantly expressed in the central nervous system, and has been shown to regulate a range of intracellular signaling pathways (Shimizu *et al.* Cell, 2007). Using viral-mediated, basolateral amygdala (BLA)-specific knockout of *Scop*, we demonstrate that deletion of SCOP in the BLA exerts anxiolytic effects on the elevated plus maze at early subjective night, thereby blunting the circadian variation in the anxiety-like behavior. We conclude that the circadian expression of SCOP in the BLA plays a key role in generating circadian rhythmicity in the anxiety-like behavior. Our results demonstrate SCOP as a regulator of anxiety-like behaviors and reveal its key role in the anxiogenic functions of the BLA. (Nakano *et al*. Sci Rep, 2016)

Title: Efficacy of voluntary exercise in reducing anxiety in female mice

Authors: *C. NEELY[1], L. ROSARIO[2], A. SANCHEZ[2], B. ADAMS[2], J. FLINN[1]
[1]Dept. of Psychology, [2]Interdisciplinary Program in Neurosci., George Mason Univ., Fairfax, VA

Abstract: Women experience anxiety at a higher rate than men, and strategies that benefit men may not generalize across gender. We sought to explore the effect of exercise on anxiety in

female mice as an analogue for women. Mice *(N*=16) were housed in two conditions: one with a running wheel and one with a standard PVC pipe as enrichment. Data were collected via the elevated zero maze following 27 days of housing conditions. Prior to data collection, we hypothesized that access to a running wheel in the homecage would reduce anxiety-like behaviors in comparison to standard housing. Data did not violate the assumption of equal variances; therefore, we conducted a one-sided independent samples *t*-test to analyze the beneficial effects of the presence of a running wheel on percentage of time spent in the open arms and risk-assessment behaviors in the EZM. Mice with running wheels spent more time in the open arms of the maze (21.2 ± 10%) compared to mice without running wheels (15.2 ± 11.6%); however this difference was not significant, $t(14) = 1.11$, $p = 0.14$. Mice with running wheels also exhibited more head-dips in the open arms (22 ± 5.4) compared to mice without running wheels (15.8 ± 8.2). This difference in risk-assessment behavior was significant, $t(14) = 1.80$, $p = 0.05$. This study showed decreases in anxiety because of an available running wheel in the homecage. This study is currently being replicated with larger sample sizes, male mice, and additional behavioral tests. Overall, results show that exercise may be a promising research topic for anxiety treatments oriented towards women.

Title: Candidate anxiolytic drug testing in human approach-avoidance anxiety: Comparison of lorazepam, pregabalin, and valproate

Authors: *D. R. BACH, C. W. KORN, A. BANTEL, J. VUNDER
Univ. of Zurich, Zurich, Switzerland

Abstract: Preclinical screening of potential anxiolytic substances in non-human animals relies on the premise that the neurochemistry of anxiety is sufficiently conserved across species. Some anticonvulsant drugs with strong preclinical evidence for acutely anxiolytic properties in rodents, such as valproate, have not been translated to clinical application, urging cross-species investigation. Here, we capitalised on a recently developed human anxiety test emulating rodent approach-avoidance conflict such as elevated plus maze (EPM), open field, or operant conflict. Our "stay and play" test has been shown sensitive to the impact of the GABAergic anxiolytic lorazepam, and of both hippocampal and amygdala lesions. In a double-blind, randomised, placebo-controlled trial, participants played a computer game while under the established

GABAergic anxiolytic pregabaline (200 mg), the candidate anxiolytic valproate (400 mg), or placebo. Primary outcome measure (presence in safe place) and a priori contrast (linear drug x intra-epoch time adaptation) were chosen based on a previous study with 1 mg lorazepam. Peak saccadic velocity and subjective ratings were assessed as control measures for drug-induced sedation. Both valproate and pregabaline were anxiolytic in the primary and several secondary outcome measures. Bayesian model comparison indicated no differences between the two drugs. Subjective and objective sedation was significantly more pronounced under pregabalin than valproate, but did not explain anxiolytic effects. In comparison, 1 mg lorazepam had a stronger anxiolytic effect than the drug doses used here. In summary, our results suggest a potential use of valproate as anxiolytic drug. More generally, we propose a strategy of screening drugs in human preclinical models that can directly be compared across species, such as the approach/avoidance computer game used here. This approach could thus facilitate translational anxiety research.

Title: Neural correlates of subjective pleasure and displeasure in nociceptive pain

Authors: *V. RIMEIKYTE[1], J. L. WHITLOCK[2], A. K. ANDERSON[1]
[1]Human Develop., [2]Bronfenbrenner Ctr. for Translational Res., Cornell Univ., Ithaca, NY

Abstract: Nociceptive pain signals damage to body tissue and thus avoiding it is paramount to survival. In line with this function, nociceptive pain is commonly considered inherently aversive. However, despite the aversive qualities of nociceptive pain, some people intentionally and repeatedly engage in self-harming behaviors. In addition, prior research suggests that subjective pain experience can be pleasurable in certain contexts as well as during experience of pain relief. These findings indicate that there may be appetitive components to pain in addition to its aversive qualities. In current study, we aimed to disentangle pleasure and displeasure components of pain experience. Healthy young adult participants (N=10) experienced painful pressure to their thumbs [3-7 kg/cm^2] for 8-11s while undergoing an fMRI scan. After each trial, participants rated pleasant and unpleasant their experience was on a given trial. In our sample, pleasure ratings were only mildly negatively correlated (r = -.32) allowing us to examine the neural activity associated with each component during pain stimulation. Activity in supplementary motor and premotor areas, as well as in inferior parietal lobule scaled with both pleasure and displeasure ratings. Activity in dorsal and posterior cingulate cortices, as well as precuneus and hippocampus, scaled only with displeasure ratings. In addition, displeasure ratings

were correlated with activity in areas associated with self-regulation dorsolateral prefrontal cortex, thalamus, and dorsal striatum (caudate/putamen). In contrast, pleasure ratings were tracked by activity in left inferior frontal gyrus and bilateral insula, which has been previously associated with processing positive emotions. These findings provide preliminary evidence for distinct appetitive components of nociceptive pain and may help elucidate why people intentionally engage in self-harming behaviors.

Title: Relationship between growth mindset and stress

Authors: *C. FOX[1], I. DESTA[1], L. YOON[2], B. SHIBLEY[1], K. MOORE[1], S. PAJOR[1], M. DEANDA[1]
[1]Psychology, Holy Cross Col., Notre Dame, IN; [2]Psychology, Univ. of Notre Dame, Notre Dame, IN

Abstract: Research on Carol Dweck's Implicit Theory of Intelligence is relatively new. Studies have shown various beneficial effects of having or developing a Growth Mindset that reflects a belief that intelligence and abilities are plastic and subject to growth. However, very little research has been done on the relationship between Mindset and stress or anxiety. A preliminary study with 103 college students examined the effect of Mindset on five indicators of stress (physical, sleep, behavioral, emotional and personal habits) as well as anxiety and found that behavior stress is higher in subjects with Growth Mindset. More data is being collected and analyzed. Furthermore, we want to validate these results by collecting saliva cortisol measurements from subjects at the time of stress and anxiety testing. We plan to have the cortisol results ready for the Society for Neuroscience conference in November 2017. In conclusion, Growth Mindset might be beneficial for people but maybe at a cost of higher behavior stress.

Title: Caffeine administration and elevated plus-maze exposure in rats activate populations of serotonergic neurons in the dorsal raphe nucleus relaxin-3 neurons in the nucleus incertus: Implications for the role of relaxin-3 in modulating serotonergic systems in the control of anxiety states

Authors: A. J. LAWTHER[1], *S. KENT[1], A. M. FLAVELL[1], S. MA[2], C. A. LOWRY[3], A. L. GUNDLACH[2], M. W. HALE[1]
[1]Psychology & Publ. Hlth., La Trobe Univ., Melbourne (Bundoora), Australia; [2]The Florey Inst. of Neurosci. and Mental Hlth., Melbourne, Australia; [3]Dept. of Integrative Physiol. and Ctr. for Neurosci., Univ. of Colorado Boulder, Boulder, CO

Abstract: Anxiety is a complex and adaptive emotional state controlled by a distributed and interconnected network of brain regions, and disruption of these networks is thought to give rise to the behavioural symptoms associated with anxiety disorders in humans. The dorsal raphe nucleus (DR), which contains the majority of forebrain-projecting serotonergic neurons, is implicated in the control of anxiety states and anxiety-related behaviour via neuromodulatory effects on these networks. However, the diverse functions of the serotonergic system means that drugs, such as SSRI's, which are used in the treatment of anxiety are often accompanied by unpleasant side effects, or are ineffective. Therefore, understanding how subsets of the serotonin system are modulated by other neurotransmitters, such as relaxin-3, may help improve our understanding of anxiety disorders, and lead to more targeted and effective treatments for these disorders. Relaxin-3 is the native neuropeptide ligand for the Gi/o-protein-coupled receptor, RXFP3, and is primarily expressed in the nucleus incertus (NI), a tegmental region immediately caudal to the DR. RXFP3 activation has been shown to modulate anxiety-related behaviour in rodents, and RXFP3 mRNA is expressed in the DR. In this study, we examined the response of anxiety-related brain regions, including relaxin-3-containing neurons in the NI and serotonergic neurons in the DR, following pharmacologically-induced anxiety and exposure to an aversive environment. We administered an anxiogenic dose of the adenosine receptor antagonist, caffeine (50mg/kg), or vehicle to adult male Wistar rats and, 30 min later, exposed them to either the elevated plus-maze or home cage control conditions. Immunohistochemical detection of c-Fos was used to measure activation of nuclei within anxiety related brain regions of the cortex, septum, amygdala, thalamus, hypothalamus and hippocampus, and to determine activation of serotonergic neurons in the DR and relaxin-3 neurons in the NI, measured 2 h following drug injection. Analysis revealed that caffeine administration and exposure to the elevated plus-maze

are both associated with an increase in c-Fos expression in relaxin-3-containing neurons in the NI, serotonergic neurons in the DR, and that these changes are associated with changes in c-Fos expression in multiple anxiety-related forebrain regions. These data are consistent with the hypothesis that relaxin-3 systems in the NI and serotonin systems in the DR interact to form part of a network involved in the control of anxiety-related behaviour.

Title: Anxiety: Ethanol and hydroxyzine oral consumption after reward devaluation

Authors: *L. MANZO[1], *L. MANZO[1], A. GORDILLO[2], A. C. TAFOLLA[2]
[1]Univ. Michoacana De San Nicolas De Hidalgo, Morelia, Mexico; [2]Univ. Michoacana San Nicolas de Hidalgo, Morelia, Mexico

Abstract: Male rats from the Low-avoidance strain (but not from the Roman High-avoidence strain) increased preference for ethanol after exposure to Appetitive extinction (Manzo et al. Physiol Behav 2014 123:86-92). Such increased fluid preference did not occur after acquisition (reinforced) sessions or in groups with postsession access to water, rather than ethanol. Because ethanol has anxiolytic properties in reward loss tasks, oral consumption after extinction sessions was interpreted as anti-anxiety self-medication. To test this hypothesis, Wistar (nonselected) rats received training in an instrumental extinction (reward loss) task in a straight alley after acquisition with continuous reinforcement (CR; 12 pellets per trial) vs. 50% partial reinforcement (PR; 12 or zero pellets per trial in random sequence) event in a PR situation were given a two-bottle, 2-h preference test immediately after extinction sessions. One of the two bottles contained 2% ethanol, 1 mg/kg hydroxyzine, or water for different groups (the second bottle contained water for all groups). Hydroxyzine is a anxiolytic used in the psychiatric treatment of individuals suffering from anxiety disorders. Three additional groups received the same postsession preference tests, but were always exposed to 12 pellets during CR. Rats showed during extinction session effect, suppressing behavior after the downshift relative unshifted controls. This effect was accompanied by a selective increase in both ethanol and hydroxyzine oral intake during the initial downshift sessions. Downshifted animals with access to water or unshifted controls with access to the anxiolytics failed to exhibit any changes in

preference during the postsession test. Such ethanol and hydroxyzine consumption depended on the degree of emotional activation induced by prior experience (i.e. PR vs. CR training) and also self-medication may provide insights into the early stages of addictive behavior.

Title: Anxyolitic effects of oxytocin in nucleus accumbens

Authors: *S. D. GONZALEZ-GARCIA[1], A. D. HERNANDEZ[2], S. P. CAÑARTE-VARELA[2], E. N. LEVARIO-RAMIREZ[2], M. CRESPO[2], M. PEREZ DE LA MORA[2]
[1]UNAM Facultad de Medicina, Ciudad De Mexico, Mexico; [2]Neurociencia Cognitiva, UNAM Inst. de Fisiologia Celular, CDMX, Mexico

Abstract: Anxiety is an adaptative response which detects and protects an individual against danger. Nucleus accumbens is a brain structure that participates in modulation of emotion and motor behaviors. Several neurotransmitter and neuromodulators are involved in anxiety such as oxytocin that is a hypothalamic neuropeptide with anxiolitic effects into the brain. The paraventricular nucleus of hypothalamus projects oxytocinergic fibers to nucleus accumbens. However is less known about the role of oxytocin in the nucleus accumbens. The aim of this work was to evaluate the role of oxytocin in the nucleus accumbens in locomotions and anxiety behaviors. Here we used adult male wistar rats with weighting 240-260 g. Placed in a home cage Cycle dark light 12/12 (turn off lights 7:00). Oxytocin doses 0.3, 3 and 30 nanograms were injected intra accumbens. We used the open field test (50cm x 50 cm) to assess locomotor activity and anxiety behavior. In conclusion these results suggest that the oxytocin has no effect in locomotion activity in any doses used. In other hand the oxytocin at highest dose evoked an anxiolitic effect.

Title: Induced anxiety impairs cognitive emotion regulation

Authors: *I. SARIGIANNIDIS[1,2], O. J. ROBINSON[1], J. ROISER[1], M. ERNST[2], C. GRILLON[2]
[1]Inst. of Cognitive Neurosci., London, United Kingdom; [2]NIMH-NIH, Bethesda, MD

Abstract: Cognitive conceptualisations of anxiety posit a central role of emotion regulation in the etiology of the disorder. In order to better understand the relationship between anxiety and emotion regulation, it is essential to disentangle the role of trait and state anxiety. Previous studies suggested that state anxiety dramatically impairs cognitive processes such as working memory and attention, processes that are essential for emotion regulation. Taking this into account, we investigated the possibility that state anxiety impairs an adaptive cognitive regulation strategy, reappraisal, whose underlying principles form the basis of cognitive behavioural therapy. We hypothesised that state anxiety will impair the ability to use reappraisal in order to modulate emotional responses. To this end, we used a well-validated technique, threat of unpredictable shock, to induce anxiety in healthy individuals while they performed an emotion regulation task. Participants viewed pictures and were asked to respond naturally, increase (upregulate) or decrease (downregulate) their negative response by reappraising the content of the pictures. Simultaneously, we recorded the magnitude of startle reflex, a widely used marker of emotional reactivity. Preliminary findings suggest that the difference in startle magnitude between conditions of upregulation and downregulation is diminished in the induced-anxiety condition. In other words state anxiety impaired to ability to use reappraisal to modulate emotional responses, in line with our hypothesis. Future studies could explore how the interaction between high trait and state anxiety affects the ability to regulate emotions, in order to better understand the role of emotion regulation in the pathogenesis of anxiety disorders.

Title: Serotonin transporter inhibition induced behavioral alterations in *Drosophila*

Authors: *P. G. MANDELA
Dept. of Pharmaceut. Sci., Univ. of St. Joseph, Hartford, CT

Abstract: Our research goal is to identify the behavioral deficits that arise as a result of inhibiting serotonin transporter in *Drosophila melanogaster*. Drosophila serotonin transporter (dSERT) shares structural and functional similarities with human serotonin transporter (hSERT). Our preliminary results indicate that fluoxetine an SSRI, decreases locomotor activity in DAM and reiterative negative geotaxis (RING) experiments. These observations were in agreement with findings in rodent models. Most antidepressants alleviate despair behavior in rodent models. Drosophila demonstrates despair behavior when subjected to prolonged inescapable exposure to hot temperatures (37^{o}C). Our results demonstrate that pretreatment with fluoxetine drastically alleviated Drosophila despair behavior which was identical to observations in rodent behavioral models. These preliminary data supports our hypothesis that Drosophila serotonin transporter inhibition can produce behavioral effects similar to hSERT inhibition.In our future studies, we plan to establish other behavioral tests that can confirm antidepressant efficacy. We want to generate a Drosophila mutant that expresses GFP tagged hSERT which would enable us to overcome pharmacological differences at the same time monitor the transporter regulation. We also plan to create a complete SERT knockout Drosophila which enables us to delineate SERT dependent and independent effects of antidepressant drugs.

Title: The effects of maternal exposure to organophosphate flame-retardants on offspring feeding and exploratory behaviors

Authors: *S. WALLEY[1], A. YASREBI[2], T. A. ROEPKE[3]
[1]Dept. of Animal Sci., Rutgers, New Brunswick, NJ; [2]Animal Sciences, SEBS, [3]Animal Sci., Rutgers, The State Univ. of New Jersey, New Brunswick, NJ

Abstract: Metabolic syndrome, while multifactorial, can be caused by endocrine disrupting compounds (EDC). Most EDCs are ubiquitous in the environment and accumulate in human tissues leading to concerns for potential effects during sensitive periods such as gestation and lactation. Organophosphate flame retardants (OPFR) are within one such group of EDCs that are found in many household products (furniture, toys, clothing electronics), with little data existing of OPFR effects on the fetus or neonate. OPFRs have agonistic/antagonistic activity for estrogen receptor alpha (ERα) and peroxisome proliferator-activated receptor (PPAR)γ, both are central pathways responsible for energy balance, motivated behaviors, and glucose homeostasis in the hypothalamus. We hypothesize that perinatal OPFR exposure impacts ERα-regulated genes in the hypothalamus leading to disruption of the hypothalamic melanocortin circuitry and alteration of activity in a sex-dependent manner. To test our hypothesis, we fed antenatal WT mice a peanut butter and OPFR mixture (triphenyl phosphate, tricresyl phosphate, and tris(1,3-dichloro-2-propyl) phosphate) from GD7 to PND14 and measured anxiety like behaviors (EPM and OFT) on week 19. Subsequent experiments will characterize the impact of OPFRs on metabolic parameters.

Title: The role of ERa-mediated ERE-dependent and ERE-independent signaling in feeding and exploratory behaviors in male and female mice

Authors: *A. YASREBI[1,3], T. A. ROEPKE[2]
[1]Animal Sciences, SEBS, [2]Animal Sci., Rutgers, The State Univ. of New Jersey, New Brunswick, NJ; [3]Grad. Program in Endocrinol. and Animal Biosci., Rutgers Univ., New Brunswick, NJ

Abstract: The reproductive steroid hormone, 17β-estradiol (E2), control feeding and exploratory behaviors associated with mood disorders. The loss of circulating E2 puts menopausal woman at a increased risk for developing obesity and mood disorders when compared to premenopausal woman. Therefore, it is critically important to understand the role of sex steroids and their receptors in the neuroendocrine control of feeding and mood. The goal of this project is to understand the role of estrogen response Element (ERE)-dependent and ERE-independent ERα signaling on behavior by characterizing feeding patters and exploratory behaviors in male and female mice lacking either total ERα signaling or lacking ERE-dependent ERα signaling. We hypothesize that ERE-independent ERα is partially sufficient to restore feeding and exploratory behaviors that are lost in total ERα knockout mice. We tested three strains of mice: two ERα transgenic models, a total ERα knock out (ERKO) and a novel ERα knock in/knock out (KIKO) that lacks a functional DNA-binding domain) and their wild type (WT) C57 littermates using a real-time feeding behavior monitoring system and series of standard behavior tests (open field tests, elevated plus maze, forced swim test). Each experiment was initially done with intact animals and then again repeated in ovariectomized (OVX) animals split into either an oil treated control group or an E2-treated group. By using these ERα transgenic mouse models, we will investigate the contribution of ERE-mediated ERα signaling in controlling feeding and exploratory behaviors.

Title: What is happening in our brain when we feel music-induced chills and don’t feel chills?

Authors: *A. YANG, K. I. KOBAYASHI
Doshisha Univ., Kyoto, Japan

Abstract: We sometimes feel extremely pleasant when we listen to music. This emotion is called chills. The sensation of chills is so strong that it is far beyond the ordinary sense of pleasure frequently resulting in goose bumps or shivers. The purpose of this study is to find out the neural mechanism of musical chills sensations. We investigated the difference in brain activities when a “chill” sensation occurs and when it doesn’t while listening to an identical music by using fMRI. We aimed to identify the specific activation related to the chills. Thirteen subjects listened to four pieces of music. These pieces were selected by each subject and

expected to cause the sensations. We defined them as original music. To prevent the subjects from feeling the sensation, we added noise to four pieces of music (noisy music). In total, subjects listened to eight stimuli (four pieces of original music and four pieces of noisy music) under the MRI scan. In the experiment, they reported whether they were feeling chills or not by pressing a button. We defined feeling chills as chill-on and defined not felling chills as chill-off. We measured and compared the brain activity of each subject. In the results, noisy music significantly shortened the average duration of chills compared with original music. As for fMRI analysis, brain activities during chill-on condition caused by original music contrasted with during chill-off condition caused by original music showed significant increase of activities in the caudate. The same region was activated when subjects felt chills in noisy music condition. It suggests that the caudate is the key to distinguish the difference of chill-on and chill-off. Next, brain activities during chill-on condition caused by original music contrasted with during chill-on condition caused by noisy music showed significant increase of activities in the putamen, the insula and the parahippocampus. The same regions were activated during chill-off condition caused by original music contrasted with during chill-off condition caused by noisy music. It suggests that the activation areas are not exclusively related to the chills, rather helped to feel chill when subjects listened to chill-inducing music. Based on our research, the activation in the caudate could be important for the chill sensation. In addition, the activation in the putamen, the insula and the parahippocampus could be involved in general musical sensation, such as whether they listened to original or noisy music. Our research will contribute to find out the neural mechanism of chills.

Title: Stress Reduction from a Music Intervention

Authors: *E. E. LEAVER[1], L. ST. PIERRE[1], R. WARFIELD[1], B. HEARN[1], H. ENNERFELT[2], V. FALLON[1]
[1]Psychology, [2]Psychology Dept., Salisbury Univ., Salisbury, MD

Abstract: Research suggests that music listening can affect mood (McGregor et al. 2011) and physiological states (Thoma et al. 2013). Much of this research has focused on long-term effects occurring over the course of multiple sessions and many of the studies have focused on behavioral variables such as self-reported changes in mood that result from music intervention. The purpose of this Stress Reduction with a Musical Intervention study was to expand the

previous work in two major ways. We wanted to compare the stress reducing effects of music listening versus music playing. Secondly, we utilized psychophysiological measures of stress in addition to self-report measures. We were also interested in changes that occur in one session (as opposed to multiple sessions). Specifically, participants were exposed to a stressor task while recording EDA measures. Self-report behavioral measures were also assessed. After the stressor task was complete, participants were assigned to one of three recovery conditions; Control (CG), Music Listening (ML), or Music Playing (MP). Behavioral and physiological results from post stressor and post recovery were compared. We performed a manipulation check by comparing baseline behavioral and physiological data versus post stressor data for each subject to ensure that we successfully stressed the participants. Results indicated that participants exhibited significant increase in behavioral and physiological stress response as a result of the stressor task. In comparing the groups, behavioral data was mixed while the physiological data showed a trend towards greater stress reduction for both experimental groups.

Title: Measuring physiological markers of restorative landscapes using virtual reality environments

Authors: *M. MURARIK[1], *C. L. JIMENEZ CHAVEZ[2], J. LADNER[2], T. PEGORS[2]
[2]Dept. of Psychology, [1]Azusa Pacific Univ., Azusa, CA

Abstract: Nature is often referred to by many as the fountain of inspiration, peace, and restoration. Research has shown that even minimal exposure to natural environments has been associated with increases in cognitive performance, attention and mood. Additionally, studies have shown significant decreases in stress after such exposure. What remains unknown, however, are the physiological responses during nature exposure and their relationship to these post-exposure changes in stress and behavior. In this study, we used ECG to measure heart rate variability (HRV) while participants were exposed to two nature and two urban environments in a virtual reality (VR) paradigm. Using VR rather than real-world exposure allowed us to move the subject through immersive environments without inducing physical exertion on the participant's behalf. Each subject was exposed to four environments (design using Unity

software): an open valley, a narrow forest, an open plaza, and a narrow street. Environment order was counterbalanced between participants. Within each environment, participants were transported to six locations for 30s within the environment. Participants were asked to remain seated and refrain from excessive movement below the neckline, but they were encouraged to look around within their environment and to take pictures of beautiful views. (An Oculus Rift VR unit was used to provide a 360 degree, high-resolution spatial view.) An initial 6m baseline HRV was collected after a practice environment, then 3m resting baselines were introduced before each environment. After 30-min VR exposure, participants exited VR and were then asked to create a brochure of their top-ten views (created with custom code), describing and ranking the pictures they themselves had taken. Using time domain measures, the standard deviation of the normal-to-normal intervals (SDNN) was lower for urban environment immersion than for natural environment immersion. Additionally, root mean square of the successive difference values (RMSSD) was higher for natural environments than for urban environments, thus indicating higher parasympathetic activity during nature immersion. Additional analyses will correlate differences in HRV to behavior measures, including 1) number of pictures taken, 2) ranking of pictures, 3) verbal description of pictures. Given that people tend to have some control over their environment, pinpointing the physiological mechanisms underlying the benefits of natural environments is important to making changes that increase our health, cognitive abilities, and psychological well-being.

Title: Focusing on slow breathing modulates early and late components of affective pictures

Authors: *W. ZHANG[1,2], L. LIANG[4], P. LI[4], X. LIU[5], B. SUN[6], H. LI[3]
[1]Mental Hlth. Ctr., Yancheng Inst. of Technol., Yancheng City, China; [2]Chengdu Univ., Cheng, China; [3]Chengdu Univ., Chengdu, China; [4]Liaoning Normal Univ., Dalian, China; [5]Beijing Normal Univ., Beijing, China; [6]Zhejiang Normal Univ., Jinhua, China

Abstract: An emerging body of research has applied breath-focused attention training in mindfulness interventions to reduce multiple symptoms of stress, anxiety, and depression. However, yet little is known regarding the neural mechanism of how focusing on slow breathing modulates time course of emotional responses. Here we recorded event-related potentials (ERPs) of 20 healthy undergraduate volunteers when they performed a breath-focused attention task during the viewing of affective pictures. Before the experiment, all the participants were instructed to practice slow breathing for 3 minutes. In the viewing condition, early component (P1, N1, and N2) and late positive potential (LPP) amplitudes to affective pictures increased more than those to neutral pictures. However, focusing on the sensation of slow breathing attenuated affective modulation of these ERPs. In the breath-focused condition but not in the viewing condition, P1 amplitudes for emotional minus neutral pictures correlated positively with the ability to focus attention measured by the Attentional Control Scale; N2 amplitudes for emotional minus neutral pictures correlated positively with individual differences in dispositional mindfulness measured by the Mindful Attention Awareness Scale. However, LPP amplitudes for emotional minus neutral pictures predicted subsequent arousal rating scores for emotional minus neutral pictures, regardless of the viewing or breath-focused condition. These observations suggest that even in the face of emotional stimulation, focusing on slow breathing induces attention-concentrated mindful states that increase the stability of attention and promote early emotion regulation, which deepens our understanding of the temporal processing mechanism of breath-focused mindfulness.

Med., Linkoping Univ., Linkoping, Sweden; [7]Fac. of Medicine, Inst. of Basic Med. Sciences, Dept. of Behavioural Sci. in Med., Oslo Univ., Oslo, Norway

Abstract: Introduction: Ongoing slow stroking is perceived as pleasant over an unexpectedly long time (Triscoli et al., 2014). Low threshold, unmyelinated C-tactile afferents respond preferentially to this type of touch. In two studies, we investigated both neural and autonomic (heart rate variability) responses during long-lasting slow stroking.
Methods: In both studies, stroking was performed with a brush on the forearm for ~ 40 minutes at 3 cm/s (the velocity that optimally activates C-tactile fibres). In study 2, we added a control group (20 subjects) that received vibration stimulation. In study 1, 25 subjects were scanned with functional magnetic resonance imaging. In study 2, we calculated heart rate variability (HRV) in 40 subjects. In both studies, pleasantness ratings for the brush stroking (and vibration in study 2) were collected.
Results: In both studies, stroking was never rated as unpleasant; the perceived pleasantness of stroking, however, declined over time. In study 1, activation in primary and secondary somatosensory cortices (S1 and S2) decreased over time while activation in orbito-frontal gyrus (OFC) and putamen strongly increased until plateauing after 20 min. Only at the end of the stimulation, posterior insula, middle cingulate and striatal regions became functionally connected. In study 2, HRV increased during brush stroking, but not vibration. Interestingly, both OFC activation and HRV increased up to 20 minutes from the onset of brush stroking and plateaued afterwards.
Discussion: Similar increases in OFC activation and HRV over a common interval suggest a link between neural and autonomic systems in response to long-lasting stroking performed at C-tactile optimal velocity. OFC activation may reflect updating of reward value. Increased HRV found for stroking, but not for vibration, may reflect adaptive self-regulation to emotional stimuli. Our findings highlight parallel time courses for the neural and autonomic adaptation to pleasant tactile experiences.

Title: The Fusiform Face Area shows distinct patterns of fMRI activity to African American and Caucasian faces in different emotional contexts

Authors: *B. NARDOS[1], E. RUBIEN-THOMAS[3], E. E. SCHIFSKY[2], B. J. CASEY[4], D. A. FAIR[5]
[1]Behavioral Neurosci., [2]Oregon Hlth. & Sci. Univ., Portland, OR; [3]Psychology, Yale Univ., New Haven, CT; [4]Weill Cornell Med. Col., New York, NY; [5]Oregon Hlth. Sci. Univ., Portland, OR

Abstract: Recent events in the United States have brought to the forefront issues related to the presence and severity of racial discrimination towards African Americans. While emotions often run high in these discussions, empirical evidence describing differential brain responses in individuals confronted with African American (AF) versus Caucasian (CAU) faces is lacking. In addition, how these brain responses might differ in emotionally arousing contexts is also unclear. Using an emotional go/no-go impulse control fMRI task in two independent groups of healthy AF and CAU young adults (Dataset 1: AF - N=17, mean age 23, 5 female; and CAU - N=39, mean age 21, 23 female; Dataset 2: AF - N=44, mean age 26, 22 female; and CAU - N=39, mean age 27, 21 female), this study explored potential differences in brain activity related to processing black versus white faces with different emotional expressions (calm, happy, fearful) in different sustained emotional contexts (neutral, negative, positive). The fusiform face area (FFA), a brain region involved in processing face stimuli, emerged as one of the brain regions whose activity was sensitive to the interactive contributions race and emotional context. Black and white faces elicited similar levels of activity in FFA in neutral contexts, while exhibiting differential levels in emotional contexts. In positive contexts greater activity was elicited for Caucasian faces; whereas in negative contexts greater activity was elicited for African American faces. fMRI activity in the noted brain regions was correlated with the level of false alarms in the GO/NO-GO task as well as Implicit Association Test scores, with different patterns of brain/behavior relationships as a function of race and emotional context. Participant race had no bearing on these findings. These results indicate inherent differences in how the brain responds to race in a context-dependent manner.

Title: Multivoxel pattern analysis of affective picture processing: A simultaneous EEG-fMRI study

Authors: *K. BO[1], S. YIN[2], Y. LIU[3], A. KEIL[4], M. DING[5]
[1]Dept. of Biomed. Engin., [2]Biomed. Engin., Univ. of Florida, Gainesville, FL; [3]Ctr. for Mind and Brain, Univ. of California Davis Ctr. for Mind and Brain, Davis, CA; [4]The Dept. of Psychology and the NIMH Ctr. for Emotion and Attention, [5]Univ. Florida, Gainesville, FL

Abstract: Both electroencephalography (EEG) and functional magnetic resonance imaging (fMRI) studies have shown that affective pictures elicit enhanced visual processing relative to neutral pictures. The latency of this enhanced visual processing, as indexed by the EEG late positive potential (LPP), is consistent with the reentry hypothesis. In this study, recognizing that univariate analysis employed up to date has limited capability in uncovering distributed neural representations, we examined the multivoxel patterns evoked by affective pictures. Simultaneous EEG-fMRI were recorded from healthy subjects during passive viewing of pleasant (erotica, romantic courtship, sport scenes), neutral/calm (house hold scenes, people), and unpleasant (mutilation, human violence, attacking animals) pictures, selected from the International Affective Picture System (IAPS). Each picture was shown for 1000ms. The inter-trial interval (ITI) varied randomly from 6000 to 9000ms. Applying the support vector machine (SVM) technique to single-trial BOLD responses obtained using the beta-series method, we decoded pleasant-versus-neutral conditions and unpleasant-versus-neutral conditions. The following results were found. First, the decoding accuracy is above chance level in all areas along the visual hierarchy. Second, the decoding accuracy follows a top-down cascading pattern, with high-order visual areas having higher decoding accuracy than low-order visual areas. Third, the decoding accuracy is positively correlated with the magnitude of LPP, a well-established index of motivationally facilitated attention. Collectively, these results show that emotionally arousing stimuli are distinctively represented in the visual system, and that enhanced visual processing of these stimuli is effected by re-entrant projections originating in high-order emotional processing areas of the brain.

Title: Investigation of Emotional Valence using EEG

Authors: *W. R. MCGARRY
Human Factors and Applied Cognition, George Mason Univ., Brooklyn, NY

Abstract: Neural activity reflecting emotional valence has been a large topic of study for decades, yet there is still a great deal of conflict in the literature pertaining to which neural features are thought to reflect positive and negative emotional valence. The purpose of this study was to investigate the specific neural signals believed to reflect emotional valence. EEG recordings were obtained as participants were given a visual emotion processing task. Results demonstrated empirical support for specific neural features underlying positive and negative states of emotional valence.

Title: Temporal and spectral changes of human EEG according to emotional arousal

Authors: *H. KIM, ***H. KIM**, P. SEO, D. YEO, S. HER, J. CHOI, J. CHOI, K. KIM
Bio medical engineering, Yonsei Univ., Wonju, Korea, Republic of

Abstract: Background: An emotional arousal refers to perceived activation state to the proprioceptive feeling of physiological arousal induced by an affective stimulus. Neural mechanisms underlying the emotional states are not identified. Here we tried to investigate the changes in cortical activities according to emotional arousal states during watching emotional

video clips. **Methods**: Twenty healthy university students participated in the experiment. Thirty-two affective video clips were presented in one-minute. Sixty-four channel electroencephalograms (EEGs) were recorded. The alpha and gamma frequency bands within 30 - 50 seconds intervals were selected as the region of interest by applying a mass univariate analysis (MUA). Subsequently, statistical comparison between high and low arousal was performed using two sample t-test. False discovery rate correction (FDR<0.05) was used for multiple comparison. **Results**: The power within the time-frequency window of interest (alpha and gamma bands, 30 - 50 seconds) was significantly different between high and low arousals. Widespread alpha power was significantly decreased in high arousal (FDR<0.05). Strong alpha activity was observed at frontal and left parietal areas (FDR<0.01). In contrast, gamma powers in lateral temporal and parietal areas were significantly increased for high arousal. Furthermore, the alpha powers were found to be significantly anti-correlated with self-assessment scores of arousal. **Conclusion**: The widespread alpha and temporoparietal gamma bands powers were highly correlated with arousal. In line with previous studies, the widespread suppression of alpha power in high arousal may represent cortical disinhibition by affective attention. These characteristic changes in EEG would provide useful biomarkers for the design of pattern classifiers for emotion recognition.

Title: Time-frequency analysis of the electroencephalogram evoked by skin conductance response to emotional events

Authors: P. SEO, H. KIM, D. YEO, S. HER, J. CHOI, J. CHOI, *K. KIM
Yonsei Univ., Wonju, Korea, Republic of

Abstract: Emotional status affects the physiological signals reflecting the activities of central and autonomic nervous systems (CNS and ANS). However, the relationship between the physiological signals of the CNS and ANS was not investigated. Here we tried to identify the relationship between two major arousal indicators, electroencephalogram (EEG) and skin conductance response (SCR) evoked by emotional events. Seventeen healthy university students participated in the experiment. Multichannel EEGs and electrodermal activity (EDA) were recorded during watching movie clips extracted from Korean movies, intended to evoke emotional arousals. The SCR peaks were detected from the EDA signal, and the SCR peaks larger than 10% of the maximum SCR peak amplitude were further analyzed. The EEG segments within -3500~3500 ms epoch around the SCR peaks were obtained. Time-frequency analysis was performed to obtain event-related spectral perturbation (ERSP). To investigate characteristic changes in the SCR-related EEGs, the statistical comparison of the ERSPs were made between the ERSPs of SCR-related EEGs and baseline EEGs without SCR responses. Significant differences were found mostly in bilateral central areas. Alpha- and beta-band powers were significantly increased for the SCR-related EEGs, mainly during -2500~2500 ms, compared to baseline conditions. Right centrotemporal region showed increased alpha-band power, and left centrotemporal region showed increased beta-band power. This increases could be related with asymmetric activities due to the emotionally arousing events in the movie stimuli.

Title: Changes in posterior cingulate cortex current density in response to emotional visual stimuli

Authors: *D. YEO, J. CHOI, K. CHA, H. KIM, P. SEO, S. HER, K. KIM
Yonsei Univ., Wonju / Gangwon-Do, Korea, Republic of

Abstract: In this study, we investigated event-related changes of cortical current density in response to emotional visual stimuli. Nineteen healthy male subjects without neurological and psychiatric illness were enrolled in the experiment (age: 23.18±1.92 years). 64-channel

electroencephalogram (EEG) was recorded while the subjects were watching pleasant, unpleasant and neutral pictures. Event-related potential (ERP) at scalp electrodes and event-related changes of cortical current source density were analyzed. For the event-related current density analysis, mass univariate analysis was applied after source localization with weighted minimum norm estimation. Significant increase of the cortical current density was found in right inferior temporal cortex (ITC) and left posterior cingulate cortex (PCC) in late temporal epoch (400-800 ms). The current density level was proportional to the arousal level. It is well known that ITC deals with color or shape of visual stimuli and relates to visual memory. It is recognized that PCC is related to retrieval of episodic memory. Recent studies suggest that PCC performs functions related to emotional evaluation as well. The most significant activation of PCC in our results may imply that the PCC plays more important role in evaluating emotion than previous assumptions.

Title: Dopamine D1 and D2/3 receptor antagonism effect on tickling induced 50-kHz ultrasonic vocalizations in the adolescent rats

Authors: *M. HORI[1], R. SHIMOJU[2], J. OHNISHI[4,1], K. MURAKAMI[1], M. KUROSAWA[2,3]
[1]Fndn. For Advancement of Intl. Sci., Tsukuba / Ibaraki, Japan; [2]Grad. Sch. of Hlth. and Welfare Sci., [3]Dept. of Pharmaceut. Sci., Intl. Univ. of Hlth. and Welfare, Ohtawara, Japan; [4]Dept. of Food and Nutr., Tokyo Kasei Univ., Tokyo, Japan

Abstract: Adolescence, the transition period between childhood and adult life, is a critical period for neural and social development. The maturation of dopaminergic neurotransmitter systems, particularly in the prefrontal cortex and limbic regions, also occurs during adolescence, and determines the sensitivity to rewarding effects of food and drugs, etc.
Additionally, social interactions are important for neuronal and behavioral development. Therefore, social isolation is noxious and increase the stress vulnerability, whereas play behavior during juvenile and adolescence is considered to facilitate neural and social development in rodents. Since the level of rough-and-tumble play is regulated by pharmacological manipulations of brain dopamine system, rough-and-tumble play is thought be itself a kind of “pleasure or joy”. Meanwhile, adolescent rats emit 50-kHz ultrasonic vocalizations (USVs), a marker of positive emotion, during rough-and-tumble play. The emission of 50-kHz USVs is mediated by dopamine release in the nucleus accumbens. We recently showed that tickling, which mimic rough-and-tumble play with human hand, triggers dopamine release with 50k-Hz USVs in the nucleus accumbens, and tickling-induced 50-kHz USVs were inhibited by the direct microinjection of dopamine receptor antagonist into the nucleus accumbens.
In the present study, we investigate whether there are differences between D1 and D2/3 receptor subtypes antagonism to response by tickling in the nucleus accumbens. As a result, D1 or D2/3 receptor antagonism alone altered the production of 50kHz USVs, but also these dopamine receptor subtypes appear to influence acoustic parameters to different degrees. Pretreatment with raclopride, D2/3 receptor antagonist, inhibited the expression of positive emotion faster than that with SCH23390, D1 receptor antagonist, since the numbers of 50-kHz calls in the raclopride treatment group was lower than those in the SCH23390 treatment group at 2min after the antagonist administration. These results may indicate that during adolescence the potentially different contributions receptor subtypes play in positive emotion control in the nucleus accumbens.

Title: HPA axis activation in various tasks evaluating memory and anxiety

Authors: *N. L. GARCIA SALDIVAR[1], M. R. A. GONZÁLEZ-LÓPEZ[2], S. E. CRUZ-MORALES[2]
[2]Psychopharmacology, [1]UNAM FES-Iztacala, Tlalnepantla, Mexico

Abstract: Components of different behavioral procedures that evaluate memory and anxiety generally involve a training session and a test session. Each session may contain stressors that activate the adrenal hypothalamic-pituitary axis (HPA) differentially. Thus, in the task of inhibitory avoidance (IA), the stressor is the shock; in the Elevated T-Maze (ETM) and Elevated Plus-Maze (EPM) the open spaces are the stressors, while the task of object recognition (RO) seems to have no stressors. The objective of the present study was to evaluate the stressful effect of the components of various tasks used in the study of memory and anxiety. Eight groups of male rats (N = 8) were assigned to one of the following treatments: control (C), 2 groups exposed to IA, 2 groups exposed to ETM and two more groups exposed to OR, in all cases one group of each procedure was exposed to training session (T IA, T ETM, T OR) or to training and test sessions (IA, ETM, OR); one more group was exposed to the EPM. The subjects were sacrificed immediately after training and a blood sample was obtained to measure the concentration of corticosterone in plasma by ELISA. The release of corticosterone was greater in the subjects during the training phase in the RO task than in all groups, whereas when the two training and test sessions were performed in all the tasks, no significant differences were observed, although there is a tendency in the group exposed to IA training and testing to show a higher concentration of corticosterone. Although it has been proposed that the task of MRO is a less aversive task, the first session involves the participation of an event that activates the HPA axis and this factor has to be considered when evaluating the effect of other stressors on memory.

Title: Neurobiological components of varying coping strategies: Influence of behavioral, endocrine, neural and dynamic genome markers

Authors: *K. G. LAMBERT[1], J. PERDOMO-TREJO[2], M. KENT[1], C. SYDNOR[1], A. A. BARTLETT[3], H. E. LAPP[3], S. SCAROLA[2], S. NEAL[2], B. THOMPSON[2], S. LAMBERT[2], D. VAVRA[1], M. BARDI[2], R. G. HUNTER[3]

Abstract: Although Hans Selye described the *general* adaptation syndrome highlighting similar stress responses within and across species, subsequent research has identified individual differences associated with stress responsivity. Given the influence of certain patterns of stress responsiveness on the emergence of various illnesses, it is important to identify relevant neurobiological markers associated with susceptibility to maladaptive stress responses. In the current study, two cohorts of rats were investigated to examine neurobiological correlates of varying coping strategies. In the first study, male rats profiled as passive, active or flexible copers via the back-test restraint assessment adapted for rats in our laboratory (n=8 each group) were exposed to a problem-solving digging task and a novelty suppressed feeding task. Following the problem-solving challenge, fecal samples were collected and subsequent assays indicated that the flexible copers had higher DHEA levels (associated with emotional resilience) than active and passive copers ($p<.005$). In the feeding task, flexible profiled rats exhibited more exploratory behavior in the form of rearing responses, but consumed less food ($p=.03$ and .04, respectively). One hemisphere of each brain was subsequently processed for Golgi/Cresyl double staining; the other hemisphere was processed for BDNF-immunoreactivity (ir). Preliminary data indicate that the passive copers have less dense dendritic spines in the anterior cingulate cortex; BDNF-ir is currently being quantified. In a second cohort of 34 coping-profiled male and female rats (n=4-6 per group), a nonsignificant trend indicated that flexible copers exhibited a longer latency to cross a novel barrier to consume a food reward ($p=.08$). Hippocampus tissue was processed for markers of epigenetic regulation and, in the males, a marginally significant effect of coping strategies was observed for H3K9me3 levels ($p=.055$), with the largest difference between the passive and active animals. Further, a significant effect of coping profile on B2 SINE RNA, a retrotransposon implicated in stress induced regulation of global gene expression, was observed ($p=.001$), with flexible copers exhibiting higher levels than active copers. In sum, these findings suggest that individual mammalian responses to perceived threats are associated with the activation of a multifaceted cascade of neurobiological events. Further research is needed to illuminate the complex associations among these variables and relevant influence on adaptive stress responses.

Title: Discrete roles for the ventral pallidum in depression

Authors: *D. KNOWLAND, V. LILASCHAROEN, C. PACIA, S. SHIN, E. WANG, B. LIM
UCSD, San Diego, CA

Abstract: Patients with major depressive disorder (MDD) display a common, but often variable set of symptoms making successful, sustained treatment difficult to achieve. Separate depressive symptoms in patients may be encoded by differential changes in distinct neural circuits in the brain, yet how discrete circuits underlie behavioral subsets of depression and how these circuits adapt in response to stress has not yet been addressed. We have identified two discrete circuits of parvalbumin-positive (PV) neurons in the ventral pallidum (VP) projecting to either the lateral habenula (LHb) or ventral tegmental area (VTA) contributing to depression. First, we surprisingly find that a subpopulation of PV neurons are glutamatergic. Next, we observe that these populations undergo different electrophysiological adaptations in response to social defeat stress, which are normalized by antidepressant treatment. Furthermore, manipulation of each population separately mediates either social withdrawal or behavioral despair behaviors, but not both. These results propose that distinct components of the ventral pallidal parvalbumin-positive circuit can subserve related, yet separate depressive-like phenotypes in mice which could ultimately provide a platform for symptom-specific treatments of depression.

Title: Inhibitory control of a thalamic stress circuit

Authors: B. S. BEAS[1], B. J. WRIGHT[1], Y. LENG[1], O. KOITA[1], N. RINGELBERG[1], *M. A. PENZO[2], *M. A. PENZO[1]
[1]Natl. Inst. of Mental Hlth., Bethesda, MD; [2]NIMH, NIH, Bethesda, MD

Abstract: Stress typically leads to adaptive responses aimed at reinstating homeostasis. However, stress is also known to both exacerbate and facilitate the onset of several psychiatric conditions including anxiety and depressive disorder. Surprisingly, our knowledge of the neuronal circuits controlling the impact of stress on behavior is far from complete. The paraventricular nucleus of the thalamus (PVT), a member of the midline thalamic nuclei, has recently emerged as a candidate structure bridging the gap between stress sensing and stress responding. The PVT shares anatomical connections with several brain areas involved in stress processing, such as the amygdala, the nucleus accumbens, and the medial prefrontal cortex. In addition, PVT is activated following a wide range of physical and psychological stressors, and has been previously proposed to be the ‘stress memory’ center of the brain However, the neuronal mechanisms and afferent inputs to the PVT that enable its recruitment following a stress event remain unknown. Here we addressed this question using a combination of fiber photometry, optogenetics, and chemogenetics to investigate both the mechanisms and neuronal circuitry involved in the recruitment of PVT circuits by stress. Our results indicate that a long range input to the PVT triggers a rapid and persistent decrease in GABAergic inhibition that contributes to the formation of a stress memory and the control of stress susceptibility.

Title: Dual processing in the primate dorsal raphe nucleus for choice behavior under different mood

Authors: *M. YASUDA, Y. UEDA, K. NAKAMURA
Dept. of physiology, Kansai Med. Univ., Hirakata, Japan

Abstract: The emotion often affects decision making. It is thus important to understand emotions in terms of their effects on cognitive behavior. Previously, we found that many neurons in the dorsal raphe nucleus (DRN) were modulated by emotional contexts. The DRN neurons also exhibited activity associated with reward-seeking behavior. To investigate whether and how the emotional and cognitive processing are represented in single DRN neurons, we recorded neuronal activity in DRN while a monkey performed a reversal choice task, but manipulating its emotion by presenting conditioned cues.
In the task, after fixation on the central fixation point, two different objects were presented simultaneously in left and right. The monkey chose one of them by making a saccade. A reward was given for one object (correct) but not for the other (wrong trial). The object-reward contingency was fixed for a block of trials, but it was reversed after reaching a behavioral criterion. To manipulate the monkey's emotion, we chose one of three emotional cues, previously-learned reward (appetitive) -, tone (neutral) -, or air puff (aversive) -associated CS, and presented it in the inter-trial interval (ITI) during consecutive 2 blocks. We monitored the monkey's heart rate and pupil size as biological markers of emotional state.
We observed significantly larger pupil diameter and higher heart rate in aversive than in the other two emotional states, suggesting emotional stress. The 108 task-related DRN neurons were equally divided into three sub-populations depending on overall responses in each emotional state: ‘appetitive-highest’ (33%), ‘neutral-highest’ (33%), or ‘aversive-highest’ (33%). The neurons were also grouped in relation to monkey’s performance; “correct type” or “wrong type”. The ‘correct-type’ neurons were characterized by their sustained increase in activity during central fixation and the stronger activity in correct than wrong trials during ITI and/or fixation period, suggesting the contribution of preparatory signal for making correct choice. The wrong-

type neurons were characterized by sustained decrease in activity during central fixation and enhanced response after wrong choice, suggesting the coding of the history of negative outcomes. Notably, the wrong-type neurons included more aversive (42%) than appetitive (29%) and neutral (29%) type, while the correct type included more appetitive (40%) and neutral (40%) than aversive (20%) type. These results indicate the interacting nature of emotional and cognitive signals in single DRN neurons in specific temporal dynamics. The DRN may coordinate behavior under different moods through its widespread projections.

Title: Virally-transduced deletion from locus coeruleus norepinephrine neurons suggests a role for glucocorticoid receptors in preventing depression-like behavior

Authors: *L. JACOBSON
Dept. of Neurosci. & Exptl. Therapeut., Albany, NY

Abstract: Glucocorticoids can cause a variety of psychiatric symptoms including depression, anxiety, mania and psychosis that can be an obstacle to immunosuppressive glucocorticoid therapy and have been implicated in clinical mood disorders. Transgene-mediated glucocorticoid receptor (GR) deletion from all norepinephrine (NE) cells has been reported to increase depression-like behavior in female but not male mice, suggesting that GR may mediate mood-elevating effects in a sex-dependent manner. Such antidepressant-like actions could represent targets for treating depression, but the specific NE cells responsible for these effects have not been identified. I hypothesize that these antidepressant-like effects are mediated by locus coeruleus (LC) NE neurons, which express GR and are the primary source of NE in the brain. To test this hypothesis, I used lentiviral vectors (provided by Sergei Kasparov, Univ. of Bristol, UK) to transduce expression of Cre recombinase or green fluorescent protein in NE neurons of female floxed GR mice under the control of a multimerized Phox2 response (**PRS**) element (PRS-Cre or PRS-GFP, respectively). Bilateral LC injection of PRS-Cre produced complete GR deletion within 2 weeks that was limited to the LC. Female floxed GR mice with LC GR deletion exhibited significantly lower social interaction, a measure of depression-like avoidance behavior, compared to those receiving equivalent injections of PRS-GFP. There were no differences in non-social exploratory behavior between the groups. These results suggest that LC NE GR could

account for the depressive effects previously reported in female mice from transgenic deletion of GR from all NE cells, and indicate that LC NE GR can mediate mood-elevating effects of glucocorticoids. Such antidepressant-like actions could explain the contradictory array of potential psychiatric side effects from clinical glucocorticoid treatment and may represent novel targets for depression medication.

Title: Transcriptional signatures of experience reveal Egr2 as a regulator of behavioral response to aversive stimuli

Authors: *B. M. IGNATOWSKA-JANKOWSKA[1], B. GONZALES[2], L. IZAKSON[2], D. HARITAN[2], C. COHEN[2], N. BLEISTEIN[2], A. TEREM[2], D. MUKHERJEE[2], E. ITZKOVITZ[2], H. TURM[1,2], A. CITRI[1,2]
[1]Edmond and Lily Safra Ctr. for Brain Sci., [2]Alexander Silberman Inst. for Life Sci., Hebrew Univ. of Jerusalem, Jerusalem, Israel

Abstract: Our previous studies revealed unique transcriptional patterns of immediate early gene (IEG) induction in specific brain regions that characterize distinct experiences. Robust transcriptional programs were identified, and dramatic differences were revealed in the encoding of aversive (LiCl, foot shock) vs rewarding (cocaine, sucrose) experiences so that a signature of a handful of IEGs was sufficient to decode the recent experience of individual mice with over 90% accuracy. In response to aversive experiences, we have identified a group of IEGs, including *Fos, Arc, Egr2* showing characteristic strong induction in the Amygdala as well as other components of the Extended Amygdala formation. We hypothesized that specific and selective IEG induction that we observed, plays a role in altering behavior in response to aversive experiences that produce their transcription. In order to test the role of IEG induction in response to aversive experiences, we aimed to determine whether selective and local suppression of this induction will alter behaviors associated with aversive experiences that induce their expression. We have suppressed the activity of the most prominently induced IEG, *Egr2*, through viral adeno-associated virus transfection of short hairpin RNA (shRNA) (n=8) as well as dominant negative (DN) mutation antagonistic to the gene product (n=8). This manipulation suppressing *Egr2* gene activity resulted in a behavioral change of coping strategy of mice as compared to animals injected with the control virus (n=8). We have found that inhibition of the *Egr2* that is robustly induced by aversive experience caused increased conditioned place aversion

response to LiCl, decreased freezing in response to footshock but shortened latency to escape environment associated with shock. Moreover, animals subjected to these manipulations showed higher activity and spent less time immobile during forced swim test, as compared to controls. This indicates that suppression of *Egr2* affects behavioral coping strategy in response to aversive stimuli, shifting it towards active coping - including an increase in locomotor activity and promoting avoidance and escape behaviors. The mechanism through which *Egr2* affects behavior and the role of *Egr2*-expressing neuronal ensembles remains to be unraveled. Our results indicate that unique transcriptional patterns characterizing experiences reveal new roles of IEGs in altering behaviors in response to experience that induced their transcription. This approach will help to identify new genes and neuronal ensembles allowing to manipulate behavioral response as well as unravel its underlying mechanisms.

Title: Activation of basolateral nucleus of the amygdala on dopamine activity in behaving rats

Authors: *C.-W. LAI, C.-H. CHANG
Inst. of Systems Neurosci., Natl. Tsing Hua Univ., Hsinchu, Taiwan

Abstract: Basolateral nucleus of amygdala (BLA) is responsible for processing negative emotions, but the relation between BLA and dopamine (DA) reward system is largely unclear. The number of spontaneously firing DA neurons, which is defined as “population activity” in ventral tegmental area (VTA), decides the amplitude of DA response to external stimuli. Previous electrophysiological studies have shown that rats that underwent chronic mild stress or acute restraint stressor resulted in an attenuation of DA population activity, which is restored with blockade of BLA activity. In this study, we aimed to examine how BLA activation impacts DA population activity and related negative emotions in rats. DA neuron population activity was assessed by the behavior responses of the animal to psychostimulant, amphetamine (AMPH); several studies have shown that the level is positively correlated with the AMPH-induced increase in locomotor activity. Negative emotional states were explored with elevated plus maze

(EPM; anxiety-like behavior) and forced swim test (FST; despair-like behavior). BLA was pharmacologically activated with N-methyl-D-aspartate (NMDA, 0.75µg/0.5µl per side) or vehicle control (VEH) before each of the behavioral assays. Our preliminary results suggest that after acclimation to the open field arena (30 min), systemic injection with AMPH (0.5mg/kg, i.p.) significantly increase the locomotor activity (total travel distance in 90 min), which was dampened with BLA activation. Compared to VEH controls, animals showed a trend of increase in the time spent in open arms (5 min test) in EPM (decreased anxiety) and decrease in immobility (5 min test) in FST (decreased despair). Our preliminary data suggests that under BLA activation, these animals were in an anxiolytic state but at the same time displayed dampened DA population activity, as if they were less anxious but also less responsive to potential reward stimuli. More work is in progress to confirm the conclusion.

Title: Neuronal activity related to preference of visual stimuli in monkey amygdala

Authors: *K. KURAOKA[1,2], M. INASE[2]
[1]Dep.of Physiology, Kansai Med. Univ., Hirakata-Shi, Japan; [2]Dep. of Physiology, Kindai Univ. Fac. of Med., Osaka-Sayama-Shi, Japan

Abstract: Visual stimuli can serve as positive or negative reinforcer for nonhuman primates even though those stimuli are not accompanied with fluid reward or aversive punishment. Especially, social stimuli that are visually presented attract much interest of nonhuman primates. One of candidates for neural substrate processing social value conveyed by visual information is the amygdala that is known to respond to social stimuli and reward. To elucidate the involvement of the amygdala in processing sociality-related visual information, we recorded the activity of neurons in the monkey amygdala while an arbitrary geometric pattern was associated with one of the subsequent visual images of conspecifics or fluid reward. Behavioral data showed that the subject monkeys preferred images of the opposite sex, while they avoided the negative facial expressions of others. Of the recorded 173 neurons in the macaque monkey amygdala, 42 (24%) and 39 (23%) neurons showed excitatory and inhibitory responses to at least one of sociality-

related visual stimuli, respectively. A two-thirds (28/42, 67%) of neurons that showed excitatory responses to the visual stimuli also responded to fluid reward. The population activity of these neurons in response to preferred visual stimuli was significantly stronger than that in response to unprefered visual stimuli. To estimate how well individual neurons discriminate the monkeys' preference of visual stimuli, we conducted an ROC curve analysis comparing neuronal responses to between the preferred and unpreferred visual stimuli, and calculated an area under the curve (AUC). The AUCs of neurons showing excitatory responses were significantly higher than 0.5 which is indifferent point between two populations. In contrast, the AUCs of neurons showing inhibitory response were not different from 0.5. These results mean that only neurons showing excitatory responses detect the value difference of the visual stimuli. We also computed the temporal change of the mean AUC in the neurons showing excitatory responses. Results showed that the AUC transiently elevated just after presentation of visual stimuli. These results indicate that neurons showing excitatory responses in the monkey amygdala convey information of the value of visual stimuli.

Title: Distribution of functional serotonin receptors in relation to the dopaminergic system

Authors: N. M. WLODARSKI[1], A. M. MITZEY[2], *M. S. BROWNFIELD[3]
[1]Dept. of Comparative Biosci., Univ. of Wisconsin, Madison, WI; [2]Comparative Biosci., Univ. of Wisconsin, Madision, WI; [3]Dept Comp Biosci., Univ. Wisconsin, Madison, WI

Abstract: Serotonin and dopamine mechanisms are both important factors in neuropsychiatric disease separately or togther through their release of neurotransmitters and interactions with other neurotransmitters in specific areas of the brain. Serotonin
affects feeding, mood, and social behavior, and is believed to interact with dopamine, a neurotransmitter affecting reward and addictive related behaviors. Dopaminergic pathways arising from the substantia nigra, ventral tegmental area and paraventriclar and arcuate nuclei project to the caudate nucleus, ventral forebrain, periaccubmens area, and hypothalamic sites. We question whether serotonergic and dopaminergic systems might affect each others' activities by cross communication or simply project specifically, directly and separately to important behavioral sites. To test the cross communication hypothesis we expect that specific serotonin

receptors are expressed by dopamine neurons. If the second hypothesis holds true then we should find serotonin receptors within and around the dopaminergic projection sites. To test these hypotheses we employed double immunofluorescence microscopy to map the distribution of serotonin agonist induced cfos expression in combination with localization of dopamine neurons by targeting its biosynthetic enzyme tyrosine hydroxylase. We administered 5HT1a, 5HT2a, 5HT2c, 5HT4, 5HT6, and 5HT7 selective agoinsts singly to Sprague-Dawley rats and studied induced fos expression in relation to dopaminergic neurons and terminals.Results failed to show functional 5HT receptor exception by dopamine neurons, exceptor for rare fos positive tyrosine hydroxylase cells. In contrast, dopamine terminal targets or closely adjacent structures contain dense expression of each of the 5HT receptors we tested.
These results favor the direct selective independent projection of dopaminergic and serotonergic systems to target sites.
Because evidence shows that disorder of these pathways may lead to Parkinson's disease, attention deficit hyperactive disorder, obsessive-compulsive disorder and addiction, or more, we can infer that serotonin receptor activation and specific dopamine neurons interact at brain behavioral sites, not by direct serotonergic modulation of dopaminergic activity. Whether the reverse may be true remains to be investigated.

Title: Bridging the gap between pro-environmental concern and behaviour: The role of biological and psychological facets of learned helplessness

Authors: *N. R. LANDRY[1], T. MILFONT[2], A. C. WEEKS[1], R. GIFFORD[3], S. ARNOCKY[1]
[1]Psychology, Nipissing Univ., North Bay, ON, Canada; [2]Psychology, Victoria Univ. of Wellington, Wellington, New Zealand; [3]Psychology, Univ. of Victoria, Victoria, BC, Canada

Abstract: Previous research has identified a gap between pro-environmental concern and behaviour, such that many concerned individuals nevertheless refrain from engaging in meaningful pro-environmental action. This has sparked calls for further study of psychological barriers to action. The present study proposes that psychological and endocrinological facets of learned helplessness may act as one such barrier. In a sample of 437 young Canadian adults, we examined the roles of trait learned helplessness and basal cortisol in moderating the concern - behaviour relationship. Results showed that learned helplessness moderated links between environmental concern and self-reported pro-environmental behaviour (B = -0.23, SE = .08, p = .004), as well as in-vivo measure of making a monetary donation to an environmental organization (B = -0.78, SE = 0.29, p = .007), and joining an on-campus environmental activism group (B = -0.62, SE = 0.30, p = .03). Individuals high in cortisol reported engaging in less self-reported pro-environmental behaviour (B = -0.24, SE = 0.11, p = .02). Cortisol also moderated links between concern and support for geo-engineering initiatives (B = -0.26, SE = 0.08, p = .001). Taken together, these results suggest that psychological and endocrine facets of learned helplessness act as barriers to pro-environmental behaviour in the face of environmental concern.

Title: Exploring possible cortical brain regions involved during the experience and observation of pain in mice

Authors: *R. BRULS[1], M. CARRILLO[1], K. L. KOOIJ[2], A. ROMAGUERA ÁLVAREZ[3], N. JELINEK[4], V. GAZZOLA[1], C. KEYSERS[1]
[1]Social Brain Lab., Netherlands Inst. For Neurosci., Amsterdam Zuidoost, Netherlands; [2]Fac. of Sci., Univ. of Amsterdam, Amsterdam, Netherlands; [3]Earth and Life Sci., VU university, Amsterdam, Netherlands; [4]FH Campus Vienna, Univ. of Applied Sci., Vienna, Austria

Abstract: Mirror neurons, neurons that are activated both during the self-experience and observation of emotions, are thought to underlie empathic responses, which allow humans to share and understand emotions in others. Although human fMRI data has provided indirect evidence for regions involved in emotional mirroring, these techniques do not have the spatial or temporal resolution to answer questions at the cellular level. Rodents possess the fundamental attributes of empathy, and allow for the examination and understanding of neural mechanisms of empathy, at multiple levels. So far the main focus has been on the anterior cingulate cortex, a region involved in the pain matrix and hypothesized to contain mirror neurons for emotions in rodents. From human results, we know that there are various other cortical regions that are part of the empathy network, such as the somatosensory cortex. In this study, we investigated a broad range of cortical regions to explore other possible areas involved in the neural mechanisms of empathy for pain in mice. For this we combined widefield fluorescence imaging with the clear skull technique. Widefield fluorescence imaging is a powerful technique that allows measuring neuronal activity of the whole cortex at once. Several experiments were conducted in Thy1-GCaMP6 5.17 mice focusing on the self-experience and observation of pain. For the observation of pain, shock-experienced observer mice witnessed familiar demonstrators experience painful footshocks. For the self experience of pain, observers received painful footshocks, both when anesthetized and awake. Additionally, a fear conditioning task was performed consisting of the playback of a tone previously associated to shock onset to the observer. During all tasks, changes in fluorescence (delta f/ f) were recorded from the cortical surface of observer animals. Results show a widespread activation over the whole cortex during the self experience of pain while awake. This response is suppressed when mice are under anesthesia. When observing a conspecifc in pain, the activation pattern is reduced even more so, but still present, although

highly variable among mice. When examining areas more closely that are hypothesized to be involved in the empathy network (such as the somatosensory cortex, motor cortex and ACC) we find these areas to increase their activation pattern compared to baseline period, for the self experience and observation of pain.

Title: Empathy for pain: Alteration of hormonal levels and serotonergic and dopaminergic neurotransmission within amygdala and insula in mice living with a conspecific in chronic pain

Authors: *A. CANTO-DE-SOUZA[1,2,3], D. BAPTISTA-DE-SOUZA[1], I. CARMONA[1,2], C. R. ZANIBONI[1,2], R. L. NUNES-DE-SOUZA[3,4]

Abstract: AIM: We have recently shown that mouse living with a conspecific suffering with chronic pain [e.g., pain induced by sciatic nerve constriction (SNC)] displays increased nociceptive responses assessed with the writhing test. Furthermore, previous findings have shown the modulatory role of oxytocin, testosterone and corticosterone in empathy responses. Here, we investigated whether living with a conspecific suffering with chronic pain changes plasma oxytocin, testosterone, corticosterone and serotonin and dopamine turnover in the amygdala and insula in cagemates mice. **METHODS AND RESULTS:** Male Swiss mice (n=8-11 per group) were housed in pairs for 28 consecutive days. On day 14th, pairs of mice were grouped as follow: cagemate nerve constriction (CNC; i.e. one animal from each pair was subjected to SNC surgery) or cagemate sham (CS; i.e. one animal from each pair was subjected to SNC sham surgery). After that, each pair was returned to its homecage to live together for further 14 days. In Experiment 1, on testing day (day 28th), the observer cagemates were subjected to the writhing test. In Experiment 2, the cagemates were sacrificed and plasma

oxytocin, testosterone and corticosterone levels quantified through ELISA Kits. In Experiment 3, the cagemates were sacrificed and their brains removed for analysis of the serotonin and dopamine levels in the amygdala and insula through the high performance liquid chromatography (HPLC). Student *t*-test revealed that the CNC group displayed higher number of abdominal writhes ($t(14)=5.83$; $P< 0.05$), lower levels of testosterone ($t(12)=2.88$; $P< 0.05$), higher levels of oxytocin ($t(14)=-3.19$; $P< 0.05$), increased dopamine ($t(14)=-2.31$; $P< 0.05$) and serotonin ($t(17)=-2.59$; $P< 0.05$) turnover in the amygdala compared to the CS group. For the insula Student t-test revealed the increased of dopamine turnover ($t(18)=-2.59$; $P< 0.05$), but not significant effects for the serotonin turnover ($t(18)=0.01$; $P>0.05$). Student *t*-test did not reveal significant effects for corticosterone levels ($t(12)=-2.42$; $P>0.05$). **CONCLUSIONS:** These results demonstrate that living with a mouse subjected to SNC induces hyperalgesia, reduction of testosterone, and increased of oxytocin levels in the observer cagemate. In addition we observed the accentuation of dopaminergic and serotonergic turnover in amygdaloidal complex and the increased of dopaminergic turnover in the insular cortex. Taken together, the present results suggest that the plasma testosterone, oxytocin, dopamine and serotonin neurotransmission plays a role in the modulation of pain empathy in mice.

Title: Neural mechanisms of emotional contagion behavior in rats

Authors: *Z. WANG, C. ZHENG
Inst. of Neurosciences, CAS, Shanghai, China

Abstract: Abstract Empathy is thought to be an advanced capability in human, which allows the individual to comprehend other's feelings by taking a stand on others. Recently, rodents have been successfully used in studying empathy-related behavior. Since the new technologies, such as optogenetics, chemogenetics, multi-channel electrode recording and fMRI, can be readily used in rodents, we could now study the mechanism of empathy-related behavior in a more thorough way. We employ the strategy of small animal functional magnetic resonance imaging (fMRI), to identify the specific brain region related to emotional contagion— the primary empathy in rodents. First, we are establishing an emotional contagion paradigm for rats which is compatible

in MRI. The brain activities of demonstrator and observer rats will be recorded and analyzed. After the emotional contagion-related brain regions are confirmed, we will trace the neural circuit through viral labeling and tracing to identify their downstream and upstream. Optogenetic or chemogenetic techniques will be used to manipulate the activities of the components in emotional contagion neural circuits in order to demonstrate the causality of their activities to the behavior.

Title: Understanding the neural basis of empathy in rodents

Authors: *M. CONTRERAS[1], A. HATFIELD[1], J. CUMMINGS[1], K. CRUZ[2], J.-M. FELLOUS[1]
[1]Psychology, Univ. of Arizona, Tucson, AZ; [2]MIT, Cambridge, MA

Abstract: There is increasing support for the idea that empathy is evolutionarily conserved and shared across mammalian species. This suggests that the neurophysiological mechanisms of empathy, currently unknown, might be elucidated using an animal model. Previously, we have shown that rats exhibited empathic responses to conspecific distress while they performed an operant task, which seems to capture some of the natural individual differences observed in human empathy. Moreover, we have shown that the pharmacological manipulations of the oxytocin system altered some of the empathic responses observed during the task. The current study extends this work by assessing the role of arginine vasopressin system in rat empathy. Animals were trained to obtain food pellets by pressing either one of two cued levers in an operant chamber. During the empathy test, one of the levers was programmed to also deliver a footshock (0.5 mA, 0.5 sec) to a conspecific animal which was placed in full view, in an adjacent chamber. Single lever (forced-choice trial) or both levers (free-choice trial) were cued throughout the course of testing. We observed that intracerebro-ventricular administration of an antagonist of arginine vasopressin disrupted the expression of empathic responses. We further explore the involvement of the insular cortex, a region that has been associated with human empathy, in empathic responses exhibited by rats. Previously, we have shown that the neural

activity of the anterior insular cortex decreased during the empathy test. In this study we conducted several additional analyses to better understand the participation of the insular cortex in empathy. We also explore the role of 22 kHz ultrasonic distress vocalizations and social context and the extent to which they are necessary or sufficient for the expression of empathic-like responses. This research may have implications for the treatment of empathy deficits and related anti-social behaviors.

Title: Rodent model of Empathy: Rats employ taught behavior to help cagemate that remains intact during environmental change

Authors: *M. H. BLYSTAD, D. ANDERSEN, E. B. JOHANSEN
Dept. of Behavioral Sci., Oslo and Akershus Univ. Col. of Applied Sc, Oslo, Norway

Abstract: In Social Neuroscience, empathy has received increased attention during the last decades. Animal models are emerging as possible venues for further probing of the mechanisms of empathy (Keum & Shin, 2016), but much work remains. This study uses the pro-social helping paradigm originating from Bartal, Decety, and Mason (2011) in which one rat is taught to release a trapped cagemate from a restrainer (Illustration 1). The original findings implicate empathic distress as a possible motivator for rodent helping behavior. However, in the original studies, the rats were trained in the same situation as used for pro-social testing. We wanted to investigate whether training of door opening with food reward affected door opening with a trapped cagemate.
We also measured ultrasonic vocalizations (USV) of the rats. USVs play a large role in social-emotional communication (Brudzynski, 2013), and the influence of USVs are largely unknown in pro-social experiments. Thus, the present study investigated the association between positive USVs and pro-social situations.
In experiments on environmental change, all rats were trained and tested for pro-social behavior in a highly illuminated setting ("bright", 200-400 lux), and tested again in an almost pitch black setting ("dark", ≥2 lux).
Our results support the findings from Bartal et al., (2011): 1) Rats will act pro-socially towards

cagemates, and, 2) Rats will not open the door/show much longer latency, when the restrainer is empty. Prior door opening training produced much faster pro-social behavior than in the original study (1 day vs ≈ 7). No effect of changing illumination from bright to dark, or vice versa, was found on pro-social behavior. Finally, preliminary analysis of positive USV's show no systematic influence on pro-social behavior.

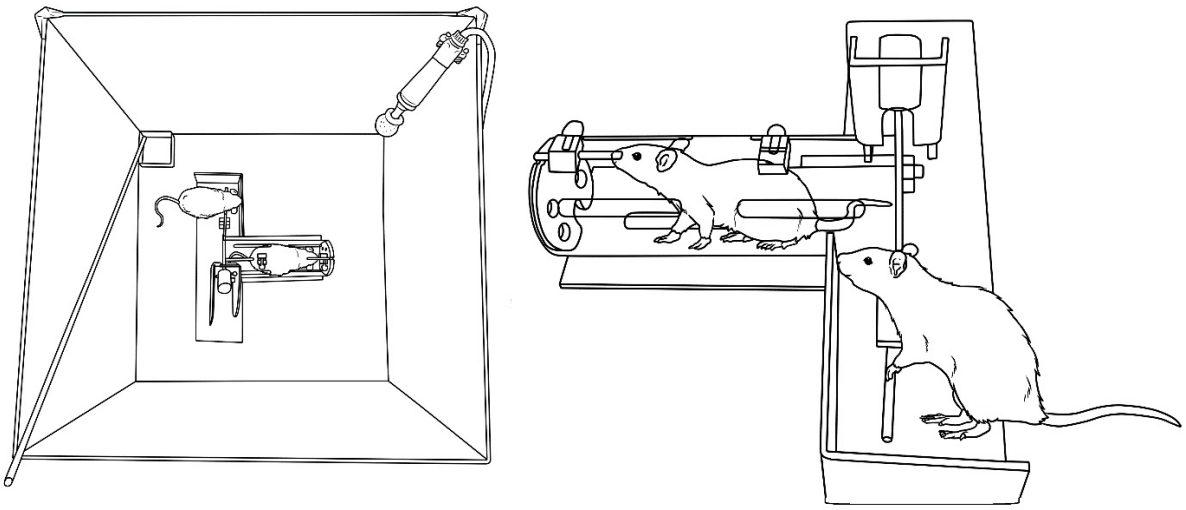

Illustration 1 Above left: The arena with restrainer and opening mechanism. On the left wall is a pipe extending outside of the arena for administration of food pellets during training. In the top right corner a microphone is attached for recording of USVs. Above right; detailed view of opening mechanism.

Title: Parsing the neural circuits for visual empathy

Authors: *H. JUNG[1], A. D. HUBERMAN[1,2]
[1]Dept. of Neurobio., Stanford Univ. of Sch. of Med., Stanford, CA; [2]Dept. of Ophthalmology, Stanford Neurosci. Institute, and BioX, Stanford Univ. Sch. of Med., Stanford, CA

Abstract: The ability to perceive and respond appropriately to the emotions of others is fundamental to social interactions and our evolution as a species. This process relies on an

integration of sensory perceptions and emotions, but where in the brain that merging occurs is unknown. Moreover, the failure of that circuitry to function properly likely underlies various developmental disorders of cognition, such as autism spectrum disorder. Despite a considerable number of studies exploring the neural correlates of empathy in humans and non-human primates, we still understand little about the cell types, circuit architecture, and computations that allow for empathy.
As a first step to remedy that, we developed a behavior paradigm in mice in which they view other members of their species engaged in visual fear (Yilmaz and Meister, 2013; Salay et al., in preparation) and asked:
1) Can mice visually determine the emotional state of their conspecifics?
2) What behavioral repertoires do the observer mice perform?
3) What are brain areas causally linked to this feature of 'visual empathy'?
We found that observer mice display empathic behaviors after observing a series of defensive reactions in conspecifics (demonstrators) who are under an immediate visual threat. Molecular genetic exploration for the neurons that read out visual empathy revealed a novel subset of subcortical and cortical nuclei implicated in this form of sensory-emotional integration and cognitive control. To parse the anatomical and functional roles of these identified brain regions, we are applying viral tracing as well as optogenetic and chemogenetic control over neural activity in the context of our 'empathy' assays. Our results provide evidence that the ability to relate to the emotional state of others exists in rodents and may have a common neural substrate.

Title: "Observational learning: Comparing a foraging and aversive motivated task in female rats"

Authors: *R. TROHA, D. DONG, T. PIETRUSZEWSKI, A. AGRAWAL, K. MATHEW, N. HERNANDEZ, E. MARKUS
Univ. of Connecticut, Storrs, CT

Abstract: Observational, or imitative, learning is a vital skill for survival. This type of social learning plays an important role in human development (e.g. Bandura) but is also relevant for

other species. Learning from the trial and error of others is more efficient than searching yourself when foraging the environment for food. It is also "safer" to acquire information regarding locations of danger in the environment by watching where conspecifics are threatened and how they may/may-not escape the danger.
We have developed an observational learning paradigm in which rats observe the solution in a T-shaped maze. This is a working memory task with the correct goal changing on a daily basis. Therefore, the observer must attend to the demonstrator rat's performance on a daily or continuous basis.
As noted above, there are two types of circumstances in which observational learning can facilitate survival. The first is escaping an aversive situation, such as observing which behaviors prevented predation and which did not. The second is using observation to facilitate food seeking success (e.g. where other members of the species are finding food).
For the escape situation, 8 female F344 rats were trained on a T-shaped maze submerged in water. Animals were placed at the stem of the T-maze and needed to navigate to the arm containing the escape platform on that day.
For the foraging task, a different group of 8 female F344 rats were used. These animals were placed on a T-maze with a food reward at the end of one arm.
In both paradigms the goal location varied across days and the animals had the opportunity to observe a conspecific perform the correct response. Performance was related to number of exposure trials, identity of the observer, identity of the demonstrator, and effects of the estrous cycle.

Title: Effects of placebo analgesia on the multi-voxel representations of directly experienced pain and pain empathy

Authors: *I. WAGNER, M. RÜTGEN, C. LAMM
Social, Cognitive and Affective Neurosci. Unit, Univ. of Vienna, Wien, Austria

Abstract: Empathy for pain engages similar brain regions as a direct, painful experience. This suggests common representations for the two experiences that appear anchored in mid-cingulate and anterior insular cortices (MCC, AI). Definitive evidence for such common representations is, however, missing. We recently demonstrated that placebo analgesia reduces both pain empathy and self-pain (Ruetgen et al., 2015). Here, we re-analyzed the fMRI data of this study. We used multi-voxel pattern analysis (MVPA) to investigate the neuronal representations of pain empathy and self-pain and how they were affected by placebo analgesia.
Participants (placebo/control group, *N*=49/53) underwent fMRI while receiving painful and non-painful electrical stimulation, or when observing another person being exposed to such stimulation. MVPA primarily focused on MCC and AI was used to test representations of self- and other-directed stimulation (pain/no pain), and common or distinct representations between self- and other-directed stimulation (self/other).
We found that MCC and AI representations of self-directed stimulation partly generalized to other-directed stimulation and vice versa. Self- and other-directed painful and non-painful stimulation were dissociable in the control group, but this was not possible for other-directed stimulation in the placebo group. Initial whole-brain searchlight results point towards altered prefrontal control processes following placebo analgesia.
In conclusion, placebo analgesia appears to change neuronal representations that underlie direct pain and pain empathy.

Abstract: The rostral cingulate cortex lies at the heart of neuroscientific models of emotion, pain, and cognitive control. Work in these three basic domains has, in turn, profoundly influenced contemporary perspectives on more complex phenomena, including social processes and psychopathology. Yet, key questions about the functional organization and significance of activity in the rostral cingulate remain unresolved. Perhaps the most basic question is whether emotion, pain, and cognitive control are segregated into distinct subdivisions of the cingulate or are integrated in a common region, with recent reports providing conflicting answers. Here, we used a combination of brain imaging techniques—including large-scale meta-analyses and high-resolution analyses of individual subjects—to provide converging evidence that negative affect, pain, and cognitive control recruit an overlapping region of the anterior midcingulate cortex (MCC). 'Automated' meta-analyses were performed using computer-generated databases (70-478 studies) and NeuroSynth (q<.01). 'Gold standard' meta-analyses were performed using manually curated databases (43-90 studies) and GingerALE (p<.05). Our results show that meta-analyses performed using different databases and different analytic approaches revealed three-way overlap in the MCC, suggesting that this effect is both reproducible and generalizable. Nevertheless, it is well known that such meta-analyses entail an enormous loss of spatial resolution, which can create spurious regions of overlap. To address this, fMRI data were acquired from 23 individuals while they completed tasks that elicited negative affect (threat-of-shock), induced pain (hot thermal stimulation), or demanded cognitive control (MultiSource Interference Task). To maximize resolution, data were normalized using diffeomorphic techniques. Results revealed three-way overlap in anterior MCC, both for spatially smoothed (6-mm) and unsmoothed data (qs<.05). A final set of analyses focused on spatially unsmoothed, single-subject data. This demonstrated that a higher proportion of subjects showed multi-task overlap in MCC compared to a control region, both for smoothed and unsmoothed data (ps<.001). The extent of multi-task overlap also was greater in MCC versus the control region (ps<.004). In sum, negative affect, pain, and cognitive control show substantial overlap in MCC—even for high-resolution data examined in individual subjects. Collectively, these results provide a new, neurobiologically grounded framework for understanding the contribution of the MCC to a broad spectrum of psychological processes and psychiatric disorders.

Title: Neurophysiology of emotional reactivity from a corpus of affective speech: Theory of mind and referential proximity

Authors: *F. ISEL[1], A. LACHERET-DUJOUR[2]
[1]Paris Nanterre - Paris Lumières Univ., Nanterre Cedex, France; [2]Sci. of Language, Paris Nanterre - Paris Lumières Univ., Nanterre, France

Abstract: Previous event-related brain potentials (ERPs) using IAPS pictures have shown that emotional reactivity is often associated with the late positive potential (LPP). Few studies have examined emotional reactivity from an affective speech. In the perception of an emotion expressed linguistically, the theory of mind, i.e., the ability to represent the emotional state in question can be mobilized to different degrees. It depends on whether the referent designated by the agent and/or the patient of the event that causes him a particular emotional state are referentially related, if not identical to the speaker who reports the event. In the present ERP study, we aimed to test this issue. For this purpose, we constructed 320 French sentences including 120 sentences with positive valence, 120 with negative valence and 120 with a neutral valence. In half of the sentences the referent designated by the agent and/or the patient of the event that causes a particular emotional state were referentially related to the speaker (a) « C'est avec cet objet que le crâne de mon père a été fracassé. », *It is with this object that the skull of my father was shattered*), while in the other half not (b) « C'est avec cet objet que le crâne d'un homme a été fracassé. », *It is with this object that the skull of a man was shattered*). We hypothesized that if the theory of mind is activated, then the empathy of the individual perceiving the emotion should be larger in (a) than in (b). This should be reflected by an enhancement of the LPP. While the effect of referential proximity gave a consistent picture in the behavioral data with a stronger emotional impact for sentences with a close referential proximity, unexpectedly a reduced LPP was found for these sentences. The present findings suggest that emotional sentences, in the same way to IAPS pictures, may constraint differently emotional states. Moreover, and more importantly, our data supported the prediction that linguistic material creating a particular emotional state because of referential proximity was able to modulate the LPP amplitude.

Title: Hatano rats suitable as metabolic syndrome model focusing on feeding behavior and physiological strain differences

Authors: A. ISOBE[1], G. SHIMAZAKI[1], T. SAKAWA[2], T. SHIMADA[3], M. ABURADA[4], T. NAKAMURA[2], R. OHTA[5], M. KAWAGUCHI[1]
[1]Sch. of Agriculture, Meiji Univ., Kanagawa, Japan; [2]Fac. of Pharmaceut. Sciences, Teikyo Heisei Univ., Nakano, Tokyo, Japan; [3]Kanazawa Univ., Kanazawa, Ishikawa, Japan; [4]Musashino Univ., Nishitokyo, Tokyo, Japan; [5]Food and Drug Safety Ctr., Hatano Res. Inst., Hadano, Japan

Abstract: Metabolic syndrome refers that the abdominal circumference is over a certain size and at least two of the three following conditions are also met; 1. High blood pressure, 2. High plasma glucose level, 3. Dyslipidemia. It is closely linked to leading causes of death like heart disease and cerebrovascular disease, affecting many people worldwide. Some studies have reported that stress can effect eating patterns and appetite, and that stress eating can cause metabolic syndrome. Therefore, the risk of metabolic syndrome can be related to stress response and stress sensitivity. Although many studies have established metabolic syndrome models, there are few models focusing on stress response and stress sensitivity. Therefore, it is important to establish a metabolic syndrome model focusing on stress. In this study, we used Hatano high-avoidance animals (HAA) and low-avoidance animals (LAA) that were derived from Sprague-Dawley rats by selectively breeding for high and low avoidance rates in shuttle-box active avoidance tests. Some previous studies have shown that HAA shows higher stress response and higher stress sensitivity than LAA. Also, there are endocrinological stress differences, for example, LAA shows higher corticotropin-releasing hormone levels in the paraventricular nucleus than HAA. However, the strain difference on feeding behavior has not been clarified. Given that stress is related to eating and appetite, it is assumed that there could also be a strain difference in feeding behavior between HAA and LAA. In this study, we determined whether the stress related endocrinological differences between the Hatano rat strains could be useful for a metabolic syndrome model. We examined food intake, blood pressure, plasma component levels and animal fat contents. HAA rats had more active feeding behavior, higher blood pressure, higher percent fat and higher triglyceride levels than LAA rats. These features of the HAA rats correspond to some of the metabolic syndrome symptoms. Therefore, it suggests that HAA can be used as a metabolic syndrome model focusing on stress response and stress sensitivity. This

study was supported by Research Project Grant A by Institute of Science and Technology Meiji University.

Title: Previous inescapable stress interferes with the immunizing, but not the acute, effect of later escapable stressors

Authors: *K. L. BARTHOLOMAY, S. TILDEN, J. AMAT, L. WATKINS, S. F. MAIER
Dept. of Psychology and Neurosci., Univ. of Colorado Boulder, Boulder, CO

Abstract: For many years it has been known that behavioral control over an adverse event, referred to here as a stressor, can prevent the immediate behavioral and neurochemical impacts typically associated with an adverse event. Additionally, behavioral control has been shown to immunize, or protect, against the behavioral and neurochemical effects of future stressors, even in the absence of control. However, there are no previous studies that investigate the proactive impact that an initial experience of a stressor without behavioral control might have on the acute protection and immunization provided by future controllability. Here, a stressor over which the subject had no behavioral control was administered prior to a stressor which the subject could control in order to determine the impact on the acute and immunization effects typically associated with controllability. Behavioral results suggest that prior stressor exposure without the experience of control has no impact on the acute protection provided by future controllability, but blunts the ability of later control to immunize against future adverse events. Clinically, these results imply that prior trauma may impact the ability to reestablish behavioral control over future stress, which may prevent trauma survivors from developing resistance or resilience to cope with stress via behavioral control.

Title: SABV and the limitations of animal studies for addressing gender disparities in neurobehavioral health

Authors: *L. S. ELIOT[1], S. S. RICHARDSON[2]
[1]Dept. Neurosci., Rosalind Franklin Univ. of Med. & Sci., North Chicago, IL; [2]History of Sci., Harvard Univ., Cambridge, MA

Abstract: Many brain and behavioral disorders differentially affect men and women. The new NIH requirement to include both male and female animals in preclinical studies aims to address such health disparities, but we argue that the mandate is a flawed approach to this problem. Sex differences are highly species-specific, tied to the mating system and social ecology of a given species or even strain of animal. Sex itself is complex phenotype, not the simple binary variable that this mandate assumes. In many cases, animal models poorly replicate male-female differences in brain-related human diseases such as depression, anxiety, and chronic pain disorders. Gender disparities in human health have a strong sociocultural component that is intimately entangled with biological sex and not addressed by this policy. We support research that investigates sex-related variables in hypothesis-driven studies of animal brains and behavior. We also support full transparency in reporting of animal sex in all scientific publications. However, institutional policies that give sex special salience over other sources of biological variance distort research. We further caution that the imposition of sex analysis on all animal research entrenches neuroscientists' presumption that gender differences are largely hormonal or genetic in origin and overlooks the powerful social, psychological and cultural contributors to male-female neuropsychiatric health gaps. Although well-intentioned, the new policy is unlikely to reduce gender disparities in human neurobehavioral health, while posing a large burden on basic scientists.

Title: The anxiolytic-like effect of Montanoa tomentosa depend of endocrine condition

Authors: *E. M. ESTRADA[1], D. M. ISLAS-PRECIADO[2], I. SOLLOZO-DUPONT[3], C. LOPEZ-RUBALCAVA[4]
[2]Neuropsicofarmacología, [1]Inst. Natl. Psiquiatria, Distrito Federal, Mexico; [3]Ctr. de Investigación y Estudios Avanzados, Mexico, Mexico; [4]CINVESTAV-IPN, Mexico DF, Mexico

Abstract: *Montanoa tomentosa* "zopatle" or "cihupatli" is a native plant of Mexico that has been used in traditional medicine mainly as a remedy for reproductive impairments and relaxing actions. Although females are the main users of this plant, there are no studies that evaluate the potential impact of the endocrine milieu that could affect its antianxiety actions. Therefore, the present work was conducted to assess the anxiolytic-like effects of *Montanoa tomentosa* (fam: Asteraceae) lyophilisate (MT) on female rats under different endocrine conditions. For this purpose, in experiment 1 intact young female Wistar rats in a condition of high (proestrus-estrus) - or low- (metestrus-diestrus) hormone levels and ovariectomized were treated with vehicle or MT and tested in the elevated plus-maze test (EPM). In experiment 2, the effect of MT was compared with diazepam in rats under progesterone withdrawal (PW) treatment schedule. Finally, in experiment 3, the participation of $GABA_A$ receptor in the anxiolytic-like action of MT was evaluated in ovariectomized female rats using picrotoxin as anantagonist to chloride ion channel. MT increased the time in open arms entries in female rats in a low hormone level condition and at low doses, MT-induced anxiety in rats tested in a high hormone level condition. MT-induced an anxiolytic-like effect in females under PW treatment schedule in contrast to diazepam that was ineffective. MT's anxiolytic-like effect was blocked by picrotoxin suggesting the participation of GABAA receptor complex.

Title: Low-yawning line showed higher anxiety and depression respect to high-yawning and Sprague-Dawley rats

Authors: *J. EGUIBAR[1], C. CORTES[2], A. UGARTE[2], L. DIAZ[2], A. TRUJILLO[3]
[1]Benemerita Univ. Autonoma De Puebla, Puebla, Pue., Mexico; [2]Physiol., [3]of Biol., Benemérita Univ. Autonoma de Puebla, Puebla, Mexico

Abstract: High- and low-yawning (HY and LY, respectively) rats were obtained by strict inbreeding process for more than 80 generations. HY rats had more grooming bouts when exposed to novel environment or after wetting the fur and in the open-field arena (OFA) showed higher ambulation and less number of fecal boluses respect to low-yawning (LY) rats suggesting that HY are less emotionally reactive than LY rats. The aim of this study was to analyze the responses of HY, LY and Sprague-Dawley (SD) rats on the elevated-plus maze (EPM) to evaluate anxiety and using forced swimming test to measure depression.
We used 48 subjects (Ss, eight from each group of rats) which were maintained under standard animal room conditions and with free access to rodent pellets and purified water. Ss were under 12:12 light-dark cycle (lights on 0700), all experiments were done between 1000 to 1400 in a sound-proof room with a 300 lux illumination and the observer was blinded respect to group of rats tested. EPM and forced swimming test were done when rats were 100 days of age and both tests were recorded and analyzed using The Observer XT software (Noldus, Netherlands). All procedures followed the NIH rules and the protocol were approved by IACUC No. EGCJ-SAL-17-G.
Our results showed that in EPM HY explore more and had more vertical displacements (rearings + wall-leanings) than LY and SD rats. Additionally, HY had more entrances and spent more time in the open arms respect to obtained in LY and SD rats ($P \leq 0.05$). In forced swimming test HY rats showed more active behaviors: swimming and scaling than other two groups of rats ($P \leq 0.05$). On the opposite, LY subline showed higher immobility time respect the other rats ($P \leq 0.05$). In base of these results HY showed less anxiety trait, and lower depression because had more active behaviors particularly scaling and less diving to the bottom of the cylinder that

means scape. On the other hand, LY rats showed higher anxiety in EPM and depressive-like behavior in forced swimming test.
In conclusion, HY rats is a useful animal model to analyze the psychobiological basis of resilience to anxiety and depression and the change of these behaviors are probably due to the strong inbreeding process

Title: Contextual fear conditioning test in Hatano high and low avoidance rats

Authors: *T. OKAWARA[1], R. OHTA[2], T. INOUE[3], M. KUBONOYA[3], M. KAWAGUCHI[3]
[1]Sch. of Agr., Meiji Univ., Kanagawa, Japan; [2]Food and Drug Safety Ctr., Hatano Res. Inst., Hadano, Japan; [3]Sch. of Agriculture, Meiji Univ., Kanagawa, Japan

Abstract: Inbred strains of Hatano rats, high- (HAA) and low-avoidance (LAA) animals, have been selectively bred for high and low performance in a two-way shuttle-box active avoidance task. When compared to LAA rats, HAA rats show higher anxious behavior in the elevated plus maze, and show higher avoidance performance in passive avoidance test. These results suggest that there are strain differences in response to aversive stimulus. It is known that rats show freezing reactions to electric shocks, and also that they emit ultrasonic vocalizations (USV) at 22 kHz when they receive aversive stimuli, which reflect their negative state. We measured freezing responses and number of USV of Hatano and SD male rats in a fear conditioning test and a fear extinction test. In the fear conditioning test, the rats were put in a device that delivered electric shocks at regular time intervals. For the fear extinction test, the rats returned 24 hours later to the place where they received the electric shocks.The frequency of freezing responses was greater in both LAA and HAA rats compared to SD rats in the conditioning test. However, LAA rats showed lower freezing responses than HAA rats in the fear extinction test. Furthermore, there was no difference in total number of USVs in the conditioning test, but LAA showed lower number of USVs than SD and HAA rats in the fear extinction test. These results clearly suggest that HAA rats show greater memory to aversive stimuli than LAA rats. We will provide comparing the activities and size of brain areas related to these strain differences. Research Project Grant A by Institute of Science and Technology Meiji University.

Title: Chronic stress-induced changes in parvalbumin cells of the prefrontal cortex contribute to increased anxiety in a sex-specific manner

Authors: *L. COUTELLIER[1], R. SHEPARD[1], K. HESLIN[1], C. PAGE[2]
[1]Dept. of Psychology, [2]Dept. of Neurosci., Ohio State Univ., Columbus, OH

Abstract: Hypoactivity of the prefrontal cortex (PFC) has been well described in both humans and rodent models of stress-induced depressive and anxious behaviors. However its origin is unknown and its contribution to behavioral changes, specifically in females who have increased risk for stress-related mood disorders, remains poorly studied. We hypothesized that prefrontal hypoactivity following exposure to stress is the result of stress-induced changes in the prefrontal GABAergic system, and that these changes are predominant in females, providing a possible mechanism mediating sex differences in stress-related mood disorders. We previously observed that female mice exposed to unpredictable chronic mild stress (UCMS) in adulthood express higher levels of parvalbumin (PV) mRNA, and display increased number of PV interneurons (PV-I) in their prefrontal cortex (PFC), which was positively correlated with increased emotionality (including anxiety- and depressive-like behaviors). Our goals with the present study were (1) to determine whether the increase in PV in the PFC following UCMS is the result of stress-induced chronic activation of these cells leading to their state of hyperactivity even once UCMS ceased; (2) to establish a causal relationship between increased activity of prefrontal PV-I and increased emotionality in a sex-specific manner. To address the first point, we used double immunofluorescent techniques to measure the level of PV-I expressing cFos (as a measure of neuronal activity) following UCMS. We observed a significant increase in the number of PV-I in the PFC that express cFos at rest and under stimulated conditions, particularly in female mice. To address the second point, we used a chemogenetics (DREADD) approach. Chronic PV-I activation in the PFC leads to high anxiety in female mice, but not in males as measured in the open-field and novelty suppressed feeding tests, but do not induce changes in depressive-like behaviors, as measured in the forced swim test. Altogether, we conclude that chronic stress exposure can lead to an over active prefrontal PV system particularly in female mice, and that changes within this system are causatively responsible for increased anxious behaviors. This

heightened sensitivity of the prefrontal PV system in females could explain increased risk of females to stress-related mood disorders.

Title: Age and sex dependent effects of repeated social stress on rat prefrontal cortical pyramidal neuron morphology

Authors: *K. R. URBAN[1], E. GENG[2], S. BHATNAGAR[3], R. J. VALENTINO[4]
[1]Gen. Anesthesia, [2]Children's Hosp. of Philadelphia, Philadelphia, PA; [3]Dept Anesthesiol., Univ. Pennsylvania, Children's Hosp Philadelphia, Philadelphia, PA; [4]Pediatrics/Anesthesiol Crit Care Med., Children's Hosp Philadelphia, Philadelphia, PA

Abstract: Chronic stress can lead to psychiatric illness characterized by impairments of executive function, implicating the prefrontal cortex as a target of stress-related pathology. Previous studies have shown that multiple types of chronic stress reduce dendritic branching, length and spines of medial prefrontal cortex (mPFC) pyramidal neurons. However, these studies largely focused on layer 2/3 pyramidal neurons in adult male rats. Whereas these neurons process incoming information, layer 5 is the major output layer. Because the prefrontal cortex develops throughout adolescence, stress during this period may have a greater impact on structure and function than stress occurring during adulthood. Furthermore, females display greater risk of stress-related psychiatric disorders, indicating sex-specific responses to stress. In this study, male and female adolescent (42-48 days old, 4 rats per group) or adult (68-72 days old, 4 rats per group) Sprague-Dawley rats were exposed to repeated social stress as 5 days of resident-intruder stress or control manipulation. Brains were Golgi stained 24 hrs after the final manipulation, cells were visualized on a Nikon Eclipse scope, and Neurolucida was used to trace neurons and analyze dendrites. Stress resulted in layer, age, and sex-specific effects. In layer II/III, stress reduced apical dendritic branching in male and female adolescents (Age*Stress interaction: $F(1,238)=12$, $p=0.0006$) and basal dendritic branching of adult male rats (Age*Sex*Stress interaction: $F(1,238)=6.6$, $p=0.01$; Tukey's post-hoc, $p<0.05$). Notably, in layer V, stress increased apical branching in adult males and decreased it in all other groups

(Age*Sex*Stress interaction: $F(1,257)=7.2$, $p<0.01$; Student's t-test $p<0.05$). Social stress also, increased branching of layer V basal dendrites selectively in adult male rats (Age*Sex*Stress interaction: $F(1,257)=12.4$, $p=0.0005$). These results suggest that repeated social stress particularly during adolescence reduces PFC neuronal complexity, which may result in impairments in executive function and PFC-dependent cognition. That resident-intruder stress had the unique ability to increase mPFC dendritic complexity of adult males implies that this experience is perceived differently by this population and suggests that the experience of fighting for dominance may selectively enhance cognitive processing for this group.

Title: Strain differences in learning ability and emotional behavior of Hatano high and low avoidance rats

Authors: *K. KAWAKAMI[1], T. OKAWARA[2], K. MUSYA[2], Y. HORI[2], R. OHTA[3], M. KAWAGUCHI[2]
[1]Sch. of Agriculture, Meiji Univ., Kawasaki-shi, Japan; [2]Sch. of Agriculture, Meiji Univ., Kanagawa, Japan; [3]Food and Drug Safety Ctr., Hatano Res. Inst., Hadano, Japan

Abstract: Inbred strains of Hatano high- (HAA) and low- (LAA) avoidance rats, derived from the Sprague-Dawley strain, were selectively bred based on their respective avoidance performances in the shuttle-box active avoidance task. To clarify the behavioral characteristics of the Hatano rats, male HAA and LAA rats, were subjected to behavioral tests for learning ability (step-through type passive avoidance, social recognition and novel object tests) and for emotionality (elevated plus maze test). As a result, the avoidance performance in the passive task was significantly greater in HAA than LAA rats. In elevated plus maze test, LAA rats showed higher percentage time spent exploring open arms compared to HAA rats. Also, in the social recognition tests HAA spent more time investigating novel animals than familiar animals but LAA showed no differences. In contrast, there was no strain difference between the HAA and LAA rats in the novel object tests. These results suggest that avoidance performance in the Hatano HAA and LAA rats is almost not resulted in cognitive function. Although the HAA rats

showed higher anxiety behavior than LAA rats, avoidance learning and social recognition are known to be associated with emotion. Therefore, Hatano HAA and LAA rats can be useful models which show clear strain differences in learning ability involved with anxiety behavior. Part of this experiment was conducted by a Meiji University Priority Research grant.

Title: Unguided identification of mouse behavioral phenotypes

Authors: *J. G. MCCALL[1], C. C. HAMMARSTEN[3], A. A. BORD[3], M. E. SHELTON[3], T. D. SHEAHAN[2], J. P. GOLDEN[2], R. W. GEREAU, III[2]
[1]Anesthesiol., Washington Univ., Saint Louis, MO; [2]Anesthesiol., Washington Univ., St. Louis, MO; [3]Mathematics, Lafayette Col., Easton, PA

Abstract: Preclinical animal studies are critical to advancing basic neuroscience and clinical medicine. However, most animal behavior assays rely on preconceived notions regarding the important observed features of the dataset, rather than unbiased assessment of the fundamental structure of the data. To address this shortcoming, we used persistent homology, a mathematical method for computing important topological data structures, to blindly identify salient features in mouse behavior data. This approach generated a 'diagnostic framework' to assess the behavioral phenotype of individual animals. As a proof-of-principle, we examined the locomotor behavior of more than one hundred mice that had either been stressed or not. In a double-blind fashion, the persistent homological analyses successfully identified two groups of mice. These two mathematically-identified were largely segregated by stress exposure. Using the persistent homological features of these two groups, we were then able to test new animals against this ‘training set’ to blindly determine whether new animals had been stressed. Testing new animals against this ‘training set’ we can blindly predict whether new animals had been stressed and whether commonly used anxiolytics could reverse these unguided classifications. This approach yields greater than 90% accuracy using only the XY position coordinates in an open field. We next asked if the same could be done for pain. Acute models of inflammatory pain do not classify as stressed in this system, while chronic, injury-induced models of neuropathic pain do cause animals to be blindly ‘diagnosed’ as stressed. This distinction may be useful in considering and

modeling psychiatric sequelae following evoked pain, but it will be important to use an analogous persistent homology approach to generate a new 'diagnostic framework' for identifying spontaneous pain in animal models. This mathematical approach is capable of identifying critical features of animal behavioral data that may not otherwise be recognized by human observers. Such an unguided 'diagnostic framework' may be useful in modeling psychiatric disorders and potential therapeutic approaches.

Title: Analgesic effects of tramadol in male and female rats with an anxious trait

Authors: *C. CORTES[1], J. EGUIBAR[2], S. L. RUGERIO[3], M. MARTINEZ-GOMEZ[4]
[1]B. Univ. Autonoma de Puebla, Puebla, Mexico; [2]Benemerita Univ. Autonoma de Puebla, Puebla, Pue., Mexico; [3]Inst. de Fisiología, Benemérita Univ. Autónoma De Puebla, Puebla, Mexico; [4]Inst. de Investigaciones Biomédicas UNAM, Tlaxcala, Mexico

Abstract: A close relationship has been established between anxiety and pain. On the other hand, chronic stress exposure is associated with an increase in pain sensitivity, because produce a greater response to it, known as: stress-induced hyperalgesia. The high- and low- yawning (HY and LY, respectively) are two selectively inbreed lines from Sprague-Dawley (SD) rats. The HY and LY rats differ in the number of grooming bouts in a novel environment or after wetting the fur and in the open-field arena HY rats showed higher ambulation scores and thigmotaxis suggesting a higher anxiety respect to LY. The aim of this study was to analyse the sexual

dimorphism and the analgesic effect of tramadol on HY and LY using the tail-flick latency apparatus. The involvement of opioid receptors in the analgesic mechanism was investigated using adult female and male rats from both lines. All rats were maintained under standard conditions with 12:12 light: dark cycle (lights on 0700). We measured tail-flick latencies in three experimental sessions, at 30, 180 and 360 min after intraperitoneal injection of 10 mg/Kg of tramadol, an opioid drug with high affinity for mu opioid receptors. Each session consisted of three determinations of tail flick latencies after drug administration with 30-second intervals between them. All data are the mean ± error standard of mean. All procedures described were performed followed the NIH guide for the Care and Use of Laboratory Animals. Benemérita Universidad Autónoma de Puebla Animal Care and Use Committee approved all experimental procedures COSCM-SAL17-G. Our results showed that nociceptive response in the female and male rats differ between sublines and SD strain. HY rats had a lower pain threshold respect to LY and SD (ANOVA, $F_{(2,1)} = 22.4$, $P < 0.001$, followed by Tukey test, $P < 0.001$) and was lowest in females than males. Systemic administration of tramadol increased pain threshold in female rats (ANOVA, $F_{(2,1)}=3$, $P<0.05$), but it produced lower effects in all group of rats, being higher in LY and SD rats, and the opposite happen in HY line. In conclusion, pain responses are sexually dimorphic. The analgesic responses were modified by tramadol in female rats but it is not the case in all three groups of male rats.

Title: Rats bred for high propensity to anxiety- and depression-like behavior display altered mitochondrial markers in limbic brain regions

Authors: *J. P. HUAMAN, C. R. MCCOY, S. M. CLINTON
Sch. of Neurosci., Virginia Polytechnic Inst. and State Universit, Blacksburg, VA

Abstract: Affective disorders like major depression and anxiety have been studied extensively, yet the molecular underpinnings of these debilitating illnesses have yet to be completely identified. While dysfunction of monoamine neurotransmission has long been associated with the pathophysiology of affective disorders, other theories posit that disturbances of mitochondrial function and metabolic activity within certain limbic brain regions also plays a role. The present

study uses a rodent model of a depression/anxiety-like phenotype to examine how metabolic differences in the limbic brain may relate to high levels of anxiety and depression-like behavior. Specifically, we use rats bred for low vs. high behavioral response to novelty; low novelty responding (LR) rats exhibit high levels of anxiety- and depression-like behavior compared to high novelty responding (HR) rats. Our previous transcriptome profiling study revealed numerous metabolism-related gene differences in the amygdala and hippocampus of LR vs. HR rats. We also found evidence of metabolic differences in the developing HR/LR brain by examining activity of Cytochrome C Oxidase (COX), one of the enzymes responsible for ATP production and a metabolic activity marker. The current study aims to find if these differences persist in adulthood. We first assessed COX activity in the hippocampus and amygdala of adult male HR/LR rats and found reduced COX activity in the central nucleus of the amygdala of LR versus HR rats. We next analyzed basal oxygen consumption with a Seahorse Biosciences XF24 Flux analyzer. Using freshly dissected hippocampus and amygdala of adult male HR/LR rats, we isolated mitochondria through differential centrifugation and a Ficoll gradient. In ongoing experiments, we expect that oxygen consumption levels will correlate with COX activity in both the amygdala and hippocampus. Therefore, we anticipate that LR rats will have decreased oxygen consumption relative to HRs in the amygdala and hippocampus. Overall, our results add to a growing literature suggesting that perturbations of metabolic and mitochondrial activity in the limbic brain may lead to disparate emotional behavioral phenotypes and affect vulnerability to emotional disorders.

Title: A sex-specific role of prenatal testosterone in adult alcohol and water drinking in mice

Authors: *C. P. MUELLER[1], I. ZOICAS[1], M. REICHEL[1], C. MUEHLE[1], C. BUETTNER[2], A. B. EKICI[2], B. LENZ[1], J. KORNHUBER[1], S. E. HUBER[1]

Abstract: Correlational studies in humans suggested organizational testosterone effects during embryonic development as a risk factor for adult alcohol dependence. However, a causal relationship has never been demonstrated. The aim of this study was to investigate the role of dihydrotestosterone (DHT) and flutamide, a synthetic testosterone receptor antagonist, administered during the prenatal period on adult emotional behavior and alcohol consumption in

male and female mice. Here we demonstrate a relationship between prenatal androgen receptor (AR)-activation and adult alcohol as well as water drinking in mice in a sex-specific way. Prenatal flutamide decreased adult alcohol consumption only in males. In contrast, prenatal AR activation by DHT led to an increase in adult alcohol consumption only in females. Virtually opposite effects were observed for adult water drinking. Prenatal flutamide increased adult water consumption only in females and DHT increased water consumption only in males. Prenatal flutamide reduced locomotion and anxiety in adult males, but was ineffective in females. Furthermore, we found that prenatal AR activation controls adult levels of monoaminergic modulatory transmitters in the brain and blood hormone levels in a sex-specific way. A RNA-Seq analysis confirmed a prenatal AR mediated control of adult expression of alcohol drinking-related genes like *Bdnf* and *Per2*. These findings suggest an important organisational role of prenatal AR activation in adult alcohol- as well as water drinking behavior, which is sex-specific.

Title: Developmental ethanol exposure and prefrontal layer VI neurons: Near-term effects on neuron structure and function

Authors: *E. L. LOUTH, C. D. SUTTON, L. K. SPATAFORA, C. F. KUPKA, C. D. C. BAILEY
Dept. of Biomed. Sci., Univ. of Guelph, Guelph, ON, Canada

Abstract: Chronic exposure to ethanol during development can lead to a variety of teratogenic outcomes known in humans as Fetal Alcohol Spectrum Disorders (FASD). Although attention deficits comprise one of the most prevalent neurocognitive impairments associated with FASD, the neural mechanisms underlying this outcome remain unknown. We have shown previously that adult mice exposed to ethanol during development exhibit impaired performance on an attention task, along with dysregulated morphology and physiology of pyramidal neurons in the medial prefrontal cortex (mPFC) layer VI that are critical for normal attention. This current study aims to determine whether these developmental ethanol-induced alterations to mPFC layer VI

neurons are also present early in postnatal life, to gain a better understanding of how and when the adult phenotype emerges. Developing mice were administered binge-like ethanol treatment or air (control) using vapour chambers from gestational days 10 to 18 (term, 19 days) and from postnatal days (P) 4 to 14. Electrophysiological and morphological properties of mPFC layer VI pyramidal neurons were measured at P15 and P25 in male and female mice. Electrophysiological experiments reproduced known effects of age and sex on neuron physiology in control mice. In contrast with previous findings for male mice in adulthood, there were no effects of developmental ethanol treatment on basic electrophysiological properties, or on nicotinic and AMPA receptor function in male mice at P15 or P25. Nicotinic receptor function was increased by developmental ethanol treatment in female mice, suggesting that this alteration to layer VI neuron physiology varies by sex and occurs earlier in females. Reconstruction and morphological analysis of recorded neurons also shows sexually dimorphic effects of developmental ethanol exposure on dendrite morphology and spine density. Together, these results demonstrate sex-specific alterations to mPFC layer VI neuron physiology and morphology in young postnatal mice following developmental ethanol exposure.

Abstract: Prenatal environmental challenges such as alcohol or drug exposures increase risks of learning and intellectual disabilities in children. Our previous report showed that the activated Heat Shock signaling is required for protection of the cells in the embryonic mouse cerebral cortex exposed to such prenatal challenges. However, the long term consequences of these survived cells and their contribution to neurobehavioral deficits remain elusive. To address these questions, we developed a novel reporter system, which enables lineage tracing of these cells. By performing single cell RNA sequencing of the reporter positive and negative neurons in the adult mice exposed to alcohol prenatally, we identified epigenetic changes, revealed by differentially expressed genes (DEGs) between the reporter-positive and -negative neurons. These DEGs include the genes whose functions are critically involved in the long-term potentiation of the neurons, suggesting a possibility that the epigenetic changes linked to the prenatal activation of Heat Shock signaling contribute to the neurobehavioral impairments in those mice. Pharmacological treatment for one of the identified epigenetic changes improved motor learning deficits in the mice that were exposed to alcohol prenatally. These results showed that reversal of key epigenetic changes may become a therapeutic approach for those who are exposed to prenatal challenges and show neurobehavior problems.

Title: A novel pseudogene-encoded long noncoding RNA mediates fetal alcohol effects

Authors: *N. SALEM[1,2], A. M. TSENG[1], A. H. MAHNKE[1], C. GARCIA[1], R. C. MIRANDA[1,2]

Abstract: Prenatal alcohol exposure is a leading non-genetic cause of neurodevelopmental disability. Neural stem cells (NSCs) that give rise to most neurons of the adult brain during the first and second trimester are particularly vulnerable. We previously found that ethanol exposure did not result in NSC death, but rather, the loss of NSCs due to premature maturation. This effect was mediated in part by the loss of specific miRNAs in NSCs. Here, we investigate whether ethanol also specifically prevents NSC renewal. We assessed the regulation of the homeobox transcription factor, Oct4/POU5F1, which is important for maintaining stem cell renewal and pluripotency. The Oct4 family includes a number of transcribed pseudogenes that are thought to be long non-protein coding RNAs (lncRNA). We hypothesized that these lncRNAs sequester miRNAs, though they may also have additional functions. We identified Oct4pg9 as one pseudogene-derived lncRNA transcript that was expressed in NSCs at significantly higher levels than the parent Oct4 mRNA transcript. Moreover, Oct4pg9 is transcribed at significantly higher levels in NSCs than differentiating neurons. Oct4pg9 binds Ago2 in both the nucleus and cytoplasm of NSCs, supporting its role as a miRNA sponge. Additionally, preliminary data shows that Oct4pg9 associates with ribosomes suggesting that it may regulate RNA translation or encode novel micro-peptides. Ethanol exposure results in elevated levels of Oct4pg9, whereas Oct4 protein levels are reduced. We studied the effect of ethanol exposure on the expression of Oct4 and Oct4pg9. Oct4 protein level was decreased in NSCs by ethanol exposure, and Oct4pg9 lncRNA was increased. We assessed the effect of elevated Oct4pg9 on stem cell fate markers in NSCs and compared it to the effects of ethanol. Oct4pg9 overexpression resulted in decreased Nestin, but increased GLAST, DCX, NeuN and GFAP transcripts. This effect was mimicked by ethanol exposure. In contrast, siRNA-mediated Oct4pg9 knockdown results in elevated Oct4, REST and Nestin mRNA transcripts and downregulation of DCX mRNA. These data suggest that ethanol-mediated elevation of Oct4pg9 shifts NSCs towards a neuronal/oligodendrocytic fate. Our results suggest that this novel lncRNA member of the Oct4/Pou5f1 family may regulate NSC renewal and mediate some of the teratogenic effects of ethanol.

Title: Adolescent ethanol exposure induces social anxiety and alters the balance between the oxytocin and vasopressin systems

Authors: *C. DANNENHOFFER[1], D. F. WERNER[2], E. I. VARLINSKAYA[3], L. P. SPEAR[4]
[1]Psychology, [3]Dept Psychol, [2]Binghamton Univ., Binghamton, NY; [4]Ctr. For Develop. and Behavioral Neurosci., Binghamton, NY

Abstract: Adolescent intermittent ethanol exposure (AIE) produces lasting, sex-specific adverse social consequences, with male, but not female, rats exhibiting social anxiety-like alterations (i.e., decreases in social investigation and social preference) as adults. Oxytocin (OXT) and vasopressin (AVP) brain systems play critical, although often opposite, roles in regulating social preference/avoidance, with OXT predominantly increasing approach to and AVP increasing avoidance of social stimuli. Using biochemical and psychopharmacological approaches, the present study tested the hypothesis that social anxiety seen in adult males after AIE is associated with a shift in the balance between the OXT and AVP systems toward AVP. Specifically, we assessed (1) effects of AIE on OXT, vasopressin V1a and V1b receptors (OXTR, V1aR, and V1bR, correspondingly) surface expression in the hypothalamus, and (2) effectiveness of pharmacological activation of the OXT system and blockade of endogenous activity at AVP receptors in reversing AIE-induced social anxiety using a modified social interaction test. Sprague-Dawley rats housed in groups of four littermates were given 4 g/kg ethanol (25%) (AIE) or water (control) intragastrically every 48 hr for a total of 11 exposures from postnatal days (P) 25-45. Behavioral testing and brain tissue collection occurred during early adulthood (P70 - P84). For social testing, subjects were injected intraperitoneally (i.p.) with vehicle, or a selective OXTR agonist WAY 267,424 (0.0, 2.5, or 5.0 mg/kg), V1aR antagonist SR 49059 (0.0, 1.0, 3.0, or 9.0 mg/kg), or V1bR antagonist SSR 149415 (0.0, 5.0, 10.0, or 20.0 mg/kg). Results indicated that AIE decreased OXTR, but increased V1bR neuronal surface expression relative to water-exposed controls. V1aR was not impacted. Behavioral testing again revealed decreases in social investigation and social preference in AIE males, confirming our prior findings of lasting social anxiety induced by AIE in males. Importantly, this AIE-induced social anxiety was reversed by the selective OXTR agonist and V1bR antagonist, whereas the V1aR antagonist did not rescue normal social behavior. Taken together, these results support the hypothesis that social anxiety induced by AIE is associated with an OXT/AVP imbalance, providing support for a novel pharmacotherapeutic approach to reverse the lasting consequences associated with adolescent binge-level ethanol exposure.

Title: Gestational exposure to low concentrations of tobacco smoke components, nicotine and benzo-a-pyrene, diminishes normal sex-differences in behavior in rats

Authors: *A. B. HAWKEY, S. JUNAID, L. YAO, Z. SPIERA, M. CAULEY, C. WELLS, H. WHITE, E. LEVIN
Psychiatry & Behavioral Sci., Duke Univ., Durham, NC

Abstract: Tobacco smoke is a complex mixture containing thousands of different chemicals. Tobacco smoking during pregnancy has been associated with impaired neurobehavioral development in their children. In our earlier studies, tobacco smoke extract has been shown to cause persisting hyperactivity and cognitive impairment in rats. Nicotine, the primary psychoactive component in tobacco, can cause cognitive impairment in rats, although there are a variety of other bioactive compounds in tobacco smoke which may also play a role. Prominent among these are polyaromatic hydrocarbons (PAHs). The prototypic PAH is benzo-a-pyrene (BaP), which has also been shown to cause neurobehavioral impairment in rats. The current study was conducted to characterize the individual and combined neurotoxicity of nicotine and BaP during gestational development, including their impacts on behavior in adolescence. Female Sprague-Dawley rats were implanted with osmotic minipumps delivering nicotine (2 mg/kg/day), BaP (0.03 mg/kg/day), both or neither. The male and female offspring were assessed in a behavioral test battery including tests of locomotor activity, as well as emotional and cognitive function. Gestational BaP exposure caused locomotor hyperactivity in male offspring but not females. This effect eliminated the normal sex difference in activity, with BaP treated males rising to control female levels. Additionally, gestational exposure to either nicotine or BaP enhanced the suppression of feeding in a novel environment among male subjects, but not females. This effect eliminated normal sex differences in this outcome. Gestational exposure of rats to low-doses of BaP and nicotine, two constituents of tobacco smoke, caused lasting neurobehavioral effects particularly in male offspring, by diminishing normal differences between males and females. This work was supported by the Duke University Children's Environmental Health Center funded by the National Institutes of Health (ES022831) and by the U.S. Environmental Protection Agency (83543701).

Title: Developmental nicotine exposure and Chrna5 D397N genotype impact pre-pulse inhibition across multiple generations: A model for differential outcomes in schizophrenia?

Authors: *H. C. O'NEILL, J. A. STITZEL
Univ. of Colorado Boulder Inst. for Behavioral Genet., Boulder, CO

Abstract: The nonsynonymous variant (rs16969968) in the α5 nicotinic receptor subunit gene (CHRNA5), known to be a strong genetic risk factor for nicotine dependence, has recently been linked to schizophrenia. Studies have shown the adult mouse homozygous for the nicotine dependence risk allele (N397, as opposed to the wild-type [WT] D397) suffers from hypofunctionality in the prefrontal cortical region as well as impaired prepulse inhibition (PPI) as compared to D397 WT mice. We have investigated PPI in adolescent mice and found it is impaired by 45 days of age in the N397 mouse. Building on these studies, we have evaluated both first generation offspring (F1) of D397N mice directly exposed to nicotine (100 μg/ml in 0.2% saccharin) from conception through weaning (dev nic) as well as mice who are the second generation (F2) offspring (themselves not exposed directly to nicotine except germline) of F1 mothers exposed to nicotine. Both sexes were evaluated. Following developmental nicotine exposure in the F1 offspring, the D397 dev nic mouse has impaired PPI as compared to their same-genotype vehicle controls; N397 dev nic mice show improved PPI. Interestingly, we see this phenomenon persist in F2 mice, with D397 mice having similar impairments in PPI as F1 dev nic mice. N397 F2 mice are similar to F1 dev nic mice with improvement in PPI as compared to their genotype vehicle controls. This suggests epigenetic modifications of DNA are persisting at least into the F2 generation following developmental nicotine exposure. Early evaluation of global methylation changes indicates significant changes in both the prefrontal cortex and the striatum of mice in F1 and F2 generations respectively. Combined, these data indicate the significant impact of the interaction of the rs16969968 risk variant with developmental nicotine exposure over multiple generations. Further evaluation of epigenetic alterations in pathways relevant to these behaviors will allow a better understanding of how these interactions have the potential to impact multiple generations.

Title: Age-dependent effects of low-dose nicotine pre-exposure on adolescent and adult alcohol and cocaine preference

Authors: *A. M. CARDENAS[1], J. A. TIRTORAHARDJO[2], S. W. LIU[3], Y. YIN[3], Y. BAI[3], S. LOTFIPOUR[2]
[1]Pharmacol., [2]Emergency Med., [3]Univ. of California, Irvine, Irvine, CA

Abstract: In human and rodent studies, adolescent nicotine exposure enhances the use of other drugs of abuse (i.e. the 'gateway hypothesis'). To test the hypothesis in our laboratory for alcohol and cocaine, we pre-exposed adolescent and adult male C57BL/6J mice to low-dose nicotine (equivalent to 1-2 cigarettes) and subsequently assessed drug self-administration or preference. For alcohol, we pre-exposed adolescent and adult male mice to a 7-day treatment regimen of nicotine (2x 0.5 mg/kg/s.c./day) or vehicle and assessed drug intake and preference using the Drinking in the Dark and two-bottle choice behavioral paradigms, respectively. For cocaine, we pre-exposed adolescent and adult male mice to a 4-day treatment regimen of nicotine (2x 0.5 mg/kg/s.c./day) or vehicle and assessed drug reward using the unbiased conditioned place preference behavioral paradigm. For alcohol, after a 7-day washout, late adolescent mice consume significantly more fluid than adults, independent of nicotine pretreatment or fluid self-administered. On alcohol preference test, all groups of animals illustrate preference, except for nicotine pre-exposed alcohol drinking adults. For cocaine preference, after a 7-day washout, nicotine pre-exposure during adolescence, but not adulthood, enhances cocaine reward. The effects are not confounded by differences in blood alcohol levels or cocaine-induced locomotion. Taken together, results provide supportive evidence for age-dependent effects of nicotine pre-exposure on alcohol and cocaine preference in mice.

Title: Prenatal nicotine alters membrane and synaptic responses of laterodorsal tegmental (LDT) neurons to postnatal alcohol exposure

Authors: ***A. N. FREITAS**[1], N. SONI[2], K. A. KOHLMEIER[3]
[1]Univ. do Estado do Rio de Janeiro, Rio de Janeiro, Brazil; [2]Yale Univ., New Haven, CT 06520, EUA, CT; [3]Univ. of Copenhagen, University of Copenhagen, Denmark

Abstract: Using drugs of abuse while pregnant has tremendous negative consequences for the developing fetus. Chief among the negative legacies bestowed to the exposed individual is an enhanced proclivity to addict to drugs later in life. The heightened likelihood that a person exposed to addictive drugs *in utero* will addict suggests that early exposure to drugs changes the developing brain in such a way that biases it towards addiction, presumably via alterations in the developmental trajectory of neurons important in development of addiction, which can lead to later life changes in responsiveness to stimuli. However, it is not well understood what changes are induced by prenatal exposures to nicotine in drug addiction-related areas, such as the LDT. Via projections sent to the ventral tegmental area (VTA), the LDT gates the behaviorally relevant firing pattern signaling stimuli saliency in mesoaccumbal circuits. Therefore, we investigated whether prenatal exposure to nicotine alters the responsiveness of neurons in the LDT to another addictive drug, alcohol. Accordingly, using whole-cell, voltage clamp recordings, we examined miniature postsynaptic inhibitory and excitatory currents (mIPSCs, mEPSCs) and membrane currents induced by alcohol (40mM) in neurons of the LDT from NIMH mice (PN9 to PN20) prenatally exposed to nicotine (PNE; 300µg/ml of nicotine with 2% saccharine) and compared those to control animals (SAC; 2% saccharine). We found that alcohol induced an outward current in the majority of LDT cells from the SAC animal, which was not an effect seen in LDT PNE neurons. Although alcohol tended to increase the frequency of mIPSCs in the SAC and decrease the frequency in the PNE, this differential effect was not significant. Further, while alcohol enhanced the amplitude of mIPSCs in PNE cells, and tended to decrease it in SAC neurons, these effects were not consistent enough to achieve significance between the two animal models. In the SAC animal, alcohol failed to have a significant effect on the frequency or amplitude of mEPSCs. Similarly, the amplitude of mEPSCs was not altered in the PNE by alcohol. However, in a stark contrast to findings in the SAC animal, the frequency of

mEPSCs was decreased by alcohol in all LDT PNE cells. In summary, PNE was associated with alterations in membrane and synaptic responses to postnatal exposures to alcohol. The differences in alcohol responses in the PNE could lead to differential output from the LDT to the VTA, and alterations in this output could play a role in biasing coding of relevant stimuli, which could participate in the enhanced proclivity to addict in those exposed during gestation to nicotine.

Title: Effects of ketamine on the unconditioned and conditioned locomotor activity of male and female preadolescent and adolescent rats

Authors: *A. E. MORAN, T. J. BAUM, M. J. APODACA, V. REAL, V. GOMEZ, S. A. MCDOUGALL
Dept. of Psychology, California State Univ., San Bernardino, CA

Abstract: Ketamine is a dissociative anesthetic used to induce anesthesia in children and adults, a quick-acting treatment for major depression, and an illicit drug commonly used at rave parties. Although ketamine is a non-competitive NMDA receptor antagonist, it may produce some of its anesthetic, anti-depressive, and psychotropic effects via actions involving the DA system. The ability of ketamine to enhance DA neurotransmission has been attributed to the modulation of afferent inhibitory interneurons in DA target areas, while others suggest that ketamine acts as an indirect DA agonist. The purpose of this project was to examine the effects of ketamine on the unconditioned and conditioned locomotor activity of male and female rats during early ontogeny. Because of the potential translational relevance to young humans, we compared rats from the preadolescent and adolescent periods. It was originally hypothesized that adolescent female rats would exhibit more robust unconditioned and conditioned locomotor activity than male rats. Preadolescent rats were also hypothesized to show ketamine-induced unconditioned and conditioned activity, however no sex differences were predicted in this prepubertal age group. To assess unlearned locomotor activity, rats were injected with saline or ketamine (5-40 mg/kg) and distance traveled was measured on PD 21-25 or PD 41-45. To assess conditioned activity, rats

were injected with saline or ketamine (10 or 40 mg/kg) in either a novel test chamber or the home cage on PD 21-24 or PD 41-44. One day later, rats were injected with saline and conditioned activity was assessed. Among adolescent rats, ketamine produced a dose-dependent increase in locomotor activity that was significantly stronger in females than males. Preadolescent rats also exhibited a dose-dependent increase in ketamine-induced locomotor activity, but the drug effects did not differ according to sex. In both age groups, repeated ketamine treatment neither caused a day-dependent increase in locomotor activity (behavioral sensitization) nor produced conditioned activity. The activity-enhancing effects of ketamine are consistent with the actions of an indirect DA agonist, while the inability of ketamine to induce conditioned activity is unlike what is observed after repeated cocaine or amphetamine treatment. This dichotomy could be due to ketamine's ability to both enhance DA neurotransmission and antagonize NMDA receptors. Additional research will be necessary to parse out the relative contributions of DA and NMDA system functioning when assessing the behavioral effects of ketamine during early ontogeny.

Title: Repeated administration of ketamine and phencyclidine in adolescence has effects that last into adulthood

Authors: *T. ZAFAR[1], A. ROCHA[2], K. A. TRUJILLO[1]
[1]Dept. of Psychology, [2]California State Univ. San Marcos, San Marcos, CA

Abstract: Dissociative drugs, a class that includes ketamine, phencyclidine and related drugs, are popularly abused, especially by teens and young adults in club and rave settings. According to users, at low doses these drugs produce stimulation and excitation, feelings of euphoria, lucid intoxication, and increased empathy. Since research has concentrated on adult drug abuse little is known of the effects of these drugs in adolescents, and potential differences between adolescents and adults. Tolerance and sensitization are types of neuroplasticity that contribute to drug abuse and addiction. Whereas tolerance is a decrease in an effect of a drug after repeated use,

sensitization is an increase in an effect of a drug after repeated administration. The present study examined ultrasonic vocalizations (USVs) in adolescent and adult Sprague Dawley rats after repeated exposure to PCP and KET. USVs reflect the affective state of the animal and are increased by drugs of abuse, most notably the psychomotor stimulants. We hypothesized that PCP and KET would induce a successive increase in ultrasonic vocalizations across days of treatment, reflective of sensitization, and that adolescent rats would show greater sensitization than adults. Animals received saline, KET (10 mg/kg s.c) or PCP (3 mg/kg s.c), once daily for seven days and USVs were assessed each day. On day 1 of treatment, both ketamine and PCP induced short-lived increases in USVs that were greater in adolescents than adults. Surprisingly, sensitization was seen following repeated administration of KET in adolescents, but tolerance was apparent following repeated administration of PCP - these changes were seen in adolescents, but not adults. Thus, while repeat administration of KET leads to behavioral sensitization in adolescents, repeat administration to PCP leads to tolerance. Interestingly, these changes persisted when adolescents were tested again as adults. Further research will help to determine the factors involved in KET sensitization and PCP tolerance. The results may lead to better prevention and treatment for KET and PCP abuse and addiction in teenagers.

Title: NMDA receptor blockade has differential effects on the synaptic proteome in juvenile versus adult mice

Authors: *K. BORGMANN-WINTER[1], A. BANERJEE[3], J. JOHNSON[2], N. M. BOWMAN[4], W. BILKER[5], S. J. SIEGEL[6], C.-G. HAHN[5]

Pennsylvania Sch. of Med., Philadelphia, PA; [4]Univ. of Pennsylvania Dept. of Psychiatry, Philadelphia, PA; [5]Dept Psychiat, Univ. Pennsylvania Sch. Med., Philadelphia, PA; [6]Dept Psychiat, USC, Los Angeles, CA

Abstract: Previously we observed that chronic ketamine decreased N-methyl-D-aspartame (NMDA) receptor signaling in adult mice but increased it in juveniles. In addition, we found that

NMDA receptor signaling changes persisted following cessation of treatment at least for 2 weeks in juvenile animals. Such differential effects of NMDA receptor blockade between juveniles and adults are of interest from the perspective of schizophrenia pathophysiology as well as increasing prevalence of ketamine abuse among adolescents. In this study we examined the proteome of synaptic membrane fractions in juvenile and adult mice at 24 hours and two weeks after cessation of a 2 week ketamine treatment. Ketamine (20mg/kg) was administered to adult (10 week) and juvenile (4 week) C3H male mice daily for 2 weeks. Mice were sacrificed after either 24 hours or a two week washout period. Crude synaptic membrane fractions were isolated by centrifugation of the post nuclear extracts of homogenized mouse cortical tissues. Ten µg of synaptic membrane extracts were mixed with [13C6]lysine-labeled internal standards. Samples were trypsin-digested, and processed for LC-SRM/MS on a triple quadrupole mass spectrometer for 200+ synaptic proteins. Peak areas for “light” endogenous peptides and “heavy” standard peptides were calculated, and ratios (l/h) between the two were used as dependent variables. Repetitive ketamine injection started in the juvenile period compared to adulthood (daily injection for 14 days followed by 24 hrs drug washout) led to alterations in more than 60 proteins that differed between the groups including SRC, GluN2B and GluR3 along with multiple mitochondrial proteins (p=0.03, Wilcoxin Rank Sum; multiple comparisons were accounted for using the FDR). Some protein alterations persisted two weeks later in animals exposed to NMDA receptor blockade during the juvenile period. These results point to interesting differences in the effects of the onset of NMDA receptor hypofunction in the juvenile period compared to that in the adult period.

Title: Effects of adolescent cannabinoid exposure on conditioned and unconditioned natural reward seeking in adult rats

Authors: *C. RUIZ[1], M. HUERTA[2], H. SCHOCH[3], R. R. CAMPBELL[4], S. V. MAHLER[5]
[1]Neurobio. and Behavior, [2]UC Irvine, Irvine, CA; [3]Neurobio. and Behavior, Univ. of California Irvine, Irvine, CA; [4]Univ. of California, Irvine, Irvine, CA; [5]Neurobio. and Behavior, Univ. of California Irvine Dept. of Neurobio. and Behavior, Irvine, CA

Abstract: Cannabis use is becoming increasingly widespread in the general pubic and especially among adolescents. Eight states and the District of Columbia have legalized it for recreational use and twenty-eight states have legalized it for medicinal use. As more states consider recreational legalization, there will be an increase in adolescent usage during a critical time of neurodevelopment. The brain's own endocannabinoid signaling, especially anandamide (AEA) and 2-arachidonoylglycerol (2-AG), is critically involved in adolescent neurodevelopment, and one possibility is that exogenous cannabinoid exposure during adolescence disrupts ECB-dependent development of reward-related neural circuits. Studies have already shown adolescent cannabinoid exposure (ACE) leads cognitive and memory impairments, as well as to increased heroin seeking (Ellgren 2007), and decreased social reward (Wei 2016). Here we examine effects of ACE on conditioned and unconditioned reward seeking in male long evans rats. Rats were delivered at post-natal day (PD) 21-23 and on PD30 started daily 1.2mg/kg IP injections of WIN55,212-2 (CB1 agonist) or vehicle for 14 consecutive days. The fourteen-day WIN exposure was succeeded by a fourteen-day washout period with no drug exposure. Following the washout period, the animal completed a Pavlovian conditioned approach task (sign/goal tracking) with a palatable food reward. This task examines individual differences of targeting motivation and rats are identified as sign trackers (preference for predictive lever) or goal trackers (food cup preference). ACE rats showed altered sign and goal tracking as compared to the control group, with more ACE rats showing unusual approach to both sign and goal cues. Next, we examined ACE effects on unconditioned food and novelty reward-related behaviors. Rats were tested for free intake of familiar and novel palatable foods, homeostatic regulation of intake by acute hunger or satiety, locomotor response to novelty, and novel context preference. We observed increased binge-like intake, altered modulation of intake after hunger, and altered responses to novelty. Finally, we examined ECB responses to acute food restriction in several brain regions including nucleus accumbens, medial prefrontal cortex, and cerebellum. In sum, we observe in ACE rats a robust phenotype of increased natural reward seeking, altered responses to reward cues and novelty, and altered ECB system reactivity, potentially indicating an addiction-prone phenotype after adolescent cannabinoid use.

Title: Gestational cannabinoid exposure influences extracellular kynurenic acid and glutamate levels in the medial prefrontal cortex of adolescent offspring

Authors: *S. BEGGIATO[1], L. FERRARO[1], R. SCHWARCZ[2]
[1]Life Sci. and Biotech., Univ. of Ferrara, Ferrara, Italy; [2]Maryland Psychiatric Res. Ctr., Baltimore, MD

Abstract: Cannabis is the illicit drug most commonly abused by pregnant women. The main psychoactive component of marijuana, delta^9-tetrahydrocannabinol (Δ^9-THC), can reach the fetus through the placenta and the blood-brain barrier. Several longitudinal studies of children and adolescents prenatally exposed to marijuana reported a significant impairment of higher cognitive functions (Smith et al., 2006; El Marroun et al., 2011; Huizink, 2013), as well as a link to psychiatric disorders (Jutras-Aswad et al., 2009; Mathews et al., 2014). Preclinical studies indicate that prenatal exposure to cannabinoids induces cognitive deficits in rat offspring (Ferraro et al., 2009). Moreover, these impairments are associated with alterations of aminoacidergic neurotransmission in the hippocampus and the prefrontal cortex (PFC) (Mereu et al., 2003; Antonelli et al., 2005). In particular, some of the deleterious effects on cognitive functions resemble those observed in adult rats, which had been prenatally exposed to the tryptophan metabolite (L-) kynurenine, the direct bioprecursor of the neuroactive compound kynurenic acid (KYNA) (Pocivavsek et al., 2014). We therefore investigated whether alterations in KYNA levels in the rat brain might play a role in the short- and long-term consequences of prenatal cannabinoid exposure. Pregnant Wistar rats were treated daily with Δ^9-THC [5 mg/kg or vehicle (sesame oil) by oral gavage] from gestational day (GD) 5 through GD 20. Three vehicle-treated and five Δ^9-THC-treated dams were euthanized at GD 20, and the levels of kynurenine and KYNA were determined in maternal and fetal plasma and brain. The remaining dams (n=4 per group) gave birth, and one adolescent [postnatal day (PD) 35-45] male rat per litter was used to determine the extracellular levels of KYNA and glutamate by *in vivo* microdialysis in the medial PFC (mPFC).
No changes were found in kynurenine and KYNA levels in the fetal and maternal plasma or in the fetal and maternal brain. However, extracellular basal KYNA levels in the mPFC were significantly higher in prenatally Δ^9-THC-exposed adolescent rats ($p<0.01$) compared to the vehicle group. In addition, following gestational Δ^9-THC treatment, adolescent rats had significantly lower extracellular glutamate levels than the vehicle group ($p<0.05$). The present data demonstrate that prenatal cannabinoid exposure leads to long-term alterations of KYNA and glutamate levels in the mPFC in adolescence. As an increase in KYNA levels has been associated with cognitive dysfunction and psychiatric disorders, the possibility that this mechanism could underlie the detrimental effects of prenatal marijuana exposure is hypothesized.

Title: Neurobehavioral effects of early opioid exposure in mice: Influence of the Oprm1 A112G single nucleotide polymorphism

Authors: *S. A. ROBINSON[1], A. D. JONES[1], M. E. EHRLICH[2], J. A. BLENDY[1]
[1]Systems Pharmacol. and Translational Therapeut., Univ. of Pennsylvania, Philadelphia, PA; [2]Neurology/Pediatrics, Mt. Sinai Sch. Med., New York, NY

Abstract: Infants exposed to opioids in utero are at high risk of developing Neonatal Abstinence Syndrome (NAS), a combination of somatic withdrawal symptoms including high pitched crying, irritability, gastrointestinal distress, and in some cases seizures. Despite being one of the leading causes of neonatal hospital admissions in the U.S., the factors impacting NAS severity are unknown. Furthermore, how this experience impacts behavior later in life has not been well documented. A potential genetic influence of NAS outcome may be a single nucleotide polymorphism (SNP) in the opioid receptor gene (*OPRM1*), which has recently been shown to be associated with shorter length of stay in the hospital for infants with this SNP (Wachman et al., 2015). Using our mouse line possessing the equivalent nucleotide/amino acid substitution in the *OPRM1* gene (A112G), we sought to determine if this SNP modulates the short and/or long term behavioral effects of neonatal opioid exposure in mice. Newborn pups harboring either the A/A or G/G alleles were injected with morphine (10mg/kg) from postnatal day (PND) 1-14 (equivalent to the third trimester of human gestation) and observed for emergence of developmental milestones and withdrawal symptoms. We observed delays in reaching important developmental milestones, such as eye opening, forelimb grasping and ambulations in an open field, with morphine-exposed mice taking longer to reach criteria and trends toward a genotype x morphine interaction. To determine if neonatal morphine exposure and withdrawal produces long lasting effects on behavior, mice exposed to morphine from PND 1-14 were assessed on anxiety-like behavior and drug sensitivity in adulthood. Morphine treated animals showed increased anxiety-like behavior, as measured by reduced time spent in the open arms of the elevated zero maze. Sensitivity to repeated morphine administration assayed through locomotor response showed that morphine exposed animals exhibit significantly blunted locomotor sensitization to repeated morphine. The further development of a mouse model of NAS will allow for more in

depth investigation into the influence of genetic variability as well as provide insights into the underlying neurobiology of this syndrome.

Title: Prenatal oxycodone self-administration and postnatal outcomes

Authors: *E. M. BYRNES[1], A. TOORIE[2], M. LAPOINTE[3], F. M. VASSOLER[4]
[1]Tufts Univ. Cummings Sch. Vet Med., North Grafton, MA; [2]Biomed. sciences, Tufts Univ., North Grafton, MA; [3]Biomed. Sci., [4]Dept. of Biomed. Sci., Tufts Univ. Cummings Sch. of Vet. Med., North Grafton, MA

Abstract: The levels of prescription opioid use and abuse are at historic levels in the U.S. In addition to increased rates of heroin addiction and opioid-related deaths, this increased exposure to opioids has also resulted in a dramatic rise in the number of babies born to opioid using mothers, many of whom display neonatal abstinence syndromes (NAS). Our understanding of factors that can exacerbate or ameliorate NAS in opioid using women is limited. The use of preclinical models to examine the relationship between specific drug regimens and offspring outcome, including severity of NAS could provide valuable information. The present set of studies utilizes a model of both short and long access oxycodone self-administration in rats which begins prior to conception and continues throughout pregnancy. Outcomes examined include drug-induced alterations in ultrasonic vocalizations, deficits in maternal care, and differences in neural expression of both mu-opioid receptor (MOR) and methyl CpG binding protein 2 (MeCP2) during the early postnatal period.

Title: Modeling opioid-mediated neonatal abstinence syndrome (NAS) to improve our understanding of challenges in neurodevelopment

Authors: *S. STEVENS[1], A. SIEFERT[2], S. MOHAN[1]
[1]Dept. Pharmaceut. Sci. and Res., Marshall Univ. Sch. of Pharm., Huntington, WV; [2]Dept. Biol., Univ. of Kentucky, Lexington, KY

Abstract: Opioid dependence is at epidemic levels in the USA, it is estimated that over 2.1 million people are suffering from substance use disorders related to prescription opioid pain relievers. Opioid exposure in pregnancy has led to the increase in neonatal abstinence syndrome (NAS). In the US, NAS has increased 5-fold in the last 10 years and was the single greatest reason for neonatal hospital admissions in 2015. Neonates chronically exposed to opioids and thus activation of opioid receptors while in-utero, will experience symptoms of NAS with the abrupt discontinuation of these mechanisms after birth. This leads to increased activation of intracellular signaling, ionic imbalances and increased neurotransmitter activity. Presentation of NAS symptoms are suggestive of such imbalances and are subsequently managed through medicinal opioid therapies to first achieve homeostasis and then to slowly wean the infant off the opioid substance. Currently, the neuropathology behind opioid-mediated NAS is unknown and therefore, warrants further research to improve our understanding of the effects of opioid withdrawal in neonates - this could positively impact clinical outcomes (short and long-term) of infants born with NAS. Data from adult animal models have greatly contributed to our understanding and treatment of opioid tolerance, addiction and withdrawal, however, only a limited number of studies have been conducted to understand the same in neonates. Data from these studies has led to us to conclude that processes are different between adults and neonates, and that neonatal models of opioid withdrawal are vital to understand and develop effective treatment regimens for NAS. Previous models of opioid withdrawal have included large (i.e. sheep and pigs) and small (i.e. guinea pigs, rats and mice) animals using either the spontaneous or precipitated opioid withdrawal paradigm. However, challenges exist with all animal models and in small mammal models brain development at birth differs from that in human neonates. However, using a unique rodent species, the spiny mouse (A. cahirinus) we have developed a spontaneous opioid withdrawal model. With an extended gestational period, A. cahirinus may be an ideal animal model to study NAS. By studying changes in behavior and analyzing brain tissue obtained from aged A. cahirinus born with opioid-induced NAS we hope to determine gender differences that may be used to improve clinical outcomes.

Title: Social-based voluntary abstinence prevents the emergence of incubation of drug craving

Authors: *M. VENNIRO, M. ZHANG, D. CAPRIOLI, Y. SHAHAM
Natl. Inst. On Drug Abuse, Baltimore, MD

Abstract: Background: We recently developed a rat model of incubation of drug craving after voluntary abstinence achieved by providing rats with a mutually exclusive choice between methamphetamine and palatable food for several weeks. Here we determined whether this incubation phenomenon would occur after a period of voluntary abstinence where the alternative reward is access to a social peer. Methods: We first trained rats to lever-press for either access to a social peer (60-s, 2-h/day, 6 days) or palatable food (5 pellets) and then methamphetamine (0.1 mg/kg/infusion, 6-h/day, 12 days). We then assessed relapse to drug seeking after 1 and 15 abstinence days. Between tests, different groups of rats underwent either social-based voluntary abstinence (15 trials/day), food-based voluntary abstinence (15 trials/day), or homecage forced abstinence. Results: As in our previous studies, non-reinforced responding on the methamphetamine-associated lever in the relapse tests was higher after 15 days of food-choice voluntary abstinence or forced abstinence (incubation of methamphetamine craving). More importantly, rats demonstrated a strong preference for the social peer over methamphetamine (social-based voluntary abstinence). Additionally, prior exposure to social-based voluntary abstinence prevented the emergence of incubation of methamphetamine craving (lever-presses during the relapse test were similar on test days 1 and 15). Conclusions: Results show that exposure to social -based voluntary abstinence prevented the emergence of incubation of drug craving and demonstrate the critical role of social factors in drug relapse, as assessed in animal models. We are currently exploring brain mechanisms underlying the inhibitory effect of social-based voluntary abstinence on incubation of drug craving.

Title: Influence of serotonin transporter SLC6A4 genotype on interaction between stimulant effects and risk-taking in the orbitofrontal cortex

Authors: *A. Z. NITENSON[1], J. E. MCGEARY[2], T. L. WHITE[1]
[1]Neurosci., [2]Psychiatry and Human Behavior, Brown Univ., Providence, RI

Abstract: Serotonin is believed to be heavily involved in risk-taking and assessment, and different serotonin levels in the brain may influence drug response and vulnerability to substance abuse. Brain regions along the serotonergic pathways, including the orbitofrontal cortex (OFC), have been shown to be involved in these mechanisms. The serotonin transporter protein 5-HTT (SERT) is a target site for amphetamines, blocking reuptake and thus increasing synaptic levels of serotonin. In humans, this protein is encoded by the *SLC6A4* gene. The current study investigated the possible influence of a common polymorphism of this gene, 5-HTTLPR, on the interaction between amphetamine effects and the brain's response during risk-taking as measured by fMRI. The within-subject, repeated-measures protocol investigated effects in 52 healthy participants (26M/26F), of whom a final sample of 37 participants (18M/19F) provided genotype information for 5-HTTLPR. Participants underwent two fMRI scan sessions, during which they performed a gambling task with three "Stakes" values (Low, Medium, High). Stakes corresponded to the amount of real-world money that can be earned per trial. Participants consumed a capsule containing either placebo (PLC) or 20-mg *d*-amphetamine (AMP) 90 minutes prior to scanning. Physiological (heart rate, blood pressure) and subjective effects of the capsule were collected over the course of each session. Repeated-measures ANOVAs revealed a significant Drug x Stakes interaction in the left OFC ($F=4.86$, $p=.014$). In this region AMP disrupted the decrease in BOLD activity in response to increased stakes observed in the PLC condition. Our Drug x Stakes x 5-HTTLPR Genotype analysis revealed that this pattern was altered in participants as a function of allelic load. Homozygotes for the high expressing allele showed increased PLC over AMP BOLD activity in the low stakes condition, and those with two

low expressing alleles showed increased AMP over PLC BOLD activity in the high stakes condition. The interaction was significant when using both the biallelic (F=3.41, p=.019) and triallelic (F=4.03, p=.009) genotyping approaches. Furthermore, participants who demonstrated a greater drug response in the left OFC under the high stakes condition reported a greater subjective response to AMP effects (r=.43, p=.003), and were more likely to possess one or more hypofunctional 5-HTTLPR alleles (t=2.37, p=.024). These findings provide insight about the causes of heterogeneous response to stimulants in humans, and suggest a gene/behavior/brain network that underlies susceptibility to drug effects and use.

Title: Interactions between methamphetamine and cocaine on dopamine neuron synaptic currents following self-administration experience

Authors: *A. M. HAGER[1], S. DOMINGUEZ-LOPEZ[2], M. J. BECKSTEAD[3]
[1]Physiol., Univ. of Texas Hlth. Sci. Ctr. At San A, San Antonio, TX; [2]Univ. of Texas Hlth. Sci. Ctr., San Antonio, TX; [3]Univ. of Texas at San Antonio, San Antonio, TX

Abstract: Dopaminergic neurons are key mediators of substance abuse and addiction-related behaviors. In the midbrain, somatodendritic dopamine release activates inhibitory postsynaptic currents through D2 autoreceptors (D2-IPSCs) coupled to G protein potassium (GIRK) channels on dopamine neurons. The highly addictive psychostimulants cocaine and methamphetamine, alter the mesolimbic dopamine pathway and somatodendritic dopamine neurotransmission. Cross-sensitization between cocaine and methamphetamine has been shown in self-administration behavioral paradigms, however few studies have examined the cellular mechanisms underlying cross-sensitization. In this study we examined the effects of methamphetamine self-administration in mice and alterations in dopamine neurotransmission. Adult mice were trained to nose-poke under a fixed ratio 3 schedule for intravenous infusions of methamphetamine (0.1 mg/kg/infusion) in daily 2 h sessions for 7 to 12 days. Their average intake of methamphetamine was 2.8 mg/kg/day. Whole-cell patch clamp electrophysiology was performed 24 hours following methamphetamine intake. Horizontal brain slices containing

substantia nigra and ventral tegmental area dopamine neurons were taken to examine alterations in D2-IPSCs in response to bath perfusion of various concentrations of methamphetamine or cocaine (100nM-10μM). While methamphetamine self-administration resulted in a downward shift in the methamphetamine concentration-response curve of D2-IPSCs compared to drug-naïve controls, this was not seen in response to bath application of cocaine. Both psychostimulants' mechanism of action involves the dopamine transporter and other cellular adaptations are being investigated such as calcium-dependent mechanisms. These results indicate that doses of methamphetamine sufficient to produce strong behavioral responding are not necessarily high enough to evoke alterations in D2-IPSCs in response to cocaine in midbrain dopamine neurons. A calcium-dependent decrease in dopamine inhibitory neurotransmission in response to methamphetamine but not to cocaine indicates that there is little adaptation in dopamine transporter function following methamphetamine self-administration.

Title: Spatiotemporal suppression of striatal excitability elicited by amphetamine in Wistar rat

Authors: *A. LOTFI, O. LAGSTRÖM, B. SÖDERPALM, M. ERICSON, L. ADERMARK
Univ. of Gothenburg, Gothenburg, Sweden

Abstract: Amphetamine addiction is a chronic brain disorder, characterized by diminished ability to control drug seeking and a high tendency to relapse. While rewarding effects of amphetamine has been linked to dopaminergic neurotransmission in nucleus accumbens, compulsive drug intake and cue-induced drug craving after protracted abstinence appears to engage dorsal striatum. In fact, selective and hierarchical recruitment of striatal subregions has

been implicated in transition from recreational to compulsive drug use. Additionally, amphetamine-induced structural plasticity strengthens inputs to dorsolateral striatum (DLS), while weakens inputs to dorsomedial striatum (DMS), after protracted abstinence. Therefore, the aim of this study was to define progressive modulations in neuronal excitability and synaptic plasticity in the form of endocannabinoid-mediated long-term depression in dorsal striatal subregions after repeated administration of amphetamine. To this end, adult Wistar rats received five daily injections of amphetamine (2.0 mg/kg), and treatment effects on striatal neurotransmission was monitored by *ex vivo* slice electrophysiology for up to ten weeks of abstinence. We found that five days of amphetamine administration enhanced amphetamine-induced locomotion and rearing activity in a manner that sustained for at least 10 weeks. Measurement of evoked field excitatory post-synaptic potentials (fEPSPs) showed that amphetamine treatment depressed neuronal excitability in DMS and DLS in a temporal manner that was concurrent with a decrease in probability of neurotransmitter release. In addition, high frequency stimulation of afferent fibers of dorsal striatum revealed that endocannabinoid-mediated long-term depression was enhanced in the DLS of amphetamine-treated rats after protracted abstinence. In parallel, bath application of the dopamine D2 receptor agonist quinpirole (5 μM), depressed fEPSPs to a greater extent in slices from vehicle-treated rats as compared to rats treated with amphetamine ten weeks earlier. The data presented here suggests that passive administration of amphetamine initiates progressive reorganization of brain regions associated with goal-directed behavior and habitual performance, which continue to develop even after discontinuation of amphetamine administration. These neuroadaptations might contribute to the development of compulsive drug seeking and an increased susceptibility to relapse.

Title: Antagonism of neurotensin receptors in the ventral tegmental area decreases methamphetamine self-administration in mice

Authors: *S. DOMINGUEZ-LOPEZ[1], W. B. LYNCH[1], M. WOLLET[1], A. L. SHARPE[2], M. J. BECKSTEAD[1]

Abstract: Neurotensin is a peptide found in the brain and known to modulate dopamine neurotransmission and dopamine-related behaviors. Recently, we reported that neurotensin depresses inhibitory post-synaptic currents mediated by dopamine D_2 autoreceptors in midbrain dopamine neurons, thus enhancing or potentiating dopamine neurotransmission. In line with this finding, the rewarding properties of neurotensin in the ventral tegmental area has been documented using electrical and optogenetic self-stimulation, showing that neurotensin is able to facilitated operant behavior. Here we test the hypothesis that neurotensin input in the ventral tegmental area facilitates methamphetamine self-administration in mice. For this, male DBA/2J mice were implanted with an indwelling catheter in the right jugular vein and a bilateral cannula in the ventral tegmental area. A week after surgery, mice were trained to nose-poke for an intravenous infusion of methamphetamine (0.1 mg/kg/infusion) in daily operant sessions of 2 h. Animals receiving microinfusions of the neurotensin receptor antagonist SR142948A in the ventral tegmental area (10 ng/per side), during the first five days of methamphetamine exposure, required on average more days of training to acquire methamphetamine self-administration ($P=0.0075$ vs. Saline). The SR142948A group also showed a decreased number of infusions during acquisition and stabilization of methamphetamine self-administration ($P<0.001$ vs. Saline). The effect induced by SR142948A was not related to changes in basal locomotor activity or changes in methamphetamine induced-locomotion. Our results suggest that neurotensin receptor activation in the ventral tegmental area facilitate acquisition of methamphetamine self-administration in mice.

Title: Discovery of novel DAT inhibitors based on the modafinil scaffold for the treatment of psychostimulant abuse

Authors: J. GIANCOLA[1], A. BONIFAZI[1], J. CAO[1], R. SLACK[1], A. GADIANO[1], R. RAIS[2], B. SLUSHER[2], *A. H. NEWMAN[1]

Abstract: Methamphetamine is a highly addictive psychostimulant, yet to date, no pharmacological treatment is available for methamphetamine use disorders. Like methamphetamine, the clinically available and wake-promoting drug modafinil binds to the dopamine transporter (DAT); however, unlike methamphetamine, it has low abuse potential. Modafinil has been evaluated for the treatment of methamphetamine abuse with mixed results. We have recently developed several novel analogues, based on the modafinil scaffold (e.g. JJC8-016, JJC8-088, JJC8-089 and JJC8-091; Cao et al 2016, Zhang et al 2017) and tested them on intravenous methamphetamine self-administration in rats that were allowed short access (1 h; ShA) or long access (6 h; LgA) exposure to the drug (Ho et al, 2017). Although several analogues were effective, the analogue with highest binding affinity (Ki=2.6 nM) and selectivity for DAT (JJC 8-088) was least effective in these models of methamphetamine abuse, possibly due to its poor pharmacokinetics. Hence, we extended our structure-activity relationship study by chemically manipulating the oxidation state of the sulfoxide group and by replacing the metabolically susceptible piperazine ring of the JJC series with a variety of bioisosteres, resulting in several novel lead molecules. Evaluation for binding affinities at DAT, SERT and sigma-1 receptors led to the selection of a subset of compounds to be evaluated for metabolic stability in liver microsomes, as well as pharmacokinetic studies in rats. In total, these studies will serve to identify the next lead compound(s) for behavioral evaluation and development toward pharmacotherapeutic treatment of psychostimulant abuse.

Title: Chronic voluntary oral Methamphetamine administration disrupts spatial-memory performance by producing a long-lasting neuroinflammatory response that disrupts synaptic protein trafficking in the hippocampus of adolescent mice

Authors: *D. SHOR[1], J. A. AVILA[1,3], R. ZANCA[1,3], N. PALEOLOGOS[1], A. ALLIGER[1], M. E. FIGUIEREDO-PEREIRA[2,3], P. A. SERRANO[1,3]

Abstract: Methamphetamine (MA) is a neurotoxic drug of abuse that induces neurodegenerative processes in the brain affecting behavior and cognition. Previous studies have focused largely on examining MA-induced neurochemical and behavioral deficits by injecting high doses (30 mg/kg MA; Braren et al., 2014), identifying the upper limits of MA-induced neurotoxicity. Little is known about the lower limits of MA doses necessary to produce neurotoxicity and behavioral deficits. Accordingly, we have developed an appetitive model of voluntary oral MA administration (VOMA) in rodents based on the consumption of palatable oatmeal chips containing a known amount of MA. In the current VOMA study, mice were given new presentations of sweetened oatmeal chips containing 1 mg/kg MA every 15 min for 3h every day for 28 days. We show that mice on VOMA consumed on average 1.743 mg/kg bw MA/hour, and an average of 5.23 mg/kg bw MA/day over 28 consecutive days (an average of 146.4 mg/kg total MA over 28d). During a brief abstinence period, working memory and reference memory assessments on the radial arm maze revealed long-lasting spatial memory deficits after 28d of VOMA. To delineate the molecular mechanisms that 28d VOMA disrupts in the hippocampus, a brain region pivotal to spatial memory processing, we analyzed whole-hippocampi for changes in synaptic and neuroinflammatory marker expression. We hypothesize that increased neuroinflammation following VOMA disrupts the trafficking of synaptic plasticity markers in the hippocampus, which leads to cognitive deficits in-vivo. Our results show that 28d of VOMA significantly increases expression of neuroinflammatory markers GFAP and COX2, and decreases levels of prostaglandins (PG) D2 and E2. Expression of highly neurotoxic PGJ2 was unchanged, suggesting that 28 days of VOMA induces a prolonged but not chronic neuroinflammatory response in the hippocampus. PKMζ, GluA2, and PSD95, markers pivotal to synaptic plasticity and memory in-vivo, were significantly decreased after 28d VOMA. This suggests that the prolonged neurotoxicity of 28d VOMA, despite not elevating PGJ2, is sufficient to disrupt synaptic plasticity that results in poor memory performance in-vivo. 28d of VOMA also disrupted dopaminergic function in the hippocampus by decreasing TH and DAT expression, effects observed in previous models. Our data reveal that 28d of VOMA produces a prolonged increase in markers of neuroinflammation and decreased expression of markers necessary for synaptic plasticity and spatial memory processing in the hippocampus. Future studies will evaluate the progression of this neurotoxic state using the VOMA model in male and female mice.

Title: Two-weeks of voluntary oral Methamphetamine administration produces acute spatial-memory deficit and increases chronic neuroinflammatory activity in the hippocampus of adolescent male C57Bl6 mice during abstinence

Authors: *J. A. AVILA[1,3], D. SHOR[1], F. TAVERNIER[1], R. M. ZANCA[1,3], D. ALVARADO-MATEO[4], A. TANG[1], M. E. FIGUEIREDO-PEREIRA[2,3], P. A. SERRANO[1,3]

Abstract: Methamphetamine (MA) is a neurotoxic drug of abuse producing neurodegenerative processes that impair cognition. The mechanisms that produce neurotoxicity and cognitive deficits following MA abuse have been characterized in bolus-dose models (Braren et al., 2014), in which high doses are administered acutely. However, little is known about the lower limits of MA doses necessary to produce these deficits. Additionally, it is unclear how chronic dosing and, separately, abstinence, contribute to the progression of these deficits. To understand these features of MA abuse, we have developed a novel rodent voluntary oral administration model of MA (VOMA), with presentations of oatmeal chips containing 1 mg/kg MA for oral consumption. In the current study, adolescent male C57Bl6 mice received MA presentations every 15 min during 4h every day for 14 days. Following VOMA, mice underwent a forced-abstinence period, during which we assessed spatial-memory performance on the radial arm maze (RAM), depressive phenotype using a tail-suspension test, and VOMA-induced contextual sensitization. Following behavioral assessments, we analyzed whole hippocampi for expression of synaptic and neuroinflammatory markers. Tracking of MA consumption revealed two distinct consumer groups. High-consuming mice consumed an average of 0.765 mg/kg bw MA/hr and an average of 3.059 mg/kg bw MA/day over 14d (average of 42.833 mg/kg bw MA total over 14d). Low-consuming mice consumed an average of 0.346 mg/kg bw MA/hr and an average of 1.385 mg/kg bw MA/day over 14d (average of 19.4 mg/kg bw MA total over 14d). Contextual sensitization measures showed that mobility before VOMA delivery is increased in High-consuming mice at 8d of VOMA, and decreases in the same group at the end of the 14d VOMA

period. RAM assessments revealed an acute spatial working memory deficit in High-consuming mice following VOMA. Prolonged abstinence rescued this memory deficit in a subsequent 10-day learning assessment on the RAM. Preliminary molecular analyses have revealed that abstinence increases expression of COX-2 and highly neurotoxic PGJ2 in mice hippocampi, suggesting that susceptibility to chronic neuroinflammation increases after MA abuse has ended. VOMA accurately models voluntary MA abuse in humans by producing discreet consumer populations in mice that exhibit acute and dose-dependent cognitive deficits. Additionally, our data have revealed that abstinence promotes the development of chronic neuroinflammatory pathways in the hippocampus despite evading prolonged cognitive dysfunction. Current work is examining the behavioral and neurochemical responses to this paradigm in female mice.

Title: Regulation of calcium binding proteins in the anterior cingulate area correlates with methamphetamine addiction and maladaptive sexual behavior

Authors: *L. B. KUIPER[1], L. M. COOLEN[2]
[1]Neurosci., Univ. of Mississippi Med. Ctr., Madison, MS; [2]Physiol. & Biophysics, Univ. of Mississippi Med. Ctr., Jackson, MS

Abstract: It is well known that drugs of abuse and natural rewards affect common brain circuitry, and that drug use in a socio-sexual context leads to compulsive sex- and drug-seeking behaviors. Our laboratory has demonstrated that concurrent experience with methamphetamine (Meth) and sexual behavior increases relapse to Meth seeking and resistance to extinction, as well as maladaptive sexual behavior. CaMKII-immunoreactive projection neurons in the anterior cingulate area (ACA) of the medial prefrontal cortex play a key role as Meth and sex co-activate these cells and chemogenetic inhibition during Meth and sex experience prevents increased relapse vulnerability. Moreover, concurrent Meth and sex experience causes long-lasting increases in basal neuronal activity of these cells, as evidenced by increased phosphorylation of MAP kinase. The current study tests the hypothesis that the effect of concurrent Meth/sex on neuronal activity of CaMKII cells in the ACA is accompanied by alterations in expression of calcium binding proteins in GABAergic inhibitory neurons. Male rats received Meth (1 mg/mL/kg s.c.) or saline and mated to one ejaculation (Meth/sex or sal/sex) for 4 consecutive

days. In addition, males received non-concurrent Meth or saline and mating experience: 4 consecutive days of mating, followed by 4 consecutive days of drug treatment (Meth or sal). One week after the final treatment session, animals were taken from their home cage and perfused. Immunohistochemistry was performed to visualize parvalbumin, calretinin, and calbindin, which are expressed in inhibitory interneurons. Cell were counted in the ACA. Results showed that concurrent Meth/sex significantly decreased the numbers of neurons labeled for parvalbumin, but not calretinin or calbindin, compared to the sal/sex concurrent group. Non-concurrent exposure to sex and Meth did not affect immunoreactivity, nor did sexual experience alone. This reduction of parvalbumin neurons may lead to reduced inhibition of ACA pyramidal cells. Further research will investigate the loss of parvalbumin inputs on pERK-immunoreactive CaMKII neurons. Together, these results demonstrate a synergistic effect of Meth and sex on neuroplasticity in ACA interneurons. Closer investigation of the molecular mechanisms leading to this plasticity will help us better understand how drug use in a socio-sexual context leads to vulnerability for drug addiction and hypersexuality.

Title: Methamphetamine and psychological stress activate corticotropin-releasing factor receptor 1 cells in a sex dependent manner

Authors: *J. JACOBSKIND[1], Z. J. ROSINGER[1], N. J. JUSTICE[2], D. G. ZULOAGA[3]
[1]SUNY Albany, Albany, NY; [2]Ctr. for Metabolic and Degenerative Diseases, Inst. of Mol. Med., Univ. of Texas Hlth. Sci. Ctr., Houston, TX; [3]Univ. at Albany, Albany, NY

Abstract: Corticotropin releasing factor (CRF) and specifically it's binding to the CRFR1 receptor subtype has repeatedly been shown to play a key role in drug-related behaviors including drug seeking, self-administration, and reinstatement after withdrawal. Sex differences in patterns of methamphetamine (MA) abuse have been observed in humans and rodents. Women begin using MA at an earlier age, are more committed to MA, and show an accelerated spiral into MA addiction compared to men. In addition, female rodents show greater MA seeking and reinstatement following a withdrawal period. Because MA is a potent activator of the hypothalamic-pituitary-adrenal (HPA) axis and is known to stimulate the brain CRF system, we hypothesized that exposure to MA would activate CRFR1 cells, and this effect would differ between males and females. To test this, C57BL6J CRFR1 reporter mice were i.p. injected with MA (5 mg/kg) and sacrificed 120 minutes later when brains were collected. Co-localization of

transcription/neuronal activation marker phosphorylated CREB (pCREB) with CRFR1 in stress responsive brain regions was assessed via immunohistochemistry. Our previous work has shown that MA increases neural activation in stress responsive brain regions in a pattern distinct from psychological stress. Therefore, another cohort of mice was restraint stressed for 30 minutes to compare levels of CRFR1 cell activation between psychological stress and MA exposure. In the rostral anteroventral periventricular hypothalamus (AVPV/PeN) and central amygdala (CeA) restraint stress increased co-localization more so in females. MA increased co-localization of pCREB with CRFR1 in the medial preoptic area (MPOA) and AVPV/PeN in females more than males. In the paraventricular hypothalamus (PVN), MA increased co-localization to a greater extent in males. These findings suggest that CRFR1 expressing cells are differentially activated by psychological stress versus MA. Furthermore, these effects appear to be sex dependent, suggesting that these differences may underlie observed sex differences in behavioral patterns of drug abuse. Future studies will seek to determine the extent to which CRFR1 expressing cells contribute to sex differences in addiction-like behaviors.

Med. Ctr., Amsterdam, Netherlands; [5]Dept. of Neurobio., Weizmann Inst. of Sci., Rehovot, Israel; [6]Dept. of Diagnos. & Publ. Hlth., Univ. of Verona, Verona, Italy

Abstract: Background: We recently developed a rat model of relapse after choice-based voluntary abstinence that mimics human relapse after cessation of contingency management, a behavioral treatment that uses alternative non-drug rewards to maintain abstinence. Here, we studied the role of central amygdala (CeA) and its afferent projections in relapse after voluntary abstinence.
Methods: We trained rats to self-administer palatable food (6 d) and intravenous

methamphetamine (14 d). We then assessed relapse to methamphetamine seeking after 14 voluntary abstinence days (achieved via a discrete choice procedure between methamphetamine and palatable food).
Results: Relapse to methamphetamine seeking after voluntary abstinence was associated with increased expression of the activity marker Fos in CeA but not basolateral amygdala (BLA). Systemic injections of the dopamine Drd1-family receptor antagonist SCH39166 decreased relapse and CeA Fos expression; in situ hybridization showed higher co-labeling of Fos with Drd1 than with Drd2. CeA SCH39166 injections decreased relapse after voluntary abstinence; in contrast, BLA SCH39166 injections or CeA injections of the dopamine Drd2-family receptor antagonist raclopride were ineffective. Double-labeling of Fos with the retrograde tracer cholera toxin subunit-B (CTb, injected in CeA) demonstrated that relapse after voluntary abstinence was associated with selective activation of ventral anterior insula (AIV)→CeA projection. AIV inactivation with GABA receptor agonists or chemogenetic inactivation of AIV→CeA projection decreased relapse after voluntary abstinence. Electron microscopy data showed that AIV vGluT1-expressing projection-neurons form excitatory asymmetric synapses on CeA neurons.
Conclusions: Our data demonstrate a critical role of CeA Drd1 and the AIV→CeA glutamatergic projection in relapse after cessation of contingency management-induced voluntary abstinence.

Title: Role of anterior intralaminar nuclei of thalamus projections to dorsomedial striatum in incubation of methamphetamine craving

Authors: *X. LI[1], K. WITONSKY[1], F. SURJONO[1], J. ZHANG[2], J. M. BOSSERT[1], Y. SHAHAM[1,2]
[1]Behavioral Neurosci. Res. Br., Natl. Inst. On Drug Abuse, Baltimore, MD; [2]Key Lab. of Mental Hlth., Inst. of Psychology, Chinese Acad. of Sci., Beijing, China

Abstract: Background: Methamphetamine seeking progressively increases after withdrawal from drug self-administration (incubation of methamphetamine craving). We previously demonstrated an important role of dorsomedial striatum (DMS) activity in this incubation. Here, we studied the role of glutamatergic and dopaminergic afferent projections to DMS in incubation of methamphetamine craving.
Methods: We trained rats to self-administer methamphetamine (6-h/d for 10 d) and then tested for relapse to drug seeking after 1 or 30 withdrawal days. In Exp.1, we measured projection-specific activation on withdrawal day 30 relapse test, using double-labeling of cholera toxin subunit B (retrograde tracer, injected into DMS)+Fos (neuronal activity marker) in cell bodies of the projection areas. Based on Exp. 1 results, we determined the effect of reversible inactivation [muscimol+baclofen(GABAa+GABAb agonists), 3+15 ng/0.3 µl/side] of the anterior intralaminar nuclei of thalamus (AIT) on incubated (day 30) methamphetamine seeking (Exp. 2). Next, we used an anatomical disconnection procedure [muscimol+baclofen injection (3+15 ng/0.3 µl/side) into AIT; SCH23390 (Drd1 antagonist) injection into DMS (0.75 µg/0.5 µl/side)] to determine the role of the AIT-to-DMS projection in incubated methamphetamine seeking (Exp. 3).
Results: Incubated methamphetamine seeking was associated with activation of the AIT-to-DMS projection but not other projection areas. Bilateral (but not unilateral) AIT inactivation, and both contralateral and ipsilateral disconnection of the AIT-to-DMS projection decreased incubated methamphetamine seeking.
Conclusions: Results demonstrate that the AIT and its projection to DMS plays a critical role in incubation of methamphetamine craving. Our results also suggest a novel role of the AIT-to-DMS projection in drug addiction and other motivated behaviors.

Title: Chemogenetic inhibition of dopamine neurons reveals phasic dopamine release as a critical substrate for amphetamine induced dopamine activation and hyperlocomotion

Authors: *S. M. CONWAY[1,2], M. F. ROITMAN[1]
[1]Univ. of Illinois At Chicago, Chicago, IL; [2]Grad. Program in Neurosci., Chicago, IL

Abstract: Amphetamine (AMPH) is thought to increase extracellular dopamine concentrations in the nucleus accumbens (NAc) primarily through action at dopamine terminals. Characterized as a dopamine releaser in *in vitro* studies, AMPH invades the presynaptic terminal via the dopamine transporter (DAT), compromises vesicular packaging, and increases extracellular dopamine through reverse transport. As such, AMPH activates nonexocytotic dopamine release and eliminates the ability of dopamine neurons to phasically signal through exocytotic release. Yet, AMPH increases the frequency of phasic dopamine release events (dopamine transients) *in vivo*, a signaling pattern inconsistent with reverse transport. Thus, our study seeks to determine the extent to which AMPH-induced increases in NAc dopamine and hyperlocomotion target phasic dopamine release signaled by neural activity at the dopamine cell bodies in the ventral tegmental area (VTA). While the reverse transport model predicts nonexocytotic dopamine activation occurs independent of VTA neural activity, we predicted that inhibition of VTA dopamine activation would attenuate AMPH-induced increases in NAc dopamine transients and hyperlocomotion. To achieve inhibitory control of VTA dopamine neurons, we virally delivered the Cre-dependent inhibitory (hM4Di) designer receptor exclusively activated by designer drug (DREADD) to transgenic rats expressing Cre recombinase under control of the tyrosine hydroxylase promotor (TH:Cre+) and wildtype littermates (TH:Cre-). In this manner, hM4Di expression is restricted to VTA dopamine neurons in TH:Cre+ rats, and using fast-scan cyclic voltammetry, we show that systemic administration of the DREADD ligand, clozapine-n-oxide (CNO) suppressed electrically evoked phasic dopamine release only in TH:Cre+ rats. We went on to measure changes in the frequency of dopamine transients in the NAc in response to AMPH (2.5 mg/kg, IP). Similar to recent work in behaving rats, we observed AMPH-induced increases in dopamine transient frequency. This effect was significantly reduced with CNO pretreatment (1 mg/kg, IP) relative to vehicle in TH:Cre+ rats, results consistent with the idea that AMPH activates exocytotic dopamine release in behaving rats. Furthermore, we have observed a suppression in AMPH-induced hyperlocomotion with systemic CNO to TH:Cre+ rats. Future work aims to determine the precise anatomical site along the mesolimbic pathway underlying these effects by repeating locomotor testing using intra-VTA CNO delivery. Taken together, these results corroborate *in vivo*-based conclusions supporting VTA dopamine activity as a critical target for AMPH action.

Title: Virus-mediated inactivation of GluA1 in ventral tegmental area dopamine neurons prevents social stress-induced psychostimulant cross-sensitization in rats

Authors: *M. L. RUDOLPH[1,2], R. N. HENDERSON[1], R. L. NEVE[3], R. P. HAMMER[1,2], E. M. NIKULINA[1]
[1]Univ. of Arizona Col. of Med., Phoenix, AZ; [2]Neurosci. Program, Arizona State Univ., Tempe, AZ; [3]MIT, Cambridge, MA

Abstract: Evidence from both human and animal studies demonstrates the importance of social stress in the development of addiction-related behavior. In rats, social defeat stress induces long-lasting social avoidance and psychostimulant cross-sensitization. Our recent data reveal heightened expression of AMPA receptor GluA1 subunit in rat ventral tegmental area (VTA) tissue, which occurs concurrently with social stress-induced amphetamine cross-sensitization. The objective of the present study was to determine whether social stress induces GluA1 expression primarily in dopamine cells, and to examine whether GluA1 is necessary for social stress-induced behaviors. Male Sprague Dawley rats that express Cre-recombinase under the control of an endogenous TH promoter, were exposed to aggressive Long-Evans rats four times over a period of 10 days; control rats were handled at the same times. Such intermittent social stress exposure increased GluA1 expression in VTA dopamine neurons as evidenced by a greater density of GluA1/TH double-labeling in VTA neurons of rats subjected to social stress compared to handling. In order to examine whether GluA1 is necessary for the effects of social stress, a Cre-dependent dominant negative pore-dead GluA1 construct packaged in AAV (AAV-pd-GluA1) was used to selectively reduce GluA1 function in TH neurons. The viral construct was bilaterally infused into the VTA three weeks before rats were subjected to social defeat stress; control rats had sham surgeries. Behavioral testing was performed 10-14 days after stress termination. Amphetamine (1.0 mg/kg i.p.) challenge significantly augmented locomotion in rats with normal GluA1, while virus-mediated overexpression of AAV-pd-GluA1 prevented amphetamine cross-sensitization. By contrast, in the three-chamber approach/avoidance test, functional inactivation of GluA1 did not affect stress-induced social avoidance. Taken together, these results suggest that GluA1 expression in VTA dopamine neurons is necessary for stress-induced psychostimulant cross-sensitization, but not for stress-induced social avoidance. This differential effect suggests that different neural pathways may be implicated in these behaviors. Clarifying such cellular mechanisms of social stress-induced cross-sensitization may be critical to the development of therapeutic agents for the treatment of stress-induced substance abuse susceptibility.

Title: Compulsive methamphetamine taking is associated with increased CARTpt expression in the rat dorsal striatum

Authors: *J. L. CADET, I. KRASNOVA, S. JAYANTHI, B. LADENHEIM, M. MCCOY
Mol. Neuropsychiat Br., NIH, Baltimore, MD

Abstract: Methamphetamine addiction is a common neuropsychiatric disorder that affects a vast number of people throughout the world. Addiction can be mimicked, in part, by using drug self-administration paradigms in several animal species including rodents. Nevertheless, addiction is actually more than self-administration because addiction includes the presence of adverse consequences as a criterion to reach that diagnosis in humans. Recently, we have begun to include footshocks as adverse consequences to influence drug self-administration by rats. We trained rats to self-administer methamphetamine for 20 days. All rats escalated their methamphetamine intake during this training phase. Thereafter, 50 percent of lever presses were punished by mild footshocks for 5 days. Response-contingent punishment reduced methamphetamine taking in some rats (shock-sensitive, SS) but not in others (shock-resistant, SR). Rats also underwent extinction test at one day and 30 days after the last shock session to test if there were increases in lever pressing in the absence of methamphetamine. Rats were euthanized one day after the second extinction test to collect striatal tissues to measure genome-wide transcriptional consequences of methamphetamine SA and footshocks in rat brain. At the second extinction test, shock-resistant rats showed significantly higher incubation of methamphetamine craving than punishment-sensitive rats. We found significant increases in striatal CARTpt mRNA in the shock-resistant rats by both microarray and PCR analyses. These observations support a potential role of striatal CARTpt in incubation of methamphetamine seeking after a long withdrawal interval. These findings also suggest that treatment approaches that impact this neuropeptidergic system might be beneficial to methamphetamine-addicted individuals.

Title: RGS12 modulates the dopamine transporter in ventral striatum and locomotor responses to psychostimulant drugs-of-abuse

Authors: *J. D. GROSS, S. W. KASKI, A. B. SCHROER, K. WIX, D. P. SIDEROVSKI, V. SETOLA
Physiol. & Pharmacol., West Virginia Univ., Morgantown, WV

Abstract: The Regulators of G protein Signaling comprise a family of intracellular proteins that accelerate the termination of effector stimulation after G protein-coupled receptor (GPCR) activation. RGS12 is the most complex family member, with at least five different functional motifs. Surveying RGS12 expression in various brain tissues, we have found marked expression in the mouse ventral striatum. Given the role of the ventral striatum in psychostimulant-induced locomotor activity, we tested whether RGS12 function is involved in amphetamine- and cocaine-stimulated hyperlocomotion. RGS12 loss resulted in decreased hyperlocomotion to lower doses of both psychostimulants; however, outcomes of repeated administration (sensitization and conditioned place preference) were unaffected. To test whether RGS12 might have a role in dopamine transporter (DAT) expression and/or function, we prepared crude membranes from the brains of wild type and *Rgs12*-null mice and measured DAT-selective [^{3}H]WIN 35428 binding, revealing an increase in DAT levels in the ventral—but not dorsal—striatum of *Rgs12*-null mice compared with wild type tissue. To address whether this increase in DAT expression translated into increased DAT function, we prepared ventral striatal synaptosomes and measured [^{3}H]dopamine uptake. Consistent with increased [^{3}H]WIN 35428 binding, DAT-specific [^{3}H]dopamine uptake in RGS12-null ventral striatal synaptosomes was increased compared with wild type preparations. Observations of decreased psychostimulant-induced locomotor activity, increased [^{3}H]WIN 35428 binding, and DAT-specific [^{3}H]dopamine uptake were recapitulated with an independent *Rgs12*-null mouse strain. RGS12 is thus a previously unidentified negative

regulator of DAT expression and function in the ventral striatum, affecting psychostimulant-induced increases in dopamine levels that specifically elicit acute hyperlocomotor responses.

Title: A possible role of orexin signaling pathway in methamphetamine-mediated drug addiction

Authors: C. LEE[1], G. PARK[2], *J.-H. JANG[1]
[1]Dept. of Pharmacol., Sch. of Medicine, Keimyung Univ., Daegu, Korea, Republic of; [2]Col. of Pharm., Kyungpook Natl. Univ., Daegu, Korea, Republic of

Abstract: Methamphetamine (METH) is a powerful neurotoxic psychostimulant affecting dopamine transporter (DAT) activity and leading to blockage of dopamine reuptake, which results in continuous excess extracellular dopamine levels between pre- and post-synaptic neurons. In this study, we have tried to elucidate a new molecular regulator involved in METH-induced reward and drug addiction. METH (1 mg/kg/day, *i.p.*) was injected to C57BL/6 mice for four alternative days and locomotor as well as conditioned place preference (CPP) tests were performed as behavior analysis. Markers of dopamine system integrity and changes of orexin-related signaling molecules were examined to investigate underlying mechanisms. Orexin has been reported to play a crucial role in the regulation of arousal, wakefulness, and motivated behavior for drug abuse. METH-administered group exhibited increased locomotor activity and sensitivity to place preference compared with saline-treated control group on locomotor and CPP tests, respectively. METH significantly decreased dopamine-related markers such as DAT, dopamine 2 receptor (D2R), and tyrosine hydroxylase (TH). Conversely, METH increased expression levels of orexin and orexin-1 receptor particularly in the brain regions of hypothalamus and amygdala. Moreover, METH caused oxidative stress and neuronal damages by increasing lipid peroxidation and decreasing antioxidant defense capacity. These findings suggest that orexin may play a role for the behaviors associated with reward and/or reinforcement of METH and disrupt dopamine neurotransmissions via augmentation of oxidative neuronal damages.

Title: Phosphorylation by PKC but not PKA of AMPA receptor GluA1 subunit residues in the nucleus accumbens is required for expression of sensitized amphetamine-induced locomotion and self-administration

Authors: *P. VEZINA, J. BROWN, N. NEUGEBAUER, K. RODVELT, D. LI, N. BUBULA, P. MASCIA
Dept Psychiatry and Behavioral Neurosci., The Univ. of Chicago, Chicago, IL

Abstract: Recently we reported that basal phosphorylation by PKA of an AMPA receptor GluA1 subunit residue in the rat nucleus accumbens (NAcc) was increased weeks following sensitizing exposure to amphetamine, suggesting a potential role in the expression of sensitization by this drug. Here we report that when amphetamine exposed rats were challenged with the drug, a condition necessary for the expression of sensitization, PKA activity was surprisingly reduced in this site. Conversely, no change in phosphorylation by PKC of GluA1 subunit residues was detected basally weeks following amphetamine exposure. However, when rats were challenged with amphetamine, PKC activity was increased. Together, these results suggest that phosphorylation by PKC but not PKA in the NAcc is required for the expression of amphetamine sensitization. To assess this possibility, rats in different groups were exposed to 5 injections of amphetamine (1.5 mg/kg, IP; 1 injection every other day). One week later, they were infected in the NAcc with lentivirus bearing GFP or the serine-alanine mutants GluA1(S845A) or GluA1(S816A-S818A). Phosphorylation of these PKA and PKC residues, respectively, is known to facilitate GluA1 insertion into the plasma membrane which in turn can enhance glutamatergic transmission and enable the expression of sensitization by amphetamine. Two weeks following infection, rats in one experiment were tested for their locomotor response to NAcc amphetamine (2.5 µg/side). Rats in a second experiment were prepared with an IV catheter and given the opportunity to self-administer amphetamine (100 µg/kg/infusion) on a PR schedule of reinforcement. Preventing GluA1 phosphorylation by PKC blocked expression of the sensitized locomotor response to NAcc amphetamine as well as the enhanced self-administration of IV amphetamine normally observed in rats exposed to the drug. Remarkably, preventing phosphorylation by PKA spared enhanced responding to (locomotion) and for the drug (self-administration). These results, consistent with the biochemical profiles of PKA and PKC activity observed following exposure to amphetamine, support the need for NAcc PKC but not PKA

phosphorylation in the expression of behavioral sensitization by amphetamine and highlight the importance of NAcc AMPA receptor regulation by PKC in generation of the sensitized response.

Title: The brain mechanisms of methamphetamine-induced behavioral sensitization: Nucleus accumbens core and shell

Authors: *C.-N. CHENG[1,2], C. A. HUANG[1]
[1]Fo Guang University, Psychology, Fo Guang University, Psychology, Taipei, Taiwan; [2]Natl. Central Univ., Taoyuan, Taiwan

Abstract: Abused drugs have been shown to underlie the brain mesolimbic dopamine system to result in drug addiction. In particular, some studies suggested that the nucleus accumbens of the mesolibmic dopamine system is essential for drug addiction. However, whether the brain subareas of nucleus accumbens including nucleus accumbens core and shell play separate roles the development of drug addiction remains unclear. The present study focuses on this issue. Initially, half of all rats were injected a high dose of NMDA to destroy nucleus accumbens shell or core. After 7 days for recovery, all of rats were continuously administrated with methamphetamine (MAMPH, 1mg/kg) or vehicle (normal saline), and then they were assigned into Saline and MAMPH groups (n = 16, per group) one trial a day for 7 days. Later, the withdrawal phase was conducted for 7 days. After that, a low dose of methamphetamine (0.5mg/kg) was challenged to measure the locomotor activity. The results showed that MAMPH induced hyperactivity for behavioral sensitization in drug addiction.
NMDA injections interfered with behavioral sensitization and showed decreased locomotor activity on test phase. NMDA injections did not affect locomotor activity for behavioral sensitization during the sensitization acuqisition phase. For nucleus accumbens shell, during acquisition phase, NMDA injections into the nucleus acumens shell would facilitate locomotor activity for behavioral sensitization. During testing, NMDA injection into the shell of the nucleus accumebns probably increased locomotor activity. Some findings of the present study for drug addiction and dependence need to be discussed further.

Title: Repeated exposure of adolescent mice to 3,4-methylenedioxypyrovalerone activates transcriptional mechanisms that persist until adulthood and are similar to those activated by cocaine

Authors: L. DUART-CASTELLS[1], *M. H. BUENROSTRO-JAUREGUI[2], P. MUÑOZ-VILLEGAS[3], R. LÓPEZ-ARNAU[1], J. CAMARASA[1], D. PUBILL[1], E. ESCUBEDO[1]
[1]Univ. of Barcelona, Barcelona, Spain; [2]Dept. of Psychology, Univ. Iberoamericana, Mexico City, Mexico; [3]Ctr. de Enseñanza Técnica Industrial, Guadalajara, Mexico

Abstract: 3,4-Methylenedioxypyrovalerone (MDPV) is a new synthetic cathinone with psychostimulant properties. It selectively blocks the dopamine transporter (DAT), similarly to cocaine, but with higher potency. Moreover, in mice, an early (adolescence) exposure to MDPV induces long-lasting adaptive changes that lead to a major responsiveness and vulnerability to cocaine in adulthood. Accordingly, it is of interest to describe which transcriptional mechanisms are activated after a chronic exposure to MDPV (1.5 mg/kg, s.c., twice daily for 7 days) once the treatment is finished, 21 days after (adulthood), and after a saline or cocaine (7.5 mg/kg, i.p.) challenge administered at the end of the withdrawal. In parallel, behaviors such as anxiety and impulsivity once the drug was withdrawn were assessed by the elevated plus maze (EPM) and the open field test (OF), respectively. The expression of several factors in the striatum was

determined by Western blot and radioligand binding assays. Dopamine receptor 1 (DR1), activity-regulated cytoskeleton-associated protein (Arc), cyclin-dependent kinase 5 (CDK5), ΔFosB and tyrosine hydroxylase (TH) levels were increased just after the treatment. Interestingly, after 21 days of withdrawal a few markers still remained altered compared with the control group: CDK5, ΔFosB and TH remained increased while DR1 and Arc decreased. In any case the exposure to MDPV altered the effects of a cocaine challenge on the expression of those factors. 4-hydroxynonenal (4-HNE) and glial fibrillary acidic protein (GFAP) levels were also determined in the dorsal striatum in order to assess any possible neurotoxic effect of MDPV. Only 4-HNE was significantly increased 24h post-treatment, possibly due to the synaptic oxidation of dopamine, while no change was observed in GFAP. Regarding the behavioral tests, no anxious-behavior was observed in the EPM neither 48h nor 21 days after treatment. Furthermore, 21 days after treatment, the OF test results suggest an increased impulsive-behavior in MDPV-treated mice since they explored more time the central area of the arena. In conclusion, repeated MDPV exposure during adolescence activates transcriptional mechanisms similar to those described after chronic cocaine exposure. Some of them persist until adulthood. These results explain our previous findings about the effect of MDPV on the behavioral responses related to cocaine effects, including locomotor sensitization, reward and the strength of cocaine as a reinforcer. In addition, the increased expression of ΔFosB in the orbito-frontal cortex in MDPV-treated mice could be correlated with the major impulsivity observed after 21 days of withdrawal.

Title: Roles for prelimbic prefrontal cortex projections to nucleus accumbens or rostromedial tegmental nucleus in cue-induced reinstatement of cocaine seeking

Authors: *L. S. LAIKS[1], T. H. KIM[2], T. C. JHOU[3], R. J. SMITH[1]

Abstract: Distinct sublayers within the prelimbic (PL) area of prefrontal cortex project to nucleus accumbens (NAc) core and rostromedial tegmental nucleus (RMTg), two structures that often have opposing influences on cocaine-seeking behavior. We hypothesized that PL projections to RMTg play an inhibitory role in cue-induced reinstatement of cocaine seeking, in contrast to the well-established role for PL projections to NAc core in driving reinstatement. Here, we used a contralateral disconnection technique to test this hypothesis. Male Sprague Dawley rats self-administered intravenous cocaine paired with discrete tone and light cues for 10 days (0.2 mg/infusion; fixed ratio 1). After animals reached a criterion for extinction of responding in the absence of cocaine and cues, reinstatement was elicited by the tone and light cues. Prior to cue-induced reinstatement of cocaine seeking, rats were given microinjections of the GABA receptor agonists baclofen/muscimol into unilateral PL and the AMPA receptor antagonist NBQX into contralateral NAc core or RMTg, or were given vehicle microinjections. Preliminary findings indicate that cue-induced reinstatement was decreased by disconnection of PL and NAc, and increased by disconnection of PL and RMTg. Further study of both the behavioral function and anatomical connectivity of these distinct PL pathways is necessary to understand the role that PFC dysfunction plays in addiction.

Title: Goal-directed and habitual cocaine seeking using ratio and interval schedules of reinforcement

Authors: *R. J. SMITH[1], T. H. KIM[2], H. F. SPENCER[1]
[1]Dept Psychology, Texas A&M Univ., College Station, TX; [2]Dept Psychological & Brain Sci., Johns Hopkins Univ., Baltimore, MD

Abstract: Ratio and interval schedules of reinforcement have been shown to generate goal-directed and habitual responding, respectively, for food and alcohol. However, it is unclear whether these different schedules will also generate goal-directed and habitual responding for cocaine. To assess instrumental response strategy, we developed an outcome devaluation procedure for intravenous cocaine using sensory-specific satiety. Male Sprague Dawley rats were trained on a seeking-taking chained schedule of cocaine self-administration, in which presses on a seeking lever gave access to a separate taking lever reinforced with intravenous cocaine (0.5

mg/kg/infusion). The seeking link of the chain required completion of a random ratio (RR20) or random interval (RI60) schedule, and the taking link was reinforced under a fixed ratio (FR1) schedule. Outcome devaluation was carried out via administration of non-contingent intravenous cocaine, followed by evaluation of responding on the seeking lever for 10 minutes under extinction conditions. We found that animals trained on a random ratio schedule were sensitive to outcome devaluation, indicating goal-directed behavior. In contrast, animals trained on a random interval schedule were insensitive to outcome devaluation, indicating habitual behavior. Further experiments showed that pre-training lesions of dorsomedial striatum caused rats to be insensitive to cocaine devaluation regardless of schedule, whereas pre-training lesions of dorsolateral striatum caused rats to be sensitive to cocaine devaluation. Given established roles for dorsomedial and dorsolateral striatum in goal-directed and habitual behavior, these data support the validity of this outcome devaluation procedure developed for intravenous cocaine. Altogether, these findings indicate that different schedules of reinforcement generate a bias toward goal-directed or habitual responding for cocaine.

Title: Ventral pallidum roles in mixed appetitive/aversive motivational states related to cocaine relapse

Authors: *M. R. FARRELL, C. RUIZ, H. SCHOCH, E. CASTILLO, C. KHANBIJIAN, S. LIU, S. V. MAHLER
Neurobio. and Behavior, Univ. of California Irvine, Irvine, CA

Abstract: In drug-addicted individuals, abstinence is generally voluntarily chosen, often due to negative consequences associated with drug use, but many current animal models fail to emulate this aspect of relapse. Here, we model cocaine relapse after punishment-induced abstinence (modified from (Marchant et al., 2013)), in which rats voluntarily cease cocaine self-administration due to negative consequences associated with drug taking (i.e., lever-press contingent footshock). Male and female Long-Evans rats were trained to lever press to self-administer i.v. cocaine and discrete light+tone cue (increasing on a variable interval schedule) in

context A for 14 days. Then they were moved to context B, in which lever presses yielded cocaine and cues, but also a mild footshock on 50% of trials. Training continued until all animals showed voluntary suppression of seeking. Reinstatement of cocaine seeking was then tested under three conditions: in context A with response-contingent cues (but no cocaine), in context A without cues, and in context B with cues. To characterize roles for ventral pallidum (VP) in reinstatement following voluntary abstinence, we examined 1) activation of VP cells during reinstatement, and 2) effects of chemogenetic (DREADD) inhibition of VP on punished cocaine seeking and reinstatement behavior. We found that c-Fos analysis of VP activity varied by behavioral group, and VP subregion. We also found that VP inhibition with DREADDs blocked both context- and context+cue-induced reinstatement following abstinence, and modestly affected punished cocaine seeking as well. Finally, we characterized effects of chemogenetic VP inhibition on cocaine-induced locomotor behavior. These results indicate a novel role for VP in context- and cue-induced reinstatement to cocaine seeking in a translationally-relevant punishment-based model, and provide clues as to the complex and heterogeneous role for VP subpopulations in mixed appetitive/aversive motivational states related to cocaine relapse.

Title: Role of anterior dorsal lateral hypothalamic area perineuronal nets in cue-induced reinstatement of cocaine-seeking behavior

Authors: *J. M. BLACKTOP, B. A. SORG
Dept. of Integrative Physiol. and Neurosci., Washington State Univ. Vancouver, Vancouver, WA

Abstract: Addiction involves drug-induced neuroplasticity of the circuitry of motivated behavior, which includes the medial forebrain bundle and the lateral hypothalamic area. Emerging at the forefront of neuroplasticity regulation are specialized extracellular matrix structures that form perineuronal nets (PNNs) around certain neurons, mainly parvalbumin positive (PV^+) fast-spiking interneurons (FSINs), making them a promising target for the regulation of drug-induced neuroplasticity. Brain regions within the circuitry of motivated

behavior with comparatively high PNN expression may provide neurobiological insight into maladaptive drug-induced neuroplasticity and subsequent drug seeking. Very little is known about how PNN-expressing neurons in the LHA control drug-seeking behavior. We previously reported that the dorsal and intermediate zones of the anterior lateral hypothalamic area (LHAad) exhibited robust PNN expression using the PNN marker *Wisteria floribunda* agglutinin (WFA), and that approximately two-thirds of WFA positive neurons co-expressed PV. Removal of PNNs with the enzyme chondroitinase ABC (Ch-ABC) expression blocked the acquisition of cocaine- but not sucrose-induced CPP and self-administration. Here we focused on the rodent model of relapse (reinstatement). The goals of this set of experiments were to: 1) determine whether PNN expression within the LHAad is necessary for cue-induced reinstatement 2) characterize the phenotype of LHAad PNN-surrounded neurons, and 3) determine mesocorticolimbic inputs to and projections from the LHAad. Here we report that LHAad PNNs are necessary for the expression of cue-induced reinstatement of cocaine-seeking behavior. Furthermore, the phenotype of LHAad PNN-surrounded neurons was determined using the excitatory markers VGLUT2 and glutamate and the inhibitory markers GAD65/67 and GABA. Predominant co-localization of WFA with VGLUT2 and GABA over GAD65/67 and glutamate suggests that the PNN-rich LHAad receives dense glutamatergic input (VGLUT2) and is predominantly GABAergic. Moreover, retrobead injection into the LHAad, NAc, and VTA demonstrates that the LHAad receives robust prefrontal cortex input while providing moderate input into the VTA and minimal input into the NAc. In summary, these data indicate that PNN expression in the LHAad: 1) is necessary for expression of cue-induced reinstatement of cocaine-seeking behavior 2) is predominantly co-localized with PV+ GABAergic neurons that receives robust glutamatergic inputs, and 3) receives input from layer V of the prefrontal cortex and provides input into the VTA.

Title: Calcineurin regulates cocaine-cue neuroplastic changes in the amygdala to alter relapse-like behavior

Authors: *M. T. RICH[1,2], T. J. CAHANAP[2], Y. H. HUANG[2], M. M. TORREGROSSA[2]
[2]Psychiatry, [1]Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Drugs of abuse induce neuroplastic changes within brain reward circuits, which create strong associative memories that can trigger drug-seeking behaviors. Disrupting these memories in individuals struggling with addiction may help maintain abstinence. The lateral amygdala (LA) is a key regulator of emotionally-salient memories, as it integrates thalamic and cortical input, including auditory and somatosensory information, to help guide behavior. Interfering with memory reconsolidation or inducing memory extinction within the LA may serve to weaken maladaptive memories. Extinction therapy, for example, has helped treat anxiety-based disorders, and has shown promise for preventing drug relapse. Previous studies have identified thalamic and/or cortical excitatory synapses within the LA as loci for cue-mediated learning. They are strengthened by associating a cue with a fearful or rewarding stimulus, and are weakened by fear-memory extinction. However, these mechanisms have not been well studied in the context of drug-associated learning. Extinction and reconsolidation are regulated by various protein kinases and phosphatases, such as CaMKII and calcineurin (CaN). Indeed, inhibiting CaMKII enhances the extinction of and interferes with the reconsolidation of drug-associated memories. To further investigate the synaptic mechanisms that regulate drug-cue memories, we utilized an approach that combined cocaine self-administration with *ex vivo* electrophysiology in male rats. We examined the effect of cocaine-cue learning at thalamic and cortical synapses in the LA, and whether these synapses were altered by cue extinction and reconsolidation. We then tested the behavioral and physiological effects of LA administration of chlorogenic acid (CGA), an activator of CaN. We found that cocaine training potentiated thalamo-amygdala but not cortico-amygdala synapses relative to saline-trained controls. This potentiation was unaltered by either instrumental extinction training or context exposure alone, and was not potentiated significantly more by reconsolidation. Alternatively, synaptic strength was progressively reduced by increasing levels of cue extinction. Finally, CGA infusions in the LA following extinction or reconsolidation significantly reduced both EPSC amplitude and cue-induced reinstatement relative to vehicle-infused controls. Together, our results suggest that inducing drug-cue memory extinction or inhibiting reconsolidation reverses cocaine-induced potentiation at thalamo-amygdala synapses in a CaN-dependent manner, and that this activity is important for reducing drug-seeking behavior.

Title: Mesolimbic endocannabinoid signaling involvement in chronic electric footshock stress-induced escalation of cocaine intake in rats

Authors: *J. R. MCREYNOLDS[1], C. P. WOLF[1], D. M. STARCK[1], R. SCHAPS[1], C. J. HILLARD[2], J. R. MANTSCH[1]

Abstract: Stress is an important contributing factor to addiction and is problematic as stress is unavoidable in daily life. Addiction can be characterized by a loss of control over drug intake that, in the rat, is modeled by escalating patterns of drug self-administration (SA). We have previously shown that a stressor, electric footshock stress, administered daily at the time of SA induces an escalation of cocaine intake in rats that would otherwise demonstrate stable cocaine SA under short-access conditions (2-h/day). Stress-induced escalation of SA is likely the consequence of neuroplastic changes that may involve neurobiological mediators that connect stress-responsive and reward systems in the brain, such as the endocannabinoid system (eCB). These changes likely occur in regions implicated in both stress and reward, such as the nucleus accumbens shell (NAc) and ventral tegmental area (VTA). We hypothesize that repeated stress at the time of SA induces a persistent increase in eCB signaling, particularly in the NAc shell and VTA, which results in escalation of cocaine use and increased susceptibility to later reinstatement. Male SD were trained to SA cocaine (0.5 mg/kg/inf) on a FR 4 schedule in 4 X 30 min SA sessions separated by 5-min drug-free periods. Some rats received shock in the SA chamber during the 5 min drug-free period over 14 days. Shock administration resulted in an escalation of cocaine intake and this effect persisted for at least 5 days after cessation of shock. Systemic administration of the CB1R antagonist AM251 prior to the SA session attenuated cocaine intake only in stress-escalated rats. Surprisingly, intra-VTA administration of AM251 prior to the SA session attenuates cocaine intake regardless of stress condition. We are currently examining the effects of CB1R antagonism in the NAc shell on stress-induced escalation. Separate groups of rats were tested for reinstatement of drug-seeking behavior to a priming injection of cocaine (2.5, 5, or 10 mg/kg, i.p.). Rats who received shock during SA demonstrated augmented reinstatement to all doses of cocaine. Furthermore, as with SA, the CB1R antagonist AM251 given prior to injection of cocaine (10 mg/kg, ip) significantly attenuated cocaine-primed reinstatement only in stress-escalated rats. We are currently examining alterations in molecular components of the eCB system in stress- and reward-related brain regions. These data suggest that stress-induced neuroplastic changes occur, likely in the eCB system, in regions of the brain that influence expression of escalated cocaine intake and augmented cocaine-primed reinstatement and that these changes may be glucocorticoid-dependent.

Title: Sex differences in vulnerability to cocaine seeking are exaggerated by stress

Authors: *G. LIDDIARD[1], E. M. DONCHECK[1], M. C. DEBAKER[1], L. M. BARRON[1], C. D. KONRATH[1], J. R. MCREYNOLDS[1], E. N. GRAF[1], C. J. HILLARD[2], J. R. MANTSCH[1]

Abstract: Female cocaine addicts display enhanced relapse vulnerability compared to their male counterparts, particularly during periods of stress. This phenomenon is poorly understood, and progress toward the identification of relapse-prevention targets has relied heavily on male-based investigations. Therefore, to pursue female-appropriate effective treatment targets, we investigated sex differences in stress-enhanced relapse vulnerability. Using the preclinical cocaine self-administration model, we previously found in males that under conditions where stress doesn't directly induce the reinstatement of drug seeking, it does augment reactivity to other triggers. Specifically, electric footshock stress (EFS; 0.2-msec, 0.5mAmp triplicate footshocks, 40-sec avg ITI, delivered randomly during a 15-min period prior to access to the previously cocaine-paired lever) and stress-response level corticosterone (CORT; 2 mg/kg, i.p., 40-min pretreatment) potentiate reinstatement in response to an ordinarily subthreshold dose of cocaine (2.5mg/kg, i.p.). To interrogate for sex differences in this phenomenon, we subjected gonadally-intact females to the same cocaine self-administration (0.5 mg/kg/0.2 mL i.v. infusion, 2-hr sessions x 14-days) and extinction conditions as the males. Despite equivalent, stable cocaine seeking during self-administration (avg active lever presses/session: 122.1 ± 0.9 males, 125.5 ± 2.1 females), and comparable extinction behavior (8-day avg to first extinction criterion for both sexes), females reinstated drug seeking to a cocaine dose that was subthreshold in males (2.5 mg/kg, i.p.). We next tested for CORT effects on a lower dose of cocaine (1.25 mg/kg, i.p.), which we found to be subthreshold for reinstatement in both sexes. While in females neither stress-level CORT nor 1.25 mg/kg cocaine alone were sufficient to produce reinstatement, pretreatment with CORT potentiated reinstatement to the ordinarily subthreshold 1.25 mg/kg cocaine. Significant reinstatement to 1.25 mg/kg cocaine was not observed in males, either alone or in concert with CORT. This suggests that females exhibit a lower threshold for cocaine-primed reinstatement, and that CORT potentiates reinstatement to ordinarily subthreshold cocaine doses in both sexes. This finding is consistent with clinical observations that females

exhibit enhanced relapse vulnerability compared to males, a difference exaggerated in the context of stress. Studies are underway to contrast the effects of EFS between males and females, and to determine whether the CORT dose that is physiologically-relevant in males is also physiologically relevant in females.

Title: The prelimbic cortical endocannabinoid system mediates stress-enhanced cocaine-seeking vulnerability: Investigation of sex differences

Authors: *E. M. DONCHECK[1], J. R. MCREYNOLDS[1], E. N. GRAF[1], O. VRANJKOVIC[1], M. C. DEBAKER[1], G. T. LIDDIARD[1], L. M. BARRON[1], C. D. KONRATH[1], L. A. URBANIK[1], Q.-S. LIU[2], C. J. HILLARD[2], J. R. MANTSCH[1]

Abstract: Relapse is provoked through distinct neurobiological mechanisms between subpopulations of cocaine addicts. Probing for individualized therapies is therefore more liable to identify effective relapse prophylactics. Key population differences emerge in the context of stress, as it only directly triggers relapse in a subset of addicts. Still, under conditions where stress cannot induce the reinstatement of cocaine seeking, we find that it can augment reactivity to other triggers. Following cocaine self-administration and extinction, neither stress-level corticosterone (CORT; 2 mg/kg) nor low-dose cocaine (2.5 mg/kg, i.p.) alone induce reinstatement, but do so in combination. This phenomenon occurs within the prelimbic cortex (PrL), as intra-PrL CORT (50 ng/side) is sufficient to potentiate reinstatement, an effect likely induced by CORT (100nM)-suppressed inhibition of PrL pyramidal neurons. Endocannabinoids (eCBs) mediate these effects, as intra-PrL cannabinoid receptor-1 (CB1) activation (AM251; 300 ng/side) and 2-arachidonoylglycerol synthesis (DO34; 0.1 & 1 µg/side) are necessary for potentiated reinstatement. Thus, we hypothesize that CORT-mobilized eCBs render PrL

projections more excitable by ordinarily subthreshold stimuli, resulting in greater reinstatement vulnerability.
However, these data were solely collected from males, and another key population difference emerges between the sexes. As females display enhanced relapse vulnerability, particularly during periods of stress, we tested for sex differences in CORT-potentiated reinstatement. Despite comparable drug seeking during self-administration (0.5 mg/kg/inf i.v., 2 hr/day *x* 14 days) and time to extinction criterion, females exhibit CORT-potentiated reinstatement to a lower subthreshold cocaine dose (1.25 mg/kg, i.p.) than males. Otherwise, intra-PrL CORT is sufficient, while intra-PrL CB1R activation is necessary, for potentiated reinstatement in females. Although such parallels suggest no sex difference in PrL eCB-mediated CORT-potentiated reinstatement, they do not explain the enhanced sensitivity observed in females. As females also exhibit relapse variability across the ovarian hormone cycle, testing is underway to correspond estrous phase to reinstatement responding. Our preliminary data indicate greater reinstatement when blood estrogen (E2) levels are elevated. Furthermore, we find that E2 (100nM) augments excitation of female PrL pyramidal neurons. Therefore, we hypothesize that E2 may complementarily interact with CORT-induced eCB-mediated disinhibition of PrL pyramidal neuron output to amplify relapse vulnerability in females.

Title: Corticosterone potentiates reinstatement of cocaine seeking through activation of the cortico-accumbens pathway

Authors: *P. J. GOTTSHALL[1], J. R. MCREYNOLDS[1], T. STOLLENWERK[2], X. LIU[2], Q.-S. LIU[2], C. J. HILLARD[2], J. R. MANTSCH[1]

Abstract: Stress not only can act as a powerful trigger for relapse to drug seeking, but it can potentiate responsiveness to other triggers for drug use. We have shown that under self-administration conditions where it does not reinstate cocaine-seeking, electric footshock stress

can potentiate reinstatement when paired with low-dose cocaine. This effect of shock is corticosterone (CORT)-dependent and is mimicked by systemic or intra-prelimbic cortex (PL) CORT administration, indicating that CORT is necessary and sufficient for stress-potentiated reinstatement and that the PL is a critical site of CORT action. CORT likely potentiates reinstatement through interactions with the endocannabinoid (eCB) system, as stress increases eCB production in the PL in a glucocorticoid-dependent manner. Supporting this, we have shown that systemic or intra-PL cannabinoid receptor 1 (CB1R) antagonism blocks stress- and CORT-potentiated reinstatement. Given that these CB1Rs are located primarily on GABAergic interneurons in the PL, CORT effects may be the result of eCB-mediated inhibition of GABA. Indeed, bath application of CORT to nucleus accumbens core-projecting neurons in PL slices attenuated inhibitory neurotransmission in a CB1R-dependent manner. Therefore, we hypothesize that this CB1R-dependent attenuation of inhibition in the PL leads to increased activation of pyramidal projection neurons, and increased output to the nucleus accumbens core (NAc), a pathway critical for reinstatement. Male SD rats self-administered cocaine (14 x 2-h/day) and then received an intra-NAc core injection of the retrograde tracer cholera toxin subunit B (CTb). Following recovery, rats underwent extinction training followed by reinstatement tests. Rats received an injection of CORT (2 mg/kg, i.p.) alone, subthreshold cocaine alone (2.5 mg/kg, i.p.) or both and were perfused after the reinstatement test. We utilized a double label immunohistochemical approach to determine CTb co-expression with an immediate early gene, cFos. Preliminary data indicates that CORT-potentiated reinstatement results in an increase in activation of the cortico-accumbens pathway. We are currently investigating the contribution of the eCB system to this effect and the behavioral relevance of this pathway to potentiated reinstatement utilizing an intersectional DREADD viral approach. These findings support the hypothesis that CORT acts in the PL, through CB1R-mediated inhibition of GABA, to potentiate reinstatement of cocaine seeking through increased activation of the cortico-accumbens pathway.

Title: Perineuronal net removal decreases cue-induced reinstatement in cocaine self-administering rats

Authors: *J. WINGERT[1], R. P. TODD[2], B. A. SORG[3]
[1]Neurosci., Washington State Univ., Cook, WA; [2]Neurosci., [3]Integrative Physiol. and Neurosci., Washington State Univ., Vancouver, WA

Abstract: After the acquisition and consolidation of a memory, a memory trace can be made labile again by subsequent reactivation. Following reactivation, a memory trace undergoes a process called reconsolidation in which the memory trace must be stabilized if it is to persist. Reconsolidation can be initiated with the addition of a novel change from the preexisting memory trace. If the process of memory reconsolidation is disrupted by the activity of a drug or amnesic agent, the memory trace may be removed or left weakened. The medial prefrontal cortex (mPFC) is a key structure in processing rewarding stimuli and is important for cocaine-induced drug seeking behavior and memory. A subset of GABAergic interneurons within the mPFC expresses dense extracellular matrix structures called perineuronal nets (PNNs). Removal of PNNs with the enzyme chondroitinase-ABC (Ch-ABC) has been shown to induce a state of neural plasticity. We investigated the effects of Ch-ABC on the reconsolidation of a cocaine memory during a cocaine self-administration experiment. Male Sprague-Dawley rats were trained to lever press for cocaine on a fixed ratio 1 (FR1) schedule of reinforcement for 10 days. They were then given Ch-ABC or vehicle into their mPFC and, three days later, were given a 30-min memory reactivation session that used a variable ratio 5 (VR5) schedule instead of the FR1 schedule they were trained on. During the VR5, rats received both cocaine and the cocaine-associated cue light. The next day, rats were tested for memory reconsolidation by first measuring lever-pressing behavior for 30 min in the absence of the cue light (under extinction conditions) and for 30 min under cue-reinstatement conditions, in which rats were allowed to press for the cocaine-associated cue light. Injection of Ch-ABC into the mPFC did not change the response during the 30 min extinction session. However, rats given Ch-ABC decreased their response during the cue reinstatement session. Our results suggest that the removal of PNNs in the mPFC by Ch-ABC is effective at disrupting the reconsolidation of a cocaine-induced memory. The change in the self-administration paradigm (FR1 to VR5) may be required to make the memory labile for disruption by Ch-ABC.

Title: Sex and estrous cycle effects on the attenuation of cue-primed reinstatement of cocaine-seeking by ceftriaxone

Authors: *P. HAMOR, A. R. BECHARD, M. SCHWENDT, L. A. KNACKSTEDT
Dept. of Psychology, Univ. of Florida, Gainesville, FL

Abstract: Effective pharmacological treatments to prevent cocaine relapse remain elusive. Sex differences have been reported in human cocaine addicts for both intake and susceptibility to relapse; yet little is known about sex differences in pharmacological treatment of animal models of relapse. In male rats, the beta-lactam antibiotic ceftriaxone has consistently been demonstrated to reduce relapse to cocaine-seeking. Here, we assessed the ability of ceftriaxone to attenuate cue-primed reinstatement of cocaine-seeking in male and female rats. We also assessed the effects of estrous cycle on the ability of ceftriaxone to attenuate reinstatement in female rats. Male and female Sprague-Dawley rats self-administered cocaine (0.5 mg/kg per infusion) in the presence of discrete cues (light and tone) for 12 days (2h/day), followed by 2-3 weeks of extinction training of the operant response (lever presses). During the last week of extinction training, animals were treated with daily injections of ceftriaxone (200 mg/kg) or vehicle (saline), and then returned to the operant box for a cue-primed reinstatement test. We found that although female rats self-administered more cocaine across the 12 days, ceftriaxone attenuated cue-primed reinstatement of cocaine-seeking behavior similarly in both males and females. However, when reinstatement testing occurred during estrus, ceftriaxone did not attenuate cocaine-seeking. To investigate this effect further, we will use Western blot analyses to quantify proteins in the nucleus accumbens core that are known to be affected by ceftriaxone, such as xCT, GLT-1, GluA1, GluA2, mGlu5, an mGlu2/3. Our study is the first to confirm the ability of ceftriaxone to attenuate cue-primed reinstatement of cocaine-seeking behavior in females, dependent on estrous cycle. The current findings highlight the overall potential for ceftriaxone as a pharmacological treatment to prevent human cocaine relapse.

Title: Chemogenetic inhibition of pyramidal neurons in prelimbic cortex blocks BDNF-mediated attenuation of cocaine seeking

Authors: *G. GIANNOTTI, S. M. BARRY, B. M. SIEMSEN, J. F. MCGINTY
Med. Univ. of South Carolina, Charleston, SC

Abstract: A major clinical issue in addiction is the high rate of relapse even after prolonged abstinence. Our lab has shown that a single BDNF infusion into the prelimbic (PrL) cortex immediately after the last cocaine self-administration (SA) session attenuates reinstatement of cocaine-seeking. Moreover, inhibition of the TrkB receptor, ERK/MAPK activity, or AMPA/NMDA receptor function prevents BDNF's ability to attenuate relapse, indicating a relationship between BDNF-mediated suppression of cocaine-seeking and synaptic activation. Based on this evidence, we employed a chemogenetic approach to modulate glutamatergic activity in the PrL cortex by infusing an adeno-associated virus (AAV5, 0.75µL/side) carrying the cell type-specific promoter, CaMKIIα, to drive the expression of inhibitory $hM_4D(Gi)$ DREADD (Designer Receptors Exclusivity Activated by Designer Drugs) or eGFP in pyramidal neurons of the PrL cortex. Male rats were trained to self-administer cocaine (0.2 mg/infusion) for 14 consecutive days. Immediately after the last cocaine SA, all rats received an injection of clozapine-N-oxide (CNO, 10 mg/kg, I.P.) followed by an infusion into PrL cortex of PBS or BDNF 30 min later. Rats then underwent 6 days of abstinence followed by a post-abstinence test under extinction conditions, extinction training to criterion, a cue-induced reinstatement test, re-extinction, and a final cocaine prime-induced reinstatement test. As expected, infusion of BDNF in the eGFP-expressing rats attenuated relapse and activation of the Gi DREADD blocked BDNF's ability to attenuate cocaine seeking. It is important to note that 85% of mCherry neurons expressed CaMKIIα immunoreactivity. Surprisingly, the Gi DREADD, in the absence of BDNF, induced a long-lasting attenuation of relapse, raising the possibility that multiple brain regions receiving glutamatergic afferents from the PrL cortex contribute to subsequent relapse. To explore this possibility, we selectively inhibited glutamatergic activity in PrL neurons that project to the nucleus accumbens (NAc) core by infusing an AAV5 (0.75 µL/side) carrying a floxed form of the Gi DREADD into PrL cortex and a retrograde transducing CAV2-Cre virus (0.75 µL/side) into the NAc core of the same rats. As expected, infusion of BDNF in the eGFP-expressing rats attenuated relapse and CNO-mediated activation of the Gi DREADD blocked BDNF's ability to suppress cocaine seeking. However, activation of the Gi DREADD in the absence of BDNF did not affect relapse. Future experiments will explore the contribution of different brain regions receiving glutamatergic projection from the PrL cortex that may be involved in attenuation of relapse.

Title: The effect of chemogenetic activation of the prelimbic cortex on relapse to cocaine-seeking: A potential role for glutamatergic pathway specificity

Authors: *B. M. SIEMSEN, G. GIANNOTTI, C. J. HU, J. A. MCFADDIN, J. F. MCGINTY
Med. Univ. of South Carolina, Charleston, SC

Abstract: Cocaine self-administration (SA) in rats transiently decreases phospho-ERK2, GluN2A/B- containing NMDA receptors, and activates striatal-enriched protein tyrosine phosphatase (STEP) within the prelimbic (PrL) cortex during early abstinence, suggesting a hypofrontal state. These neuroadaptations are critical for relapse to subsequent cocaine-seeking and are blocked by intra-PrL infusion of BDNF or the STEP inhibitor, TC-2153. Here we investigated the effect of activating the PrL cortex during early abstinence on relapse to cocaine-seeking using Designer Receptors Exclusively Activated by Designer Drugs (DREADDs). We hypothesized that chemogenetic activation of the PrL cortex immediately after the final SA session would prevent relapse to cocaine-seeking by normalizing the PrL cortical disturbance in phospho-proteins during early abstinence. Rats received chronic indwelling intravenous catheters followed by intra-PrL microinjections of an AAV5 encoding the excitatory DREADD hM3Dq driven by the CaMKIIα promoter (AAV5-CaMKIIα-hM3Dq-mCherry) or the control eGFP vector (UNC vector core, 0.75 µl/side; *n*=10/group), and were trained to self-administer cocaine (0.2 mg/infusion) for 12-14 days (2 hr/day) on an FR1 schedule of reinforcement. Immediately following the final session, rats were injected with CNO (3 mg/kg; i.p.) followed by 6 days of forced abstinence, a post-abstinence (PA) relapse test under extinction conditions, further extinction to criterion, a cue-induced reinstatement test, re-extinction, and a cocaine prime-induced reinstatement test. Contrary to our hypothesis, chemogenetic activation of the PrL cortex had a marginal effect on suppressing active lever pressing during the PA test and had no effect on cued or cocaine prime-induced reinstatement. This overall lack of effect on cocaine-seeking may be due to the recruitment of opposing projections arising from the PrL cortex, such that

activation of specific pathways may accentuate relapse, while simultaneous activation of alternative pathways may suppress relapse. In support of this hypothesis, preliminary data indicate that activation of the PrL cortex-nucleus accumbens core (NAc core) glutamatergic pathway during early abstinence using an intra-NAc core infusion of the retrogradely-transported CAV2-Cre in combination with an intra-PrL cortical floxed DREADD potentiates PA context-induced relapse and cue-induced reinstatement, but not cocaine prime-induced reinstatement. Future experiments will further dissect the effect of activating alternative pathways arising from the PrL cortex in cocaine-seeking after abstinence.

Title: Activation of amylin receptors in the nucleus accumbens reduces cocaine taking and seeking in rats

Authors: *Y. ZHANG, C. A. TURNER, H. D. SCHMIDT
Biobehavioral Hlth. Sci., Univ. of Pennsylvania, Philadelphia, PA

Abstract: Amylin is a peptide hormone co-secreted with insulin from pancreatic β-cells. Amylin crosses the blood brain barrier and activates amylin receptors expressed throughout the brain, including the mesolimbic dopamine system. Interestingly, there is a high density of amylin receptor binding sites in the nucleus accumbens (NAc), a brain region known to play a critical role in motivated behaviors. Central amylin signaling has been shown to regulate food intake. Specifically, activation of amylin receptors in the mesolimbic dopamine system has been shown to reduce the hedonic value of food. Given that the reinforcing effects of natural rewards and drugs of abuse are regulated by the mesolimbic dopamine system, these findings suggest that central amylin signaling may play an important role in addiction-like behaviors. The goal of these studies was to determine the role of amylin receptors expressed in the nucleus accumbens (NAc) shell and core in voluntary cocaine taking and the reinstatement of cocaine-seeking behavior. Using a within-subjects, counterbalanced design, amylin (0, 0.04, and 0.4 μg/μl) was administered directly into the NAc shell or core prior to self-administration and reinstatement test sessions. Our results show that intra-NAc shell amylin reduced cocaine self-administration under a fixed ratio 5 (FR5) schedule. In addition, amylin (0.4 μg/μl) in the NAc shell and core

attenuated cocaine reinstatement in rats. To determine whether the effects of amylin in the NAc generalize to other non-drug reinforced behaviors, separate groups of rats were used to study the role of central amylin receptors in operant responding for sucrose pellets. Our results indicate that administration of amylin directly into the NAc shell and core did not alter sucrose self-administration in either *ad libitum* fed or food-restricted rats. Taken together, these findings demonstrate an important role for central amylin receptors in preclinical models of cocaine addiction.

Title: Intermittent cocaine self-administration induces strong potentiation of incubation of cocaine craving in female rats

Authors: *C. NICOLAS, A. PIERCE, Y. SHAHAM, S. IKEMOTO
Behavioral Neurosci. Res. Br., Natl. Inst. On Drug Abuse-Irp, Baltimore, MD

Abstract: Cocaine seeking progressively increases during abstinence, a phenomenon termed 'incubation of cocaine craving'. Incubation of cocaine craving has been demonstrated after limited (2-h daily sessions) or extended access (6-h daily sessions) continuous cocaine self-administration. Recently, Zimmer et al. (NPP 2012) introduced an intermittent access self-administration procedure in which rats have access to cocaine for 5 min every 25 min during the daily sessions. They showed that this procedure increases the motivation to self-administration cocaine. Here, we studied whether intermittent cocaine self-administration will increase incubation of cocaine craving.
We first trained female rats to self-administer cocaine (0.75 mg/kg/infusion) continuously or intermittently for 12 days for 8-h/day, then assessed drug seeking in relapse tests after 2 or 29 abstinence days. During testing, lever presses were not reinforced with cocaine (extinction conditions). We found escalation of cocaine self-administration over 12-day drug sessions and higher non-reinforced lever presses after 29 abstinence days than after 2 days (incubation of cocaine craving) under both training conditions. More importantly, prior intermittent access cocaine self-administration led to significant increases in drug seeking on both day 2 and 29 and overall significant potentiation of incubation of cocaine craving (a significant interaction of access condition x abstinence day).
Our results extend previous reports showing that intermittent cocaine access increases the

motivation to seek cocaine by demonstrating that this training condition also causes potentiation of incubation of cocaine craving.

Title: Oxytocin infused into the nucleus accumbens core decreases cocaine seeking and increases extracellular glutamate

Authors: C. N. LOGAN[1], R. WEBER[4], J. PERIS[2], K.-C. LEONG[5], L. A. KNACKSTEDT[3], *C. M. REICHEL[6]
[1]Psychology Dept., [2]Dept. of Pharmacodynamics, [3]Psychology, Univ. of Florida, Gainesville, FL; [4]Dept. of Neurosciences, [5]Dept. Of Neurosciences, [6]Neurosciences, Med. Univ. of South Carolina, Charleston, SC

Abstract: Multiple neuropsychiatric disorders, including addiction, may benefit from oxytocin treatment. Oxytocin effectively reduces reinstated drug seeking in male and female rats. However, the underlying mechanisms of this effect have not been identified. It is well-established that glutamatergic synaptic transmission in the nucleus accumbens core (NAc) is dysregulated following cocaine self-administration. Here we suggest that oxytocin regulates activity of presynaptic glutamate terminals in the NAc. Male and female (Sprague-Dawley) rats self-administered cocaine, underwent extinction training, and were tested for cued cocaine seeking. During cued reinstatement, responses on the drug-associated lever resulted in a presentation of the light+tone stimulus complex originally associated with cocaine delivery. Before testing, rats received oxytocin or saline directly into the NAc or PFC. Some rats also received the mGlu2/3 receptor antagonist LY341495 or saline in the NAc before oxytocin. All rats readily acquired cocaine self-administration, and the majority met extinction criteria during the 8 extinction sessions. Oxytocin directly into the PFC did not impact lever responding for cocaine-conditioned cues relative to vehicle infusions. However, NAc oxytocin markedly decreased cued reinstatement and LY379268 in NAc reversed this effect. We hypothesize that oxytocin exerts these effects in the NAc through increases in extracellular glutamate levels thereby restoring tone on presynaptic glutamate terminals and decreasing cued reinstatement. To

begin to test this hypothesis, cocaine-naïve rats underwent reverse dialysis of 3.6 mM oxytocin in the NAc. The efflux was collected at 5 min intervals and glutamate content was quantified via HPLC. We detected a significant increase in extracellular glutamate following reverse dialysis of oxytocin. Together, our results show: 1) oxytocin increases NAc glutamate, 2) NAc oxytocin attenuates cued reinstatement, and 3) mGlu2/3 antagonism reverses oxytocin's effect. The precise mechanism by which oxytocin increased NAc glutamate is yet to be determined. One possibility is that oxytocin receptors on astrocytes in the NAc may increase astrocytic glutamate release through a Gq signaling mechanism to restore tone on presynaptic mGlu2/3 receptors. Another possibility is that oxytocin receptors may reside on presynaptic glutamate neurons in the NAc to directly regulate glutamate release. Future studies will target cell-type specificity of the oxytocin receptor to determine the source of increased glutamate and will determine whether NAc oxytocin increases glutamate in animals with a cocaine history.

Title: Opposite effects of BLA inactivation on context-induced relapse to cocaine seeking after suppression of drug self-administration by extinction versus punishment

Authors: *A. M. MINIER-TORIBIO, J. BOSSERT, Y. SHAHAM, Y. PELLOUX
Behavioral Neurosci. Br., NIH/NIDA/IRP, Baltimore, MD

Abstract: Background: Studies using the classical renewal procedure showed that basolateral amygdala (BLA) inactivation reduces context-induced relapse to cocaine seeking after extinction of the drug-reinforced responding. Here, we determined whether BLA inactivation would also inhibit context-induced relapse in a variation of the renewal procedure in which intermittent punishment suppresses drug-taking behavior, an animal model of human relapse after self-imposed abstinence due to adverse consequences of drug use. **Methods**: We trained rats to self-administer cocaine for 12 days for 6 h/day and then exposed them to either extinction or punishment training in context B (8 days). During punishment, 50% of cocaine-reinforced lever presses caused an aversive footshock; we increased the shock intensity daily by 0.1 mA from 0 mA to 0.7 mA. We then tested the rats for cocaine seeking in the absence of cocaine or shock in contexts A and B after BLA injections of vehicle or GABA agonists (muscimol+baclofen). Next,

we retrained the rats for cocaine self-administration in context A, reexposed them to the punishment or extinction conditions in context B, and retested for context-induced relapse after BLA vehicle or muscimol+baclofen injections. **Results**: BLA inactivation decreased context-induced relapse in context A after extinction in context B. In contrast, BLA inactivation increased context-induced relapse in context A after punishment in context B and provoked relapse in context B. **Conclusion**: Results demonstrate that BLA's role in drug relapse is critically dependent on the method used to achieve abstinence, highlighting the importance of studying drug relapse under abstinence conditions that more closely mimic the human condition.

Title: Pavlovian extinction and ceftriaxone differentially attenuate context- versus cue-primed cocaine relapse

Authors: *L. A. KNACKSTEDT, Y. PADOVAN HERNANDEZ, A. BECHARD
Psychology, Univ. of Florida, Gainesville, FL

Abstract: Relapse prevention is a significant challenge in the treatment of cocaine addiction, and no effective pharmacotherapies are currently available. Drug-associated cues maintain conditioned reinforcing properties that can trigger craving, leading to relapse. In human addicts, cue exposure therapy, which consists of repeated non-reinforced presentations of drug-associated cues, is used in an effort to reduce the association between cues and drug intake. Using an animal model, we sought to assess the effects of cue exposure therapy (Pavlovian extinction) in conjunction with ceftriaxone, an antibiotic that has previously been used to successfully attenuate relapse. Male Sprague-Dawley rats were trained to self-administer intravenous cocaine in the presence of discrete cues (light and tone). After 12 days of self-administration, rats entered a 3-week period of abstinence (remained in the home cage with daily handling). Half of the rats experienced Pavlovian extinction of drug-associated cues during the third week of abstinence (1h/day for 6 days). Rats were placed into a novel context and received 30 non-contingent presentations of the light and tone previously paired with cocaine delivery. During this time, rats were treated with ceftriaxone (200 mg/kg) or vehicle (saline). After 21 days of abstinence, rats underwent a context-primed test of relapse (no light or tone), and 24h later, a cue-primed test of

relapse. We found that, following Pavlovian extinction, ceftriaxone attenuated cue-primed relapse, but not context-primed relapse. To investigate the underlying circuitry involved in context- and cue-primed relapse after cue exposure therapy and how ceftriaxone interacts with this circuitry, in a separate group of rats we assessed the ability of ceftriaxone to reduce neuronal activation during cue vs. context primed relapse using cfos staining. Preliminary results suggest differential activation of brain regions involved in relapse induced by context versus discrete cues.

Title: Tetrahydroisoquinoline orexin-1 receptor antagonists with improved drug-like properties

Authors: *Y. ZHANG, D. A. PERREY, A. M. DECKER, T. LANGSTON
Res. Triangle Inst., Research Triangle Park, NC

Abstract: Accumulating evidence has confirmed the involvement of the orexin system, particularly the orexin-1 (OX1) receptor, in different stages of the addiction of a variety of drugs. Blockade of the OX1R attenuated motivated drug seeking behaviors of cocaine, as well as ethanol and nicotine self-administration and reinstatement. We have recently reported a series of OX1 selective antagonists based on the tetrahydroisoquinoline scaffold, and in the process identified several structural features that enhance both potency and selectivity of OX1 over OX2. Here we describe the design and synthesis of a series of new analogs that incorporate these favorable structural features at multiple positions as well as structural alterations that may lead to improved physiochemical and pharmacokinetic properties.
All synthesized compounds were characterized by MS, NMR and HPLC, and then evaluated in calcium mobilization functional assays in RD-HGA16 (Molecular Devices) cell lines stably expressing either the OX1 or OX2 receptor. The structural alterations have resulted in tetrahydroisoquinoline derivatives showing potent and selective antagonism of OX1R, several of which had Ke < 10 nM. Moreover, efforts to improve the pharmacokinetic properties led to analogs with clogP values in the 3-4 range. These compounds showed much-improved aqueous solubility, good permeability, and modest half-life. These efforts will facilitate the development

of selective OX1 antagonists as therapeutics for drug addiction and other OX1 receptor mediated conditions.

Title: Orexin A in the posterior paraventricular nucleus of the thalamus: promotion of reward seeking behavior and hypothalamic activation

Authors: *A. MATZEU[1], R. MARTIN-FARDON[2]
[1]Scripps Res. Inst., La Jolla, CA; [2]The Scripps Res. Inst., La Jolla, CA

Abstract: Orexin (Orx) neurons that arise from the dorsal hypothalamus and direct their signal to the paraventricular nucleus of the thalamus (PVT) have received growing interest as a part of reward circuitry. When injected in the posterior part of the PVT (pPVT), Orx-A reinstates (primes) cocaine-seeking behavior as well as a highly palatable food reinforcer after intermediate abstinence (Int-Abst). We previously reported that Orx-A administration in the PVT reinstated extinguished cocaine-seeking behavior in animals with short access (ShA) to cocaine (2 h/day) or long access (LgA) to cocaine (6 h/day; i.e., a model of cocaine dependence) as well as sweetened condensed milk (SCM) seeking. However, intra-PVT administration of Orx-A induced stronger reinstatement in the LgA group than in the ShA and SCM groups, which was associated with strong Fos activation and a significant increase in Orx^+/Fos^+ expression in the dorsomedial hypothalamus (DMH), perifornical area (PFA), and lateral hypothalamus (LH). Considering the long-lasting nature of drug-seeking behavior, the present study examined (1) whether the increase in Orx-A's priming effect endures after a longer period of abstinence and (2) whether this is associated with significant hypothalamic activation. Male Wistar rats were trained to self-administer cocaine ShA, cocaine LgA or SCM for 21 days. After training, the animals were subjected to protracted abstinence (Pro-Abst) that consisted of 14 days in the vivarium followed by extinction training for 14-21 days (2 h/day), during which the reinforcers were withheld. Once the animals' behavior was extinguished, they received intra-pPVT microinjections of Orx-A (0.5 µg) or vehicle and then were placed in operant chambers under

extinction conditions for 2 h. Immediately following the behavioral tests, the animals were euthanized, and their brains prepared for Fos and Orx immunolabeling in the LH, DMH, and PFA. In contrast to what was measured following Int-Abst, Orx-A did not reinstate cocaine-seeking behavior in the LgA group, but it exerted an augmented priming effect in the ShA and SCM groups, suggesting “incubation” of the priming effect of Orx-A in ShA and SCM animals but not in LgA animals. In parallel, strong brain activation (Fos^+ neurons) and a significant increase in Orx^+/Fos^+ expression were observed in the DMH, PFA, and LH in the SCM and ShA groups only. These data suggest that the functionality of Orx receptors and connectivity of the PVT□1DMH/PFA/LH circuit undergo significant neuroadaptation following Pro-Abst.

Title: Dynorphin counteracts orexin in the posterior paraventricular nucleus of the thalamus: cellular and behavioral evidence

Authors: *R. MARTIN-FARDON, M. KALLUPI, O. GEORGE, P. SCHWEITZER, A. MATZEU
Neurosci., Scripps Res. Inst. SP30-2003, La Jolla, CA

Abstract: The orexin (Orx) system is known to play a critical role in drug addiction and reward-related behaviors. The dynorphin (Dyn) system promotes depressive-like behavior and plays a key role in the aversive effects of stress. Both Orx and Dyn are co-released and have opposing functions in reward and motivation in the ventral tegmental area (VTA). Earlier studies from this laboratory showed that microinjections of OrxA in the posterior paraventricular nucleus of the thalamus (pPVT) exerted priming-like effects and reinstated cocaine-seeking behavior, suggesting that Orx transmission in the pPVT participates in cocaine-seeking behavior. The present study tested the hypothesis that Orx and Dyn interact in the pPVT and are involved in

controlling reward-seeking behavior. Using a cellular approach, brain slices from naive adult Wistar male rats were prepared for whole-cell recordings to study excitatory transmission in pPVT neurons. The superfusion of OrxA increased spontaneous glutamatergic transmission by increasing glutamate release onto pPVT neurons, whereas DynA decreased glutamate release. The augmentation of OrxA-induced glutamate release was reversed by DynA. To support the electrophysiological data, the influence of the OrxA-DynA interaction in the pPVT on seeking behavior was studied in animals that self-administered cocaine or a high palatable food reinforcer. Separate groups of male Wistar rats were trained to self-administer cocaine or sweetened condensed milk (SCM). After self-administration training, the rats underwent extinction training and then received intra-pPVT administration of OrxA±DynA under extinction conditions. OrxA reinstated cocaine- and SCM-seeking behavior, with a greater effect in cocaine animals. DynA selectively blocked OrxA-induced cocaine seeking *vs.* SCM seeking, whereas DynA alone did not exert any relevant behavioral effect in either group. These data indicate that DynA in the pPVT counteracts OrxA-induced cocaine seeking, perhaps by reversing the OrxA-induced increase in glutamate release, thus identifying a potential novel therapeutic target to prevent cocaine relapse.

Title: Glucagon-like peptide-1 receptor activation in the lateral dorsal tegmental nucleus attenuates cocaine seeking in rats

Authors: *N. S. HERNANDEZ, V. R. WEIR, C. A. TURNER, H. D. SCHMIDT
Univ. of Pennsylvania, Philadelphia, PA

Abstract: Cocaine addiction is a major public health concern for which there are no FDA-approved pharmacotherapies. Thus, new conceptual approaches to understanding the neurobiological basis of cocaine addiction are needed. Recent studies show that glucagon-like peptide-1 (GLP-1) receptor ligands reduce cocaine-mediated behaviors in rodents. GLP-1 is a

neuropeptide that is produced centrally in the nucleus tractus solitarius (NTS) of the caudal brainstem. However, no studies have examined the role of hindbrain GLP-1 receptors (GLP-1Rs) in the reinstatement of cocaine-seeking behavior, an animal model of relapse. Given that the lateral dorsal tegmental nucleus (LDTg): [1] plays a critical role in cocaine seeking, [2] expresses GLP-1Rs, and [3] receives direct projections from the NTS, the present study tested the hypothesis that GLP-1R signaling in the LDTg plays a critical role in cocaine seeking. Our preliminary data show that peripheral administration of the fluorescent GLP-1R agonist fluoro-exendin-4 (3.0 µg/kg i.p.) penetrates the brain, localizes in the LDTg and attenuates cocaine seeking. Therefore, we examined the effects of LDTg GLP-1R activation on cocaine reinstatement. Initially, rats were allowed to self-administer cocaine (0.25 mg/infusion i.v.) for 21 days on a fixed-ratio 5 schedule of reinforcement. Cocaine self-administration was then extinguished by replacing cocaine with saline. Once cocaine taking was extinguished, rats received an acute priming injection of cocaine (10 mg/kg i.p.) to reinstate drug-seeking behavior. During subsequent reinstatement test sessions, rats were pretreated with intra-LDTg infusions of the GLP-1R agonist exendin-4 (0, 0.005 and 0.025 µg) prior to a priming injection of cocaine. Here, we show that the 0.025 µg dose of exendin-4 attenuated cocaine priming-induced reinstatement. Parallel studies examining the effects of intra-LDTg exendin-4 on the reinstatement of sucrose seeking were conducted, which showed that 0.025 µg of intra-LDTg exendin-4 attenuated sucrose seeking. To assess the effects of cocaine self-administration and subsequent abstinence on endogenous central GLP-1 receptor signaling, LDTg GLP-1R and NTS preproglucagon (PPG; GLP-1 precursor) mRNA were collected following 1 day (Ext1) and 7 days (Ext7) of extinction. Using quantitative real-time PCR, we found that there were no changes in GLP-1R expression on Ext1 or Ext7 compared to yoked saline controls. However, we found a significant decrease in PPG expression levels on Ext7, which suggests a decrease in GLP-1 signaling in forebrain areas. Overall, these results highlight a novel role for hindbrain GLP-1R signaling in cocaine seeking.

Title: Nr4a2 in the medial habenula is a molecular regulator of cocaine reinstatement behaviors

Authors: *A. J. LOPEZ, P. H. HWANG, O. CHITNES, R. R. CAMPBELL, J. L. KWAPIS, Y. ALAGHBAND, T. HEMSTEDT, D. P. MATHEOS, M. A. WOOD
Dept. of Neurobio & Behavior; Ctr. for the Neurobio. of Learning & Memory, Univ. of California Irvine Dept. of Neurobio. and Behavior, Irvine, CA

Abstract: The habenula complex is an epithalamic region composed of lateral and medial (MHb) substructures. Mounting evidence has demonstrated that the MHb is able to code for the aversive properties of nicotine, serving as a substrate for nicotine withdrawal and aversion through the dense expression of nicotinic acetylcholine receptors along the MHb-interpeduncular nucleus pathway. Although typically characterized as an “anti-reward” pathway, the endogenous function of the MHb has yet to be fully characterized. Moreover, the role of this pathway with regard to other drugs of abuse remains particularly unclear. Work from our lab and others has demonstrated that the MHb is engaged by reinstatement of cocaine-associated behaviors. Our initial studies demonstrated that chemogenetic activation of the cholinergic MHb population is able to induce reinstatement of cocaine-induced CPP. Yet, the molecular mechanisms within the MHb that are altered leading up, and in response, to reinstatement of cocaine behaviors are unknown. *Nr4a2*, a transcription factor critical in cocaine-associated behaviors and known regulator of dopaminergic signaling, is enriched in the cholinergic cell-population of the MHb. Furthermore, *Nr4a2* has been shown to be necessary for MHb development, but its role within the MHb in the adult brain remains elusive, specifically, given the lack of dopaminergic neurons within the MHb. We hypothesize that *Nr4a2* may mediate changes to the epigenome to changes in circuit function within the MHb to drive relapse-like behavior. Here, we seek to characterize the role of the Nr4a2 within the MHb in driving reinstatement of cocaine-induced CPP. To that end, we overexpressed Cre-dependent NR4A2, NURR2C (an endogenously-occurring, dominant-negative variant of NR4A2), or Empty Vector into the MHb of ChAT-Cre mice. Following viral delivery, animals underwent a previously described cocaine-primed CPP Reinstatement protocol to determine if NR4A2 within the MHb is necessary and sufficient for cocaine-reinstatement behaviors. As substance use disorders are a chronic relapsing disease, understanding the molecular and circuit mechanisms that regulate the relapse response will be critical in developing future therapies. This work seeks to identify a novel molecular regulator of MHb circuit function in a cocaine relapse-like behavior and will more completely characterize the role of MHb in drug-associated behaviors.

Title: A neural pathway mediating acupuncture effect on addiction: LHb-VTA/RMTg pathway

Authors: *S. CHANG[1], Y.-H. RYU[2], K. SONG[1], J. SHIN[1], M. KO[1], E. JANG[1], C. YANG[1], H. KIM[1]
[1]Daegu Haany Univ., Suseong-Gu Daegu, Korea, Republic of; [2]Acupuncture, Moxibustion& Meridian Res. Center, Div. of Standard Research, Korea Inst. of Oriental Medicine,, Daejeon, Korea, Republic of

Abstract: Over the last four decades, public and scientific interest is increasing in acupuncture as an approach for treatment of drug addiction around the world We have shown that acupuncture activates endorphinergic input to mesolimbic dopaminergic (DA) system including VTA (Ventral Tegmental Area) or NAc (Nucleus Accumbens) to suppress the reduced DA levels in the NAc during ethanol abstinence, thereby reducing behavioral withdrawal signs. In addition, we have proposed a peripheral mechanism that the effects of acupuncture at HT7 on addiction are mediated by A-fiber activation of ulnar nerve at the wrist. However, the central pathway between peripheral acupuncture signals and mesolimbic reward circuit remains to be explored. Lateral habenula (LHb), a key epithalamic structure interconnecting sensory inputs to mesolimbic DA systems, is involved in processing of both peripheral sensory inputs (i.e., acupuncture) and reward and rostromedial tegmental nucleus (RMTg), the tail of VTA,mediates strong inhibitionof VTA activity and receives afferents neurons from the LHb. Based on these observations, we hypothesized that the LHb-RMTg circuit is involved in the inhibitory effects of acupuncture on addiction behaviors and DA release in NAc.
To test it, we examined(1) whether acupuncture stimulation inhibited cocaine-induced locomotor activity and the effects were blocked after lesioning LHb in rats, (2) the response of LHb activity following the acupuncture stimulation, (3) if an inhibitory effect by acupuncture on cocaine-induced both activation of NAc and DA release was affected by lesion of RMTg.
Bilateral lesions of either LHb or RMTg prevented the inhibitory effects of acupuncture

stimulation on the NAc neuronal activity and DA release following cocaine treatment. LHb neurons projecting to the VTA/RMTg regions, including GABAnergic neurons, were excited by acupuncture stimulation and LHb lesions reversed the acupuncture effects on cocaine locomotion. Taken together, these findings suggest that LHb-VTA/RMTg pathway is crucially involved in the acupuncture effect on the psychomotor response to cocaine.

Title: Corticostriatal circuit representations of the incubation of cocaine craving in rats

Authors: *N. E. ZLEBNIK[1], J. F. CHEER[2,3,4]
[2]Anat. and Neurobio., [3]Psychiatry, [4]Program in Neurosci., [1]Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract: Relapse to drug use is often preceded and accompanied by robust craving elicited by drug-paired cues and environments, and reports suggest drug craving or drug seeking progressively increases over a prolonged abstinence period. This “incubation” of drug seeking is linked to adaptations in brain circuits that are theorized to promote vulnerability to relapse. In particular, the nucleus accumbens (NAc) is a locus of convergence for motivationally relevant information from limbic and cortical (e.g., medial prefrontal cortex, mPFC) regions. However, the precise mechanisms of mPFC-NAc network encoding of cocaine cues and cocaine seeking in behaving animals are unknown. Simultaneous in vivo mPFC and NAc electrophysiological recordings demonstrate that incubation of craving is accompanied by amplified cue-evoked network oscillations in the mPFC and NAc as well as increased functional mPFC-NAc coherence. Importantly, cocaine seeking and these neural correlates are diminished following cell-type specific chemogenetic inactivation of mPFC to NAc projections. These findings suggest that progressive adaptations in the mPFC-NAc network may underlie cue-elicited cocaine craving and susceptibility to relapse after prolonged abstinence. These findings are likely to improve our potential to predict relapse vulnerability and to identify effective pharmacological and behavioral therapies.

Title: Activity-guided inhibition of the infralimbic cortex reveals a critical temporal window in the extinction of cue-driven cocaine seeking

Authors: *K. NETT[1], A. L. GUTMAN[1], R. T. LALUMIERE[2]
[1]Psychological and Brain Sci., [2]Dept Psych, Univ. of Iowa, Iowa City, IA

Abstract: Prior evidence indicates that the medial prefrontal cortex regulates cocaine-seeking behavior. In particular, studies suggest that the ventral portion of this region, known as the infralimbic cortex (IL), mediates the inhibition of cocaine seeking. However, the precise temporal relationship among IL activity, lever pressing, and the extinction of cocaine seeking remains unclear. To address this issue, we used an activity-guided "closed-loop" optogenetic approach in which IL activity was silenced during specific periods of reinstatement testing. Male Sprague-Dawley rats received bilateral injections of AAV-CaMKIIα-eArchT3.0 into the IL and bilateral fiber optic probes aimed at the IL. They then underwent two weeks of daily 2 h cocaine self-administration sessions, in which active lever presses produced a cocaine infusion (200 μg/infusion), light/tone cues, and retraction of the lever for 20 s. Following this, rats underwent extinction training, in which active lever presses yielded no cocaine or cues but still led to lever retraction, prior to initiating reinstatement testing (cued and cocaine-primed). During reinstatement, active lever presses resulted in a 20 s lever retraction and bilateral illumination of the IL for 20 s to produce temporally restricted inhibition of IL activity. Each rat underwent reinstatement twice, receiving illumination or no light (sham-control) in a counterbalanced manner, with re-extinction between each reinstatement. The results indicate that IL inhibition after a lever press significantly increased active lever pressing during the cued reinstatement session, suggesting that the inhibition disrupted the within-session cued extinction encoding. In contrast, IL inhibition after each lever press during a cocaine-primed reinstatement had no effect on lever pressing during the session. Finally, to determine whether the post-lever press period was critical for the within-session extinction encoding during cued reinstatement, a separate cohort of rats underwent cued reinstatement but received the 20 s bouts of IL inhibition in a pseudo-random manner that was unrelated to the lever pressing. In this case, inhibition had no effect on active lever presses during the session. These findings suggest that the 20 s period following a lever press during cue-driven cocaine seeking reflects a critical window during

which IL activity encodes the new contingencies between the cues and lack of a cocaine reinforcer.

Title: Limbic projections to the claustrum in the rhesus monkey (Macaca mulatta)

Authors: *J. T. JACOBS, M. GORSICH, M. MISHKIN, R. C. SAUNDERS
Lab. of Neuropsychology, NIMH/NIH, Bethesda, MD

Abstract: The claustrum is a subcortical grey matter structure situated lateral to the striatum and medial to the insula within the primate brain. Little is known about its function, with theories ranging from sensory integration to direction of attentional resources. Though many studies have confirmed claustral connectivity with all sensory cortical areas, relatively little is known about its connectivity with limbic regions. A better understanding of limbic projections to the claustrum might provide insight into its function. To examine limbic inputs into the claustrum we injected retrograde tracers into various dorsal-ventral (DV) and rostral-caudal (RC) locations within the claustrum. We also injected anterograde tracers into several limbic areas (amygadala, cingulate cortex, and rhinal cortex) to confirm and extend the findings of the retrograde injections. Retrograde labeled cells were found in all limbic regions except for the hippocampus. Cingulate area 24 displayed dense labeling in deep and superficial layers after rostral injections, and moderate labeling after caudal injections. In contrast, there were fewer labeled cells in area 25. In all cases enthorhinal cortex, area 28, exhibited a moderate degree of labeling limited to deep layers. Areas 35 and 36 of the perirhinal cortex had a greater density of labeled cells in both the deep and superficial layers. In the amygdala, labeling was generally denser following ventral injections, however the lateral basal nucleus showed dense labeling in all cases. Moderate to dense labeling was present in the accessory basal, central, and medial nuclei after rostral to mid-RC injections, while caudal injections resulted scarcer label. In contrast, the lateral nucleus had a moderate to high degree of labeling after injections into the mid-RC to caudal claustrum, but not after rostral injections. The hippocampus did not exhibit labeling in any of the retrograde cases. Cortical anterograde tracer injections supported the retrograde findings. Cingulate injections resulted in moderate labeling throughout the claustrum, especially in the mid-DV to ventral regions with the density of label decreasing in caudal sections. After injections into the perirhinal cortex labeling was moderate in caudal sections and limited to the ventral region. Entorhinal injections resulted in labeling of the mid-DV to ventral claustrum predominantly at the mid-RC

to rostral levels. Amygdala injections led to a moderate amount of labeling, mainly in the caudal ventral claustrum but also in the mid-DV claustrum. These findings suggest that the claustrum serves as a point of convergence for both sensory and limbic information.

Title: Functional and metabolic connectivity of the awake and anesthetized primate brain

Authors: A. B. MCMILLAN[1], A. Z. RAJALA[2], S. A. HURLEY[2], B. J. STIEVE[2], R. L. JENISON[3], R. M. BIRN[4], *L. C. POPULIN[2]

Abstract: Functional connectivity, correlated fluctuations of the BOLD signal, is thought to reflect an evolutionarily conserved aspect of the functional organization of the brain, as they are observed under awake and anesthetized conditions. As a fundamental measure of brain organization that, as postulated, transcends levels of consciousness, it should remain unaltered under different physiological states. We tested this hypothesis directly using Rhesus monkeys imaged awake and anesthetized within the same sessions.
Because most of the energy consumed by the brain is used to maintain essential metabolic processes, i.e., the basic functional organization of the brain, we simultaneously measured metabolic activity using 18F-FDG along with the BOLD signal. We hypothesized that both measures should remain unaltered by the administration of ketamine (Ket).
Three monkeys were trained to sit quietly during imaging. Four 13.5 min runs of PET/MR data were obtained; the 1st and 2nd under awake conditions, and the 3rd and 4th after injection of 4 and 2 mg/kg of Ket (IV), respectively. Imaging was performed on a GE 3T Signa PET/MR scanner. fMRI parameters were: 1.8s TR, 20.5ms TE. During fMRI, 18F-FDG was infused at a rate of 0.01 mL/s (~3.5 mCi/scan). Data analysis for fMRI used a seed-based approach with field-map correction, motion correction, bandpass filtering, and smoothing. PET was reconstructed from list mode data with 30s frame duration using an iterative, time-of-flight reconstruction. Dynamic PET (dPET) data were processed like the fMRI data (motion correction, global brain signal, and smoothing). Seed-based resting connectivity correlation analysis was

performed in both fMRI and dPET data to identify networks. Effective connectivity between regions was assessed using time-domain conditional Granger causality (CGC) based on a state-space model. The magnitude of each conditional pair-wise CGC between network nodes was tested using nonparametric permutation tests corrected for multiple hypotheses.
Both fMRI and dPET analysis identified a similar fronto-parietal network (FPN). CGC analyses demonstrated significant directional flow between brain regions (nodes) of the FPN in the awake state. Administration of Ket produced a large and significant disruption in fMRI, dPET, and CGC connectivity measures, indicating that these networks are not maintained across different physiological states.

Title: Innervation differences of layer 5a and 5b Martinotti cells in frontal cortex

Authors: *Y. KAWAGUCHI, M. MORISHIMA
Natl. Inst. Physiol Sci., Okazaki, Japan

Abstract: Martinotti cells (MCs) are one of the major GABAergic cell subtypes in the neocortex, and express somatostatin. Their ascending axons innervate mainly dendrites of pyramidal cells. In layer 5 (L5), some somatostatin MCs exhibit calcium-dependent low-threshold spikes (LTS-MCs). In the rat frontal cortex, L5 is composed of the upper (L5a) and lower (L5b) sublayers. L5b receives more robust input from thalamocortical fibers than L5a. The major subtype of L5 PCs is corticopontine (CPn) cells that project to the striatum of basal ganglia and the pontine nuclei innervating the cerebellum. CPn cells in L5a more preferentially send their axons to other cortical areas than L5b, whereas L5b CPn cells more to the spinal cord. These suggest that their inhibitions from Martinotti cells may be also different within the L5 sublayers. Therefore, we compared the connections with CPn cells and axonal arborization of L5a and L5b LTS-MCs, using in vitro whole cell recording and morphological reconstruction of recorded cells in rat frontal cortex. Both L5a and L5b CPn cells were innervated by LTS-MCs,

and IPSC amplitudes were similar between the sublayers. However, the reciprocal connections were more found in L5a than L5b. LTS-MC axon densities in layer 1 (L1), another thalamocortical-recipient zone, preferentially arose from L5a LTS-MCs. The spatial overlap of CPn cell dendrites and LTS-MC axons suggest that L5a LTS-MCs innervate not only basal and apical oblique dendrites of CPn cells, but also their dendritic tufts within L1. On the other hand, L5b LTS-MC axons target more selectively the basal and oblique dendrites of CPn cells. These results suggest that LTS-MCs innervating CPn cells are further differentiated according to the L5 sublayers and L1 innervation pattern, related to the thalamocortical inputs. Abstract: Gigantopyramidal neurons, referred to as Betz cells in primates, were first identified in the primary motor cortex by Betz in 1874 and are characterized by large somata and extensive

basilar dendrites (Lewis, 1878). Although there have been morphological descriptions and drawings of gigantopyramidal neurons in a limited number of species, quantitative analyses have typically been limited to measures of soma size. The current study thus quantitatively investigated gigantopyramidal neurons in the primary motor cortex of 19 species across eight taxa: feliforms (caracal, clouded leopard, lion, mongoose, Siberian tiger), primates (baboon, golden tamarin, human, lemur), artiodactyls (blue wildebeest, giraffe, kudu), caniforms (African wild dog, domestic dog), perissodactyls (mountain zebra, plains zebra), a diprotodont marsupial (wallaby), a lagomorph (rabbit), and a murid rodent (rat). Of the 617 neurons traced, 181 were gigantopyramidal neurons; for comparative purposes, deep pyramidal (n = 203) and superficial pyramidal (n = 233) neurons were also quantified. Gigantopyramidal neurons were not identified in the wallaby, mongoose, rabbit, or rat. Qualitatively, dendritic morphology varied considerably across taxa, with both perissodactyls and artiodactyls exhibiting widely bifurcating, V-shaped apical dendrites. Quantitatively, most dendritic measures were significantly greater in gigantopyramidal neurons than in superficial and deep pyramidal neurons. Cluster analyses of dependent measures revealed that most taxa could generally be discriminated with a high degree of accuracy for both superficial and gigantopyramidal neurons. Finally, in agreement with Brodmann (1909), gigantopyramidal neurons were particularly large in feliforms, presumably due to specializations in muscle fibers and muscle coordination in this taxon.

Title: Utilizing 24(S)-hydroxycholesterol to identify patient populations and clinical endpoints: Negative emotion processing in Huntington's disease as proof of principle

Authors: *M. C. LEWIS[1], J. DAI[1], J. KENNEDY[1], B. BOROWSKI[2], A. MOHAN[2], S. TABRIZI[3], A. ROBICHAUD[1], J. DOHERTY[1], M. QUIRK[1]
[1]Sage Therapeut., Cambridge, MA; [2]CHDI, New York, NY; [3]Univ. Col. London, London, United Kingdom

Abstract: 24(S)-hydroxycholesterol (24(S)-HC) is an endogenous, brain specific, cholesterol metabolite that acts as a positive allosteric modulator of the N-methyl-D-aspartate (NMDA)

receptor. Alterations in plasma and/or brain levels of 24(S)-HC have been identified in several diseases, including Smith-Lemli-Opitz syndrome, Niemann Pick, Huntington's disease (HD), and some forms of dementia. Although a broad range of pathology and core symptomology is observed across these different disorders, all manifest some degree of behavioral and psychiatric symptoms. One important question to be addressed is whether 24(S)-HC is associated with these symptoms and, if so, which features are most directly associated with decreased glutamatergic tone. Cognitive deficits are a hallmark of HD, and can precede the onset of motor impairments by decades. One of the most consistent cognitive findings in HD are deficits in emotional face processing, which are present in both manifest and pre-manifest HD. Previous work has established that levels of 24(S)-HC are decreased in plasma and brain in HD patients, suggestive of decreased NMDA receptor function. Here, we investigated the relationship between 24(S)-HC and emotional face processing in samples from TRACK-HD, a longitudinal biomarker study of pre-manifest and early stage HD. Plasma samples from the TRACK-HD study (60 control; 60 Pre-HD; 60 HD) were analyzed for 24(S)-HC via liquid-liquid extraction and analyzed with LC-MS/MS. Regression analysis was then performed between oxysterol levels and performance on the Ekman and Friesen emotion recognition task. We find that 24(S)-HC levels are positively correlated with performance on an emotional face processing task that is not due to overall neurodegenerative processes. Importantly, we found no relationship between emotional face processing and other oxysterols (25- and 27-HC) suggesting a specific role for central nervous system derived 24(S)-HC. These data support a critical role for NMDA receptor function in negative emotion processing in HD, and identify emotion recognition as a potential clinical endpoint.

Title: A pharmacological characterization of novel oxysterol modulators of nmda receptors

Authors: *M. A. ACKLEY, A. ALTHAUS, M. C. QUIRK, G. MARTINEZ-BOTELLA, F. G. SALITURO, A. J. ROBICHAUD, J. J. DOHERTY
SAGE Therapeut., Cambridge, MA

Abstract: NMDA receptors (NMDA-R) are intimately involved in neuroplasticity and network activity of neuronal circuits and as such, represent targets of interest for drug development for CNS diseases. Positive modulators of NMDA-R are in development for their potential to alleviate cognitive deficits in diseases such as schizophrenia and dementia as well as in other areas of demonstrated NMDA hypofunction such as anti-NMDA encephalitis and neurodevelopmental disorders. We recently reported that the endogenous oxysterol, 24(S)-hydroxycholesterol (24(S)-HC) directly modulates the NMDA-R and positively impacts plasticity in the hippocampus (Paul *et al*, 2013). Subsequently, we have developed synthetic positive modulators of NMDA-R and two prototypical compounds demonstrated here are SGE-301 and SGE-550. We have previously characterized the electrophysiological properties of these novel positive allosteric modulators in heterologous cell lines expressing human NMDA-R in multiple electrophysiology platforms. Here we further characterize the subunit selectivity and demonstrate that SGE-550 displayed broad activity across all subunit combinations, whilst SGE-301 lacked activity at GluN2C subunits. We have also undertaken a series of mechanistic experiments to show a differential response for how these compounds affect glutamate, glycine and d-serine concentration-response curves at NMDA-R. For example, both SGE-301 and SGE-550 shifted the Glutamate and Glycine concentration-response curves to the left, so that the agonist appeared more potent. Both compounds increased the maximum current response to glutamate, but not to glycine. To understand the interaction of SGE-301 and the endogenous oxysterol, 24(S)-HC, we ran an occlusion experiment. In the presence of ascending concentrations of 24(S)-HC, the concentration response to SGE-301 was shifted to the right suggesting a competitive interaction at the putative oxysterol site on the receptor. Although we believe this oxysterol binding site to be distinct from the agonist sites, we chose to see if oxysterols could overcome the effect of competitive inhibitors at these sites. L-Phenyalanine has been shown to inhibit NMDA-R by acting as a glycine site antagonist. We confirmed that L-Phenylalanine inhibited NMDA-R and we could overcome this inhibition using SGE-550. Finally, oxysterols enhanced evoked NMDA post synaptic potentials in brain slices, confirming

their activity at native NMDA-R. The data presented further characterize the pharmacology of compounds the oxysterol class of NMDA-R modulators.

Title: Novel oxysterol NMDA receptor positive allosteric modulators exhibit diverse effects in an *In vitro* model of cortical network activity

Authors: *A. L. ALTHAUS, M. ACKLEY, M. QUIRK, G. MARTINEZ BOTELLA, F. SALITURO, A. ROBICHAUD, J. DOHERTY
Pharmacol., Sage Therapeut., Cambridge, MA

Abstract: 24(S)-hydroxycholesterol (24(S)-HC) is a potent endogenous NMDA receptor positive allosteric modulator (PAM). The NMDA receptor plays a critical role in neuronal excitability and plasticity. As a result, compounds that positively modulate current through the NMDA receptor might have therapeutic utility in conditions that are associated with NMDA receptor hypofunction. Synthetic analogues of 24(S)-HC retain and expand the PAM activity at

the NMDA receptor and display a range of potency and Emax across different NMDA receptor subtypes in vitro. We profiled oxysterol-based NMDA receptor modulators, in an *in vitro* model of cortical network activity in order to understand the impact of enhancing NMDA receptor function on spontaneous neuronal activity.
We compared 24(S)-HC with a series of novel synthetic analogues that displayed a range of modulatory activity at NMDA receptors. Mouse primary cortical neurons were cultured on multielectrode array plates and network activity was measured after 27 days in vitro (DIV) with the Plexon system by NeuroProof (Rostock, Germany). The baseline activity profile of each culture (N = 10 per compound) was recorded for one hour followed by the administration of eight cumulatively increasing concentrations of the test compound. Network activity was assessed for one hour per concentration and the results were normalized to the culture's own baseline activity.
24(S)-HC produced a significant, concentration-dependent increase in network activity as measured by spike rate, with an EC_{50} of 146nM. Most synthetic analogues also significantly increased spike rate with similar or greater potency. Interestingly, some of the compounds did not significantly increase spike rate of the network, despite their NMDA receptor PAM activity in heterologous cells. Indeed, a minority of the compounds tested even significantly reduced spike rate at some concentrations. The compounds also differentially affected network oscillatory activity and synchrony.
We found that oxysterol-based NMDA receptor PAMs can alter spontaneous cortical network activity in vitro in a concentration-dependent fashion. Though all compounds tested had NMDA receptor PAM activity, effects on network activity were complex, with some compounds increasing spike rate, burst firing, and synchronous activity, whereas others decreased or did not affect these parameters.. Ongoing work aims to elucidate the mechanistic differences observed with NMDA PAMs in these in vitro cortical networks.

Title: Cognitive interaction between territorial infarction and chronic cerebral hypoperfusion in a rat model

Authors: D. BACK, *H. KIM
Konkuk Univ. Sch. of Med., Seoul, Korea, Republic of

Abstract: Background: Poststroke dementia (PSD) is one of main consequences after ischemic stroke. Ischemic stroke is accompanied by secondary neurodegenerative with upregulation of β amyloid precursor protein (APP) and amyloid β (Aβ) deposits localized to the ischemic core and surrounding penumbra. After territorial infarction, some patients develop PSD and some do not. To elucidate this unresolved question, chronic cerebral hypoperfusion (CCH) as a frequent consequence of cerebrovascular dysfunction has considered as the major cause for exacerbating the development of dementia following ischemic stroke.
Methods: The adverse effects of CCH on a neurodegenerative status which deteriorate cognitive functions in the course of post stroke were investigated by a novel animal model. Primarily, the right middle cerebral artery was transiently occluded (tMCAo) for 90 min in Wistar rats to mimic focal cerebral ischemia clinically, yielding territorial infarction which triggered the accumulation of Aβ aggregates. After 2 week, tMCAo rat models were subjects to permanent occlusion of bilateral common carotid arteries (BCCAo) for 6 weeks to mimic CCH mechanism. In addition to tMCAo + BCCAo models, three types of models were added to be compared: sham + sham operated rats; tMCAo + sham operated rats; and sham + BCCAo operated rats. Spatial memory, motor, perception and cognition functions were assessed in Morris water maze test, modified neurological severity score test, foot fault test, and parallel bar test. To evaluate the degree to which either ischemia or CCH, or both of them affected neurodegeneration, various antibodies for immunoreactivity in the rat brain including the cortex, hippocampus, striatum, thalamus, and penumbra were used as follows: Aβ, APP, tau, ionized calcium binding adaptor molecule 1, glial fibrillary acidic protein, NeuN, and microtubule associated protein 2.
Results: Compared to the other three types of rat models, tMCAo + BCCAo group showed considerable spatial memory impairment. Interestingly, BCCAo group representing the effect of CCH revealed more memory decline than tMCAo group. As a result, CCH may be an aggravating factor to acute territorial infarction, potentially bringing PSD. Immunohistochemical analysis may also suggest that the aggravation in aggregated Aβ, tau, inflammatory responses and neuronal loss in tMCAO + BCCAo models explaining PSD mechanism.
Conclusion: tMCAo + BCCAo model provided a novel insight into how CCH has a deleterious effect on the development of PSD after acute territorial infarction. CCH may be the major aggravating factor to develope cognitive dysfunction after territorial infarction, leading to PSD.

Title: Functional classification of claustrum neurons

Authors: *M. GRAF, G. J. AUGUSTINE
Lee Kong Chian Sch. of Med., Nanyang Technological Univ., Singapore, Singapore

Abstract: We characterized the intrinsic electrical properties of neurons within the claustrum, a poorly-understood structure that is the most highly interconnected part of the brain (Human Brain Mapping 36: 827). Whole-cell patch-clamp recordings in acute brain slices were used to determine neuronal intrinsic properties based on responses to depolarizing current pulses at current levels twice action potential (AP) threshold, to side-step differences in cell input resistance. Based on recordings from more than 350 neurons, several parameters were correlated with at least one other parameter: (1) amount of AP frequency adaptation, (2) ratio of first-to-last interspike intervals, (3) amplitude of AP after-hyperpolarization (AHP), (4) rate of AP repolarization; and (5) ratio of rates of AP rise/decay. Based on the correlations between these parameters, the data were clustered pairwise in an unsupervised manner (ClustVis software) to define specific cell types. This analysis revealed that claustrum neurons can be grouped into 2 main populations, depending on whether they show strong (SA) or mild (MA) AP frequency adaptation. SA cells also had smaller AHP amplitudes compared to MA cells and were further subdivided into at least 2 subgroups based on other differences in their intrinsic properties. One SA subgroup exhibited the highest amount of adaptation, as well as small AHP amplitudes and a tendency to fire 2 or 3 APs at the beginning of a depolarization. The second SA subgroup had a rate of AP repolarization that was slower than for the other SA cells. Post-hoc immunostaining revealed that all SA neurons are glutamatergic projection neurons because they expressed tbr1, a marker for projection neurons. MA neurons were more heterogeneous and typically expressed either tbr1 or interneuron markers, such as parvalbumin, somatostatin, or VIP. Thus, MA neurons include both projection neurons and interneurons. Both groups of MA cells also showed differences in their intrinsic properties: interneurons usually had larger AHPs, a faster rate of AP repolarization and a smaller ratio of AP rise/decay than MA projection neurons. In summary, our results indicate that the diverse array of neurons found in the claustrum can be classified according to their intrinsic electrophysiological characteristics. This information will facilitate future efforts to characterize claustrum neuron function and network dynamics.

Title: Reciprocal circuits linking the prefrontal cortex and thalamus

Authors: *D. COLLINS, P. ANASTASIADES, J. MARLIN, A. CARTER
Ctr. for Neural Sci., New York Univ., New York, NY

Abstract: Bidirectional communication between the prefrontal cortex (PFC) and thalamus is critical for cognition and attention. However, the cell-type and pathway-specific circuits that link these two brain regions remain poorly understood. Here we use optogenetics, whole-cell physiology and 2-photon microscopy to study cortico-thalamo-cortical loops in the mouse brain. We first study connections from the PFC onto relay neurons in the thalamus. We then examine synapses from the thalamus onto cortico-thalamic neurons in the PFC. Finally, we examine the properties of thalamic inputs onto other subpopulations of projections neurons within the PFC. Together, our findings reveal open and closed feedback loops involved in multiple PFC and thalamic circuits.

Title: Motor cortical control of thalamus projecting inhibitory neurons in the brainstem

Authors: *V. M. PLATTNER[1], E. BőSZ[1], M. A. DIANA[2], L. ACSÁDY[1]
[1]Inst. of Exptl. Med. HAS, Budapest, Hungary; [2]Pierre et Marie Curie Univ., Paris, France

Abstract: Our previous data demonstrated that glycine transporter2 (GlyT2) positive inhibitory neurons in the pontine reticular formation (PRF) project to the intralaminar nuclei of the thalamus (IL). Selective activation of PRF-IL fibers evoked immediate behavioural arrest for the duration of stimulation. The strong motor response was surprising given that PRF has been implicated in arousal but not in motor control. In this study, we aimed to examine the inputs of the PRF inhibitory cells possibly carrying motor signals and the impact of these inputs on the activity of PRF inhibitory neurons. Retrograde tracer injected into the PRF labelled L5 pyramidal cells located selectively in the cingulate and M2 cortices as well as neurons in the deep cerebellar nuclei. This connectivity is consistent with a possible motor function but inconsistent with the presumed role in arousal. Injections of AAV-DIO-ChR2-mCherry into the M2/cingulate cortex of RBP4-Cre/Glyt2-eGFP double transgenic mice revealed that the entire PRF receives L5 inputs. Within PRF cortical afferents contacted mostly thin distal dendrites. Cortical inputs to GlyT2 cells were confirmed at the EM level. Juxtacellular recording and labelling in PRF under ketamine/xylazine anaesthesia demonstrated that rhythmic activity of Glyt2 cells was tightly linked to slow cortical oscillation and was disrupted upon spontaneous desynchronization. Pharmacological inactivation of the cortex led to decreased irregular firing of the GlyT2 neurons, whereas photoactivation of M2 L5 cells evoked short latency action potentials with high probability in PRF. These experiments together indicate strong motor cortical control over PRF-GlyT2 cells. In *in vitro* preparation optogenetic activation of M2 fibers reliably produced purely glutamatergic synaptic responses in PRF-GlyT2 cells. Both AMPA and NMDA receptors were functional at these synapses, which showed non-depressive behaviour during stimulation trains. Our results indicate that synchronous higher order motor (M2) cortical activity can reliably activate inhibitory neurons of the PRF, thus likely convey a behavioural signal computed by frontal, motor cortical regions. PRF GlyT2 cells in turn transfer this signal to the IL thalamus affecting thalamocortical and thalamostriatal activity.

Title: Contributions of specific cell types to sensorimotor decision making

Authors: *J. ESSIG[1], G. FELSEN[2]
[1]U. of Colorado Anschutz Med. Campus, Aurora, CO; [2]Dept. of Physiol. and Biophysics, U. of Colorado Sch. of Med., Aurora, CO

Abstract: The midbrain superior colliculus (SC) is critical for selecting targets for movement, but the circuitry underlying this computation is not well understood. While contralateral targets are represented by the activity of SC neurons at specific locations in a well-described topographic map, little is known about the role of specific cell types in target selection. Approximately one-third of neurons in the SC are inhibitory and may function to shape inter- and intra-SC dynamics to direct behavior toward spatial targets. Here, we examine this idea by recording from optogenetically-identified inhibitory SC neurons in behaving mice. We first expressed channelrhodopsin-2 (ChR2) in GABAergic neurons via an AAV-mediated Cre-dependent construct delivered to the left SC of Gad2-Cre mice. Following virus injection, mice were trained on a two-alternative spatial choice task in which an odor delivered to a central port cued selection of the left or right reward port. Trained mice were then implanted with an "optetrode" drive, an optic fiber surrounded by four tetrodes, to enable light delivery to and extracellular recordings from the same population of SC neurons. Following each behavioral session, ChR2-expressing GABAergic neurons were identified based on short-latency light responses (i.e., "optotagging"); we then determined which neurons recorded during the task were GABAergic by comparing light-elicited waveforms to those collected during the behavioral session. We found GABAergic SC neurons exhibited increased activity during movement to the target (i.e., reward port), with mixed preferences for ipsilateral and contralateral movements. One potential function for this pattern of activity is to suppress nearby output neurons representing competing targets as the movement is executed, ensuring a unitary movement. Future studies will further delineate functional SC circuitry underlying target selection by examining the activity of projection-defined SC cell types (e.g., commissural cells or premotor output cells), and by determining the necessity and sufficiency of cell type-specific activity for target selection.

Title: A midbrain mechanism for computing instinctive escape behavior

Authors: *D. EVANS[1,2], S. RUEHLE[1,2], A. STEMPEL[1,2], R. VALE[1,2], T. BRANCO[1,2]
[1]UCL Sainsbury Wellcome Ctr., London, United Kingdom; [2]MRC Lab. of Mol. Biol., Cambridge, United Kingdom

Abstract: Animals face frequent threats from predators and must generate appropriate behavioral responses to ensure survival. To achieve this, they process sensory cues to estimate the presence and imminence of predatory threats, and transform this information into innate defensive actions. In this study, we have used a combination of behavioral and neurophysiological methods in the mouse to investigate how the decision to escape from predatory threats is computed.
First, we developed an innate decision making paradigm in which a mouse is presented with threats of varying intensity during foraging and chooses whether or not to escape to a shelter. The performance data in this assay show a gradual increase in escape probability and flight vigor with increasing threat intensity, a relationship that is well captured by a signal detection theory model of decision making where threat values are compared to an escape boundary. We then performed calcium imaging in freely-moving mice to probe for neural correlates of decision elements and flight behavior in brain areas necessary for the flight responses: we found that VGLUT2$^+$ neurons in the deep layers of medial superior colliculus (dSCm) gradually increase their activity during threat presentation, while activation of VGLUT2$^+$ neurons of the dorsal periaqueductal gray (dPAG) coincides with escape initiation. Optogenetic activation of dSCm-VGLUT2$^+$ neurons in vivo recapitulates the statistics of escape probability evoked with threatening stimuli, while activation of VGLUT2$^+$ neurons in the dPAG evokes escape responses in an all-or-nothing manner. Finally, using monosynaptic G-deleted rabies tracing and channelrhodopsin-2-assisted circuit mapping, we show that over half of dPAG-VGLUT2$^+$ neurons receive monosynaptic connections from dSCm-VGLUT2$^+$ neurons via low release probability synaptic connections that act as a high-pass activity filter.
These results suggest excitatory neurons in the dSCm encode evidence of threat, which is thresholded by dPAG neurons to determine whether or not escape is initiated. Our findings provide a mechanism for the computation of escape decisions, and advance our understanding of how neurons process information in a circuit critical for implementing basic behaviors.

Abstract: Historically, female subjects have been omitted from preclinical stress studies, despite evidence that women are more liable to develop anxiety and depression. In particular, studies of stress susceptibility and resilience have focused on males since the commonly used paradigm -- chronic social defeat stress -- does not work in females. By using pheromones to increase resident male aggressive behavior, we have developed a readily accessible version of this paradigm that can be used in female mice. Using this approach, we find that female mice that undergo repeated social defeat stress develop social avoidance (Wilcoxan rank sum; $p<0.001$), decreased sucrose preference ($p<0.05$) and spend less time in the open arms of the elevated plus maze ($p<0.05$) relative to control mice. Moreover, a subset of the female mice who undergo repeated aggression display resilience, maintaining control levels of social exploration and sucrose preference. This method closely follows a standard protocol used for chronic social defeat stress in male mice and produces similar results to those obtained in male mice. We anticipate that the development of this easy-to-use method for social defeat stress in female mice will greatly facilitate the inclusion of female subjects in stress research.

Title: The role of prefrontal interneuron subtypes in working memory

Authors: *A. I. ABBAS[1], M. J. M. SUNDIANG[1], E. MYHRE[1], B. HENOCH[1], M. P. MORTON[1], S. S. BOLKAN[1], A. Z. HARRIS[1], C. KELLENDONK[1], J. A. GORDON[2]

Abstract: Schizophrenia has previously been hypothesized to result from a failure of functional connectivity in the brain. Accumulating evidence supports this view, though the cellular mediators of functional connectivity within the brain are not well understood. Given data showing that two classes of inhibitory neurons, parvalbumin- (PV) and somatostatin-expressing (SOM) interneurons, exhibit abnormal expression of markers, GABA synthetic enzyme, and GABA transporter in individuals with schizophrenia, we hypothesized that prefrontal cortical interneurons support working memory by facilitating functional connectivity. To test this hypothesis, we used the light-activated proton pump Arch3.0 to selectively silence prefrontal PV or SOM interneurons in the medial prefrontal cortex of mice performing the delayed non-match to sample T-maze test of spatial working memory. We simultaneously recorded neural activity in the medial prefrontal cortex (mPFC) and other brain areas known to be involved in working memory, including the dorsal and ventral hippocampus (dHPC and vHPC), and mediodorsal thalamus (MD). We used measures of LFP-LFP and spike-LFP synchrony to characterize the functional connectivity between these various structures. Silencing SOM interneurons during the sample or delay phases of the task significantly impaired working memory performance when the delay length was 10 seconds or 60 seconds. SOM silencing during the sample phase of the working memory task was also associated with a decrease in phase locking, as measured by PPC, between mPFC neurons and vHPC theta oscillations and dHPC theta oscillations. SOM silencing during the sample phase was also associated with impaired spatial representations of goal location by mPFC neurons. Silencing PV interneurons had no effect on working memory behavior, functional connectivity, or spatial representations in the mPFC. Our evidence is consistent with SOM interneurons supporting spatial encoding during working memory and facilitating hippocampal-prefrontal synchrony. These findings suggest that interneuron dysfunction may contribute to cognitive deficits in schizophrenia by disrupting long range synchrony between the hippocampus and prefrontal cortex.

Title: Frequency-specific facilitation of hippocampal-prefrontal transmission increases anxiety-like behavior

Authors: *N. PADILLA COREANO[1], S. E. CANETTA[2], E. TEBOUL[3], A. GARCIA-GARCIA[3], R. WARREN[3], C. KELLENDONK[3], J. A. GORDON[4]

Abstract: Avoidance of potentially dangerous locations, such as the open arms of an elevated plus maze, has been used to study the neural circuitry underlying conflict-based anxiety-like behavior in rodents and may be of relevance to human anxiety disorders. We and others have demonstrated a key role for the ventral hippocampus (vHPC) and the medial prefrontal cortex (mPFC) in these behaviors (Kjelstrup et al., 2002; Maren and Holt, 2004; Shah and Treit, 2003). Exposure to anxiogenic environments enhances synchrony between the vHPC and mPFC, specifically in the theta-frequency (4-12 Hz) range (Adhikari et al., 2010), facilitating the construction of neural representations of aversion within the mPFC (Adhikari et al., 2011; Padilla-Coreano et al., 2016). Optogenetic inhibition of the direct projections from the vHPC to the mPFC ablates these representations and reduces both theta-frequency synchrony and avoidance behavior (Padilla-Coreano et al, 2016; Kjaerby et al., 2016). The specific relevance of theta-frequency activity, however, remains unclear. Here we dynamically modulated vHPC terminals in the mPFC using optogenetic stimulation. Terminal activation with an 8 Hz, but not 20 Hz, oscillatory stimulus was sufficient to increase avoidance behavior, while surprisingly pulsatile 8 Hz stimulation had no effect on behavior. *Ex vivo* and *in vivo* neural recordings demonstrated that the 8 Hz oscillatory stimulus entrained neural activity in the entire vHPC-mPFC network, particularly during exposure to an anxiogenic environment. These data support the importance of theta-frequency activity in vHPC-mPFC communication for the regulation of anxiety-like avoidance behavior.

Abstract: The mediodorsal thalamus (MD) shares reciprocal connectivity with the prefrontal cortex (PFC) and decreased MD-PFC connectivity is observed in schizophrenia patients. Patients also display cognitive deficits including impairments in working memory, but a mechanistic link between thalamo-prefrontal circuit function and working memory is missing. Here, using pathway-specific inhibition we found directional interactions between MD and medial PFC (mPFC), with MD-to-mPFC supporting working memory maintenance and mPFC-to-MD supporting subsequent choice. We further identify mPFC neurons that display elevated spiking during the delay, a feature that was absent on error trials and required MD inputs for sustained maintenance. Strikingly, delay-tuned neurons had minimal overlap with spatially-tuned neurons and each mPFC population exhibited mutually exclusive dependence on MD and hippocampal inputs. These findings indicate a role for the MD in sustaining prefrontal activity during working

memory maintenance. Consistent with this idea we found that enhancing MD excitability was sufficient to enhance task performance.

Title: Environmental enrichment impacts place avoidance memory in zebrafish

Authors: *J. NISSANOV[1], T. VICKERY[2]
[1]Basic Sci., Touro Univ. Nevada, Henderson, NV; [2]MHS, Touro University, Nevada, Henderson, NV

Abstract: Environmental enrichment has been shown to enhance learning and memory retention in vertebrates. We assessed if this holds true for zebrafish tested on place avoidance, a one-trial learning paradigm. To do so, juveniles were reared in either a control environment consisting of bare tanks or in tanks containing a complex maze of objects. They were trained and then each tested once at a later time point and the degree of memory decrement assessed. The training and test apparatus consisted of a shuttle box divided into a lit and a dark compartment. To train and test, fish where placed in the disfavored compartment and a shock was delivered once they entered their prefered half of the box. The fish were removed and, for testing, transferred back into the disfavored compartment of the shuttle box. The latency time to swim to the preferred compartment, as measured off video, dropped to baseline more slowly for the experimental over the control group. The differential performance observed establishes that environmental enrichment does alter memory decrement in a one-trial place avoidance paradigm. This simple memory assessment is amendable to large-scale pharmacological, toxicological, and genetic studies on the interaction between organism and its environment.

Title: Cognitive deficit correlated with changes in neuronal activity in Disc1$^{\Delta 2\text{-}3/\Delta 2\text{-}3}$ mice in touchscreen-based visual discrimination task

Authors: *B. WULAER[1], T. NAGAI[1], A. SOBUE[1], K. KURODA[2], K. KAIBUCHI[2], T. NABESHIMA[3], K. YAMADA[1]
[1]Dept. of Neuropsychopharm. and Hosp. Pharm., [2]Dept of Cell Pharmacol., Nagoya Univ. Grad Sch. Med., Nagoya, Japan; [3]Fujita Hlth. Univ., Toyoake, Japan

Abstract: Cognitive deficit is one of core symptoms in schizophrenia. Genetic and functional studies have implicated Disrupted-in-Schizophrenia 1 (DISC1), a risk gene for multiple mental disorders, in cognitive function. Altered expression of DISC1 has been identified in schizophrenia. To explore its function, we have previously generated mice lacking exons 2 and 3 of the Disc1 on a C57BL/6J genetic background (Disc1$^{\Delta 2\text{-}3/\Delta 2\text{-}3}$ mice). In the present study, to evaluate the dorsal striatum-dependent associative learning and behavioral flexibility in Disc1$^{\Delta 2\text{-}3/\Delta 2\text{-}3}$ mice, we observed performance of the mice in a translatable touchscreen-based visual discrimination task. To study whether the abnormal behavior observed in the visual discrimination task was accompanied by differences in neuronal activity, we used c-Fos immunohistochemistry to examine the patterns of activation on the first and last visual discrimination learning session. The total number of c-Fos immuno-positive cells was counted in the dorsal striatum. Finally, the effect of clozapine in Disc1$^{\Delta 2\text{-}3/\Delta 2\text{-}3}$ mice in visual discrimination task was also analyzed. Disc1$^{\Delta 2\text{-}3/\Delta 2\text{-}3}$ mice exhibited retarded performance in the visual discrimination task, which was mainly due to high perseverative response compared to wild-type animals. c-Fos expression was specifically increased in the dorsomedial, but not dorsolateral striatum after the first visual discrimination day in Disc1$^{\Delta 2\text{-}3/\Delta 2\text{-}3}$ mice compared to the wild-type animals. The daily treatment of clozapine ameliorated the impairment by normalizing the preservative behavior. These results show that enhanced repetitive and compulsive-like behaviors in Disc1$^{\Delta 2\text{-}3/\Delta 2\text{-}3}$ mice may lead to cognitive impairment. Daily treatment with clozapine could ameliorate the impaired performance. Hyperactivity in Disc1$^{\Delta 2\text{-}3/\Delta 2\text{-}3}$ mice in the dorsomedial striatum might be responsible for the abnormal phenotype.

Title: Functional significance of the repetition suppression of the neural firing in the perirhinal cortex during object recognition

Authors: J. AHN, Y. KIM, *I. LEE, PhD
Brain and Cognitive Sci., Seoul Natl. Univ., Seoul, Korea, Republic of

Abstract: It has been suggested that cells in the medial temporal lobe (MTL) signal relative familiarity of a stimulus by subsequently decrementing their response magnitude toward a repeated stimulus. The phenomenon called “repetition suppression” has been implicated as a potential neural substrate for recognition memory. It remains unknown, however, whether the repetition-sensitive neurons in the MTL can correlate with actual recognition behavior. To investigate this issue, we trained rats (n=7) in an object-cued response selection task. Experiments were performed on a linear track (46 x 7.5 cm) with a custom-made response box (13 x 6 x 13 mm) positioned at the other end of the track. One of two perceptually distinct 3-dimensional object stimuli (House and Icecream) was attached to the box, and the rat had to produce a differential response (e.g., pushing or nose-poking) to the box depending on the identity of the object. Rats were trained to criteria (>= 75% correct performance for 2 consecutive sessions) with the two objects, and underwent surgery to implant a microdrive targeting the hippocampus (HIPP) and perirhinal cortex (PER) simultaneously. During recording sessions, a pair of novel objects (Phone and Owl) were introduced and presented along with the familiar objects in an intermixed fashion. Cells in both regions (n=121 in HIPP and n=59 in PER) responded to the objects by significantly decrementing or incrementing their firing rates as the same objects were repeated within a session. Most of the PER neurons (37/59) showed a selective response toward a particular object stimulus, whereas a smaller proportion of neurons (39/121) did so in the HIPP. PER neurons were more likely to alter their response toward novel objects (n=23) than familiar ones (n=14). In the HIPP, the number of neurons responding to novel (n=19) and familiar objects (n=20) was similar. We also measured the slope of the

response change by fitting a linear regression model to the trial-by-trial firing rates for each object. In both regions, the magnitude of the slope tended to be higher for less familiar objects. It is expected that our preliminary results shed light on the novel functional aspect of the repetition-sensitive neurons in the MTL.

Title: Role of feedback and statistical density in rat visual category learning

Authors: *M. B. BROSCHARD[1], J. KIM[1], L. CASTRO[1], E. A. WASSERMAN[1], V. M. SLOUTSKY[2], J. H. FREEMAN[1]
[1]Psychological and Brain Sci., Univ. of Iowa, Iowa City, IA; [2]Psychology, Ohio State Univ., Columbus, OH

Abstract: Categorization is a fundamental process underlying adaptive behavior. Human visual category learning is influenced by the statistical density of category-relevant features and the level of supervision (Kloos & Sloutsky, 2008, JEP: General, 137, 52-72). The current experiment examined the roles of statistical density and supervision in visual category learning in rats. Using an operant chamber outfitted with a touch screen, four groups of rats (n = 6 per group) were either presented with 'high density' stimuli (three of five features were category-relevant) or 'low density' stimuli (one of five features was category-relevant) and either under 'high supervision' (food reward was given only for correct responses) or 'low supervision' (food reward was given for all responses). Accuracy for each category was recorded and criterion was defined as 75% correct on both categories for two consecutive sessions. After meeting the training criterion, the rats were given testing sessions in which training stimuli were mixed with probe trials. Probe trials included novel exemplars (novel irrelevant features), relocated stimuli (in which the relevant features appeared in different locations), and singleton stimuli (only one relevant feature was presented). All rats in the high density-high supervision condition (6/6) showed rapid learning of the two categories. They also showed very high accuracy with novel stimuli. Accuracy dropped significantly when rotated or singleton stimuli were presented, suggesting that the rats' representations of the categories included feature-location binding. Some of the rats in the low density-high supervision condition (2/6) learned and showed substantial generalization to novel exemplars. Like rats in the high density-high supervision

condition, rats in the low density-high supervision condition that learned showed a significant drop in accuracy during presentations of the rotated and singleton test stimuli. Rats trained in the high density-low supervision and low density-low supervision conditions did not learn. Only one rat in the high density-low supervision condition reached criterion performance. The results indicate that unlike humans, rats require supervision to learn both high and low density categories. Moreover, humans consistently learned in the low density-high supervision condition. The species differences in category learning may be related to differences in medial prefrontal and/or hippocampal function.

Title: Lateral habenula inactivation impairs delayed alternation performance but not working memory in rats

Authors: *P. M. BAKER, E. M. GARCIA, B. K. LEUNG, S. J. Y. MIZUMORI
Psychology, Univ. of Washington, Seattle, WA

Abstract: The lateral habenula (LHb) has been implicated in behaviors that are reliant on working memory to perform. However, it is unclear whether these deficits are due purely to an inability to recall aspects of the task required to solve it or an inability to apply the rule requiring working memory. In order to address this, we employed a delayed spatial alternation task in which naïve rats perform significantly above chance levels due to an innate preference for choosing arms less recently visited. Specifically, a modified automated plus-maze was used in which two arms (east and west) were designated as reward arms and two arms (north and south) were designated as start arms. Prior to behavioral testing, male Long-Evans rats were implanted with bilateral cannula aimed at the LHb. After recovery, rats were pretrained to explore maze arms by obtaining rewards in reward arms and then returning to start arms. Once rats performed this sequence at least 45 times over 30 min, they began test sessions. On a given test trial, a rat was placed on a start arm (pseudorandomly chosen). After a 10 sec delay, the two reward arms were presented simultaneously. The rat was required to choose the arm that was least recently visited in order to receive two 45mg sugar pellets. A repeat choice was not rewarded. Rats were randomly divided into three groups: saline - saline treatment (Sal-Sal); saline - inactivation (Sal-

Inact); and inactivation - saline (Inact-Sal). LHb Inactivation was accomplished by administration of the GABA agonists, baclofen and muscimol (50ng/0.2µL) 6 min prior to testing. Treatments occurred either during the first three days of the test sessions (Learning), or for three days after at least 80% correct alternations (Asymptote). If an animal was unable to recall the arm it had last visited, then chance performance would be predicted. However, inactivation during the learning state resulted in above chance performance ($t_{(2)} = 7.94$, $p = 0.015$) with no differences between treatment groups ($F_{(2,32)} = 0.37$, $p = 0.70$). In contrast, inactivation during asymptotic performance led to a significant impairment in performance ($F_{(2,32)} = 30.09$, $p < 0.01$). Overall, these results indicate that the LHb is not involved in working memory per se, but rather in conditions in which a learned strategy must be enacted utilizing working memory.

Title: Single episode of neonatal status epilepticus impairs sociability but not cognitive function in rats

Authors: *R. M. CYSNEIROS[1], A. PACÍFICO[2], S. P. BATISTA[2], P. BASTOS[2], G. L. BARBOSA[2]
[1]Univ. Presbiteriana Mackenzie, Sao Paulo, Brazil; [2]Mackenzie Presbyterian Univ., São Paulo, Brazil

Abstract: A single episode of *status epilepticus* (SE) in rats produce an autistic phenotype, characterized by social play impairment, low preference by novelty and deficit in social discrimination unrelated with emotionality, but the underlying mechanism is unknown. We investigated memory of social recognition and cognitive function in adults male rats subjected to a single episode of neonatal SE induced by pilocarpine (380 mg/kg, ip) at PN9. Social memory was assessed using habituation/deshabituation paradigm and cognitive function was assessed

using T maze and Operant conditioning paradigms. Gene expression for oxytocin (OT) and oxytocin receptor (OTR) was assessed in hippocampus (HP), amygdala (AMG) and hypothalamus (HYP). In habituation/deshabituation paradigm experimental animals spent less time investigating the unfamiliar conspecific (F(1,124)=5.64, p= 0.023) and no difference in investigation was noted when the conspecific was replaced by a new social stimulus. In operant conditioning, the number of sessions for associative learning did not differ between groups (t=0.45, gl=12, p=0.65). The continuous reinforcement (CRF) did not differ between groups ($F_{[1,36]}$= 0.018, p= 0.89) but increased across sessions ($F_{[3,36]}$= 9.51, p< 0.0001), suggesting acquisition of associative learning and formation of long-term memory. In the discriminative stimuli, the percentage of corrects response did not differ between groups ($F_{[1,108]}$ = 2.12, p= 0.17) but increased across sessions ($F_{[9,108]}$ = 9.14, p < 0.0001), suggesting no changes in working memory. In forced-alternation task, the accuracy increased across sessions ($F_{[3,69]}$=4.32, p=0.007), with no difference between groups ($F_{[1,69]}$=0.45, p= 0.50). In the left-right discrimination task, the percentage of corrects responses did not differ between groups ($F_{[1,69]}$=1.58, p= 0.22) and increased across session ($F_{[9,69]}$=10.33, p<0.0001), suggesting no difference in reference memory. In behavioral flexibility task, the percentage of corrects responses did not differ between groups ($F_{[1,69]}$=3.87, p= 0.061) but increased across session ($F_{[9,69]}$=37.21, p<0.0001). In the gene expression, mRNA for OT did not differ between groups in HP, (t(8)= 0.53, p= 0.61), HYP (t(8)= 0.82, p=0.10) and AMG (t(8)= 0.81, p= 0.43). For the OTR, mRNA expression was significantly lower in the HP (t(8)= 2.43, p = 0.04), but not differences was noted in AMG (t(8)= 0.85, p= 0.45) or HYP(t(8)= 0.58, p= 0.58). We showed that a single neonatal SE does not impair cognitive function but produce impairment of social recognition memory may be related to decrease of OT signaling in hippocampus.

Title: Developmental lead exposure reduces encephalization and cortical quotients resulting in dysexecutive functions in the rat

Authors: *L. S. NEUWIRTH[1], Y. KIM[2], S. R. RUBI[3], S. KAUR[4], N. MATHEW[4], S. MASOOD[4], B. TRANQUILLE[3], V. THIRUVERKADU[3], T. J. JOSE[4], C. JO[3], T. F. DACIUS, Jr.[4], J. R. BONITTO[3], J. C. SKEEN[3], A. ALVIRA[4], E. KHAIRI[3], A. IQBAL[4]

Abstract: Lead (Pb) is a developmental neurotoxin that causes lifelong cognitive executive dysfunction. However, it is unclear how developmental exposure to Pb effects cortical volume and a variety of neurochemical signals which are responsible for not only regulating cognition, but also global brain excitability. Here we evaluated how Pb exposure alters cortical volume and neurochemical signaling in the adult rat brain following developmental exposure to Pb. We hypothesized that developmental Pb exposure would decrease cortical volume and increase brain excitability by reducing GABA levels and the ratio of GABA to other important neurotransmitters (i.e., glutamate, dopamine, norepinephrine, epinephrine, serotonin, and taurine) as a function of Pb exposure and sex. Results show that dependent upon the developmental time-period of Pb exposure and sex, that Pb differentially reduces cortical volume. The neurochemical analysis revealed differences in the patters of neurotransmitter profiles in specific brain regions (i.e., PrL = prelimbic cortex, IL = infralimbic cortex, OV = ventral orbital frontal cortex, OVL = ventrolateral orbital frontal cortex, dHP = dorsal hippocampus, & vHP = ventral hippocampus) dependent upon sex and developmental time-period of exposure. Our data suggest an emerging profile of which neurotransmitters in specific regions of the rat brain may contribute to cognitive dysexecutive functions and accompanying learning and memory problems associated with the attention set-shift task (ASST).

Title: Advanced techniques for characerizing rodent brains with diffusion MRI

Authors: ***L. DO**[1], A. BERNSTEIN[1], P. K. BHARADWAJ[2], G. E. ALEXANDER[2], C. A. BARNES[3], T. TROUARD[1]

Abstract: Diffusion magnetic resonance imaging (DMRI) can help to characterize neurological processes, such as cognitive aging. Rodent models are important tools for seminal investigations of such processes, however methods designed for analysis of human DMRI data have not been well translated to rodents. The purpose of this study is to evaluate a preprocessing pipeline that has been optimized for rodent brain imaging. Fisher 344 rats (n=7) underwent 3D T2-weighted RARE (150 micron isotropic) and 64 direction diffusion weighted single shot echo planar imaging sequence at b=1000, 2000, and 3000 s/mm^2, on a 7T Bruker Biospec MRI scanner. DMRI data were semi-automatically brain extracted using *ITKsnap* and *MRIcron*, bias field corrected using *N4ITK* implemented in *ANT*s, EPI distortion corrected using *TOPUP* within *FSL*, eddy current distortion correction using *EDDY* within *FSL* and de-noised using local principal component analysis in *MATLAB*. Diffusion tensors were estimated using a weighted linear least squares fit of the diffusion data and derived scalar maps including fractional anisotropy and mean diffusivity were computed with *MRTrix*. Manual brain extraction of the 3D RARE images took 4±1 hours whereas the semi-automated method took 4±0.5 minutes. The dice coefficients (DC) indicating overlap between manual and semi-automated methods with a N4 bias field correction were higher than those obtained when the bias field correction was **not** applied. Applying non-parametric Wilcoxon Signed Rank Test revealed significance between the DCs (Z-score = -2.366, p = 0.018. Eddy current correction effectively eliminated distortions between DMRI scans, but *TOPUP* failed to completely remove the EPI distortion as evidence by the remaining signal pile up at the bottom of the brain. Results show automated brain extraction produces similar accuracy compared with the manual method while reducing analysis time in 3D RARE images. Furthermore, distortion correction, eddy current corrections, and noise reduction followed by bias correction show improvement in image quality in the minimization of distortions in DMRI images. Further testing is needed with a larger cohort and refinement of the pipeline to further minimize the pile up artifact not addressed by *TOPUP* by registering the images to a T2 anatomical space. The bias field correction step in automated brain extraction maintained the accuracy of the manual method while also reducing analysis time in T2-weighted 3D RARE data. Preprocessing of DMRI data show that this pipeline has the potential to be implemented in rat brain data to minimize distortions resulting from the collection scheme.

Title: Decoding brain areas using the local field potential

Authors: *S. J. HOFFMAN, N. M. DOTSON, C. M. GRAY
Cell Biology/Neuroscience, Montana State Univ. Bozeman, Bozeman, MT

Abstract: Neuronal oscillations are widely believed to play a key role in the coordination of neural activity. However, little is known about the regional and temporal variations in the local field potential (LFP) during cognitive tasks. To elucidate the large-scale spatio-spectral patterns of activity underlying visual working memory, we developed a large-scale semi-chronic recording system that enables the long-term measurement of neuronal activity from up to 256 independently movable microelectrodes spanning an entire cerebral hemisphere in non-human primates. We implanted this instrument in two macaque monkeys and recorded neuronal activity for 6 and 9 months, respectively, while the animals performed an object-based, delayed match-to-sample (dMTS) task and a set of control tasks. In total, we obtained recordings of neuronal activity from over 60 separate cortical areas and subcortical structures. To determine if each cortical area has a distinct spectral signature, we trained a machine learning classifier to decode cortical areas using LFPs. We find that cortical areas can be reliably predicted based solely on properties of the LFP. These findings show that there are robust anatomically correlated variations in the LFP power spectra. Additionally we found task dependent variations during the delayed match-to-sample task. These variations were heterogeneous and dispersed broadly, indicating task dependent changes in LFP power occur across the brain.

Title: Iterated Prisoner Dilemma boost the emergence of high reciprocal altruism-based cooperative behaviors in rats

Authors: G. DELMAS[1], *S. E. LEW[2], B. S. ZANUTTO[3]
[1]Inst. de Ingeniería Biomédica, Univ. de Buenos Aires, Buenos Aires, Argentina; [2]Univ. de Buenos Aires, Capital Federal, Argentina; [3]Univ. Buenos Aires-CONICET, Buenos Aires, Argentina

Abstract: The underlying mechanisms that explain cooperative behaviors among unrelated remain unclear in evolution theory. However, it was shown that the use of appropriate 2x2 pay-off matrices in the iterated Prisoner Dilemma (iPD), boost the emergence of reciprocal altruism-based cooperative behaviors, as a way to learn to maximize reward. When subjects face an opponent with cooperative strategy (Tit for Tat) and iPD matrix, the biggest long-term reward is available when both actor and opponent subjects cooperate mutually. It happens when mutual cooperation is the most probable state out of the four possible states in the game. Although, iPD is successfully learnt in humans it has not been found in animals. Here, we show for the first time that using a specific pay-off matrices and punishment (timeout), *long-Evans* rats were able to learn reciprocal altruism behaviors with cooperation rates over 80%. Two groups of unrelated male Long-Evans rats (two months old) were trained using dual opposite operant chambers, visual contact between animals was allowed through a small window. The experimental and opponent groups were food restricted in order to maintain their weights at 90-95% and 80%-85% of their *ad libitum* weights, respectively. When modeled as *Markov chain transition probabilities,* rats behaviors show a strong preference to stay in the mutual cooperation state or to return to it as soon as a wrong response is executed.

Title: What you see is what you get? - Testing predictions of overexpectation derived from the Rescorla-Wagner model

Authors: *J. PACKHEISER[1], R. PUSCH[1], O. GUNTURKUN[1], M. UENGOER[2]
[1]Biopsychology, RUB, Bochum, Germany; [2]Dept. of Psychology, Philipps-Universität Marburg, Marburg, Germany

Abstract: Learning about the predictive power of stimuli for appetitive or aversive events is a crucial ability for an organism's survival. The Rescorla-Wagner model has been used in various research fields to predict the behavior during learning processes. It bases its predictions on changes in associative strength of stimuli in relation to the discrepancy between the predicted and actual outcome. The model has been validated for many behavioral paradigms to accurately model natural learning in humans and non-human animals. One of the many predictions offered by their model concerns the role of overexpectation. Overexpectation refers to extinction that occurs after learning positive (excitatory) associations with two individual stimuli A+ and B+. If these stimuli are then presented together as the compound AB+, extinction will occur if the amount of reward is not increasing accordingly meaning that the amount of reward is doubling. We conducted an experiment using pigeons (*Columba livia*) to evaluate a novel prediction related to the effects of overexpectation. The model predicts a total loss in associative strength for A+ during the presentation of the compound if B+ is still presented individually and is continuously rewarded. Additionally, we tested whether a novel stimulus Z paired with an initially learned stimulus C+ followed by no reinforcement (CZ-) functions as a conditioned inhibitor. Here, overexpectation by the Rescorla-Wagner model predicts no total loss of the associative strength of C as Z gains negative associative value. Our results revealed that neither the prediction for A+ nor C+ holds true. A+ did not decrease in associative value during the process of overexpectation, whereas C+ demonstrated an absolute loss of associative strength. We conclude that the Rescorla-Wagner model is not sufficient to systematically anticipate learning in every conceivable condition. Instead, it appears to be more accurately estimated by configural theories of learning.

Title: Hasty decision-making delays accomplishment of learning

Authors: *Y. YAWATA, K. MAKINO, Y. IKEGAYA
The Univ. of Tokyo, Tokyo, Japan

Abstract: For appropriate decision-makings, rapidness and correctness of decisions are both important. However, little is known about the relationship between the length of time required to decision-making and the overall task performance. In this study, we conducted a nose-poke behavior test in which rats were rewarded by poking their noses into one of two holes in an operant chamber. Either one of the two holes was randomly illuminated as a light cue, which indicated the incorrect hole (no reward delivered). All rats reached the learning criterion of 80% correct rate within a 4-d task, in which the number of sessions to the criterion varied across animals. The number of omission (i.e., trials without nose poking) increased transiently immediately before the learning performance reached the criterion. We found that rats with shorter latencies to poke spent more sessions to reach the learning criterion (i.e., slow learners). Although the latencies in correct trials (LC) was significantly longer than those in incorrect trials (LI), rats with low LI / LC ratios learned more slowly. These results suggest that earlier decision-making do not provide benefits to task performance and that deliberative decision-making is more crucial for learning than correctness in each trial.

Title: Gaussian process regression for inferring the temporal evolution of neuronal activity during within-session learning in monkeys

Authors: *F. A. MUNOZ[1], G. JENSEN[2], V. P. FERRERA[3]
[1]Neurosci., [2]Columbia Univ., New York, NY; [3]Neuroscience, Psychiatry, Columbia Univ. Press, New York, NY

Abstract: Uncovering the relationship between behavioral performance and neuronal activity during learning is one of the hardest problems in Neuroscience. Classical analysis tools work best for data acquired during steady-state behavior, which means the subject must be overtrained on a particular task to satisfy the assumptions of the statistical model. Overtraining avoids problems arising from non-stationary data, but precludes any attempt to study learning itself. Statistical methods used for machine learning applications may be useful for analyzing data

where the underlying rates vary within and across trials. We present here an application of Gaussian process regression (GPR), a non-parametric method based on Gaussian process priors for inferring probabilistically varying firing rate functions. We used this method to model real-time changes in firing rate in recordings from neurons in parietal area LIP in monkeys during a transitive inference task. In each session, which lasted 20-30 minutes, subjects were presented with never-before-seen photographic stimuli, and learned how those stimuli were implicitly ordered through trial and error responding. Performance was necessarily at chance levels (50% correct) at the start of each session, but gradually improved to 70% (on average) over the course of ~630 trials. As a multivariate regression procedure, Gaussian processes relates the neural response to all explanatory variables of interest at once. In this approach, the spike trains are considered as a Cox process (i.e. a mixture of Poisson processes) whose rate parameters are governed by a posterior distribution of *Gaussian processes.* These rates are thus recovered from the covariance structure of the data itself. *This allows the changing firing rates to be estimated without presupposing the functional form of the time series*. Underlying rate fluctuations derived from GPR can be compared to behavioral performance changes, which may also be modeled as a Gaussian process. In conclusion, we can explore the evolution of the neural response as a function of explanatory variables (e.g. stimulus rank) and reveal the emerging tuning in direct relation to learning.

Title: Cerebellar simple spikes report the trial outcome during sensorimotor learning

Authors: *N. SENDHILNATHAN[1], M. SEMEWORK[2], M. E. GOLDBERG[3], A. E. IPATA[4]
[1]Columbia Univ. Dept. of Neurosci., New York, NY; [2]Dept. of Neurosci., Columbia Univesity, New York, NY; [3]Neurosci., Columbia Univ. Press, New York, NY; [4]Mahoney Ctr. For Brain and Behavior Res., Columbia Univ., New York, NY

Abstract: The cerebellum (CB) plays a key role in motor learning, and there is a consensus that its role is to identify motor errors and correct the movement. However, recent tract-tracing and

fMRI connection studies have shown that the CB is reciprocally connected to areas such as prefrontal cortex that are far removed from the details of motor control. In keeping with these anatomical data, we have shown that Purkinje cells in monkey mid-lateral cerebellum track the learning of arbitrary visuomotor associations in a manner in which there were no obvious changes in the kinematics of the movement (Ipata et al. SfN 2014,2015; Sendhilnathan et al. NCM 2017). We trained two monkeys on a visuomotor association task, which began when the monkeys grasped two bars, one with each hand, after which a fixation point appeared for 800 ms. Then one of a pair of symbols appeared at the center of gaze. One symbol signaled the monkey to release the left bar and the other to release the right bar. The monkey was rewarded for releasing the hand associated with that symbol. We began by presenting the monkey with the same over-trained symbol pair every session, and after a number of trials, changed the symbol pair to two novel symbols that the monkey had never seen before. Over 20 to 40 trials, the monkey gradually learned which symbol was associated with which hand. When the monkey had learned the new association, we reversed the pairing. The monkey usually took longer (40 to 60 trials) to learn the reversal. When we brought back the over-trained symbol pair, the monkey performed perfectly without making any error. Although the reaction time of the response increased at the symbol change the monkey made the same movements in response to well-learned and newly changed symbols. The majority of cells responded equivalently when the monkey moved either hand. The simple spike activity of Purkinje cells has a memory of the trial's outcome, during the visuomotor association learning period. Neurons that report the prior trial's outcome show change in firing activity in the fixation, symbol, and pre-movement epochs, while neurons that report the current trial's outcome show change in firing rate after the reward period. We also identified a small group of neurons that report the prior trial's outcome as well as the current trial's outcome. This firing rate change occurred in a specific short epoch of the trial for a given neuron, and across the sample the change in activity of the cell sample continuously tiled the entire trial duration. This epoch-specific trial-to-trial difference decreased, for both groups, as the monkey learned the association, so that, after the learning phase, the difference in activity did not change.

Title: Input pathways for value-coded visual responses in midbrain dopamine neurons

Authors: *N. TAKAKUWA[1,2,3], R. KATO[1,2], P. REDGRAVE[4], T. ISA[1,2,3]
[1]Developmental Neurosci., Kyoto Univ., Kyoto-Shi/Kyoto-Hu, Japan; [2]Dept Dev. Physiol., Nat'l Inst. Physiol. Sci., Okazaki, Japan; [3]SOKENDAI, Hayama, Japan; [4]Dept. Psychol., Univ. of Sheffield, Sheffield, United Kingdom

Abstract: Responses of midbrain dopamine (DA) neurons can reflect reward prediction errors that are thought necessary to acquire classically conditioned responses triggered by predicting sensory stimulus (Schultz., 1998). This learning is important to anticipate and acquire reward, or to avoid punishments. However, the neural mechanisms by which sensory inputs are conveyed to the ventral midbrain and the computational processes required to transform them into the reward prediction error signals remain to be determined.In the case of visual associative learning, the visual information is most likely conveyed to DA neurons either via the primary visual cortex (V1), and/or the midbrain superior colliculus (SC). In our previous study with macaque monkeys, we reported that the visual signals mediated via the SC are required elicit conditioned responses and to generate value-coded responses in DA neurons when V1 was disabled. However, while SC are exquisitely sensitive to retinal luminance change, SC neurons are largely insensitive to color, high spatial frequencies (form), and texture. Thus, in cases where conditioned stimuli are discriminated according to these additional features, it is likely that visual processing in V1 would be required.To address this question, we investigated whether visual signals originating in V1 can activate midbrain DA neurons in monkeys with unilateral lesions of V1. This was achieved by inactivating the SC with a unilateral microinjection of $GABA_A$ receptor agonist, muscimol, on the side of the brain where cortical visual processing remained intact. In our experimental paradigm, we simultaneously observed the animals' ability to exhibit classically conditioned anticipatory licking prior to the delivery of juice-reward, and responses of DA neurons evoked by conditioned visual stimuli presented to the visual field where V1 cortical processing remained intact.Stimuli processed by the intact V1 were able to induce similar amounts of conditioned anticipatory licking to that observed prior to the SC being inactivated. Similarly, visual CSs evoked responses in putative DA neurons that reflected predicted reward value. These results suggest that visual signals through V1 are sufficient to evoke classically conditioned responses and value-coded activation of midbrain DA neurons.In conjunction with our previous results, we conclude that both cortical and subcortical visual processing can independently elicit classically conditioned behavior and conditioned physiological responses in DA neurons.

Title: Astrocytic modulation of neuronal oscillations is associated with changes in cognitive flexibility

Authors: *A. T. BROCKETT, G. A. KANE, E. GOULD
Princeton Univ., Princeton, NJ

Abstract: Astrocytes are a highly heterogeneous and relatively understudied cell type. Across evolution, animals with more complex brains capable of more complex behavior also have more numerous and morphologically complex astrocytes. This suggests that astrocytes may be active participants in complex cognition. Recent evidence suggests that astrocytes in the medial prefrontal cortex (mPFC) change under conditions associated with enhanced cognitive flexibility (Brockett et al., 2015), while temporary disruption of astrocyte functioning is associated with diminished neuronal oscillations typically associated with cognitive behavior (Lee et al., 2014). Improvements in mPFC-dependent cognitive abilities such as cognitive flexibility are generally associated with changes in neuronal oscillations, particularly in the gamma and theta frequency ranges (Dajani et al., 2015). It is unclear what the cellular mechanism(s) responsible for the generation/ regulation of neuronal oscillations is, however, a recent study suggests that an astrocyte protein, S100β may be important for the regulation of rhythmic firing in neurons (Morquette et al., 2015). Few studies have examined whether manipulation of astrocyte functioning is associated with changes in cognitive flexibility and, subsequently, changes in neuronal oscillations. In order to investigate whether manipulation of astrocyte functioning alters cognitive flexibility and neuronal oscillations, we treated animals with either the drug L-alpha-aminoadipic acid (L-AAA), an astrocyte specific toxin or S100β, an astrocyte protein associated with enhanced rhythmic firing and tested rats on the attentional set-shifting task (ASST). We found that reduction of astrocyte number using L-AAA in the mPFC was associated with impaired cognitive flexibility, and conversely that infusion of S100β into the mPFC, enhanced cognitive flexibility. In a separate cohort of rats, we recorded unilateral local field potentials (LFPs) in the mPFC of rats treated bilaterally with either L-AAA or S100β. L-AAA treatment was associated with decreased power in the delta (0-4 Hz), alpha/ beta (12-20 Hz), and gamma (30-80 Hz), but not theta (6-10 Hz) frequency ranges. By contrast, infusion of S100β produced no changes in power across any frequency ranges, however, S100β infusion was associated with increased synchrony between theta and gamma oscillations, similar to what has been observed under conditions of enhanced cognitive ability. Collectively, these findings suggest that astrocyte

manipulations that alter cognitive flexibility are associated with changes in neuronal oscillations thought to be important for mPFC function.

Title: A recurrent neural network model of task switch cost

Authors: ***X. LI**[1], Z. ZHANG[2], J. C. ERLICH[3]
[2]Computer Sci., [1]New York Univ. Shanghai, Shanghai, China; [3]Neural Sci., NYU Shanghai, Shanghai, China

Abstract: Flexible task switching based on the relevant context is a key component of executive control. When humans and animals switch from one task to another, there is commonly a “switch cost”: an increase in error rate and/or reaction time. In task-switching paradigms where one task is more difficult than the other, such as the Stroop task or the Pro/Anti orienting task, the switch-cost is often asymmetric: the switch from the hard task (e.g. color-naming or Anti-orienting) to the easy task (e.g. word-reading or Pro-orienting) induces a larger cost than the reverse switch. This counter-intuitive phenomenon has been observed in humans, monkeys, and rats, and provides strong support for the "task-set inertia" theory of switch cost: that the cost is mostly due to a temporal carryover of the previous task set (Allport et al., 1994).
Despite the prevalence and robustness of this phenomenon, the fundamental question of how such as asymmetric switch cost is developed remains unknown. To understand the source of task switch cost and its underlying mechanism, we trained recurrent neural networks (RNN) to perform the Pro/Anti task-switching behavior using the same training procedures as those described in a recent rat study (Duan et al., 2015). Specifically, we used a simple RNN with 5 input nodes, 10 hidden nodes, 3 output nodes; and random Xavier initialized connection weights. The model was trained with a supervised learning rule using the Minpy implementation of backpropagation through time (https://github.com/dmlc/minpy). After going through the shaping steps identical to those experienced by the rats, the majority of our agents demonstrated the asymmetric switch-cost phenomenon. These results argue that the switch cost and its asymmetry are properties shaped by experiences, and not constrained by specific neural circuits. Having

simulated switch cost asymmetry in our agents, we then conducted an experiment impossible to do with current neuroscience techniques: we silenced the recurrent feedback but preserved the input activity of the network. This eliminated task switch-cost, providing evidence that the memory of the previous task maintained in the internal dynamics of the network interferes with the rule on switch trials, supporting the "task-set inertia" theory.

Title: Increasing orbitofrontal coordination and restoring behavioral flexibility after prenatal alcohol exposure

Authors: *J. A. KENTON, JR[1], K. MARQUARDT[2], J. L. BRIGMAN[2,3]
[2]Neurosciences, [1]Univ. of New Mexico, Albuquerque, NM; [3]New Mexico Alcohol Res. Ctr., Albuquerque, NM

Abstract: Increasing evidence demonstrates that moderate alcohol consumption during pregnancy can have negative impacts on executive function including attention, working memory and behavioral flexibility. We have previously shown that moderate prenatal alcohol exposure (PAE) in the mouse via a drinking in the dark paradigm impairs executive function by significantly increasing perseverative responding on a touchscreen visual reversal-learning task. Single unit and local field potential (LFP) recording during task performance found that moderate PAE mice had significantly decreased coordinated activity in the orbitofrontal cortex (OFC) after correct responses during early reversal. This loss of OFC LFP coherence was accompanied by decreased synchrony between the OFC and the dorsal striatum (dS). In the current studies, we investigated whether precise stimulation of the OFC pyramidal neurons or OFC-dS projection neurons following choice would 1) reintroduce OFC coherent activity lost in PAE mice and 2) reduce PAE induced maladaptive perseveration and increase behavioral flexibility. PAE (10% EtOH available 4 hours every day, throughout gestation; BAC: ~90mg/dL) and control mice from dams who drank saccharine only (SAC) were obtained from the NMARC Scientific Core. Mice were trained through discrimination and then microinfused with channelrhodopsin-expressing lentivirus (α-CAMKII-ChR2(H134R)-EYFP) directly into the OFC

or retrograde expressing herpesvirus (hEF1α-hChR2(H134R)-mCherry) into the dS. Mice were then implanted with recording optrodes that allowed single-unit and LFP recording of OFC and dS and light stimulation of OFC. Four weeks post-injection, PAE and SAC mice were tested to ensure discrimination learning retention and then tested on the reversal. During reversal session 1, 3, and 4, where PAE mice are shown to be significantly more perseverative, PAE and SAC mice received light pulses (10 Hz, 5mW, 5ms pulse for 1s) or no stimulation 1 second following a correct choice while waveform and LFP activity was recorded. We found that optogenetic stimulation was able to increase OFC firing *in vivo* and alter coordinated activity following correct choices during reversal. Targeted stimulation during early reversal also reduced perseveration in PAE mice compared to non-stimulated controls. These data provide evidence that stimulation of specific populations of cortical neurons may aid in value updating and reduce the impaired flexibility seen after PAE.

Title: Maternal fructose intake during pregnancy and lactation reduces learning capability in adult offspring

Authors: *F. A. TOBAR, S. R. ZAMUDIO, Sr, L. QUEVEDO, Sr
Dept. de Fisiología, Inst. Politécnico Nacional, Ciudad de México, Mexico

Abstract: Fructose is a monosaccharide present naturally in fruits, vegetables and honey. Due to its high sweetness and low cost, fructose use and consume has increased significantly in the last few decades, which has resulted in an increased risk in the development of various metabolic disorders, as obesity, dyslipidemia, insulin resistance and type II diabetes. Experiments in adult rats have shown that fructose consumption induces metabolic changes and reduces synaptic plasticity in hippocampus and cognitive performance. Several studies have demonstrated a significant relationship between maternal fructose intake and metabolic disorders in their offspring. However, there is less evidence about the long-term effects of fructose intake on the cognitive performances in adult offspring. Therefore, a study to evaluate the long-term effects of fructose intake on the metabolism and behavior in adulthood of offspring of dam rats fed a high-fructose diet was performed. Virgin female Sprague-Dawley rats (210-230) were divided into two groups: control group fed with regular diet and fructose group with high-fructose diet (50%

w/w), both groups were fed whit their respective diets during gestation and lactation stages. A tendency to higher body weight in offspring of fructose group compared with control group at postnatal day 60 was observed. This difference became significant on the postnatal day 100, including higher fat deposits. Results also shown a significant difference in fasting insulin, the HOMA index, in the insulin AUC and triglycerides, but not in cholesterol of adult offspring of fructose group compared with control group. In Barnes maze test, results shown that adult offspring of fructose group learn slower than adult offspring of control group. In this regard, we conclude that consumption of a high-fructose diet during gestation and lactation induces metabolic programing associated with deficits in learning process in adult offspring.

Title: Maternal overnutrition leads to cognitive and neurochemical abnormalities in the offspring

Authors: *D. PELEG-RAIBSTEIN, C. WOLFRUM
Translational Nutr. Biol. Lab., ETH Zurich, Schwerzenbach, Switzerland

Abstract: Ample evidence from epidemiological studies have linked maternal obesity with metabolic disorders such as obesity, cardiovascular disease and diabetes in the next generation. Recently, it was also shown that maternal obesity has long-term effects on the progeny's central nervous system. However, very little is known as to how maternal overnutrition may affect in particular the cognitive abilities of the offspring. Here, we examined whether maternal high-fat diet (HFD) exposure in mice may induce long-term cognitive impairments and neurochemical dysfunctions in the offspring during different age trajectories: peripubertal (postnatal day 35), adult (postnatal day 70) and aged adults (postnatal day 180). We found that maternal HFD led to cognitive disabilities in adult HFD offspring compared to controls. It was mostly evident in a discrimination learning paradigm in the T-Maze task and in active avoidance learning. In contrast, working memory performance in the Y-Maze was intact. Impairments were evident in the adult aged group. In addition, adult and adult aged HFD offspring showed potentiation of prepulse inhibition (PPI). The cognitive impairments observed at adulthood were associated with attenuations of amino acid levels in the medial prefrontal cortex and the hippocampus regions of HFD offspring. These data suggest that HFD offspring are at an increased risk to develop cognitive deficits, affecting learning and memory processes in adulthood. Furthermore, maternal

HFD exposure may enhance brain aging manly in the hippocampal and prefrontal cortex structures that may explain the cognitive deficits observed in the offspring.

Title: Cell penetrating fusion protein in postoperative cognitive dysfunction model

Authors: *B. KOO
Yonsei Univ., SEOUL, Korea, Republic of

Abstract: Impaired cognitive functioning is commonly presented after surgical operations and some patients who received surgery are vulnerable to postoperative cognitive dysfunction (POCD). Signs of POCD are closely associated with development of systemic or hippocampal inflammation. However, the precise pathophysiological mechanisms and effective therapy for POCD still remain unclear. After injury, the transcriptional factor, nuclear factor kappa (κ) B (NF-κB) is considered as a key regulator/stimulator of inflammation amplification. Therefore, here we developed cell-penetrating fusion protein called nt-p65-TMD, which inhibits NF-κB activation by translocating into nucleus efficiently, and discovered a potent role of nt-p65-TMD in surgery-induced cognitive impairment. In this study, abdominal surgery model was induced by rubbing intestine and clamping superior mesenteric artery in ICR adult mice. We evaluated behavioral parameters related to cognition and memory functions after nt-p65-TMD treatment by elevated plus maze, novel object recognition test, and passive avoidance test. We assessed vascular integrity impairment and immune cell recruitment in the brain, and inflammatory and anti-inflammatory mediator levels in the spleen and hippocampus. Also, inflammatory and anti-inflammatory mediator levels were measured in cultured microglia and macrophage cell line after treatment nt-p65-TMD under LPS challenge. Our data showed that the nt-p65-TMD has strong immune-regulatory properties to reverse surgery-induced increment of cerebrovascular integrity impairment, subsequent peripheral immune cell infiltration and inflammation amplification, which can lead to decline cognition. Especially, nt-p65-TMD has a novel function to regulate systemic inflammation toward anti-inflammatory environments. Conclusively, nt-p65-TMD will be of great significance in the treatment of POCD.

Title: Nasal administration of mesenchymal stem cells promote recovery from cisplatin-induced chemobrain

Authors: *G. S. CHIU[1], N. BOUKELMOUNE[1], A. KAVELAARS[1], V. RAO[2], C. KINGSLEY[3], S. R. KESLER[2], C. J. HEIJNEN[1]

Abstract: Chemotherapy-induced cognitive impairment (CICI), termed “chemobrain”, is a common neurotoxic side effect of cancer treatment and significantly reduces patient’s quality of life. We explored the possibility of treating chemobrain by nasal administration of bone-marrow derived mesenchymal stem cells (MSC). Male C57BL/6J mice were injected with cisplatin for two 5-day cycles followed by nasal administration of murine MSC at 48- and 96-hours after cisplatin treatment. Cisplatin- induced deficits in executive functioning and working memory were assessed by the puzzle box test, novel object/place recognition test, and the Y-maze. Nasal MSC administration promoted recovery from CICI, as shown by a reversal of the deficit in executive functioning and of working memory. Cisplatin-treated mice showed lower global efficiency of the functional connectome compared to sham controls as determined by resting-state functional magnetic resonance imaging (rs-fMRI). However, MSC-treated animals showed similar global efficiency to sham controls. On the cellular level, cisplatin treatment resulted in a synaptosomal mitochondrial dysfunction, whereas nasal MSC were capable of promoting full recovery of mitochondrial function. Our data support the hypothesis that nasal administration of MSC promote recovery from chemotherapy-induced cognitive deficits, and restore decreased global efficiency of neuronal connectivity and synaptosomal mitochondrial dysfunction. Nasal MSC treatment may thus offer a realistic treatment for chemobrain.

Title: Lateral prefrontal cortex single neuron and ensemble activity during associative learning in virtually navigating monkeys

Authors: *L. DUONG[1], R. A. GULLI[2], B. W. CORRIGAN[3], M. L. LEAVITT[3], G. DOUCET[4], J. C. MARTINEZ-TRUJILLO[5]
[1]Robarts Res. Inst., London Ontario, ON, Canada; [2]Dept. of Pharmacol. and Physiol., Western Univ., London, ON, Canada; [3]Physiol., [4]McGill Univ., Montreal, QC, Canada; [5]Physiol. and Pharmacol., Univ. of Western Ontario, London, ON, Canada

Abstract: Associative learning and memory is imperative to our cognition and informed decision making. This essential function is mediated by coordinated activity across several brain areas. In primates, the lateral prefrontal cortex (PFC) and the hippocampus are highly coordinated during associative learning (Brincat & Miller, 2015). Changes in single neuron activity in dorsolateral PFC correlate with changes in behavioral performance during associative learning tasks (Asaad et al., 1998) and rule context (Rainer et al., 1998), corroborating primate dlPFC lesion studies resulting in impaired performance on associative learning tasks (Petrides,1987). However, little is known about how prefrontal single neuron activity and ensemble interactions support associative learning. To study this, we recorded ensembles of extracellular spiking activity from two male macaque monkeys performing a novel joystick task in a 3D virtual X-shaped maze (Doucet et al. 2016), incorporating elements of learning, and spatial navigation in a naturalistic environment with unconstrained navigation and eye movement.
Our task was a classical A-B-A block design wherein both blocks A and B of each session contained a context-object associative learning task. In both blocks, monkeys used a joystick to freely navigate through the maze towards a branched decision point. The monkeys then chose to navigate towards one of two colored discs, with the correct disc being contingent on the texture of the maze walls (context: wood or steel). In block A trials, the context-object association was fixed across all sessions (wood context, purple>orange; steel context, orange>purple). In block B

trials, a novel pair of colored discs were presented, and monkeys learned the new context-object association by trial-and-error. This bookended block design allowed us to compare the consolidated neural state during block A trials against the learning states during block B. We recorded neural activity from two chronically implanted multielectrode arrays in the left dorsolateral and ventrolateral prefrontal cortex of macaque monkeys while they performed the task.
We regressed animal behavioural and experimental parameters onto single unit trial activity during block A (consolidated state) and B (learning state), and found an emergence of tuning for various task parameters. Furthermore, we then analyzed ensemble interactions and temporal dynamics on a trial-by-trial basis, and found striking differences between consolidated and learning trajectories in state-space. Taken together, our findings show the complexity of PFC single neuron and ensemble activity during associative learning.

Abstract: The hippocampus has long been studied as a component of two functional systems in the brain: cognitive mapping of the sensory environment, and memory (O'Keefe and Nadel, 1978; Buzsaki and Moser, 2013; Eichenbaum and Cohen, 2014; Schiller et al., 2015). How neurons in the hippocampus could simultaneously support these diverse cognitive functions is unclear. To determine whether these functions are simultaneously supported by a common or

distinct neural substrate within the hippocampus, we recorded single-neuron spikes from the hippocampus of two rhesus monkeys (Macaca mulatta) while they performed two tasks in the same virtual reality environment (VE): 1) foraging; and 2) a context-object associative learning (AL) task.
In the foraging task, animals navigated through the VE towards a red volume randomly positioned in the maze (https://youtu.be/aWvheMzxMJo). In the AL task, monkeys learned a reversed two-context, three-object reward value hierarchy embedded into the VE (https://youtu.be/RHx9Lw65oDw). The context was defined by the texture of the walls of the maze, and these were fixed across days. The context and object pair on every trial was selected randomly, and new object colors were pseudo-randomly selected daily from a seven-color set; thus, a new associative hierarchy was learned daily.
In both tasks, place fields of hippocampal neurons cover the entire maze, and this activity can be used to decode the subject's position in the maze. Spatial decoding improves when accounting for heading direction in the maze, and furthermore when decoding gaze position in the environment rather than subject position. However, in all cases, these "cognitive maps" do not generalize across tasks, even though the environment is unchanged. Changes in the cross-task neural code are attributed to encoding of attended features of the associative learning task in single neurons: namely neurons encoding the texture of the walls, the colored objects, and the conjunction of these two in the AL task. The development of these selectivities mirrors the subjects' learning in the AL task.
This work suggests that the hippocampus does not strictly encode sensory maps to guide survey navigation. Instead of framing the hippocampus as the brain's Geographical Positional System, the flexible representations observed here reflect the mnemonic processes inherent in a General Processing System (Tulving, 1985). Hippocampal neurons may provide a substrate for rapid encoding behaviorally relevant associations in a context dependent manner. These representations may be consolidated in neocortex, including but not limited to prefrontal cortex (see, Duong, Gulli, et al., SfN 2017).

Title: Prefrontal cortex ensemble activity during associative visuomotor rule learning in primates

Authors: *M. L. LEAVITT[1], C. BOULAY[2], R. A. GULLI[3], L. DUONG[4], A. J. SACHS[5], J. C. MARTINEZ-TRUJILLO[6]
[1]Physiol., McGill Univ., Montreal, QC, Canada; [2]Neurosciences, Ottawa Hosp. Res. Inst., Ottawa, ON, Canada; [3]Dept. of Pharmacol. and Physiol., Western Univ., London, ON, Canada; [4]Robarts Res. Inst., London Ontario, ON, Canada; [5]Div. of Neurosurg., Ottawa Hosp. Res. Institute, Univ. of Ottawa, Ottawa, ON, Canada; [6]Physiol. and Pharmacol., Univ. of Western Ontario, London, ON, Canada

Abstract: Lateral prefrontal cortex (LPFC) is necessary for learning associations between arbitrary pairs of stimuli and responses. Lesions to LPFC area 8a severely impair the ability of macaques to learn associations between more than one stimulus-response pair simultaneously (Petrides, 1987). Saccade direction selectivity in single LPFC neurons has also been shown to emerge earlier in a trial as macaques learn the associations between objects and saccade directions (Asaad et al., 1998). However, the ensemble-level mechanisms of conditional associative learning in macaques remain poorly understood. The need to average neuronal activity across multiple instances of learning in single neuron recordings can mask the underlying neuronal dynamics. In order to investigate this issue, we recorded from microelectrode arrays implanted in macaque area 8a while subjects learned pairs of conditional visuomotor associations.
We trained two monkeys to perform the following task: First, a rule was generated at the beginning of a recording session. Two of three possible color cues were randomly chosen, and one of four possible pairs of target locations were also randomly chosen. Each color was associated with one of the targets, for example blue = top target, green = bottom target. A single trial started with central fixation (700ms), then presentation of the two targets (250-500ms), presentation of one of the two colors cues (1000ms), removal of the color cue and a delay epoch (300ms), and extinguishing of the fixation point, cueing the animal to make a saccade to one of the targets. If they chose the target associated with the color cue, they received a juice reward. Trials were repeated until the animal reached criterion, which we defined as two blocks of 30 trials with at $\geq$ 80% success. After reaching criterion, a new rule was generated by randomly sampling, with replacement, from the pool of cue colors and target locations.
Animals performed 2-10 rule switches in a single recording session. We used a linear classifier to decode ensemble activity, and found that saccade direction decoding was more robust after compared to before learning; this difference emerges roughly 500ms after presentation of the color cue and persists throughout the remainder of a trial. We also found that decoding performance during the final 200ms of the delay epoch correlates with instantaneous measures of behavioral performance (median $\rho = 0.75$).
Our results indicate that ensemble representation of saccade direction is stronger after learning, and that the robustness of ensemble saccade representation correlates with learning-related fluctuations in behavioral performance.

Title: The macaque fronto-striatal-hippocampus axis encodes feature-specific prediction errors

Authors: *M. OEMISCH[1], S. WESTENDORFF[1], D. KAPING[1,2], T. WOMELSDORF[1,3]
[1]Dept. of Biol., York Univ., Toronto, ON, Canada; [2]Natl. Inst. of Mental Hlth., Klecany, Czech Republic; [3]Dept. of Psychology, Vanderbilt Univ., Nashville, TN

Abstract: When only one stimulus feature among many predicts reward, it is pivotal for an agent to learn which specific feature is causally linked to changes in reward outcomes. This linkage could be achieved through feature-specific prediction error (PE) signals, but it is unknown where these feature-tuned PEs might be encoded and whether PE signals carry sufficiently detailed feature information to serve as selective learning signals for updating synaptic weights. To find feature-specific PEs, we combined data from neuronal recordings in anterior cingulate cortex (ACC), dorsal prefrontal cortex (PFC) and hippocampus (HPC) of two macaques, and of ACC, PFC, caudate nucleus (CD) and ventral striatum (VS) of one macaque. All animals performed one of two variants of a feature-based reversal learning task. The task presented, peripherally to the gaze center, two moving gratings that differed in color, location, and motion. In one task variant, animals reported the rotation of the grating, in the second variant, the motion direction of the grating with the reward-associated color, respectively. The rewarded color was reversed uncued between blocks, with rotation/motion direction and location varying independently of color. PEs were quantified using a reinforcement learning model with Bayesian feature-weighting. Neurons were identified as encoding positive (pPEs), negative (nPEs) or absolute (unsigned PE) prediction errors when their firing rate correlated with the magnitude of the PE. PE signals were identified as feature-specific when they were selectively larger for e.g. a specific rewarded color. We found that on average 55% of all neurons encoded a PE signal. For 85% of those neurons the PE signal was selective for the feature giving rise to the PE. These feature-specific PEs (1) were found in all areas tested, (2) were more strongly encoded than nonspecific PEs, and (3) for pPEs were most often specific to the reward-associated color dimension. Feature-specific PEs were consistently encoded earliest in the HPC and latest in VS. These results document that across the entire fronto-striatal-hippocampus axis, prediction error encoding is tuned to the features that give rise to the PEs. The latency analysis suggests that the HPC plays an essential role in identifying which sensory features give rise to unexpected outcomes. We speculate that the feature specificity of the error signals allows to identify those

synapses across the network that need updating during learning, enabling selective credit assignment in feature space.

Abstract: Selecting an action to achieve a desired outcome in response to a conditional stimulus requires learned stimulus-action-outcome mappings. However, if the causal features are separated in time or intermingled with distractors, how does the neural activity provide a stable, cross-temporal representation? This is the credit assignment problem. We designed a task in which two non-human primates performed a credit assignment task. We recorded multiple single neurons in the lateral prefrontal cortex and dorsal striatum simultaneously. Here, we mainly focused on analyzing prefrontal-striatal interactions. We observed sustained neural activity across the prefrontal cortex and striatum beginning with feedback but extending well past this. This sustained, feedback-triggered activity may contribute to credit assignment.

Title: Structural changes in the primate brain following cognitive training

Authors: *J. SIMON, IV[1], C. G. DAMATAC[1], J. OLMSTEAD[2], J. NAGY[1], S. FROUDIST-WALSH[1], D. L. DICKSTEIN[3], M. VARGHESE[1], W. G. JANSSEN[1], L. FLEYSHER[2], R. O'HALLORAN[2], P. L. CROXSON[1]
[1]Neurosci., [2]Icahn Sch. of Med. At Mount Sinai, New York, NY; [3]Icahn Sch. of Med. At Mount Sinai, Rockville, MD

Abstract: Background:
Cognitive training therapy has been used to assist in recovery after loss of function. However, how long these interventions last and the underlying neuronal dynamics remain unknown. We investigated this using MRI measures of structural change and microstructural measures of neuron morphology. We hypothesized that training monkeys on an object recognition memory task that depends on the ventrolateral prefrontal cortex (VLPFC) would lead to volumetric increases in grey matter that would have specific microstructural correlates.
Methods:
We injected pyramidal neurons from layers 2/3 of the VLPFC and a control region, perirhinal cortex (PRh) via electric current (10nA) with Lucifer Yellow dye. Neurons were traced in Neurolucida at 40x. We performed Sholl analysis of traced neurons with concentric circles every 30um. We also analyzed high resolution z-stack images of dendritic segments (63x magnification approximately 50-100um away from the soma) for spine characteristics.
Results:
Monkeys learning the VLPFC-dependent task showed increases in grey matter volume selectively in VLPFC compared with control monkeys. Sholl analysis revealed increased basal dendritic branching complexity in the VLPFC. This finding was reversed in the PRh, which displayed increased basal dendritic branching complexity in the control monkeys, which learned a version of the task dependent on PRh. There was also a group difference for spine density, apical head diameter and spine volume.
Conclusions:
Cognitive training resulted in dynamic long-lasting changes that can be measured with both MRI

and microstructural measures of dendritic arborization and spine growth. This is the first study of this relationship in non-human primates.

Title: Impaired cognitive flexibility after neonatal perirhinal lesions in rhesus macaques

Authors: ***A. R. WEISS**[1,2], J. B. WHITE[2], R. RICHARDSON[2], J. BACHEVALIER[2]
[1]Oregon Hlth. and Sci. University/Onprc, Beaverton, OR; [2]Emory University/YNPRC, Atlanta, GA

Abstract: Previous research showed that monkeys with neonatal perirhinal lesions (Neo-PRh) were impaired on working memory tasks that generated proactive interference, but performed normally on working memory tasks devoid of interference (Weiss et al., 2016, Front Sys Neurosci, 9:179), suggesting that working memory processes were spared after the Neo-PRh lesions. However, these findings also showed that Neo-PRh lesions may have disrupted cognitive processes important for resolving proactive interference, such as behavioral inhibition and/or cognitive flexibility. For example, increases in perseverative errors observed in the Neo-PRh animals could be due to failure to suppress the influence of previously acquired stimulus-reward associations (behavioral inhibition), resulting in repetitive tendencies. However, a second interpretation is that the impairment could be due to difficulty shifting attention towards new stimulus-reward associations (cognitive flexibility), resulting in a tendency to choose the previously rewarded stimulus. Lesion studies in monkeys have already demonstrated a double-dissociation between behavioral inhibition supported by the orbitofrontal cortex (OFC), and cognitive flexibility supported by the ventrolateral prefrontal cortex (vlPFC) (Dias et al., 1997, J Neurosci, 17:9285). Given that the PRh has interconnections with both of these cortical areas (Suzuki, 1996, Op Neurobiol, 6:179), it is possible that the PRh also may play a role in mechanisms underlying behavioral inhibition and/or cognitive flexibility. To distinguish between these two possible explanations, we characterized the ability of the same Neo-PRh monkeys to

perform a task that taps both capacities: the Intradimensional-Extradimensional set-shifting paradigm. The results indicated that Neo-PRh monkeys completed the simple and compound discrimination stages, the intradimensional shift stage, and all reversal stages (measuring behavioral inhibition) comparably to controls, but made significantly more errors on the extradimensional shift stage of the task (measuring cognitive flexibility) as compared to age- and experience-matched controls [t(9)=-2.320, p=0.045]. These data demonstrate that impaired cognitive flexibility is the likely source of increased perseverative errors made by the same Neo-PRh monkeys when performing WM tasks, rather than impaired behavioral inhibition, and imply that the perirhinal cortex may play a unique and critical role in the development of attentional set shifting abilities supported by the vlPFC. This work was supported by grants MH-58846 and NSF-GRFP DGE-1444932.

Title: Transient inactivation of the parahippocampal cortex impairs nonnavigational spatial memory in macaques

Authors: *E. LAFLAMME[1], H. WAGUESPACK[2], P. A. FORCELLI[3], L. MALKOVA[4]
[1]Pharmacol. & Physiol., [2]Neurosci., [3]Dept of Pharmacol., Georgetown Univ., Washington, DC; [4]Dept Pharmacol & Physiol and the Interdisciplinary Program in Neurosci., Georgetown Univ. Med. Ctr., Washington, DC

Abstract: Our lab has previously reported that transient pharmacological inactivation of the hippocampus severely disrupts performance on the Hamilton Search Task (HST), a self-ordered non-navigational test of spatial memory (Forcelli *et al.*, 2014). In this task animals are presented with an array of eight boxes, each containing a food reinforcer; one box may be opened per trial, with trials separated by a delay. Only the spatial location of the boxes serves as a cue to solve the task. The optimal strategy is to open each box once without returning to previously visited locations. Following hippocampal inactivation animals performed at chance levels on 30 sec delay trials. In accordance with the dorsal-ventral stream hypothesis (Ungerleider & Mishkin, 1982), spatial information enters the hippocampus through a relay in the parahippocampal cortex (PHC). Here, we hypothesized that inactivation of the PHC would thus disrupt memory

performance on the task. Three male rhesus macaques (*Macaca mulatta*) were pre-trained on the HST prior to implantation of an MRI-guided stereotaxic microinfusion platform. Subject Y received seven bilateral microinfusions of the glutamatergic antagonist kynurenic acid (KYNA, 100mM, 1.5µl) and six of physiological saline (1.5µl) in the PHC; subject L received seven bilateral microinfusions of KYNA (100mM, 1.5µl) and four of saline (1.5µl); and microinfusions for subject S are under way. The preliminary data demonstrate that transient inactivation of the PHC impairs HST performance in comparison to saline controls. The number of trials to complete the task and the repetition index (a measure of the frequency and severity of opening errors) fell to chance levels. It did not impair performance on a variation of the HST which has color cues in addition to spatial cues, providing the option of a non-spatial strategy. This finding is consistent with our previous data showing impairment after hippocampal inactivation.

Title: Mapped or to be mapped? Learning the meaning of new stimuli increase the cross-correlated activity of prefrontal neurons

Authors: *S. NOUGARET, L. FERRUCCI, E. MARCOS, A. GENOVESIO
Dept. of Physiol. and Pharmacol. Vittorio Erspamer, Sapienza Univ. of Rome, Roma, Italy

Abstract: To face of new situations, animals have to learn the appropriate behavior and reduce the number of unproductive choices to be the most effective in no time. The prefrontal cortex is assumed to be a key component in such a learning implying that each new association must be represented at its neuronal level. Nevertheless, whether and how this signal is encoded by the prefrontal cell-assemblies in not clear. In the present study, to better understand this mechanism we analyzed the correlated firing of simultaneously recorded pairs of neurons and the variability of their firing rate in the dorsolateral and the mediolateral part of the prefrontal cortex of two rhesus monkeys performing a conditional motor tasks in which three stimuli should be associated to three spatial targets with either new (new mapping task) or familiar associations (familiar mapping task). In this tasks after a period of fixation, a visual instruction stimulus appeared at that location, and three potential response targets appeared in three positions: right, left, and up from center. One stimulus was selected in each trial from a set of three and the disappearance of

the stimulus served as the go signal for the saccade to one target. Each stimulus was mapped to only one response. The only difference between these two tasks was that in one case, the mapping between stimuli and targets was new and required learning while in the other case was already acquired previously. Of the 422 simultaneously recorded pairs of neurons, we found a higher number of neural pairs significantly correlated during stimulus presentation in the new mapping task (38/422, 9%) than during the presentation of stimuli in the familiar mapping task (16/422, 4%) (2-sample χ^2 test, $p < 0.01$). Moreover, during the same epoch, the variability of the firing rate of these prefrontal neurons was significantly higher in the new mapping task than in the familiar mapping task (Fano factor, 2.1 vs 1.8, paired t test, $p < 0.001$). These results demonstrate that the correlation structure and the variability represent major components of the learning processes of conditional motor associations in the prefrontal cortex.

Title: Learning sound sequences in mouse auditory cortex

Authors: *A. G. LIBBY[1], T. BUSCHMAN[1,2]
[1]Princeton Neurosci. Inst., [2]Dept. of Psychology, Princeton Univ., Princeton, NJ

Abstract: Making accurate predictions is a core cognitive function: by predicting upcoming events, we can respond faster and optimize our actions. Our ability to make predictions relies on implicitly learning the common statistical relationships in our environment. However, the circuit mechanisms that allow the brain to learn these regularities remain unknown. To study how associations are learned locally at the sensory level, we performed chronic electrophysiological recordings in mouse auditory cortex, while they repeatedly listened to a sequence of chords: a common chord sequence (A-B-C-D) and an uncommon sequence (A-B-C*-D). To probe the extent to which an association within the sequence is learned, we morphed the 3rd sequence element between the common (C) and uncommon (C*) chords. Using data from multiple channels within auditory cortex, we built a classifier to track how the information within the neural responses changes during repeated experiences with the common sequence. We find shifts in the neural responses to mixtures of C and C*after learning. Specifically, the neural responses

to C* increasingly match the response to C. This suggests exposure to statistical relationships changes the organization of neural representations in early sensory cortex.

Title: Memory through randomness: A spiking network model for flexible working memory

Authors: *F. BOUCHACOURT[1], T. BUSCHMAN[2]
[1]Princeton Neurosci. Inst., Princeton Neurosci. Inst., Princeton, NJ; [2]Princeton Neurosci. Inst. & Dept of Psychology, Princeton Univ., Princeton, NJ

Abstract: Working memory is the cognitive ability to actively maintain information during mnemonic delays of several seconds. Importantly, working memory is extremely flexible: we are able to hold anything in mind. However, working memory is often modeled as an attractor-like persisting state of activity in the dynamics of tightly tuned sensory neurons. These models rely on carefully controlled excitatory connections between neurons, and thus are not flexible.
Here we present a novel network model that captures the flexibility of working memory. The network uses a two-layer structure combining selectively tuned neurons and randomly connected neurons. The first “sensory” layer of selective neurons encodes each input to the network. Inputs are then maintained through bi-directional recurrent connectivity between the sensory layer and the second “control” layer composed of randomly connected neurons. These interactions are sufficient to hold multiple, independent memoranda. Importantly, due to the untuned, parameter-free nature of these interactions, the model is able to maintain any type of incoming information, showing the flexibility of working memory.
In addition, this model captures several important experimental observations. First, mnemonic activity is distributed across multiple layers, as seen in human imaging and monkey electrophysiology. Second, the control layer is composed of high-dimensional mixed-selective neurons observed in prefrontal cortex. Third, the model exhibits limited capacity due to interference between representations in the control layer.
Finally, it was recently shown that the brain compensates for the capacity limitation of working memory by exploiting the statistical structure of the current task, i.e. by encoding jointly similar features of stimuli into mnemonic “chunks”. Ongoing work is investigating whether hebbian

plasticity in the network is sufficient to learn such chunks and if doing so matches behavioral improvements in mnemonic accuracy.

Title: Navigating in neural and behavioral manifolds with mutli-site electrical microstimulation

Authors: *S. TAFAZOLI[1], K. LETAI[2], T. BUSCHMAN[3]
[1]Princeton Neurosci. Inst., [3]Princeton Neurosci. Inst. & Dept of Psychology, [2]Princeton Univ., Princeton, NJ

Abstract: Electrical microstimulation is often used as a tool for mapping sensory-motor functions and studying the neuronal basis of cognition. We have recently shown that multi-site microstimulation can produce a multi-dimensional neural response. However, the relationship between dynamics of responses produced by micro stimulation and sensory stimulation is unknown. To test this, we combined simultaneous multi-electrode recordings, multi-site electrical stimulation, and visual stimulation in anesthetized mice. Electrical stimulation and recording were performed with 64-channel silicon probes placed in primary visual cortex. Using 32 channels for recording and 32 channels for stimulation allowed us to simultaneously record from small populations of single neurons while patterning stimulation at nearby sites. Electrical stimulation trials were interleaved by brief presentation of visual stimuli (drawn from the Caltech 101 database). We found that both visual and electrical stimulation can reliably elicit patterns of neural activity. Further analysis revealed that the response manifolds generated by both visual and electrical stimulation were largely overlapping. These findings suggest that electrical stimulation can produce neural dynamics close to natural sensory stimulation and provides a building block for probing complex neural dynamics and new generation of neural prosthetics.

Title: Compression of information in visual working memory

Authors: *P. KOLLIAS, T. BUSCHMAN
Princeton Univ., Princeton, NJ

Abstract: Working memory has a limited capacity; the average adult can only remember ~4 items. However, what constitutes an 'item' in working memory is unknown. We argue that items are formed by grouping together representations that regularly co-occur together (Brady etAl, 2009). For example, statistical regularities between the letters 'S', 'f', and 'N' create a 'SfN' item that is easier to remember than the sum of its parts. To understand the neural mechanisms underlying such 'chunking', we trained monkeys on a visual working memory task where certain objects were chunk-able. Specifically, monkeys were presented with a sample array. After a memory delay, a single cue item was presented at fixation and subjects were required to saccade to its location in the remembered sample array. Chunk-able items were created by manipulating the relative frequency of some configurations of stimuli over others (i.e. there was statistical regularities between the locations of objects). As predicted, subjects memory performance was significantly better when displays contained such chunked items in comparison to 'unchunked' arrays (i.e. when constituent stimuli were in a different pattern). This effect was particularly true when memory load was increased, suggesting the chunked items were compressed in working memory, allowing for more information about other items to be stored. Importantly, patterns of error responses indicate that improvement in performance could not be explained by post-perceptual inference strategies. In summary, our results suggest that monkeys, as humans, can exploit statistical structure of stimuli to form compressed working memory representations.

Title: Oscillatory neural activity for perceived and memorized representations of motion direction in the primate lateral prefrontal cortex

Authors: *M. ROUSSY[1], D. MENDOZA-HALLIDAY[4], J. C. MARTINEZ-TRUJILLO[2], L. PALANIYAPPAN[3]
[2]Physiol. and Pharmacol., [3]Biophysics and Psychiatry, [1]Univ. of Western Ontario, London, ON, Canada; [4]MIT, Cambridge, MA

Abstract: The macaque lateral prefrontal cortex (LPFC) is proposed to monitor both externally driven sensory stimuli during visual perception and internally driven mnemonic visual representations during working memory maintenance. Within this region, distinct populations of neurons have been identified to encode either mnemonic or perceived representations of motion direction. However, it remains unclear whether local networks in the LPFC generate different oscillatory activity during perceptual and mnemonic states. Here we address this matter by examining local field potential (LFP) oscillations and single unit activity during two different task conditions, contingent on either perception or working memory. We recorded neural activity from LPFC areas 8a and 46 in two male rhesus macaques while they performed two variants of a match to sample task. In all trials, the animals were presented with a sample random dot pattern moving in one of four directions. In the perceptual condition, the sample persisted during a delay period and the animal was required to match the direction of the sample to that of a test stimulus. In the mnemonic condition, the sample disappeared during the delay period which required the animal to complete the task using a mnemonic representation of the sample. We recorded LFP oscillations and computed their power spectrum during the delay periods using a multitaper method. We then calculated the proportion of explained variance (PEV) contributed by motion direction to test for direction selectivity of LFP sites during both task conditions. A significant number of LFP sites showed direction selectivity across all frequency bands during either the perceptual or mnemonic delay period. In addition, within the theta frequency band (4-8Hz), more sites expressed direction selectivity during the mnemonic state than the perceptual state. We also computed the proportion of sites that displayed selectivity for motion direction in the different frequency bands as a function of the encoding properties of simultaneously recorded neurons. During the mnemonic delay period, LFP sites containing memory encoding neurons showed

greater PEV in the theta frequency range than sites containing perceptual neurons. These findings suggest that different oscillatory phenomena characterize perceptual and mnemonic states across different LPFC sites and that these phenomena are linked to the coding properties of neurons within a given site. Future analysis will further examine the relationship between spiking activity and these oscillatory behaviors.

Title: Structural variability across the primate brain

Authors: *P. L. CROXSON[1], S. J. FORKEL[2], L. CERLIANI[3], M. THIEBAUT DE SCHOTTEN[3]
[1]Neurosci., Icahn Sch. of Med. at Mount Sinai, New York, NY; [2]Kings Col. London, London, United Kingdom; [3]Inst. du Cerveau et de la Moelle épinière (ICM), Paris, France

Abstract: A large amount of variability exists across human brains; revealed initially on a small scale by *post mortem* studies and, more recently, on a larger scale with the advent of neuroimaging . We considered that variability may be a useful index of complexity, and therefore a tool for understanding differences between species. However, whether brain variability is greater in humans and should be considered another layer of complexity when compared to other species is unknown. Here, we quantified the amount of structural variability in the cortex and white matter and compared the human and macaque monkey brain.
T1-weighted and fractional anisotropy maps were obtained from two sets of 10 adult healthy controls (5 males per set; age range 26 - 35 years) from the Human Connectome Project (HCP) after determining the optimal number of participants to build a template, and *in vivo* from 10 adult healthy rhesus macaque monkeys (*Macaca mulatta;* 6 males; age range 3 - 5 years). We used diffeormorphic deformation to produce optimal templates for each species (using Advanced

Normalization Tools (ANTs), and established the amount of inter-subject variability for T1 and FA maps using Gibbs' equation. Using the Jacobian determinant of the deformation, which is independent of brain volume, we compared these values between species, and assessed the hemispheric differences within species.
Grey matter was significantly more variable than white matter in both species. However, the human brain was not significantly more variable overall than the monkey brain. Both species overall showed distinct increased variability in specific regions, and there was a high degree of overlap between these regions and phylogenetically recent regions. Both species also showed an increased variability for the superficial white matter and lower variability for deep white matter structures.
Compared to monkeys, humans showed specifically lower variability in the anterior portion of the lateral prefrontal cortex. Humans also showed hemispheric differences in variability across a wide range of cortical regions, while monkeys showed almost no hemispheric differences apart from two regions of the parietal cortex. This is potentially one way in which evolution has led to divergence between the human and monkey.

Title: Dynamic plasticity of the functional connectome is predicted by pre-lesion connectivity in the non-human primate brain

Authors: *S. FROUDIST-WALSH[1], P. G. F. BROWNING[1,2], J. J. YOUNG[1], K. L. MURPHY[3], R. B. MARS[4,5], L. FLEYSHER[1], P. CROXSON[1]

Abstract: The brain displays a remarkable ability to adapt following injury in order to recover function. However, the principles that govern which areas undergo plasticity, and when, are not well known. This is partly due the difficulty in obtaining pre-lesion MRI scans in otherwise healthy human subjects.
Here, we investigated the time-course of plasticity in monkeys after a focal neurotoxic lesion to the hippocampus using multi-modal MRI. We used a hierarchical connectivity analysis approach to analyze plastic functional connectivity changes across a range of spatial (global, cognitive and local networks) and temporal (acute and chronic) scales. We additionally acquired high-resolution structural MRI scans in order to analyse structural plasticity.
We found that widespread functional connectivity alterations occurred throughout the brain, and that timing of connectivity changes was critically dependent on connectivity with the hippocampus before the lesion. Acutely following the lesion the greatest changes occured in areas that were least functionally connected with the hippocampus, but over time this pattern reversed, indicating dynamic reorganisation. This happened despite structural damage being stable, and limited to structures directly connected with the hippocampus.
The brain responds to injury by widely increasing the connectivity between the majority of spared areas during the acute phase, before some normalisation of global connectivity during the chronic phase post injury, perhaps due a need to develop an energy-efficient brain network. The timing of connectivity changes in particular brain regions however is heavily dependent on pre-lesion connectivity with the injured brain area. This is likely to reflect the differing timescales of plastic responses occurring in areas with and without direct connections to the lesioned area, ranging from the release from synaptic inhibition (seconds to hours after lesion) to axon regeneration and sprouting (weeks to months later). Our findings shed light on the time-course of functional connectivity changes following damage in the otherwise healthy brain, and suggest a simple spatiotemporal rule governing plasticity: the more connected a brain region is to the lesioned area, the longer it will take to plastically adapt its connectivity.

Abstract: A growing body of literature has demonstrated the ability to delineate cortical areas in the human brain based upon the detection of spatial transitions in functional connectivity (FC) profiles (Cohen et al., 2008; Wig et al., 2014). Here, we demonstrate the feasibility of extending the application of parcellation approaches to non-human primates (NHP), demonstrating the reliability of these parcellations and the distinct FC between awake and anesthetic conditions. We collected awake and anesthetized functional MRI scans from a male rhesus macaque monkey (11 sessions, 3 anesthesia sessions with MION agent [monocrystalline iron oxide particle], 5 awake sessions with MION, and 3 awake sessions without MION). We calculated FC-similarity maps, followed by the spatial gradient and edge detection computation on native surface. The spatial correlations were calculated to investigate the reproducibility and the requirement of scan time for a relatively robust boundary map for each condition. We further explored the parcel-based FC within and between network under different conditions.The overall pattern of the functional boundaries in the NHP was concordant with the measured surface geometry (e.g. strong gradients parallel to the posterior extent of the cingulate gyrus, lunate sulcus, superior temporal gyrus), though also revealed distinct characteristics (Figure 1A-B). The gradients and edge density were higher reproducibility between scans with 50 min scan data (Figure 1A-B). Strikingly, compare to awake, the FC under anesthesia exhibited decreased within- and between-networks connectivity for primary visual, sensorimotor, cingulo-opercular and frontal-parietal networks (Figure 1C).By examining the transition pattern of FC similarity in macaque under awake and anesthetic conditions, we have demonstrated the ability to detect functional boundaries using fMRI in macaque, suggesting a reliable scheme for delineating cortical organization in macaque. The unique FC patterns under awake and anesthesia provide a valuable insight into different brain states.

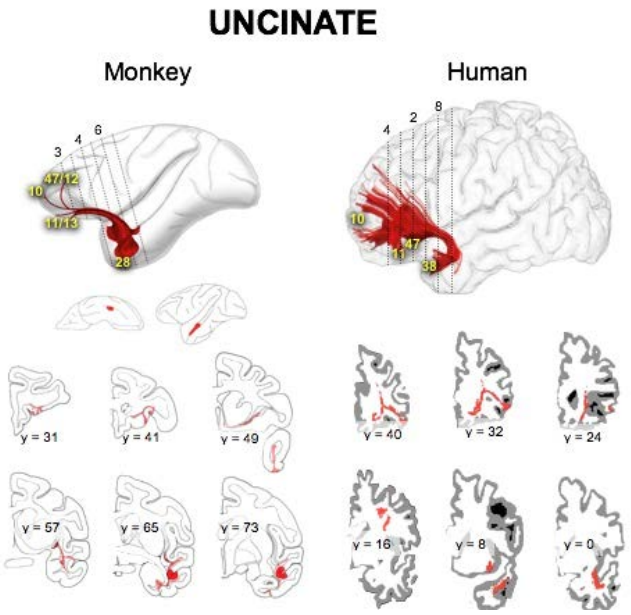
Title: Monkey to human comparative anatomy of the frontal lobe association tracts

Authors: *M. THIEBAUT DE SCHOTTEN
BCBlab, Frontlab, Inst. Du Cerveau Et La Moelle Épinièr, Paris, France

Abstract: The greater expansion of the frontal lobes along the phylogeny scale has been interpreted as the signature of evolutionary changes underlying higher cognitive abilities in humans. However, it is unknown how an increase in number of gyri, sulci and cortical areas in the frontal lobe have coincided with a parallel increase in connectivity. Here, using advanced tractography based on spherical deconvolution, we produced an atlas of human frontal association connections that we compared with axonal tracing studies of the monkey brain. For instance for the uncinate, the comparison between post-mortem axonal tracing in monkey (cases 13 and 14 modified from Schmahmann and Pandya, 2006) and human in vivo SD tractography suggests simian-human similarities.



Alternatively for the arcuate fasciculus, the comparison between post-mortem axonal tracing in monkey and human in vivo SD tractography (common anatomical features between human and monkey are reconstructed in red whereas anatomical differences have been coloured in blue) suggest ossible evolutionary changes in the connectional anatomy of the frontal lobes underlying unique human abilities such as advanced language and litteracy.

Title: Systematic flexibility of global functional connectivity patterns supports flexible cognitive control

Authors: *D. H. SCHULTZ, T. ITO, L. SOLOMYAK, R. CHEN, R. MILL, K. KULKARNI, M. W. COLE
CMBN, Rutgers-Newark, Newark, NJ

Abstract: Humans are highly skilled at flexibly applying previously learned rules in novel situations. Converging evidence suggests that activity in the frontoparietal control network (FPN) contributes to this ability to effectively perform novel tasks. Additionally, global patterns of functional connectivity (FC) from the FPN are highly flexible across task demands, suggesting the FPN is composed of flexible hubs. Flexible hubs are brain regions that can flexibly and rapidly alter connectivity across the entire brain depending on current task goals. We hypothesized that FC variability is an important aspect of flexible hubs that contributes to the performance of flexible control tasks. We therefore predicted that individual differences in FC variability would be correlated with individual differences in flexible control task performance. We tested this hypothesis in a large dataset (100 young adults) in which participants completed several flexible control tasks (Raven's progressive matrices, Cattell's culture fair test, Dimensional card sort, and Flanker task). Participants also completed a recently developed flexible control task called the Concrete Permuted Rule Operations (C-PRO) paradigm in the scanner. The C-PRO paradigm consists of three rule types with four variants of each type. When all of the rules are permuted it results in 64 unique rule combinations. FC was calculated for each of the 64 unique rule combinations between a standard set of regions. Consistent with our hypothesis, we found that the flexibility/variability in FPN FC patterns was greater in individuals demonstrating greater flexible control abilities. This suggests that an individual's flexible control ability is supported by the capacity of the FPN to rapidly and flexibly modify FC. We also identified regions where FC stability was related to flexible control. Stability in the FC patterns for these regions may reflect the representation of task-general information, such as "meta-task" information shared across the 64 tasks. Together these results suggest that the ability of the FPN

to flexibly yet systematically adapt functional connections is not simply a general characteristic of the network, but reflects the ability of each individual to perform tasks requiring flexible control.

Title: The frequency-dependent dynamics of the primate frontal executive networks in a state of action preparation

Authors: *S. E. SEIDL, W. M. USREY, E. G. ANTZOULATOS, 95618
Ctr. for Neuroscience, Dept. of Neurobiology, Physiology, and Behavior, Univ. of California Davis, Davis, CA

Abstract: The cognitive control of behavior does not simply stop once the executive networks of the brain have evaluated the odds and selected an action in a context- and goal-dependent manner. Rather, even after the action has been selected, these networks must maintain a highly attentive state, in order to either carry out necessary last-moment modifications in the action plan, or to protect the action plan from interference. Successful action preparation and execution, thus, require the coordination of multiple brain networks, executive, motor, premotor and sensory. In the absence of cognitive computations, the state of action preparation offers a unique opportunity to observe the basic neurophysiological properties of the frequency-dependent coordination of large-scale executive networks. We employed techniques of multiple, spatially distributed microelectrodes in the rhesus macaque brain to record neural signals of population activity (i.e., LFPs and MUAs) from several frontal cortical and striatal regions at the same time, during action preparation. During visual fixation on a central target, a brief visual stimulus signaled to the animals the onset of a preparatory stage (preparatory cue). Following a brief and variable delay, another visual stimulus (Go cue) signaled to the animals to push a joystick for reward. Our simultaneous recordings from the caudate nucleus, anterior cingulate, dorsal

premotor, lateral and caudal prefrontal cortices revealed the temporal structure of the local network oscillations and the interactions among them. Robust changes in oscillatory power and synchrony in all these areas were predominantly concentrated in three frequency bands: the delta (1-4Hz), alpha (8-12Hz), and beta-2 (20-30Hz). Differences among the three bands were observed in (a) their trial epoch-dependence and (b) the pairs of areas they preferentially coordinated. For example, the most prominent power-changes of beta-2 were seen during the preparatory cue display, while alpha was more prominent during the preparatory delay and the inter-trial interval. In addition, the lateral prefrontal cortex was strongly synchronized with the caudate in all three bands, but synchronized with the cingulate only in the delta and alpha bands. Our data on time-frequency-dependent interactions may provide new insight into mechanisms of predictive timing and may shed light on the cooperation between the executive and motor aspects of behavioral control.

Title: Covert and overt face recognition, one or two routes?

Authors: *D. GÓNGORA[1], A. M. CASTRO-LAGUARDIA[1], J. IGLESIAS-FUSTER[1], E. KARAHAN[3], M. LI[3], M. VALDÉS-SOSA[1], E. GONZÁLEZ-DALMAU[2], E. GONZÁLEZ-ALEMAÑY[2], P. VALDES-SOSA[3], M. A. BOBES[1]

Abstract: Cognitive models about face recognition postulate two independent streams of processing, one conscious involved in processing personal semantic information and another unconscious related to the affective reaction to this identity. These two streams of processing could be supported either by two parallel neural circuitries or by one single route operating in sequence. The temporal resolution of functional magnetic resonance imaging (fMRI) is too low to provide information to disentangle this matter. One strategy to overcome this issue is to reveal face information gradually in order to potentially disclose relative timing differences between different brain areas while using a very short sampling rate of BOLD acquisition. Here we adapt a paradigm from Gentile et al. (2016) to explore timing of conscious and unconscious (subliminal presentation) of familiar face processing in typical subjects. The sample was composed by 10 young healthy subjects (four females). The stimuli were unfamiliar and familiar

faces (tailored to each subject, consisting of family members or close acquaintances) of ten identities each. Face visibility was varied parametrically by creating a graded sequence of 20 images from each stimulus with decreasing degrees of phase-scrambling. The recognition threshold was determined individually as the sooner picture at which the subject was able to give the name of any person. Subliminal presentation threshold was defined as two-phase step backward of the identity's recognition threshold. We found that response latency for unconscious and unconscious familiar face processing is similar in V1 and occipital face area, whereas for face fusiform gyrus, amygdala and insula the latency is shorter for unconscious than for conscious processing. In conclusion, this support the existence of two different streams operating in parallel for familiar face processing.

Title: Stable representations in the prefrontal cortex of unrestrained monkeys: Linking neurophysiology to causal evidence from lesion studies

Authors: *S. TREMBLAY, C. TESTARD, M. PETRIDES
Neurol. & Neurosurg., Montreal Neurolog. Inst., Montreal, QC, Canada

Abstract: In the study of the primate caudal lateral prefrontal cortex (area 8A), there is a discrepancy between what has been demonstrated causally in lesion studies and what has been observed using single-neuron recordings in monkeys. Neurophysiologists using standard visual-saccadic paradigms have mostly described neurons encoding visual-attention and eye movement signals in this area. However, we know from lesion studies that bilateral ablation of area 8A produces no deficits in visual attention nor in eye movement control. In fact, bilateral lesions of area 8A result only in a specific impairment in using "if-then" instructional cues to select visual objects from the environment. We believe that this discrepancy between neuropsychological (i.e. lesion) and neurophysiological evidence is the result of the low ecological validity of standard visual-saccadic paradigms ubiquitous in monkey neurophysiology. Although these paradigms are

useful to study visual areas of the brain, we posit that they offer a limited portrait of higher-order associative areas such as the prefrontal cortex. In the current study, we introduce a new paradigm that combines multi-electrode neurophysiology in monkeys with ecologically valid cognitive testing. By performing intracranial multi-electrode recordings in monkeys that are unrestrained in their head, eye and arm movements, we show that neural ensemble activity in area 8A encodes the cognitive process predicted by lesion studies (i.e. conditional visual selection; accuracy >90%). Importantly, we show that this cognitive representation is stable even while the monkey is freely moving and looking around. We hope that this paradigm will provide a more accurate portrait of the neuronal properties of associative areas and help close the gap between neuropsychological and neurophysiological studies of the primate prefrontal cortex.

Title: Impact of noise correlations on information scaling in large neural ensembles from the macaque prefrontal cortex

Authors: *R. BARTOLO, R. C. SAUNDERS, P. G. BROWNING, A. R. MITZ, B. B. AVERBECK
NIMH/NIH, Bethesda, MD

Abstract: Characterizing information scaling in large populations of neurons has been difficult due to technical limitations in recording large numbers (hundreds) of neurons simultaneously from awake, behaving animals. Multi-electrode recording techniques have recently made such large scale recordings possible. We recorded single and multiunit activity using multi-electrode arrays (8 X 96 = 768 channels) implanted bilaterally in the prefrontal cortex (PFC) of macaques (Macaca mulatta). We were able to isolate hundreds of neurons (>500) during the execution of an oculomotor saccade task, maintaining the isolations for a large number of trials (>1500 trials). The animals were required to fixate centrally, then saccade towards a target (randomly presented either to the left or right) to obtain rewards. We were interested in estimating information scaling with ensemble size, as many theoretical models have suggested that information saturates in large neuronal populations. In addition, we studied the effect of the time bin length on information scaling. Therefore, we selected multiple random subsets of neurons of a range of population sizes within a recording session (25-700 units) and estimated information in each

subset. Spike counts within a time bin after stimulus onset were used to train a generalized linear model to predict saccade direction. First, 90% of the trials (randomized), 5% of trials were used to stop the training (early stopping regularization) and the remaining 5% were used for decoding. We further projected population activity on the linear decision boundary, and used the distribution of projected data to estimate d-prime as an information measure. We repeated this procedure using time bins of varying length (16-500 ms). We show that decoding accuracy rapidly increased as a function of ensemble size, and was nearly perfect for ensembles with more than 150 neurons. On the other hand, d-prime continued increasing with ensemble size. We then fitted nonlinear functions to the d-prime data to estimate the asymptotic value. Both the asymptotic value and the measured d-prime increase as a function of the length of the time bin, reach a peak, and then decrease. As expected, we observed that noise correlation increases as a function of time bin length. Altogether, our findings suggest an optimal time resolution that maximizes the information in the neural ensemble and minimizes the impact of correlated noise and raises questions about how this information is read-out in the brain.

Title: Contribution of the basal forebrain cholinergic system to cortico-cortical network interactions

Authors: *P. GOMBKOTO, M. GIELOW, C. CHAVEZ, L. ZABORSZKY
Rutgers The State Univ. of New Jersey, Newark, NJ

Abstract: The basalo-cortical projection system has a complex topographic organization consisting of segregated and overlapping pools of projection neurons. The measure of overlap is related to the degree of connectivity between the cortical target of projection populations, suggesting that the organization of projections from the basal forebrain (BF) to cortical regions reflects cortico-cortical connectivity patterns (Zaborszky et al., 2015). In this study we investigated the functional circuitry between specific locations in the BF, orbitofrontal (VO/VL) and visual cortex (V2) in a visual discrimination task, in transgenic ChAT-Cre rats using high-density electrophysiology recording. Extracellular spikes were recorded simultaneously using 64-contact silicon probes chronically implanted in the BF. In addition, two 32-contact silicon

probes were implanted in the VO/VL and the V2 cortex. These cortical areas are presumed to receive strong projections from the BF regions that we targeted with our optrodes. Cholinergic neurons were optogenetically tagged by laser stimulation (10ms, <5mW) after the behavioral experimental period but within the same recording session. Functional connectivity was examined based on short-latency temporal interactions of excitatory and inhibitory neurons using a spike jittering cross-correlation method. The oscillatory pattern of cortical areas modulated by cholinergic and non-cholinergic input was calculated using spike-triggered averaged LFPs. To detect behavior dependent coherence events, we computed the probability of high coherence ($r > 0.7$) values using continuous wavelet coherences between specific BF and V2-VO/VL contact sites that show specific probability changes between different behavior epochs, including visual stimulus detection, decision making, and approach to food reward. During cholinergic activation, the cortico-cortical coherence increased at alpha and gamma bands, however beta band coherence decreased at the same locations. The dense recording sites on silicon-based recording probes in combination with optogenetic tagging of cholinergic neurons can help to disentangle the contribution of the cholinergic system to coordinate functionally related cortical areas.

Title: Persistent neurons drive stable population-level working memory representations

Authors: K. WIMMER[1], J. M. BARBOSA[2], A. GALÁN[2], C. CONSTANTINIDIS[3], G. MONGILLO[4], *A. COMPTE[2]
[1]Univ. Pompeu Fabra and Ctr. de Recerca Matemàtica, Barcelona, Spain; [2]IDIBAPS, Barcelona, Spain; [3]Wake Forest Univ. Sch. of Med., Winston Salem, NC; [4]Neurophysics and Physiol. UMR 8119 CNRS - Paris Descartes Univ., Paris, France

Abstract: Neurophysiological experiments in primates have found that during the delay period of working memory tasks, a fraction of neurons in the prefrontal cortex carry information about

the stimulus as sustained activity, therefore supporting a stable code during the whole delay period. However, many neurons show strong temporal dynamics, which has given rise to the dynamic coding model for working memory. This model proposes that due to the time-varying dynamics of single neurons, a stable memory representation can only be achieved at the population level through a linear combination of individual neural responses of a sufficiently large population of neurons.

Here we set out to investigate how prefrontal neurons with different delay-period dynamics contribute to population dynamics during an oculomotor delayed-response task (Constantinidis et al. 2001). We first characterized the delay dynamics of single neurons based on their firing rate autocorrelation. Autocorrelation decays were heterogeneous, ranging from persistent neurons with slow decay to dynamic neurons with more transient delay activity autocorrelation. We tested if these neurons contributed differently to delay coding by running PCA on pseudo-population responses constructed from the *persistent* and *dynamic* neurons, respectively. Extending the result of (Murray et al. 2016), we found that the *persistent* neurons alone are sufficient to span a stable, low-dimensional mnemonic subspace and that such a subspace representation was not apparent for the population of *dynamic* neurons. Finally, we used linear decoders on small neuronal ensembles from these two putative subpopulations (*persistent* and *dynamic*) and compared stimulus information during different time points throughout the whole trial period. Persistent neurons carried more information on any tested time point.

In sum, we conclude that persistent neurons are the main drivers of memory-selective delay period dynamics in our data.

Title: Behavioral correlates of deliberation and habit on a contingency switching task for rats

Authors: *B. HASZ[1], A. D. REDISH[2]
[1]Neurosci., Univ. of Minnesota, Minneapolis, MN; [2]Dept. Neurosci, Univ. of Minnesota Dept. of Neurosci., Minneapolis, MN

Abstract: Mammalian decision-making involves multiple separable systems, including deliberation (simulation of actions and evaluation of their outcomes) and procedural learning (recognition of a situation and the release of a well-learned action). Work in rodents on spatial mazes suggest that vicarious trial and error (VTE), a behavior where rats look back and forth at choice points in a maze, occurs in indecision during deliberation. Conversely, stereotyped paths through a maze appear to reflect procedural learning.
On many spatial tasks, animals deliberate early but transition to procedural behavior with experience. We designed a task which allowed animals to repeatedly transition from deliberative to procedural decision-making, but sporadically forced them back into deliberative mode. This task consisted of a topologically sideways figure-8 maze, with reward sites at the left and right sides and a third reward site at the base of the central track. The reward site at the center encouraged rats to stop and initiate new journeys from the same point. Reward was delivered under 3 contingencies: L (rats were rewarded at left and center for going left), R (rats were rewarded at right and center for going right), A (a different choice from the previous choice was required for reward). Rats were allowed to run freely on the maze for 60 min/session. The contingency changed randomly every 30+/-5 trials.
4 rats ran 185 +/- 37 trials per session, with at least 15 sessions per rat (one per day), and 5.5 +/- 1.4 contingency switches per session. VTE increased immediately after each contingency switch, and then decreased over the course of each contingency block, while path stereotypy decreased following each switch, and paths became more stereotyped over each contingency block.
To determine whether rats were aware of the contingencies, we fit a model-free reinforcement learning algorithm and a contingency-aware working memory algorithm to the behavior. The model-free algorithm explained rat choices better than chance; however, the contingency-aware algorithm explained rat choices significantly better than the model-free algorithm. VTE was correlated with uncertainty as to what contingency was in place.

Our results suggest that rats were aware of the contingencies, automated behavior within each block, and deliberated after contingency switch. Furthermore, VTE was related to indecision within the contingency-aware algorithm. The contingency switch task could be a promising avenue for investigating neural correlates of switching between deliberation and procedural decision-making.

Title: Indecisive behavior in response to environmental threat

Authors: *C. J. WALTERS[1], A. D. REDISH[2]
[1]Univ. of Minnesota, Minneapolis, MN; [2]Dept. Neurosci, Univ. of Minnesota Dept. of Neurosci., Minneapolis, MN

Abstract: Anticipation of future threat is a defining feature of anxiety. Many rodent models of anxiety use highly controlled environments that fail to replicate natural conditions where anxiety is typically experienced. Avoid-approach conflict tasks are thought to more closely mimic the internal and external conditions that result in the expression of anxiety in both health and disease by placing reward-seeking and threat-avoiding decision-making systems in conflict with one another. As a result, avoid-approach conflict tasks have emerged as a preferred paradigm for modeling human anxiety disorders.
A recent avoid-approach conflict task designed to amplify motivational conflict in an ecologically valid setting requires rodents to risk potential attack from a robotic predator each time they venture from an enclosed nest space to forage for food made available at the end of a linear track. This predator-inhabited arena task is run in four phases: Phase 1) linear track training, Phase 2) exposure to the robotic predator, Phase 3) the robotic predator attacks the foraging rodent, Phase 4) post-attack foraging.
Anxious behavior was quantified through three measures: mid-track aborts on outbound journeys (toward the predator), deliberative pausing at the exit of the enclosed nest space, and time spent occupying the nest zone. Mid-track aborts on return journeys (away from the predator) as well as

pausing and occupancy on other portions of the track provided controls. We tested six Brown-Norway (BN) rats (four males, two females) and four Fischer-Brown Norway first generation hybrids (FBNF-1) (two males, two females).
Brown Norway rats exhibited an increased number of anxiety-like hesitation behaviors (i.e. mid-track aborts, deliberative pausing, and nest-zone occupancy) during Phases 3-4 of the task. In contrast, FBNF-1 rats did not exhibit an increased number of hesitation behaviors across any of the four task phases.
These data corroborate a body of literature that identifies Brown Norway rats as being naturally more anxious than FBNF-1 rats. Furthermore, this work establishes new protocols for quantifying anxiety-like behaviors on the predator-inhabited arena, thus making several metrics available that can be used to measure anxious behavior using this task.

Title: DREADD disruption of mPFC alters hippocampal economic decision making processes

Authors: *B. SCHMIDT[1], A. D. REDISH[2]
[1]Neurosci., Univ. Minnesota, Minneapolis, MN; [2]Dept. Neurosci, Univ. of Minnesota Dept. of Neurosci., Minneapolis, MN

Abstract: While traversing an environment, hippocampal place cells fire in sequence within each theta cycle. These sequences have been hypothesized to reflect planning of future paths in both space and time. Previous work has found that the length of the theta cycle and the number of gamma cycles in any given theta cycle is related to the length of the spatial path represented by the sequence. Theoretical models have suggested that these planning processes entail interactions between hippocampus and medial prefrontal cortex (mPFC).
To test how mPFC affected hippocampal theta cycles and sequences, we reversibly disrupted mPFC with DREADDs while recording neural ensembles from the hippocampus and mPFC in rats trained on the spatial neuroeconomic task Restaurant Row. In this neuroeconomic task, rats run around a circular maze, encountering a serial set of skip or stay choices for differently flavored food reward. On each choice entry, rats hear a tone indicating the length of delay before

food will be delivered. Rats have 60min to gather their daily intake of food. Thus, rats must budget the delays that they will accept to maximize subjective value.
We measured theta (6-10 Hz) and gamma (25-55 Hz) oscillations during decision and control portions of the maze. Average theta period was longer in decision making epochs. Length of the theta cycle correlated with delay of the individual trial on the maze during the decision, suggesting that planning sequences depended on the length of the expected delay. Disrupting mPFC with CNO reduced hippocampal theta period and reduced this correlation, suggesting that disrupting mPFC disrupted theta planning processes. There were significantly more gamma cycles per theta cycle on the decision-making epoch compared to the control epoch. Disrupting mPFC with CNO reduced the average number of gamma cycles per theta cycle.
In decisions, rats will often pause and orient towards their optional trajectories, this vicarious trial and error (VTE) behavior is a reflection of deliberative decision making and indecision. We have previously reported that disrupting mPFC with CNO reduced VTE behavior. Theta period was larger for VTE than nonVTE entries, consistent with increased planning during VTE. Theta period was correlated with delay for both VTE and non VTE trials. However, only nonVTE trials showed this significant correlation on CNO days, VTE trials did not.
These data support the hypothesis that the length of a theta cycle is indicative of planning processes, and that mPFC engages with hippocampus during planning through a theta process, which was disrupted by our DREADD manipulations.

Abstract: Sunk costs are irrecoverable investments that can inflate the subjective value of a pursued reward. Intertemporal choice occurs when decisions have to be made between options with consequences occurring at different times, such as in foraging tasks. In foraging tasks, choices are often made between present and future rewards. If sunk costs inflate the subjective value of a reward, it may affect intertemporal choice, particularly present choices. Previous work has suggested that discounting rates can differ between intertemporal choices made between two future options and intertemporal choices which involve stay/leave options. It remains unclear whether mice are sensitive to sunk costs, and whether sunk costs interact with the perceived expenditure of time when making intertemporal decisions.
To test how sunk cost might differentially influence reward opportunity seeking decisions separate from reward taking decisions, we adapted a neuroeconomic foraging task for mice (Restaurant Row). In this task, mice were trained to forage for food rewards by running around a square maze with four distinct feeding sites (restaurants). As mice encountered each restaurant, the cost of waiting for food was indicated by pitch of a tone. Delays on each encounter were random from 1-30 sec. Each restaurant offered a unique flavor and contained separate offer and wait zones. Delay was indicated on entry into the offer zone, but did not start counting down until entry into the wait zone. If mice left the offer zone for the next restaurant (skip) or changed their minds after entering the wait zone (quit), the offer was rescinded and the tone ceased. Importantly, mice had a limited time on the track (60 min) to earn food for the day, so time had to be budgeted.
32 C57BL/6J male mice were trained for 65 days. Mice revealed stable economic preferences for different flavors similar to both rats and humans on these foraging tasks. Time spent within the offer zone deciding to accept or skip did not influence the likelihood of quitting in the wait zone despite detracting from the 60 min budget. However, time spent in the wait-zone decreased the likelihood of quitting compared to offers accepted with equivalent countdown time remaining yet with less prior time invested. These data suggest that mice are sensitive to sunk costs, but only in the wait-zone, in the patch itself. These findings suggest that the decision to choose between versus the decision to opt out may access different decision-making processes that are differently susceptible to sunk costs.

Title: The role of extracellular matrix molecules for spatial representations in medial entorhinal cortex

Authors: *A. CHRISTENSEN[1], K. K. LENSJØ[2], M. E. LEPPEROD[3], M. FYHN[4], T. HAFTING-FYHN[1]
[1]Inst. of Basic Med. Sci., Univ. of Oslo, Oslo, Norway; [2]Univ. of Oslo, OSLO, Norway; [3]Ctr. for Integrative Neuroplasticity, Univ. of Oslo, Oslo, Norway; [4]Dept. of Biosci., Oslo, Norway

Abstract: Perineuronal nets (PNNs) are specialized extracellular matrix structures that condense around the soma and proximal dendrites of mainly parvalbumin (PV+) expressing inhibitory neurons. During postnatal development, PNNs gradually mature and are thought to stabilize synaptic connections, restrict plasticity in the adult brain and perhaps play a role in remote memory storage. However, functional studies of PNNs for neural network- and cognitive function are lacking. Their role in spatial memory processing which likely depends on stable spatial representations in the medial entorhinal cortex (MEC), a hub in a distributed network of the brain's navigational system, has not been investigated. The spatially modulated 'grid cells'in the MEC possess a remarkable repetitive activity pattern. Grid cells are likely connected through a network of PV+ inhibitory neurons, suggesting that this network of inhibition is essential for the spatial representations of grid cells. Using a combination of local enzymatic degradation of the PNNs and single unit recordings in MEC of free-roaming adult Long Evans rats, we asked if the PNNs play a role in the grid cell network or spatial processing. Immunohistochemical mapping of the PNNs' expression patterns and cell type specificity in the MEC revealed that in addition to surrounding PV+ neurons, PNNs in MEC also co-localize with reelin and calbindin expressing neurons. Furthermore, we demonstrate that the maturation of PNNs in MEC coincides with the reported appearance of grid cell activity, while strong PV+ immunoreactivity is present from early postnatal age. In order to examine how PNNs contribute to spatial representations in the MEC, PNNs were enzymatically degraded and single unit activity was recorded using implanted tetrodes in MEC of rats exploring open fields (1x1m). To compare stored representations with the encoding of novel maps, the same units were recorded on consecutive trials in familiar and novel environments. Removal of the PNNs affects spatial representations and unit activity. Grid cells from MEC without PNNs in show show increased average firing rates and reduced spatial information. Simultaneously recorded putative inhibitory units show a trend of reduced average firing activity, which is in accordance with a recent report from visual cortex (Lensjo et al., 2017). When placed in a novel environment, gridness scores drop dramatically and grid cells show a lower spatial correlation throughout the recording session compared to grid cells from control animals. Together, these results indicate that PNNs may play a role for the stability of spatial representations of MEC in adult animals.

Title: Perineuronal nets in the lateral secondary visual cortex are essential for remote visual fear memory

Authors: *E. H. THOMPSON[1], K. K. LENSJØ[1], M. B. WIGESTAND[1], T. HAFTING-FYHN[2], A. MALTHE-SØRENSSEN[3], M. FYHN[1]

Abstract: Memories can last a lifetime even though the half-life of molecules found to be important for memory storage is much shorter. Preservation of connectivity of the involved network may therefore be facilitated by other and more stable molecular components, such as the extracellular matrix structure of perineuronal nets (PNNs). Here, we test this hypothesis in remote visual fear memories in adult rats. Recent evidence indicates that over time, visual fear memories become dependent on the lateral secondary visual cortex (V2L) (Sacco & Sacchetti, 2010). We asked if intact PNNs in V2L are required for remote visual fear memory. Remarkably, degrading PNNs using local injections of the enzyme Chondroitinates ABC (chABC) in V2L one week prior to remote memory retrieval selectively disrupted retrieval of the visual fear memory. The behavioral responses were supported by simultaneous recordings of local field potentials from V2L and basolateral amygdala (BLA) and revealed increased coherency between V2L and BLA in the theta range during memory recall in controls. However, in chABC treated animals no increased coherency was recorded, suggesting reduced or lack of synchronous activity between the brain regions at the time of the retrieval test. The effect was selective to the V2L as removal of the PNNs in the primary visual cortex had no effect on the fear memory. Furthermore, chABC injection in V2L before fear conditioning had no impact in acquisition or recent memory retrieval. Degrading PNNs after fear conditioning had no effect on recent memory, and remote memory could be retrieved properly if PNNs had time to regenerate before testing. These findings indicate that PNNs in V2L are critical for remote but not recent visual fear memory. Furthermore, based on our discoveries and the inherent properties of PNNs, we propose that PNNs are critical for stabilizing the neural network responsible for proper recall.

Title: Population density model of the entorhinal stellate-cell network with adaptation

Authors: *M. E. LEPPEROD[1], Y. LAI[3], M. FYHN[2], G. T. EINEVOLL[4], T. SOLSTAD[5], T. HAFTING[1], M. DE KAMPS[3]

Abstract: The medial entorhinal cortex (MEC) is important for spatial memories and navigation and contains grid-cell networks. The grid-cells display a hexagonal spatial firing pattern with spiking coherent with theta (4-12 Hz) oscillations in the local field potential (LFP). One of the main cell types expressing the grid pattern with a strong inhibitory surround are the stellate cells, located in layer 2 of MEC. The biophysical properties of stellate cells are well-characterized but their interaction with the neural network in MEC remains elusive. While single cell sampling from vast networks of neurons yield important information about single cell function it fails to reveal population dynamics. In this study, we assessed the population response of MEC stellate cells to oscillating inputs in network simulations. Computations were performed with the MIIND simulator to describe the nonlinearity of adaptive dynamics underlying a noise process with high computational efficiency. The dynamics of the stellate cells were modeled as an adaptive phenomenon represented by a population-density model consisting of adaptive exponential integrate and fire (AdEx) neurons. The parameterized AdEx model reproduced temporal dynamics of stellate cells consistent with single cell patch-clamp experiments (e.g. resonance, sag, rebound spiking). In this parameter regime, the population density of the stellate cells was assessed over the model phase space. We show that this infinite population of stellate cells act as a bandpass filter resonating in the theta band, indicating that large-amplitude theta oscillations in MEC may be a network resonance evoked by disinhibitory inputs, likely from the medial septum. Furthermore, the adaptive dynamics of the AdEx neurons displayed strong transient responses when the population was primed with inhibitory input. The results of the present study show the limitations of predicting population dynamics of cell networks based on single cell experimental or modelling studies.

Title: Conditional knock-out of the ACAN gene removes aggrecan and perineuronal nets in adult mice and induces life-long brain plasticity

Authors: *K. K. LENSJØ[1], D. ROWLANDS[3], T. DINH[2], M. R. ANDREWS[4], T. HAFTING-FYHN[2], M. FYHN[2], J. W. FAWCETT[3], G. DICK[2]
[1]Univ. of Oslo, OSLO, Norway; [2]Univ. of Oslo, Oslo, Norway; [3]Cambridge Univ., Cambridge, United Kingdom; [4]Inst. of Biol. Sci., Southampton, United Kingdom

Abstract: Perineuronal nets (PNNs) are a specialized form of extracellular matrix in the CNS that mainly enwraps parvalbumin (PV) expressing inhibitory interneurons. They assemble in parallel with the maturation of the inhibitory network and with the closure of critical period plasticity. Several lines of evidence support a role for PNNs in stabilizing synapses and limiting adult brain plasticity. While the mature PNN is a complex structure of several components, recent work suggests that the proteoglycan aggrecan, a product of the ACAN gene, is essential for the PNNs. However, because aggrecan is also an integral part of cartilage throughout the body, global ACAN knock-out is lethal. Thus, to investigate the role of aggrecan for PNN assembly and stability, and its contribution to brain plasticity, we established a CRE-inducible conditional ACAN knock-out mouse. The transgenic construct is a design of the European Conditional Mouse Mutagenesis Program and has had two loxP sites inserted into the genome, flanking exon 4 of the ACAN gene. Two approaches were used to remove aggrecan from these mice, either by (1) injecting a viral vector expressing CRE recombinase under control of the synapsin promoter to obtain area specific knock-outs in adult mice, or (2) crossing with Nestin-Cre mice for global neuron knock-out. Aggrecan and PNNs were determined by immunohistochemical staining against aggrecan, the PNN specific lectin *Wisteria floribunda* agglutinin and other components of the PNN. In the visual cortex, local injections of AAV9.Syn.Cre caused removal of WFA and aggrecan staining. Activity-dependent plasticity was induced by monocular deprivation and assessed by intrinsic optical signal imaging. Removal of aggrecan caused persistent ocular dominance plasticity in adult mice. Furthermore, the ACAN-Nestin-Cre mice lacking PNNs in the entire brain showed enhanced performance in a spontaneous object recognition task. Taken together, our results provide the first direct evidence that aggrecan is the main functional constituent of PNNs restricting plasticity. Our studies promote the ACAN mouse as a robust tool to investigate the role of PNNs in plasticity and disease

Title: Sensory-motor coordination during spontaneous exploration of rats

Authors: *E. BLANCO, J. GRABOSKI, A. SIROTA
Biol. II, Ludwig Maximilian Univ. of Munich, Munich, Germany

Abstract: Active sampling of the environment entails a coordination of sensing and action. One of the major components of the sensory experience of a rodent exploring their environment is the sense of smell. The odor space is sampled rhythmically, driving air in and out of the nose at frequencies ranging from 6 to 12 Hz. This sniffing behavior is not only related to odor sampling but also modulated, by expectation and motivation. Detailed experiments have shown the sniffing cycles constitutes the unit of sensory processing during both detection and discrimination, coordinating the neural processing of the odor information. Nevertheless, how sniffing behavior is coordinated with other sensory modalities and integrated within the rich behavior expressed by freely-moving rodents when exploring their surroundings has been less studied. To gain an understanding of a more naturalistic organization of exploration in rodents and its relationship with sniffing behavior, we recorded pressure sensor signals from the nasal cavity of rats concurrent with high-resolution body tracking during spontaneous exploration. We identified discrete behavioral modes: walk, rear, turn, pause, groom, and sit, each behavior showing a characteristic correlation of kinematic and postural variables, allowing generalized classification between individuals. Rats explore their surroundings in “bouts” of activity composed of several of the behaviors described. During these “bouts” we observe the coordination between sniffing and head movements constrained within 6 to 12Hz. Head motion shows a stereotypic displacement in the 3d space, with excursions defined by the peaks of inhalation and exhalation. Detailed analysis of the direction of motion between peaks of inhalation and exhalation shows than this coordination is mostly expressed at lower head pitch when the tip of the nose is near the floor, reflecting potentially, the synchronization with

whisking, in sharp contrast, when the nose is far from the ground this coordination is less frequent and change in phase. Furthermore, this sensory-motor coordination is occurring simultaneously with different behaviors of rats and changes within the trial. Overall our results show that the sensory-motor coordination occurring during spontaneous exploration changes dynamically, depending potentially, on the demands for coordinated processing of different streams of sensory information.

Title: Capturing attractor dynamics in hippocampal place cell remapping through micro-endoscopic imaging in freely moving mice

Authors: *E. ITZCOVICH[1], N. KARALIS[2], A. V. HERZ[3], A. M. SIROTA[4]

Abstract: The hippocampal formation plays a fundamental role in the acquisition, consolidation and retrieval of episodic memory as well as in spatial navigation. A potential key mechanism supporting stable yet flexible representations of space within the entorhino-hippocampal formation are attractor dynamics. Attractor networks have been used to describe various brain functions, such as memory, classification, and motor behavior and have long been proposed to underlie stable place, grid and head direction components of spatial representation. Attractor properties of hippocampal spatial maps have been linked to the phenomenon of abrupt remapping of place fields elicited by morphing of environmental cues. The study of hippocampal attractor dynamics, which are thought to operate at the population level, has until now been limited by the relative difficulty of recording sufficiently large populations of cells across days. The recent development of head-mounted microscopes enabling imaging activity of large

neuronal ensembles over long periods of time in freely moving animals gives us now the opportunity to go into a deeper characterization of attractor dynamics. We have used micro-endoscopes (UCLA Miniscope) to record large ensembles of neurons in hippocampal area CA1 while manipulating the external environment. We habituated male mice to two connected environments that differed in visual, tactile and auditory features, both containing an empty compartment. To probe the basin of attraction of the hippocampal representations of these two environments we briefly exposed the animal to an environment with intermediate features compared to the two previous ones. Next we introduced a female into the compartment of one of these original environments, which resulted in an increased preference of the male mouse for this environment in subsequent retrieval sessions without female. We compared levels of remapping between all three environments, testing if the valence of a female-paired environment leads to differential expression of the basins of attraction of hippocampal CA1 spatial maps. In the next set of experiments we are investigating attractor properties of hippocampal representation via controlled manipulation of the visual environmental features using a virtual environment for freely moving animals. We expect that these experiments will contribute to better understanding of attractor dynamics associated with hippocampal remapping phenomenon.

Title: Slow oscillations in the lateral and medial entorhinal cortex differentially couple to hippocampal ripples in non-anaesthetized sleeping rats

Authors: *G. SCHWESIG, J. MARTINEZ ALCANTARA, A. SIROTA
Ludwig-Maximilians-Universität München, Muenchen, Germany

Abstract: Synchronous activity associated with hippocampal sharp-wave ripple events occurring during offline brain states has been implicated in systems memory consolidation, associated with a shift of memory trace retrieval dominance from hippocampus to neocortex. During sleep this process is thought to rely on the temporal coordination of neural activity in both hippocampal and cortical circuits emerging from the biasing of hippocampal sharp-wave ripple occurrence by

the down-up transitions of neocortical slow oscillations. However, the distributed and heterogeneous nature of neocortical slow oscillations calls for a refinement of this early model. Importantly, the lateral and medial entorhinal cortices are the major cortical gateways of the hippocampal formation, connecting it bidirectionally with widespread but distinct neocortical networks. To examine if cortical slow oscillations and hippocampal ripple dynamics during sleep are differentially coupled via these distinct gateways, we recorded unit activity and local field potentials across layers of the dorsal hippocampus (HPC), lateral (LEC) and medial entorhinal cortex (MEC) in freely moving and sleeping rats. Analysis of the up-down state transitions in MEC and LEC shows that slow oscillations dynamics in the two structures are qualitatively distinct and only weakly temporally correlated. Moreover, HPC sharp-wave ripples were differentially entrained by LEC and MEC slow oscillation dynamics. To further elucidate this effect we investigate the bidirectional effect of HPC ripples and LEC/MEC Up states on respective target structures via anatomically-resolved current-source-density signal analysis. These results imply that the interaction of cortical slow oscillations and hippocampal ripples is not globally synchronous and is differentially gated via two entorhinal circuits, providing a possible framework for distinct brain-wide memory consolidation sub-systems.

Title: Respiratory entrainment of memory circuits

Authors: *N. KARALIS, A. SIROTA
Dept. Biol. II, Ludwig-Maximilians-Universität München, Planegg, Germany

Abstract: Decades of research have identified neural oscillations as a mechanistic substrate for the formation of cell assemblies and the coordination of information transfer between remote brain regions. During exploratory behavior, the hippocampus and the prefrontal cortex are organized by theta oscillations, known to support memory encoding and retrieval, while during sleep the same structures are dominated by slow oscillations that are believed to underlie the consolidation of recent experiences.

Although most known neural oscillations are generated by intra-cerebral pacemakers and circuits, here we focused our attention to breathing, the most fundamental and ubiquitous rhythmic activity in life. We report respiratory entrainment of limbic circuits, including the prefrontal cortex and hippocampus, two structures critically involved in memory consolidation and retrieval.
Using a combination of extracellular recordings using high-density silicone probes, calcium imaging, photometry, pharmacological and optogenetic manipulations in mice, we identify that a rhythmic oscillation (2-6 Hz and termed respiratory θ rhythm) entrains neuronal activity across structures. We characterize the translaminar and transregional profile of the respiratory entrainment of the prefrontal cortex and hippocampus and demonstrate a causal role of re-afferent respiratory inputs in synchronizing neuronal activity and network dynamics between these structures in a variety of behavioral scenarios in the awake and sleep state. Prefrontal 4Hz oscillations, recently identified as a physiological signature of fear memory in mice, are a manifestation of the differential cortical entrainment by the respiratory θ rhythm during behavior. Our results highlight respiration, a persistent rhythmic input to the brain, as a novel oscillatory mechanism mediating inter-regional synchronization of limbic memory circuits and contributing to the formation and expression of neuronal ensembles.

Title: Impaired spatial reorientation in the 3xTg-AD mouse model of Alzheimer's disease

Authors: *A. C. STIMMELL[1], D. BAGLIETTO-VARGAS[2], V. LAPOINTE[4], F. M. LAFERLA[3], B. L. MCNAUGHTON[5,3], A. A. WILBER[1]
[1]Florida State Univ., Tallahassee, FL; [2]Neurobio. and Behavior, [3]Univ. of California, Irvine, Irvine, CA; [5]Dept. of Neurosci., [4]The Univ. of Lethbridge, Lethbridge, AB, Canada

Abstract: Spatial navigation is affected early in the symptopathology of Alzheimer's disease (AD), since deterioration of spatial navigation is observed in prodromal cases of this disease. A preponderance of evidence suggests that the internal map of the environment is represented in

world-centered (allocentric) coordinates; however, movements and perception of the environment are in body-centered (egocentric) coordinates. Therefore, in order to navigate, it is essential for coordination and translation between these coordinates. Parietal cortex (PC) and hippocampal activity patterns play a key role for transforming landmark representations from egocentric to allocentric coordinates. Emerging findings suggest abnormal communication between the PC and hippocampus in preclinical AD cases may be involved in impaired navigation in AD. Here, we seek to investigate in a preclinical model of AD, the 3xTg-AD mouse, the molecular mechanisms by which spatial orientation is impaired in AD.
We assessed 3xTg-AD mice in male (6 & 13 months) and female (3 & 6 months) mice using a task previously shown to be sensitive to impaired hippocampal map realignment. This task requires mice to learn and remember the spatial location of a small reward zone that is in a fixed location with respect to distal cues, but otherwise unmarked. Mice were trained to shuttle to the end of a track and back to an enclosed start box to receive a water reward. Next, bilateral stimulating electrodes targeting the medial forebrain bundle were implanted, and mice were trained to continue shuttling for water, but also stop in the reward zone to receive a brain stimulation reward. The track slides to a random start location for each trial. Thus, distal but not local cues were informative. The time required to remain in the zone for a reward was increased in 0.5s increments from 0.5-2.5s across training.
We found that female 3xTg-AD mice showed a more pronounced impairment than male 3xTg-AD mice compared to non-Tg age/sex-matched controls. Specifically, by 6 months female mice had robust impairments in the proportion of correct trials. In addition, 6-month female 3xTg-AD mice slowed significantly less slowing than controls in the reward zone. The impairments observed in 3xTg-AD mice are not explained by differences in reward responding, as operant responding for reward did not differ in 3xTg-AD mice compared to non-Tg controls. Thus, AD may cause spatial disorientation as a result of impaired use of landmarks to maintain spatial orientation. We are recording from the PC and hippocampus in 6-month female 3xTg-AD mice to assess a potential role of the PC-hippocampal network in AD-related impaired spatial reorientation.

Title: Decoding kinematic motion from neural recordings in the parietal cortex using a generalized linear model

Authors: I. SKELIN[1], W. WU[2], B. L. MCNAUGHTON[3], *A. A. WILBER[2]
[1]Neurosci., Univ. of Lethbridge, Lethbridge, AB, Canada; [2]Florida State Univ., Tallahassee, FL; [3]Dept. of Neurosci., The Univ. of Lethbridge, Lethbridge, AB, Canada

Abstract: The parietal cortex (PC) neuronal populations show tuning to self-motion state, a compound measure of linear and head angular velocity. Self-motion tuning in PC is organized at the modular level, where the tuning parameters are similar across the cortical layers, but have sharp boundaries in the lateral directions. This study develops a Bayesian state-space framework to decode the self-motion state from pooled multineuronal activity or high frequency local field potential (HF-LFP) envelope simultaneously recorded from up to 18 tetrodes in rat parietal cortex in rats that had been trained to either run a cued random spatial sequence to 32 light locations evenly spaced around the perimeter of a circular platform. We encoded the neural data using a generalized linear model, which assumes that the multineuronal activity or HF-LFP envelope amplitudes on a single tetrode follow a Poisson distribution whose mean depends on a normalized combination of linear and head angular velocity. This model is learned from training data along with a linear Gaussian model that characterizes kinematic motion over time. Inference of kinematics is performed using a point process filter which gives an efficient recursive method in real-time. Two-fold cross-validation was performed on four datasets from two rats and has shown a high decoding accuracy, with averaged correlation coefficient being 0.60 (±0.05) for multineuronal activity and 0.67 (±0.03) for HF-LFP-based model. The present results demonstrate the high predictive validity of the population activity in PC for decoding the self-motion state.

Abstract: Hippocampal place cell ensemble shows sequential activation that is locked to position when animals move in an environment. Computational models hypothesize that the hippocampus generates an indexing code that is broadcasted to the entire neocortex to associate information across different modalities. The format of this indexing code, and the neocortical regions that mediate this information flow is unknown. The retrosplenial cortex (RSC) is immediately connected with the hippocampal formation. Neurons in RSC exhibit similar activation patterns to hippocampal place cells during the same task. Whether the hippocampus contributes to the generation of retrosplenial place cell activity or vice versa is unclear. To address this question, we combined hippocampus lesion (NMDA excitotoxic lesion; 2 lesion sites, AP: -2.3, ML: 1.5, DV: 1.8 and AP: -3.2, ML: 2.5, DV: 2.0) with 2-photon calcium imaging of superficial RSC neurons in head-fixed mice (Thy1-GCaMP6s GP4.3 transgenic mice) during a virtual path integration task. RSC place cell fraction was similar between mirrored left and right hemispheres ($p = 0.20$, paired t-test; $n = 5$ mice). Bilateral, but not unilateral, dorsal hippocampus lesion significantly disrupted RSC place cell fraction ($p < 0.05$, one-way ANOVA; $n = 3$ mice with intact hippocampus, $n = 3$ mice with unilateral hippocampus lesion, $n = 4$ mice with bilateral hippocampus lesion) and reduced position decoding accuracy ($p < 0.05$, one-way ANOVA) when taking the entire imaged neuron population into consideration. These results indicate that the hippocampus is necessary for the expression of intact place cell activity in RSC.

Title: Hippocampal contributions to V1-dependent memory and plasticity

Authors: *P. S. FINNIE[1], Y. LI[2], H. KIM[2], S. F. COOKE[3], M. F. BEAR[1]
[1]MIT, Cambridge, MA; [2]Wellesley Col., Wellesley, MA; [3]The Maurice Wohl Clin. Neurosciences Inst., Kings Col. London, London, United Kingdom

Abstract: The requirement for hippocampus is well established for several forms of memory, yet the specific encoding functions this structure supports remain poorly understood. Several theories posit that hippocampus rapidly encodes ongoing multimodal sensory experience, which is then processed by more stable neocortical circuits to gradually extract underlying statistical regularities. Yet accumulating evidence is beginning to reveal the capacity for rapid neocortical plasticity, even following brief hippocampus-dependent episodes. If the requirement for hippocampus during a given task is not a consequence of the slow rate of neocortical plasticity, then what does this structure contribute to memory encoding? The hippocampus is a major component of the limbic system, which controls neuromodulatory signaling throughout the brain. Such modulation robustly drives protein synthesis, which is typically necessary for long-term memory consolidation. Thus we hypothesized that even forms of long-term memory and plasticity reliant primarily on primary visual cortex (V1) should be subtly disrupted by hippocampal ablation. To test this possibility we used a simple visual training protocol in which an oriented grating stimulus is repeatedly presented to mice over days. This training produces both behavioral (orientation-selective habituation; OSH) and electrophysiological (stimulus-selective response potentiation; SRP) changes that can each be assessed at short-term, long-term, and remote time-points. We report that mice receiving either excitotoxic or sham lesions of hippocampus exhibit no significant differences in either measure. The percent change in electrophysiological evoked responses may even be enhanced in mice lacking hippocampus, although this dissipates prior to remote testing sessions. Lesions were confirmed both behaviorally and histologically. We also observed little impact of transgenic NMDA-receptor knockout restricted to hippocampus. We conclude that hippocampus is not required for the acquisition or expression of this form of visual recognition memory, but may influence systems-level consolidation processes in neocortex.

Title: Communication between the hippocampus and olfactory system is needed for contextually cued retrieval of odor memories

Authors: *N. HERNANDEZ[1,2], L. RAIT[2], J. DOBBIN[3], T. CLELAND[2], C. LINSTER[3], D. M. SMITH[2]
[2]Dept. of Psychology, [3]Neurobio. and Behavior, [1]Cornell Univ., Ithaca, NY

Abstract: Context is a potent retrieval cue. Many studies have shown that unique ensembles of hippocampal neurons are activated in each environment a subject encounters. Upon revisiting a familiar environment, these hippocampal context representations are automatically reactivated and they prime context-appropriate behaviors and memories. Individual sensory cues are thought to be represented in primary sensory areas and those representations are also reactivated during retrieval. Thus, communication between the hippocampus and primary sensory areas may underlie contextual priming of memory. Olfaction provides an excellent way to study memory in rodents and there is a direct pathway from the ventral hippocampus (vHPC) to the anterior olfactory nucleus (AON), a structure known to modulate processing in the olfactory bulb and piriform cortex. Thus, this pathway could mediate top-down context-based modulation of olfactory memory by the hippocampus. To test this hypothesis, we trained rats on a contextually cued odor discrimination task. Rats learned to dig for a reward in one cup of odorized digging medium (odor A) and to refrain from digging in a different cup (odor B) when they were presented in one context (the black side of the box). The reward contingencies were reversed when the same odor cues were presented in the other context (the white side of the box). Thus, the rats had to use the context (black or white) in order to guide their choice behavior. After rats learned the task, we conducted three temporary inactivation experiments. In the first two experiments, we performed bilateral inactivation of the AON and vHPC. In the third, we used cross-hemisphere infusions of muscimol (i.e. inactivation of the vHPC in one hemisphere and the AON in the other) in order to disrupt vHPC-AON communication. All three inactivation procedures significantly impaired performance (vHPC: $t(5)= -7.72$, $p < 0.001$ and AON: $t(5)= -6.52$, $p < 0.001$, compared to saline controls; cross-hemisphere inactivation: $F[2,4]= 46.619$, $p < 0.001$, compared to saline and unilateral muscimol controls). These results indicate that each structure is independently needed and moreover, that communication between the vHPC and AON is critical for contextually cued odor memory. This supports the general hypothesis that contextual priming of memories involves hippocampal modulation of primary sensory representations.

Title: Rapid sensory-evoked modulation of hippocampal spatial activity

Authors: *R. ZEMLA, M. DUFOUR, S. SUNDAR, A. HAIRSTON, J. BASU
Neurosci. Inst., New York Univ. Sch. of Med., New York, NY

Abstract: Rapid association of relevant sensory events in the environment with their spatial location is important for the formation and recall of episodic memories. The dorsal CA1 region of the hippocampus exhibits spatially-selective activity in its excitatory pyramidal neurons. As an animal navigates through its environment, place cells fire at distinct spatial locations - also known as place fields - which stabilize with experience. Long-range projections from layers II and III of the medial entorhinal cortex (MEC) convey spatial information to the dendritic tree of CA1 pyramidal neurons via direct and indirect pathways. Interestingly, the neighboring lateral entorhinal cortex (LEC), which integrates polymodal sensory, novelty- and context- related information also sends projections to CA1 pyramidal neurons. While there is a gradient in the anatomical distribution of the MEC and LEC inputs along the proximal-distal axis of area CA1, pyramidal neurons in the medial CA1 sub-region receive inputs from both MEC and LEC. Additionally, MEC and LEC inputs are conveyed trisynaptically from dentate gyrus and CA3 through the Schaffer collateral pathway to integrate sensory and spatial information contents routed from LEC and MEC. The convergence of spatial and sensory information onto the same population of neurons in CA1 suggests that changing environmental sensory input may modulate spatially-dependent CA1 activity. Using in vivo two-photon imaging, we tested this hypothesis by first establishing that CA1 pyramidal neurons and interneurons show somatic calcium activity in response to odor stimulation *in vivo.* Using mice trained to navigate head-fixed on a textured treadmill track , we are now testing how enrichment of specific spatial zones on the track with odor stimuli influences the spatially tuned calcium activity of CA1 pyramidal neurons. Furthermore, by performing volumetric imaging of somatic and dendritic planes of CA1 pyramidal neurons we are assessing how manipulation of genetically defined local and long-range inhibitory inputs shape short-term and long-term changes in sub-compartment specific calcium activity during an odor-place association task.

Title: Retrieval specificity of remote memory is affected by the order of retrieval

Authors: *A. SINGH, S. KUNDU, R. SUGANDHITA, S. KUMAR, A. DAS, J. BALAJI
Ctr. for Neurosci., Indian Inst. of Sci., Bangalore, India

Abstract: Retrieval of memories long time after their acquisition has been shown to depend on training conditions. In order to consider the nature of remote memories, the role of cortico-hippocampal connections has been debated for a long time across theories such as standard model and multiple trace theory. While various training conditions have been considered to understand memory retrieval, testing conditions have been looked at in a relatively uniform manner across existing studies. One aspect that has received minimal attention is that during testing, each retrieval event is also a new learning experience. We propose that the learning experience during remote memory retrieval modulates the memory trace in a different manner in comparison to recent memory retrieval. In our study, such effect is evident as the specificity of remote memory is found to be affected by the order of testing.We explore this phenomenon with novel modifications in rodent behavior protocols for generalization and discrimination testing of contextual fear memory. First, we propose a theoretical description for a model of remote memory retrieval emerging from our study in order to incorporate the effect of new learning during retrieval. We then test the effect of retrieval order on remote memory specificity with mice and show that specific testing conditions can allow recall of such hard-to-find memories. Using hippocampal lesions, we find hippocampus to be required for manifesting the effect of retrieval order on the specificity of remote memory. Further, we explore the neuronal underpinnings of this phenomenon using in vitro and in vivo imaging techniques coupled with our behavior paradigms.

Title: An *In vivo* approach to identify and segregate neuronal ensembles of multiple memories using temporal expression dynamics of a single immediate early gene

Authors: *M. PRABOD KUMAR[1], S. KUMAR[2], T. CHERIAN[2], B. JAYAPRAKASH[2]
[2]Ctr. for Neurosci., [1]Indian Inst. of Sci., Bengaluru, India

Abstract: Immediate early genes (IEGs) are widely used as a marker for neuronal plasticity. Yet, techniques to identify the temporal coupling of IEG expression to different behaviors or events (e.g. cellular compartment analysis of temporal activity by fluorescent in situ hybridization (catFISH), Fos-tTA,Tet-tag transgenic mice) are limited. All these techniques are limited to *in vitro* applications and provide a snapshot of the different neuronal populations that were activated during behavior. However, if one were to follow these populations *in vivo* then it amounts to several imaging sessions that are interspersed between behavioral tasks. This leads to anesthetizing the mice several times for identifying these neurons. Further, if one were to investigate the synchronous IEG activation of the neurons in an ensemble, it is harder and in many instances it is not viable. Here, we model the dynamics of an IEG expression *in vivo* and experimentally show that this approach can be used to identify distinct neuronal subsets. The rationale is to use the kinetics of expression to estimate when the activity of the neuron was induced. We present a generalized theoretical framework of such a dynamical system. We show that the fluorescence measurement of cFOS-EGFP protein in the transgenic mice over time, from

the onset of stimulus, is well fit to an analytical expression derived to describe the above model. Using this approach we obtain the general method by which we are able to distinguish between neurons that took part in multiple events that are separated in time, by looking at the level of fluorescence of individual neurons.

Title: Systems consolidation of temporal content in episodic memory

Authors: *S. SHRIDHAR, V. PAL SINGH, S. KUNDU, B. JAYAPRAKASH
Ctr. for Neurosci., Indian Inst. of Science, Bengaluru, Bengaluru, India

Abstract: Episodic memory is remembering the what, when and where of an autobiographical event. In this regard, the concept of time in autobiographical memory is fundamental to human experience. In animal models, it has been shown to have important implications in foraging behavior. We know that memories once acquired change over time; they might lose the richness of detail and generalize the stimulus they were presented with and their contextual information. However, very little is known about the nature of temporal aspects of these memories and to what extent they are preserved over time. Our current research aims to understand consolidation of temporal memory, and how it evolves over time.
We have modified behavioral paradigms and have designed novel flavor place association tasks that introduce an explicit temporal component, Through these paradigms the mice are trained and

are tested for different aspects of temporal memory during retrieval to study how these aspects evolve during the process of systems consolidation.

Abstract: Two-photon uncaging combined with calcium imaging is a critical experimental tool to investigate synaptic plasticity rules in a spatio-temporal scheme. In order to perform simultaneous uncaging and imaging, typically ultrafast laser pulses from two separate laser systems are used in conjunction with two independent sets of galvanometric mirrors. However, such a setup is instrument intensive and requires synchronized operation of two laser systems making it relatively tedious to operate and maintain. Here, we report a single ultrafast laser system based optical setup that uses a single set of galvanometric mirror based regular scanning assembly to perform simultaneous two-photon uncaging and calcium imaging in a hippocampal neuron. A fast operating optical shutter operating along with our delay line optics and galvanometric mirror is used to generate patterned uncaging excitation. Spatial control of uncaging is measured and shown to be close to the optical resolution. The accuracy and synchrony is shown to be within few microseconds. We put to use the good control of uncaging location in these experiments to investigate the cooperative and associative plasticity.

Title: Fluorescence saturation dynamics based *In vivo* classification of spines

Authors: *S. KUMAR[1], B. JAYAPRAKASH[2]
[1]Ctr. for Neurosci., Indian Inst. of Sci., Bangalore, India; [2]neurobiology, Indian Inst. of Sci. Malleshwaram Bangalore, Bangalore, India

Abstract: In this work we present a new method that utilizes optical saturation to measure absolute absorption cross section. Until recently it has not been possible to measure absorption cross-section in absolute manner *under a microscope*. Here we propose a method that utilizes parameters that characterizes optical saturation to estimate absolute cross-sections of fluorophores independent of concentration, collection efficiency and other such parameters that is difficult to account for. Our method is easily implementable in any confocal/multi-photon microscope to image the cross-section as a function of space across the sample. This made it possible for us to propose a new imaging contrast (β) representing the local micro-environment of the fluorophores. We have used this method for *in vivo* imaging of mice to generate information based on the parameter (β) that allows for classification of spines. The spines imaged in a field of view can be classified using the relative contrast parameter. Imaging the spines longitudinally and with behavioral manipulations reveal the functional significance of imaging contrast (β) in spines. In addition, we demonstrate the generality of our method by measuring the absolute three photon cross-section of L-tryptophan (reported for the first time).

Title: Bayesian nature of remote memory assisted learning (mental Schema) and its role in problem solving in mice

Authors: *V. SINGH[1], R. BHATT[1], S. KUNDU[1], S. SHRIDHAR[1], S. SAUMITRA[2], A. SINGH[1], B. JAYAPRAKASH[1]
[1]Ctr. for Neurosci., [2]Ctr. for Nanoscience and engineering, Indian Inst. of Sci., Bangalore, India

Abstract: Memories of related events and facts are thought to be stored in neocortex in the form of associative networks (mental Schema). The dynamics for consolidation and retrieval are different from that of single event learning. Although neocortex is shown to be involved, but no mathematical/statistical model has been proposed and tested to explain the evolution of a mental schema and how it can assist learning of similar information rapidly. In order to address this we trained animals to learn same sets of flavour place associations (paired associates) in two different ways viz., i) Solitary Learning: Two sets of association are presented independently one after the other ii) Relational Learning: Second set is presented in relation to first set. We find that only the animals that underwent relational learning were able to acquire both set of flavours. We show that older memories help in acquisition of new memories only if presented in a relational manner. We hypothesise and show that such behaviour is consequence of Bayesian learning mechanisms of the neocortex.

Title: Acute effects of social defeat stress on cortical neuronal activity

Authors: *R. NAKAYAMA, T. SASAKI, Y. IKEGAYA
Grad. Sch. of Pharmaceut. Sci., The Univ. of Tokyo, Tokyo, Japan

Abstract: Stressful experiences cause a variety of dysfunctions in the body. As early studies have focused on biological phenomena restricted within a single peripheral organ, it remains to be elucidated how the organ activity is affected by the brain and autonomic nervous system during stress responses. To address this question, electrophysiological changes in cortical and cardiac activity were recorded from rats that were subject to social defeat stress. In stress-susceptible rats, which showed a significant decrease in heartbeat rates after the stress load, the power of cortical local field potentials was attenuated immediately and transiently in response to social stress. These power decreases occurred across multiple brain regions, including the hippocampus, the neocortex, and the thalamus. In addition, cerebral microdialysis revealed that the extracellular concentration of serotonin, a monoamine neurotransmitter, was pronouncedly increased after social stress. These dynamic changes in cortical activity may be a possible mechanism to disrupt peripheral organ functions in response to mental stress episodes.

Title: Interaction of multiple memory systems during spatial alternation task in the rat

Authors: *N. T. REITZ, J. L. VINCZE, J. B. HALES
PSYCHOLOGICAL SCIENCES, UNIVERSITY OF SAN DIEGO, SAN DIEGO, CA

Abstract: Multiple memory systems in the brain work to successfully form declarative and non-declarative long-term memories. Declarative memories, memories for facts and events, are encoded by the medial temporal lobes, including the hippocampus, whereas non-declarative memories are formed in other regions of the brain, including the neocortex, striatum, and amygdala (Squire, 2004). Although the hippocampus is critical for declarative memory formation, hippocampal-lesioned rats are often still able to reach control levels of performance over time on typically hippocampus-dependent tasks (Morris & Frey, 1997; Hales et al., 2014), suggesting the recruitment or ongoing involvement of an alternative memory system. Our study is designed to probe two possibilities of memory system interaction. One possibility is that an alternative memory system, such as the striatal system, compensates for the damaged hippocampus and only engages if the hippocampus is not functional. Another possibility is that the striatal memory system is always engaged in gradually learning the spatial memory task, but the more efficient and dynamic hippocampal memory system masks, or even inhibits, any contribution from the striatum (Sutherland et al., 2010). To examine these possibilities, we tested rats with bilateral excitotoxic hippocampal lesions or sham lesions on the alternating T-maze task. Once rats consistently alternate, a 10-second delay was added between trials, as previous studies have shown that a 10-second delay will disrupt performance in hippocampal-lesioned rats (Ainge et al., 2007). All rats were trained until they reached criterion performance. For the hippocampal-lesioned rats and half of the sham rats, 90 minutes after the last training session, the rats were perfused and brains were stained for c-Fos expression using immunohistochemistry. The other half of the sham rats continued training past criterion until the number of testing days matched the number for each hippocampal-lesioned rat, using a yoked design. These "overtrained" sham rats were then perfused, and brains were stained for c-Fos. The critical comparisons for the overtrained sham rats is the level of c-Fos expression in the hippocampus compared to the other sham rats and in the striatum compared to the hippocampal-lesioned rats. Such comparisons directly examine the relative contributions of two distinct memory systems during spatial learning.

Title: The effect of eye movements and gaze on hippocampal activity in non-human primates in virtual environments

Authors: *B. W. CORRIGAN[1], R. A. GULLI[1], G. DOUCET[2], J. C. MARTINEZ-TRUJILLO[1]
[1]Physiol. and Pharmacol., Univ. of Western Ontario, London, ON, Canada; [2]McGill Univ., Montreal, QC, Canada

Abstract: Exploration of the environment differs significantly between rodents and primates: while rodent exploration is largely multisensory, primates rely heavily on their highly-developed vision to look at their immediate surroundings and more distant locations. While place-like cells have been found in primates exploring real and virtual environments (Ono et al., J Neurophys., 1993; Matsumura et al., J Neurosci., 1999), cells encoding eye position as well as gaze location have been found in the hippocampus (Ringo et al., J Neurophys., 1994; Georges-François & Rolls, Cerebral Cortex, 1999), and entorhinal cortex recordings have found saccade direction cells (Killian et al. PNAS 2015). To further test and disambiguate the selectivities of hippocampal units, we trained two male *Macaca mulatta* to do a cued saccade task and two different tasks in a virtual environment. We recorded single units within the right hippocampus. We tracked the eye movements, and classified them into saccades and foveations. We then analyzed firing rate selectivities of units for saccade direction, target screen location, target world location and place in the environment. Using non-parametric analyses to determine selectivity. We found that while some units showed selectivity for saccade direction or screen location, these selectivities did not carry over to other tasks. Using a virtual environment allowed us to record the virtual position of the subject, as well as the gaze location in three dimensions of each foveation in the environment. We binned space in the virtual environment, and will ran analyses to test selectivity of a neuron for position and gaze location. This research will help characterize the encoding that happens in the primate hippocampus.

Title: Head direction cell instability in the anterior dorsal nucleus of the thalamus following intraseptal microinfusions of the $GABA_A$ agonist muscimol

Authors: *I. PASTOR, C. P. CERVANTES ALDANA, M. Y. HURTADO, J. L. CALTON
Psychology, California State Univ., Sacramento, CA

Abstract: Head direction (HD) cells, found in many regions of the rat Papez circuit, are believed to reflect the animal's directional orientation and are thought to play a critical role in navigation. Previous studies have shown that septal infusions of the $GABA_A$ agonist muscimol eliminates hippocampal theta activity (Givens & Olton, 1990), leads to a decrement in the positional signal carried by place cells, and produces navigational deficits (Brazhnik, Muller, & Fox, 2003). Interestingly, the pathways that mediate the hippocampal theta rhythm bear a remarkable similarity to the adjacent nuclei mediating head direction signals (Taube, 1998), and neurons possessing both HD and theta properties have been identified in the two nuclei mediating the HD generative circuit (Stackman & Taube, 1998). More recent studies have demonstrated the existence of theta modulated HD signals in some, but not all areas known to contain HD cells; however, little has been done to examine the influence of theta oscillations on HD cells in their most abundant location, the anterior dorsal nucleus of the thalamus (ADN). Given the relationship between the hippocampal theta rhythm and the location-specific firing of place cells, and findings that indicate an interrelationship between place cells and HD cells, it is likely that the HD system may also be associated with theta. Thus, the present investigation sought to characterize the effects of reversibly inactivating the medial septum using microinjections of the $GABA_A$ agonist muscimol on (1) the basic directional characteristics of ADN HD cells, (2) the ability of HD cells to shift their preferred direction following visual landmark rotation, and (3) the maintenance of a stable preferred firing direction using idiothetic cues in darkness. EEG recordings were made before and after inactivation of the medial septal area, and hippocampal theta power was significantly reduced following inactivation. In the landmark rotation experiment, intraseptal administration of muscimol produced a population of HD cells with preferred directions that shifted unpredictably between sessions, suggesting that cue control was affected. Further, following septal inactivation a significant population of HD cells was unable to maintain a stable preferred firing direction when the animals locomoted in the dark, suggesting that idiothetic cue processing was affected. These findings suggest that theta oscillations are necessary to maintain the directional stability of HD cells in anterodorsal thalamus.

Title: Galantamine potentiates neuroprotective effect of taurine & coenzyme Q 10 & their interaction against Aβ (1-42) induced cognitive dysfunction

Authors: *A. SINGH, A. KUMAR
Panjab Univ., Chandigarh, India

Abstract: Background: Taurine, 2-aminoethanesulfonic acid, acts as a neuromodulator, prevent mitochondrial dysfunction, apoptosis and oxidative stress. Also prevent the neurotoxicity of amyloid beta peptide [(Aβ) (1-42)] by binding on $GABA_A$ receptor. Coenzyme Q 10 (CoQ10), a lipophilic, endogenous, vitamin-like antioxidant compound. It has been reported to improve cognition, restored mitochondrial function and facilitates ATP synthesis.
Aim: We aimed to evaluate the neuroprotective effect of galantamine on taurine and CoQ10 and their interaction in Aβ (1-42) induced cognitive dysfunction in rats.
Materials and methods: Intrahippocampal (*i.h.*) Aβ (1-42) (1µg/µl; 4µl/site) were administered, followed by drug treatment with taurine (25, 50 and 100 mg/kg), CoQ10 (10 and 20 mg/kg) galantamine (2 mg/kg) and their combinations for a period of 21 days. Various neurobehavioral parameters followed by biochemical, AChEs level, mitochondrial enzyme complex level (I-IV), TNF-α level, neurotransmitter level and histopathological alterations were assessed.
Results: Administration of Aβ (1-42) significantly impaired cognitive performance in Morris water maze (MWM) test, causes oxidative stress, raised AChEs level, neurotransmitter levels, neuroinflammation, mitochondrial dysfunction and alterations in histopathology as compared to sham treatment. Treatment with taurine (25, 50 and 100 mg/kg), CoQ10 (10 and 20 mg/kg) and galantamine (2 mg/kg) significantly improved the cognitive performance as evidenced by reduced transfer latency and increased time spent in the target quadrant in MWM test, reduced AChEs activity, neuroinflammation, oxidative damage (reduced LPO level
and restored SOD and GSH levels), TNF-α level, restored mitochondrial respiratory enzyme complex (I-IV) activities, histopathological alterations and neurotransmitter levels as compared to Aβ (1-42) treated animals. Further, combinations of taurine (25 and 50 mg/kg) and CoQ10 (10 and 20 mg/kg) with galantamine (2 mg/kg) significantly modulate the neuroprotective potential of taurine in Aβ (1-42) treated animals.
Conclusion: The present study suggests the neuropotentiating effect of galantamine on taurine and CoQ 10 as indicated by improved behavioral parameters, oxidative stress, AChEs levels, TNF-α level, mitochondrial functions, neuroinflammation, neurotransmitter levels and histopathological alterations.

Title: Determinants of sparse population coding in a computational model of the rat dentate gyrus

Authors: ***I. RAIKOV**[1], A. D. MILSTEIN[3], I. SOLTESZ[2]
[2]Sch. of Med., [1]Stanford Univ., Stanford, CA; [3]Neurosurg., Stanford Univ. Sch. of Med., Stanford, CA

Abstract: The hippocampus provides the basis for spatial navigation and episodic memory in the brain, remembering events experienced in the past and linking them with their spatio-temporal context (O'Keefe and Nadel, 1978). The dentate gyrus (DG) is one of the major subfields of the hippocampus, with excitatory input arriving from Layer II of the entorhinal cortex (EC). The principal cells of the dentate gyrus are the granule cells (GCs). The cellular and circuit characteristics of the dentate gyrus combine uniquely to constrain the number of active GCs in order to maintain sparse population activity. GCs receive strong inhibition from local GABAergic interneurons (INs), however, a very conspicuous feature of the dentate circuitry is that GCs also receive direct excitatory glutamatergic input from mossy cells (MCs) . One of the great enigmas of the hippocampus, the net effect of MC input on GCs, is a topic of active research, as mossy cells also activate local INs that inhibit the GC population, and the resulting balance of inhibition and excitation has not yet been fully understood (Danielson et al., 2017, GoodSmith et al. 2017, and Sensai and Buzsáki, 2017). In the present study, we used a full-scale, data-driven computational model of the rat DG to investigate the role of MC and different IN populations in the encoding of realistic spatial trajectory input. By applying entorhinal stimuli that mimicked grid cell path trajectories and perturbing the connections and properties of different cell types, we found that GC responses were modulated by all IN classes differentially, and were able to form distinct place fields in response to largely overlapping simulated grid cell patterns. However, when our model was configured with the connectivity distributions developed for previous versions of the model (Dyhrfjeld-Johnsen et al., 2007), we were unable to replicate the results of recent experimental results, which have suggested that mossy cells have multiple place fields, higher peak firing rates, and robust spatial remapping. This has led us to

implement revisions to the model such that molecular layer perforant pathway (MOPP) interneurons have an increased role in feedforward inhibition of GCs (Li et al., 2013), and such that hilar perforant pathway (HIPP) interneurons have an increased role in feedback inhibition of GCs. With these revisions, the GC and MC model cells were able to achieve firing rates and place field characteristics consistent with recent experimental studies. In summary, our results suggest several important avenues for further investigation of the mechanisms that underlie sparse coding in the dentate gyrus.

Title: Neural correlates of goal representations and planning in a multi-step navigation task

Authors: *N. ZARR[1], J. W. BROWN[2]
[1]Psychological and Brain Sci., [2]Indiana Univ., Bloomington, IN

Abstract: A primary aim of cognitive control research is to understand how people organize their behavior in pursuit of goals. In many contexts, goal information needs to be maintained across an extended period of behavior, but the neural substrate of this information is uncertain. Complicating matters, multiple subgoals often need to be reached before a final goal can be achieved.
Past studies using univariate analyses have implicated a variety of regions including dorsolateral prefrontal cortex (DLPFC) and parietal cortex in goal representation, planning, and goal execution. Multi-voxel pattern analysis (MVPA) provides a complementary set of evidence by asking which groups of voxels contain information about a particular condition, including goal identity. Past MVPA studies revealed different substrates for maintained sensory information in working memory tasks versus those identified by univariate analyses, with sensory cortex representing sustained modality-specific information.
Human subjects performed a multi-step planning task while being scanned with fMRI. We asked which regions are responsible for representing final and intermediate goal states, using MVPA to identify the loci of representations. A secondary question concerned the degree to which patterns of neural activity instantiating a goal are similar to the patterns elicited when that state is finally reached.
We found evidence that perceptual coding can be extended to representations of goals in a spatial navigation task. A searchlight analysis demonstrated that the identity of a goal state could be decoded with significantly above-average accuracy from visual cortex, both for intermediate and

final goals, but not from other regions including DLPFC.
Overall, our results suggest that functions previously attributed more to frontal regions, such as goal directed behavior and planning, may instead depend more heavily on primary sensory cortical regions.

Title: Neuroprotective effects of quercetin loaded nanoconstructs in murine neurocognitive model

Authors: *C. SINGH
Univ. Inst. of Pharmaceut. Sci., Panjab Univ., Chandigarh, India

Abstract: In the present study, Formulation by Design (FbD) enabled lipidic nanostructured system were formulated for quercetin (Q-NLCs). They were evaluated for their efficiency in nose-to-brain targeting and biodistribution in a suitable animal model after intranasal delivery. Further, particles size characterization revealed the particle size in the nano range. Stability studies indicated refrigeration found to be the preferred storage condition. FTIR, DSC, PXRD and SEM studies revealed formation of less ordered crystalline structure of lipid matrix favouring higher encapsulation of quercetin. *In vitro* antioxidant performance was improved after encapsulation in nanolipidic carriers. Moreover, the biochemical profile of brains of the animals receiving the drug in the form of Q-NLCs was close to that of the normal animals. Aluminium chloride was able to induce reduction in GSH levels only upto 53.98 ±3.51% in the group of animals receiving plain quercetin as the drug. On the other hand, the Q-NLCs were able to significantly resist the decrease in reduced GSH levels ($p < 0.05$). Similarly, the treatments were able to resist brain MDA levels increase in the group receiving Q-NLCs compared to free quercetin alone ($p < 0.05$). Further, the higher %drug targeting efficiency (%DTE) and drug transport percentage (DTP) were observed for Q-NLCs vis-à-vis free quercetin. Hence, the current investigation demonstrates the potential of nano-antioxidant as a potent therapeutic intervention for HIV associated neurocognitive disorders with improved biopharmaceutical attributes.

Title: Calcium imaging in tethered behaving honeybees

Authors: *M. HELD[1], L. LAVIS[1], V. JAYARAMAN[1], K. PFEIFFER[2]
[1]HHMI Janelia Res. Campus, Ashburn, VA; [2]Biocenter Univ. of Wuerzburg, Wuerzburg, Germany

Abstract: Honeybees have a remarkable repertoire of complex sensory-guided decision-making behaviors like adaptive navigation based on terrestrial landmarks and sky-compass cues. These abilities have been demonstrated in a number of behavioral studies. The neural circuits implicated in navigation in other insects — pathways leading to and including a region called the central complex — have also been traced and identified anatomically in bees (Zeller et al. 2015, Held et al. 2016). Studies that probe the physiology of the involved brain regions have used calcium imaging of neurons in the anterior optic tubercle — a region known to be involved in the sky-compass pathway of other species (Pfeiffer et al. 2005) — in completely fixed bees (for example, Mota et al. 2013). In addition, multi-site local field potential recordings have been performed in the optic lobes of tethered walking bees (Paulk et al. 2014). We seek to combine the strengths of these approaches in a paradigm that establishes stable, targeted two-photon calcium imaging in the brain of tethered behaving honeybees walking on an air-supported ball. The movements of the bee on the ball are used to move visual patterns on a surrounding virtual reality arena giving the bee closed-loop control of its visual environment. For calcium imaging, we label populations of neurons using bulk loading of a new generation of synthetic calcium sensors that are masked with acetoxymethyl esters to minimize the damage of these neurons. We are specifically targeting brain regions that are likely involved in landmark and sky-compass navigation based on work in other insects (Pfeiffer and Homberg 2014, Seelig and Jayaraman 2015). These regions include the anterior optic tubercles, the bulbs, and the central complex. We will discuss our ongoing efforts to record the physiological responses of neurons in these regions during different tasks like single or multiple stripe fixation and object discrimination. Ultimately, we hope to use the paradigm to probe neural functions of honeybees during navigational behavior, but this technical advance will also open-up the possibility of studying a wider range of compelling questions relating to decision-making and memory.

Title: How the ultrastructure of the fly compass circuit shapes its dynamics

Authors: S. ALI, A. SHERIDAN, T. PATERSON, R. FRANCONVILLE, D. B. TURNER-EVANS, S. WEGENER, T. WOLFF, J. S. LAURITZEN, D. BOCK, *V. JAYARAMAN
Janelia Res. Campus, HHMI, Ashburn, VA

Abstract: The central complex (CX) is a highly conserved brain region implicated in spatial navigation in insects. The region comprises several neuropils, including the protocerebral bridge (PB), ellipsoid body (EB), and the paired noduli (No). Physiological recordings from populations of identified CX neurons have revealed compass-like neural dynamics, including a localized "bump" of persistent activity in the donut-shaped EB that tracks the fly's orientation in visual surroundings and in darkness. In particular, the anatomy and activity of two specific populations of columnar neurons, E-PG and P-EN neurons, suggest they are connected in a recurrent loop that helps maintain and move the activity bump in response to rotations of the fly (Turner-Evans*, Wegener* et al., eLife, *in press*). The gross morphology of E-PG and P-EN neurons is stereotyped, with each individual neuron connecting a specific wedge of the donut-shaped EB with a single column of the handlebar-shaped PB. Light-level analysis suggests that the E-PG neurons send their axons to the PB and their dendrites to the EB, while the P-EN neurons appear to have complementary dendritic and axonal innervation patterns. Now, using high-throughput transmission electron microscopy of serial thin-sections of a complete fly brain, we have reconstructed several of these and other CX neuron types to map their synaptic connectivity. We discovered that, in addition to the PB-EB recurrent loop between E-PG and P-EN neurons, these neurons are also densely and recurrently connected within the EB. We are now analyzing how this local recurrence influences attractor dynamics in the structure. Connectivity in the PB was more complex still, with wide-field interneurons mediating connectivity between E-PG and P-EN neurons. In addition to relating the anatomy of these neurons to physiology, we will describe our efforts to use compartmental modeling to understand what role these structural motifs and synaptic connections play in the generation, maintenance and propagation of compass-like activity in the circuit.

Title: Understanding neural activity and behavior during visual learning in *Drosophila*

Authors: *C. DAN, J. WITTENBACH, A. HERMUNDSTAD, V. JAYARAMAN
Janelia Res. Campus, HHMI, Ashburn, VA

Abstract: Many animals, including *Drosophila melanogaster*, can effectively navigate their visual environment to search for food, find conspecifics, and avoid predators. It is also critical to their survival to be able to adjust their navigational strategies based on past experience, for example, by remembering the negative or positive consequences of being in specific visual surroundings. However, the neural circuit mechanisms that enable animals to make such associations and thereafter modify their behavior are not yet fully understood. *Drosophila* can associate visual patterns with a heat punishment in a flight simulator, remember the location of a cool spot in an otherwise hot environment using visual place learning, and associate color or light intensity with a reward or punishment. Combined with precise genetic access to various cell types, this offers an opportunity for detailed mechanistic understanding of adaptive visual navigation.

To understand the behavioral logic of visual learning, we analyzed the actions of head-fixed flying *Drosophila melanogaster* in a closed-loop visual virtual reality environment in which changes in their wingbeats were used to control the angular rotation of a visual scene. Similar to flight simulator learning reported previously, the flies were trained to associate visual patterns (conditioned stimulus, CS) with a heat punishment (unconditioned stimulus, US) delivered by an infrared laser pointed at their back. We found that their flight actions underwent coordinated changes through training, and that these changes were highly correlated to their learning performance. We are constructing an empirically informed model using a reinforcement learning framework to quantitatively characterize such moment-to-moment correlations between visual stimuli and the fly's actions.

To investigate the neural mechanisms underlying changes in the fly's behavior, we also monitor the activity of specific neural populations using two-photon calcium imaging during this task. We have identified neural activity correlated to the negative reinforcement, flight action, and visual orientation in the central complex, a region implicated in visual navigation in the fly, and

we are investigating these neural responses before, during and after training. In the long term we hope to use a model-driven approach to establish causal links between neural circuit activity and changes in the fly's decision-making over the course of visual learning.

Title: Monkey Hippocampal

Authors: *W. K. PAGE, C. J. DUFFY
Dept Neurol, Ctr. Visual Sci., Univ. of Rochester, Rochester, NY

Abstract: Hippocampal place cell activity is linked to the animal's location in navigational space, in both rodents (O'Keefe and Dostrovsky, 1971) and old world monkeys (Hori, et. al, 2003). This activity is modulated by the hippocampal local field potential's theta rhythm in rodents (O'Keefe and Recce, 1993), with hippocampal theta linked to saccadic visual exploration in monkeys (Jutras, et. al, 2013). We have now examined potential links between saccades, theta, and hippocampal place cell activity in our continuing studies of cortical-hippocampal interactions in monkeys.
We trained a Rhesus monkey to actively steer its real self-movement through a lighted room. Movement trials begin with the monkey glancing down at a small video display that briefly indicated the monkey's current room location and the next target room location. The monkey used an X-Y joystick to steer a continual path through the room across successive target room locations. The monkey received liquid reward on its arrival at each target location.
During real self-movement, we recorded single neuron activity and local field potentials (LFPs) from microelectrodes placed in medial superior temporal (MST) extrastriate visual cortex, and in the hippocampus. These signals were combined with magnetic search coil eye position records, and with sled interface mediated joystick deflection, room location, and sled movement records. MST neurons showed direction sensitive, self-movement related activity like that attributed to visual and vestibular integration in earlier studies (Page and Duffy, 2003; Fetsch, et al., 2010). This activity showed discrete pauses during saccadic eye movements as the monkey explored its

continually changing view of the room. Hippocampal neurons showed room location related activity with discrete pauses related to increases in theta power associated with its approaching the target room location. In some neurons, theta effects were seen in MST and saccade effects were seen in the hippocampus.
Our findings suggest that cortical self-movement analysis may be projected to the hippocampus, and hippocampal place analysis may be projected to MST cortex. Cortical-hippocampal interactions may create a network supporting navigation and spatial orientation.

Title: Biasing head-direction activity of single presubicular neurons by juxtacellular stimulation

Authors: *S. COLETTA[1,2], M. FREY[1], K. NASR[1,2], P. PRESTON-FERRER[1], A. BURGALOSSI[1]
[1]Werner Reichardt Ctr. for Integrative Neurosci., Univ. of Tübingen, Tübingen, Germany; [2]Grad. Training Ctr. of Neurosci. - IMPRS, Univ. of Tübingen, Tübingen, Germany

Abstract: In order to support navigation, the firing of head-direction (HD) neurons must be tightly anchored to the external space. Indeed, inputs from external landmarks can rapidly reset the preferred direction of HD cells. Landmark stimuli have often been simulated as excitatory inputs from ‘visual cells’ (encoding landmark information) to the HD attractor network; when excitatory visual inputs are sufficiently strong, preferred directions switch abruptly to the landmark location.
In the present work, we tested whether mimicking such inputs via juxtacellular stimulation would be sufficient for shifting the tuning of individual presubicular HD cells, recorded in passively-rotated rats. We found that in a cue-rich environment, HD activity was remarkably stable; evoking spikes outside the preferred direction did not lead to significant changes in HD tuning. However, when the number of available landmarks was reduced to a single proximal cue, the large majority of HD cells showed a drastic reduction in HD tuning and stability. Under these conditions, single-cell stimulation induced a spiking bias at the stimulus location. We propose

that, under conditions of HD cell instability, single-cell stimulation can be sufficient for anchoring HD activity.

Title: Coherence and stability of head direction cells in an open-loop state in pre-eye opening rat pups

Authors: *J. P. BASSETT[1], T. J. WILLS[2], F. CACUCCI[1]
[1]Neuroscience, Physiology, and Pharmacol., [2]Cell and Developmental Biol., Univ. Col. London, London, United Kingdom

Abstract: Head direction (HD) cells fire as a function of an animal's directional orientation in its environment. One of several classes of spatially modulated neuron, they are found in a variety of hippocampus-connected sites and are believed to be fundamental for the neural representation of space in the brain. During development, HD cells precede other spatially tuned cell types in maturation, reaching adult levels of spatial tuning by post-natal day 16 (P16). To date, HD cells have been recorded in rat pups as early as P12, up to 3 days before eye opening. Prior to eye opening, HD cell firing is characterised by low spatial information content and directionally unstable firing. Both Spatial firing characteristics improve with age, and a sharp increase in the number of HD cells, their information content, and their stability occurs around after eye opening.To test whether pre-eye opening HD cells can be stabilised by altering sensory cues, we recorded ADN neurons whilst while rat pups explored an environment much smaller than used in previous studies (20cm side square). In this smaller box, we observe HD cells with adult-like directional tuning and stability from P13 onwards. In a standard recording environment (60cm side square), directional tuning of the same HD cells is poor or non-existent. Nonetheless, on a short time scale, the separation angles between HD cell pairs' firing are fully preserved in the large environment. This suggests that a coherent and robust internal representation of space is present from P13, and that impaired directional tuning results from the drift of the ensemble with

respect to the external environment. To investigate the precise nature of the drift and its origin, we used the known offset angles of the HD cells in the small box to perform standard Bayesian decoding of signalled direction in the large environment. We find that signalled direction slowly drifts with respect to true direction, in a manner consistent with under-signalling of angular head velocity. This pattern of velocity under-signalling is consistent with the open-loop state of the vestibular signal before visual feedback becomes available upon eye opening. We conclude that the internal structure of the HD cell network is adult-like before eye opening, but that it will operate in an open-loop mode until vision, or alternative sensory feedback modalities, are available.

Title: Egocentric border cells upstream of the entorhinal cortex

Authors: X. GOFMAN[1], S. WEISS[2,1], S. RAPOPORT[1], *D. DERDIKMAN[1]
[1]Technion - Israel Inst. of Technol., Haifa, Israel; [2]Tel-Aviv Univ., Tel-Aviv, Israel

Abstract: The hippocampal formation encompasses populations of spatially selective cells, which form together an internal cognitive map. It is hypothesized that the input to those areas is generated mainly from self-motion and visual cues in an egocentric (self-centered) reference frame, which are then transformed to an allocentric (world-centered) reference frame downstream in the hippocampal formation. An important question is how the transition between those two references frames occurs. In order to answer this question, we recorded cells in V2 and the postrhinal cortex (POR), upstream of the entorhinal cortex, in awake behaving rats while they were performing a random foraging task.
Our hypothesis is that there are cells with egocentric spatial properties in the POR, which function as an input source for border cells. So far, our data shows a new type of cell that has a selectivity to the borders of the arena in egocentric coordinates. This type of egocentric border

cell fires when the wall is at a given orientation relative to the rat, in an egocentric coordinate frame. Our results suggest that these egocentric border cells are the generators of allocentric border cells downstream in the entorhinal cortex. Thus, we show here a candidate for generation of spatially selective cells, upstream of the hippocampal formation.

Title: *In vivo* Imaging of entorhinal inputs to hippocampal area CA1 in behaving mice

Authors: *J. BOWLER[1], A. LOSONCZY[2]
[1]Neurobio. and Behavior, [2]Neurosci., Columbia Univ., New York, NY

Abstract: The hippocampus is thought to be a critical for the storage of episodic memories and contextual representations with the primary cortical source of input to the hippocampus being the Entorhinal Cortex (EC). The EC is split into medial (MEC) and lateral (LEC) regions with the former thought to primarily represent spatial aspects of context and the later representing non-spatial aspects. The EC is known to send projections to the hippocampus through via the perforant pathway to the CA1 subregion. Hippocampal place cells remap rapidly when exposed to new environments and are known to persist between multiple exposures to the same environment. However, the precise nature of information carried by MEC and LEC inputs remain unknown. Using two-photon imaging combined with virally targeted Ca2+ indicators we observed and characterized activity in MEC and LEC axonal projections to the hippocampal area CA1 in mice. Through the use of head-fixed virtual reality navigational tasks performed on a custom setup it is possible to image activity in MEC and LEC axonal projections while presenting and switching visual, olfactory and auditory contextual cues. Our initial results indicate that projections from MEC carry some degree of spatial information during head-fixed naviagation. Future experiments aim to characterize the nature of the spatial and non-spatial information originating from MEC and LEC and to classify distinctions between the projections originating in both LEC and MEC.

Title: Oscillatory dynamics in the limbic thalamo-cortical network reveal subcortical information flow to and from the hippocampal formation

Authors: *G. VIEJO[1], G. BUZSAKI[2], A. PEYRACHE[3]
[1]Montreal Neurolog. Inst., Univ. McGill, Montreal, QC, Canada; [2]New York University, Sch. of Med., New York, NY; [3]Montreal Neurolog. Inst., McGill Univ., Montreal, QC, Canada

Abstract: The thalamus relays sensory signals to the cortex, but also between cortical areas. These networks exhibit a wide range of oscillatory dynamics, modulated by various factors such as brain states and attentional recruitment. These interactions arise from a combination of feed-forward (thalamo-cortical) and feedback (cortico-thalamic) controls. The sensory and motor components of these networks, involving the posterior thalamus, have been widely studied *in vitro* as well as *in vivo* models. In contrast, the anterior part of the thalamus is a key part of the limbic system: it receives subthalamic inputs from the mammillary bodies, and is reciprocally connected with the hippocampal formation and the midline cortex. These thalamo-cortical networks are essential for navigation and memory formation, among other limbic-related functions, yet they have only been poorly characterized *in vivo* so far. To further our understanding of these networks, we collected thalamo-hippocampal and thalamo-cortical neuronal ensembles and Local Field Potentials (LFP) during freely moving behavior and sleep. We show that thalamic nuclei of the anterior thalamus, including the antero-dorsal (AD), antero-ventral (AV), and antero-medial (AM), can be discriminated on the basis of their influence on, or entrainment by hippocampal and cortical activity. In particular, thalamic neurons were differentially modulated during non-REM sleep by the thalamo-cortical slow waves (the fluctuation between DOWN and UP states) and the hippocampal sharp-waves ripples (SWRs). The onset of UP states in AD precedes UP states in neighboring nuclei by up to 100ms. The late-onset neurons in AV and AM were strongly responsive to SWRs and were generally highly modulated by theta oscillations during wakefulness and REM sleep. These results suggest that AD neurons, which transmit a signal related to head-direction to cortical and hippocampal areas, may play a key role in activating downstream targets. In contrast, other anterior thalamic nuclei are mainly driven by cortical and hippocampal feedback and may play a key role in transmitting hippocampal outputs to other cortical areas.

Title: Thalamic processing of the head-direction signal

Authors: *A. J. DUSZKIEWICZ, D. WANG, A. PEYRACHE
Montreal Neurolog. Inst. and Hosp., McGill Univ., Montreal, QC, Canada

Abstract: As we navigate the world, it is crucial to maintain a robust sense of where we are. Head-direction (HD) cells serve as the brain's internal 'compass' and each of them is tuned to the specific direction the animal is facing, independently of its location and ongoing behavior. The anterodorsal thalamic nucleus (AD) is a key relay of the HD signal. AD neurons seem to be reciprocally connected with the reticular nucleus (TRN) - an inhibitory thalamic nucleus believed to control the routing of sensory information. Recurrent inhibition is important in shaping attractor network dynamics and it may select subsets of neurons coding for the same direction. Therefore, although the HD signal itself may originate from subthalamic nuclei, the AD-TRN system may play a central role in its processing. Still, connectivity and functional importance of the AD-TRN circuit remain elusive. In order to characterize the functional significance of the AD-TRN circuit, we used a combination of high-density single unit recordings and projection-specific optogenetic interrogation in freely moving mice. Preliminary results show that optogenetic TRN stimulation leads to uniform inhibition of HD cells in AD at short latency, which in turn indicates monosynaptic inhibitory connection. Further experiments using selective optogenetic inactivation of AD to TRN and TRN to AD projections will determine whether thalamic inhibition plays a role in shaping the attractor dynamics of thalamic HD cells.

Abstract: In Blodgett's (1929) experiments, rats that were pre-exposed to a maze without rewards were able learn a task on that maze faster. This phenomenon was named latent learning. In this work we present a model of Blodgett's multiple-T maze experiments. Our model updates intra-hippocampal synaptic weights during pre- exposure trials. During the task, those weights are used to generate replay events that drive off-line learning. We show that pre-exposed artificial rats are able to learn the task significantly faster, validating the hypothesis of the model. We also show that the effect is increased with the number of pre-exposed trials and replay events per trial. We also present an analysis of the shortcomings of this replay model and propose possible solutions. This work is part of our current project on assessing the role of the intra-hippocampal synapse modulation in tasks reminiscent of the "Traveling Salesperson Problem" (TSP), where rats have to optimize their navigation to multiple rewarded feeders.

Title: Extracting grid and border components from field potentials in hippocampus and entorhinal cortex

Authors: *S. MACKESEY[1], M. MATENA[2], F. T. SOMMER[3]
[1]Univ. of California Berkeley, Berkeley, CA; [2]Univ. of California, Berkeley, Berkeley, CA; [3]Univ. California, Helen Wills Neurosci Inst., Helen Wills Neurosci. Inst., Berkeley, CA

Abstract: Advances in recording technology driven by large-scale neuroscience projects (e.g. BRAIN initiative, Human Brain Project) promise to deliver unprecedented high-resolution recordings of brain activity. In particular, extracellular arrays with hundreds to thousands of electrodes are generating high-dimensional field potential ("FP") datasets. There are significant advantages to decoding behavioral information from FPs (as opposed to spikes) but the information encoded in FPs is still poorly understood. One successful approach to FP analysis and decoding is as follows: (1) filter to a band of interest; (2) apply unsupervised learning methods to the filtered data; (3) assess the correlation of learned features with stimulus, behavioral, or other physiological variables using supervised learning methods. This approach has revealed that theta-filtered hippocampal FPs recorded in hippocampal subregions CA1 and CA3 encode the location of a navigating rat. Decomposition of these FPs into independent components yields components tuned to specific locations ("featured-tuned field potentials", or "FFPs"), analogous to place cells. Here we investigate whether other functional cell types in hippocampus and entorhinal cortex, such as grid cells, head direction cells, and border cells, also have corresponding FFP components. Our results show that this is indeed the case. We further examine the spatial patterns of the discovered FFPs with respect to hippocampal anatomy. To quantify the relationship between field potentials, spikes, and spatial variables we use linear decoding and mutual information analysis. We analyze various experimental datasets varying in the subject, number and location of electrodes, and experimental task.

Title: Hippocampal subregion CA1 requires CA3 input to encode novel space

Authors: *I. SHANK[1], M. P. BRANDON[2]
[1]Integrated Program in Neurosci., [2]Psychiatry, McGill Univ., Montreal, QC, Canada

Abstract: Substantial work on the entorhinal-hippocampal circuit has revealed a myriad of spatially tuned neurons, yet the details on how these cell types interact and generate new codes for novel space remain limited. Our prior work has argued against a grid-to-place cell

feedforward transfer model, whereby region CA1 requires entorhinal grid cell input to establish new spatial maps. Here, we explore the possibility that the CA1 place code relies on previously generated assemblies, or maps, that are stored within the CA3 auto associative network. Previous work has assessed and rejected this possibility in familiar environments, however we suggest that transfer of information from CA3 to CA1 would be most critical as animals initially establish a spatial map when exploring a novel environment. To examine this, we used a chemogenetic approach in Grik4-cre transgenic mice to silence CA3 neurons while animals were introduced to a novel environment. We first assessed the effect of CA3 inactivation on the entirety of CA1 by conducting cfos immune-labelling approach. A cre-dependent AAV that expresses the hM4di inhibitory DREADD was injected into CA3 of Grik4-cre mice. The hM4di receptor is activated upon binding of its ligand, Clozapine-N-Oxide (CNO). Mice were then injected with either 1) saline, 2) 1 mg/kg of CNO, or 3) 10 mg/kg of CNO, 40 minutes prior to exposure to a $90cm^2$ novel open field for 20 mins. We observed a CNO dose-dependent decrease in cfos labelling across the entire hippocampal CA1 population compared to control mice. In a second approach, we performed chronic *in vivo* recordings of CA1 neurons in CA3 hM4di expressing Grik4-cre mice. Prior to CNO injection, a baseline recording was taken in a $90cm^2$ familiar open field (F1). Forty minutes after a 5 mg/kg CNO or saline injection was administered mice were exposed to a novel environment (N1), the familiar environment (F2) and again the novel environment (N2). Recovery recordings were obtained from the familiar (F3) and novel (N3) environments 12 hours after injection. Preliminary data indicates that CA1 neurons fail to form discrete place fields in the absence of CA3 input in N1 & N2. We also observed a reduction of place cell stability and increased field size in F2. These results suggest that information flow from CA3 to CA1 pyramidal cells is a prerequisite to build and sustain CA1 spatial maps. We propose that the auto associative capacity of CA3 enables it to store pre-existing cell assemblies to be used for encoding new information. Further work is needed to validate these ideas and to determine whether pre-existing networks in CA3 support coding beyond the spatial realm to facilitate one-shot learning and episodic memory.

Title: Investigation of the head direction signal in the anterodorsal thalamic nucleus using miniaturized microscopes in behaving mice

Authors: *Z. AJABI[1], M. P. BRANDON[2]
[1]Integrated Program in Neurosci., [2]Psychiatry, McGill Univ., Montreal, QC, Canada

Abstract: Head direction (HD) cells are one of the most abundant spatially tuned neurons in the brain. These cells are found in a series of regions starting in the brainstem and extending through the hypothalamus, thalamus, and up into the cortex areas that govern navigation and spatial memory. One area of interest is the Anterodorsal Thalamic nucleus (ADN), which contains a high concentration of HD cells (60%) and is directly downstream of the circuitry believed to initially generate the HD signal, between the dorsal tegmental nuclei and the lateral mammillary bodies. Moreover, ADN has a crucial role in the stability of the signals of other spatial cells such as the place cells and the grid cells. One major obstacle to obtaining data from this region, especially in mice, is its small size (a spherical nuclei with a 0.3mm diameter). Thus, previously reported data has rarely shown recordings of more than 10 HD cells simultaneously. Here, we show calcium imaging of more than 50 HD cells at once and during behaviour. We use a miniaturized microscope built following the guidelines of the “Miniscope” project at UCLA (miniscope.org). To reach the ADN, we implanted 0.5mm-diameter GRIN relay lenses, in mice that were injected, beforehand, with a non-specific adeno-associated virus (AAV) to express GCaMP6f, in the target region. As such, damage to the brain tissue was reduced to its minimum and recordings were stable over the course of at least two months. Calcium transients allowed us to identify HD cells by means of a simple thresholding of the fluorescence changes as well as a deconvolution-based spike inference algorithm. However, on rare occasions, GCaMP6f kinetics were not fast enough to track very quick head turns which meant that head-turn velocity had to be taken into account during the analysis. Our recordings also show a stable preferred firing direction of HD cells for more than two months. Interestingly, our data shows a possible clustering of the HD cells with regards to their preferred firing directions and a potential topographical representation of the animal’s head direction in the ADN. This preliminary finding needs to be investigated further. This technique provides the opportunity to in vivo imaging of a substantial population of HD neurons and, apart from revealing the physical arrangement of these cells, it will allow us to analyze the network dynamics of the HD system in such a way that would have been impossible otherwise.

Title: Dissecting the role of medial septal circuits in the hippocampal code for time

Authors: *H. YONG[1], M. P. BRANDON[2]
[2]Psychiatry, [1]McGill Univ., Montreal, QC, Canada

Abstract: Recent work has shown that hippocampal neurons code for the time spent in the delay period on a delayed spatial alternation task. These 'time cells' have been shown to require input from the medial septum, as muscimol inactivation of the medial septum disrupted the activity of time cells and impaired memory performance. However, the exact role of the medial septum in time cell function remains unclear as muscimol-induced inactivation of the medial septum persists for the full duration of the delayed spatial alternation task. It remains possible that time cells may require information computed outside of a delay zone by other brain regions that rely on the medial septum. Further, inactivation of the medial septum with muscimol silences the activity of all septal neurons, thus it remains unknown which cell populations within the medial septum supports time cell activity. We therefore pursued an optogenetic strategy to selectively silence genetically defined cell populations within the medial septum only when the animal ran on the treadmill in a delayed alternation task. Here, we specifically tested the role of GABAergic neurons in the medial septum, which are widely believed to underlie the generation of the hippocampal theta rhythm. In this approach, we injected a cre-dependent viral vector to induce expression of Archaerhodopsin in medial septum GABAergic neurons using VGAT::Cre transgenic mice. Animals were trained to run reliably on the motorized treadmill and to alternate between the left and right arms of the maze for water reward. Animals were required to run for 20s on the treadmill between each alternation trial. Activity of time cells was recorded from CA1 region of the hippocampus with tetrodes while the medial septal GABAergic neurons were selectively silenced with a green laser (530nm) when the animal ran on the treadmill. We found that optogenetic inactivation of septal GABAergic cells cause a 70-80% reduction in theta power, similar to reduction observed with muscimol inactivation. We also found laser stimulation caused a substantial decrease in the theta rhythmicity in the spiking of individual CA1 pyramidal neurons. We are now analyzing the extent by which time cells and behavioral performance are disrupted during this optogenetic silencing of GABAergic septal cells. Next, we plan to assess the role of the remaining cell types in the medial septum including cholinergic and glutamatergic neurons. Together this data will reveal which medial septum populations are important for time cell function in the hippocampus which will help to shed light on the underlying mechanisms that code for time in the hippocampus.

Title: Potential role of cholinergic medial septal inputs in coding speed and location in the entorhinal cortex

Authors: *H. DANNENBERG[1], M. E. HASSELMO[2]
[2]Ctr. for Systems Neurosci., [1]Boston Univ., Boston, MA

Abstract: A range of experiments show the potential role of inputs from the medial septum in coding of running speed as well as spatial location in the medial entorhinal cortex (mEC). In particular, inactivation of the medial septum causes loss of spatial periodicity of grid cells in the mEC (Brandon et al., 2011, Koenig et al., 2011), and causes the loss of spiking rhythmicity modulated by running speed that may contribute to the loss of location coding (Hinman et al., 2016). However, the cell-type specific contribution of the cholinergic neurons in the medial septum to speed and location coding in the mEC has not been addressed so far. Therefore, we use cell type-specific and stereotactically guided viral transduction of ArchT3.0 for optogenetic inactivation of medial septum cholinergic neurons during unit recording studies of the mEC in mice exploring an open-field environment. Preliminary data show that the slopes in speed tuning curves as well as the strength of speed tuning are statistically significantly reduced during laser stimulation in ArchT3.0 expressing mice, whereas no change is observed in control animals. This points to a possible role of cholinergic medial septal inputs to speed coding. In addition, our experiments reveal caveats of using laser stimulation for optogenetic inhibition of neuronal activity in the medial septum presumably due to either overheating of neuronal tissue or strong visual input due to scattered laser light. Light delivery into the medial septum in control mice causes an increase in theta frequency during movement independent of running speed. This effect is abolished by preventing light entry onto the brain indicating tissue heating as the most likely cause. In contrast to the effect of laser on field potential theta frequency, the visual input of scattered laser light alone was noted to cause significant changes in the firing rates of mEC neurons in control mice that could be reduced by better sealing of the implant. Preliminary

recording of location coding in control mice indicates that the nonspecific side effects of light delivery onto medial septum neurons do not change spatial tuning of grid cells.

Title: Egocentric representation of environmental boundaries in the striatum

Authors: *J. R. HINMAN[1], G. W. CHAPMAN, IV[3], M. E. HASSELMO[2]
[1]Ctr. for Systems Neurosci., [2]Psychological and Brain Sci., Boston Univ., Boston, MA; [3]Dept. of Psychology and Neurosci., Univ. of Colorodo, Boulder, CO

Abstract: Movement through space is a basic behavior, necessary for the survival of all animals. Sensory information about the world and the movements executed are both represented within an egocentric reference frame, one that is centered on the agent. An animal sees something to its left and executes movements in a given direction relative to itself based on that information, such as walking straight ahead (of itself) or turning (away from) its left. Despite the fact that sensory information and behavioral output are represented within an egocentric reference frame, an extensive allocentric, world-centered, spatial representation is maintained within the hippocampal formation that is utilized for navigating to distant goals. In order for the allocentric translation vectors generated by the hippocampal formation to be acted upon they must first be transformed into an egocentric reference frame. The hippocampal formation including the entorhinal cortex is known to mediate allocentric navigation strategies, with several allocentric spatial cell types having been identified including grid, border, head direction and place cells. An alternative, egocentric, navigation system is localized within the striatum, yet little is known about how spatial information is represented within an egocentric reference frame. We implanted rats with hyperdrives targeting the medial portion of the striatum and recorded multiple single units while they foraged in a large open field. A novel spatial cell type was identified that represents the boundaries of the environment within an egocentric reference frame that we have termed egocentric boundary cells (EBCs). Egocentric boundary cells fire when an animal is heading with a specific orientation and distance to any of the boundaries of the environment. So a given cell would fire whenever a boundary is within 10 cm on the animal's right or 20 cm to

the animal's front left for example. Across the population of EBCs the presence of boundaries at a range of angles around the animal are coded. Unlike the allocentric spatial representation in the hippocampal formation that remaps across environments, EBCs maintain a stable egocentric representation of boundary locations relative to the animal across multiple familiar, as well as novel, environments. In addition to EBCs, there are also cells that code for head direction, as well as self-motion information similar to what has been observed in parietal cortex. Overall, the medial striatum contains navigation related cells including EBCs that may be part of a larger egocentric spatial representation involved in implementing allocentric translation vectors generated by the hippocampal formation.

Title: Reverse replay strengthens forward pathways to reward through Hebbian learning and short-term depression

Authors: *T. HAGA[1], T. FUKAI[2]
[1]RIKEN Brain Sci. Inst., Wako-Shi, Saitama, Japan; [2]Brain Sci. Inst., RIKEN, Wako, Japan

Abstract: In hippocampus, it has been observed that the firing sequence of place cells corresponding to a pathway experienced before is replayed in spontaneous neural activity during both sleep and awake state. Interestingly, some of sequences are replayed in reverse direction from the original experience, which is called as reverse replay (Foster and Wilson, 2006). It selectively appears when the animal is consuming reward after traversing the pathway, and is considered to be related to encoding the pathway to get reward. To generate reverse replay from the forward experience and potentiate forward memory by reverse replay in a recurrent neural network, anti-Hebbian synaptic timing-dependent plasticity (STDP) which potentiates a synapse when the postsynaptic neuron fires before the presynaptic neuron (post-to-pre) seems suitable. However, conventional STDP found in Schaffer collateral and neocortex was Hebbian (pre-to-post), the experimentally observed property of STDP in hippocampal recurrent network (CA3) was symmetric (Mishra et al., 2016), and anti-Hebbian STDP has not been experimentally observed in hippocampal excitatory synapses. Here we propose a recurrent neural network model

that overcome this inconsistency. In the presented model, we implemented the modulation of STDP effect by short-term synaptic plasticity (Froemke et al., 2006) in the recurrent network that was designed to propagate burst firing. After the generation of firing sequences, we found that recurrent synapses that transmits firing in the reverse direction were potentiated more strongly than those for the forward direction in this model. We obtained qualitatively same results in wide parameter range of short-term plasticity, and in both Hebbian and symmetric STDP. Using firing rate model, we discuss the mechanism how this phenomenon is produced by Hebbian-learning with short-term depression. We finally show that two-dimensional recurrent neural network model with Hebbian learning, short-term depression, and modulation of learning speed by reward-elicited dopamine could learn optimal pathways to the reward from any starting point on the maze.

Title: A continuous-attractor model of head direction determination by retrosplenial 'flip cells'

Authors: *A. V. SAMSONOVICH[1,2], H. PAGE[3], K. J. JEFFERY[3]
[1]Krasnow Inst. Adv Study, George Mason Univ., Fairfax, VA; [2]Dept. of Cybernetics, Natl. Res. Nuclear Univ. MEPhI, Moscow, Russian Federation; [3]Inst. of Behavioural Neurosci., Univ. Col. London, London, United Kingdom

Abstract: Head direction (HD) cells in the rat brain cooperate to form the sense of direction. A typical HD cell fires when an animal faces in a particular direction and is silent otherwise, and HD cells in most regions maintain their relative preferred firing directions even if absolute direction is altered, such as when an orienting landmark is moved. This property is generally attributed to attractor dynamics in the underlying neuronal networks. According to the standard ring attractor model[1,2], HD cells together form a ring in some abstract space such that cells close to each other on the ring excite each other and more distant cells inhibit each other, producing a compact activity bump that can be shifted by both self-motion cues and landmarks. In apparent contradiction with this standard model is the discovery of a new type of neuron in the

dysgranular retrosplenial cortex[3], which may have a critical role in linking landmarks to the direction sense. Unlike HD cells, which encode head direction in a global reference frame, these cells rotate their directional firing by 180 degrees when an animal transitions between environmental subcompartments in which local landmark layouts are 180 degrees reversed in global space. The directional firing of these 'flip cells' can thus be disconnected from classic HD neurons. Moreover, some of these cells can exhibit a mixture of both rotation and non-rotation. Another finding challenging the standard model is that HD cells underrotate in response to landmark rotations. To reconcile these observations with the standard model we assume that there is not one, but two or more weakly inter-connected attractor rings. Some rings are strongly bound to particular landmarks, while others are mostly driven by background cues, which include the current heading estimation sustained by self-motion cues. To validate the concept we performed simulations of a simple two-ring continuous-attractor neural network model, using non-spiking linear-threshold units with a Gaussian distribution of excitatory connections and global inhibition that stabilizes the total number of active units. Under a choice of parameters consistent with published experimental data, the model easily reproduces all qualitative aspects of observed dynamics, including discordant HD representations and the flip cell phenomenon. It may explain how retrosplenial cortex contributes to the landmark control of the direction sense.

Title: Two star mazes, but a single representation of space in the monkey hippocampus

Authors: P. BARADUC[1], S. PINEDE[2], A. PLANTÉ[2], *J.-R. DUHAMEL[2], S. WIRTH[2]
[1]Dpt Speech and Cogntion, Gipsa-Lab, CNRS / U. Grenoble-Alpes UMR 5216, Saint-Martin d'Hères, France; [2]Neurosci., Inst. Des Sci. Cognitives UMR-5229, Bron, France

Abstract: How does the brain code similarities between different experiences while also discriminating their specificity? Studies of spatial memory have provided ample evidence that different episodes are coded by distinct patterns of cell activity. In the rodent foraging for food, hippocampal cells signal the animal's location through a place field. These place fields change when elements of the environment are altered, and a global remapping occurs when the animal is placed in different enclosures. Here we asked how hippocampal cells in the monkey code two virtual reality environments bearing a similarity of structure but different visual landmarks. We previously showed that the primate hippocampus codes space during wayfinding in more complex ways than simple place-coding, and includes task-related information, among which the progression towards the goal (Wirth et al., 2017, *PLoS Biol* 15(2): e2001045). We now compare the activity maps obtained when the animal searches for a hidden reward in a familiar, well-known star maze vs. a novel maze of same shape, but differing in the visible landmarks. We showed that while 35% coded only one environment, 29% of cells coded both environments. In 71% of the latter cells, activity maps showed a higher cross-correlation than expected by chance between the familiar and the novel maze. Thus, while physical landmarks changed, these cells maintained a goal-centered and task-related representation of space. This abstract representation progressively formed as a function of learning, as the cross-correlation steadily increased across learning epochs. Crucially, this progression was apparent when decoding cell activity in task-related state space or goal-centered physical space, but not as a function of either view direction or point of gaze. To summarize, some cells abstracted from the physical details of the maps and only coded high-level, goal- and task-related information in schema-like representation; the other maze-selective cells could concurrently represent the uniqueness of the perceptual and/or episodic experience.

Title: Cheap, scalable camera system for tracking rat behavior in large spaces

Authors: R. SAXENA, D. JAIN, I. R. JAKHALEKAR, W. BARDE, A. BISHNOI, *S. S. DESHMUKH
Ctr. for Neurosci., Indian Inst. of Sci., Bangalore, India

Abstract: The hippocampal spatial map is thought to be a cognitive construct, representing the abstract notion of space rather than sensory stimuli. Barring a few heroic efforts, studies have remained limited to environments smaller than $1m^2$, thanks to the limits imposed by cables running from the animal to the recording system. Wireless recording enables us to record in larger and more complex environments, approaching the scale and complexity of natural environments. Most commercial neurophysiology systems, however, use one camera (or at most two) to track the animals, further limiting the experiments to small spaces.
We have developed a novel tracking system comprising 8 overhead Raspberry Pi cameras, which is capable of tracking animal position in a large environment. The video tracking system is temporally synchronized with neural data recorded on a Neuralynx Cheetah data acquisition system using TTL pulses. The Pi cameras have a jitter of ±0.025ms in the inter-frame intervals as compared to the ±8ms jitter in the inter-frame interval of the Neuralynx camera system. This reduction in jitter allows a more accurate estimation of the animal's position at any given time, by reducing the misalignment between tracking and neural data streams. This system is scalable and hence can be used for environments larger than the one used in the present study. Also, the system is adaptable for use with complex environments with multiple occlusions. Use of cheap, off-the-shelf components makes this system significantly cheaper than off-the-shelf multi-camera video tracking systems. Furthermore, it is temporally more accurate compared to commercially available neurophysiology systems. We will present data showing neural correlates of space in hippocampus and related areas recorded using this system and an explicit comparison of recordings from the Pi camera system with a commercial system.

Title: *In vivo* two-photon imaging of cortical head direction cells during passive rotation

Authors: *A. R. CHAMBERS[1], E. HENNESTAD[1], R. LANTON[1], W. TANG[2], K. VERVAEKE[1]

[1]Inst. of Basic Med. Sci., Univ. of Oslo, Oslo, Norway; [2]Letten Ctr. and GliaLab, Div. of Physiology, Dep. of Mol. Med., Inst. of Basic Med. Sciences,University of Oslo, Oslo, Norway

Abstract: Accurate spatial navigation depends upon the brain's capacity to generate an internal, continuous representation of head direction (HD). Neurons that are selectively active when the animal is facing a specific direction, so-called HD cells, form the neural basis for this representation, and can be found in multiple brain areas, including the retrosplenial cortex (RSC). The RSC boasts reciprocal connections with several key brain regions for memory and navigation, such as the hippocampal formation and anterior thalamic nuclei, however its microcircuit architecture and exact role in navigation remain unclear. In addition, it is unknown whether RSC HD cells transform incoming directional information to generate HD tuning, or whether they simply inherit this tuning from upstream regions. Cellular studies of HD representation are generally performed with extracellular recordings, which are limited in their ability to reveal the spatial organization and cellular identity of HD-tuned neurons, and lack the ability to densely sample the whole population. Extracellular recordings may also display a bias toward active neurons, thereby complicating an accurate estimate of HD tuning prevalence. For these reasons, a paradigm for chronic, *in vivo* two-photon imaging of HD cells is of great interest to the field. HD cell tuning, however, depends on vestibular stimulation and is anchored to visual cues. Therefore, we developed a setup that allows rotating awake and head-fixed mice under the microscope objective, while keeping visual cues on the surrounding arena stable. Using a genetically encoded Ca2+ indicator (GCaMP6f) to measure neural activity, we found that passive rotation is sufficient to elicit tuned responses from HD cells. We are currently characterizing the properties of HD neurons in light and dark conditions, and in response to visual rotations, as well as mapping the spatial distribution of these cells across cortical layers and subdivisions of the RSC.

Title: Search for allocentric navigation encoding in the goldfish brain

Authors: E. VINEPINSKY, *O. DONCHIN, R. SEGEV
Ben Gurion Univ., Be'er Sheva, Israel

Abstract: The ability to navigate in the world is extremely important to almost all animals. In mammals, the neural navigation system is believed to be based on place cells and grid cells which are found in hippocampus and the entorhinal cortex. However, it remains an open question whether similar navigation system exists in other animal classes. To address this fundamental issue, we use the goldfish as a model animal since it possesses a defined neuroanatomical region associated with allocentric navigation. Using a wireless recording system, we measured the activity of single cells in the lateral pallium while it swims in a quasi-1D aquarium. We found two unique cell types: velocity cells and speed cells. Velocity cells encode swimming direction and speed and therefore have allocentric properties, while speed cells encode only the speed independent of direction. We have also found some evidence of border cells, i.e. cells which are active when the fish is near the boundary of the environment. Our study sheds light on how the fish brain encodes spatial information and how the mechanisms of a neural navigation system are preserved across evolution.

Title: L-Thyroxine normalizes hypothyriodism-induced suppression of CaMKII pathway during hippocampus-dependent learning and memory processes

Authors: K. H. ALZOUBI[1], *K. A. ALKADHI[2]
[1]Jordan Univ. of Sci. & Technol., Irbid, Jordan; [2]Univ. Houston Col. Pharm., Houston, TX

Abstract: Calcium/calmodulin protein kinase II (CaMKII) is a crucial molecule for hippocampus-dependent learning and memory. Activation of CaMKII is triggered by an increase in intracellular calcium concentration, which activates PKCγ. This frees calmodulin, which activates CaMKII forming phosphorylated (P-) CaMKII. Recently, we have shown that hypothyroidism impairs hippocampus-dependent learning and memory in adult rats. L-thyroxine treatment, on the other hand, alleviates cognitive deficits during hypothyroidism. In this study, we investigated the interactive effect of L-thyroxine and hypothyroidism on the CaMKII pathway during learning and memory processes. To locate a hidden (2cm under water) platform, each rat was trained in the radial arm water maze (RAWM) for 8 consecutive learning trials. Thirty minutes later, a memory test was done, and immediately after that hippocampi were

dissected out, and CA1 areas were removed and processed for determination of P-CaMKII, total CaMKII, PKCγ and calmodulin protein levels. Results from RAWM-trained rats were compared with those from age-matched controls, hypothyroid and L-thyroxine treated/hypothyroid animals that underwent the same number and duration of swimming trials, but to locate a clearly visible (2cm above water) platform in an open (non-RAWM) swim field.
Western blot analysis revealed a significant increase in P-CaMKII in the CA1 region of the hippocampus in RAWM-trained control and L-thyroxine treated/hypothyroid groups, but not in the hypothyroid group compared to non-RAWM corresponding groups.
However, no significant increase was found in the levels of total CaMKII, calmodulin, and PKCγ in CA1 area of the hippocampus of all RAWM trained rats compared to non-RAWM corresponding groups. Therefore, our study shows that chronic L-thyroxine treatment normalizes hypothyroidism-induced suppression of P-CaMKII levels during hippocampus dependent learning and memory.

Title: Oral minocycline hydrochloride prevents hippocampal-dependent cognitive impairment associated with cafeteria diet both before and after the onset of obesity

Authors: *S.-J. LEIGH[1], R. F. WESTBROOK[2], M. J. MORRIS[3]
[1]UNSW Sydney, Unsw Sydney, Australia; [2]Dept. of Psychology, [3]Dept. of Pharmacol., UNSW Sydney, Sydney, Australia

Abstract: Background: While a large body of literature indicates that obesogenic diets are associated with cognitive impairment in both human and animal models, the underlying mechanisms remain controversial. A key mechanism proposed to drive these cognitive changes is increased inflammatory signalling associated with obesity. The anti-inflammatory minocycline hydrochloride (MH) has been routinely used to depress microglial activity as it easily crosses the blood brain barrier. We used a rodent model to test the hypothesis that blocking inflammatory signalling in the periphery and brain with MH would alleviate cafeteria-diet-induced cognitive deficits. **Methods:** Rats were pre-exposed to vehicle (syrup) or MH (40mg/kg/day) for three

days before half were switched from regular chow to a cafeteria diet, consisting of regular chow, various cakes, biscuits, savoury foods and 10% sucrose. Memory was tested using novel object and place recognition tasks (NOR and NPR respectively) at two, four and six weeks of diet; EchoMRI performed at four and six weeks determined body composition. Two to three days following final behavioural testing and EchoMRI, rats were euthanised and brain, blood and peripheral tissues collected. **Results:** Rats fed cafeteria diet and vehicle were impaired on the hippocampal-dependent NPR throughout the experiment, and a mixed three-way ANOVA revealed no effect of time on NPR performance. Average place task exploration ratios showed a significant interaction effect between diet and drug; while MH administration spared NPR performance in cafeteria-fed rats (similar exploration ratios to rats fed chow and vehicle), chow rats treated with MH performed worse than those treated with vehicle. For both chow and cafeteria rats administered vehicle, final body weight was negatively associated with average NPR exploration ratio ($r=-.60$, $p<.001$) with heavier rats performing worse on the hippocampal-dependent task. This association was not observed in MH-treated rats: final body weight was not associated with performance on NPR. MH administration did not alter 24-hour energy intake in either diet group. **Conclusions:** Cafeteria diet produced persistent deficits in NPR and this deficit was prevented by ingestion of the anti-inflammatory drug MH, indicating that these cognitive impairments may be associated with increased inflammatory signalling. However, since MH also has antibiotic activity, further investigation into the role of the gut-brain axis in diet-induced cognitive impairments is underway.

Title: Lactate mediates the effects of exercise on learning and memory through Sirt-dependent BDNF induction

Authors: *S. SLEIMAN, L. EL-HAYEK, V. ZIBARA, R. ABI ASSAAD, N. EMMANUAL, N. KARNIB, R. EL-GHANDOUR
Natural Sci., LAU Sch. of Arts and Sci., Byblos, Lebanon

Abstract: Exercise induces beneficial responses in the brain, which is accompanied by an increase in BDNF, a growth factor associated with cognitive improvement and the alleviation of depression and anxiety. However, the exact mechanisms by which physical exercise produces an

induction in brain *Bdnf* gene expression are not completely understood. Here, we report that an endogenous molecule released after exercise is capable of inducing *Bdnf* promoters. The metabolite lactate, which is increased after prolonged exercise in the blood, induces *Bdnf* expression and Trkb signalling in the hippocampus. Indeed, we find that lactate-dependent increases in hippocampal BDNF are associated with improved spacial learning and memory retention and rescue of chronic social defeat. We have discovered that the action of lactate is dependent on Sirt induction and activation potentially by affecting the activity of the transcriptional coactivator PGC1α. These results reveal an endogenous mechanism to explain how physical exercise leads to the induction of BDNF and identify novel targets that allow us to harness the therapeutic potential of exercise.

Title: Obesogenic diets affect cognition in rats through gut microbiome and associated chnages in brain neuroplasticity and inflammation

Authors: *M. J. MORRIS, J. BEILHARZ, J. MANIAM, N. KAAKOUSH
Univ. New South Wales, Kensington, Australia

Abstract: A range of studies in animals and humans have demonstrated that exposure to diets rich in either fat and sugar, or sugar alone, can have detrimental effects on cognition. The hippocampus appears particularly sensitive to dietary insult, specifically hippocampal-dependent place recognition memory. People who report greater consumption of fats and sugars showed more marked loss of hippocampal volume. While the Western diet is known to have detrimental effects on cognition and the gut microbiota, few studies have investigated how these may be related. Our lab examines the relationship between diet-related changes in gut microbiota, hippocampal gene expression and behavioural deficits using Sprague Dawley rats. Exposure to a cafeteria diet rich in fat and simple sugars impairs hippocampal dependent spatial learning within 1 week, prior to significant weight changes. Purified diets that were enriched in saturated fats or simple sugars had a similar impact, with changes in microbiota composition in the absence of changes in body weight. We next examined whether probiotic administration could prevent diet-induced memory deficits. Rats were pre-exposed to vehicle, low or high doses of the probiotic

VSL#3 daily for 2 weeks before half were switched from chow to a cafeteria diet for 25 days; VSL#3 treatment continued throughout. Fecal DNA extraction was performed by PowerFecal® DNA Isolation Kit. Cafeteria fed rats were heavier with greater fat mass than those consuming chow, and the probiotic had no impact on these measures. High dose VSL#3 prevented cafeteria diet-induced memory deficits on the hippocampal-dependent place task, but the probiotic led to deficits on the perirhinal-dependent object task, irrespective of diet or probiotic dose. No differences were observed in anxiety-like behaviour on the elevated plus maze. Gut microbial diversity was dramatically decreased by cafeteria diet and here, VSL#3 was able to increase the abundance of some taxa contained in the probiotic such as *Streptococcus* and *Lactobacillus*. In the hippocampus, the cafeteria diet increased expression of many genes related to neuroplasticity and serotonin receptor (5HT) 1A, which was normalised in cafeteria rats on high dose VSL#3. Neuroplasticity genes in the perirhinal cortex were also affected by diet. Object memory performance was correlated with perirhinal 5HT2C expression. These results show that probiotics can be beneficial in situations of gut dysbiosis where memory deficits are evident but may be detrimental in healthy subjects.

Title: Polyphenol-enriched green tea extract restores depressive symptoms and hippocampal synaptic plasticity in ovariectomized rat

Authors: *S. KO[1], S. CHUNG[2]
[2]Physiol., [1]Yonsei Univ., Seoul, Korea, Republic of

Abstract: The depressive disorder is a common but serious disorder that causes severe symptoms that affect feel, think, and handle daily activities. The depressive disorder is more abundant in post-menopausal woman because it is commonly caused by the loss of ovarian follicular activity. Many research showed that synaptic strength changes by stress in cortex, hippocampus, and amygdala are implicated in depressive symptoms, which lead to abnormality of cognition and memory impairment. Recent studies showed that green tea has brain tranquilizing effect, and intake of green tea decreased the stress response in human. In addition, tea polyphenols of green tea has been known to be the main effector for these effects. In this study, therefore, we hypothesized that intake of green tea polyphenol restores hippocampal synaptic dysfunction which induces cognitive deficits in post-menopausal state. To investigate this hypothesis, we tested the effect of polyphenol-enriched green tea extract (PeGTE) on the

impairment of synaptic function at the CA1-Schaffer's Collateral (SC) pathway in hippocampus in depressed, ovariectomized (D-OVX) female rat. It was found that the synaptic strength efficiency at SC pathway in D-OVX rat was significantly suppressed compared to Sham-operated rat. This synaptic impairment was mainly due to serious loss of silent synapses formation, which led to impairment of functional connectivity and LTP capability at the hippocampal SC pathway in D-OVX rat. Surprisingly, these impairments of the hippocampal synaptic function in D-OVX rats were significantly ameliorated by PeGTE treatment. Taken together, these data showed that the synaptic function in hippocampus was significantly deteriorated by depression induction in OVX female rats compared to sham-operated groups. In addition, PeGTE treatment significantly improves the synaptic dysfunctions in D-OVX rats. From these findings, we suggest the possibility that green tea polyphenol may be therapeutic strategy to increase resilience and reduce the cognitive deficits in women who are susceptible to stress and memory impairment by menopause.

Title: Impaired hippocampal gamma-frequency oscillations and mitochondrial dysfunction in a mouse model of alpha-synucleinopathy

Authors: *F. E. RANDALL[1], C. TWEEDY[2], E. ROBSON[2], A. REEVE[2], G. J. CLOWRY[2], E. OLKHOVA[2], J.-P. TAYLOR[2], P. J. ATKINSON[3], F. E. N. LEBEAU[2]
[1]Andover Innovative Medicines Institute, Eisai Inc., Andover, MA; [2]Newcastle Univ., Newcastle upon Tyne, United Kingdom; [3]Eisai Ltd, Hatfield, United Kingdom

Abstract: The misfolding and aggregation of the protein alpha-synuclein is a key pathological feature of the alpha-synucleinopathies, a group of diseases which includes Lewy body dementia and Parkinson's disease. A common symptom of alpha-synucleinopathy is cognitive dysfunction and dementia. Impairment in hippocampal gamma-frequency oscillations may underlie some of the cognitive deficits associated with alpha-synucleinopathy. The Thy-1 A30P mouse model overexpresses human mutant alpha-synuclein, with mice developing hippocampal spatial memory impairment by 12 months of age (Freichel et al. 2007). The aim of this study is to explore age-related hippocampal network changes in 2-3 month and 10-16 month old A30P mice to assess the effect of overexpression of mutant alpha-synuclein on cortical network oscillations

in vitro. Following sucrose perfusion of anaesthetised mice, 450µm transverse hippocampal slices were prepared. Persistent gamma-frequency oscillations can be evoked by the cholinergic agonist carbachol, with oscillation power building over 2-4 hours before reaching stability. Extracellular field recordings were carried out in the CA3 region of A30P and wild-type mice. Mitochondrial function is crucial for the generation of GFO's (Whittaker et al. 2011) and was assessed by COX/SDH double labelling histochemistry on a separate cohort of snap frozen brains. Compared to wild-type mice, A30P mice display an impairment in the build-up and stabilisation of gamma-frequency oscillations at 10-16 months (n=6, p=0.035), but not at 2-3 months (n=10, p=0.838). Mitochondrial function was also found to be impaired in 10-16 month A30P mice compared to 2-3 month A30P mice (n=5 mice each, p=0.04). Mitochondrial dysfunction may be a cause or consequence of gamma-frequency oscillation impairment within the CA3 region of the hippocampus. These changes have implications for the pathogenesis and treatment of alpha-synucleinopathies and will be explored further.

Title: Early hippocampal network hyperexcitability in a mouse model of alpha-synucleinopathy

Authors: ***C. TWEEDY**[1], J. CURRY[1], G. J. CLOWRY[1], A. REEVE[1], E. OLKHOVA[1], J.-P. TAYLOR[1], F. E. RANDALL[2], P. J. ATKINSON[3], F. E. N. LEBEAU[1]
[1]Newcastle Univ., Newcastle upon Tyne, United Kingdom; [2]Andover Innovative Medicines Inst., Eisai Inc, Andover, MA; [3]Eisai Ltd, Hatfield, United Kingdom

Abstract: A balance of excitation and inhibition within the hippocampal network is crucial for the timing and synchrony of network rhythms critical to learning and memory processes. Sharp waves are believed to be involved in memory consolidation and in an acute brain slice preparation of isolated hippocampus (450µm thick), spontaneous sharp waves can be observed in CA3. Changes in sharp wave properties could indicate a network imbalance and therefore underpin the impairment of hippocampal memory processes in diseases such as dementia. The second most common cause of neurodegenerative dementia is alpha-synucleinopathy (including

Lewy body dementia and Parkinson's disease). A mouse model of alpha-synucleinopathy was used to explore changes in the hippocampal excitatory-inhibitory network and investigate its relation to memory deficits. Thy-1 A30P mice overexpress human mutant alpha-synuclein throughout the brain, and develop cognitive dysfunction by 12 months of age (Freichel et al. 2007). Following transcardial perfusion with a high sucrose solution, spontaneous sharp waves were recorded in A30P and wild-type control mouse slices at 2-3 and 10-12 months of age. Sharp waves were found to be of significantly greater amplitude within the 2-3 month A30P hippocampus compared to all other groups (n=7-9 mice per group, 14-21 slices each, p=0.011). Network dysfunction was further explored with exposure to 150nM kainate. At 2-3 months all wild-type control slices exhibited persistent gamma-frequency oscillations with kainate (n=8 slices). However, in 2-3 month A30P mice, 56% of slices also exhibited interictal discharges (n=11 slices). Ageing led to a small increase in the incidence of interictal activity in 10-12 month wild-type mice (9% of slices, n=22). Interestingly, there was a reduced incidence of interictal activity in 10-12 month A30P mice (13% of slices, n=16 slices), suggesting that excitability returned to similar levels as wild-type with ageing. This suggests an early hyperexcitable hippocampal network, becoming less excitable with ageing in A30P mice as cognitive dysfunction becomes apparent. Hyperexcitability may therefore contribute to, or be a predictor of, later wider network dysfunction and therefore act as an early biomarker or potential point of intervention.

Title: MPH reestablish the behavior and hippocampal plasticity in a mouse model of ADHD induced by prenatal nicotine exposure

Authors: D. CONTRERAS PACHECO[1], C. A. CARVALLO[3], R. PIÑA[1], G. UGARTE[1], M. ZEISE[2], R. A. DELGADO[4], J. KLAGGES[1], D. MORALES[1], M. ALBORNOZ[1], C. A. ROZAS[5], *B. E. MORALES[6]
[1]Univ. of Santiago of Chile, Estacion Central, Chile; [2]Univ. of Santiago of Chile, University of santiago of Chile, Chile; [3]Univ. De Santiago De Chile, Santiago, Chile; [4]Univ. of Chile, Santiago, Chile; [5]Biol., Univ. of Santiago de Chile, Santiago, Chile; [6]Univ. of Santiago, Santiago, Chile

Abstract: Attention deficit and hyperactivity disorder (ADHD) is the most prevalent psychiatric disorder of childhood and is characterized mainly by hyperactivity, impulsivity, impaired attention and learning deficit. Methylphenidate (MPH) is the most commonly medication used to treat ADHD, however the molecular mechanisms involved in this process are still unknown . In this study we examined the effects of MPH on hipocampal synaptic plasticity in a model of ADHD induced by prenatal nicotine exposure (PNE). Using electrophysiological approaches and Western blot analysis we investigated TBS-dependent LTP in CA3-CA1 synapses of hippocampus and the insertion of AMPA receptors in the postsynaptic membrane. The characterization of the ADHD was assessed measured the locomotor activity using Open Field Test (OFT), working memory with Y-Maze test and attention with an Object Base Attention test (OBA). LTP was induced by applying theta burst stimulation (TBS, 5 trains, 100 Hz) in hippocampal slices (300 µM) obtained from Control and PNE mice (3-4 weeks old). Our results show that PNE mice exhibit the symptoms of ADHD and that oral administration of therapeutic doses of MPH (1 mg/kg) decreases these behavior significantly. PNE mice showed a significant reduction of LTP compared to controls: from 152.9±0.68% to 127.0±0.81% (n=10,10; *p<0.05). This effect was reverted after of oral administration of 1mg/Kg MPH to levels similar to the observed in control mice: from 127.0±0.81% (n=10,10) to 151.9±1.34 (n=4,4; *p<0.05). In or der to evaluated the molecular mechanism involved in this process we measured the change in the phosphorylation levels of GluA1 subunits of AMPA receptors. Our experimental approach was to collect CA1 areas from hippocampal slices used in electrophysiological experiments for Western blot analysis. Consistent with our electrophysiological results, a significant decrease in phosphorylation ratio for GLUA1-Ser831 was found in PNE mice that showed reduced LTP versus controls mice (PNE: 0.67±0.05, n=5; Controls: 0.93±0.01, n=4; **p<0.01). No significant change in the phosphorylation ratio of GLUA1-Ser845 was observed (PNE: 0.55 ±0.9, n=5, control: 0.6 ±0.12 n=4; p > 0.05). Taken together, our results suggested that oral administration of MPH reestablished the low LTP observed in PNE mice, we hypothesized that this effect is possibly by mobilization of AMPA receptors to the postsynaptic membrane in the CA3-CA1 synapses.

Title: Differential cFos expression after Morris Water Maze exposure in cortical malformation model

Authors: *W. J. CURRY, III
Neurosci. Grad. Program, Univ. of Vermont, Burlington, VT

Abstract: Malformations of cortical development (MCDs) are disruptions of neuronal migration and development that often accompany childhood epilepsy, with 40% of children with refractory epilepsy exhibiting these malformations. MCDs in children with epilepsy are also associated with cognitive impairment and developmental delay. When injected into pregnant dams at embryonic day (E17), methylazoxymethanol acetate (MAM), a DNA alkylating agent, produces offspring with cortical dysplasia that mirrors the phenomenon in humans. Previous work indicates that MAM animals indeed have disorganized hippocampi, hyperexcitability leading to increased seizure susceptibility and perform worse on hippocampus-dependent tests of spatial navigation such as the Morris water maze and place avoidance tasks. Our current work seeks to understand the degree to which neurons directly affected by MAM versus those neighboring neurons that developed in the context of the MAM abnormality are involved in the aberrant network activation that leads to hyperexcitablility. We tested this by performing immunohistochemical analysis of brain sections from 4 cohorts of rats: 1) Control, 2) Control + Morris Water Maze exposure, 3) MAM, and 4) MAM + Morris Water Maze exposure. Levels of hippocampal network activation were measured by levels of c-Fos, a marker of neuronal activation and MAM-affected neurons were labeled with co-administered BrdU. Interestingly, analysis revealed that after water maze exposure, control animals showed greater levels of cFos activation, whereas there was no difference in cFos expression between MAM and MAM + Water Maze groups. Future studies are ongoing to confirm these findings and examine the relationship between BrdU/c-Fos positive and BrdU/c-Fos negative populations. Additional studies are being conducted in order to determine the relationship between putative network abnormalities and cognitive impairment.

Title: Characterizing the effect of asynchronous distributed microelectrode stimulation on spatial memory

Authors: O. ASHMAIG[1], M. J. CONNOLLY[2], R. E. GROSS[4], *B. MAHMOUDI[3]
[1]Neurosurg., Emory Univ. Sch. of Med., Atlanta, GA; [2]Neurosurg., [3]Emory Univ., Atlanta, GA; [4]Dept Neurosurg., Emory Univ. Sch. Med., Atlanta, GA

Abstract: Introduction: There is a great need of a therapeutic method for treating epileptic patients that is characterized by a high success rate in seizure frequency reduction and minimal side effects. Asynchronous Distributed Microelectrode Stimulation (ADMETS) has been shown to significantly reduce seizure frequency in the tetanus toxin rat model of epilepsy. However, critical to developing novel neural modulation therapies will be rigorous assessment of how they impact behavior. In this project, we aim to characterize the effects of ADMETS on the hippocampal circuity and its manifestation in terms of spatial memory.
Methods: A rat was implanted in the CA1 and CA3 regions of the hippocampus with a 16-channel microelectrode array, with alternating 8 stimulating and 8 recording channels. The ADMETS stimulation parameters that were studied were the standard 4 Hz, 2V stimulation as well as a 7 Hz, 4V stimulation. The spatial object recognition task utilizes the innate behavior of rats to explore novelty to assess spatial memory. The rat was allowed to explore 3 objects in an open-field box for 3 minutes. The rat is then removed from the arena, the objects are cleaned to remove olfactory cues, and 2 of the objects switch positions. After a short delay, the rat is re-introduced to the open-field box. Normal memory function is characterized by an increase of interaction time on the objects that switched positions. The task was assessed for the pre-stimulation, stimulation/sham-stimulation, and post-stimulation periods.
Results: Both ADMETS stimulation parameters showed a significant decrease in memory during stimulation as well as during the post-stimulation period when compared to the pre-stimulation trial. The average discrimination score for the stimulation and sham-stimulation trials for the standard ADMETS was 0.59 and 0.28 respectively (p-value=<0.001), and 0.44 and -0.19 for the 7 Hz, 4 V stimulation(p-value=0.01). A more positive score is indicative of better memory.
Discussion: The results indicate that for both ADMETS stimulation parameters, functionality of the hippocampus was affected detrimentally during stimulation as well as 10 minutes after stimulation. Comparing the stimulation and sham-stimulation trials for both experiments, we calculated an effect size of 0.97 for the 4Hz, 2V stimulation and an effect size of 1.34 for the 7

Hz, 4 V stimulation. This suggests there is a dynamic relationship between seizure frequency and spatial memory for different stimulation parameters that are utilized.
Conclusion: Optimization of both stimulation paramaters and behavioral biomarkers is critical in the development of novel neuromodulation therapies.

Title: The effect of multiple levels of chronic zinc supplementation on b6 mice

Authors: *T. DIMOPOULOS, M. L. SMITH, W. R. KOCHEN, N. COSCHIGANO, J. M. FLINN
George Mason Univ., Fairfax, VA

Abstract: Zinc is an essential biometal located in multiple areas of the brain, predominantly in Zinc-enriched Neurons (ZENs) in the hippocampus. The role of zinc homeostasis in the brain has been implicated in many disorders. Zinc has been shown to bind to tau and exacerbate Tauopathy, having a detrimental effect in both in vitro and in vivo studies. On the other hand, elevated Zinc in a patient's urine following a Traumatic Brain Injury directly correlated to the injury severity as well as depression levels after injury pointing towards the importance of zinc in the brain. Both of these examples point to the critical role of zinc homeostasis in the brain; however, no study has looked at the effect of multiple levels of chronic zinc exposure to determine the potential beneficial or detriment study examined the effect of zinc exposure for 6 months on mice consuming either lab water, or water supplemented with 10, 20, or 40 parts per million zinc supplemented water. These mice were then tested on nesting activity, fear conditioning, and the Morris water maze. Histochemistry including Zinpyr staining was also performed to assess the role and location of zinc in the brain.

Title: Cognitive impacts of recurring inflammatory/infection-like experiences during aging

Authors: *E. B. ENGLER-CHIURAZZI[1,2,3], J. M. POVROZNIK[1,2,3], A. E. RUSSELL[1,2,3], K. N. PORTER[3,4], D. WANG[1,2], B. G. SCHREURS[1,2], J. W. SIMPKINS[1,2,3]
[1]Physiol. and Pharmacol., West Virginia Univ., Morgantown, WV; [2]Blanchette Rockefeller Neurosciences Institute, West Virginia Univ., Morgantown, WV; [3]Ctr. for Basic and Translational Stroke Research, West Virginia Univ., Morgantown, WV; [4]Dept. of Pharmaceuticals, West Virginia Univ., Morgantown, WV

Abstract: Infections are common occurrences in life. In addition to inducing sickness behaviors, infections also acutely impact cognition. While the immediate consequences of infection are known, the long-term cognitive consequences of repeated intermittent infections are not well-studied; some evidence suggests that higher lifetime infection burden is associated with greater cognitive decline. Here, we investigated recurring inflammatory/infection-like experiences, health outcomes, and cognitive performance in aging mice, hypothesizing that repeated immune activation could explain, at least in part, age-related cognitive decline. C57BL/6 male mice (10 months) received an intraperitoneal injection of vehicle or LPS every 14 days for 2.5 months. For each injection, the dose of LPS was increased according to the following: 0.4 (Injection 1), 0.8 (Injection 2), 1.6 (Injection 3), 3.2 (Injection 4), and 6.4 (Injection 5) mg/kg. We evaluated sickness behaviors using a 20-point scale at 4 hours, and 14 days, post-injection. Following the final injection/recovery period, animals were cognitively characterized. A subset of the cognitively tested mice as well as groups of behaviorally naïve animals subjected to the same treatment regimen as described above were assessed for long-term potentiation. We predicted that 1) following each exposure, LPS treatment would induce a moderate sickness response from which animals would make a full or nearly full recovery, and 2) this repeated inflammatory/infection-like experience would detrimentally impact cognitive ability and reduce long-term potentiation. Results indicated that at each injection, LPS treatment induced moderate sickness behavior within 4 hours of exposure; 2 weeks post-injection, LPS-treated animals exhibited health/sickness scores similar to Vehicle-treated controls. For behavioral outcomes, LPS-treated mice showed inferior learning on tests of cognitive performance (i.e. passive avoidance). As well, field potential recordings revealed that LPS administration produced a pronounced reduction in LTP expression in mice that had been behaviorally characterized or

who were behaviorally naïve. Thus, recurring infection-like experiences via repeated LPS injections during mid-life transiently produced sickness behaviors but induced long-lasting detrimental cognitive impacts and modulated synaptic plasticity of the hippocampal CA1 neurons that may mediate the observed functional changes. These findings indicate that frequency of immune activation may influence the trajectory of age-related cognitive decline and could be a therapeutic target to facilitate 'graceful aging'.

Title: Learning and memory enhancing efficacy of Withania somenifera in aged mice

Authors: *M. LATA[1], P. SRIVASTAV, 302021[2]
[1]Dept. of Zoology, Univ. of Rajasthan, JAIPUR, India; [2]Dept. of Zoology, university of Rajastha, JAIPUR, India

Abstract: In learning activation of neuron occur in specific area whereas memory is a storage form of learned information and retain them over period of time. Poor memory, lower retention are common problem in old age. In Ayurveda ,Madhya rasayna, are said to prevent aging, have rejuvenate property and supposed to have influence on brain function. *Withania somenifera* is one of them.
Aim: The aim of this study was to evaluate the effect of *Withania somenifera* on behavior changes (learning and memory)of aged mice when administrated the extract for various duration in varying doses i.e., 100mg/kg and 200mg/kg bw.
Method: We divided the animals of 8months , 10months and12months old mice into2-,4-week pre treated and control(n=6 for each group). After the treatment period, the mice along with age matched normal and control mice were subjected to spatial learning(radial arm maze) and passive avoidance tests.
Result: The data was compared with those of age matched control mice. *Withania somenifera* attenuated GPx activity and inhibit LPO in dose dependent manner. The result of radial maze tests in treated group showed significant improvement in learning behavior ($p<0.001$). whereas retention test, treated group spent less time in the smaller compartment but not significantly significant as compared to respective control.
Conclusion: Results clearly indicate the oral administration of *Withania somenifera* extract improved learning and memory in aged mice.

Title: Conditioning-induced modulation of theta activity in dentate gyrus, entorhinal cortex and perirhinal cortex

Authors: *E. E. SUTER[1], C. WEISS[2], J. F. DISTERHOFT[3]
[1]Northwestern Univ., Chicago, IL; [2]Dept Physiol., Northwestern Univ. Dept. of Physiol., Chicago, IL; [3]Northwestern Univ. - Chicago, Chicago, IL

Abstract: Theta oscillations are important in acquisition and retention of hippocampal-dependent tasks, and stimulus-specific theta modulations in CA1 remain strong throughout acquisition and consolidated performance of trace eyeblink conditioning. However, dentate gyrus theta rhythm is less well explored and it is unclear whether hippocampal subregions express similar theta modulation during trace eyeblink conditioning, or express differences—such as those found in single-neuron recordings—between subregions. We analyzed LFP in the theta band (4-8Hz) in rabbits undergoing trace eyeblink conditioning and 1-month retention testing, and yoked pseudo-conditioned controls. Recordings from dentate gyrus (DG), lateral entorhinal cortex (latEC) and perirhinal cortex (PR) were analyzed. While all three regions showed increased theta amplitude and phase reset to CS (whisker vibration) and US (corneal airpuff) in conditioned animals, the timeline of modulation and results in pseudo-conditioned animals differed. Preliminary findings show a decrease in both amplitude and phase resetting to the CS in PR, latEC and DG after behavioral criterion was reached (>8 conditioned responses per 10 trials), suggesting a role in acquisition, but not retention. Interestingly, the theta response to the US also decreased following criterion in DG, but was maintained throughout conditioning and

post-consolidation in PR and latEC. The response to CS was markedly lower in pseudo-conditioned as compared to conditioned animals in all three regions. Of note, the unpaired US evoked an increase in theta amplitude and phase resetting was maintained over conditioning and consolidation. The theta activity results in DG as well as PR and latEC differ from those reported by our laboratory in CA1, confirming that hippocampal theta is subregion-specific and differentially modulated by time-bridging learning. Changes in activity over the course of learning and between conditioned and pseudo-conditioned animals support differential roles for these MTL regions in forming associations. These findings suggest the need for further studies of hippocampal and parahippocampal slow-wave activity in forebrain-dependent learning.

Title: Trace eyeblink conditioning in head-fixed mice pairing vibrissae stimulation and corneal airpuff

Authors: L. T. VINSON[1], A. RAPP[1], L. N. MILLER[1], *C. WEISS[2], J. F. DISTERHOFT[2]
[1]Northwestern Univ. Interdepartmental Neurosci., Northwestern Univ., Chicago, IL; [2]Dept Physiol., Northwestern Univ. Med. Sch., Chicago, IL

Abstract: Trace eyeblink conditioning (tEBC) has been used as a declarative memory task across species (e.g. humans, rabbits, rats and mice). We have used vibration of the mystacial vibrissae and corneal airpuff to establish a hippocampal-dependent learning paradigm in head-fixed C57BL6 mice to allow for a more in-depth analysis of the neural circuitry involved. In tEBC, a neutral conditioned stimulus (CS), such as vibration of the whiskers, is repeatedly paired with an aversive unconditioned stimulus (US), such as a corneal airpuff, which elicits a reflexive eyeblink response which we detect with subdermal microwires to record electromyographic (EMG) activity from the upper eyelid. The two stimuli are separated by a stimulus free “trace” interval. Acquisition of the tEBC task is evidenced by conditioned responses (CRs), defined as blinks elicited by the CS before onset of the US. Our results indicate that conditioned animals show a higher percentage of CRs compared to those of control animals which received in

random order unpaired CS and US trials. Our results also indicate that the whisker vibration conditioning stimulus (CS) evoked a minimal number of short latency startle responses. This paradigm allows us to set and monitor in real time the amplitude of the vibration CS with a Micro-Epsilon laser-optical displacement sensor. Additionally, the mice are monitored with a webcam to ensure trial presentation only when the animals are not moving (e.g. running, grooming and whisking). The use of whisker vibration and airpuff stimuli will permit the study of learning and memory in aging animals, as other sensory modalities such as vision and audition deteriorate with aging. In addition, these stimuli will allow for *in vivo* recordings during training and following memory consolidation. This mouse based paradigm is ideal for molecular genetic techniques, such as Designer Receptors Exclusively Activated by Designer Drugs (DREADDs) and optogenetics, to be used in future experiments to investigate the role of brain regions including the somatosensory cortex and limbic regions in learning and memory.

Title: Cholinergic agonist carbachol reduces the postburst AHP and increases [Ca^{2+}] in CA1 pyramidal neurons of aged rats

Authors: M. M. OH[1], *J. F. DISTERHOFT[2]
[1]Dept Physiol., Northwestern Univ. Med. Sch., Chicago, IL; [2]Northwestern Univ. - Chicago, Chicago, IL

Abstract: The enlarged postburst afterhyperpolarization (AHP) of CA1 pyramidal neurons is hypothesized to be a main source of the learning and memory (L&M) impairments observed in aging subjects (Disterhoft & Oh 2006). Since the AHP is comprised mainly of Ca^{2+}-dependent potassium conductances, the increased cytosolic Ca^{2+} levels ([Ca^{2+}]) during a train of action potentials (APs) observed in aged CA1 neurons (Oh et al. 2013) has also been hypothesized to be a source of L&M deficits. Thus, many studies have focused on reducing Ca^{2+} rise in aged CA1 neurons to rescue the aging-related deficits (Disterhoft & Oh 2007). Other pharmacological manipulations have also been proven to reduce the AHP and rescue aging-related deficits; such

as increasing cholinergic levels with cholinesterase inhibitors in the brain (Disterhoft & Oh 2007). However, it is unknown if AHP reduction and rescued L&M deficits with cholinergic intervention are due to $[Ca^{2+}]$ changes in aged CA1 neurons. Therefore, the present study was designed to determine if bath application of the cholinergic agonist, carbachol, causes a change in $[Ca^{2+}]$ evoked with AP trains in young (3-4 mo) and/or aged (27-33 mo) CA1 neurons from male F344xBN rats.

Whole-cell current clamp and Ca^{2+}-imaging (Oregon Green BAPTA-6F and Alexa 594) data evoked with 100Hz AP trains were collected using a custom built 2-photon laser scanning microscope system before and 20 min after 10μM carbachol was added to the perfusate. Our preliminary data suggest that bath application of carbachol caused ~35% increase in evoked $[Ca^{2+}]$ in aged (n = 10) as compared to ~19% increase in young (n = 8) CA1 neurons. Approximately 13% rise in $[Ca^{2+}]$ was observed in both young (n = 10) and aged (n = 5) CA1 neurons in control experiments. Moreover, carbachol abolished the postburst AHP in both age groups. Minimal change in the postburst AHP was observed in the control groups.

These preliminary data suggest that cholinergic therapeutics that have been shown to rescue aging-related L&M deficits and currently used to slow the progression of Alzheimer's disease (AD) may increase $[Ca^{2+}]$ evoked by AP trains in aging CA1 neurons. This contradicts the major focus of the 'Calcium hypothesis of AD and brain aging', which emphasizes that $[Ca^{2+}]$ be reduced to rescue and/or slow the cognitive decline. Moreover, these data suggest that abolishing the postburst AHP with neuromodulators (e.g., acetylcholine) is a key factor in enhancing $[Ca^{2+}]$ necessary for activating Ca^{2+}-dependent signaling cascades (e.g., gene transcription/translation and cellular machinery) for synapse formation/stabilization as well as altering intrinsic excitability for successful learning and memory formation.

Title: Aging-related changes in the intrinsic excitability of layer III pyramidal neurons of the LEC

Authors: *C. LIN, M. M. OH, J. F. DISTERHOFT
Dept. of Physiol., Northwestern Univ., Chicago, IL

Abstract: Normal aging is often associated with a decline in hippocampus-dependent learning and memory. Previous research has implicated altered intrinsic excitability of hippocampal neurons as mediating these changes in learning ability. In the CA1 region, for example, the intrinsic excitability of pyramidal neurons decreases with aging, as evidenced by an enlarged postburst afterhyperpolarization (AHP). In the CA3 region, on the other hand, there is no difference between the young and aging population in the size of the postburst AHP. CA3 neurons from the aging population, however, can fire more action potentials in response to synaptic stimulation. This increased excitability is mediated by more rapid repolarization due to an enhanced fast AHP (fAHP). The current project focuses on determining whether and how the intrinsic excitability of lateral entorhinal cortical (LEC) neurons changes due to aging. The LEC has been suggested to support hippocampus-dependent temporal associative learning and is also the initial site of manifestation for Alzheimer's disease. The project focuses on pyramidal neurons from layer III, as these neurons project directly to the CA1 of the hippocampus via the temporoammonic pathway. Current clamp recordings were made from layer III pyramidal neurons of the LEC from young adult (3-6-month-old) and aged (29-32-month-old) F1 F344xBN hybrid rats. Our preliminary data indicate that neurons from the aging population (n=6) can fire more spikes in response to increasing depolarizing current injections, relative to neurons from young animals (n=16), despite no difference in the postburst AHP. Neurons from aged animals have a shorter inter-spike-interval (ISI) relative to their young counterparts, which may reflect an enhanced fAHP in the LEC of aged animals. These results suggest that layer III LEC pyramidal neurons undergo similar aging-related intrinsic excitability changes as in the CA3 region of the hippocampus. Although the mean are not significantly different, the data also indicate a separation in the aging population in the postburst AHP, such that there is a population of neurons that have a larger amplitude AHP and another population of neurons with a smaller amplitude AHP. These latter findings suggest a separation in the aging population in terms of learning ability. Experiments are being conducted to test the hypothesis that the smaller postburst AHP comes from a learning unimpaired population and a larger postburst AHP comes from a learning impaired population.

Title: Age differences in ERP correlates of subjective recollection and source memory

Authors: *E. D. HORNE, J. D. KOEN, N. HAUCK, M. D. RUGG
Ctr. for Vital Longevity, Behavioral and Brain Sci., Univ. of Texas At Dallas, Dallas, TX

Abstract: In light of the well-attested vulnerability of episodic memory to increasing age, several prior studies have contrasted the ERP correlates of successful recollection in young and older participants, revealing a variety of different findings. Here, we investigated age differences in ERP correlates of subjective recollection according to whether this was accompanied by an accurate or inaccurate source memory judgment. Young (N = 20) and older (N = 20) adults studied concrete nouns while making one of two judgments (fit in a shoebox or manmade). During a subsequent recognition memory test, participants made memory judgments to test words using the RKN procedure. For words receiving a 'Remember' (R) response, a source memory judgment (which study task?) was then required. We examined ERPs elicited on R trials where source retrieval was correct (R+SC), on R trials with incorrect source retrieval or a 'don't know' response (R+SIDK), on 'Know' (K) trials, and on correct rejection (CR) trials. Young, but not older adults, displayed graded (R+SC > R+SIDK > K) left parietal retrieval success effects (500-800ms). Recollection effects in older adults were however dominated by a large, posterior-maximum, negative-going deflection that did not differ according to source accuracy. Both young and older adults demonstrated a positive-going right frontal recollection effect that did not differ with source accuracy (1000-2000ms). Topographic analyses on range-normalized difference ERPs (contrasting memory conditions) indicated significant differences in the scalp distribution of ERP effects for young and older adults in both early (500-800ms post-stimulus) and late (1000-2000ms) time windows. The findings for the young adults are consistent with numerous prior reports that left parietal ERP recollection effects covary with the amount and fidelity of recollected information. More interestingly, the findings provide striking evidence for the engagement of different retrieval processes during recollection in young and older adults.

Abstract: The common marmoset (*Callithrix jacchus*) is an increasingly attractive model for aging research. The present data are part of an ongoing longitudinal project investigating sex differences in age-related cognitive decline and their neural correlates in the marmoset. The monkeys (n= 22, 4-6 years old, 11 females) were tested on a battery of tasks assessing cognition, stress reactivity and motor function. A subset was also imaged for Magnetic Resonance Spectroscopy (MRS) and awake resting state functional connectivity (RSFC). Monkeys performed reversal learning and the Intradimensional/Extradimentional (ID/ED) set shifting task, using the Cambridge Neuropsychological Test Automated Battery (CANTAB). Stress reactivity was assessed by separating each monkey from their colony for 7 hours and analyzing urinary cortisol and behavioral measures pre-, during and post- separation. Subjects also performed the Hill-and-Valley task as a measure of fine motor skills. Females were impaired in performing the reversals in both the Reversal Learning task and the ID/ED shifts. Females were also more sensitive than males to the social stressor, as indicated by more agitated locomotion and greater increases in cortisol during separation from the colony. No sex difference was observed for motor skills. Reversal Learning performance was positively associated with glutamate/glutamine (Glx) concentrations in the frontal cortex and this association was stronger in males than in females. Collection of the RSFC data is ongoing. Future studies will determine whether cognitive sex differences and their neural correlates are maintained with increasing age.

Title: Age differences on cognition and emotion related behaviors

Authors: *A. MORA-GALLEGOS, J. FORNAGUERA
Univ. of Costa Rica, San Jose, Costa Rica

Abstract: On one side, aging is often related to learning and memory decline and on the other side, earlier developmental stages have been related to impulsivity and emotional reactivity. However, there are controversial results and they are also poorly described. In our study, our aim was to compare young (postnatal day 28) and middle-aged male Sprague-Dawley rats (postnatal day 330) performance using different emotional and cognitive tests: open field test (OFT), object recognition (OR) test, active avoidance (AA) and fear conditioning (FC). All rats were tested in OFT and OR but only the half were submitted to AA and the other half to FC tests. In OFT young rats showed more total locomotion, rearing and grooming than middle-aged rats. In OR test middle-aged rats showed a decrease in the exploration of both new and familiar objects, while young rats increased the exploration of both. In AA test, avoidance behavior markedly increased in middle-aged rats along 4 days of test compared to young rats that slightly increased this behavior. In FC test both groups increased time spend on freezing but this behavior differed significantly on training session between age groups, where young rats showed more freezing compared to middle-aged rats. First, these results suggest that young rats have greater emotional reactivity in OFT and FC tests than middle-aged rats who showed a better behavior performance in AA test. In OR test we found opposite trends in the total exploration of both objects between groups but not in the exploration between objects from the first to the second session. Taken together, our results highlight the importance to study different ages to evaluate their performance in different behavioral tests. In this way, we can characterize and better understand the functioning of the nervous system throughout development

Title: Dissociation of performance in hippocampus- and prefrontal cortical-dependent tasks in aging fisher 344 rats

Authors: *N. J. CAREY[1,2], M. A. ZEMPARE[1,2], C. J. NGUYEN[1,2], K. M. BOHNE[1,2], M. K. CHAWLA[1,2], S. SINARI[3], M. J. HUENTELMAN[1,4], D. BILLHEIMER[3], C. A. BARNES[1,2,5]

Abstract: It is well established that cognition and cognitive performance declines with age-related diseases, but it also declines during normative aging. Even within normal aging, there is a spectrum of performance levels at any given chronological age, where people show differing levels of behavior within a specific age, as well as across ages. This spectrum of decline is also observed in animal models. In this study, we use Fisher 344 (F344) rats of three different ages (young 6mo, middle-aged 15mo, and aged 23mo) in attempt to identify behavioral and molecular markers that may reveal clues to successful cognitive aging. All animals are tested on a thorough cognitive assessment battery to identify their level of performance on multiple domains of behavior that rely on the functional integrity of different brain regions. The first tests are the spatial and cued versions of the Morris water maze, the former relying on the function of the hippocampus, the latter is a test of visual and motor competence. These tests are followed by a spontaneous object recognition task, which relies on the function of the perirhinal cortex. A delayed-match-to-place version of the Morris water maze is then given, to test working memory that is dependent on the prefrontal cortex. Additionally, hippocampus subregion functionality is then assessed using a spatial and temporal ordering task with differing levels of interference. We used the performance level on the spatial version of the Morris water maze task to categorize each animal into a cognitive performance level of low, average, or high, within the young, middle-aged and old age groups. When we used this categorization scheme to group performance on the working memory task, this grouping did not correspond to low, average, and high performance for working memory in the middle aged and older animals, but did correspond to low, average, and high performance for working memory in the young animals. Taken together, these data suggest that beginning in middle-age, the relationship between spatial and working memory performance begins to change: different animals can exhibit a high hippocampal and low frontal cortex performance, low hippocampal and high frontal cortex performance, high performance in both, or low performance in both tasks. This is reminiscent of other data in rats (Bizon et al., 2009) and human studies (Glisky & Kong, 2008) where correlations between hippocampus- and prefrontal cortical-dependent performance is often only weakly related within individuals (Alexander et al., 2012). This suggests that more work is needed to elucidate intervention targets that will be effective for personalized optimization of cognitive aging.

Title: Deficits in aged rats on the W-track continuous spatial alternation task suggest impaired hippocampal-prefrontal interactions

Authors: *A. J. KAPELLUSCH[1,2,3], A. W. LESTER[2,3], B. A. SCHWARTZ[2,3], J. R. BREWSTER[2,3], C. A. BARNES[2,3,4]

Abstract: The hippocampus and the PFC are part of a functional system involved in memory-guided decision making, a cognitive process particularly vulnerable to age-related decline in human and animal models of aging. Groups of young and old rats were tested on a continuous spatial alternation task (Frank *et al*., 2000) in which they learned to alternate arm visits on a W-shaped track in order to receive a food reward. There are two interleaved components of this task: (1) an “outbound” or alternation component (working-memory) and (2) an “inbound” component, requiring the animal to remember to return to the center arm (spatial memory). The inbound component is primarily hippocampus dependent. The outbound component, in contrast, likely utilizes both the PFC to maintain a working memory of the previously visited arm, as well as the hippocampus to localize the currently rewarded position in absolute space. Rats with hippocampal lesions are impaired in learning both components of the task and show a pattern of perseverative inbound errors during initial learning (Kim & Frank, 2009). Although lesioning the hippocampus results in slower learning rates, animals are still able to reach learning criterion with time, suggesting adaptive compensation among parallel cognitive networks. Additionally, both aged rats and those with lesions to the mPFC show delayed learning on a T-maze spatial alternation task which also requires rats to maintain a working memory of the previously visited feeder (Ramos *et al*., 2003 , Divac & Wikmark, 1975). In the present study, aged rats made more outbound errors throughout testing, resulting in significantly more days to reach learning criterion, as compared to young rats. Furthermore, while all animals were able to learn the hippocampus-dependent inbound component of the task, 4 of 6 aged animals remained at or near chance level on the outbound component, even after extended testing days. Aged rats may be more impaired on the outbound part of the task because it requires cooperation of both the hippocampus and mPFC, each of which is compromised with age. In addition, there are striking

individual differences among aged animals in their ability to learn this task. The next step in the study will be to perform dual-region ensemble recordings from both the hippocampus and the mPFC while animals complete the alternation task in order to answer how age impacts network dynamics between these two regions, as well as identify the source of significant variation in performance among aged rats.

Title: Sparser representation of experience by aged rat Lateral Entorhinal Cortex

Authors: *A. COMRIE[1,2], J. P. LISTER[1,4], M. K. CHAWLA[1,2], C. A. BARNES[1,2,3]
[1]Evelyn F. McKnight Brain Inst., [2]Div. of Neural Systems, Memory and Aging, [3]Departments of Psychology, Neurol. and Neurosci., Univ. of Arizona, Tucson, AZ; [4]Dept. of Pathology and Lab. Med., UCLA, Los Angeles, CA

Abstract: The hippocampus undergoes biological changes with age that are related to changes in memory function. Subregions of the hippocampus receive major inputs from and send backprojections to superficial and deep layers of Lateral Entorhinal Cortex (LEC), respectively. In contrast to the well-studied Medial Entorhinal Cortex (MEC), LEC neurons do not show substantial spatial selectivity in their firing patterns. Rather, LEC is thought to be involved in representing non-spatial features of experiences, such as objects and odors. The role of LEC in odor discrimination and how the corresponding neural activity may change with age remain unknown. In this study, we examined whether LEC neuronal populations are selectively activated in response to distinct odors during track running, and hypothesized that aging may alter these activity patterns and contribute to memory dysfunction. To test this, adult and aged rats were trained to run laps on a circular track in a constant environment. After training, one behavioral group (AA) experienced the same set of 6 odors around the track during two run

sessions, separated by 20 minutes. A second group (AB) also had two run sessions, but the odor stimuli were distinct between the two epochs. In principal neurons, the mRNA of the immediate-early gene *Arc* is localized to discrete cellular compartments based on the time since activation. We used cellular compartment analysis of temporal activity by fluorescence *in situ* hybridization (catFISH) and confocal microscopy to visualize this time-dependent subcellular distribution of *Arc* mRNA. We identified neurons activated during the first, second, or both run sessions in superficial and deep LEC. We found that AA and AB behaviors elevated activity in LEC compared to a non-behavioral control condition. However, the population activity failed to distinguish between the distinct A and B odor experiences. This suggests that LEC neural population activity stably represents higher order features of the track-running experience regardless of altered odor input. Surprisingly, more cells reached *Arc* activation thresholds during the second epoch than the first. This may indicate that LEC circuits are sensitive to priming by similar past experience. Additionally, we report that a lower proportion of LEC neurons participated during the behavior in aged rats than in adult rats. This latter result might be explained in at least two ways: the representation of multimodal experience by LEC is either refined or reduced by aging. The question of whether a sparser network representation results in maintained, improved, or reduced behavioral function across the lifespan awaits future investigation.

Title: A separable state-space model of learning across trials and days in an aging study in macaque monkeys

Authors: N. MALEM-SHINITSKI[1], Y. ZHANG[2], D. T. GRAY[3,4], S. N. BURKE[7], *A. SMITH[5,3], C. A. BARNES[3,4,6], D. BA[2]

Aging,, [6]Dept. of Psychology, Neurology, and Neurosci., [5]Univ. of Arizona, Tucson, AZ; [7]Evelyn F. McKnight Brain Institute, Dept. of Neurosci., Univ. of Florida, Gainesville, FL

Abstract: Understanding how learning and memory changes with normal aging is increasingly important as the aged population grows. Obtaining objective measures of behavioral changes associated with aging is challenging since learning is dynamic, varies considerably between individuals, and observations are frequently binary. We introduce a method for analyzing binary response data from young and aged macaque monkeys performing tasks across multiple days that enables us to compare within-day and across-day performance. The data set comprises 14 female bonnet macaques-6 young and 8 old animals-performing a reversal learning task in the form of a modified Wisconsin Card Sort Task. Conventional methods to analyze these data are unable to capture their inherent two-dimensional nature, fail to distinguish groups, and cannot adequately assess inter-individual differences in performance. We propose a separable two-dimensional (2D) random field (RF) model of the binary data from these experiments, wherein the joint probability of a monkey's correct performance as a function of task and trial depends on two latent Markovian state sequences that evolve separately but in parallel. In this instantiation of the model, we use a Laplacian random walk prior for the monkey-dependent latent process that characterizes the dynamics of a monkey's learning across days. This captures abrupt transitions and allows the detection of change points in the observations across days due to reversal. A Monte Carlo Expectation-Maximization (EM) algorithm is used to maximize the marginal likelihood of the data from the separable 2D RF, followed by a Maximum a Posteriori estimation algorithm for change point detection. The method results in an estimate of performance within a day for each age group, and a learning rate across days for each monkey. We show that as a group the older monkeys find the tasks harder than the young monkeys, and that the cognitive flexibility of the younger group is higher. We further demonstrate the efficacy of the model by using the resulting estimates of performance as features for clustering the monkeys into two groups. The clustering results in two groups that, for the most part, coincide with those formed by the age groups. Simulation studies suggest that clustering based on the model's results captures inter-individual differences in performance levels, which allows us to identify "high performing" old monkeys. These analyses, therefore provide a method to estimate an animal's behavioral/cognitive age independent of chronological age.

Title: Preserved overall basal firing rates in aged rat basolateral complex of the amygdala, but neurons from aged rats are more engaged in anticipation of rewards compared to young rats

Authors: *R. D. SAMSON[1,2], L. DUARTE[1,2], C. A. BARNES[1,2,3]
[1]Evelyn F. McKnight Brain Inst., [2]Div. of Neural Systems, Memory and Aging, [3]Departments of Psychology, Neurol. and Neurosci., Univ. of Arizona, Tucson, AZ

Abstract: Decision making abilities change across the lifespan as a result of altered brain networks and the accumulation of knowledge and experience. One structure known to be important for detecting changes in value, is the basolateral complex of the amygdala (BLA). Cell numbers in BLA are preserved in aging, but there is a decrease in dopamine transmission as well as receptor density. We recently reported an increase in oscillatory power in the beta-band frequency (~20 Hz) in the BLA, coinciding with the expectation of large rewards in aged rats. We investigated the possibility that the activity of BLA neurons also differs in aged rats during discrimination learning or decision making. To better characterize the activity of BLA neurons in aging, we recorded the single-unit activity of young and aged rats during rest and as they acquired and performed decision making tasks in which reward probabilities and magnitudes were manipulated. Firing properties of BLA neurons during a 30-min rest period before the task was initiated preserved between young and aged rats. During task performance, however, we found that a greater proportion of neurons in the aged rat BLA modulated their firing following entry to the food area (about 2 seconds before reward delivery), whereas the proportion of cells was similar across age groups for all other task events (light cue, lever press and reward). The evoked activity of single neurons was then visualized using peri-event time histograms, and patterns of activation were found to vary in duration, amplitude, sign and onset time. To characterize the firing rate modulation with respect to trial parameters such as reward magnitude and probability, we applied robust statistics to assess the change in firing rate for each neuron individually (at peak firing rate). Using this method, we found that after food cup entry and reward onset, over 20% of BLA neurons in young and aged rats modulated their firing rate to reward size or reward probability, but not trial type (free vs forced choice) nor recent choice history (win/stay-lose/shift). This proportion was greater in aged rats after food cup entry (~35% vs 25%), whereas the proportions were similar across age groups after reward onset (~25%). Finally, we found that more aged rat's BLA neurons displayed greater duration evoked responses following food cup entry (mean 550ms in young and 1650ms in old) and reward onset (mean 1400ms in young and 2700ms in old). Further analyses will investigate the properties of these extended evoked responses. Overall, our results suggest that aging impacts the activity of BLA neurons primarily when animals anticipate or expect rewards, but not as they experience actual rewards.

Title: The alpha-2 noradrenergic receptor agonist guanfacine impairs flexible attention in young and aged macaques

Authors: *D. T. GRAY[1,2], A. C. SMITH[1], S. N. BURKE[4], C. A. BARNES[1,2,3]
[1]Evelyn F. McKnight Brain Inst., [2]Div. of Neural Systems, Memory and Aging, [3]Departments of Psychology, Neurol. and Neurosci., Univ. of Arizona, Tucson, AZ; [4]Evelyn F. McKnight Brain Institute, Dept. of Neurosci., Univ. of Florida, Gainesville, FL

Abstract: Prefrontal cortex-dependent cognitive operations are among the earliest to show declines in normative aging. These observations have stimulated interest in developing potential therapeutic interventions to minimize these changes. The alpha-2 noradrenergic receptor agonist guanfacine enhances many prefrontal cortex-dependent behaviors in aged animals, including sustained attention, which involves an animal's ability to focus on one or multiple stimuli for continuous periods of time (e.g., Arnsten and Contant, 1992). Another frontal lobe-dependent process also impaired during aging is known as flexible attention, and becomes engaged when animals serially switch their focus across stimuli (e.g., Clapp and Gazzaley, 2011). It is presently unknown whether guanfacine also improves this form of attention. Because anatomical substrates mediating distinct categories of attention differ across the frontal lobe, as does the relative expression of noradrenergic receptor subtypes, the possibility arises that a given compound could uniquely impact different aspects of attention. The primary aim of this study was to determine whether guanfacine also enhances flexible attention in monkeys. Six young and seven aged macaques were trained to perform delayed nonmatching-to-sample and object discrimination tasks, and were required to switch attention between the two paradigms. Saline or two doses of guanfacine (Low Dose: 0.001 mg/kg; High Dose: 0.05 mg/kg.) was administered prior to testing, and performance with and without drug were compared. The results reveal behavioral impairments in both age groups under both the low and high doses of guanfacine compared to saline. This suggests that flexible attention does not benefit from alpha-2 noradrenergic stimulation like sustained attention does. Thus, guanfacine treatment may be a good option for an individual with deficits in sustained attention, but a bad option for someone

with multitasking deficits. These data argue for person-specific strategies of intervention, ones tailored to an individual's specific pattern of cognitive aging.

Title: Semi-automated layer classification tool for defining cortical architecture

Authors: V. SOMASUNDAR[1], R. PADMANABHAN[1], B. ROYSAM[1], C. A. BARNES[2,3,4], *J. P. LISTER[5,2]
[1]Dept. of Electrical and Computer Engin., Univ. of Houston, Houston, TX; [2]Evelyn F. McKnight Brain Inst., [3]Div. of Neural Systems, Memory and Aging, [4]Departments of Psychology, Neurol. and Neurosci., Univ. of Arizona, Tucson, AZ; [5]Dept. of Pathology and Lab. Med., David Geffen Sch. of Med. UCLA, Los Angeles, CA

Abstract: Early cytoarchitectonic attempts to define brain regions were performed wholly on visual cues, i.e., the morphology and distribution of cell bodies and processes throughout nervous tissue as revealed using appropriate staining methods. A variety of attempts have been made to define cortical architecture using quantitative approaches, but despite advances in imaging technology and image processing techniques, for small samples it is still standard practice in most laboratories to identify brain regions in histological samples by hand. This process is labor intensive and introduces variability between observers and fails to scale efficiently with the dramatic expansion in ability to image larger volumes of tissue with cellular resolution. New methods to query the activity of every cell (e.g., CLARITY) within increasingly larger blocks of tissue creates a demand for tools that can remove this bottleneck and automate the process of cortical demarcation. Most previous attempts at quantitative cytoarchitecture have aimed at generating values specific for discrete cortical regions but do not represent the inter-laminar changes within cortical regions themselves. As a first step we report here a semi-automated learning method to delineate cortical layers within a cortical region. Our method utilizes large-scale segmentation of neuronal cell bodies from which we can then extract computed features such as volume, eccentricity, and elongation of the cell body, nearest neighbor

distance, and a variety of staining intensity and texture features. Associative measurements can also be computed and the presence of study-specific biomarkers in association with individually segmented nuclei can be utilized to sort the cells into user-defined classifications (e.g., neuron, glial cell, endothelial cell). In addition to these features, the user defines the contour of the cortical surface, and a depth from this surface is computed for each segmented cell, forming the basis for layer classification using a semi-automated learning algorithm. We have tested the validity of our tool on several fluorescent image datasets acquired from sections of rat entorhinal cortex, collected with a confocal microscope and stitched together into 3D montages, and demonstrated that this classification scheme can sort segmented cells into layers with a distinct combination of morphological values at unique distances from the cortical surface. Our current method, implemented as a component of the FARSIGHT package of image analysis tools, achieved a success rate above 90% in layer classification compared to the results of fully manual layer discrimination by an expert in the field.

Title: Age-associated changes in awake hippocampal sharp-wave ripples during spatial eyeblink conditioning

Authors: *S. L. COWEN[1,2,3], D. T. GRAY[2,3], J.-P. WIEGAND[2,3], L. A. SCHIMANSKI[2,3], C. A. BARNES[2,3,1,4]
[1]Dept. of Psychology, [2]Evelyn F. McKnight Brain Inst., [3]Div. of Neural Systems, Memory and Aging, [4]Departments of Neurol. and Neurosci., Univ. of Arizona, Tucson, AZ

Abstract: Sharp-wave ripples are brief (~70 ms) high-frequency oscillatory events that are generated in the hippocampus. Ripples that occur during rest periods following a learning experience are believed to support memory consolidation. Normal aging reduces the rate of occurrence of ripple events and reduces the oscillatory frequency of ripples during rest (Wiegand et al., 2016). Although ripples during rest have been implicated in memory consolidation,

waking ripples may also be involved in short-term planning and memory recall. It is unknown how normal aging alters features of waking ripples. Accordingly, we investigated whether characteristics of waking ripple oscillations and associated single-unit activity undergo age-dependent changes in rats. Local-field and single-unit activity were recorded from the CA1 region of the hippocampus. Sharp-wave ripple events were examined in old (n = 5) and young (n = 6) F344 male rats as they performed a place-dependent eyeblink conditioning task. Comparisons between ripples occurring during rest and waking behavior and between aged and young animals revealed two effects. First, although ripples in aged rats had a significantly lower oscillatory frequency relative to young rats during rest ($p < 0.01$, t-test, n aged = 5, n young = 6), there was no difference between aged and young rats on this measure during behavior ($p = 0.83$). Second, the modulation of principal neuron firing activity by waking ripples was reduced in aged animals when compared to young rats (aged: n = 233 neurons, young: n = 167 neurons, Wilcoxson rank sum test, $p < 0.001$). Modulation was measured as the difference between the mean firing rate during the ripple compared to the mean firing rate during 100 ms intervals that preceded and followed each ripple (+/- 350 to 450 ms). Even though ripple oscillatory frequency was normalized in aged rats during behavior, modulation of single cell activity within a ripple was reduced. Given the involvement of waking ripples in memory recall, these changes in the dynamics of waking ripples could contribute to age-associated memory loss.

Title: Dynamic expression of RNA stress granule components in aging brains: From flies to rats

Authors: B. BAGEVALU SIDDEGOWDA[1], M. K. CHAWLA[2,3], S. YAO[1], C. A. BARNES[2,3,4], *D. C. ZARNESCU[5,1]
[1]Dept. of Mol. and Cell. Biol., [2]Evelyn F. McKnight Brain Inst., [3]Div. of Neural Systems, Memory and Aging, [4]Departments of Psychology, Neurol. and Neurosci., [5]Univ. of Arizona, Tucson, AZ

Abstract: RNA stress granules are dynamic cytoplasmic structures that assemble in response to various cellular insults. In the process, these non-membrane bound organelles sequester specific mRNAs causing inhibition of translation initiation, with the goal of protecting the cell from spending precious resources during times of stress. Upon stress removal, RNA stress granules disassemble and translation is reinitiated. These dynamic changes in RNA stress granules have been linked mechanistically to age-related neurodegenerative diseases suggesting that they may be playing key roles in the aging process. Despite some existing reports that translation inhibition changes with aging, it remains unclear whether RNA stress granules are undergoing dynamic changes as organisms grow older. To shed light on this question, we began by profiling the expression of RNA binding proteins associated with RNA stress granules including TIAR, PABP, FMRP, Gcn2 as well as the translation initiation factor eIF2alpha in aging fly and rat brains. Analyses of both transcript and protein expression of these RNA stress granule/translation initiation markers indicate dynamic changes in aging fly and rat brains. While Gcn2 and phosopho-eIF2alpha expression decline, there is an increase in TIAR levels with age. In addition, the expression of TAR DNA binding protein (TDP-43), a key RNA binding protein implicated in neurodegeneration exhibits a reduction in expression in both fly and rat brains, during aging. These findings support the hypothesis that RNA stress granules undergo dynamic changes during aging. Current experiments including polysome fractionations and expression profiling are aimed at elucidating the role of cellular stress responses in aging brains from the perspective of RNA stress granules.

Title: Brain region-specific changes in melanocortin receptor expression in aged rat brain

Authors: *M. K. CHAWLA[1,2], Y. ZHOU[3], L. WANG[3], N. J. CAREY[1,2], M. A. ZEMPARE[1,2], C. J. NGUYEN[1,2], V. J. HRUBY[3], C. A. BARNES[1,2,4], M. CAI[3]
[1]Evelyn F. McKnight Brain Inst., [2]Div. of Neural Systems, Memory and Aging, [3]Dept. of Chem. & Biochem., [4]Departments of Psychology, Neurol. and Neurosci., Univ. of Arizona, Tucson, AZ

Abstract: It has been reported that the human melanocortin 4 receptor (hMC4R) is involved in neurodegenerative disease (Shen et al., 2016). Melanotropins may protect against the progression of Alzheimer's disease (Giuliani et al., 2014). Furthermore, administration of α-MSH or its more stable analog [Nle^4,D-Phe^7]-α-MSH (NDP-α-MSH) has been observed to enhance learning and memory (Beckwith, et al. 1975). However, the impact of age with respect to melancortin receptor expression remains unexplored. Here we systematically investigated the expression of melanocortin receptors in brain of young (9 months) and aged (23 months) rats, who were assessed for their cognitive status in memory tasks. Six regions of the brain were extracted from each animal, including the frontal cortex + anterior midbrain, parietal cortex, cerebellum, posterior midbrain, hippocampus and occipital lobe. We collected the membrane fragments from each region of all animals in each age group, then ran a specific binding assay using iodine labelled NDP-α-MSH on a high throughput Micro Beta II radiation counter. Six samples were measured from each animal for each region, and then averaged to produce a single count for each animal in each region. All measurements were collected in a blind fashion. We discovered that melanocortin receptor expression was reduced in the aged rats in four of the six regions studied. This finding potentially opens a new window of discovery for exploring and developing new treatments for cognitive changes that arise in normal aging and in neurodegenerative disease.

Title: Temporal contiguity predicts reward association learning in bonnet macaques

Authors: *C. KYLE[1], A. C. SMITH[1], D. T. GRAY[1], S. N. BURKE[4,5], C. A. BARNES[1,2,3]
[1]Evelyn F. McKnight Brain Inst., [2]Div. of Neural Systems, Memory and Aging, [3]Departments of Psychology, Neurol. and Neurosci., Univ. of Arizona, Tucson, AZ; [4]Evelyn F. McKnight Brain Institute, Dept. of Neurosci., [5]Inst. on Aging, Univ. of Florida, Gainesville, FL

Abstract: When human subjects freely recall items from a list, they are more likely to name a neighbor of the item they last recalled. This finding, known as the temporal contiguity effect, has

led to the development of the “temporal context model” of memory which theorizes that temporally neighboring events share similarity in the underlying neural representations (Howard and Kahana, 2002). While this model is supported by studies examining brain activity using local field potential or functional MRI measurements in humans (Hsieh et al., 2014, Kyle et al., 2015, Manning et al., 2011), because only humans can perform free recall, the scope of research on this topic has remained limited. However, state-space models, which through Bayesian statistics can uncover the precise timing of learning, make it possible to investigate temporal contiguity in tasks that do not rely on verbal responses. Here we utilize a state-space model and new methods to calculate the conditional probabilities in a fixed-sequence, forced-choice reward association task performed by 16 bonnet macaques. The results suggest that during multiple days of association-pair learning, newly-learned pairs tend to be more temporally contiguous to recently-learned pairs than to more distant pairs in both young (10 yrs, n=7) and old (23 yrs, n=9) monkeys {figure below}. To our knowledge, our data represent the first evidence that temporal contiguity can underlie reward association learning and extends the study of contiguity using conditional probabilities to non-verbal tasks.

Title: An alternative to dye-based approaches to remove lipofuscin-induced background autofluorescence from primate brain tissue

Authors: W. PYON[1,2], D. T. GRAY[1,2], M. K. CHAWLA[1,2], *C. A. BARNES[1,2,3]
[1]Evelyn F. McKnight Brain Inst., [2]Div. of Neural Systems, Memory and Aging, [3]Departments of Psychology, Neurol. and Neurosci., Univ. of Arizona, Tucson, AZ

Abstract: Lipofuscin results from the collection of lipid residues in lysosomes within cells throughout the body, including neurons. An accumulation of this pigment is one of the most consistent findings across age in the brains of primates with its appearance being correlated with chronological age. This process has generally been considered to be the result of normal cellular "wear-and-tear." Such age-related pigment accumulation, however, presents challenges for fluorescence-based cell quantification in the midbrain since these pigment molecules possess fluorescent emission spectra that invade the normal collection range of most fluorescent microscopes. The use of fluorescence microscopy for anatomical studies has multiple benefits including the ability to label multiple fluorophores, which necessitates a standardized procedure for reducing the background effects of neurolipofuscin-induced autofluorescence that can obscure relevant fluorescent signals. Current strategies to combat such autofluorescence include the use of lipophilic dyes to mask native fluorescent emission from brain tissue (Schnell et al., 1999; Romjin et al., 1999). While these dyes successfully remove autofluorescence, they also degrade the emission of fluorophores commonly used in immunofluorescent microscopy. Here we present an alternative method for removing lipofuscin-induced autofluorescence. This strategy involves defining lipofuscin's emission spectrum given laser lines ranging from 405nm - 633nm on a Leica SP5-II spectral confocal microscope. These spectra are used to subtract lipofuscin-based autofluorescence from fluorescent channels commonly used in immunofluorescent studies. This collection protocol reliably diminishes native autofluorescence while preserving the fluorescence of tyrosine hydroxylase- and calbindin-immunolabelled cells in the ventral tegmental area of young and aged rhesus macaque brains. Here the autofluorescence subtraction procedure is compared to the standard method (Sudan Black B protocol) in order to evaluate which technique most successfully reduces autofluorescence while maintaining the integrity of relevant fluorescent signals.

Title: Role of wine derived polyphenolics as novel epigenetic modifiers in age related cognitive impairment. From responsible nutrition to promotion of neuroresilience

Authors: *A. SHARMA, S. C. M. DE BOER, A. ESTEBAN-FERNANDEZ, J. WANG, B. VALCARCEL, G. M. PASINETTI
Neurol., Icahn Sch. of Med. At Mount Sinai, New York, NY

Abstract: Modifiable lifestyle factors such as moderate red wine intake are receiving increasing attention in their potential preventative impact on mechanisms associated with progression of Alzheimer's disease cognitive decline. The mechanisms through which brain bioavailable red wine derived phenolic acids exert their beneficial effects in humans has been strongly investigated in relation to microbiome metabolism and demonstrated that certain microbes from intestinal flora generate phenolic acids able to improve cognitive decline (Ho *et al*., 2014) . We continued to characterize several bioactive polyphenol metabolites and gut derived phenolic acids *in vitro* as potential epigenetic modifiers that might influence long term nutritional benefits in response to grape derived phenolic acids. Interestingly we found that mRNA expression of DNA *de novo* methylation enzyme DNMT3b is significantly decreased ($p< 0.05$) while the expression of the DNA hydroxymethylation enzyme TET2 ($p<0.05$), but not TET3, is increased following treatment with quercetin-3-O- glucuronide (500 nM, 72 hr) in primary embryonic cortico-hippocampal neuronal cultures. We also found that the microbiome derived phenolic acids 3-hydroxybenzoic acid and 3-(3'-hydroxypheyl) propionic acid (10µM, 72 hr) significantly promoted TET2 ($p<0.05$) expression. After bioavailability and structural identification of polyphenols, we continued to validate our findings *in vivo*. Excitingly, we found that the expression of DNMT3a ($p<0.01$), DNMT3b ($p<0.05$) TET2 ($p<0.05$) and TET3 ($p<0.01$) is selectively decreased in the hippocampal formation of mice following oral administration of a standardized bioavailable bioactive dietary polyphenolic preparation (BDPP). While this study strongly supports the need to further dissect select BDPP components, they also support ongoing investigations regarding the role of DNA methylation in response to bioavailable polyphenol metabolites and gut-derived phenolic acids. Based on this evidence using representative bisulfate

sequencing approaches we are currently sequencing at base-pair resolution for methylated CpG sites to further investigate novel dynamic methylation of the genome in mice treated with BDPP. The outcome of this study therefore provides for the first time a stepping stone to generate wine/grape based mimetic probiotics to promote resilience via brain bioavailable polyphenol metabolism against age-related psychological and cognitive impairment which we found may involve long term responses through epigenetic mechanisms.

Title: Apoaequorin differentially modulates fear conditioning in adult and aged rats

Authors: *V. L. EHLERS[1], J. A. TUMA[1], K. L. FELDMANN[1], J. R. MOYER, Jr.[2]
[1]Psychology, [2]Psychology and Biol. Sci., Univ. of Wisconsin Milwaukee Dept. of Psychology, Milwaukee, WI

Abstract: The population of aging individuals worldwide is dramatically increasing. Although advancing age is associated with increased risk for dementia, the elderly may also suffer from cognitive impairment in the absence of dementia. The study of learning and memory can tell us how information processing changes as a function of aging, and can be a vital tool for understanding aging-related cognitive decline. Animal studies have demonstrated that aging is accompanied by impaired hippocampal-dependent associative learning. For example, aged rodents demonstrate impaired trace and context fear memory. A proposed contributor to these learning and memory deficits is dysregulation of neuronal calcium. Normally, cells are able to regulate calcium levels by utilizing calcium-binding proteins (CaBPs), but expression of these proteins is reduced in aged animals. One CaBP that has demonstrated neuroprotective properties is apoaequorin (AQ), a protein isolated from the jellyfish *Aequorea victoria*. Data from our lab indicate that direct infusion of the AQ protein into the dorsal hippocampus prior to an *in vitro* ischemic insult reduces cell death. Thus, our question was whether infusion of AQ into dorsal hippocampus could effectively mitigate aging-related fear memory deficits. In our initial experiment, adult and aged rats were randomly assigned to receive a bilateral dorsal hippocampal infusion of vehicle (Adult-Veh; Aged-Veh) or AQ (Adult-AQ; Aged-AQ) one day prior to trace fear conditioning. All rats were tested one day following conditioning. During the test, Aged-

Veh and Aged-AQ rats froze significantly less than Adult-Veh and Adult-AQ rats ($p < .05$), suggesting infusion of AQ does not rescue aging-related trace fear memory deficits. In our next set of experiments, we sought to determine whether AQ infusion could induce state-dependent learning in either age group by infusing it 1 h before conditioning and testing. Adult and aged rats were randomly assigned to one of four infusion groups: vehicle pre-training and pre-testing (Veh-Veh), vehicle pre-training and AQ pre-testing (Veh-AQ), AQ pre-training and vehicle pre-testing (AQ-Veh), and AQ pre-training and pre-testing (AQ-AQ). While AQ infusion prior to training and testing did not mitigate trace fear memory impairment in aged rats, aging-related context fear memory impairment was not significant ($p = .1$), suggesting AQ infusion induces a state-dependent enhancement of context fear memory. The results of these experiments implicate a role for AQ in the modification of cognitive function in aged rats.

Title: Deterioration of visual discrimination learning in aged marmosets

Authors: A. TAKEMOTO[1], E. L. MUNGER[2], M. RAGHANTI[3], *K. NAKAMURA[1]
[1]Primate Res. Institute, Kyoto Univ., Inuyama, Japan; [2]Anthrop., [3]Dept Anthropol & Sch. Biomed Sci., Kent State Univ., Kent, OH

Abstract: Learning and memory processes are similarly organized in humans and nonhuman primates. Therefore, behavioral and cognitive studies in nonhuman primates can be used to understand human learning and, in particular, the effects of aging on cognitive processes. Macaques have been widely used in cognitive learning research, though recently common marmosets (*Callithrix jacchus*) have been suggested as a nonhuman primate model for aging and neuroscience research. However, the effect of aging on cognition has been poorly studied in this species. The present study examined the effects of age on the ability of common marmosets to

learn visual pattern discrimination tasks and reversal learning. Four research-naïve marmosets aged ten years or older participated in this study (2 males and 2 females). For the visual discrimination learning, two different square graphic pattern stimuli (27 mm x 27 mm) were presented either to the left or right of center on the touch screen. One image, if touched, would provide the marmoset with a reward and a tone where the other would not. The marmosets would complete a single session of 100 trials per day. The marmoset would continue with the same visual discrimination learning experiment until 90 correct responses out of 100 trials in one day were achieved. Once the marmoset reached the learning criterion, a new learning task was presented the following day. The marmosets in this study completed three visual discrimination learning experiments (N1, N2, N3) followed by a reversal learning (R3). Once the 90% criterion was reached in the first reversal learning, the marmosets completed a fourth visual discrimination (N4) followed by a second reversal learning (R4). We found that aged marmosets commit significantly more errors in the initial stages of visual discrimination and more perseverative errors in reversal learning, indicating prefrontal dysfunction. On the other hand, they showed comparable performance with the younger marmosets in the later stages. Our present data demonstrate that marmosets can be good nonhuman primate model for aging.

Title: Does acarbose treatment differentially modulate cognitive healthspan with respect to age, genetic background, or neurodegenerative disease?

Authors: *S. J. MOORE[1], R. C. PARENT[1], L. OUILLETTE[1], G. G. MURPHY[1,2]
[1]Mol. & Behavioral Neurosci Inst., [2]Dept. of Mol. and Integrative Physiol., Univ. of Michigan, Ann Arbor, MI

Abstract: As an increasingly large segment of society reaches the oldest age brackets, there is growing interest in identifying treatments that can slow or eliminate distinct aging processes. These clinical interventions may extend lifespan, improve mobility, or preserve cognitive

function, any or all of which may both increase the quality of life for the individual as well as reduce the global health care burden.
Acarbose has been identified by the National Institute on Aging's Interventions Testing Program as a drug which significantly extends lifespan in a genetically heterogeneous mouse line, UM-HET3. Because acarbose is already used in a clinical capacity in humans and is known to be safe and well-tolerated, it has the potential for rapid translation into clinical studies. Therefore, we investigated whether acarbose was also effective in improving or preserving cognitive function in young and middle-aged wild-type (WT) mice and those harboring five familial Alzheimer's disease (AD) mutations on the UM-HET3 genetic background. Our previous data suggested that acarbose treatment improved learning and memory performance (as assayed by the Morris Water Maze) in both WT and AD mice compared to those maintained on control chow, at least at 9 months of age.
Our current work expands the scope of these previous studies in two important respects: 1. We extend our investigation to significantly older ages by testing whether acarbose treatment improves cognitive function in aged WT and AD UM-HET3 mice at ~24 months old; and 2. We examine the generalizability of the effectiveness of acarbose treatment by assaying cognitive function in 9 month-old WT and AD mice on a C57Bl/6 genetic background. Together, these new studies will further elucidate the potential of acarabose as a therapeutic intervention aimed at ameliorating cognitive decline in the aging population and in those affected by neurodegenerative disease.

For Neurogenomics & Cognitive Research, VU Univ., Amsterdam, Netherlands

Abstract: Detailed knowledge on the age-of-onset of behavioral abnormalities in mouse models of neurodegenerative diseases could facilitate our understanding of the early sequence of events

leading to neurodegeneration and may create a window of opportunity for preclinical testing of prophylactic treatments. Earlier studies by us and others showed that undisturbed behavior of individually housed mice in a home-cage environment equipped with a shelter is highly discriminative between mouse strains. To identify changes in home-cage behavior that are specific for different neurological symptoms in neurodegenerative disease models, we analyzed mouse models with pure motor function deficits and/or cognitive deficits, and compared their behavioral profiles with ageing C57BL/6J mice. For this systematic analysis AHCODA-DB was used, a data repository with web-based mining tools for the analysis of automated high-content mouse phenotypic data. Ageing C57BL/6J mice showed a profound decrease in general activity with increased age. In contrast, mouse models that developed strong motor function deficits by 20 weeks, including the SOD1*G93A mouse model of amyotrophic lateral sclerosis (ALS) and a model of Tau pathology, showed rather specific changes in activity parameters (e.g. maximum velocity) when compared to age-matched wild-type controls. Interestingly, SOD1*G93A mutant mice displayed alterations in sheltering behavior as early as 12 weeks of age, preceding pathology. Furthermore, whereas ageing C57BL/6J mice showed a strong deterioration of their circadian pattern with increasing age, this was not evident in mouse models of Alzheimer's disease at ages when pathology is present (6 months and older). Mouse models with cognitive function impairments, including two models of Abeta (Aβ) toxicity (APP/PS1 and 5xFAD) showed specific changes in the distribution of short visits to their shelter, already at ages when no pathology was present. In conclusion, different aspects of home-cage behavior are sensitive to different neurological conditions, and are clearly distinguishable from normal ageing. Most importantly, several changes were detected at early ages when classical pathology is not evident, suggesting that alterations in home-cage behavior reflect molecular or cellular changes that precede classical pathology.

Title: The early life immune stimulation induces a sex differences in long lasting modifications in cognitive behavior in middle aged rats

Authors: *I. BERKIKS[1], A. EL HESSNI, 14000[2], A. MESFIOUI[2]
[1]Ibn Tofail Univ., Kenitra, Morocco; [2]ibn tofail, kenitra, Morocco

Abstract: Background: Aging is one of many factors associated with an increased susceptibility to neurodegenerative disorders which can be related to early life inflammation. Early life immune stimulation, however, can be characterized by the increase in cytokines, oxidative stress as well as changing in microglia phenotypes from activated to priming during the age. Indeed the early neuroinflammation can profoundly affect brain function which can elicit behavioral impairments and cognitive deficits.
Objective: The aim of our study is to explore the sex differences and the possibilities to accelerate the cognitive decline associated with aging after a neonatal immune stimulation.
Methods: Male and females Wistar rats were treated on a postnatal day 14 with PBS or LPS, and then tested for learning & memory at 3 or 10 months of age, using novel object, Y-maze, and a spatial water maze task.
Results: Neonatally-infected rats exhibited memory impairments in the water maze, but only at 10 months. And no significant differences in novel object and Y-maze. Neonatally-infected rats also exhibited greater aging-induced increases in a number of microglia-activating in DG, CA1, and CA3, as well as an increase in Nitrite Oxide and lipid peroxidation but not TNFα within the hippocampus, but not in prefrontal cortex compared to controls.
Conclusion: Taken together, these data suggest that early-life infection leads to less successful cognitive aging, which may be linked to changes in microglial reactivity.

Title: Pupil-linked arousal adjusts the perceptual decision process to changing environments

Authors: *P. MURPHY, T. PFEFFER, K. TSETSOS, T. H. DONNER
Dept. of Neurophysiol. and Pathophysiology, Univ. Med. Ctr. Hamburg-Eppendorf, Hamburg, Germany

Abstract: Many decisions involve the temporal accumulation of evidence in favor of each available alternative. To make optimal choices in different environments, decision-makers must be able to flexibly adjust two components of this accumulation process: (i) the criterial level of

cumulative evidence required for decision commitment ('decision bound') and (ii) the timescale (or 'leakiness') of the accumulation. The mechanisms underlying either type of adjustment are not known. Here, we examined whether pupil-linked arousal, which regulates global brain state and modulates decision-related neural dynamics, helps adjust the decision bound or accumulation timescale to changing environmental statistics. Thirty human subjects monitored two patches of fluctuating luminance, one on each side of fixation, and were asked to report the location of near-threshold increments in mean luminance (the 'signal') embedded in longer streams of dynamic noise. We compared two conditions that differed in the distribution of signal durations: one with predominantly short (150 ms) and another with predominantly long (900 ms) signals. Simulations from an accumulator model showed that reward maximization on this task necessitates adjustments to both decision bound and accumulation timescale between conditions: when signals tend to be short, one should adopt a lower decision bound and shorter time constant. By contrast, analysis of observed behavior, psychophysical kernels and model parameter estimates indicated that while subjects strongly adjusted their decision bound, there was no adjustment of timescale in the expected direction. Pre-trial pupil diameter, a proxy for central arousal state, changed with environmental context and predicted behavioral adjustments. Pupil diameter was larger when signals were predominantly short (the context associated with lower decision bounds); and, this increase in pupil diameter predicted the context-related change in signal detection rate and response time in ways that support an association between pupil-linked arousal and decision bound adjustment. Trial-to-trial fluctuations in pre-trial pupil diameter also predicted the same behavioral metrics within each environmental context. Our results indicate that pupil-linked arousal helps adjust decision bounds. This adjustment might be implemented via global changes in synaptic gain, consistent with the neuromodulatory properties of pupil-linked arousal systems. The lack of timescale adjustment contrasts with recent results from a less demanding version of the same task (Ossmy et al, *Curr Biol*, 2013).

Title: Choices bias the accumulation of perceptual evidence in the next trial

Authors: *A. E. URAI[1,2], A. BRAUN[1], T. H. DONNER[1,2,3]
[1]Dept. of Neurophysiol. and Pathophysiology, Univ. Med. Ctr. Hamburg-Eppendorf, Hamburg, Germany; [2]Dept. of Psychology, [3]Amsterdam Brain and Cognition, Univ. of Amsterdam, Amsterdam, Netherlands

Abstract: Perceptual choices under uncertainty are biased by previous choices, a phenomenon referred to as serial choice bias. We aimed to uncover how this bias affects decision dynamics, as described by the accumulation of noisy sensory evidence towards opposing bounds for each choice option. We used the drift diffusion model (DDM) to disentangle two possible biasing mechanisms: an offset of the accumulation *starting point*, or a bias in the *drift* (accumulation rate) towards one of the choice bounds.
We fit a hierarchical DDM to four different data sets, all involving random dot motion discrimination tasks in humans (total: N = 201): (i) up vs. down (fixed motion coherence near psychophysical threshold) reaction time task; (ii) up vs. down (varying coherence levels) fixed duration task with different stimulus repetition probabilities (0.2, 0.5, 0.8, blocked by session); (iii) 2-interval forced choice coherence discrimination (varying coherence increments/decrements); (iv) as (iii), but fixed coherence increments/decrements near threshold. We estimated the following model parameters: non-decision time, starting point, boundary separation, mean drift rate, drift rate variability, and an additive drift bias. In different versions of the model, starting point, drift bias, or both were free to vary with previous choices and stimuli, and formal model comparison was used for model selection.
The DDM fit all data well, including those from fixed duration tasks. The estimated mean drift rate depended lawfully on evidence strength and correlated with perceptual sensitivity (d'). Across data sets, model fits improved by incorporating serial choice bias, where the predominant effect of previous choice was on drift bias. When stimuli predominantly alternated or repeated, the drift bias and (to a lesser extent) starting point tracked these biased serial statistics. When stimulus sequences were random (repetition probability of 0.5), drift bias (without starting point bias) was sufficient to account for serial choice patterns. In all data sets, the effect of previous choice on drift bias correlated with the model-free proportion of choice repetitions. For starting point, this correlation was weaker or absent. Reaction time, a measure of decision uncertainty (Urai et al. 2017), reduced the impact of choices on subsequent drift bias.
We conclude that the history of choices primarily biases evidence accumulation towards a particular choice option. This contrasts with biases induced by manipulations of stimulus frequency or payoff, which primarily shift the starting point of evidence integration. These insights put constraints on the neural basis of serial choice bias.

Title: GABAergic competition boosts the irrationality of human decision making

Authors: *K. TSETSOS, T. H. DONNER
Neurophysiol. & Pathophysiology, Univ. Med. Ctr. Hamburg, Hamburg, Germany

Abstract: Humans often violate the principles of rational choice theory. For instance, they may prefer *A* over *B*, *B* over *C* but *C* over *A*, disclosing thus inconsistent preferences. Such violations of decision rationality imply that the valuation of an alternative is *context-sensitive*, being influenced by the properties of other available alternatives. This context-sensitivity has been recently attributed to a *selective gating* mechanism: In choice tasks requiring the accumulation of temporally discrete psychophysical or numerical samples, momentarily less-valued samples are accumulated with a lower gain (Tsetsos et al., *PNAS*, 2012; 2016). We hypothesized that this gating is mediated by intra-cortical competition among incoming samples through GABAergic inhibition. We tested this hypothesis by combining placebo-controlled pharmacological manipulation of $GABA_A$ receptors (boosting intra-cortical inhibition) with computational modelling of choice behaviour in a numerical integration task.
Human participants (*N*=32) performed 3 sessions, the first one without pharmacological manipulation, followed by two sessions after intake of lorazepam (1 mg) or placebo (order counterbalanced). On each trial, participants observed pairs of numerical values presented rapidly (1.25 HZ) and sequentially, to the left and right of a central fixation point. The sequence stopped after a fixed number of pairs (5-8), and participants had to judge which side had the higher average. In a subset of trials, we controlled the temporal distribution of values to quantify context-sensitivity. Choice behavior was modeled using a sequential sampling model, in which the incoming values are dynamically transformed (by inhibiting each other) and continuously fed forward (“in cascade”) into choice accumulators.
Choice accuracy did not differ between drug and placebo sessions. However, diagnostic

behavioral signatures of context-sensitivity increased under lorazepam. Fitting the model explained the $GABA_A$-induced elevated context-sensitivity as a consequence of increased mutual inhibition at the level of input representation. By contrast, other decision-relevant model parameters, specifically internal noise or the time constant of value accumulation, were not affected by the pharmacological intervention.
Our results illuminate the neural basis of context-sensitive valuation phenomena (and by extension decision irrationality), linking these behavioral phenomena to competitive dynamics that have been observed in other domains of cortical computation, such as multi-stable perception (van Loon et al, *Curr Biol*, 2013).

Title: Dissociated catecholaminergic and cholinergic shaping of large-scale cortical correlations

Authors: *T. PFEFFER[1], A. PONCE-ALVAREZ[2], G. NOLTE[1], R. L. VAN DEN BRINK[3], S. NIEUWENHUIS[3], A. K. ENGEL[1], G. DECO[2], T. H. DONNER[1]

Abstract: The catecholaminergic (noradrenergic and dopaminergic) and cholinergic systems have long been implicated in the regulation of brain states and behavior. The brainstem centers of these systems have widespread projections to most parts of the cortex. Influential theories

postulate that these neuromodulatory systems play important, and distinct, computational roles in learning, inference, and decision-making. Yet, it remains unknown how these systems shape the large-scale cortical dynamics underlying cognition and behavior. Here, we unravelled and compared the effects of catecholamines and acetylcholine on the large-scale correlations of intrinsic neural dynamics in the human brain.
We boosted catecholamine (using atomoxetine) or acetylcholine (using donepezil) levels through selective pharmacological interventions (randomized, placebo-controlled, cross-over design) in 28 healthy human subjects. We measured the effects on intrinsic cortical dynamics with magnetoencephalography (MEG), during two steady-state conditions: blank fixation ('rest') and covert counting of bistable perceptual alternations under continuous visual drive, in the absence of motor movement ('task'). Subjects were administered placebo, atomoxetine, or donepezil before MEG in separate sessions. MEG was recorded during two rest and two task blocks (a 10 min), in counterbalanced order. MEG sensor level signals were projected onto 90 regions of the AAL (Automated Anatomical Labelling) atlas using adaptive linear spatial filtering ('beamforming'). We correlated the amplitude envelopes of neural signals in several frequency bands between all 90 regions, controlling for volume conduction by orthogonalization of the underlying carrier signals.
We find that catecholamines *increased* cortex-wide amplitude envelope correlations in the alpha-band (~11 Hz), but only during constant visual drive (task) and not during blank fixation (rest). By contrast, acetylcholine *decreased* cortex-wide amplitude envelope correlations, but only during blank fixation and not during visual drive. Our results reveal a context-dependent dissociation between the large-scale effects of key neuromodulators on human cortical dynamics. We next plan to uncover the biophysical mechanisms explaining this dissociation through large-scale computational modeling.

Title: Computational and neuromodulatory correlates of pupil dilation during perceptual choice

Authors: *O. COLIZOLI[1,2], J. W. DE GEE[1,2], T. H. DONNER[1,2,3]
[1]Dept. of Neurophysiol. and Pathophysiology, Univ. Med. Ctr. Hamburg-Eppendorf, Hamburg, Germany; [2]Dept. of Psychology, [3]Amsterdam Brain and Cognition, Univ. of Amsterdam, Amsterdam, Netherlands

Abstract: Brainstem neuromodulatory systems respond phasically during decisions (Aston-Jones & Cohen, *Annu Rev Neurosci*, 2005). At different times during a decision, these responses signal two computational variables that are key for decision-making: (i) decision uncertainty before feedback and (ii) prediction errors (i.e., deviations from expected outcomes) after feedback (Lak et al., *Curr Biol*, 2017). Responses in several brainstem systems correlate with pupil dilation (de Gee et al., *eLife*, 2017). Here, we aimed to pinpoint the computational variables and neuromodulatory brainstem systems driving pupil responses during decision formation and after feedback about decision outcome.
Fifteen human subjects performed an up vs. down motion discrimination task, with two difficulty levels and feedback, during functional magnetic resonance imaging (fMRI) and eye tracking. After a variable delay (4-12 s) following choice, we presented visual feedback that was coupled to a monetary reward. Motion coherence varied from trial to trial, so that observers performed at 70% correct in 2/3 of trials ('hard') and at 85% correct in 1/3 of trials ('easy'). Physiological noise was removed from the fMRI data using a previously established protocol (de Gee et al., 2017).
Pupil dilation before and after feedback was modulated by decision difficulty (hard vs. easy) and accuracy (correct vs. error), exhibiting significant interactions between both factors. In line with previous findings (Urai et al., *Nature Comm*, 2017), this interaction reflected the level of decision uncertainty prior to feedback. After feedback, the interaction reflected (the inverse of) a prediction error signal. Pupil dilation before and after feedback was qualitatively in line with a partially observable Markov decision process (Lak et al., 2017). Further, both components of the pupil response were coupled to fMRI responses in several modulatory brainstem centers: the noradrenergic locus coeruleus, dopaminergic midbrain nuclei, cholinergic basal nucleus, and serotonergic raphe nuclei (even after accounting for their co-correlations). The locus coeruleus was only coupled to pupil dilations before (not after) feedback. During both intervals, we also found robust pupil-linked fMRI responses in the striatum, which receives strong dopaminergic but no (or only sparse) noradrenergic input.
Our results shed new light on the computational processes and neuromodulatory centers driving evoked pupil-linked arousal boosts during decision-making under uncertainty. They also point to a significant non-noradrenergic (specifically: dopaminergic) component of pupil dilation.

Title: Cortical dynamics reflecting Bayesian uncertainty and surprise about the timing of perceptual events

Authors: *T. MEINDERTSMA[1,2,3], N. A. KLOOSTERMAN[1,2,4], A. K. ENGEL[3], E.-J. WAGENMAKERS[1], T. H. DONNER[1,2,3]
[1]Dept. of Psychology, [2]Amsterdam Brain and Cognition, Univ. of Amsterdam, Amsterdam, Netherlands; [3]Dept. of Neurophysiol. and Pathophysiology, Unversity Med. Ctr. Hamburg-Eppendorf, Hamburg, Germany; [4]Max Planck UCL Ctr. for Computat. Psychiatry and Ageing Res., Max Planck Inst. for Human Develop., Berlin, Germany

Abstract: Knowledge about the timing of relevant events in the sensory environment can benefit decision-making. Several subcortical brain regions seem to be driven by uncertainty about event timing, as well as violations of timing expectations (‘surprise’). Less is known about how the temporal statistics of the environment affect the dynamics of cortical networks that mediate sensory-motor decisions. Here, we used magnetoencephalography (MEG) to exhaustively map the trial-to-trial correlation between variations in uncertainty or surprise about event timing and cortical dynamics in a simple visual decision task.
28 human subjects judged (by button press or after silently counting) the on- and offsets of a salient visual target (full contrast Gabor) surrounded by a moving distractor. The intervals between the perceptual events varied randomly from trial to trial (hazard rates following either Gaussian or uniform distribution, on different blocks). We used a Bayesian learning model to update internal beliefs about event timings, based on the previously encountered intervals between events. From the resulting posterior distribution over intervals, we extracted two information-theoretic variables that varied from event to event: (i) entropy, a measure of uncertainty about the occurrence of the upcoming event; (ii) Shannon information, a measure of

surprise elicited by the occurrence of the event. We correlated both variables with MEG activity, across the cortical power spectrum and MEG sensors, but either before (for uncertainty) or after the event (for surprise), using cluster-based permutation statistics in space, time and frequency. Uncertainty and surprise correlated positively with trial-to-trial variations in reaction time in the button-press condition, for both target on- and offsets. Thus, both variables affected behavior. Uncertainty correlated negatively to medial centroparietal MEG power in the 8-15 Hz frequency range before target offsets. Surprise correlated negatively to power modulations after perceptual events, with peaks at around 5 Hz and 20 Hz. The distributions of these correlations were widespread and different between target on- and offsets. This correlation with surprise was not due to the duration of the preceding interval only.
We conclude that uncertainty and surprise about the timing of behaviorally relevant perceptual events shapes cortical population dynamics across widespread brain regions and frequency bands.

Title: Phasic pupil-linked arousal reduces decision biases in mice and men

Authors: *J. W. DE GEE[1,2], K. TSETSOS[1], D. A. MCCORMICK[4], M. J. MCGINLEY[5], T. H. DONNER[1,2,3]
[1]Neurophysiol. und Pathophysiology, Univ. Med. Ctr. Hamburg-Eppendorf, Hamburg, Germany; [2]Dept. of Psychology, [3]Amsterdam Brain & Cognition, Univ. of Amsterdam, Amsterdam, Netherlands; [4]Kavli Inst. for Neurosci., Yale Univ. Sch. of Med., New Haven, CT; [5]Neurosci., Baylor Col. of Med., Houston, TX

Abstract: The state of the brain changes constantly, with profound consequences for cortical computation and behavior. We have recently shown that (i) pupil diameter in mice closely tracks variations in cortical state (McGinley et al, *Neuron*, 2015); and (ii) evoked pupil dilations in humans predict a reduction in perceptual choice biases (de Gee et al, *eLife*, 2017). Here, we

performed a direct comparison of the behavioral correlates of evoked pupil responses in humans and mice performing the same auditory decision task. We built on observations in both species, that rapid pupil dilations are associated with phasic responses of the noradrenergic system (Reimer et al, *Nature Comm*, 2016; de Gee et al, *eLife*, 2017).
We tracked the pupil diameter of 20 humans and 5 mice during a challenging auditory go/no-go detection task. Each trial consisted of 2-7 noise tokens (1 s duration each), with a weak signal tone (pure sine wave) superimposed onto the last noise token. Subjects had to respond to the signal, and withhold a response for pure noise sounds. Humans responded with a button press, mice by licking for sugar water reward. Errors (false alarms and misses) were followed by timeouts (8-s). We quantified the evoked pupil response for each sound in terms of the change in pupil diameter from sound onset to median reaction time. Humans also performed a yes-no (forced choice) version of the task, which entailed a single tone and a button press (for 'yes' or 'no') on each trial. We used these data to validate and compare several measures of the evoked pupil response.
Both species exhibited robust evoked pupil responses on all trial types, including misses and correct rejects (i.e., without motor response). Also in both species, task-evoked responses predicted a reduction in conservative bias (i.e., an increased tendency to respond 'yes') but no change in sensitivity. Critically, the same effect was present in the yes-no task in humans, in which motor responses were balanced across 'yes' and 'no'-choices. The bias reduction could neither be explained by pre-trial 'baseline' pupil diameter levels, nor by non-linearity of the pupil response (e.g., floor or ceiling effects).
In sum, pupil-linked, phasic arousal suppresses decision bias in humans and mice. This trial-to-trial variation of decision bias accounts for a large part of the behavioral variability, which would appear as random 'noise' without tracking arousal. We propose that pupil dilation can be used as a common reference signal that cuts across species and levels of analysis, from single neurons to complex behaviors.

Title: The role of saccades and visual information quantity on spatiotemporal patterns of parietofrontal ERPs underlying the perception of complex tool-use affordances

Authors: *N. NATRAJ[1,2], S. BASUNIA[2], B. ALTERMAN[2], L. A. WHEATON[2]
[1]Univ. of California, San Francisco, San Francisco, CA; [2]Sch. of Biol. Sci., Georgia Inst. of Technol., Atlanta, GA

Abstract: Understanding the affordances of tools (i.e. how they are grasped and used) is vital for daily life. Prior research has identified the importance of parietal and frontal regions in recognizing the affordances of tools. However, parietofrontal regions are multifaceted and in particular, they underlie the control of eye movements and visuospatial attention. It is plausible that parietofrontal activity in response to viewing tools could be coupled with activity underlying attention and gaze control. Yet it is unclear how parietofrontal processing of affordances are influenced by attention and eye movements. To this end, we sought to evaluate the relationship between the two aforementioned processes via EEG and eye tracking as participants evaluated contextual and grasp-specific, static tool-use scenes in two distinct experiments. The first experiment was a flash experiment where stimuli durations were 100ms, automatically negating saccades and forcing participants to rely on extrafoveal information. In the second experiment, stimuli durations were increased to 500ms, allowing for the reemergence of saccades and foveal attention. Participants were instructed to judge whether the tool-object relationship was correct or incorrect. Response accuracies and latencies were similar in both experiments. The key result showed that the polarity, spatiotemporal patterns of parietofrontal activity and cortical source activations when evaluating the type of tool-grasp were sensitive to visual information quantity and the observer's ability to foveally parse the scene. Distinctively, parietofrontal activity when evaluating tool-use contexts were largely unaffected by gaze behavior/visual information quantity and was similar in both experiments. Results here shed new light on how eye movements and visual information specifically modulate grasp-specific parietofrontal circuits.

Title: Changes to post-sensory processing predict performance enhancements in human multisensory decision making

Authors: *G. M. DE SOUSA[1], L. FRANZEN[1], C. KAYSER[2], M. G. PHILIASTIDES[2]
[1]Sch. of Psychology, [2]Inst. of Neurosci. and Psychology, Univ. of Glasgow, Glasgow, United Kingdom

Abstract: Real-world decisions often require the integration of congruent information across sensory modalities. Multisensory integration in perceptual decision making can improve decision accuracy compared to using unisensory information alone, however it is unclear whether behavioural improvements result from changes to early sensory or post-sensory processing. Our previous human EEG studies have identified temporally distinct components encoding early sensory evidence ('Early' component) and later decision-related evidence ('Late' component). Here we exploit these neural representations to test whether multisensory enhancements are due to early-sensory or post-sensory processing. We initially trained 31 participants on separate speeded image (face/car) and sound (speech/car) categorisation tasks. Behavioural and EEG data was then collected using visual (unisensory) and audio-visual (multisensory) interleaved trials. We used four levels of visual noise and one - subject-specific - auditory difficulty level, obtained at peri-threshold performance during training. We found increased decision accuracy but reduced reaction times during multisensory trials. As expected participant accuracy increased and reaction times decreased as visual noise in the stimuli increased. We ran a linear multivariate discriminant analysis of stimulus-locked EEG data to classify between face-vs-car trials (collapsing across trial modality). This produced a measurement of the single-trial discriminating component amplitudes of the Early and Late components we reported in earlier work, indexing sensory and decision evidence respectively. After identifying subject-specific Early and Late components (based on timing, topography and discriminator performance), we subdivided trials by modality. We found that discriminator amplitudes of our Late, but not the Early, component were significantly higher for multisensory compared to unisensory trials. Crucially, the Late component amplitude difference between unisensory and multisensory trials predicted behavioural improvements across participants. Our results suggest that the inclusion of auditory evidence provides more information leading to improved decision accuracy, and that this additional information increases the processing time but also the quality of post-sensory decision-related visual evidence. The absence of any multisensory effects during early sensory encoding in our task suggests that a near simultaneous unimodal processing of sensory evidence precedes a later post-sensory processing of multimodal evidence for combining congruent sensory information to form a decision.

Title: Temporal characterization of the neural correlates of multisensory perceptual decision making in adult dyslexia

Authors: *L. FRANZEN, G. M. DE SOUSA, C. KAYSER, M. G. PHILIASTIDES
Univ. of Glasgow, Glasgow, United Kingdom

Abstract: Recent evidence has shown that adults with dyslexia exhibit obvious fundamental deficits spanning multiple sensory systems when performing simple integration tasks. These studies suggest that deficits start as early as the initial perceptual encoding of the evidence. Particularly, dyslexics are believed to exhibit reading impairments since this process requires the integration of congruent multisensory information across audiovisual modalities. As a consequence, these impairments can lead to hampered development of linguistic proficiency. However, it remains unclear whether dyslexic adults exhibit similar impairments when integrating audiovisual multisensory evidence in a perceptual decisions task.
Here we trained 28 dyslexics and 22 age matched controls on separate speeded image (face/car) and sound (speech/car) categorisation tasks. Behavioural and EEG data was then collected using visual (unisensory) and audiovisual (multisensory) trials. We used four levels of visual noise and one – subject-specific – auditory difficulty level, obtained at perithreshold performance during training. We found increased decision accuracy but reduced reaction times during multisensory trials for both groups, however, overall dyslexics benefited less than controls. As expected participant accuracy increased and reaction times decreased as visual noise in the stimuli decreased for both groups. Overall, dyslexics were slower than controls.
Our previous EEG work in non-dyslexics revealed temporally distinct components encoding early sensory evidence (‘Early’) and later decision-related evidence (‘Late’). Here, we exploited these components to investigate the extent to which multisensory integration affects early or later processing stages in the two groups. Specifically, we ran a linear multivariate discriminant analysis of stimulus-locked EEG data to classify between face-vs-car trials (collapsing across trial modality). This produced a measurement of the single-trial discriminating component amplitudes of the Early and Late components we reported in earlier work.
We found that while controls exhibited increased component amplitudes for the Late, but not the Early, component for multisensory compared to unisensory trials – consistent with a post-sensory influence of multisensory integration – this effect was less pronounced for dyslexics. Our neural results suggest that adult dyslexics can benefit from audiovisual integration of complex perceptual stimuli but to a lesser extend and with increased deliberation times compared to controls.

Title: Concurrent increases in spatial stability and temporal neural dynamics during perceptual decision making

Authors: *N. A. KLOOSTERMAN[1], J. J. FAHRENFORT[2], D. D. GARRETT[1]
[1]Max Planck Inst. for Human Develop., Max Planck UCL Ctr. for Computat. Psychiatry, Berlin, Germany; [2]VU Univ., Amsterdam, Netherlands

Abstract: Recent work has shown that upon conscious perception, the stability of neural activity increases across cortical sites (Schurger et al., *PNAS*, 2015). Such spatial stabilization could reflect attractor dynamics that draw network activity toward a low-energy decision state. Another line of research, however, links increased moment-to-moment neural *variability* to improved cognitive processing (Garrett et al., *Neurosci Biobehav Rev*, 2013). Here, we aimed to test the intriguing possibility that brain activity can stabilize spatially around a perceptual decision, while simultaneously becoming more temporally dynamic. Specifically, we asked whether spatial neural stabilization (i) occurs either during or after a perceptual decision; (ii) whether it can be modulated by level of decision certainty, and; (iii) how the underlying temporal neural dynamics behave during spatial stabilization.
We addressed these questions by quantifying the spatial and temporal variability of the EEG of 16 human subjects reporting faint target stimuli within a stream of non-targets. Subjects completed three one-hour sessions separated by days. In different conditions, we encouraged subjects to require either low or high certainty for reporting targets by penalizing either misses or false alarms, respectively. We quantified spatial EEG variability by computing directional variance (dva), which treats each sample across electrodes as a multi-dimensional vector, and measures the directional dispersion of these vectors. We computed dva within trials using a sliding window of 100 ms. We quantified concomitant changes in temporal EEG variability using multi-scale entropy (mse) for time scales 1 (256 Hz) until 42 (time series coarse grained to ~6 Hz) (Grandy et al., *Sci Rep*, 2016). For both dva and mse, we subtracted variability in pre- from post-target stimulus intervals, focusing on transient changes in neural dynamics.
We found that spatial stability increased in high vs. low certainty conditions. In line with an intra-decisional role, this increase occurred ~0.5 s before report, but not after. Critically,

heightened spatial stabilization predicted individual differences in high versus low certainty increase (in behavior), suggesting that such stabilization reflects the level of certainty when reporting a target. Strikingly, during spatial stabilization, within-electrode temporal entropy also increased across most time scales. We conclude that the human brain appears to invoke a spatially similar, yet temporally dynamic regime during effective perceptual decision making.

Title: The impact of sustained and dynamic uncertainty on simultaneous perceptual- and reward-based decision making

Authors: *M. GHANE[1,2], S. JAPEE[3], J. A. RICHEY[1], L. G. UNGERLEIDER[4]
[1]Virginia Tech., Blacksburg, VA; [2]Natl. Inst. of Mental Hlth., Bethesda, MD; [3]NIH, Bethesda, MD; [4]Natl. Inst. of Mental Hlth., Bethesda, MD

Abstract: In complex environments, individuals must determine simultaneously what objects are and what they are worth. There is growing evidence that choices are driven by optimal integration of perceptual and reward information. However, the degree to which the underlying mechanisms of decision making are domain-specific or domain-general, is not clearly understood. Differing theoretical frameworks and task designs within perceptual and reward domains make it difficult to comparably study their distinct and overlapping neural substrates. The current study aimed to test how sustained and dynamic manipulations of perceptual uncertainty (PU) and reward uncertainty (RU) impact decision making.
Participants completed two versions of a combined probabilistic reward and perceptual choice task. On each trial, participants viewed a face and a house (target stimuli) and two car images (distractor stimuli), presented in four locations around a central fixation. To manipulate PU we varied the relative phase coherence of the face and house target images (5 levels). RU was manipulated by changing the probability of receiving 8 and 2 cents for selecting either target (5 levels). Distractor images were always of low coherence and were associated with no reward. Participants were instructed to make choices that maximized reward. To test the impact of domain-specific task manipulations, in one version of the task RU was fixed within each run (varied across runs), while PU was manipulated across trials. In the second version, PU was fixed within run (varied across runs), and RU was manipulated across trials.

Average choice percentages for each stimulus type in each task revealed that individuals were less likely to select a stimulus if it was associated with high perceptual or reward uncertainty. This is consistent with evidence that perceptual and reward information is integrated to drive complex choice. Additionally, choice was not impacted by task type, suggesting that domain-specific sources of uncertainty did not uniquely contribute to behavioral effects. Instead, behavior appears to be driven by a domain-general system that reflects the overall degree of environmental uncertainty through an optimal combination of perceptual and reward information. To further test this hypothesis, we plan to collect fMRI data while subjects complete each task. We aim to use a predictive coding model to computationally define behavior and underlying neural activity. Results from these experiments will shed light on the degree of domain specificity in decision making and provide further insight into the neural mechanisms that drive complex choice behavior under varying sources of uncertainty.

Title: Variability in psychopathology is linked to confidence but not performance in perceptual decision-making

Authors: *T. SEOW[1], M. ROUAULT[2], C. M. GILLAN[1], S. M. FLEMING[2]
[1]Sch. of Psychology, Trinity Col. Dublin, Dublin, Ireland; [2]Univ. Col. London, London, United Kingdom

Abstract: Distortions in the ability to evaluate one's own behavior are associated with poor mental health. However, it remains unknown whether such shifts in self-evaluation are due to alterations in metacognition, or a downstream consequence of changes in sensory and decision processes. Using perceptual decision-making as a model system, we related parameters governing both decision formation and confidence to self-reported trans-diagnostic symptom dimensions in a large general population sample (N~1000). Variation in psychopathology was unrelated to either speed or accuracy of decision formation. In contrast, we reveal a bidirectional link between psychopathology and confidence: a symptom dimension related to anxiety and depression was associated with lower confidence, whereas a dimension characterizing intrusive thoughts was associated with higher confidence and disrupted metacognition. Our results indicate that shifts in metacognitive evaluation may represent a pervasive computational

correlate of psychiatric symptoms, creating a bridge between impaired decision-making and the emergence of common expressions of psychopathology.

Title: Neural mediators of changes of mind about perceptual decisions

Authors: *S. M. FLEMING[1], E. J. VAN DER PUTTEN[2], N. D. DAW[3]
[1]Univ. Col. London, London, United Kingdom; [2]Amsterdam Brain and Cognition Ctr., Univ. of Amsterdam, Amsterdam, Netherlands; [3]Princeton Neurosci. Inst., Princeton Univ., New York, NY

Abstract: Changing one's mind on the basis of new evidence is a hallmark of cognitive flexibility. To update one's confidence in a previous decision, additional evidence must be represented in a coordinate frame that tracks the accuracy, rather than the identity, of a previous choice, but how this process unfolds in the human brain remains unknown. To address this question we manipulated whether additional sensory evidence supports or negates a previous motion direction discrimination judgment while recording markers of neural activity in the human brain using fMRI. After an erroneous decision, stronger post-decision evidence led to progressively lower confidence ($P < 0.001$ for both behavioural and fMRI sessions) whereas after a correct decision, confidence was increased due to the confirmatory influence of new evidence ($P < 0.001$ for both behavioural and fMRI sessions). We used an incentive scheme in which people were paid both for being highly confident and right, and unconfident and wrong, allowing the dissociation of accuracy updates (change in P(correct|new evidence)) from changes in both evidence strength and decision value. A computational signature of accuracy update was observed in the activity of posterior medial frontal cortex (pMFC). In contrast, distinct activity profiles in lateral prefrontal cortex mediated changes in subjective confidence independently of changes in decision value. Together our findings reveal neural mediators of post-decisional changes of mind in the human brain, and indicate possible targets for ameliorating deficits in cognitive flexibility.

Title: Human ventromedial prefrontal cortex encodes early signatures of confidence in perceptual decisions

Authors: *S. GHERMAN, M. G. PHILIASTIDES
Univ. of Glasgow, Glasgow, United Kingdom

Abstract: The ability to estimate the accuracy of our judgments by means of confidence is a fundamental aspect of the decision making process, and crucial to adaptive behaviour. Although recent years have seen significant advances in characterising the neural basis of confidence, its spatiotemporal dynamics during perceptual decision making remain unclear. In our previous work, using time-resolved EEG measurements, we identified early confidence-related neural signals emerging during the perceptual decision itself. Here, we aimed to extend these findings and provide a more complete spatiotemporal account of confidence, using a simultaneous EEG/fMRI approach. Specifically, we hypothesised that using the trial-to-trial variability of electrophysiologically-derived (i.e., endogenous) measures of confidence to detect associated fMRI responses would provide a more accurate and temporally precise spatial representation of the confidence signals around the time of decision, than would be possible by relying on behavioural confidence ratings and fMRI measurements alone.
To this end, we collected simultaneous EEG/fMRI data from 64 scalp electrodes inside a 3T MRI scanner while participants (N=24) performed a random-dot direction discrimination task and gave confidence ratings on each trial. Motion coherence was held constant across trials to control for confounding effects of task difficulty. Using a multivariate single-trial classifier to discriminate between High vs. Low confidence trials in the EEG data, we extracted an early, stimulus- and accuracy-independent discriminant component appearing prior to participants' behavioural response. By regressing the resultant single-trial component amplitudes against the fMRI response, we identified a positive correlation with this early confidence signal in a region of the ventromedial prefrontal cortex (vmPFC), which has previously been linked mainly with value-based decisions. Importantly, this activation was additional to what could be explained by subjects' confidence ratings, as well as other potential confounds (task performance, response time, attention) included in the same model as regressors of no interest. Furthermore, a functional connectivity analysis revealed a confidence-modulated link between the activation in

the vmPFC and the right rostrolateral prefrontal cortex, a region known to be implicated in metacognitive evaluation. Our results suggest that the vmPFC may support an early confidence signal which precedes and potentially informs metacognitive evaluation, and are in line with recent work proposing a domain-general role for this region in encoding confidence.

Title: Neurocognitive processing in breast cancer patients: Harmful effects of messages perceived as a threat

Authors: *A. N. SOKOLOV[1], M. A. PAVLOVA[3], S. Y. BRUCKER[1], D. WALLWIENER[2], E. SIMOES[1]
[1]Dept. of Women's Health, Women's Hlth. Res. Inst., [2]Dept. of Women's Hlth., Eberhard Karls Univ. Hosp. Tübingen, Tuebingen, Germany; [3]Biomed. Magnetic Resonance, Univ. of Tübingen Med. Sch., Tübingen, Germany

Abstract: Breast cancer is the most common type of cancer among women. In gynecologic oncology, much negative health-related information is communicated to patients. When diagnosed with breast cancer, women are faced a lot of threatening information that may substantially hinder their cognitive abilities and decision making (e.g., during informed consent) and, eventually, result in gender-specific (and often suboptimal) coping with the disease. Previous work demonstrated gender specific influence of information delivery: Negative gender-related messages such as “men are usually better than women on a task” drastically reduce performance on a visual cognition task (without any initial gender gap documented), with a much stronger effect in women (e.g., Pavlova et al., 2014). This reduction is even greater in breast cancer patients. There are also indications on the gender-related effects of negative messages on brain activation in healthy participants. In this ongoing project, we intend to clarify whether in breast cancer patients, gender-related negative messages affect brain activation during performance of demanding cognitive tasks. Should the hypothesis hold true, this would suggest that negative information can block coping-related brain processes. We examined performance on a visual cognition task in two groups of mastocarcinoma patients (age, 40 - 55 years; with/without negative messages such as above) and two control groups of matched healthy women. With negative messages, patients scored lower than controls, and lower than patients

without negative messages, indicating effects of both disease and message. Remarkably, the lowest scores occurred in patients with negative messages. Future research will uncover brain mechanisms of these effects in breast cancer patients. The outcome shows for the first time the impact of disease and information on visual social cognition, presumably blocking visual cognitive processing. This helps to clarify the neurocognitive effects of information delivery in gynecologic oncology and oncology at large.

Title: Differences of n170 amplitudes in emotion information processing among individuals with alexithymia

Authors: *D. A. BANUELOS, K. GARCIA, K. JOHNS, S.-M. KANG
California State Univ. Northridge, Northridge, CA

Abstract: Few studies have explored how individuals with alexithymia process emotional information using Event-Related Potential (ERP). Pollatos and Gramann's study (2011) demonstrated that individuals with high degrees of alexithymia (HDA) show an early processing deficit compared to individuals with low degrees of alexithymia (LDA) by focusing on P100 and P300 peaks. However, their study did not explore differences in the amplitude of N170. Literature has shown that N170 marks the point in processing when a visual stimulus is consciously interpreted as a face and its occurrence depends on our past experience of what is a 'face' (Rossion 2014). The main purpose of the current study was to further explore differences in N170 amplitudes between individuals with HDA and LDA, when they process facial expressions.
From a pool of 1576 college students, 26 were selected based upon their score on the Toronto Alexithymia Scale (Bagby et al., 1994). Of the 26 selected, data from 14 participants (7 high and 7 low) was usable. In an individual session, a total of 11 electrodes were manually placed on a participant's head (PZ, CZ, and FZ) and face using the 10-20 international system. Each participant was asked to identify six facial expressions (angry, disgusted, fearful, happy, sad, and surprised) presented on a computer screen. A total of 42 faces taken from the NimStim Face Stimulus Set (Tottenham et al., 2002) were used in either a whole face or half face condition. In

the half face condition, either the top or bottom half of the face was randomly removed.
The results of the current study revealed that the mean amplitudes of N170 between high and low alexithymia conditions were marginally different from each other, F (1,12) = 3.74, p = .077. The average N170 amplitude of the LDA group (M = -4.48, SE = .84) was higher than that of the HDA group (M = -2.18, SE = .84). More importantly, however, there was the significant 3-way interaction effect of face (whole vs. half) x condition (HDA vs. LDA) x locations (PZ, CZ, and FZ), F (2, 24) = 13.25, p = .000. The individuals with HDA tended to use less cognitive effort to configure emotion expressions on the whole faces, whereas they put more effort for the half faces. In contrast, the individuals with LDA seemed to put similar levels of effort for both the whole and half faces. However, the highest N170 amplitude appeared on the different sites depending on the face conditions - the CZ site for the whole faces and the PZ site for the half faces, respectively. The significance and implications of the current findings were discussed.

Title: Evoked potentials of social comparisons in people with social anxiety/depression

Authors: *V. PAZ, E. NICOLAISEN-SOBESKY, G. FERNANDEZ-THEODULOZ, S. GARAT, O. NIEVAS, A. PÉREZ, D. KESSEL, Á. CABANA, V. B. GRADIN
Psychology Dept., Univ. De La República Uruguay, Montevideo, Uruguay

Abstract: Social anxiety and depression are disabling disorders that significantly impact on the interpersonal functioning of individuals. Despite the importance of social difficulties in these disorders, little is known about the neural substrates underlying such difficulties.
In an ongoing study we are measuring *event related potentials* (ERPs) in unmedicated socially anxious and/or depressed participants (n=28) and matched healthy controls (n=23). During the study, participants view their own and a co-player´s gain and loss outcomes based on their performance in a time estimation task. There are four types of outcomes: participant correct/co-player incorrect, participant incorrect/co-player correct, both correct and both incorrect.
Results showed that socially anxious/depressed participants reported significantly more anger, sadness, nervousness, guilt, shame and disappointment and less happiness in response to the task

than controls. Socially anxious/depressed participants also reported more shame for all the outcomes except "both correct", more disappointment for the outcome participant incorrect/co-player correct, more shame and nervousness about discussing the outcomes with their co-player, and having the perception that they played worse, compared with controls.
ERPs results showed an effect of outcome with negative outcomes (in which at least one player had a negative outcome) eliciting a enhanced Medial Frontal Negativity (MFN) peaking around 220-320 ms at fronto-central electrodes compared with the "both correct" outcome. There was no significant effect of group or a group*outcome interaction.
Results indicate an accentuated negative emotional response in socially anxious/depressed individuals to social comparison situations. The ERPs results are in agreement with previous studies reporting that the MFN is modulated by losses vs. gains monetary rewards and positive vs. negative social outcomes. Our results indicate that the MFN, a component that has been related to the motivational/affective impact of outcomes, is modulated by social comparison outcomes. The lack of significance of the group or the group*outcome interaction effects regarding ERP results may be due to sample limitations as recruitment is still ongoing. Once completed, this study may contribute to understand how socially anxious/depressed people process social comparisons.

Title: Reduced modulation of the language-related network during perception of acoustically degraded speech in autism spectrum disorder

Authors: *R.-I. HASHIMOTO[1,2], T. ITAHASHI[2], M. NAKAMURA[2], H. OHTA[2], C. KANAI[2], N. KATO[2]
[1]Tokyo Metropolitan Univ., Tokyo, Japan; [2]Med. Investigation of Developmental Disabilities Res., Showa Univ., Tokyo, Japan

Abstract: Individuals with autism spectrum disorder (ASD) are known to be often highly sensitive to acoustic disturbances for perception of speech sounds, which makes speech communication in everyday life difficult. However, neural mechanisms underlying such speech

perception difficulty have not been clarified in the ASD brain. Past neuroimaging studies for neurotypical individuals have shown that speech perception under acoustically degraded conditions involves the speech motor cortex, which may reflect top-down control processes on activity in speech perception areas. Therefore, it is possible that speech perception difficulty in ASD may stem from reduced load-dependent changes in functional connectivity (FC) between speech motor and perception areas.
In order to test this hypothesis, we designed a speech perception task, which consisted of three conditions that were different either in levels of acoustic degradation or speech intelligibility as follows: (1) clear speech (CS), (2) 8-channel vocoded speech (VCS), and (3) 8-channel vocoded speech with spectral rotation (VSR). 21 adult males with high-functioning ASD and 24 matched typically-developed (TD) males participated in this study. MRI signals were recorded using a 3T Siemens MRI scanner (TR = 2.5 sec, 40 axial slices, spatial resolution = 3.3 x 3.3 x 4 mm, 250 volumes). We used SPM 8 for data preprocessing and statistics. Analysis of FC was performed by generalized psychophysiological interaction (gPPI) analysis. Effects of acoustic degradation were estimated for both brain activation and FC by a contrast of [VCS vs. (CS + VSR)].
First, the acoustic degradation effect on activation was compared between ASD and TD. The contrast revealed multiple significant clusters of activation in regions related to attention and speech motor control, including bilateral anterior cingulate cortex, insular cortex, inferior frontal cortex, and premotor cortex. Second, the gPPI analysis seeding the left dorsal premotor cortex showed that the acoustic degradation effect on FC was significantly reduced in the left temporo-parietal junction. Simple regression analysis using the scores of autism quotient (AQ) revealed that reduced FC was significantly associated with the severities of autistic trait among individuals with ASD. These observations support the hypothesis that FC between speech motor and perception areas is less modulated depending on levels of acoustic degradation in the ASD brain.

Title: Late positive event-related potentials in electroencephalography can distinguish acquaintances from strangers when both groups recognize faces

Authors: *S. LEE, J.-H. KANG, I. OAKLEY, S.-P. KIM
Ulsan Natl. Inst. of Sci. and Technol., Ulsan, Korea, Republic of

Abstract: Recognition of a familiar face can be important for not only basic cognitive neuroscience but also advanced personal authentication schemes. When a person looks at faces, social and emotional aspects as well as appearance are processed in the brain, which can induce different cognitive processes between genuine users and imposters. For the development of such an authentication scheme, we proposed a new authentication paradigm using familiar faces together with electroencephalography (EEG) and compared neural activity between acquaintances and strangers while they searched for known faces via an event-related potential (ERP) analysis. 28 pictures of human faces were prepared among which 4 were designated as target faces. 29 participants belonged to one of 2 groups: the acquaintance group of 14 participants indeed knew 4 target faces for long time (> 1 years) whereas the stranger group of 15 participants had not known a priori any face but were informed of 4 target faces before the task. In each trial, participants were shown 8 faces arranged in the form of a 3x3 matrix with the center slot empty. The face matrix was presented for different durations of 1, 1.5, 2 or 2.5 s over four blocks. Half of trials in each block included a target face (i.e. familiar condition) and the rest did not (i.e. unfamiliar condition). Participants searched for a target face and located it in the matrix using a numerical keypad (3x3 matrix for of 9 keys). If they could not find the target, they pressed the center key on the keypad. EEG and eye tracking data were recorded simultaneously. The epochs for ERP analysis were time-locked to the onset of the longest fixation on correct answer in the familiar condition or the average response time of the familiar condition in the unfamiliar condition. Error rates were similar between two groups ($p > 0.05$). The block with 1s stimulus duration yielded a significantly higher error rate than others ($p < 0.001$). The ERP analysis revealed that late positive potentials (LPPs) at FC1 and F3 were significantly larger in the acquaintance group than in the stranger group ($p < 0.05$) even when the both groups successfully identified the target faces. This is in line with preceding studies showing that LPP reflects more elaborate processing such as long-term memory traces. The current study suggests plausibility of our new paradigm as a novel authenticating scheme using EEG and face recognition.

Title: Anatomical evidence of the insula connections with the mirror system in humans and macaque monkeys

Authors: G. DI CESARE[1], C. PINARDI[3], C. CARAPELLI[3], *F. CARUANA[3], M. GERBELLA[2], G. RIZZOLATTI[3]
[1]Robotics, Brain and Cognitive Sci., Italian Inst. of Technol., Genova, Italy; [2]Ctr. for Biomolecular Nanotechnologies, Italian Inst. of Technol., Lecce, Italy; [3]Univ. of Parma, Parma, Italy

Abstract: Actions can be performed with different vitality forms (e.g. in a gentle or rude way). In previous fMRI studies, we demonstrated that both observation and imagination of arm actions vitality forms are encoded in the left dorso-central insula. It appears therefore that this sector of the insula has a fundamental role in expressing our own vitality forms and in recognizing those of others. In the present study, we investigated whether the dorso-central insula is connected with the fronto-parietal nodes of the action recognition circuit in humans and monkeys. To this purpose, in humans, we used a combination of functional (Psycho-Physiological Interaction, PPI) and anatomical connectivity (Diffusion Tensor Imaging, DTI). To define the seeds of the interest for DTI, we carried out the PPI analysis on functional data showing that the anterior intraparietal sulcus and the inferior frontal gyrus are functionally connected with the dorso-central insula. An additional seed was placed in the ventral premotor cortex activated during action observation. DTI results highlighted that, in humans, the dorso-central insula is connected with both the seeds of the parietal and premotor cortex as well as with that of the inferior frontal gyrus. To assess a correspondence between the human circuit and that previously described by tract tracing studies in the monkey, we performed a DTI study, in the monkey, by placing the seeds of interest in the premotor and parietal mirror circuit nodes, and in the ventro-lateral prefrontal cortex (VLPFC), recently described to be activated during action observation. A further seed was placed in the dorso-central insula. The results showed that, as in humans, the monkey dorso-central insula is connected with the parietal and premotor mirror circuit nodes as well as with the VLPFC. Altogether, our results demonstrate that the dorso-central insula is connected with the parieto-frontal mirror network suggesting that this insular sector may modulate this circuit during vitality form perception and expression.

Title: Brain signal complexity during social perception in infancy is associated with epigenetic variability of the oxytocinergic system

Authors: *M. H. PUGLIA[1], K. M. KROL[1,2], M. MISSANA[3,2], J. P. MORRIS[1], J. CONNELLY[1], T. GROSSMANN[1,2]
[1]Psychology, Univ. of Virginia, Charlottesville, VA; [2]Max Planck Inst. for Human Cognitive and Brain Sci., Leipzig, Germany; [3]Leipzig Univ., Leipzig, Germany

Abstract: Measures of neural complexity capture the inherently fluctuating nature of the brain and are positively associated with cognitive development and behavioral performance. Oxytocin, a naturally occurring neuromodulator, regulates both social behavior and brain signaling. Individual differences in the endogenous oxytocinergic system are in part due to epigenetic variability of the oxytocin receptor (*OXTR*) through DNA methylation. We have previously identified a region of *OXTR* in which increased methylation is associated with decreased levels of transcription in human cortex. Therefore, those with low methylation likely have increased access to endogenous oxytocin. Methylation at this site shows significant variability in the population, is elevated in individuals with autism, is associated with differences in brain function and connectivity in healthy adults, and can be assessed from peripheral tissue. We hypothesized that early life differences in the oxytocinergic system drive differences in neural complexity during social perception. To test this hypothesis, we assayed *OXTR* methylation from 101 infants at 5 months of age. At 8 months of age, we presented the same infants with social auditory stimuli while undergoing EEG, and collected measures of infant social behavior. Neural complexity was quantified as the area under the multiscale entropy curve (MSE AUC). We find that infants with decreased *OXTR* methylation, or higher access to endogenous oxytocin at 5 months of age, show significantly increased neural complexity in response to social stimuli at 8 months of age. Infants with increased neural complexity also show significantly increased approach behavior at 8 months of age. These results suggest that the oxytocinergic system may impact social behaviors by establishing unique neural patterns to social stimuli early in life.

Title: Neural correlates of deceptive behavior in children with autism spectrum disorder

Authors: *S. YOKOTA[1,2], T. HASHIMOTO[2], R. KAWASHIMA[2]
[1]Kyushu Univ., Fukuoka-Shi, Japan; [2]Tohoku Univ., Sendai, Japan

Abstract: Introduction: Deception is a psychological process by which one individual deliberately attempts to convince another to accept as true what the first individual knows to be false. To deceive other person requires inhibition of true response and production of deceptive one. Successful deception involves anticipating responses and inferring what another person knows, especially in social contexts. Previous studies have revealed the difficulty and developmental delay in deception and executive dysfunction in children with autism spectrum disorder (ASD). However neurocognitive traits of ASD are poorly understood. In this study, we investigated neural correlates of deceptive behavior in children with ASD, using functional magnetic resonance imaging.
Methods: Twelve children with ASD and 14 typically developing (TD) children, aged 6 to 12-year old, participated in this study. The diagnoses of all children with ASD were confirmed using Autism Diagnostic Interview-Revised. Parent of participants answered Autism Quotient (AQ; Wakabayashi et al, 2007) about their child. Participants were scanned while performing interactive games involving deception. 1 interactive game trial took 19-seconds, and there were 64 trials in total. Trials were pseudo-randomly presented with average 4-seconds inter stimulus interval. The hemodynamic response for each event was modeled from the onset of the appearance of the question. Imaging analyses were conducted using SPM 8. This study was approved by the Institutional Review Board of the Tohoku University. As per the Declaration of Helsinki, after we had explained the purpose
and procedures of the study, written informed consent was obtained from each subject and a parent prior to MRI scanning.
Results: We found that the activation in the right inferior parietal lobule was marginally significantly different between groups and conditions. In ASD group, the activation of this

region was higher than TD group in the deception condition (MNI coordinates (42,-30, 46); uncorrected P < .001 at voxel level, FWE corrected P < .10 at cluster level). We also found that the activations of right anterior cingulate cortex (ACC) and anterior insula is significantly positively correlated with AQ score in the deception condition only in ASD group (uncorrected P<.001 at voxel level, FWE corrected P<.05 at cluster level).
Discussion: The inferior parietal lobule is the part of inhibition network (Lee et al., 2002). ACC and insula are also related with response inhibition. Especially, insula activation is correlated with costs of inhibition. Therefore these regions play a key role for making successful deception in children with ASD.

Title: A behavioral and neural study of deception

Authors: *A. SHUSTER[1,2], D. J. LEVY[1,2]
[1]Sagol Sch. Of Neurosci., Tel Aviv Univ., Tel Aviv-Yafo, Israel; [2]Coller Sch. of Mgmt., Tel Aviv Univ., Tel Aviv Yafo, Israel

Abstract: Deception plays a big part in social interactions, from mundane white lies up to multimillion dollar frauds. While from a utilitarian stand-point, people should lie whenever they can benefit from it, in reality this is not the case. For example, studies showed that people incorporate into their decision process the consequences of their lie on others. In this study, our objective was to identify the internal motivations that contribute to the decision to deceive another person, and outline the neural correlates of dishonest behavior. We used a task called *The Message Game*, in which a subject (Sender) sends out either a profitable yet deceptive message or a truthful but not-as-profitable message to another participant (Receiver). Payoffs varied across trials, in order to assess individual sensitivity to different motivations for deception. We defined three such potential motivations: Self Interest, Regard for Other, and Inequality.
Thirty-three subjects completed the task, while their neural activity was recorded using an fMRI scanner. Behaviorally, we found that on average participants sent a deceitful message on half the

trials. However, this behavior varied dramatically between subjects, and while some lied on nearly every single trial, others scarcely did so. Further subject-level analyses revealed high variability in motivations as well, both in *which* motivations drive the behavior and *to what extent*. On the neural level, we observed several regions implicated in the decision to deceive, including the superior temporal sulcus, posterior cingulate cortex and the temporoparietal junction (TPJ). Interestingly, we were able to identify motivation-specific regions of activations, modulated by how these motivations affects individual subjects' behavior. We found utilitarian motivations to correlate with activity in several regions, including ventral striatum and amygdala. Subjects with more other-oriented motivations showed activity in regions including the TPJ and the inferior frontal gyrus. Finally, we show that the connectivity between these social and utilitarian regions is associated with subjects' behavior.
Our results suggest that different people have different motivations to act honestly. Importantly, these differences may be traced to specific neural structures and connections.

Title: Beta wave oscillations distinguish between dynamic actions of initiating and terminating eye contact with a real partner

Authors: *X. ZHANG[1], J. A. NOAH[1], S. DRAVIDA[2], Y. ONO[6,3], J. HIRSCH[1,4,5,7]
[1]Dept. of Psychiatry, [3]Dept. of Psyciatry, [4]Neurosci., [5]Comparative Med., [2]Yale Sch. of Med., New Haven, CT; [6]Dept. of Electronics and Bioinformatics, Meiji Univ., Kanagawa, Japan; [7]Dept. of Med. Physics and Biomed. Engin., Univ. Col. London, London, United Kingdom

Abstract: Eye contact is a universal social cue that signals intent to communicate. The intention depends upon whether one person's eyes are moving toward the observer (initiating) or away from the observer (terminating) communication. We hypothesize that neural activity during eye-to-eye interaction between an observer and a partner will differentiate between conditions where the trajectory of eye movement is either toward or away from the observer. Specifically, we compared separate frequency bands of electroencephalographic (EEG) signals acquired during dynamic eye contact events. We recorded EEG signals from pairs of participants simultaneously (13 dyads, 26 total participants) for the following two types of dynamic eye contact: 1) "toward", in which one participant ("partner") makes eye contact with an observing participant

("observer"), or 2) "away", in which the partner diverts eye gaze away from the observer. Participant dyads were positioned 140 cm across a table from each other. The two participants alternated between observer and partner trials. In each trial, the observer's gaze was directed straight ahead. The partner's gaze, instructed by an auditory cue that was not heard by the observer, randomly alternated either toward or away (10 deg) from eye-to-eye contact with the observer. The duration of each trial alternated between 1.5 and 2.5 s. EEG signals were acquired at F3, F4, F7, F8, C5, C6, PO7, and PO8 in accordance with the 10-20 standard layout. Signals were decomposed into gamma (40-100 Hz), beta (12-40 Hz), alpha (8-12 Hz), theta (4-8 Hz), and delta (0-4 Hz) frequency bands. Event types "toward" and "away" were compared for each of the frequency bands. The phase of the beta waves between 735-785 ms differed between the "toward" and "away" condition for right hemisphere DLPFC (F8 electrode, $p < 0.013$). These findings suggest that opposite intentions to communicate, signaled by dynamic eye-to-eye contact either away or toward an observer, are represented by a specific beta wave neural signature and provide a foundation for models of communication intentions in real social conditions.

Title: Affective and cooperative interactions modulate brain connectivity within the action observation system

Authors: *S. F. CAPPA[1], M. ARIOLI[1], E. CATRICALÀ[1], D. PERANI[2,3], A. M. PROVERBIO[5], A. ZANI[6], A. FALINI[7,4], N. CANESSA[1,7]

Abstract: Decoding the meaning of others' actions, a crucial step for social cognition, involves different neural mechanisms. In particular, the respective contribution of the "mirror" and "mentalizing" systems to intention understanding is debated. Processing social interactions recruits both neural systems, with a different weight depending on cues emphasizing either shared action goals or shared mental states. We have previously shown that observing cooperative vs. affective social interactions elicits stronger activity in, respectively, the key-

nodes of the mirror (left posterior superior temporal sulcus (pSTS), posterior parietal (PPC) and premotor cortex (PMC)), or the hubs of the mentalizing (ventromedial prefrontal cortex (vmPFC)) systems. Here we aim at unveiling their neural dynamics by means of dynamic causal modeling in 36 healthy human subjects. We investigated the causal organization underlying the observation of human interactions expressing increasing cooperativity (involving left pSTS, PPC and PMC) vs. affectivity (vmPFC). We first explored the fixed connectivity between these regions and then assessed how increasing levels of perceived affectivity vs. cooperativity, as well as the observer's empathic aptitude, can modulate the direction and strength of their effective connections.We found very strong evidence for a neural model including the pSTS as gateway for both the observed interactions and the degree of their affectivity. The extrinsic connectivity of this input node is subject to oppositely valenced modulations by cooperativity and affectivity, promoting, respectively, reciprocal excitatory connectivity with PPC (mainly forward) and vmPFC (mainly backward). For a subset of effective connections, the strength of modulation displayed an inverse relationship with the subject's empathic aptitude. Empathy scores were negatively related to the strength of the modulation exerted by a) cooperativity on the connections from both PPC and pSTS to PMC, and b) affectivity on the connection from pSTS to vmPFC. Such a negative relationship may indicate that empathy is down-regulated by the early segregation of neural processing by the mirror and mentalizing systems.Consistent with *f*MRI data, such divergent effective connectivity suggests that different dimensions underlying the processing of social interactions recruit distinct, although strongly interconnected, neural pathways associated with the bottom-up visuomotor processing of motor intentions and the top-down attribution of affective and mental states.

Title: Effects of acute aerobic exercise on ocular measures of emotion processing during an emotional face perception task

Authors: C. REYES[1], *N. THOM[2], H. THOMAS[3], N. VARBERG[3], M. P. HERRING[4,5], M. J. CAMPBELL[4,5]
[1]Applied Hlth. Sci., [3]Physics, [2]Wheaton Col., Wheaton, IL; [4]Dept. of Physical Educ. and Sport Sci., [5]Hlth. Res. Inst., Univ. of Limerick, Limerick, Ireland

Abstract: *Background*: Mechanisms of exercise-induced mood enhancement are not well understood. Given the relationship between mood and emotion, adaptive changes in attentional biases to emotional stimuli plausibly could explain exercise effects on mood. *Objectives*: To examine the effects of acute aerobic exercise and/or quiet rest on eye-tracking metrics while viewing emotional facial stimuli. *Methods*: N=35 (18 women) aged 21.1±1.4y completed two counterbalanced 30-min conditions: vigorous running or seated rest. Eye-tracking occurred pre- and 20-min post-condition. Corneal reflection was measured using a Tobii x120 sampling at 120Hz.Participants viewed 45 photographs from NimStim depicting positive (n=15), neutral (n=15), and negative (n=15) facial expressions. Number of fixations, scan path length, fixation duration, and longest fixation were analyzed using 2 Condition (control/exercise) X 2 Time (pre/post) X 3 Emotion (positive/neutral/negative) repeated measures ANOVAs. Significant interactions were decomposed using Bonferroni-adjusted pairwise comparisons. *Results*: Scan path was significantly longer for negative compared to positive images in the exercise condition (condition X emotion ($F_{(1.58,50.67)}$=4.15, p<0.03), mean difference=-46.33, p≤0.008). Fixation duration was significantly longer for positive compared to neutral images at pre-condition (time X emotion ($F_{(2,64)}$=3.21, p<0.05), mean difference=50.64, p≤0.01) and non-significantly longer compared to negative images at post-condition (mean difference=37.06, p>0.08). Compared to neutral images, positive images resulted in a significantly longer longest fixation at pre-condition (time X emotion ($F_{(2,64)}$=3.12, p≤0.05), mean difference=57.04, p≤0.004). *Discussion*: Acute exercise did not significantly alter emotional response as indexed by fixation duration, fixations, or longest fixation. Eye-tracking effectively detected different emotional processing patterns and scanning strategies while viewing emotional stimuli. Significantly longer fixation durations and longest fixation for positive images at pre-condition suggests that participants preferentially fixated on positive images even prior to any intervention. Interestingly, longer scan paths for negative images indicated hyperscanning, suggesting that participants more actively avoided fixating on any relevant aspect of negative images. Further analyses to examine defined eye and mouth areas in images and pupil dilation (cognitive load) are forthcoming.

Title: Spatial and temporal dynamics of the networks for body motion processing

Authors: *M. PAVLOVA[1], M. ERB[2], G. HAGBERG[1], J. LOUREIRO[2], A. N. SOKOLOV[4], K. SCHEFFLER[3]

Abstract: Body motion delivers a wealth of socially relevant information. Yet display inversion severely impedes biological motion (BM) processing. It is largely unknown how the brain circuits for BM are affected by display inversion. As upright and upside-down point-light BM displays are similar, we addressed this issue by using ultra-high-field functional MRI (at 9.4 tesla) providing for high sensitivity and spatial resolution. Whole-brain analysis along with exploration of the temporal dynamics of the BOLD response reveals that in the left hemisphere, inverted BM activates anterior networks engaged in decision making and cognitive control, whereas readily recognizable upright BM activates posterior areas solely. In the right hemisphere, multiple networks are activated in response to upright BM as compared to scarce activation to inversion. With identical visual input with display inversion, a large-scale network in the right hemisphere is detected in perceivers who do not constantly interpret displays as shown the 'wrong way up'. For the first time, we uncover (i) (multi)functional involvement of each region in the networks underpinning BM processing, and (ii) large-scale ensembles of regions playing in unison with distinct dynamics. The outcome sheds light on the neural circuits underlying BM processing as an essential part of the social brain.

Title: Neural sources and underlying mechanisms of neural responses to heartbeats, and their role in bodily self-consciousness: An intracranial EEG study

Authors: *H. PARK[1], F. BERNASCONI[1], R. SALOMON[2], C. TALLON-BAUDRY[3], L. SPINELLI[4], M. SEECK[4], K. SCHALLER[4], O. BLANKE[1]
[1]École Polytechnique Fédérale De Lausanne, Lausanne, Switzerland; [2]Gonda Multidisciplinary Brain Res. Ctr., Ramat Gan, Israel; [3]Ecole Normale Supérieure, Paris, France; [4]Geneva Univ. Hosp., Geneva, Switzerland

Abstract: Recent research has shown that heartbeat-evoked potentials (HEPs), brain activity in response to heartbeats, are a useful neural measure for investigating the functional role of brain-body interactions in cognitive processes including self-consciousness. However, the basic properties of HEPs are not yet well understood. In two experiments, using intracranial EEG, we investigated 1) the neural sources of HEPs, 2) the underlying mechanisms for HEP generation, and 3) the functional role of HEPs in bodily self-consciousness. In Experiment-1, we recorded ECG and resting state intracranial EEG data from 599 depth electrodes in 8 epilepsy patients and computed HEPs by averaging intracranial EEG data time-locked to the ECG R-peaks. Inter-trial coherence analysis of HEPs revealed that shortly after the heartbeat onset, phase distributions across single trials were significantly concentrated in 10% of the recording sites (permutation test complemented with the FDR correction, $p < 0.05$) mainly in the insula and the operculum, but also in other regions including the amygdala and fronto-temporal cortex. Such phase concentration was not accompanied by increased spectral power (FDR corrected $p > 0.05$), and did not correlate with spectral power changes (Pearson's $r = 0.057$, $p = 0.22$), suggesting that a phase resetting, rather than an additive 'evoked potential' mechanism, underlies HEP generation. In Experiment-2, we further aimed to anatomically refine previous scalp EEG data that linked HEPs with bodily self-consciousness. For that we recruited 4 epilepsy patients implanted with depth electrodes involving the insula or the operculum and recorded ECG and intracranial EEG data while the patients were performing the full-body illusion (FBI) paradigm to experimentally alter the state of bodily self-consciousness (e.g., self-identification). We found that HEP modulations in the insula reflected an experimentally induced altered sense of self-identification in two epilepsy patients (cluster based permutation test, $p < 0.05$). Such differential HEP modulation was not observed in two other patients who reported no changes in self-identification during the FBI task ($p > 0.05$), supporting our hypothesis that differential modulations of HEPs in the insula are associated with modulations of self-identification. Collectively, these results provide novel and solid electrophysiological evidence on the neural sources and underlying mechanisms of HEPs, and their functional role in self-consciousness.

Title: Assessing effective connectivity of frontal-thalamic network interactions between OCD patients & healthy controls during basic motor control

Authors: *J. JAVED[1], *J. JAVED[1], V. A. DIWADKAR[3], A. CHOWDURY[2], P. EASTER[2], D. ROSENBERG[4], G. HANNA[5], P. ARNOLD[6]

Abstract: Introduction
Individuals with obsessive-compulsive disorder (OCD) can be characterized by uncontrollable reoccurring thoughts (obsessions) and subsequently behaviors based on these thoughts (compulsions). These differences in thoughts and behaviors may be associated with abnormal brain network function (Diwadkar et al., 2015) and basic motor paradigms involving visually guided finger tapping eloquently evoke disordered cortical thalamic interactions (Friedman et al., 2017). Here we probed the effective connectivity of cortical-thalamic brain networks during a basic visuo-motor integration paradigm (Diwadkar et al., 2017). Dynamic causal modeling (DCM; Friston et al., 2003) was applied to fMRI signals acquired while subjects performed a basic finger tapping task under variable demands. Endogenous connections between the dorsal anterior cingulate (dACC), the supplementary motor area (SMA), the primary motor cortex (M1) and the thalamus (Thal) were investigated as was their modulation by task.
Methods
Data from twenty participants (10 healthy controls and 10 OCD children; $8 \leq \text{Age} \leq 13$) were analyzed. fMRI data (Siemens Verio 3.0T) were collected using a previously employed finger tapping paradigm with variable demands (Friedman et al., 2017). The two test conditions (periodic vs random) were differentiated by creating a different contrast vector for each. 36 competing models were created. The configuration of these models were based off the connections of interest, with two being intrinsic (SMA to M1 and dACC to SMA) and two being non-endogenous (dACC to thalamus and dACC to M1). Bayesian Model Averaging (BMA)(Penny et al., 2010) was used in to estimate connectivity parameters weighted by Bayesian posteriors.
Results
In our analysis, the likeliest generative models were not characterized by contextual modulation, and parameter estimates suggested that OCD were characterized by greater SMA to M1 endogenous connectivity.
Conclusion
These preliminary results imply that effective connectivity of motor pathways is not contextually modulated by basic motor processing. We are evaluating the specificity of these results, and their consistency with other network methods.

Title: Impulsive behaviour of ADHD probands may result from biased maternal transmission of DAT and COMT gene variants

Authors: *S. MAITRA[1], S. SINHA[2], K. MUKHOPADHYAY[2]
[1]Biomed. Res. & Diagnos. Div., Manovikas Kendra,, Kolkata, India; [2]Biomed. Res. & Diagnos. Div., Manovikas Kendra, Kolkata, India

Abstract: BACKGROUND: Attention Deficit Hyperactivity Disorder (ADHD), a common childhood onset neurobehavioral disorder, is speculated to be caused by dopaminergic dysregulation. Impulsive actions and uncontrolled behaviour are the hallmarks of ADHD probands and higher occurrence in the male subjects makes it more challenging. The Dopamine Transporter (DAT) and Catechol-O-Methyltransferase (COMT), both aiding in synaptic dopamine clearance, control neural transmission, post-receptor modulation, and plasticity. We investigated the role of functional DAT and COMT gene variants in ADHD associated impulsivity and behavioural problem. **METHOD**: Nuclear families with ADHD probands (N=217) were recruited following the DSM-IV criteria, while 260 healthy volunteers were recruited based on their academic and social achievements. Peripheral blood was collected from the participants after obtaining informed written consent. Traits were assessed through Conner's rating scale for ADHD and Tsukuyama rating scale for domain specific impulsivity. Genomic DNA isolated was used for PCR based amplification of target sites followed by DNA sequence analysis. Data obtained was analyzed by population as well as family-based methods. **RESULT**: Both impulsivity and oppositional behaviour showed positive correlation with age. Quantitative trait analysis revealed influence of rs2254408, rs2981359, rs227094, rs2254408, rs28382221, rs2981359, rs2239393 on impulsivity while rs4633 exhibited effect on oppositional trait ($P<=0.05$). rs2270913 showed significant over presence in the male probands ($P=0.04$) and biased transmission from younger mothers. Allelic and haplotypic transmission bias were noticed for rs13189021, rs28382221 and rs4633-rs2239393 ($P<0.05$). **CONCLUSION**: The study revealed association of novel gene variants with ADHD endophenotypes. Biased transmission of gene variants indicates maternal contribution in ADHD associated traits. It can be inferred that instability in synaptic dopamine clearance, as predicted by the functional role of the variants,

lead to altered dopamine level culminating in a plethora of distorted cortical stimulation which may enhance ADHD related impulsivity and oppositional trait.

Abstract: Introduction: Aversive visual stimulation elicits neuronal responses in the human amygdala but a comprehensive understanding of the underlying electrophysiology is still lacking. **Methods:** We recorded intracranial electroencephalography (iEEG) from mesial temporal electrodes in 9 patients with epilepsy who viewed eight dynamic sequences of fearful faces (aversive condition), interleaved with sequences of neutral landscapes (neutral condition) with sequence duration 24 s. We analyzed heart rate, iEEG spectral power and neuronal spikes and compared to BOLD measurements in the same patients. **Results:** Comparing aversive versus neutral stimuli, enhanced high gamma power (HGP >60 Hz) was observed specifically in the amygdalae outside the seizure onset zone (9/14 nSOZ-amygdalae, p=0.019) while delta power (1-4 Hz) decreased in 11/11 nSOZ-amygdalae and also in 2/3 amygdalae within the SOZ. Over the group of subjects, the HGP enhancement occurred predominantly during the first 2 s of aversive sequence viewing, while the delta reduction lasted for the whole sequence (i.e. 24 s). In 5 patients with implanted microwires, single-neuron spike rates in the amygdala were enhanced following aversive stimuli. In one patient, the time course of HGP was highly correlated with heart rate (R = -.542), BOLD (R = 0.444), delta (R=0.67) and enhanced neuronal spiking (0.74). **Conclusions:** Aversive visual stimulation modulate power in the delta and high gamma frequency bands and neuronal spiking within the amygdala. The HGP specifically assessed amygdala responsiveness and might be clinically relevant for surgical planning. In summary, we

provide for the first time a comprehensive investigation of amygdala responses to aversive stimuli, ranging from single-unit spikes to local field potentials and BOLD responses.

Abstract: Background: Neuropsychological studies in patients with amygdala lesions have demonstrated a reduction in episodic memory for emotional stimuli. Functional neuroimaging studies have reported increased amygdala responses to emotional, relative to neutral, stimuli during memory encoding or retrieval. However, a detailed mechanistic account at the neuronal level of how emotion upregulates memory in humans is lacking. Specifically, amygdala oscillatory responses associated with successful emotional stimulus encoding, or recognition, are currently unknown. To address this, we performed direct intracranial recordings from the amygdala in epilepsy patients while they encoded and later retrieved unpleasant and neutral images.
Methods: Intracranial electrophysiological recordings were obtained from the amygdala of 11 patients (3 right, 6 left, and 2 bilateral) being evaluated for medication-resistant epilepsy. During the encoding condition, patients were presented with 120 pictures selected from the IAPS database (40 unpleasant and 80 neutral). In a second session 24h later, the same patients performed a recognition memory task: the old 120 pictures were randomly presented with 120 new pictures (40 unpleasant and 80 neutral). Patients were required to make a push-button response to indicate whether they had seen the picture before. Specifically, patients were required to make a “remember” “know”, or “new” decision. Time frequency analyses were performed to test for differential induced responses during the encoding and recognition of

unpleasant images.
Results: For the encoding session, we observed a difference of gamma activity (60-80 Hz) for unpleasant images compared to neutral from 220ms after stimulus onset. In the recognition task, we found a main effect of emotion at two frequency bands: beta2 (20-30Hz) starting from around 300ms, and high gamma oscillations (100-140 Hz) starting from around 200ms. Importantly, this gamma response was highest for old unpleasant pictures compared to the other types of stimuli.
Conclusions: Amygdala responses in the high gamma range are present not only in the perception of an emotionally salient stimuli (encoding) but also in the retrieval process of unpleasant information.

Title: Temporal dynamics of compensatory neural response to cognitive fatigue in a 3 hour Stroop task

Authors: *I. B. SAMUEL[1], C. WANG[2], B. KLUGER[3], M. DING[2]
[1]J. Crayton Pruitt Family Dept. of Biomed. Engin., [2]Univ. of Florida, Gainesville, FL; [3]Univ. of Colorado Denver, Denver, CO

Abstract: Prolonged performance of a demanding cognitive task induces cognitive fatigue. We recently demonstrated that in response to cognitive fatigue, the brain recruited neural resources that were not engaged by the task at baseline, to maintain performance. This compensatory mechanism is examined further in this study. High-density EEG (128 channels) was recorded from 15 participants between 18 and 33 years of age who performed a cued Stroop task continuously for 3 hours. Dividing the 3-hour time period into 30-minute non-overlapping time-on-task intervals we calculated the event-related potentials (ERPs) evoked by the imperative stimulus for each time-on-task interval and divided the ERPs into an early component representing mainly sensory processes (N200/P200), a mid-latency component (P300/N400) representing mainly attentional and language processes, and a late component (slow potential) representing mainly higher order cognitive control processes. While the early ERP component decreased in amplitude with time-on-task, the mid-latency ERP component exhibited a more complex pattern of response to cognitive fatigue, with the amplitude decreasing over the left

parietal region but increasing over the central frontal and right parietal regions (compensation). The rate of decline of the left-parietal ERP amplitude was significantly correlated with the rate of increase of the central-frontal and right-parietal ERP amplitude. Similarly, the late ERP component also exhibited increase in amplitude with time-on-task in the central frontal region, but decrease in amplitude over the left and right parietal regions. The rate of bilateral ERP amplitude decline was again significantly correlated with the rate of the central-frontal ERP increase. These results suggest that in distributed regions of the brain neural processing becomes impaired with the onset of cognitive fatigue and the brain employs compensatory mechanisms to cope with these impairments. In addition, owing to the exquisite temporal resolution of the ERP, we are able to uncover the temporal dynamics of the brain's compensatory response, enriching the current understanding of neural compensation derived mainly from hemodynamic studies. Given the prominent role played by neural compensation in cognitive aging this study raises the intriguing possibility that some aspects of cognitive aging may be studied using a cognitive fatigue model.

Title: The effect of motivation and valence on attentional scope: An event-related potential (ERP) study

Authors: *K. R. MICKLEY STEINMETZ[1], K. S. ARJUNE[2], P. G. BOLTON[2], A. E. BRASINGTON[2], T. J. BUNGE[2], S. V. PADULA[2], T. K. PHILLIPS[2], V. C. ZARUBIN[2]
[1]Psychology, [2]Wofford Col., Spartanburg, SC

Abstract: Previous studies have shown that valence may influence attention, with negative information narrowing attention (Easterbrook, 1959) and positive stimuli broadening it (Frederickson, 2004). However, a confounding variable may be the motivational value of these stimuli. In two studies, the influence of valence and motivation on attention was examined by looking at the N1, an early event-related potential component that has been shown to reflect focused attention. In Experiment 1, while ERP recordings were collected, participants were either primed to have global or local attention immediately before seeing pictures that were either positive and high in motivation or neutral and low in motivation. Results indicated that those primed to have focused local attention had a higher N1 amplitude when viewing positive, high motivational stimuli than neutral stimuli. In Experiment 2 participants were primed to have local attention and then viewed both negative and positive high motivational stimuli, and neutral

low motivational stimuli. Results revealed that there were no significant differences in the N1 for positive and negative stimuli. As these stimuli were matched on motivation, but not valence, this indicates that motivation is an important factor in modulating focused attention.

Title: Navarasa neural correlates

Authors: *R. P. REDDY, J. RAJESWARAN
Clin. Psychology, NIMHANS, Bangalore, India

Abstract: The aim of the study was to compare the neural correlates of Navarasa (9 emotions) with Mental Health Professionals versus other professionals (n=6). All were screened on Mini-International Neuropsychiatric Interview (MINI), Standard Progressive Matrices, Interpersonal Reactivity Index (Davis,1980), Questionnaire of Cognitive and Affective Empathy (Renate at al, 2011), Emotional Quotient (Chadda) Social Stories Questionnaire (Autism Research Centre, 2002), Faux Pas Recognition Test (Simon Baron- Cohen, 1998).
fMRI Design: Navarasa Face Paradigms (9 emotions- Śṛngāram:Love, Hāsyam: Happiness, Raudram: Anger, Kāruṇyam: Compassion, Bībhatsam: Disgust, Bhayānakam: Fear, Vīram: Brave, Adbhutam: Amazement). fMRI scanning: MRI scanning was conducted in a 3 Tesla Siemens Magnetom Skyra scanner. Anatomical scan was acquired with a T1 MPRAGE sequence, with FOV w240mm, slice thickness 0.9mm, slices per slab176, voxel size 0.9*0.9*0.9mm. fMRI was acquired with an EPI sequence. The FOV was 192mm, slice thickness 4mm, slices obtained 36, voxel size 3*3*4mm, matrix 64*64, TR 4 seconds, TE .03 seconds (E prime 1.1 / Block design paradigm/ Statistical Parametric Mapping on MATLAB). Preprocessing consisted of Realignment, Normalization and Smoothing. The first level analysis was General Linear Model with Family Wise Error (FWE), $p<0.05$. One sample t test was used in the 2nd level analysis without FWE & $p<0.001$
Results: When compared to MHP and OP there was nil significant statistical difference between the groups on behavioral data. Navarasa task activated medial, superior frontal gyrus, left inferior parietal lobule, right precuneus, right angular gyrus, left occipital, right fusiform, superior

temporal gyrus, left cingulate gyrus, bilateral posterior cingulate, bilateral cingulate, and Bilateral cerebellum.

Title: Electroencephalographic correlation during social decision-making in young women

Authors: *A. SIU[1], J. HEVIA[2], R. HIDALGO-AGUIRRE[1], M. PEREZ-HERNANDEZ[1], M. HERNANDEZ-GONZALEZ[1], M. GUEVARA[1]

Abstract: In the human, decision-making consists in the process of choosing and acting at a given moment. The decision-making considers temporal factors of their environment, such as the social context, this type of decision has been called social decision-making. In this process, specific cortical areas participate, mainly the frontopolar, dorsolateral prefrontal and parietal cortices. The electroencephalographic correlation (rEEG) is an index of similarity of morphology and polarity of two electroencephalographic signals recorded simultaneously. The aim of the present study was to characterize the inter and intrahemispheric rEEG between prefrontal (frontopolar, dorsolateral) and parietal areas, during social decision-making in young women evaluated through the execution of the “Ultimatum Game” paradigm. In the "Ultimatum Game", two players are given the opportunity to split a sum of money, one is referring as the proposer and the other one as the responder. This game allows the responder decision-making to be evaluated when deciding to accept or reject a proposal in a social or non-social condition. All offers were made by a predetermined algorithm, which ensure that all participants saw the same set of offers, but in the social condition they were told that another women, who they meet at the beginning of the recording was the person who made the proposals. The participants were eighteen young women aged 20-to-30; all participants passed through both conditions. Behavioral results (total amount of money and reaction time) do not show differences when comparing performance in social and non-social decision-making, however, their brain functionality was different. During the social decision-making, participants showed a higher rEEG between frontopolar and dorsolateral, frontopolar and parietal, dorsolateral and parietal, and between both parietal cortices. This behavioral results shown that meeting the person before playing isn’t enough to generate a state of competition The higher degree of EEG coupling

among cortices could be associated with the attentional and working memory process necessary to maintain the final target while carrying out other short-term goals.

Title: Automated measures of semantic content predict conversion to schizophrenia

Authors: *N. REZAII[1], E. WALKER[2], P. WOLFF[2]
[1]EMORY Sch. of Medicine, Dept. of Psychiatry, Atlanta, GA; [2]Dept. of Psychology, Emory Univ., Atlanta, GA

Abstract: Introduction: Predicting conversion to schizophrenia from the prodromal stage has been hampered by a paucity of reliable biomarkers. To address this challenge, recent work has turned to statistical analyses of language. Such analyses have identified semantic coherence (cosine between adjacent sentences), word uniqueness (word Type/Token ratio), and phrase length (number of words per phrase) as predictive of conversion. One feature yet to be considered, however, is poverty of content (POC), widely considered a hallmark of the language of individuals at the prodromal and more advanced stages of schizophrenia. The current research establishes how POC can be automatically extracted from free speech and used to predict conversion to schizophrenia.
Method: The meanings of words and sentences can be extracted using word-embedding methods (e.g., Word2vec) that re-express words as vectors in a multidimensional space. The number of meaning components in a sentence can be measured using a gradient descent optimization technique that identifies the word vectors that, when properly weighted and combined, can reconstitute the meaning vector of a sentence. The number of meaning components can be used as a measure of POC. This method was applied to the transcribed answers of 29 participants of the North American Prodrome Longitudinal Study (NAPLS) to the Structured Interview for Psychosis Risk Syndromes (SIPS). Of the 29 individuals (20 high- and 9 low-risk for developing schizophrenia), seven converted to psychosis within two years of the interview.
Results and Discussion: The number of meaning components was much lower (implying poorer

content) in the converters than in the non-converters (r = .638, p = .004). Also predictive was the mean number of unique words (r = .532, p = .004). Semantic coherence (r = .133, p = .508) and sentence length (r = .240, p = .228) did not predict conversion on their own. However, logistic regression indicated that conversion could be predicted with 100% accuracy if all four linguistic parameters were included in the same model.
Conclusion: This study shows that an automated measure of POC is the *single* best biomarker for predicting conversion to schizophrenia and, when combined with several other measures, may offer a new approach to predicting conversion.

Title: Deficient belief updating explains abnormal information seeking associated with delusions in schizophrenia

Authors: S. C. BAKER[1], A. B. KONOVA[2], N. D. DAW[3], *G. HORGA[4]
[1]New York State Psychiatric Inst., New York, NY; [3]Ctr. for Neural Sci., [2]New York Univ., New York, NY; [4]Psychiatry, Columbia Univ. Med. Ctr., New York, NY

Abstract: Delusions, a core symptom of psychosis, are false beliefs held with high conviction despite contradictory evidence. While Bayesian inference has long been proposed to underlie delusions, previous attempts to show this have not yielded compelling evidence. Here, using a modified, incentive-compatible information-sampling task in addition to well-characterized decision-making tasks, we sought a mechanistic understanding of delusional severity among a sample of 26 medicated and unmedicated patients with schizophrenia and 25 socio-demographically matched healthy controls. On each trial, participants decided whether to draw beads from one of two hidden jars - the identity of which was determined by their majority bead color, blue or green - or to guess the identity of the hidden jar, in order to minimize financial losses from a monetary endowment. Before each choice between drawing and guessing, participants gave a probabilistic estimate reflecting their confidence about the identity of the hidden jar. In stark contrast with previous work using hypothetical decision-making, patients with higher delusional severity tended to exhibit increased information seeking - both in absolute terms, compared to an ideal observer, and relative to healthy individuals. Increased information seeking (i.e., increased draws-to-decision) in patients was highly specific to delusional severity

as compared to hallucination severity, severity of negative symptoms, working-memory capacity, and other clinical and socio-demographic characteristics. Delusion-related increases in information seeking were unlikely to be driven by medication. Draw-wise probability estimates of the identity of the hidden jar further indicated that high-delusion patients had abnormal belief updating characterized by increased weight of prior evidence, a feature that correlated with increased information seeking across patients. Other decision-making parameters that may have potentially explained increased information seeking, including risk and ambiguity aversion, were unrelated to both delusional severity and information seeking among the patients. These results thus suggest that abnormal belief updating, characterized by enhanced reliance on prior information, may be a core computational feature underlying delusional belief formation or maintenance in psychosis. This computational mechanism may be a higher-level counterpart of increased reliance on prior information in hallucination-prone individuals during lower-level sensory discrimination, thus suggesting a convergent mechanism that may potentially explain psychosis more broadly.

Title: Response inhibition and temporal prediction errors in patients with schizophrenia

Authors: B. BOHATEREWICZ[1], M. NOWICKA[1], A. PLEWKA[2], *R. LIMONGI[3]
[1]Dept. of Psychology of Individual Differences, [2]Univ. of Social Sci. and Humanities, Warsaw, Poland; [3]Fonoaudiología, Univ. De Valparaíso Facultad De Medicina, Santiago, Chile

Abstract: In everyday life, modifying reactions helps organisms to adjust to changeable environments. These adjustments can be achieved by implicit temporal prediction —the covert estimation of a time interval. Within the context of temporal predictions, this research compares healthy subjects to patients with schizophrenia in their ability to modify actions. A total of 15 patients with schizophrenia (the patient group, mean age = 41.73; SD = 7.47) along with 15 healthy participants (the control group, mean age = 40.93; SD = 6.68) were examined. A temporal prediction task in which subjects performed GO and STOP trials was used. On GO trials, subjects predicted collisions of two white balls with constant speed whereas on STOP trials subjects inhibited their predictions when the balls turned red. We measured prediction errors (PE, the time difference between subject's temporal predictions and actual collision times) and the stop-signal delay (SSD, the delay between the go stimulus and the stop signal) for which subjects could not succeed at inhibiting predictions on 50 % of STOP trials (SSD_{50}). Quantitative

indexes of anxiety, depression, impulsiveness, and cognitive functioning were also evaluated. Results were analyzed via mixed-effect models. On GO trials, absolute PEs were larger in the patient group than in the control group ($\beta = 56.47$; SE = 13.32; $t(28.32) = 10.48$; $p < .0001$). Both groups made larger errors when they responded before collisions than when they responded after collisions ($\beta = 30.16$; SE = 3.29; $t(4430) = 9.16$; $p < .0001$). But, the patient group responded much earlier than the control group. ($\beta = 14.00$; SE = 3.29; $t(4430) = 4.25$; $p < .0001$). On STOP trials, the SSD_{50} of the control group was larger than that of the patient group, $\beta = 148.68$; SE = 7.42; $t(1404) = 20.02$; $p < .0001$. In addition, the patient group had significantly ($p = .001$) worse cognitive performance, higher impulsiveness and higher level of anxiety and depression, than the control group. This difference could be due to premature release of prepared responses, as indexed by shorter SSD_{50} values. These results are consistent with previous studies on time perception where neuropsychiatry patients overestimated the elapsed time and were less accurate in time estimation tasks than healthy participants.

Title: Altered auditory substrates observed in auditory verbal hallucination

Authors: *K. MATSUO
Dept. of Biol. Psychiatry and Neurosci., Dokkyo Med. Univ., Tochigi, Japan

Abstract: Auditory verbal hallucination (AVH) is a devastating symptom of schizophrenia. We hypothesized that an impairment in neural fibers, specifically, the auditory radiation (AR), would cause an alteration in the gray matter volume (GMV), and then result in aberrant activation in the auditory cortex. We investigated these neural correlates in relation with AVH scores using 3 types of MRI technologies; diffusion spectrum imaging (DSI), T1-weighted image and fMRI of language tasks. Four patients with schizophrenia who had AVH (age 25-54) and 8 controls (age 25-51) participated in this study. The severity of patients' AVH was measured using PSYRATS-J. We used 3-T MRI with a 32-ch head coil (GE Healthcare). DSI (max b-value 4000) underwent an LDDMM to transform individual data to a group template to extract fiber tracts in the same space. Generalized fractional anisotropy (GFA) was computed and extracted at each tract (100 steps each). GFA values in 25 steps of the AR adjacent to Heschl's gyrus were individually

averaged to use as the index of diffusion anisotropy. T1-weighted images were segmented into gray matter and other structures using SPM12. Voxel values of normalized, modulated and smoothed gray matter images within Heschl's gyrus were individually averaged to use as the index of GMV. For fMRI, averages of contrast estimates (task greater than fixation for both tasks) extracted from Heschl's gyrus were used as the index of activation. The GMV of Heschl's gyrus decreased according to the age advance. The GFA of patients in the AR was not greatly different from that of controls. In overall, activation levels were modest in patients as compared with controls. In view of each patient, declined GFA in the AR characterized dimensions of items in PSYRATS-J. A patient (age 45) who had a loud AVH that only came from outside his head had a low GFA in the right AR. The declined right AR might encompass a failure of locating the origin of the AVH. In contrast, another patient (age 39) who had a long-lasting, low and threatening AVH that only came from within her head had a preservation in GFA in the right AR. In her case, she showed relatively extensive activation against the GFA and GMV in left Heschl's gyrus, whereas other patients kept low levels of activation. The relative sensitivity in the left auditory cortex might indicate the persistency of her AVH.

Title: Hyperctivation of left temporo-parietal regions shortens resting EEG microstates in schizophrenia

Authors: *S. SONI[1], S. P. MUTHUKRISHNAN[1], M. SOOD[2], S. KAUR[1], N. MEHTA[1], R. SHARMA[1]
[1]Physiol., [2]Psychiatry, All India Inst. of Med. Sciences, New Delhi, Delhi, India

Abstract: Background: The momentary spatial configuration of the brain electric field at the scalp reflects quasi-stable "functional microstates" caused by activity of different intracranial generators. The present study was conducted to investigate microstates' mean duration and their neural generators in schizophrenia at rest (eyes closed).
Methods: Thirty four patients with schizophrenia (diagnosed as per DSM 5, aged 18-45 years), 29 first degree relatives and 25 matched healthy controls participated in the study. EEG (eyes closed) was recorded using 128 electrodes for 5-6 minutes. EEG signal was pre-processed [band pass filter (1- 100 Hz), segmented (20 epochs of 1 second each), down sampled- 250 Hz and

artifact removal (independent component analysis)] using Net station and EEGLAB softwares. Microstate analysis was performed using Cartool software where global field power (GFP) was computed at each sample in time. K-means cluster analysis determined the most dominant classes of electric field configurations with optimal number of clusters determined by minimum value of cross-validation criterion. The spatial correlation between the microstate templates of the best solution with all the resting topographic maps were computed. Group differences of map duration were assessed using Kruskal- Wallis H test and post-hoc pairwise comparisons. sLoreta was used to compute intracerebral electrical sources of microstate maps with solution space partitioned to 6239 cubic voxels of 5 mm. The localization of global, widespread correlations between the cortical voxels activity was assessed by applying the exceedance proportion test ("cluster statistics").
Results: Kruskal-Wallis H and post hoc test showed that map 5 mean duration (MD) ($\chi^2(2)=7.617$, p= 0.022 mean rank of 35.32- patients, 48.07- relatives, 52.84- controls) was significantly lower in patients compared to controls (U= 256, p= 0.010). Statistical analyses on sLORETA images showed maximum activation in left Inferior parietal lobule (MNI coordinates: -65, -35, 25, Log-F_{max} = 0.748). Based on the exceedance proportion test suprathreshold cortical voxels (Threshold: Log-F = 0.5981, p= 0.0498) with increased activations were found localized at left superior, middle and inferior temporal gyrus.
Conclusion: Hyperactivation in left inferior parietal lobule (least studied and most important part of network affected in schizophrenia) and temporal gyri might have lead to shortening of map 5 mean duration at rest in patients with schizophrenia. This may be attributed to hallucinations and delusions in patients as normally these areas are involved in sensory integration and speech perception.

Title: Role of gamma neurofeedback in working memory of persons diagnosed with schizophrenia

Authors: *E. I. HERRERA[1], F. SINGH[2], A. SMITH[1], N. DUDECK[1], Z. YANG[1], L. RING[1], S. ERIBEZ[1], A. AMELLO[1], M.-R. LIAO[1], R. CHENG[1], Y. QIU[1], R. GOSLA[1], J. A. PINEDA[1]
[1]Dept Cognitive Sci., [2]Dept Psychiatry, Univ. of California San Diego, La Jolla, CA

Abstract: Gamma neural oscillations are essential to working memory (WM) and other behavioral assessments. Persons diagnosed with schizophrenia spectrum disorders (SCZ) perform worse on working memory (WM) tasks compared to healthy controls (HC), and performance negatively correlates with WM load. Convergent evidence from recent studies supports the notion that gamma wave coherence (35-50Hz) over frontal brain regions is implicated in WM-task performance. SCZ patients demonstrate reduced gamma coherence compared to HC. In this context, we investigated the role of using neurofeedback (NFB, an operant conditioning EEG protocol) to improve gamma coherence in SCZ patients using a cross-over design - and, whether changes in gamma coherence were associated with changes in WM performance. Our hypothesis is improved gamma coherence in frontal cortex, will improve WM-task performance. Twelve SCZ patients, and 28 HC were recruited from University of California, San Diego. Subjects were randomized to receive gamma coherence neurofeedback training (G-NFB) or active placebo training (AP-NFB) after completing pre-treatment measures on frontal sites (F3 and F4). Pre-treatment measures were five-minute baseline EEG for each condition of eyes closed and eyes opened, EEG and behavioral n-back (WM-task), and Repeatable Battery for Neuropsychological Status (RBANS) data. After four weeks of coherence training, midpoint assessments were conducted (same as pre-treatment), and subjects were assigned to four weeks of coherence training in G-NFB or AP-NFB based on their previous training assignment. Post-treatment data measures were collected as in pre-treatment, and midpoint assessments. The study is anticipated to be completed in 06/2017, when all EEG and behavioral data will be analyzed. To date, four SCZ patients have completed the study protocol. The treatment was well tolerated with the exception of a single patient who reported motion sickness during one neurofeedback session, and subsequently discontinued participation.

Title: Do anomalies in millesecond timing lead to the self-disturbances in schizophrenia? experimental, phenomenological and predictive coding approaches

Authors: *A. L. MISHARA[1], A. GIERSCH[2]
[1]Dept of Clin. Psychology, The Chicago Sch. of Professional Psychology, Los Angeles, CA; [2]Dept. of Psychiatry,, INSERM U1114, Fédération de Médecine Translationnelle de Strasbourg, Strasbourg Univ. Hosp., Strasbourg, France

Abstract: Background
The subjective impression of continuity of time is so pervasive of our experience that we generally do not pay much attention to it. It is only when a breakdown occurs in this continuity do we notice its importance, e.g., dreaming, drug intoxication, and psychosis in schizophrenia. Patients with schizophrenia report bizarre symptoms, called "self-disturbances," in which they feel that thoughts are inserted into their minds or that their movements are controlled by foreign agents. These symptoms are called the "self-disturbances," because these experiences appear to occur independently from self. However, there is little understanding of what may give rise to them. We examine the hypothesis whether the disruption of the sense of time (time continuity) in schizophrenia patients may lead to the bizarre experience of the "self-disturbances." We proposed that these symptoms involve an inability of the subjects to automatically follow information over time at very brief, non-conscious intervals.
Methods: In a simultaneity/asynchrony implicit judgment task administered to both schizophrenia patients and healthy controls. Subjects had to decide whether the presentation of 2 squares was simultaneous or asynchronous by pressing on the left (simultaneous) or right (asynchronous).
Results: When stimulus asynchronies were too brief (<20 ms) to be detected consciously, response biases (Simon effect) were nevertheless observed in the healthy controls by pressing to the side of the second occurring square, whereas patients consistently pressed to the side of the first square. Phenomenological analysis of the data indicated that sensory events are processed at the ms level in terms of the retained information even if this information does not reach consciousness. The exhibited retentional (retained information) deficits in the patients at very brief intervals are also implicated in the self-disturbances. Surprisingly, the unconscious, automatic processing of subjective time is more accurate than conscious processing in the controls. Experimentally, the patients had difficulties to predict and follow events automatically at the ms level, which is consistent with a temporal processing impairment in the predictive coding and phenomenological accounts.
Conclusion: Self-disturbances of schizophrenia reflect disruption of lower nonconscious levels of temporal processing at very small timescales. Whereas the experimental approach highlights prediction impairments, phenomenological analysis provides testable hypotheses regarding the interaction between retention and the prediction mechanisms in the development of the self-disturbances.

Title: Cannabis use and aberrant salience processing: Role of cannabis use variables and personality dimensions

Authors: *C. M. O'TUATHAIGH[1], A. BICKERDIKE[2], C. O'NEILL[2], P. M. MORAN[3]
[1]Univ. Col. Cork, Cork, Ireland; [2]Cork Inst. of Technol., Cork, Ireland; [3]Univ. of Nottingham, Nottingham, United Kingdom

Abstract: Cannabis can induce acute psychotic symptoms in healthy individuals and exacerbate pre-existing psychotic symptoms in patients with schizophrenia. Inappropriate salience allocation is hypothesised to be central to the association between dopamine dysregulation and psychotic symptoms. The present study examined the possibility that frequency of cannabis use is associated with salience dysfunction, as indexed by self-report measures and performance in tasks measuring several salience dimensions (i.e. prediction error, emotional salience). Additionally, the study explored the relationship between salience processing and schizotypy. 910 third-level students completed a survey battery comprising the following measures: the cannabis experience questionnaire modified version (CEQmv); schizotypal personality questionnaire (SPQ); community assessment of psychic experience (CAPE); aberrant salience inventory (ASI). Kamin blocking (a measure of prediction error) and the 'white noise' salience task (emotional salience) was measured in 20 cannabis users and 20 non-users. Frequency of cannabis use and age of first exposure was associated with changes across specific sub-scales of the SPQ, as well as self-reported aberrant salience as measured by the ASI. Higher aberrant salience scores were also correlated with higher levels of positive schizotypy. Kamin blocking performance was also significantly affected by several cannabis use history variables. Consistent with earlier studies, aberrant salience is associated with increased schizotypal symptoms and history of cannabis use. This study also demonstrated that various dimensions of salience processing may be differentially affected by history of cannabis use.

Title: Aberrant functional connectivity between thalamus and visual cortex is related to attentional impairment in schizophrenia

Authors: *M. YAMAMOTO, I. KUSHIMA, R. SUZUKI, A. BRANKO, N. KAWANO, T. INADA, T. IIDAKA, N. OZAKI
Dept. of psychiatry, Nagoya Univ., Nagoya-Shi, Japan

Abstract: [Objective]
Schizophrenia is a severe, chronic psychiatric disorder characterized by positive symptoms, negative symptoms, and cognitive dysfunction. Attention deficit is a core feature of the cognitive dysfunction in schizophrenia and is closely linked to functional outcomes. Considerable evidence has suggested that thalamic dysfunction is related to attention deficit in schizophrenia. Resting state functional MRI (rs-fMRI) studies have revealed network dysfunction of the thalamocortical functional pathways in schizophrenia. The present study investigated the relationship between aberrant thalamocortical connectivity and attentional impairment in schizophrenia.
[Method]
Thirty-eight schizophrenic patients (20 males; mean age, 38.5 years) and 38 healthy controls (23 males; mean age, 36.2 years) underwent successive rs-fMRI and fMRI during the Flanker task. All subjects provided written informed consent to participate in the study. The ethics review committees of Nagoya University Graduate School of Medicine and Nagoya University Hospital approved this study. We identified decreased left thalamic activation (x, y, z, = -6, 10, 0) in schizophrenic patients by task fMRI in order to determine the thalamic seed. Seed-based analysis using the thalamic seed and rs-fMRI data was conducted to assess differences in thalamocortical functional connectivity between groups. Finally, we computed the correlation between degree of functional connectivity and task performance during the Flanker task in each group.
[Results]
Task performance was assessed using the Flanker effect (i.e., difference in response time between incongruent and congruent conditions), as an index of response conflict or attention. Patients showed a significantly larger Flanker effect, indicating larger distractibility by incongruent stimuli. In rs-fMRI analysis, increased functional connectivity was evident between the left thalamus seed and bilateral occipital cortices/bilateral postcentral gyri in the patient group as compared with the control group. In the patient group, significant positive correlations

($\rho = 0.44$, $p = 0.02$) between degree of connectivity from the left thalamus to bilateral occipital gyri corresponding to the visual cortex and the Flanker effect, whereas no significant correlation ($\rho = -0.15$, $p = 0.40$) was apparent in the control group.
[Conclusion]
To conclude, in schizophrenic patients, cognitive impairment as indexed by response conflict during the Flanker task may be related to increased aberrant functional connectivity between the left thalamus and visual cortex in the resting state.

Title: Connectome-wide association of resting-state connectivity with positive symptoms in medication-free patients with primary psychosis

Authors: ***A. BOROSHOK**[1], M. D. GREGORY[1], M. L. ELLIOTT[1], J. S. KIPPENHAN[1], J. CZARAPATA[1], D. P. EISENBERG[2], K. F. BERMAN[3]

Abstract: Schizophrenia is a devastating illness with a range of psychopathology, including positive symptoms such as hallucinations and delusions. Though these symptoms are well-targeted by neuroleptics, their pathophysiology is not fully understood. We previously found that functional connectivity of the striatum with motor and attention networks was related to both midbrain dopaminergic tone and antipsychotic medication treatment. Dopamine dysregulation and antipsychotic medications are known to primarily impact positive symptoms in schizophrenia, though few studies relate functional connectivity to symptom severity. Here, we performed a connectome-wide association study (CWAS) to identify regions where whole-brain functional connectivity specifically related to symptom rating scores in patients tested on and off antipsychotic medications. 3T resting-state fMRI scans were collected on 17 inpatients with a history of psychosis (26.6 ± 6.8 years, 12 males) during the medicated and medication-free arms of a double-blinded, counterbalanced medication withdrawal protocol. Positive and Negative Syndrome Scale (PANSS) scores were collected and transformed to a five-factor model. After

preprocessing, CWAS analyses were performed separately for scans on and off medication to identify brain regions where connectivity related to PANSS factors. Post-hoc analyses used these significant regions as seeds in a connectivity analysis to determine the functional networks underlying the findings. Results were thresholded at $p<0.05$, FWE-corrected, with a small-volume correction using significant striatal clusters previously identified in a CWAS analyses of dopamine functioning. CWAS analyses revealed the connectivity pattern of the bilateral caudate to be related to positive symptoms while off medications. We did not find significant associations with other PANSS factors ($p's>0.05$, uncorrected) or during the antipsychotic treatment ($p's>0.2$, uncorrected). Post-hoc seed-based analyses showed that caudate connectivity with motor and dorsal attention networks drove this finding, such that greater positive symptoms were associated with greater connectivity. Here, we show that striatal connectivity with attention and motor networks is associated with positive symptoms in psychotic patients while off medications, but not during treatment. Our results extend prior findings that suggest an association of striatal connectivity with midbrain dopaminergic tone. Together, these results suggest that this pattern of striatal connectivity with attention and motor networks may be tied to the pathophysiology of psychotic symptoms.

Title: Assessing brain activations during an "active" resting state in schizophrenia: evidence of reduced potentiation for action

Authors: *H. A. BOALBANAT[1], V. A. DIWADKAR[2], J. A. STANLEY[3], A. CHOWDURY[4], D. KHATIB[4], L. HADDAD[5], P. THOMAS[5], U. RAJAN[5], A. AMIRSADRI[5]
[1]Wayne state school of medicine, Detroit, MI; [2]Psychiatry & Behavioral Neurosci., Wayne State Univ. SOM, Detroit, MI; [3]Psych & Behav Neurosci, [4]Wayne State Univ. Sch. of Med., Detroit, MI; [5]Wayne State Univ. Sch. of Med., detroit, MI

Abstract: Background: The disordered patterns of connectivity and activation are characteristic of schizophrenia (Wadehra et al., 2013). Yet the functional role of rest periods in the schizophrenia brain are relatively understudied, despite evidence that the brain's functional states contribute to brain network proficiency (Diwadkar et al., 2017). Here we investigated activation

profiles in schizophrenia patients and healthy controls specifically during rest/rehearsal periods of a block-design associative learning paradigm. The paradigm required subjects to learn associations between different memoranda classes and is characterized by negatively accelerated learning (Stanley et al., 2017).
Methods: Fourteen schizophrenic patients and six healthy controls participated in fMRI (3.0T Siemens Verio). Object-location associative learning was assessed over eight cumulative epochs, over which participants were required to learn the associations between objects and the specific grid location they were presented in (9 total pairs). Each epoch alternated between encoding (27 s) and retrieval (27 s) blocks interrupted with rest blocks that were of specific interest herein (9 s). Evidence (Ravishankar et al., In Review) suggests that rest periods are characterized by coordinated and constructive brain network activity. fMRI data were processed using standard methods (SPM8). In second level random effects analyses we assessed group differences (SCZ ≠ HC) in activation during resting blocks ($p<0.5$ cluster level).
Results: The results indicate there was reduced activation across thalamic, hippocampal and frontal regions during rest periods in SCZ relative to HC. These effects are in contrast with observed evidence of hyper-activation in many of these regions during encoding and retrieval in patients (Wadehra et al., 2013).
Discussion: Sustained activity during resting epochs appears essential to underpinning task-related activity in subsequent encoding and retrieval periods of memory formation. These current emerging results suggest that a loss of engagement of brain regions at rest is a characteristic of schizophrenia, and may relate to increased physiological noise in the brain and/or the inability of the resting brain in schizophrenia to potentiate brain networks for action.

Title: Delusion-like thinking is linked to glutamate concentrations and alterations in the neural mechanisms facilitating about uncertain rewards

Authors: *K. M. DIEDEREN[1], J. HAARSMA[1], T. SPENCER[2], H. ZIAUDDEEN[1], P. C. FLETCHER[1]
[1]Univ. of Cambridge, Cambridge, United Kingdom; [2]King's Col. London, London, United Kingdom

Abstract: Delusional beliefs are hypothesised to arise from subtle alterations in reinforcement learning, a process dependent on dopamine and glutamate signalling. Specifically, it is thought that individuals with delusions present with altered (neural) learning patterns when outcomes are less reliable (i.e., uncertain). We sought to investigate the relationship between delusion-like thinking, learning under uncertainty and glutamate in healthy individuals.
Forty healthy volunteers predicted the value of upcoming rewards drawn from distributions with different degrees of uncertainty during fMRI scanning. On each trial, after making a prediction participants received a reward, thus yielding trial-by-trial prediction errors, learning signals that denote the mismatch between predictions and outcomes. Glutamate concentrations were measured in the prefrontal cortex and striatum in the same MRI session using MR Spectroscopy. Delusion-like thinking was assessed with the Peters Delusion Inventory. Participants were previously reported on in Diederen et al. (2016) and Diederen et al. (2017; placebo group).
As predicted, participants dampened their rate of learning as reward variability increased. The midbrain and ventral striatum adaptively coded prediction errors relative to uncertainty (Diederen et al. 2016, 2017). Individuals that scored higher on delusion-like thinking presented with a reduced tendency to attenuate learning rates as uncertainty increased. In the midbrain, the degree to which prediction errors were coded relative to uncertainty (i.e., adaptive coding) decreased as delusion-like thinking increased. Importantly, there was no significant relationship between delusion-like thinking and overall *non-adaptive* learning rates and PE coding. Delusion-like thinking furthermore correlated with glutamate concentrations.
These findings provide early support for the hypothesis that delusion-like thinking in healthy individuals is associated with changes in the degree to which learning rates and prediction errors adapt to uncertainty, rather than the strength of prediction error coding per se. Furthermore, we established a first, direct, link between delusion-like thinking, adaptive learning under uncertainty and glutamate. As such, odd beliefs may be underpinned by altered glutamate signalling and a shifted balance in the degree to which prediction errors drive learning as a function of their uncertainty.

Title: The role of dopamine and psychosis in the precision-weighting of unsigned prediction errors in the dorsal anterior cingulate cortex

Authors: *J. HAARSMA[1], K. M. DIEDEREN[2], H. J. TAVERNE[2], J. D. GRIFFIN[2], G. K. MURRAY[2], I. M. GOODYER[3], P. C. FLETCHER[3]
[1]Psychiatry, [3]Dept. of Psychiatry, [2]Univ. of Cambridge, Cambridge, United Kingdom

Abstract: Prediction errors form a critical signal for learning. However, they may be more or less reliable and optimal learning should take into account this reliability. Precision weighting of signed prediction errors during reward learning has been demonstrated in humans using fMRI (Diederen et al., 2016) and it is modulated by dopaminergic agents (Diederen et al., 2017). A deeper understanding of the precision weighting of prediction errors may be informative to our understanding of psychosis, which has been associated with aberrant learning. The current study sought to extend our understanding of precision weighting by focusing on unsigned prediction errors. This was done using three complementary analyses: (i) a reanalysis of existing normative data (n=28 healthy participants) (ii) a reanalysis of a pharmacological fMRI study (n=59 healthy participants receiving placebo, bromocriptine or sulpiride); (iii) a novel dataset (n=75 participants including, healthy, at-risk mental state and first episode psychosis). In each case, I focused on precision weighting of unsigned prediction errors. During fMRI data acquisition, participants estimated upcoming rewards drawn from pseudo-Gaussian distributions with varying standard deviations. An increase in SD responded to a decrease in outcome reliability. Reinforcement learning (computational) modelling of the behavioural data across all studies showed that individuals decreased their rate of learning when SD increased. Unsigned prediction errors (PEs) were coded relative to reliability (i.e., precision) as revealed by an increase in the steepness of PE regression slopes for lower SD conditions, thus signalling precision-weighting of unsigned PEs. Sulpiride perturbed precision-weighting of unsigned PEs in the dACC, and (precision-weighted) unsigned PE coding varied with the degree of delusion-like thinking (measured using the Peters Delusion inventory) irrespective of precision weighting in healthy controls. However, preliminary analyses revealed no dACC impairments in the precision-

weighting of unsigned PEs in patients with early psychosis. We conclude that coding of unsigned PEs in the dACC is precision-weighted, and may be dopaminergically mediated. Inter-individual variability in prediction error coding irrespective of precision weighting may relate to delusion-like thinking in health, but our results do not provide evidence of its disruption in psychotic illness. Possible explanations include patient heterogeneity, or that the mechanisms underpinning delusion-like thinking in health differ from delusion formation in illness.

Title: A greater tendency for mediated learning in a ketamine mouse model of schizophrenia

Authors: P. AHRENS, *M. KOH, M. GALLAGHER
Psychological and Brain Sci., Johns Hopkins Univ., Baltimore, MD

Abstract: Mediated learning is a behavioral paradigm that has been used in animal studies to potentially capture cognitive features of schizophrenia. In studies of mediated learning, representations of prior experience can enter into current associations. Using a ketamine animal model of schizophrenia, we investigated whether mice exposed to ketamine during late adolescence subsequently showed an increased tendency to use a representation of a prior gustatory experience to form associations in learning. Mice were given prior experience of an odor and a taste presented together. The odor was subsequently presented alone with gastrointestinal illness induced by a lithium chloride injection. A consumption test was then given to assess whether the taste, despite its absence during conditioning, entered into an association with the induced illness. Such learning would be *mediated* via a representation of the taste activated by the odor. Our results showed that control mice displayed no aversion to the taste following the procedures just described, but mice that had been treated developmentally with ketamine exhibited a significant taste aversion, suggesting a greater propensity for mediated learning. Chronic treatment with the antipsychotic drug, risperidone, in a different set of ketamine-exposed mice attenuated the mediated aversion learning to the taste, a finding that may be related to its known efficacy in reducing the positive symptoms of schizophrenia. These data provide a setting with potential relevance to preclinical research on schizophrenia, to study the

neural mechanisms underlying a propensity for aberrant associations and assessment of therapeutics.

Title: Associative activation and treatment of perceptual 'hedonic hallucinations' in a mouse model of neuropsychiatric illness

Authors: *A. W. JOHNSON[1], R. GIFFORD[1], C. MANNING[2], A. J. ROBISON[2], M. NIWA[3], A. SAWA[4]

Abstract: These studies used a transgenic mouse model with a putative expression of dominant-negative disrupted in schizophrenia 1 under the under control of the prion protein promoter (DN-DISC1-Prp). Initially, we conducted a series of short-term consumption tests with water and varying concentrations of sucrose (0.1, 0.2 & 1M). An analysis of licking microstructure was adopted to examine dissociable evaluative and motivational variables that contribute to ingestive behavior. Both the mean number of licks occurring within each burst of licking (cluster size; a measure of palatability), and the frequency of initiating novel bouts of licking behavior (cluster number; a measure of motivation) were comparable in DN-DISC1-Prp and wild-type mice. Following confirmation of intact gustatory detection, we examined the capacity for a conditioned stimulus (CS) to evoke perceptual processing of an absent sucrose reinforcer. DN-DISC1-Prp and wild-type mice received training, where one CS was minimally paired with a 0.2M sucrose unconditioned stimulus (US) (16 CS-US pairings), and a second CS that was paired more extensively (112 CS-US pairings). At test, the sucrose solution was replaced with unflavored water, and the extensively trained CS evoked significantly more licks for unflavored water in DN-DISC1-Prp compared to wild-type mice. Licking microstructure revealed that the increase in licking behavior in DN-DISC1-Prp specifically reflected an increase in the perceived palatability (cluster size) of the unflavored water—i.e., a ‘hedonic hallucination’. We also examined activity-dependent neuronal changes using the marker for neuronal activity, c-fos, in brain gustatory (insular cortex) and reward areas (nucleus accumbens). In a subsequent study, systemic treatment

(0.25 mg/kg) with the typical antipsychotic, haloperidol disrupted this 'hedonic hallucination'. A final series of experiments confirmed that these effects did not reflect stimulus-response learning, impairments in extinction and/or other motivational features of reward (e.g., progressive ratio performance). Collectively, these results suggest that external stimuli (e.g., an auditory tone) can acquire control of perceptual processing of a motivational event (e.g., sucrose solution). In DN-DISC1-PrP mice this results in a highly detailed hallucination of the event (e.g., sweet taste of sucrose), even if the event is not presented, which can be treated with a typical antipsychotic. Thus, these findings provide a novel approach in animal models to examine hallucinations, which to date the assessment of which has been restricted to neuroimaging in humans.

Title: Upregulation of a brain-enriched microRNA, microRNA-124, contributes to common endophenotypes of schizophrenia and bipolar disorder

Authors: *H. NAMKUNG[1,2], H. JAARO-PELED[1], K. SHARMA[1,3], S. KANNAN[4], R. HUGANIR[3], A. SAWA[1,2,3,4]
[1]Psychiatry, Johns Hopkins Sch. of Med., Baltimore, MD; [2]Biomed. Engin., Johns Hopkins Sch. of Med., Baltimore, MD; [3]Neuroscience, Johns Hopkins Sch. of Med., Baltimore, MD; [4]Mental Health, Johns Hopkins Sch. of Publ. Hlth., Baltimore, MD

Abstract: For the past 5-10 years, our lab has looked for clinically detectable molecular signatures associated with schizophrenia (SZ) by using olfactory neuronal cells obtained by nasal biopsy, which are promising surrogate tissues to capture molecular signatures in neurons resulting from disease-perturbed biological networks. By conducting unbiased microarray studies together with bioinformatics analyses, we have recently underscored dysregulation of microRNA-124 (miR-124) as one of the most notable molecular signatures in SZ. We further observed that miR-124 is significantly upregulated not only in olfactory neuronal cells from patients with SZ, but also in those from patients with bipolar disorder (BP). At least in our experimental systems, miR-124 is most significantly dysregulated among representative microRNAs that have been reportedly associated with and altered in SZ and BP. To address

whether the molecular signature is driven by genetic factors, we utilized polygenic risk scores (PRSs) for SZ and BP, which aggregate genotypic scores for single nucleotide polymorphisms (SNPs) associated with psychiatric conditions. Very interestingly, the PRSs for both SZ and BP significantly predicted miR-124 upregulation, indicating that common genetic variants underlying risk of SZ and BP as their sum are likely to contribute to miR-124 upregulation. Back to biology, miR-124 is known to play crucial roles in neuronal differentiation, neurogenesis, and synaptic plasticity. To investigate miR-124 upregulation-induced endophenotypes, we next generated a mouse model by overexpressing miR-124 in the medial prefrontal cortex (mPFC) that includes brain areas homologous to human brain regions critically implicated in both SZ and BP. By the upregluation, alternation of behaviors in the constructs relevant to SZ and BP, sociability and psychostimulant sensitivity, was observed. Furthermore, we examined the effect of miR-124 upregulation on glutamatergic synaptic transmission properties. We found that upregulation of miR-124 alters AMPA-R subunit composition and therefore synaptic transmission properties. We finally showed the causality of the alteration in the AMPA-Rs on the behavioral deficits. Together, the present study indicates that excessive miR-124, which is driven by common genetic risks of SZ and BP, critically disturbs AMPA-R mediated synaptic transmission that underlies pathological changes in key behavioral constructs relevant to both SZ and BP.

Title: The Dysbindin-1A isoform selectively modulates basal ganglia-related phenotypes through astrocytic-dependent functioning

Authors: *R. MASTROGIACOMO[1], D. MAURO[1], V. FERRETTI[1], A. FORGIARINI[2], F. MANAGÒ[1], R. MAROTTA[1], D. ROTHMOND[3], J. L. WADDINGTON[4], C. S. WEICKERT[3], G. ORSO[5], F. PAPALEO[1]

Abstract: Dysbindin-1 is a protein implicated in vesicular trafficking, synaptic plasticity and clinical response to antipsychotic drugs, and its expression is altered in schizophrenia. Dysbindin-1 exists in different isoforms (1A, 1B, 1C) with region-, subsynaptic- and

developmental-specific expression. However, their specific functional roles remain unknown. Using a novel floxed mouse line, we demonstrated that life-long selective disruption of the dysbindin-1A isoform (dys1A) was sufficient to produce unexpected selective molecular and behavioral phenotypes consistent with basal ganglia, but not cortical-dependent alterations. In particular, dys1A disruption resulted in increased D2 receptors on cells surface in the striatum, sensorimotor gating deficits, hyperactive phenotypes (similarly to dys1 mice with full knockout of all isoforms), as well as impairments in serial reversal learning and motivation. In contrast to dys1 full knockout, D2 expression in PFC, social and attentional set-shifting abilities were not affected by dys1A disruption. Notably, postmortem human brain analyses revealed that dys1A, but not dys1C, was reduced in the caudate of patients with schizophrenia compared to matched healthy subjects. Using a Drosophila model of dysbindin-1 disruption, we found a primary effect on morphological features and survival of astrocytes. Moreover, in mice we found that dys1A is the only isoform expressed in glial cells, and dys1A knockout mice show altered golgi complex selectively in astrocytes. Strikingly, selective knockout of dys1A in astrocytes and during adulthood (Dys1AGlast) was sufficient to recapitulate the dys1A phenotype. These findings strongly suggest a genetic-driven mechanism selectively regulating basal ganglia astrocytic functioning, opening new avenues in the biology of glial dopaminergic mechanisms potentially implicated in psychiatric disorders and related pharmacological treatments.

Title: ERRα as a putative mediator of PGC-1α-dependent gene expression: Relevance for the pathophysiology of Schizophrenia

Authors: *L. J. MCMEEKIN[1], L. M. JENKINS[1], B. M. WATKINS[2], A. S. BOHANNON[1], A. PATEL[1], A. KRALLI[3], J. J. HABLITZ[1], R. M. COWELL[1]
[1]Univ. of Alabama At Birmingham, Birmingham, AL; [2]Univ. of Miami Leonard M. Miller Sch. of Med., Miami, FL; [3]The Scripps Res. Inst., La Jolla, CA

Abstract: The transcriptional coactivator peroxisome proliferator activated receptor gamma coactivator-1 alpha (PGC-1α) is a known regulator of transcripts involved in neuronal function,

including neurotransmission, morphology and metabolism. Importantly, polymorphisms in PGC-1α have been linked to schizophrenia and bipolar disorder. Studies from our lab indicate a reduction in the PGC-1α-dependent transcripts synaptotagmin 2, complexin 1, neurofilament heavy chain and parvalbumin in the cortex, without changes in PGC-1α expression. The mechanisms underlying these changes in gene expression are not clear. We show here that a potential mediator of PGC-1α effects in the brain is orphan nuclear receptor estrogen-related receptor α (ERRα). Promoters of PGC-1α-dependent transcripts contain binding sites for members of the ERR family, ERRα inverse agonists block PGC-1α-driven gene expression, and ERRα knockout mice exhibit reductions in PGC-1α dependent genes in cortex and hippocampus. Interestingly, while ERRα null mice do not show overt motor abnormalities seen in PGC-1α null mice, these mice show impairments in prepulse inhibition, similar to mouse models of schizophrenia. These studies highlight the cell and circuit-specific roles for ERRα in the brain and suggest that modulation of this pathway could be explored for the rescue of discrete endophenotypes in psychiatric disease.

Title: Arduino-based prepulse inhibition behavioral box: A low cost method for schizophrenia symptoms assessment

Authors: *L. ANDREOLI[1], E. MORYA[2]
[2]Edmond and Lily Safra Intl. Inst. of Neurosci., [1]Inst. Santos Dumont, Macaiba, Brazil

Abstract: Patients suffering from psychosis lack the ability to inhibit their responses to incoming sensory information and select from diverse sensory input which information is relevant. Prepulse inhibition (PPI) is a widely accepted paradigm to assess sensory filtering deficits both in patients with schizophrenia and animal models of the disease. PPI consists of inhibition of a startle reflex in response to a sudden and intense stimulus (usually a loud acoustic noise of ~120 dB) by presenting a weaker pulse (usually of ~65 dB, which does not elicit startle responses) 30 to 500 ms before the loud pulse. In schizophrenia, this phenomena is disrupted and startle response magnitude is not diminished when a weak stimulus precedes a stronger pulse. Arduino based behavioral box tests are widely increasing in research laboratories due to its cost and the possibility to customize experiments. We developed a do it yourself (DIY) behavioral box to assess prepulse inhibition and other startle response measures with Arduino interface. To detect animal startle responses, we used an Arduino Uno microcontroller and an accelerometer (MPU6050, InvenSense), fixed in a rodent behavioral box. To test the behavioral box accuracy , we compared the recorded acceleration with that from a more sophisticated system, namely a Triaxial Ceramic Shear Accelerometer (PCB 356A01, 5 mV/g, PCB Piezotronics) and a Nidaq amplifier (NI cDAQ 9138 CompactDAQ, National Instruments). Our benchmark test shows that the Arduino-accelerometer device is as effective in detecting movement in the behavioral box as more expensive sensors and it is sensitive to rodents startle (Fig 1). In addition, this box can be built and customized with components commonly found in a neuroscience laboratory, thus substituting more expensive devices.

Title: Neurogranin regulates sensorimotor gating through cortico-striatal circuitry

Authors: *B. GO, J. M. SULLIVAN, III, A. N. REKER, H. W. NAM
Dept. of Pharmacology, Toxicology and Neurosci., LSUHSC-Shreveport, Shreveport, LA

Abstract: Prepulse inhibition (PPI) is the normal suppression of startle reflex when a strong startling pulse is preceded by a prepulse and the sensory prepulse inhibits (gates) the motor startle response. PPI provides an operational measure of sensorimotor gating and PPI deficits are shown in schizophrenia (SZ) patients. Genetic variants or decreased neurogranin (Ng) gene are observed in SZ patients and may regulate hypo-frontality in SZ. Therefore, in the present study, we examined whether Ng in the cortico-striatal circuitry plays essential roles in sensorimotor gating measured by PPI. In Ng knock out ($Ng^{-/-}$) mice, PPI response was significantly reduced compared to WT mice, which suggests that Ng is required for normal sensorimotor gating function. To examine brain-specific role of Ng and its PPI associations, we used viral-mediated gene expressions, optogenetics, and designer receptors exclusively activated by designer drugs (DREADD) stimulation. Using brain-specific Adeno-Associated Virus (AAV)-mediated Ng expression, we identified that Ng overexpression in the medial prefrontal cortex (mPFC) but not in nucleus accumbens (NAc) was effective to increase PPI response. This indicates that Ng in the mPFC has a functional role in regulating PPI response. To further examine cell type-specific PPI regulation in mPFC-NAc circuit, excitatory neuron-specific (CaMKII) optogenetics and inhibitory neuron-specific (parvalbumin; Pv) DREADD were utilized. The excitatory neuron - specific optogenetic stimulation in the PFC-NAc circuit showed higher PPI response, whereas PFC- and NAc-specific stimulation, respectively, did not show any changes in PPI response. In addition, inhibitory neuron-specific DREADD stimulation in either mPFC or NAc showed no changes in PPI response compared to baseline. In this study, we identified that Ng expression in the mPFC is positively correlated with PPI response. Moreover, the Ng in the mPFC and the NAc has shown brain region- and neuron subtype-specific effect in PPI response, indicating that molecular signaling cascades differently affect the schizophrenic behaviors depending on the brain region and/or neuronal subtypes.

Title: Schizophrenia-like behavioral deficits can be reproduced by regional knockdown of parvalbumin or somatostatin interneurons in the prefrontal cortex or ventral hippocampus

Authors: *A. M. BOLEY, S. M. PEREZ, D. J. LODGE
Pharmacol., UTHSCSA, San Antonio, TX

Abstract: Schizophrenia is a psychiatric disorder characterized by three types of symptoms – positive, negative, and cognitive. GABAergic deficits are consistently detected post-mortem in the hippocampus of schizophrenia patients and we posit they contribute to positive symptoms of the disease. Interneuron deficits are also seen in cortical areas such as the prefrontal cortex, which are likely to underlie negative and cognitive symptoms. Specifically, alterations in both parvalbumin-containing (PV) and somatostatin (SST) containing interneurons are consistently observed in patients; however, whether these deficits contribute to, or are a consequence of, the pathology of schizophrenia has not been established. Here, we examine region specific reductions of PV or SST in the medial prefrontal cortex (mPFC) or ventral hippocampus (vHipp) utilizing a lentiviral-mediated shRNA to knockdown (kd) expression of these GABAergic subtypes. We postulate that this specific knockdown of PV or SST will result in aberrant neuronal activity and discrete behavioral changes associated with schizophrenia. Rats with PV or SST kd in the mPFC, exhibited a decrease in social interaction, a correlate of the social withdrawal observed in schizophrenia patients. To examine cognitive flexibility, rats performed the attentional set-shifting assay. In rats with PV kd in the mPFC, deficits in reversal learning were observed. Single cell extra-cellular recordings of putative pyramidal neurons of the mPFC suggest that average firing rate and pattern are not affected by PV or SST kd. In addition, dopamine neuron activity in the ventral tegmental area (VTA) was analyzed. Predictably, manipulations to the mPFC did not affect VTA dopamine neurons, as population activity has been shown to be driven by the vHipp. Indeed, we have previously demonstrated that a decrease PV GABAergic interneurons in the vHipp is sufficient to recapitulate the dopamine system dysfunction commonly observed in rodent models of the disease and patients, as well as model positive symptoms. Here, we report the effects of hippocampal PV and SST kd on negative and cognitive behaviors. Taken together, this data suggests specific interneuron populations in discrete brain regions differentially contribute to distinct behavioral deficits associated with schizophrenia.

Title: Comparison of allelic mutations in the L-type calcium channel subunit CACNA1c, a risk factor in neuropsychiatric diseases

Authors: *P. LAU[1], E. HOBBS[1], V. TUCCI[2], G. LASSI[2], M. PARSONS[1], G. T. BANKS[1], P. M. NOLAN[1]
[1]MRC Harwell Inst., Harwell Campus, United Kingdom; [2]Neurobehavioural Genet. Group, Neurosci. and Brain Technologies, Genova, Italy

Abstract: Neuropsychiatric disorders such as schizophrenia and bipolar disorder have a large genetic component with symptoms including: anxiety, alternation in drive or emotional states, cognitive deficits and sleep/circadian disturbances. Despite this diversity in symptoms, separate Genome-Wide Association Studies have linked the L-type calcium channel subunit, *CACNA1C*, to both schizophrenia and biopolar disorder. In addition, a specific *CACNA1C* mutation has also been associated with autism and major depressive disorder, suggesting that *CACNA1C* may be a shared genetic risk factor across the psychiatric disorder spectrum. In order to validate these associations, we sought to develop mouse models that can be used to study the physiological function of *CACNA1C*. However, since knockouts of this gene in the mouse are homozygous lethal, we have screened an *N*-Ethyl-*N*-Nitrosourea mutagenized mouse archive for additional allelic variants that express more subtle and varied behavioural phenotypes.
In this study, we identified two mutations in *Cacna1c* (missense and truncation in the same domain) showing endophenotypes associated with schizophrenia and bipolar disorder. Molecular and anatomical analyses were used to investigate *Cacna1c* expression mutant primary neurons and tissues. The functional effects of the mutations were analysed using *in vitro* calcium imaging assays. The mutant mouse lines also underwent a battery of phenotyping tests with an emphasis on endophenotypes of neuropsychiatric symptoms including anxiety and cognitive deficits. We found that animals with either missense or truncation mutations show opposing anxiety-related behaviours. For example, in the open field test, missense mutants showed decreased anxiety and increased exploratory behaviour, otherwise characterised as 'mania' - an endophenotype of bipolar disorder. The same behaviours are not shared by the animals with truncated *Cacna1c*. These animals are more anxious and explore less, which is consistent with symptoms observed in schizophrenia and depressive disorder. Further tests of anxiety such as Elevated Plus maze partially validated these findings. Additionally, the truncation mutant mice show sleep fragmentation, which is notable as *CACNA1C* has also been implicated in narcolepsy, a feature often observed in patients with psychiatric diseases. Together our results suggest that these two mutant lines might be useful animal models for psychiatric disorders that have a diverse endophenotypes.

Title: Reduced synapsin II expression in the medial prefrontal cortex of rats manifests behavioural and brain metabolic changes: Implications in the pathophysiology of schizophrenia

Authors: A. M. BERNARDO[1], S. THOMSON[2], *L. P. NILES[3], R. K. MISHRA[1]
[1]Psychiatry and Behavioural Neurosci., [2]Life Sci., [3]HSC-4N77, Psychiat & Behav Neurosci, McMaster Univ., Hamilton, ON, Canada

Abstract: Schizophrenia (SZ) is a psychiatric disorder with few antipsychotic drugs (APDs) alleviating the associated spectrum of symptoms. Negative and cognitive symptoms, which can manifest as social withdrawal and memory impairment respectively, evade current APDs. Treating SZ relies on targeting APDs to the underlying pathophysiology thus, elucidation is crucial for SZ APD design. Synapsin II (SynII) is a neuronal phosphoprotein responsible for synaptic vesicle trafficking of multiple neurotransmitters involved in SZ. SynII has been implicated in SZ through genome wide association studies and reduced SynII mRNA levels in SZ post-mortem studies. To consolidate SynII's role in SZ, our study explored SZ-like behavioural phenotypes and brain metabolic changes after SynII knockdown (KD) in rats. A scrambled control or SynII lentiviral-mediated shRNA was infused *in vivo*. Rats were then tested for negative symptoms using a social interaction paradigm, and cognitive symptoms, specifically working memory, using the 8-arm radial maze (8-ARM). Brain metabolic activity was also investigated. After cognitive stimulation using the 8-ARM, computerized tomography and positron emission test images were fused for accurate region-specific glucose metabolism profiles. Behavioural results showed SynII KD animals spent significantly less time interacting in comparison to control rats, in the social interaction paradigm, consistent with social withdrawal-like behaviour. The 8-ARM revealed a significant increase in the total number of errors made by SynII KD animals, indicative of working memory deficits. Further, functional brain imaging revealed a global neural hyperactivation in SynII KD animals compared to controls. These behavioural changes and altered glucose metabolism are consistent with those found in SZ. Our findings corroborate reduced SynII in the pathophysiology of SZ and reinforce SynII as a potential therapeutic target to alleviate negative and cognitive symptoms of SZ.

Title: Subcellular localization of non-prenylatable Rho GTPases and its implication in signal cascades

Authors: ***N. G. RAUT**[1], J. M. REDDY[2], D. L. HYNDS[3]
[1]Biol., Texas Women's Univ., Denton, TX; [2]Biol., [3]Texas Woman's Univ., Denton, TX

Abstract: The Rho guanine triphosphatase (GTPase) are highly characterized GTPase proteins that act as molecular switches operating between an active GTP-bound state and an inactive GDP-bound state. Precise regulation of activity in the Rho family of guanosine triphosphatases (GTPases) is necessary for proper development and functioning of the nervous system, and alterations in Rho GTPase signaling are implicated in a variety of neurodegenerative and neurotraumatic disorders. RhoA promotes assembly of focal adhesion complexes and the organization of actin cytoskeleton. Similarly, Rac1 stimulates the peripheral actin accumulations, membrane ruffling and formation of lamellipodia and filopodia. Both require prenylation for membrane localization, though active forms of both have been found in other cellular compartments (GTP-bound Rac1 in the cytosol and GTP-RhoA primarily in the cytosol and nucleus). We designed non-prenylatable Rac1 and RhoA constructs to test how inhibiting prenylation affects morphology, localization of active RhoA and Rac1 and cell signaling pathways. Western blot analysis suggested less cofilin associated with the cytosol than membranes after transfection with the wildtype RhoA construct. ERK and JNK phosphorylation was increased in cytosol. With emerging evidence of differential activation of Rho GTPases based on their subcellular localization, elucidating the signaling cascades of the active GTPases may identify the distinct functions of these GTPases and can be used as novel targets to facilitate axon regeneration in traumatic or degenerative neurological conditions.

Title: Multiprotein complexes in plasticity

Authors: *L. A. DENNER[1], E. ISHIMWE[2], I. CORTEZ[2], E. HOSSAIN[1], K. T. DINELEY[2]
[1]Intrnl. Med., [2]Neurol., Univ. Texas Med. Br., Galveston, TX

Abstract: Multiprotein complexes allow rapid, fine-tuned integration and processing of diverse stimuli driving cellular responses that underlie physiological processes such as new gene transcription. In the periphery, ERK MAPK (extracellular-signal regulated kinase) forms a central node in multiprotein complexes that execute cellular processes as ubiquitous, yet diverse, as cell proliferation, differentiation, transformation, and death. The composition of these transcription complexes is key to conferring specificity between extracellular signals and the nucleus through temporally dynamic assembly of scaffolds to affect nuclear localization and recruitment of coregulators for new gene transcription. A fundamental problem is that we lack an understanding of ERK multiprotein transcription complexes in the CNS at the necessary resolution to achieve biologically relevant interventions (e.g., cognitive enhancement). Dysfunctional ERK multiprotein complexes contribute to neurological diseases such as Huntington's, Parkinson's, and Alzheimer's disease and it is clearly established many forms of memory consolidation require ERK-dependent gene transcription. We recently discovered that, in animal models of aging and disease, PPARγ (peroxisome proliferator activated receptor-γ) establishes a nuclear multiprotein complex with ERK that is necessary for hippocampal memory consolidation.
In this study, we established an *in vitro* model system to recapitulate ERK-PPARγ multiprotein complexes for transcriptional competency. We found that: 1) PPARγ transcriptional activity is ERK-dependent, 2) nuclear co-localization of ERK-PPARγ complexes requires ERK activity (pERK), 3) PPARγ phosphorylation occurs during this process, and 4) CREB binding protein (CBP) is a component of ERK-PPARγ complexes. Thus, we have validated a model system to recapitulate the MEK/ERK/CREB/CBP signaling pathway and it's modulation by the nuclear receptor, PPARγ. This model system forms the launching point for subsequent studies interrogating ERK-PPARγ multiprotein complexes in new gene transcription, plasticity and memory formation.

Title: Revealing the peptide inventory of neurons belonging to an insect locomotor system

Authors: *S. LIESSEM, S. NEUPERT, A. BÜSCHGES, R. PREDEL
Zoological Dept., Univ. of Cologne, Köln, Germany

Abstract: In insects, considerable information on the operation and organization of neural networks in the thoracic ganglia is available that underlie the generation of the default locomotor patterns for jumping, flying and walking. One thoroughly studied insect species, with respect to terrestrial locomotor behavior, is the Indian stick insect *Carausius morosus*. In the recent years, many studies revealed detailed information on neuronal mechanisms, which are involved in the control of walking and contributing to behavioral flexibility such as changing walking direction, speed of walking or turning. However, sparsely knowledge exists on the set of neuroactive substances like neuropeptides and protein hormones that are involved in the generation and modulation of these motor activities.
To fill this gap, we investigated the neuropeptidome of C. morosus as complete as possible by means of different mass spectrometric approaches. Furthermore, we use transcriptome data to verify our neuropeptidomic analyses. In total, 159 novel and likely bioactive neuropeptides and protein hormones were found derived from 46 precursors.
In the next step, this information will be used to get insight into the neuropeptidergic modulation of motoneurons and the premotor microcircuitry that drives locomotion. Therefore, we used single cell profiling by MALDI-TOF mass spectrometry to restrict the number of putative neuropeptides, which could be involved in locomotion processes. Preliminary mass spectrometric results revealed myoinhibitory peptides (MIP) as potential candidates. To confirm these findings, immunocytochemistry is being added to our experimental pipeline. To investigate the physiological function of MIP in the locomotor network, electrophysiological recordings will be conducted in future experiments during drug application.

Inst., osong, Korea, Republic of; [5]Departments of Biol. Sci., Seoul Natl. Univ., Seoul, Korea, Republic of

Abstract: Macroautophagy allows for bulk degradation of cytosolic components in lysosomes. Overexpression of GFP,RFP-LC3/GABARAP is commonly used to monitor autophagosomes, a hallmark of autophagy, despite artifacts related to their overexpression. Here, we developed new sensors (HyD-LIR-GFP) that detect endogenous LC3-GABARAP proteins at the autophagosome using an LC3-interacting region (LIR) and a short hydrophobic domain (HyD). Among HyD-LIR-GFP sensors harboring LIR motifs of 34 known LC3-binding proteins, HyD-LIR(TP)-GFP using the LIR motif from TP53INP2 allowed detection of all LC3/GABARAPs-positive autophagosomes. However, HyD-LIR(TP)-GFP preferentially localized to GABARAP/GABARAPL1-positive autophagosomes in a LIR-dependent manner. In contrast, HyD-LIR(Fy)-GFP using the LIR motif from FYCO1 specifically detected LC3A/B-positive autophagosomes. HyD-LIR(TP)-GFP and HyD-LIR(Fy)-GFP efficiently localized to autophagosomes in the presence of endogenous LC3/GABARAP levels and without affecting autophagic flux. We are currently modifying the numbers of LIR motifs and its combination with other motifs for its application as a selective autophagy marker on various neurological disorders.

Title: Temporal characteristics and behavioral consequences of chemogenetic oxytocin neuron activation

Authors: *T. GRUND[1], R. MENON[2], S. PROBST[2], V. GRINEVICH[3], I. D. NEUMANN[2]
[1]Dept. of Behavioural and Mol. Neurobio., [2]Dept. of Behavioral and Mol. Neurobio., Univ. of Regensburg, Regensburg, Germany; [3]German Cancer Res. Ctr., Heidelberg, Germany

Abstract: Oxytocin (OT) is well described for its anxiolytic, pro-social, and fear-attenuating effects (Neumann, 2008; Lukas et al., 2011; Zoicas et al., 2014). Herein, we analyzed the spatio-temporal dynamics of chemogenetic OT neuron activation within the rat hypothalamic paraventricular nucleus (PVN) using designer receptors exclusively activated by designer drugs (DREADDs), and its behavioral relevance. Although DREADDs allow selective activation (or inhibition) of specific neuronal populations (Armbruster et al., 2007) in order to dissect their contribution to complex behaviors and brain circuitries, the spatio-temporal dynamics of DREADD actions with respect to OT neurons remain unknown. After viral vector-based expression of an excitatory DREADD (hM3Dq) specifically in OT neurons, we monitored the dynamics of OT release within PVN, lateral septum, and peripheral blood following chemogenetic stimulation initiated by clozapine *N*-oxide (3 mg/kg, ip). Central OT release in the PVN and septum was monitored by microdialysis technique, while peripheral OT release was analyzed in plasma samples collected via jugular vein catheter. Our results demonstrate that OT release peaks 45-90 min following chemogenetic activation, which correlated with behavioral changes, such as an induction of anxiolysis, increase of self-grooming, and attenuation of ethanol intoxication, which peaked 1h following DREADD-induced activation of OT neurons. Furthermore, in social fear conditioned mice, the activation of OT neurons (1h prior to fear extinction) profoundly facilitated social fear extinction. Altogether, these results narrow down the time window, when chemogenetic stimulation of neuropeptidergic neurons can be efficiently applied for studying behavioral changes. Furthermore, our findings demonstrate that chemogenetic manipulation of OT neurons is a powerful tool for dissection of novel functional OT brain circuits and hence various OT-dependent behaviors in normal and psychopathological conditions.

Title: Protein kinase c inhibitors attenuate amphetamine-stimulated dopamine overflow

Authors: *A. G. ZESTOS[1], M. E. GNEGY[2], R. T. KENNEDY[3]
[1]Chem., American Univ., Washington, DC; [2]Univ. Michigan Med. Sch., Ann Arbor, MI; [3]Chem., Univ. of MIchigan, Ann Arbor, MI

Abstract: Over 13 million people are affected by amphetamine abuse, and there is currently no therapeutic for amphetamine addiction. Amphetamine serves as a substrate for the dopamine transporter (DAT) and reverses the transporter to cause dopamine overflow in addition to inhibiting the vesicular monoamine transporter (VMAT) to promote dopamine exocytosis. Activation of the beta subunit of protein kinase C (PKCβ) increases extracellular dopamine in the presence of amphetamine by enhancing the reverse transport of dopamine and internalizing the D2 autoreceptor. We used in vivo microdialysis with liquid chromatography-tandem mass spectrometry (LC-MS/MS) in live, behaving rats to assess the effect of the PKCβ inhibitors enzastaurin and ruboxistaurin on amphetamine-stimulated increases in catecholamines and their metabolites. A 30 min perfusion of the nucleus accumbens core with 1 μM enzastaurin or 1 μM ruboxistaurin reduced amphetamine-stimulated overflow of dopamine and its metabolite 3-methoxytyramine by approximately 50%. The inhibitors also significantly reduced extracellular levels of norepinephrine and its metabolite normetanephrine after amphetamine. The stimulation of locomotor behavior by amphetamine, measured simultaneously with the analytes, was reduced by the PKCβ inhibitors. Novel PKC inhibitor 6c also attenuated amphetamine-stimulated dopamine overflow when delivered locally and systemically (simultaneously with amphetamine and 18 hours prior). Ruboxistaurin also attenuated cocaine stimulated extracellular dopamine, a process that would not be dependent upon DAT reversal. In order to see if this process was D2 autoreceptor mediated, we examined the effect of ruboxistaurin on cocaine activation when D2 receptors were blocked with raclopride before ruboxistaurin administration. The inhibitory effect of ruboxistaurin was reduced in the presence of cocaine and raclopride, suggesting that ruboxistaurin action involved D2 autoreceptors. Using a stable isotope label (SIL) retrodialysis procedure, we determined that ruboxistaurin had no effect on basal levels of dopamine,

norepinephrine, glutamate, or GABA. Our results support the utility of using PKCβ inhibitors to reduce the effects of amphetamine.This research is funded by DA11697, T32DA007268, and NIHR37 EB003320.

Title: Clozapine N-oxide, the DREADD agonist, does not affect learning-dependent cortical plasticity

Authors: *G. DOBRZANSKI, R. ZAKRZEWSKA, M. LIGUZ-LECZNAR, M. KOSSUT
Dept. of Mol. and Cell. Neurobio., Nencki Inst. of Exptl. Biol. PAS, Warszawa, Poland

Abstract: The main idea behind the mode of action of the Designer Receptors Exclusively Activated by Designer Drug (DREADD) technique is that selective designer receptors agonist, clozapine N-oxide (CNO) is pharmacologically inert: it does not act like an agonist for native receptors and not affect other cell signaling pathways, thus does not induce unspecific behavioral outcomes. Recently, however, a study has reported that administration of CNO alone altered schizophrenia-like behavioral performance in one of the rat strain, emphasizing the need of establishing CNO control groups in chemogenetic experiments. Although in mice CNO was not reported to affect behavior, we checked it in experimental model of associative fear learning, in which stimulation of vibrissae paired with tail shock results in plastic modification of the barrel cortex activation. Expansion of the functional cortical representation of the row of whiskers activated during conditioning was revealed with 2-deoxyglucose autoradiography (Siucinska and Kossut, 1996). This experiment stands as a starting point for our further chemogenetic research aiming to assess a role of different interneuron subtypes in learning-dependent cortical plasticity. A group of wild type C57BL/6J mice underwent behavioral training consisting of 3 sessions of conditioning in three consecutive days. 30 minutes before each session mice were injected intraperitoneally with CNO (1 mg/kg). 24 hours after the third session 2-deoxyglucose brain mapping was performed. Autoradiograms of brain sections containing the barrel field were analyzed and functional representation of the conditioned row of whiskers and contralateral row on the other side of the snout were mapped. Analysis of 2-deoxyglucose labeling showed enlarged representation of the trained row in the fourth layer of barrel cortex in conditioned hemisphere in comparison to the control one. Cortical activation was also observed in other

structures like secondary somatosensory cortex and auditory cortex, which replicates the pattern of activation observed in previous experiments. The results suggest that CNO administered alone, at dose that was shown to produce unspecific behavioral results in of the rat strain, does not influence the cortical plasticity evoked by associative fear conditioning within the barrel cortex and can be employed in further chemogenetic experiments within this experimental model of learning in mice.

Title: Whole-brain activity mapping using the immediate-early promoter-driven reporter system in the cricket

Authors: *T. WATANABE[1], A. UGAJIN[2], H. AONUMA[1]
[1]RIES, Hokkaido Univ., Sapporo-Shi, Japan; [2]JT Biohistory Res. Hall, Takatsuki-Shi, Japan

Abstract: Genes expressed in response to increased neuronal activity are widely used as neuronal activity markers in recent behavioral neuroscience. In the present study, we established transgenic reporter system for whole-brain activity mapping in the two-spotted cricket *Gryllus bimaculatus*, a hemimetabolous insect used in neuroethology and behavioral ecology. First, we identified cricket homologues of four candidate neuronal immediate-early genes (IEGs): (i) *fos-related antigen* (*fra*), (ii) *jun-related antigen (jra),* (iii) *early growth response* (*egr*; an insect homologue of vertebrate *Egr-1/Zif268/NGFI-A/Zenk*), (iv) *hormone receptor 38* (*hr38*; an insect homologue of *NGFI-B/nur77/NR4A1*), and examined their expression characteristics in the brain. In the cricket brain, *Gryllus fra-B, egr-B* and *hr38* genes were inducible expressed in response to neuronal hyperexcitability caused by picrotoxin (PTX) injection. The inducible expression of these genes was resistant to inhibitors of protein synthesis, indicating these genes are expressed as neuronal IEGs. in addition, these neuronal IEGs showed differential expression time-courses after PTX treatment, as well as differential sensitivity to pharmacological activation of various intracellular signaling pathways. Next, we isolated the gene regulatory region of *Gryllus egr-B.* A 2.2 kbp genomic fragment upstream to the translation initiation site of *Gryllus egr-B* was

contained potential binding sites for stimulus-regulated transcription factors (e.g. CREB, AP-1, SRF), as well as core promoter elements and two *cis*-regulatory modules conserved across insect/crustacean *egr-B* homologues. Using the gene regulatory region of *Gryllus egr-B,* we established an immediate-early promoter-driven transgenic reporter system in the cricket. The reporter gene expression cassette contained the gene regulatory region of *Gryllus egr-B* and a nuclear-targeted destabilized EYFP (*EYFPnls::PEST*), and was integrated into the cricket genome by using the *piggyBac* transposon-mediated gremlins transformation. In the brain of transgenic crickets, the reporter gene was inducibly expressed after PTX injection, and the expression levels of the reporter gene and *Gryllus egr-B* were strongly correlated. Besides, inducible expression of reporter protein was detected in almost all neurons after PTX treatment. Our novel transgenic reporter system allows us to map the neuronal activity at cellular resolution in the cricket brain.

Title: Magnetic sorting of glutamatergic synaptosomes using a recombinant extracellular tag

Authors: *E. A. BROWN[1], L. J. SEVERS[3,4], P. WOO[3,5], S. E. P. SMITH[2]
[2]Ctr. for Integrative Brain Res., [1]Seattle Children's Res. Inst., Seattle, WA; [3]Ctr. for Integrative Brain Res., Seattle Childrens Res. Inst., Seattle, WA; [4]Neurosci., [5]Univ. of Washington, Seattle, WA

Abstract: Research on synaptic biochemistry is important for understanding synaptopathies such as autism, epilepsy, and Alzheimer's, but current methods used to isolate synapses for biochemical analysis have several functional limitations. Sucrose gradients are traditionally used to enrich resealed synapses (synaptosomes) from brain homogenates, but roughly half of the fraction of interest is made up of non-synaptic cell debris. Additionally, the population of synapses isolated in these synaptosome preparations is heterogeneous, which limits the study of individual synapse types and can contribute to poor signal-to-noise. We have developed a method to quickly purify glutamatergic synapses from traditional synaptosome preparations using magnetically activated cell sorting (MACS) technology. We designed a protein construct that consists of PSD95 (with a PDZ domain deletion) to act as an anchor at glutamatergic synapses, GFP, and truncated extracellular CD4 to allow a high-affinity binding by MACS reagents. After confirming synaptic localization of the construct *in vitro,* we expressed it *in vivo* using a lentiviral vector. We isolated P2 synaptosomes from mouse brain homogenate and used

magnetic microbeads and columns to separate CD4-tagged synapses from the preparation with magnetic columns. We compared the P2 synaptosome preparation and magnetically sorted population at each step using both flow cytometry and western blotting, and found several-fold enrichment of native PSD95 and other glutamatergic synaptic proteins after magnetic sorting. Ongoing work aims to develop an additional protein tag expressed at only recently active glutamatergic synapses, and to analyze the biochemical properties that differentiate them from inactive synapses. This method can be used to isolate other synapse types by changing the construct's anchor, and has the potential to boost signal to noise ratio in downstream applications and allow detection of subtle changes in synaptic properties that can provide insight into their function and disruption in disease.

Title: The effect of the neural environment on lifetime of enzymatic biosensors for neurotransmitter detection

Authors: *A. M. YORITA, S. CHEN, A. TOOKER, A. M. BELLE
Lawrence Livermore Natl. Lab., Livermore, CA

Abstract: We are studying the effects of the neural environment on the lifetime of enzymes immobilized on microelectrode array biosensors. Current electrochemical methods of neurotransmitter detection in near-real time in the brain involve the oxidation of neurotransmitters at the surface of a microelectrode. While some neurotransmitters are electrochemically active, others require an enzyme layer to catalyze the synthesis of an electrochemically active molecule (typically hydrogen peroxide) when the neurotransmitter of interest is present. Integration of these chemical sensors into a multifunctional microelectrode array is a vital next step towards understanding the relationship between chemical and electrophysiological signaling in the brain. However, the lifetime of these enzyme layers is significantly lower than the lifetime of sensors for electrophysiological recordings, especially upon implantation. Once implanted into the brain, enzymatic biosensors typically last on the order of days to weeks, whereas electrophysiological sensors have a lifetime of months to years. Thus, it is necessary to understand which aspects of the neural environment are most important in affecting lifetime such that we can work on improving the lifetime of the biosensor array.

We aim to understand the parameters affecting the lifetime of the immobilized enzyme layer by examining the environment to which it is exposed upon implantation. Specifically, we are studying the enzyme glutamate oxidase, which is used to detect the presence of glutamate. A polymer-based, flexible microelectrode array was fabricated, onto which glutamate oxidase was immobilized. The biosensors were then exposed to a variety of parameters, including aqueous environments at elevated temperatures with chemicals typically found in the brain. We then measured the change in sensitivity to glutamate over the course of weeks to track the lifetime of the immobilized glutamate oxidase layers. This understanding of the factors decreasing sensitivity and thus sensor lifetime is the first step in extending the lifetime of enzymatic sensors for chronic use in behavioral studies. With these results, the next step is to examine methods that will better stabilize the enzyme, thus leading to an improved implantable lifetime for biosensors.

Title: Novel lactate oxidase-modified carbon-fiber microbiosensor for monitoring rapid lactate fluctuations in the rat striatum using fast-scan cyclic voltammetry

Authors: *S. SMITH[1], S. GOSRANI[1], M. DAUSCH, 27695[1], C. A. LEE[2], G. MCCARTY[4], L. A. SOMBERS[3]
[2]Chem., [3]Dept Chem., [1]North Carolina State Univ., Raleigh, NC; [4]Pine Res. Instrumentation, Durham, NC

Abstract: Traditionally, it has been thought that glucose is the principal energy source of the brain. Recently, this widely accepted concept has been challenged by several studies demonstrating lactate as an important molecule with an essential role in energy metabolism and memory formation. As such, real-time molecular detection of lactate dynamics is imperative to understanding brain energy availability, and its involvement in neuropathological disorders such as Alzheimer's disease. However, to date, existing methods for detecting brain lactate concentrations are limited in terms of temporal and spatial resolution. We have addressed this need by developing and characterizing a novel lactate oxidase-modified carbon-fiber microbiosensor and coupling it with fast-scan cyclic voltammetry. This approach enables detection of rapid lactate fluctuations with unprecedented spatiotemporal resolution as well as excellent stability, selectivity, and sensitivity at discrete recording sites in the rat striatum. It can

be coupled with our previously developed glucose-oxidase microbiosensor to enable simultaneous detection of both essential non-electroactive molecules. Combined, these new tools enable quantitative investigation of limitations to brain metabolism in disease states.

Title: Autoradiography methodologies in CNS research

Authors: J. RYTKÖNEN, T. PARKKARI, *O. M. KONTKANEN, A. J. NURMI, T. HUHTALA
Charles River Discovery, Kuopio, Finland

Abstract: Autoradiography is a powerful technique that can be applied to study cerebral blood flow, receptor density and activation of G protein-coupled receptors (GPCRs) by novel pharmacological compounds in the brain. These methodologies are easily applicable to various disease models, and combining them with behavioral readouts allows a versatile evaluation of pathophysiology of the CNS disorders and mechanisms of action of novel therapies. GPCRs are involved in a wide variety of physiological processes, including regulation of behavior and mood. They activate intercellular signal transduction pathways and cellular responses. Cannabinoid, serotonin, dopamine, GABAB, and metabotropic glutamate receptors are among neurologically interesting GPCR targets. Ligand binding to GPCRs induces an interaction of the receptor with G protein that stimulates the release of GDP simultaneously with the exchange of GTP. ^{35}S-GTPγS autoradiography has been applied to study receptor activation after ligand binding to GPCRs of Gi and Gs types. In this study, we analyzed changes in the receptor density in rodent neurological disease models. To assess receptor density alterations, tritiated ligands to dopamine receptors 1 and 2, serotonin transporters and cannabinoid receptor 1 (CB1) were used and Bmax values of corresponding ligands were determined in relevant brain regions. Changes in Bmax values correlate with alterations in the number of available receptors sites and which may correlate with the phase or severity of the disease. We also determined the dose-response relationship of GPCR activation by the CB1 agonist HU-210 by detecting consumption of GTPγ^{35}S in the somatomotor cortex, cingulate cortex, striatum, globus pallidus and substantia nigra in mice. The potency (half maximal effective concentration, EC50) as well as efficacy (Emax) of interaction of HU-210 with CB1 was calculated from the obtained dose-response curves. The current examples demonstrate how a combination of assays can be utilized to

advance our understanding of the disease state and measure effects of pharmacological treatments. Also, applied digital scintillation autoradiography enables quantitative and real-time imaging of tritiated samples within hours, compared to minimum of several weeks of exposure time required to phosphoscreens or films. This accelerates method development and analysis substantially. As a summary, the combination of receptor and functional autoradiography offers a powerful tool to comprehensively measure changes in disease models or responses to novel molecules.

Title: Quantitative comparison of enzyme immobilization strategies for real-time glucose detection employing fast scan cyclic voltammetry

Authors: *S. GOSRANI, S. K. SMITH, L. Z. LUGO-MORALES, C. TANG, G. S. MCCARTY, S. KHAN, L. A. SOMBERS
Chem., North Carolina State Univ., Raleigh, NC

Abstract: Electrochemical detection of non-electroactive species, such as glucose, requires biosensors which are stable, selective, and have physiologically relevant sensitivities to targeted analytes. Glucose oxidase, an enzyme, enables the electrochemical detection of glucose through the production of hydrogen peroxide. This hydrogen peroxide is electroactive and serves as the glucose reporter molecule. We have demonstrated sub-second electrochemical detection of glucose fluctuations by combining glucose oxidase modified carbon fiber microelectrodes with fast-scan cyclic- voltammetry (FSCV). FSCV has the ability to distinguish different electroactive species while maintaining effective temporal resolution and sensitivity. Carbon-fiber microelectrodes are used in conjunction with FSCV to detect electroactive molecules. The sensing surface of the microelectrode can be enzymatically modified to create biosensors. The work presented herein quantitatively compares three approaches for enzyme immobilization - physical adsorption, hydrogel entrapment, and electrospinning - on a carbon-fiber microelectrode. The data suggest that each of these methods can be used to create functional microbiosensors; however, of these, hydrogel entrapment is the most effective approach to glucose oxidase immobilization on the carbon electrode surface. These implications are useful

because they define an effective strategy for microbiosensor fabrication that is broadly applicable to other oxidase enzymes, allowing the detection of non-electroactive molecules such as choline and glutamate. Overall, tools such as these will enable researchers to study multiple facets of neuroscience and tackle problems surrounding the detection of non-electroactive molecules.

Abstract: The ability to precisely monitor and manipulate neural circuits is essential to understand the brain. Advancements over the last decade in optical techniques such as calcium imaging and optogenetics have empowered researchers to gain insight into brain function by systematically manipulating or monitoring defined neural circuits. Combining these cutting-edge techniques enables a more direct mechanism for ascribing neural dynamics to behavior. Here, we developed a miniaturized integrated microscope that allows for cellular-resolution calcium imaging and optogenetic manipulation in freely behaving mice. We developed and tested this technology to minimize biological and optical crosstalk. We have demonstrated the utility of this technology by probing the causal relationship between circuit function, behavior, and network dynamics in neural circuits involved in motivated behaviors. This integrated strategy will allow for routine investigation of the causality of circuit manipulation on cellular-resolution network dynamics and behavior.

Title: Influence Mapping: All-optical, causal measurement of effective microcircuit connectivity in mouse cortex

Authors: *S. CHETTIH, C. D. HARVEY
Harvard Med. Sch., Boston, MA

Abstract: To achieve a mechanistic understanding of the function of neural circuits, it is essential to relate activity patterns observed in a neural population to the underlying structure of the network. Existing methods towards these ends, like connectomics and paired patch-clamp recordings, can probe mono-synaptic connectivity in functionally characterized neurons. However they are low-yield, terminal, and technically challenging experiments. We have developed a complementary measurement of a novel quantity we call influence: the effect of spiking activity in one cell on the spiking activity of each other cell in a network. The measurement requires causally triggering spikes in an identified neuron and measuring the resulting change in activity in other neurons. We note that influence is related but complementary to mono-synaptic connectivity patterns. Specifically, influence may change as a function of brain state, as well as reveal emergent, multi-synaptic effects which are difficult to predict from mono-synaptic connectivity matrices.
To measure influence, we use an all-optical approach based on simultaneous two-photon calcium imaging and two-photon photostimulation of neurons co-expressing GCaMP6 and C1V1 or ChrimsonR. We modified channelrhodopsins to enrich cell body localization and reduce densities in axons and dendrites, resulting in reliable activation of nearly all expressing cells with single-neuron resolution. In initial experiments in mouse V1 L2/3, we measured influence between neurons and characterized tuning properties in the same neural population. We then analyzed how influence between neurons was related to multiple dimensions of functional similarity between stimulated and responding neuron, as well as the spatial extent of these effects. Influence was spatially and functionally structured consistent with predictions from known mono-synaptic connectivity: influence was weak beyond ~250 micrometers and inhibitory on average despite stimulating only excitatory cells. Also, influence between

individual pairs correlated with similarities in functional tuning. These measurements provide a direct estimate of how local processing in mouse V1 L2/3 shapes neural representations. More broadly, influence mapping experiments have high sampling (~10,000 neuronal pairs per experiment), are rapid (3-5 hours in duration), and can be performed repeatedly across weeks and in various behavioral states. We anticipate that the influence measurement developed here affords new opportunities for insight into neural circuit function in learning and behavior.

Title: Causal mapping of brainwide dynamics by activity-targeted circuit perturbation

Authors: *N. VLADIMIROV[1], Y. MU[2], J. D. WITTENBACH[2], J. FREEMAN[2], S. PREIBISCH[1], M. AHRENS[2]

Abstract: Controlled perturbations of neural activity are crucial for discovering causal interactions in neural circuits. Neuronal targets for activation and silencing tend to be selected by anatomical location or genetic identity. Much power would be added to experiments if it were possible to perturb large brainwide populations of neurons chosen by how their activity patterns relate to specific aspects of behavior.
We introduce a system for deleting large populations of individual neurons specified by their activity patterns during behavior across the entire larval zebrafish brain. Responses of neurons during behavior are first mapped throughout the brain using light-sheet imaging and fast computational analysis. Selected by response properties and location, groups of individual neurons are then deleted by two-photon laser ablation. Post-perturbation, whole-brain activity and behavior are again recorded and differences analyzed, all in the same fish. We apply this method to brain-wide neuronal responses during visually-evoked swimming behavior. We map the effects of the deletion of specifically-tuned neurons on neural activity and behavior, and find multiple loci that perturb whole-brain dynamics and behavioral responses.
This concurrent whole-brain activity and causality mapping in the same animal promises new insights into the contributions of neuronal populations to brain-wide dynamics and behavior.

Title: Low frequency hippocampal-cortical activity drives brain-wide resting-state functional connectivity: An optogenetic functional MRI study

Authors: *R. W. CHAN[1,2], A. T. L. LEONG[1,2], E. C. WONG[1,2], L. C. HO[1,2], P. P. GAO[1,2], C. M. DONG[1,2], Y. S. CHAN[3], L. W. LIM[3], E. X. WU[1,2]
[1]Lab. of Biomed. Imaging and Signal Processing, [2]Electrical and Electronic Engin., [3]Sch. of Biomed. Sci., The Univ. of Hong Kong, Hong Kong, China

Abstract: The hippocampus, including the dorsal dentate gyrus (dDG), and cortex engage in bidirectional communication. We propose that low frequency activity in hippocampal-cortical pathways underlies brain-wide resting-state connectivity to mediate distinct cognitive functions and integrate sensory information. Since the DG primarily receives cortical terminal projections and acts as a bridge for cortico-hippocampal-cortical network communication, we examined how spatiotemporally specific activity initiated in the dDG influences cortical activity and subsequent brain-wide resting-state functional connectivity by combining optogenetic, cell-specific stimulation of CaMKIIα-expressing excitatory neurons (i.e., dDG granule cells) and large-scale functional MRI (fMRI) detection. Low (0.5-2 Hz), but not high (40 Hz), frequency stimulation of dDG excitatory neurons evoked robust cortical and subcortical fMRI responses. Subsequent local field potential (LFP) recordings revealed that only low frequency stimulation evoked strong LFP responses in bilateral V1, corroborating the fMRI results, though all tested stimulation frequencies evoked LFP responses in dDG. LFP latency measurements indicate that the first evoked responses occurred in the ipsilateral dDG and propagated to the ipsilateral V1 polysynaptically (9.5±1.3ms, $p < 0.001$), before reaching contralateral V1 via monosynaptic interhemispheric callosal connections (4.0±1.5ms, $p < 0.01$). In addition, interhemispheric resting-state fMRI (rsfMRI) connectivity was enhanced in dorsal hippocampus (dHP), primary visual (V1), primary auditory (A1) and primary somatosensory (S1) cortices during and after low, but not high, frequency stimulation. We further observed an increase in infra-slow (<0.1 Hz) rsfMRI BOLD activity in dHP, V1, A1 and S1 during and after low frequency stimulation. Subsequent LFP recordings revealed an increase in slow oscillations in dorsal hippocampus and

visual cortex, interhemispheric visual cortical connectivity, and hippocampal-cortical connectivity. Visually-evoked fMRI responses in visual regions were also increased during and after low frequency dDG stimulation. In addition, after low frequency dDG stimulation, long-term but not short-term memory was improved in novel-object recognition test compared to sham. Our results indicate that low frequency activity propagates in hippocampal-cortical pathway, drives interhemispheric cortical rsfMRI connectivity, mediates visual processing and coordinates long-term memory.

Title: High-density µLED probes on flexible and stiff substrates

Authors: *E. KLEIN, S. AYUB, C. GOSSLER, O. PAUL, P. RUTHER
IMTEK, Univ. of Freiburg, Freiburg Im Breisgau, Germany

Abstract: This paper reports on optical implants with integrated micro light-emitting diodes (µLED) on flexible or rigid substrates for optogenetic applications. The process flow is based on a 6-µm-thick GaN layer grown on a sapphire substrate which is transferred to a carrier wafer [1,2] and subsequently released from the sapphire substrate using a laser-lift-off (LLO) process [3]. This sophisticated wafer-level fabrication process is designed to realize high-density µLEDs arrays for flexible surface probes and rigid penetrating optical probes. The radiant flux of these µLEDs is measured to be 3.5 mW/mm^2 at a current density of 0.5 A/mm^2 for both types of implants, which is sufficient for optogenetic experiments.
In the case of the rigid penetrating probes, the µLEDs are transferred to silicon (Si) wafers which are further processed using deep reactive ion etching and grinding of the wafer [4] to release single probes similar to our Michigan-style recording probes. The direct integration of µLEDs onto the Si probes enables a considerable shrinkage of the overall probe dimensions at an increased LED density compared to probes realized using chip-level LED integration [5]. In

addition to the probe dimensions and µLED density, the wafer-level manufacturing improves the probe precision and the overall process yield. As an example, probes with a shaft length of 8 mm comprising 10 µLEDs at a pitch of 150 µm have been realized. The probes are suitable for acute animal experiments requiring a depth controlled optical stimulation.
For the flexible probes, µLEDs are transferred to a polymer thin film substrate comprising thin-film interconnects and bond pads. The support wafer is equipped with an innovative release mechanism based on sacrificial layers, which guarantees the optimal adhesion of the polymeric substrate during probe processing and enables a stress-free probe release once the probes are finished. The probe technology allows to realize 30-µm-thin flexible probe shanks with integrated GaN µLEDs in a wafer-level fabrication process. The probes achieve bending radii of at least 500 µm enabling the probe insertion into a mouse cochlea [2]. We processed probes of different sizes with shank lengths from 5 to 15 mm as well as 2D arrays both comprising up to 144 µLEDs individually addressable in a matrix configuration. The minimal µLED size realized so far is 50×50 μm^2 at a pitch of 100 µm.

Title: Single-scan, whole-brain functional network mapping using optogenetic fMRI with CBV

Authors: *A. WEITZ[1], M. CHOY[2], B. DUFFY[2], J. LIU[2], J. LEE[1]
[1]Bioengineering, [2]Neurol. and Neurolog. Sci., Stanford Univ., Stanford, CA

Abstract: The combination of optogenetic stimulation with simultaneous fMRI readouts (ofMRI) is an effective method for mapping the brain-wide causal influence of specific genetically- and spatially-defined neuronal populations. However, a limitation shared by previous ofMRI studies has been the large number of scans needed before signal changes are detected. To take full advantage of the ofMRI toolbox, whole-brain functional network mapping should ideally be achievable in a single scan. Here, we investigated whether measurement of cerebral blood volume (CBV) by use of a superparamagnetic iron oxide nanoparticle (SPION)-based contrast agent could enable robust single-scan detections during optogenetic brain stimulation.

To address this question, we used channelrhodopsin to stimulate excitatory neurons of the thalamic submedial nucleus in adult Sprague-Dawley rats (N=13). Prior to imaging, the SPION contrast agent Feraheme was administered through the tail vein to visualize the CBV response. Optical stimuli were presented as a block-design paradigm, with six cycles of 20s stimulation trains presented every minute. In a subset of subjects (N=5), a second series of experiments was conducted to compare single-scan activations between blood-oxygen-level-dependent (BOLD) and CBV measurements. Three consecutive scans of BOLD were collected, followed by three more scans measuring the CBV response after SPION injection.

Standard general linear model analysis techniques could detect significant brain-wide fMRI activations after a single CBV scan. The strongest signals were observed at the site of stimulation and ventrolateral orbital cortex, a major projection site of the stimulated nucleus. Time series from these regions exhibited high SNR, suggesting that robust signal modulations can be measured from a single CBV ofMRI scan. Other regions modulated by stimulation included striatum and motor/somatosensory cortex. When we directly compared BOLD and CBV in the same animal and session with identical anesthetic conditions, we found that BOLD measurement led to minimal activations while CBV again gave robust brain-wide activations. After quantifying total activation volume, we found that single-scan CBV measurements resulted in significantly more activations than a three-scan average of BOLD.

These data confirm that CBV ofMRI is a viable method for single-scan functional brain network mapping. In particular, the improvement in sensitivity afforded by CBV means that brain-wide network dynamics can be visualized and analyzed resulting from only a single - in our case, six minute - scan.

Title: Carbon fiber electrodes for single-unit recording combined with artifact-free MRI

Authors: *M. E. CHUAPOCO[1,2], B. A. DUFFY[2], H. J. LEE[2], M. CHOY[2], J. H. LEE[2,3,4]
[1]Chem. Enginering, [2]Neurol. and Neurolog. Sci., [3]Bioengineering, [4]Electrical Engin., Stanford Univ., Stanford, CA

Abstract: Combining electrophysiology and optogenetic functional magnetic resonance imaging (ofMRI) allows for cellular and network-level investigation of the brain. However, implanted metal microelectrodes used for extracellular depth recordings produce susceptibility artifacts that distort MR images. Recent work in our lab and others has shown that carbon-fiber bundles are a suitable electrode design for simultaneous local field potential (LFP) recordings and ofMRI, but there remains a need to demonstrate that carbon fiber probes can be used for single-unit recording without significantly distorting MR images. To address this need, we adopted an electrode design that uses a single carbon-fiber (~10µm in diameter) functionalized with the conductive polymer PEDOT:pTS and assess its applicability for unit recording and artifact-free MRI.

To quantify the electrical performance of PEDOT:pTS electrodes compared to commonly used metal microelectrodes, we measured the impedance of electrodes across a broad range of frequencies relevant to electrophysiology recordings (1Hz-5kHz). While uncoated carbon-fiber electrodes have higher impedance values compared to silver, platinum-iridium, and tungsten microelectrodes, all fabricated PEDOT:pTS electrode groups have lower impedance values compared to the three metal microelectrodes tested. When viewed using scanning electron

microscopy, the tips of the PEDOT:pTS electrodes show clear morphological changes due to the PEDOT:pTS functionalization. Additionally, when implanted into an agarose phantom, PEDOT:pTS electrodes distort a smaller volume of voxels compared to metal electrodes. These results demonstrate that an electrode design made from a single carbon-fiber may be ideal when trying to combine electrophysiology and ofMRI, as it has superior electrical properties and distorts a smaller volume of voxels compared to commonly used metal microelectrodes. To highlight the in vivo recording capabilities of PEDOT:pTS electrodes, we recorded spontaneous LFP and spiking activity in CA1 of rat hippocampus. PEDOT:pTS electrodes were capable of recording multi-unit activity and after offline spike sorting, distinct single units can be clearly identified. As such, this work lays the foundation for an electrode design that can be used to conduct electrophysiology and artifact-free ofMRI simultaneously. Using a probe that can record LFP and unit activity without distorting MR images during ofMRI will enable us to capture more information in regions of interest and enable us to build a more complete functional model of the brain.

Title: Motor- versus sensory- neuron selective optogenetic stimulation. Cell autonomously enhanced axon regeneration

Authors: *P. J. WARD, S. CLANTON, A. ENGLISH
Emory Univ. Dept. of Cell Biol., Atlanta, GA

Abstract: Brief neuronal activation in injured peripheral nerves is both necessary and sufficient to enhance axon regeneration, and this effect is specific to the activated motoneurons. It is unknown whether sensory neurons respond in a similar manner to neuronal activation following peripheral axotomy. Furthermore, it is unknown to what extent enhancement of axon regeneration with increased neuronal activity relies on a reflexive interaction within the spinal circuitry. We used mouse genetics and optical tools to evaluate the specificity and selectivity of system-selective neuronal activation to enhance axon regeneration in a mixed nerve. MODEL:

We evaluated sensory and motor axon regeneration in two different mouse models expressing the light-sensitive cation channel, channelrhodopsin (ChR2). We selectively activated sensory or motor axons using light stimulation immediately prior to transection and repair of the sciatic nerve. Regardless of genotype, the number of ChR2-positive neurons was greater following system-selective optical treatment, with no effect on the ChR2-negative neurons (whether motor or sensory neurons). CONCLUSIONS: Until now, it has been impossible to limit neuronal activation to sensory or motor axons alone in a mixed nerve. Medical advances will soon make this a possibility in human patients and may have desirable or undesirable effects on functional recovery depending on the nerve to be treated.We conclude that acute system-selective neuronal activation is sufficient to enhance motor and sensory axon regeneration. This regeneration-enhancing effect cell autonomous.

Title: Genetically encoded light sources for non-invasive optogenetics

Authors: *T. M. BROWN[1], G. G. LAMBERT[2], A. PAL[1], M. PRAKASH[1], N. C. SHANER[2], U. HOCHGESCHWENDER[1]

Abstract: Optogenetics is the use of light to manipulate light sensing molecules, opsins. Activation of these light-gated ion channels and pumps, when expressed by neurons, results in depolarization or hyperpolarization of cell membranes. This allows activation and silencing of neuronal circuits in behaving experimental animals via light fibers implanted into the animal's brain. We proposed a strategy for non-invasive optogenetics by switching out the light source from an invasive physical to a non-invasive biological one, i.e., a light producing protein, or luciferase. The luciferase emits light, activating the optogenetic actuator upon application of its

small-molecule substrate, coelenterazine (CTZ). We engineered fusion proteins of a light-emitting luciferase to an optogenetic light-responsive element, resulting in a luminescent opsin, or luminopsin. Activation of fused opsins will be more efficient as the light emission of the luciferase increases. One way to increase light output of luciferases is to couple them to fluorescent proteins to take advantage of BRET (bioluminescent resonance energy transfer). This class of probe is far brighter than the parental luciferase enzyme because the quantum efficiency of emission is governed not by the luciferase enzyme, but rather by the fluorescence quantum yield of the BRET acceptor. We performed mutant library screenings in E. coli towards directed evolution of luciferases to improve their enzymatic activity and towards linker length, composition, and domain geometry of BRET probes for optimization of their efficiency. The brightest new BRET probes were codon-optimized and fused to optogenetic actuators. Fusion proteins were expressed in primary cultured neurons and assessed for their effects on activating and silencing neurons in multi electrode arrays (MEAs). New luminopsin constructs had robust expression, increased light emission compared to previously used luciferase variants, and showed efficient activation of opsins by increasing and decreasing spiking of cultured neurons.

Title: Bioluminescence driven optogenetics for investigating functional synaptic communication

Authors: *M. PRAKASH[1], R. LAURENT[4], A. PAL[2], B. W. CONNORS[5], D. LIPSCOMBE[6], J. A. KAUER[7], C. I. MOORE[8], U. HOCHGESCHWENDER[3]

Abstract: In BioLuminescent driven OptoGenetics (BL-OG) a genetically encoded light source, a luciferase, activates a light-sensing optogenetic element, a channelrhodopsin or a pump. When light emitter and light sensor are tethered, as in luciferase-opsin fusion proteins (luminopsins, LMO), application of luciferase substrate and subsequent light production will change the membrane potential of the cell expressing the LMO. Here we placed the two moieties in pre- and postsynaptic ends of neurons with the goal of achieving BL-OG across the synapse. Neurons isolated from E18 rat cortex were nucleofected either with a pre-synaptically targeted luciferase construct (sbGLuc) or the anion channelrhodopsin iChloC, and were mixed and plated at a 1:1 ratio on 64 electrode 1-well multi-electrode array (MEA) dishes. The above two populations were also individually plated as controls. Silencing of spontaneous neuronal spiking activity through iChloC activation was assessed between DIV 14-21. Blue light (470 nm) from an arc lamp was used to silence iChloC expressing neurons directly, while application of the luciferase substrate coelenterazine (CTZ; final concentration 100μM) was used to silence iChloC expressing neurons across synapses. Assessment of spiking activity showed that for a number of individual electrodes CTZ treatment resulted in a similar pattern of silencing as seen with blue light stimulation. For electrodes that showed similar responses to CTZ treatment and blue light pulses, silencing with CTZ was likely due to trans-synaptic light-activation of iChloC channels. The overall extent of silencing after CTZ application to MEA cultures with mixed populations of luciferase and iChloC expressing neurons was significantly higher compared to cultures of individual populations. Such light activation across synaptic partners, interluminescence, offers the potential to optogenetically dissect synaptic communication in genetically determined neuronal partner populations.

Abstract: The development of optogenetics has fostered significant progress in neuroscience by enabling high spatio-temporal control of genetically identified cell populations. Optogenetics is an appealing tool for dissecting neural circuits, and controlling dysfunctional cell ensembles underlying pathological disorders. However, there are several barriers that limit the use of optogenetics in-vivo. In particular, invasive devices used for light delivery (e.g., optical fibers) can be perilous because implants represent a potential path for pathogens to reach the brain. Further, targeting multiple disparate foci can be punitive because it requires inserting several optical fibers that may cause tissue damage. To partly meet these needs, we devised the BioLuminescence-OptoGenetics (BL-OG) method, which leverages bioluminescence (BL) to activate optogenetic elements. In our BL-OG construct, the slow-burn Gaussia luciferase (sbGLuc) is tethered to Volvox-Channelrhodopsin1 (VCHR1), and BL is generated when Coelenterazine (CTZ), the substrate for Gaussia luciferase, is catalyzed by sbGLuc. While we and others have shown that BL-OG can modulate neural activity, there remain major follow-up questions to demonstrate that BL-OG can be a viable strategy for controlling cells' activity in-vivo. Here, we assayed whether BL-OG can be used as a gain modulator by studying whether increases in BL lead to corresponding changes in neural firing. Further, we probed whether BL-OG enhances cells' sensitivity to sensory stimuli, and whether BL-OG can be used to track and dynamically control cells' activity in-vivo. We injected the sbGLuc+VCHR1 construct in mice primary somatosensory cortex (SI), and performed simultaneous BL imaging and electrophysiological recordings while stimulating animals' whiskers prior to and after CTZ injections. Our data revealed a positive relationship between BL and neural firing, and that BL-OG enhanced stimulus-evoked activity of SI neurons. These data indicate that BL-OG systematically regulates cells' activity in-vivo. In a separate set of mice, we injected a calcium-sensitive bioluminescent molecule by splitting the sb-GLuc and linking the components with the calmodulin-M13 peptide sequence. Pilot data revealed increased BL activity during periods of high calcium concentrations. Our data provide evidence that BL-OG can be used to dynamically control the gain of cells in-vivo.

Abstract: Calcium (Ca^{2+}) is an essential second messenger that is involved in a multitude of physiological functions ranging from cellular apoptosis to neuronal firing. Therefore, in vivo Ca^{2+} imaging is a very sought after technique. We have split a mutated version of *Gaussi*a luciferase, sbGLuc, known for its high light emission, and introduced the Ca^{2+} sensing moiety Calmodulin-M13 (CaM-M13) between the two split halves, generating Lumicampsin (LMC). In the presence of both Ca^{2+} and the luciferase substrate, coelenterazine (CTZ), the enzyme emits light. Since the dynamics of Ca^{2+} flux vary quite extensively between different organelles and cytoplasmic regions, we have fitted LMC with signaling sequences such that it is localized to various organelles (ER, Golgi, Mitochondria) or is suspended from the inner cell membrane. We transfected HEK293 and Hela cells with these different versions of LMCs and found that they have robust expression, display specific subcellular localization, and faithfully report the calcium dynamics of the site they were localized to. Lastly, LMC reported Ca^{2+} spikes in Hela cells *in vitro* and in mouse barrel cortex *in vivo*.

Title: Chronic activation of dopaminergic neurons via opto-chemogenetics provides neuroprotection in a rodent model of Parkinson's disease

Authors: *F. SHIU[1], K. BERGLUND[2], A. M. FERNANDEZ[1], J. K. TUNG[3], K. MANDI[1], C.-A. N. GUTEKUNST[4], R. E. GROSS[5]

Abstract: Parkinson's disease (PD) linked to reduced dopamine (DA) levels in the striatum resulted from loss of DA neurons in the substantia nigra (SN). Previous studies have shown neuroprotective effect in physical exercise in rodent models of PD, and people who exercise often have the lowest risk of PD. This neuroprotection may be due to enhanced activity of DA neurons in SN during exercise. In this study, we tested whether increasing activity of DA neurons in the SN could protect them from neurodegeneration induced by 6-hydroxydopamine (6-OHDA) in mice. To increase activity of DA neurons, we used luminopsin, a fusion protein of channelrhodopsin (ChR) and luciferase. Upon application of its substrate coelenterazine (CTZ), the luciferase moiety of luminopsin emits bioluminescence which in turn activate the opsin moiety. To prolong its action for chronic stimulation, we developed a new luminopsin called step-function luminopsin (SFL) based on stabilized step-function opsin (SSFO) and mutated *Gaussia* luciferase which provides blue bioluminescence to SSFO. The SFL gene under control of the human synapsin I promoter was delivered to the SN via unilateral injection of an AAV vector before lesioning the ipsilateral striatum with 6-OHDA. To chronically activate neurons in the SN, CTZ was given daily to the mice for 20 consecutive days starting 5 days before 6-OHDA injection. Unilateral lesioning of DA neurons in the SN resulted in a stereotypical behavior, namely ipsiversive rotations. We assessed this behavior before, 1 week, and 2 weeks after 6-OHDA injections. At the end of experiments, the mice were subjected to immunohistochemistry for DA neurons in the SN. We did not observe a significant difference at any time point between the CTZ group and the control group which received daily injections of vehicle instead. However, there was a significant reduction in rotations from day 7 to day 14 in the CTZ group, but not in the control group. To specifically target DA neurons in SN with SFL, we then repeated the experiments using a conditional expression system, namely transgenic mice expressing Cre recombinase under control of the tyrosine hydroxylase promoter and an AAV vector with the inverted SFL gene and loxP sites. When SFL was specifically expressed in DA neurons in the SN, we observed significantly smaller number of rotations in the CTZ group in day 7 and day14 compared to the control group. These results indicate that neuronal activity of DA neurons provided neuroprotection against 6-OHDA injury and that chronic opto-chemogenetic stimulation with luminopsin could alleviate a symptom in a rodent model of PD.

Title: Optogenetic stimulation and hypoxic preconditioning enhanced wound healing and protection against inflammatory injury

Authors: *Z. Z. WEI[1,2], Y. B. ZHANG[2], J. Y. ZHANG[1], K. I. BURGLUND[3], M. R. MCCRARY[1], J. M. LI[2], L. WEI[1], S. P. YU[1]

Abstract: Cell transplantation therapy aims to promote tissue repair and functional recovery after brain injury such as ischemic stroke. Transplanted cells, however, may die from a variety of injurious mechanisms in the post-stroke brain. We previously developed a hypoxic preconditioning strategy for enhancing cell survival and the efficacy of stem cell transplantation therapy. Cells with hypoxic preconditioning showed enhanced viability, migration, differentiation, and paracrine potentials. In the present investigation, we explored the application of an optogenetic/chemogenetic approach using cells expressing the light sensitive excitatory channel protein Channelrhodopsin 2 (ChR2) or a bioluminescent luciferase luminopsin 3 (LMO3) and an opsin, Volvox Channelrhodopsin 1 (VChR1). The goal of the study is to enhance activity-dependent therapeutic potentials of transplanted cells. Human HEK293 cells and mouse neural progenitor cells (NPCs) were infected with ChR2 or LMO3-VChR1 virus. Cells were subjected to inflammation triggers including lipopolysaccharides (LPS) and/or oxygen-glucose

deprivation (OGD). 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) and wound-healing tests showed that co-applied or delayed treatment of optogenetic (10 Hz, 15 min/day) or chemogenetic (1.5 μM coelenterazine, 15 min/day) stimulation increased cell survival and homing to the injury region. We further analyzed the regulation of regenerative factors such as BDNF, SDF-1 and VEGF, and inflammatory/anti-inflammatory genes such as CD16, CD32, CD86, CD11b, TNF-α, IL-1β, CD206, Arg1, Ym1, IL-10 and TGFβ. ELISA assays were performed to measure soluble factors. In conclusion, optogenetic/chemogenetic stimulation may enhance cell therapy by generating an enriched environment with increased regenerative factors and reduced inflammation, which is favorable for cell survival and increased regenerative properties. We also propose that the chemogenetic approach using luciferase-luminopsins can be further developed as a non-invasive strategy to enhance the efficacy and efficiency of stem cell transplantation therapy.

Title: Manipulation of sleep activity using optogenetic stimulation

Authors: *D. A. JOHNSON, E. NAYLOR, S. GABBERT, D. V. AILLON, D. A. JOHNSON
Pinnacle Technology, Inc, Lawrence, KS

Abstract: The integration of optogenetics and *in vivo* brain responses requires researchers to coordinate disparate tools and timing issues. Standardized techniques and turn-key systems allow researchers to focus on the experiment and not equipment design. Pinnacle's latest system integrates LED optogenetics with EEG and EMG recordings for sleep studies in freely moving mice and rats. In validation experiments using channelrhodopsin-2 transgenic mice, alternating a blue light (445 nm) pulse (10 sec on: 10 sec off) at 40 Hz significantly increased waking activity by 51% while decreasing NREM sleep by 43% and REM sleep by 41% ($p<0.001$) compared to periods with no optical stimulation. This 40 Hz stimulation also increased both frontal (EEG 2) and posterior (EEG 1) gamma activity (25 - 40 Hz). However, a 0.1 Hz pulse protocol only increased gamma activity in the frontal cortex (EEG 2). All experiments used transgenic mice expressing channelrhodopsin 2 in the hippocampus and cortical regions [(Thy1-COP4/EYFP)9Gfng - Jackson Laboratory]. Mice were surgically implanted with two guide

cannulas (BASi, West Lafayette, IN) placed bilaterally in the thalamus along with cortical EEG and intermuscular EMG leads. All surgical procedures were approved by the University of Kansas IACUC. After recovery from surgery (1 wk) blue (445 nm) LED fiber probes were inserted into both cannulas and connected to a head-mounted preamplifier unit. For manipulation of sleep activity, transgenic mice (n=2) were bilaterally stimulated in the thalamic region using either a 0.1 Hz 20 ms stim (pulse protocol) or 40 Hz, 10% duty cycle in alternating 10 second periods (40 Hz protocol). Both protocols were applied in a cycle of 1 hour on 1 hour off for five cycles beginning at 10:00 AM. As a control, the experiment was repeated in the same mice using red (660 nm) LED fiber probes with no changes noted in sleep or gamma activity during periods of stimulation.

Title: Optogenetic and pharmacological resting-state functional MRI reveals thalamic modulation of brain-wide functional connectivity

Authors: *A. T. LEONG[1,2], X. WANG[1,2], R. W. CHAN[1,2], C. M. DONG[1,2], W.-H. YUNG[3], Y.-S. CHAN[4], K. K. TSIA[2], E. X. WU[1,2]

Abstract: The brain is a highly complex, interconnected structure with parallel and hierarchical networks distributed within and between neural systems. Functional connectivity mapping using resting-state functional MRI (rsfMRI) enables non-invasive visualization of brain-wide networks in humans and animals through coherent infra-slow (<0.1Hz) hemodynamic/BOLD activity. However, the exact underlying neural bases and functional significance remain unclear. Previous studies integrating large-scale electrical or Ca^{2+} recordings imply that slow, oscillating neural activity (<1Hz) constraints and elicits these rsfMRI BOLD activities. This indicates that interrogating the brain's underlying electrical activity can provide mechanistic insights into brain-wide rsfMRI connectivity. Numerous long-range networks exist, subserving the functions of particular systems and their interactions. One classical example is the thalamo-cortical-thalamic network, which interconnects the thalamus and neocortex via thalamo-cortical and cortico-thalamic projections. In this study, we optogenetically stimulate ventral posteromedial thalamus (VPM) thalamocortical excitatory neurons and pharmacologically inactivate VPM thalamocortical neurons, to investigate whether modulating and/or disrupting the neural activity of such an integral brain network could uncover the neural bases of rsfMRI. Optogenetic control of VPM thalamocortical excitatory neurons in adult male Sprague-Dawley rats was enabled through AAV5-CaMKIIα-ChR2(H134R). RsfMRI scans were performed before, during (i.e., 1Hz, 473nm, 10% duty cycle, 40mW/mm^2) and after optogenetic stimulation. Inactivation of VPM was enabled through the use of Tetrodotoxin (TTX; 5ul, 5ng/uL). Our results demonstrated that optogenetic excitation of the VPM thalamocortical excitatory neurons at 1Hz enhanced brain-wide rsfMRI connectivity, specifically somatosensory, visual and auditory networks, whereas, TTX inactivation of VPM decreased rsfMRI connectivity. Spectral analysis indicated that such changes were underpinned by neuromodulatory effects on the infra-slow rsfMRI BOLD activity. Our study suggests that 1Hz optogenetic stimulation of VPM initiates slow oscillations that may couple with infra-slow oscillations, leading to enhanced rsfMRI connectivity. Whereas, TTX inactivation of VPM disrupts the initiation or propagation of these oscillations, decreasing rsfMRI connectivity. By manipulating the specific activities within the thalamo-cortical-thalamic network, optogenetic rsfMRI presents a powerful approach to dissect the neural bases of rsfMRI connectivity.

Abstract: Optogenetics is a powerful research approach that allows localized electrical modulation of selected cells within an animal via the expression of genetically encoded photo-excitable ion channels. Commonly used optogentic techniques rely on the expression of microbial opsin variants, which have many excellent features but suffer from various degrees of blue spectral overlap and limited channel conductance. Here, we expand the optogenetics toolbox in the form of a tunable, high-conductance vertebrate cation channel, zTrpa1b, coupled with photo-activated channel ligands, such as optovin and 4g6. Our results demonstrate that zTrpa1b/ligand pairing offers high light sensitivity, millisecond-scale response latency, as well as adjustable channel off latency. Exogenous *in vivo* expression of zTrpa1b in sensory neurons allowed subcellular photo-activation, enabling light-dependent motor control. zTrpa1b/ligand was also suitable for cardiomyocyte pacing, as shown in experiments performed on zebrafish hearts *in vivo* as well as in human stem cell-derived cardiomyocytes *in vitro*. Therefore, zTrpa1b/optovin represents a novel tool for flexible, high-conductance optogenetics.

Abstract: Tapered optical fibers (TF) recently emerged as an important complement to existing light- delivery methods for in vivo optogenetics [1,2,3]. Here we review our recent advancements in the fabrication, development and *in vivo* use of these devices towards spatio-temporal control and simultaneous extracellular readout of neural activity.
We used TFs with a low taper angle (<4°) to obtain dynamically reconfigurable light delivery over neural structures extending from ~0.5 mm to 2 mm. The exploitation of mode division de-multiplexing properties of the fiber taper allows for two operation modalities:(i)uniform illumination of wide neural volumes obtained by injecting light within the fiber full numerical aperture [1]; (ii) spatial subsampling of the region of interest with a selectivity of a few hundreds of micrometers in the dorso-ventral direction obtained by changing the light coupling angle at the fiber input [1]. Light delivery volumes can also be confined to a few tens of micrometers by opening small optical windows on a light-shielding metal layer deposited all around the taper [2,3]. These small excitation spots, obtained by Focused Ion Beam milling or by direct laser writing, can be selectively activated by changing the light input angle [2,3].
When compared with bare TFs, this latter fabrication approach offers additional flexibility in the geometrical design of light-emitting regions, as light output can be tailored to experimental demands. For example, layer-selective light-delivery can be targeted to cortical sub-regions by fabricating ring-shaped windows around the taper. Metallized TF devices can also be empowered with further micro-fabrication processing. This allowed us to realize micro-electrodes for extracellular recording next to light-delivery spots. This was done by coating the taper with multiple metal layers that were mutually insulated by interfacing each metal surface with a parylene-c deposition. Platinum electrodes were then fabricated in milled recesses of the metal surfaces by Ion Beam Induced Deposition. These electrodes, that have impedances comparable to commercial devices, can successfully record single unit activity and LFPs signals *in vivo*. All these devices have been tested *in vivo* in both head- restrained and free moving mice.

Abstract: The ability to control the excitability of a neuronal sub-population with high spatiotemporal precision and resolution is desirable for dissecting circuit mechanisms underlying perception or behaviour. Optogenetics makes such selective manipulation feasible by combining the suitable optical method to activate or inactivate neurons that are genetically encoded with light-sensitive opsins. Two-photon (2P) parallel light-patterning with phase modulation is an effective approach to actuate opsins expressed in neurons situated deeper in the brain with enhanced temporal resolution. Here, we propose an optical system using computer-generated holography and temporal focusing for 2P optogenetic activation. Combined with an amplified laser (emission wavelength λ=1030 nm, maximum output pulse energy 20 μJ, maximum average power 10 W) our system achieves suprathreshold activation with a localized holographic spot (12 μm in diameter, 10 μm Full Width at Half Maximum optical axial resolution) of low illumination power density (0.1-0.2 mW/μm^2) and short light-pulses (2-15 ms) in layer 2/3 neurons of anesthetized mouse visual cortex *in vivo*. Using 2P-guided whole-cell or cell-attached recordings, we found that positive neurons expressing either of the three opsins, ReaChR, CoChR, or ChrimsonR, elicit spikes of small peak latencies and sub-millisecond jittering. In addition, trains of action potentials were induced in positive neurons following repetitive light-pulses up to tens of Hz. Our optical system for 2P holographic photostimulation is advantageous for altering presynaptic inputs in identifying neuronal connections. Further, it can be flexibly

combined with functional imaging methods for all-optical investigation of specific circuit dynamics.

Abstract: In the past ten years, optogenetics has been established as the key method to control the activity of specific neuronal populations using light. A major challenge is to develop innovative optical tools to target individual neurons that are distributed in three dimensions (3D) in the brain, at high spatiotemporal resolution and precision. In pioneering experiments using phase modulation methods, such as Computer-Generated Holography (CGH), in combination with temporal focusing (TF), we have demonstrated the generation of arbitrary light excitation patterns with preserved axial resolution and used this approach for neuronal activation in brain slices. Most recently, we have extended this method to the generation of spatiotemporally focused patterns at axially distinct planes by demonstrating a new configuration based on the use of two spatial light modulators (SLMs) that can jointly translate single or multiple temporally focused holographic targets. This strategy, however, was intrinsically limited to few axial planes. Here, we propose a novel optical system overcoming this limitation and capable of simultaneous

generation of hundreds of illumination targets arbitrarily arranged in 3D, with an axial resolution decoupled from the lateral size. The scheme comprises: i) a phase SLM to create a user defined two-dimensional shape, ii) a diffraction grating, placed at the image plane of the SLM to perform temporal focusing, and iii) a second SLM placed after the grating to generate multiple replicates of the original shape at distinct lateral and axial positions. The number of available replicas is now only limited by the number of illuminated pixels at the second SLM, which, compared to previous techniques, provides an increase of at least one order of magnitude in the number of different planes that can be simultaneously addressed at the sample position.
We demonstrate parallel projection of at least 50 high-resolution spots of 15 μm diameter in a volume of 300x300x500 μm^3. Finally, by combining the system with high-power Ytterbium fiber laser systems, we demonstrate that the power available at each replicated spot enables *in vivo* optogenetics control of neuronal activity in layer 2/3 of anesthetized mouse visual cortex.
The approach proposed here for performing 3D photostimulation with single neuron spatial resolution combined with two-photon excitation imaging opens the way for all-optical manipulation of neural circuits with unprecedented spatiotemporal specificity.

Abstract: A major purpose of sensory neuroscience is to understand how a neural circuit generates complex activity patterns in response to sensory stimuli. While recent works have

made possible to access the full connectome of a neural circuit, there is still a gap between its detailed anatomical reconstruction, and the functional characterization of its neural responses. To bridge this gap, we need to understand how the perturbation of each neuron will influence the activity of the circuit, and reconstruct the complete functional connectivity diagram.
The retina transforms the visual scene in spikes and transfers them to the brain. Photoreceptors transduce light into electrical currents, bipolar cells process this signal and transmit it to ganglion cells, which send spikes to the brain A key component of retinal processing is the information transfer from the intermediate bipolar cell layer to the ganglion cell layer. Our understanding of this transfer is limited: while multi-electrode arrays allow recording large populations of ganglion cells, bipolar cells cannot be easily recorded or stimulated in the intact retinal circuit Here we present a novel method where we combined several techniques to record ganglion cells with multi-electrode arrays while perturbing individual bipolar cells using optical and optogenetic tools. We used an AAV and a specific promoter to express light sensitive proteins selectively in rod bipolar cells. We then used 2 photon computer generated holography, a technique to pattern light to stimulate individual neurons, while simultaneously recording ganglion cells with a multi-electrode array. Thanks to this combination of optical and electrophysiological tools, we could stimulate selectively rod bipolar cells and record the impact of this stimulation on the spiking activity of ganglion cells. Our method also allowed us to stimulate several bipolar cells simultaneously to measure the impact of complex stimulation patterns on the ganglion cell layer.
We are currently using this technique to understand how each type of ganglion cell is modulated by rod bipolar cells. This method allows a precise probing of the retinal circuit and paves the way towards complete functional connectomics of the retina

Title: Widespread functional opsin transduction in the rat cortex via convection-enhanced delivery

Authors: *Z. YU[1], I. OZDEN[1,2], A. V. NURMIKKO[1]
[1]Sch. of Engin., Brown Univ., Providence, RI; [2]Dept. of Bioengineering, Univ. of Missouri, Columbia, MO

Abstract: For studies on the functions of the cortex, a planar structure with distributed functional regions, spatially and temporally controlled optogenetic perturbations require opsin expressions over widespread areas. However widespread opsin expression in the cortex of rats, where transgenic models for optogenetics have not been established, is not practical to achieve with the traditional diffusion-based virus transduction methods (DBD).
Here we report protocols developed for convection-enhanced delivery (CED) of virus for optogenetic transduction in the cortex of rats. Targeting the motor forelimb area as an example, we performed dual-site CED (6 μL of virus per site, 3 mm distance between sites) in the rat motor cortex.
We demonstrated widespread opsin expression over large cortical area (8.2 ± 1.4 mm in the AP direction, 4.9 ± 0.4 mm in the ML direction, N = 7 rats). Compared with the conventional DBD method, we achieved about 160-fold increase in the volume and 60-fold increase in the cross-sectional area of opsin expression. The total injection time was also reduced by at least 10 times, if similar spatial extent of expression were to be achieved with the DBD method. The optogenetic transduction was functionally robust that both optical modulation of neuronal activity and elicitation of overt motor responses were reliably observed. Around the site of each CED infusion, a region of diminished opsin expression was commonly found (0.43 ± 0.10 mm in diameter). While we were unable to rule out the possibility of tissue damage due to high infusion rates, we did not find significant reduction in neuronal population density (NeuN) or increase in astroglial scarring (GFAP) in the vicinity of the injection site. However, to minimize the influence of the potential confounding factors due to damages at the injection sites, we purposefully chose to perform the dual-site injection at the perimeter of the region-of-interest. We believe that the adaptation of CED technique to rat cortex, as introduced here, will not only benefit optogenetics studies, but also others where widespread cortical coverage is required.

Abstract: Optogenetic techniques have greatly advanced our ability to assess neural circuitry. The use of transgenic animals has allowed for increased precision with these techniques. The Thy1-ChR2 transgenic mouse is among the most commonly used transgenic optogenetic lines. The Thy1 promoter is developmentally expressed resulting in variable expression patterns between (but not within) founder lines. The expression patterns of ChR2 in the various founder lines have been characterized generally, but detailed cell-specificity has not yet been examined. An understanding of such expression can allow for a more robust interpretation of experimental results when using these optogenetic techniques. To address this need we compared expression of ChR2 in founder line 18, to expression profiles of cell specific markers in CA1 of the hippocampus using immunohistochemistry. Neurons expressing ChR2 were localized to the deep calbindin-negative sublayer of CA1 and were not colocalized with calbindin (R=0.054 +/- 0.030, n=15) or parvalbumin (R=0.200 +/- 0.041, n=14) expressing interneurons. These results highlight the utility of Thy1-ChR2-YFP line 18 mice to examine the functional role of excitatory neurons in deep CA1 pyramidal cell sublayer. These mice represent the first example of specific expression in this cell-type and should serve as a powerful model for those studying hippocampal microcircuitry.

Title: Optical manipulation of neural activity with cellular resolution *In vivo*

Authors: A. FORLI, N. BININI, D. VECCHIA, S. BOVETTI, C. MORETTI, *T. FELLIN
Inst. Italiano di Tecnologia, Genova, Italy

Abstract: Sensory information is encoded within the brain in the form of distributed spatial and temporal patterns of neuronal activity. To causally test which specific features of the sensory stimulus are encoded by these activity patterns and how this information is used to drive behavior, we need a method to perturb with single-cell resolution the activity of the multiple cell types that are engaged in sensory processing. To this goal, we combined two-photon digital holography using liquid crystal spatial light modulators to control the size and shape of the two-photon excitation volume (patterned illumination) with viral delivery of channelrhodopsin-2 (ChR2) in various cellular populations of the mouse somatosensory cortex. We validated our approach performing juxtasomal electrophysiological recordings from ChR2-positive cells during patterned illumination of their cell-body with extended shapes in anesthetized animals. Despite differences in input resistance and membrane conductance, we found that layer II/III principal neurons, parvalbumin-positive interneurons, somatostatin-positive cells, and layer IV excitatory neurons all significantly increased their firing rate in response to patterned illumination. The firing probability during patterned illumination increased with stimulation power and moving the excitation volume away from the cell body in the radial or axial directions decreased stimulation efficiency with cell-type specific spatial constants. Ongoing efforts are focused on applying patterned illumination in awake mice, in order to investigate how the concerted activity of single neurons contributes to network function and behavior.

Title: Fiberless optogenetics to manipulate neuronal activity in both *Ex vivo* and *In vivo*

Authors: *S. CHOWDHURY[1], T. MIYAZAKI[2], H. YAWO[3], A. YAMANAKA[2]
[1]Neurosci. II, RIEM, Nagoya Univ., Nagoya, Japan; [2]Res. Inst. of Envrn. Medicine, Nagoya Univ., Nagoya, Japan; [3]Tohoku Univ. Grad Sch. Life Sci., Sendai, Japan

Abstract: Brains exert their functions by forming complex neuronal networks. Last decades, optogenetics emerges as a powerful tool to decipher neuronal basis underlying intricate behaviors. However, the conventional optogenetics method requires optical fiber insertion due to low tissue permeability of visible light. It causes tissue damage and behavioral restriction. To address these problems, we developed a noble technique to manipulate neurons by using near-infrared light (NIR) which has high tissue permeability. Here, we used lanthanide-based up-conversion, which convert long wavelength NIR to shorter wavelength of visible light. This fiberless optogenetics allows us to manipulate neuronal activity in both *ex vivo* and *in vivo*. We first expressed three different channelrhodopsins: ChR2, C1V1, and ChrimsonR in HEK293 cells and recorded membrane current at holding potential of -60 mV. Cover glass containing HEK293 cells were placed on the sheet containing lanthanide (20 mg/ml). NIR was then illuminated through the objective lens. Lanthanide, NaYF4:Yb/Er, which converts NIR (976 nm) to green light (540 nm) generated the largest membrane current on HEK293 cell expressing C1V1. We next studied the permeability of NIR in mice brain, skull, and skin. We targeted two different brain area, the dorsal striatum (dSTR, ~2.0 mm depth from brain surface) and medial prefrontal cortex (mPFC, ~1.5 mm depth from brain surface). Adeno-associated virus vector containing gene to express C1V1 was infected in the dSTR or mPFC of mice brain. Brain slice recording on the lanthanide sheet confirmed that NIR can depolarize and induce firing in C1V1 expressing dSTR and mPFC neurons. Next, lanthanide particles (20 mg/ml) were injected in the same brain area expressing C1V1. NIR illumination induced increased locomotor activity in these mice. However, NIR itself did not induce increased locomotor activity in lanthanide alone or C1V1 alone injected mice, suggesting that up-conversion light emitted from lanthanide activated neighboring neurons expressing C1V1 *in vivo*. These data represented the feasibility of fiberless optogenetics in freely behaving mice.

Abstract: Optogenetics is a powerful method to control brain activity with light, and therefore to create detailed maps and models of brain circuitry. However, some very recent studies pointed out possible adverse effects of heating induced by tissue illumination, including tissue damage, spiking rate increase and fMRI artifacts due to light-driven vasodilation [1, 2]. Here we show that tapered optical fibers (TF) with a low taper angle [3] can be used to deliver light in wider brain volumes with reduced heat gradients with respect to flat fibers (FF) commonly used to deliver light into the brain. We modeled light intensity from TFs as single photons emitted with an angle with respect to the fiber axis and at specific positions along the taper, as retrieved by experiments and ray tracing simulation. These data were used as initial condition in a Monte Carlo simulation [2] that, based on tissue absorption and scattering parameters, allowed estimate the temperature increase affecting cells around the fiber. The code also returns the estimated light intensity distribution around the taper, allowing for a comparison with experimental data and used as a control simulation to assure the reliability of the implemented algorithm. We simulated three different types of tapered fiber with Numerical Apertures 0.22, 0.39 and 0.66 and taper angles 2.2°, 2.9°, 4° that allow homogeneous light delivery in dorso-ventral structures extending ~750 μm, ~1300 μm and ~1800 μm, respectively. When delivering a total of 5mW at 473nm into the brain, this resulted in an illuminated volume with powers >1mW/mm^2 of 330430 μm^3, 358130 μm^3, 389590 μm^3 with temperature gradients of 1.14°C, 0.85°C and 0.65°C for the 0.22, 0.39 and 0.66 TF. For the same light power, a FF with 200/225um core/cladding diameters allows light delivery >1mW/mm^2 on a volume of of 84000 μm^3 with a heat gradient of 2.5°C. A similar trend was observed at red-shifted wavelengths (560nm), although the illuminated volume increases and the temperature gradient decreases for both FFs and TFs. In summary, we suggest that tapered optical fibers can be used to obtain wider brain stimulation with lower temperature increase and smaller heat gradients with respect to flat-cleaved fibers.

Title: Extending optical techniques to deep brain regions through minimally invasive, splaying optical microfibers

Authors: *N. PERKINS[1], D. SEMU[2], J. SHEN[2], T. J. GARDNER[2]
[2]Dept. of Biol., [1]Boston Univ., Boston, MA

Abstract: Rapidly advancing optical techniques for recording from and manipulating neural activity have been constrained to more superficial brain regions due to light scattering. Developments in multiphoton microscopy have enabled recording up to 1mm below the surface, while implants, such as GRIN lenses and microprisms have expanded the reach of optical techniques, but with costs in terms of constrained, head-fixed recording paradigms and tissue damage at and around the implant.

Based on the principles of fiber photometry, we have developed implantable bundles of hundreds or thousands of optical microfibers, with diameters between 6μm and 8μm. During insertion, each fiber moves independently, following a path of least resistance and splaying through the target region. The small cross section of each fiber minimizes both neuronal damage and tissue response. Previously shared histology from implants in the zebra finch basal ganglia (depth of 2.9mm) showed consistent splay with an average distance of 22.9μm between neighboring fibers; immunohistochemical staining after chronic implants (3+ months) revealed neurons in close proximity to the fibers, indicative of minimal tissue damage.

The fibers exhibit total internal reflection due to the difference in the refractive index between the core (4.4μm diameter) and the cladding, enabling each fiber to bidirectionally interface with a small volume of neurons near the tip (an average of 2.8 projection neurons in the 18,000μm^3 volume that is accessible [>0.1 normalized fluence] to each fiber). The fibers have the potential to collect fluorescent traces from genetically encoded calcium or voltage indicators, as well as to stimulate opsins.

At our poster, we will present efforts to record calcium traces via the optical microfibers from the zebra finch basal ganglia and evaluate these efforts against a model of the underlying optics and mixing process that takes place as a result of the incoherent splaying of the fibers during insertion. From the model and from these initial recordings, we plan to estimate the distribution of signals reaching each fiber and how this linear mixing process can be reversed.

These initial recordings demonstrate the feasibility of using optical microfibers to extend the

powerful suite of optical techniques to previously inaccessible deep brain regions, providing a minimally invasive, bidirectional, multichannel interface for reading and modifying neural activity.

Abstract: Striatal fetal ventral mesencephalic (FVM) transplants are under investigation again after a period of moratorium as an experimental therapy in Parkinson's disease (PD) patients. However, a concern with FVM transplants is the risk of developing disabling graft-induced dyskinesias (GID). We tested the therapeutic efficacy of optogenetic and chemogenetic inhibition to overcome GID without losing the anti-parkinsonian benefits of striatal xenotransplantation. Adult SD rats were unilaterally lesioned to cause stable hemiparkinsonism (HP) as determined by a behavioral battery of tests (BBT). The denervated striatum was injected with AAV2-Ef1a-mCherry-IRES-WGA-Cre three weeks prior to transplantation. In separate experiments, single cell suspension of E13.5 mouse FVM tissue was transfected with either

AAV5-Ef1a-DIO-eNpHR3.0-EYFP or AAV8-hSyn-DIO-hM4Di-mCherry in vitro prior to stereotactic transplantation into the striatum. Thus, synaptic connectivity between the graft and the host was obligate for the expression of eNpHR3.0-EYFP or hM4Di-mCherry in these separate groups of grafted animals. Activation of eNpHR3.0 using a 590nm light source (5mW) or the administration of the DREADD activator clozapine-N-oxide to activate hM4Di caused a complete loss of graft derived behavioral benefits (Vibrissae evoked forelimb placement test; $p<0.05$) that was completely reversible. Control experiments did not produce any loss of beneficial behavioral effects. The 5-HT6 receptor agonist ST1936 induced GID that was significantly ameliorated by both optogenetic and chemogenetic inhibition (dyskinesia score; $p<0.05$) without any loss of graft derived benefits. All grafted animals had excellent survival of FVM dopaminergic neurons that demonstrated mature expression of tyrosine hydroxylase (TH) positive axonal projections. Grafted neurons that were eNpHR/EYFP/TH positive or hM4Di/mCherry/TH positive were noted to make synaptic connections with host medium spiny neurons. Microdialysis levels of dopamine, 5HT-6 receptor expression and serotonin transporter levels were also assessed. We show that functional synaptic connectivity between the graft and the host striatum is critical for anti-parkinsonian behavioral benefits from FVM cell transplantation and that ST-1936 induced GID can be markedly ameliorated without loss of graft function using chloride mediated hyperpolarization or by DREADD mediated GPCR inhibition. Our findings suggest that ionic and GPCR modulation are effective to control 5-HT6 receptor mediated GID and provide pre-clinical proof of principle for the use of optogenetic or chemogenetic inhibition to treat GID in PD.

Abstract: Bioluminescence-driven optogenetics can be useful for bimodal opto- and chemogenetic control of neural activity, including both neuronal activation and silencing. Luminopsins (LMOs), which are composed of an opsin fused to a luciferase, have proven to be versatile tools for controlling neuronal activity and interrogating neuronal circuits (PLoS ONE 8: e59759; PNAS 113: E358). Here we have expanded the luminopsin tool kit by fusing a new version of *Gaussia* luciferase (GLuc) with high light-emission, GLucM23, to depolarizing and hyperpolarizing channelrhodopsins with increased light sensitivity. The combination of GLucM23 with *Volvox* channelrhodopsin-1, VChR1, produced LMO4, while combining GLucM23 with the anion channelrhodopsin, iChloC, yielded iLMO4. The efficacy of bioluminescence-driven optogenetic activation and silencing was evaluated by whole-cell patch-clamp recordings and multi-electrode array recordings in cultured neurons. Both luminopsins proved very efficient in activating and silencing neurons upon exposure to the luciferase substrate, coelenterazine (CTZ), to generate light emission mediated by GLucM23. The coupling efficiency - a measure of the ability of light generated by GLuc to activate the channelrhodopsins - was higher for LMO4 and iLMO4 than for all previous luminopsins. Moreover, these new LMOs very efficiently controlled neuronal activity *in vivo*, as indicated by the ability of injected CTZ to alter amphetamine-induced rotations in rats. We conclude that LMO4 and iLMO4 are novel and effective tools that improve bimodal opto- and chemogenetic control of neuronal activity and brain function, from single-cell to behavioral levels.

Title: Optogenetic control of BDNF/TrkB signalling

Authors: *A. M. ZBELA, D. A. GELL, L. C. FOA, J. Y. LIN
Univ. of Tasmania, Hobart, Australia

Abstract: Brain-derived neurotrophic factor (BDNF) and its receptor, receptor tyrosine kinase B (TrkB), are involved in many forms of neuronal plasticity and are thought to be associated with functional and structural long-term potentiation (Minichiello et al., 2002, Harward et al., 2016). Nevertheless, a precise molecular mechanism of TrkB activity in synaptic plasticity as well as its role in learning and memory formation in behaving animals is still elusive. To address the question how distinct downstream signalling pathways of TrkB control neuronal plasticity and how these mechanisms in specific cells can affect learning and memory formation, we developed an optogenetic approach to activate TrkB signalling independently of BDNF. We utilized a membrane recruitment strategy with the light-induced photodimerizer CRY2/CIB1 in combination with the kinase domain of TrkB to activate the corresponding signalling pathway. In HEK293 cells expressing the engineered proteins, light illumination leads to elevated intracellular calcium, consistent with the activation of phospholipase Cγ (PLCγ) which is known to be associated with TrkB signalling. Moreover, the preliminary results showed that light also triggers the mitogen-activated protein kinase/extracellular signal-regulated kinase (ERK) and Akt kinase pathways. By generating mutant variants of the kinase domain, we are able to recruit one signalling cascade over others with our optogenetic approach, leading to the biochemical dissection of the pathways. This tool is currently being validated in cultured neurons and will be further utilized to investigate the roles of BDNF/TrkB signalling in synaptic plasticity.

Title: Examination of PTSD pathology using small world graph representations

Authors: *J. K. STATZ[1,2], R. M. MCCARRON[1,3], E. MCGINNIS[4], M. L. MEHALICK[1], S. T. AHLERS[1], P. B. WALKER[1], I. N. DAVIDSON[4], J. D. HUGHES[5]

Abstract: Previous research using functional imaging has shown that graphs constructed from these data sets demonstrate small world properties, with resting-state connectivity characterized by short path lengths and high clustering coefficients (Spoorns et al, 2000). Alteration of these properties in a network may indicate neurological dysfunction (Liu et al, 2008; Micheloyannis et al, 2006). The results of comparing these small world connectivity measures, as well as new measures and analysis methods, between a post-traumatic stress disorder group and a normal group will be presented and discussed. The dataset is the Alzheimer's Disease Neuroimaging Initiative Department of Defense. The data is represented by a graph G and consists of the nodes V, the edges that connect these nodes, and the weights of the edges that represent the distance or similarity of the two connected nodes. These graphs can be represented using the adjacency matrix A, where for nodes i and j, $A_{i,j}$ describes the edge connecting the nodes. Here the nodes are the AAL regions and edges are determined by the thresholded absolute Pearson correlation of the BOLD signals over time. The two common measures for describing the small-world properties of a graph are: average characteristic path length, which is the mean of all shortest path lengths for all node pairs; and average clustering coefficient, the mean of the individual clustering coefficients of each node, describing how connected a node is to each of its connected neighbors. In addition to these, other measures that may provide insight are: average max flow, which uses the edge weights to determine the max flow from one node to another via non-overlapping (disjointed) paths; and expected commute time, the time necessary for a random walker to travel from node i to j and back. New methods of analysis include: component analysis, which examines the size and number of connected components and common dropouts (components of size three or less) between groups; and spectral graph theory, examining the eigenvectors and eigenvalues of the graph. It was found that, on average, the PTSD cohort had a shorter characteristic path length, higher average clustering coefficient, and higher average max

flow than the control group; these observations lead to the conclusion that PTSD graphs are more connected. Examination of the mean Pearson correlations of the PTSD and control groups supports this, with the PTSD mean correlation the higher of the two, and even at lower thresholds for sparsifying the graph *G*, the control graph was much sparser. Also, low dropout overlap within the PTSD cohort during component analysis suggests that there is high variation in PTSD network structure.

Title: Neuronal hyperactivity in LRRK2 G2019S cellular models of Parkinson's Disease

Authors: *S. HACHI[1], E. LUCUMI MORENO[1], J. C. SCHWAMBORN[1], P. VANDEN BERGHE[2], R. M. T. FLEMING[1]

Abstract: Parkinson’s disease (PD) is the second most common neurondegenerative disease affecting more than 10 million people worldwide. Monogenic forms of PD are associated with mutations in various genes, including the gene encoding the leucine-rich repeat kinase 2 (LRRK2). Even though extensive investigations have been carried out to elucidate the function of this enzyme, it is still incompletely understood. Several studies have reported the effect of LRRK2-G2019S mutation on neurite branching, calcium hometostasis and mitochondrial function. However, less is known about its implication on neuronal activity. To investigate whether LRRK2-G2019S mutation alters neur- onal activity, we combined different state-of-the-art technologies including induced pluripotent stem cells (iPSCs), calcium imaging and computational image analysis. We used human neuroepithelial stem cell-derived neurons ob- tained from iPSCs as cellular models of PD. We monitored the spontaneous activity of these neurons carriyng a LRRK2-G2019S mutation using Fluo4-based calcium imaging. To analyse the calcium imaging data, we implemen- ted a fully automated image analysis pipeline that integrates automated neuronal segmentation, calcium transient measurement and transient property quantification such as inter-spike interval, spike amplitude and spike width. Interestingly, a shortening of inter-spike intervals was observed in neurons carrying a LRRK2-

G2019S mutation compared with controls. This corresponds to an increase in the rate of spontaneous calcium transients induced by action potentials. Thus, our findings suggest that this LRRK2 mutant alters the spontaneous activity of neuronal populations inducing hyperactivity in cellular models of PD.

Abstract: Autism is a severe developmental disorder in which connectivity aberrations in several brain systems at different age periods have been described. Whether or not these differences are due to aberrant developmental trajectories or idiosyncratic characteristics of ASD brains remains debated. In a multicenter, longitudinal sample of 60 subjects with Autism Spectrum Disorder (ASD) and 60 healthy controls (balanced for age, sex, head motion and acquisition site), covering an age range of 7 to 27 years, we tested whether ASD subjects exhibited differential maturation of whole brain community structure. Combining functional magnetic resonance imaging data from a well-established Theory-of-Mind task and a recently described network based multilayer community detection algorithm, we detected groups of brain regions clustered together into densely interconnected structures whose interactions change during development. We compared this brain-wide community structure over development using mutual information (MI) to create maps of similar development. Additionally, we computed flexibility of the theory-of-mind brain regions which measures the number of times brain regions change their community assignment between adjacent subjects to identify periods of marked community structure reconfigurations over development. Both MI maps and flexibility differed strikingly between ASD and healthy controls. Cluster analysis revealed that healthy subjects showed 3 periods of highly similar development, while ASD subjects exhibited only 2 such periods. Interestingly, the overall similarity between the community structures over all age periods was reduced in ASD, supporting the idea of a higher systems heterogeneity in ASD. Moreover, ASD subjects showed less frequent reconfigurations of their theory-of-mind related brain areas compared to healthy subjects.
In conclusion, our results demonstrate aberrant maturation of global network architecture during a theory-of-mind task as well as altered and less frequent periods of reconfiguration of the theory-of-mind network in ASD.

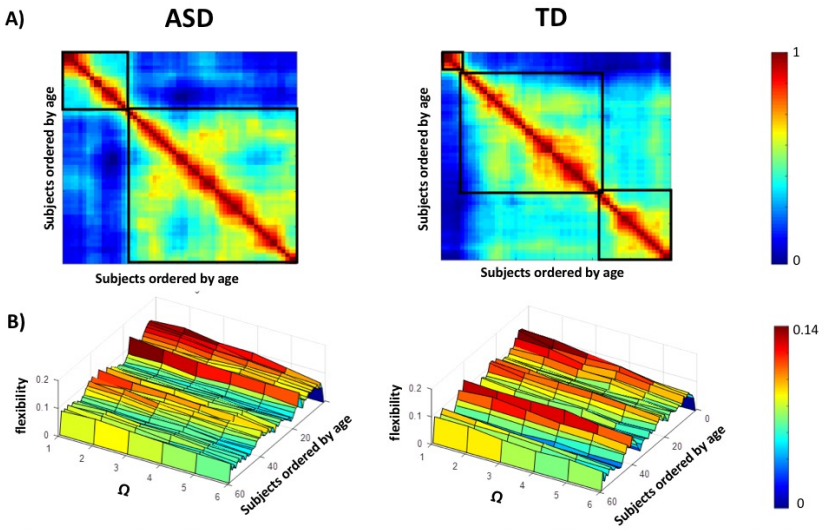

Fig1: Development of whole brain community structure in typically developing (TD) and autism spectrum disorder (ASD) subjects

A) Similarity matrix as mutual information between the community structure of ASD (left) and TD (right) subjects over development. Subjects are ordered by age, with 5 subjects per year bin. Notice the clear separation into two age/developmental clusters in ASD, while in TD the pattern falls into 3 different clusters/developmental periods.

B) Flexibility (number of community changes between ordinally ordered subjects) as a maker of system reconfigurations of the theory-of-mind system shows two major peaks in ASD and an additional pronounced peak in TD subjects in late adolescence.

Title: Pharmacophore based screening and molecular docking probing the novel inhibitors against BACE1 of Alzheimer's disease

Authors: *P. JANGAMPALLI ADI, P. REDDY
Texas Tech. Hlth. Sci. Ctr., Lubbock, TX

Abstract: The purpose of our study was to identify pharmacophore-based drugs to reduce amyloid beta (Aβ) toxicities in Alzheimer's disease (AD). Pharmacophore-based models are one of the most promising approaches in the current drug discovery process in modern biology. Aspartyl protease inhibitors, like pepstatin, are well-known potent inhibitors to reduce the cleavage of proteins. The crystal structure of the beta amyloid cleavage enzyme 1 (BACE1) protein contains 2 functional domains: ecto and internal. The ectodomain is the key functional part of catalytic cleavages is initiated by BACE1, which leads to aggregates of the pathological Aβ in AD neurons. What are the chief residues involved in the external domain catalytic process are still unknown, and currently, there are no promising BACE1 inhibitors available in the market? In the present study, we constructed a pharmacophore model of BACE1 and pepstatin, using computational screening and molecular docking. The inhibitor based pharmacophores resulted in the identification of new lead molecules showed best potentiation to reduce Aβ formation with best docking and molecular interaction studies. The top-ranking small molecules were cross checked across their suitability as drugs and toxic effects. Finalized three small molecules are potential therapeutic drug targets for the treatment of AD. Furthermore *in vitro* and *in vivo* confirmative studies are our further prospects in the development of new drugs intervention against AD.

Title: Bioinformatics analysis of a F2 mouse dataset reveals gene networks regulating sleep homeostasis and major depressive disorder

Authors: *V. GAO[1], P. JIANG[1], J. R. SCARPA[2], K. FITZPATRICK[3], M. VITATERNA[1], A. KASARSKIS[2], F. W. TUREK[1]
[1]Ctr. for Sleep and Circadian Rhythms, Northwestern Univ., Evanston, IL; [2]Genet. and Genomic Sci., Icahn Sch. of Med. at Mount Sinai, New York, NY; [3]Strategic Analysis/Support To DARPA BTO, Arlington, VA

Abstract: Sleep and sleep problems are known to be linked with psychiatric disorders, though the underlying mechanisms connecting sleep and affect are not clear. To investigate these connections, we tested about 200 (C57BL/6 x 129S1/SvImJ)F2 mice in a battery of tests for affective behaviors and recorded their sleep under baseline, sleep deprived, and restraint-stressed conditions. They were genotyped at ~2,500 informative loci across the genome, and their gene-expression transcriptome was measured using microarray in the frontal cortex, hippocampus, hypothalamus, and midbrain-thalamus. Principal components analysis was used to cluster phenotypes and discover underlying relationships between them. Weighted gene coexpression network analysis and clustering were used to identify modules of coexpressed genes in each tissue. Quantitative trait loci (QTL) analysis and a causal inference test were used to identify genes whose expression levels were causal to phenotype variation.
We found that QTL for gene expression (eQTL) are largely conserved across brain regions; however, the phenotypic associations of those eQTL-regulated genes can be diverse across regions. Some coexpression modules are also conserved across brain regions, and we find that these conserved modules are mainly driven by genetic linkage. We integrated our data with publicly-available data from others' experiments to identify which of our coexpression modules are enriched for genes that are differentially expressed during sleep deprivation. By comparing the modules' association with sleep phenotypes, we hypothesize which modules act as a sleep homeostatic signal. Similarly, we also identify differentially-regulated modules in major depressive disorder (MDD). Several coexpression modules which are differentially regulated in both sleep disruption and MDD are further investigated, with a focus on two in the frontal cortex. Analysis of key drivers in the network identifies several genes, including activity-regulated

cytoskeleton-associated protein (*Arc*) as potentially playing a key role in both sleep deprivation and MDD.

Title: Bionic legs restore the dexterity, confidence and ownership in lower-limb amputees

Authors: *S. RASPOPOVIC[1], F. PETRINI[2], G. VALLE[3], P. CVANCARA[4], A. HIAIRRASSARY[5], D. GUIRAUD[5], A. ALEXANDERSSON[6], T. STIEGLITZ[7], S. MICERA[1], M. BUMBASIREVIC[8]
[1]Ecole Polytechnique Federale De Lausanne, Lausanne, Switzerland; [2]EPFL, Lausanne, Switzerland; [3]Scuola Superiore Sant Anna, Pisa, Italy; [4]IMTEK, Freiburg, Germany; [5]Univ. of Montpellier - LIRMM, Montpellier, France; [6]OSSUR, Reykjavik, Iceland; [7]Lab. for Biomed. Microtechnology, IMTEK-Dept Microsystems Eng, Univ. of Freiburg, Freiburg, Germany; [8]Univ. of Belgrade, Belgrade, Serbia

Abstract: The lack of natural sensory feedback causes specific impairments to amputee patients: they do not perceive the prosthesis as a part of their body (low embodiment) and risk falls (low dexterity), hence do not rely on it and execute counterbalancing movements which increase fatigue. It also results in up to 60% of prosthesis abandonments (low confidence). Some efforts to restore sensory feedback in lower limb amputees have been conducted with non-invasive technologies, without success in solving these issues. In this work we developed the first prosthetic leg, which restores sensory feedback to amputees by means of implanted intraneural electrodes, in order to enable patients full recovery of dexterity, confidence and embodiment boosting. Two transfemoral amputees underwent the implant of 4 intraneural electrodes in the proximal section of tibial nerve for more than 100 days each. We showed that natural sensations of touch, pressure, vibration and muscle contractions could be elicited on the phantom leg, on the numerous positions over the foot sole and lower leg. Then these sensations were used within the bidirectional prosthetic control. A commercial prosthetic leg with an encoder embedded in the knee was equipped with a custom made sensorized sole, recording the pressure information from 7 positions of the foot sole. The readout of these sensors and encoder was used to drive wirelessly the stimulation of 5 active sites, eliciting natural touch under the foot sole and calf contraction, intuitively interpreted by the subject as knee flexion. The subjects then underwent a set of investigations, devoted to explore singular hypotheses: i) walking over obstacles, without

possibility to visually inspect (confidence test), ii) walking over the stairs, sand, gravel and straight lines (dexterity and mobility test) and iii) induced ownership (embodiment tests). Remarkably, the proposed intervention showed significantly increased confidence, higher dexterity and mobility, together with the clear embodiment augmentation. Natural sensory feedback from missing leg can be elicited to the transfemoral amputees, and integrated into the successful natural control and holds the promise to overcame the limitations of the present prosthetic devices.

Title: A mathematical network model of ischemic stroke

Authors: ***M. SARKAR**, R. A. LEE, C. J. CONTE, D. H. TERMAN
Ohio State Univ., Columbus, OH

Abstract: Brain lesions and expanding infarcts after ischemia result from multiple insults, but at its core, cell damage and death is the result of reduced oxygen and glucose supply to brain cells, which decreases mitochondrial ATP production. An immediate effect of ATP depletion is the failure of the Na^+-K^+ ATPase pump, needed to maintain proper electrochemical ion gradients. These gradients are also needed for glutamate transporters to remove glutamate from the extracellular space. The Na^+-glutamate transporters on both neurons and astrocytes can reverse their glutamate transport and secrete glutamate at concentrations capable of inducing excitotoxicity. Moreover, failure of the Na^+-K^+ ATPase pump results in elevated extracellular K^+, which leads to waves of recurrent spreading depolarizations (RSDs) in both neurons and astrocytes. We have developed a detailed biophysically-based computational model for a neuron/astrocyte network in order to explore mechanisms responsible for the initiation and propagation of recurrent cortical spreading depolarizations. The model incorporates biophysical processes not considered in the earlier models. This includes a model for the Na^+-glutamate transporter, which allows for a detailed description of reverse glutamate uptake. In particular, we consider the specific roles of elevated extracellular glutamate and K^+ in the initiation, propagation and recurrence of spreading depolarizations. Gap junctions between astrocytes are

also included in the model to understand how the strength and number of gap junction connections impact RSDs. Simulations suggest that the initiation of RSDs is due primarily to the increase in extracellular glutamate, while the propagation of RSDs is due primarily to the rise in extracellular K^+. In the model, fewer cells are required to initiate RSDs as the strength of the Na^+-K^+ pump is decreased. The evidence that gap junctions play a protective or harmful role during stroke appears mixed. At reduced gap junction strengths, a greater number of gap junctions reduced the likelihood of RSDs. However, at increased gap junction strength, more gap junctions per astrocyte increased the probability of RSDs.

Title: Modeling striatal network dynamics in disease

Authors: *A. P. PONZI[1], S. J. BARTON[2], G. V. REBEC[2], J. R. KOZLOSKI[1]
[1]IBM, Yorktown Heights, NY; [2]Program Neurosci & Dept. Psychological & Brain Sci.,, Indiana Univ., Bloomington, IN

Abstract: Dysregulated striatal information processing is thought to play a crucial role in the pathology of multiple diseases such as Huntington's disease, Parkinson's disease, depression and addiction. Previous striatal network modeling [Ponzi, A and Wickens J (2010). Sequentially switching cell assemblies in random inhibitory networks of spiking neurons in the striatum. Journal of Neuroscience, 30(17), 5894-5911. Ponzi, A and Wickens J, Optimal balance of the striatal medium spiny neuron network. PLoS Comput Biol 9, no. 4 (2013): e1002954] suggested that the normal medium spiny neuron network may be poised close to a critical state between stable and unstable dynamical regimes. To investigate how disease pathologies can affect this balance we made a similar but more detailed computational model of the striatal network comprising more biologically detailed spiny projection neurons with multiple ion channels and a network of fast spiking interneurons.
We first confirm that this more detailed model also shows a critical state in the striatally appropriate parameter regime. Next we explore how a variety of modifications, both to the individual cell ion channels and to the network structure and to synaptic properties such as excitatory drive, move the network dynamics away from this optimal critical regime. We compare these model pathological states with experimental observations from disease states, in particular from model Huntington' disease animals. This work provides insights into the physiological modifications underlying the aberrant network phenotypes and can help isolate

targets for pharmacological intervention as part of a quantitative network systems pharmacology. Finally in order to model behavioural symptom endpoints for basal ganglia diseases and therapeutics we also study how the network behaves when cortical and thalamic input varies as it might in simple discrimination behavioural tasks. As proxies for reaction times and error rates in these tasks we use the quantity of discriminative information in the striatal network. We investigate how this quantity varies with cell and network manipulations modeling disease and therapeutic states and compare results with existing experimental task studies.

Title: Towards the optimal control of nonlinear brain networks dynamics in Alzheimer's disease

Authors: L. M. SANCHEZ-RODRIGUEZ[1], Y. ITURRIA-MEDINA[3], *R. C. SOTERO[2]
[1]Biomed. Engin. Grad. Program, [2]Radiology, Univ. of Calgary, Calgary, AB, Canada; [3]Neurol. & Neurosurg., Montreal Neurolog. Inst., Montreal, QC, Canada

Abstract: We introduce the application of exogenous electric signals as an alternative for controlling the brain activity in Alzheimer's disease patients. Reports show abnormalities in the EEG spectrum as a consequence of Alzheimer's (Jeong, 2004). Fundamental research aiming to unveil the mechanisms associated with this condition is ongoing and far from offering a complete understanding of its causes and progression. Meanwhile, the application of innovative therapeutic procedures might help to reverse the effects of the disease. One criterion any proposal should fulfill is being realistic in the modeling of brain networks dynamics (Sotero et al., 2007).
We placed a set of coupled autonomous Duffing oscillators over seventy-eight regions that covered the brain's gray matter. Diffusion MRI data for healthy controls (HC) and Alzheimer's patients (AD), from the Alzheimer's Disease Neuroimaging Initiative (ADNI), was used to calculate structural connectivity matrices for the interactions between brain areas (Iturria-Medina et al., 2007-2008). Then, we proceeded to find an external signal that, inputted individually over the areas, makes the rest of them evolve towards a certain predefined state as a cost function is minimized. Previous studies have neglected the nonlinear nature of brain dynamics for the sake of mathematical simplicity. However, the choosing of Duffing oscillators for the dynamics provides both physiological reliability and easy-to-inspect effects of the non-linearities. The optimal control problem was solved by means of the so-called state-dependent Ricatti equation formalism -seldom used for biological or large-dimensional systems so far (Cimen, 2008).

Areas were ranked based on the cost of reaching absolute control. Among the areas with the lowest cost were those in the limbic system or strongly connected to it -hippocampus, amygdala, putamen, pallidum, caudate nucleus, and thalamus- for both HC and AD groups. However, regions were ranked differently in HC and AD patients. This was expected, as the progress of the pathological condition modifies the connectivity values (Iturria-Medina et al., 2016). Additionally, ranks changed with the value of the non-linearity in both HC and AD. Higher non-linearities were associated with loss of controllability from some areas. Overall, our results shed light on the nonlinear optimal control of realistic brain networks. The progress herein reported is encouraging for the development of engineering solutions to reverse the consequences of Alzheimer's disease.

Title: Shape analysis of human white matter tracts

Authors: *T. GLOZMAN[1], L. BRUCKERT[1], F. PESTILLI[2], D. W. YECIES[1], L. GUIBAS[1], K. YEOM[1]
[1]Stanford Univ., Stanford, CA; [2]Indiana Univ., Bloomington, IN

Abstract: Diffusion imaging coupled with tractography algorithms allows researchers to image human white matter tracts in-vivo. White matter tracts are three-dimensional structures with shapes that change over time during the course of development as well as in pathologic states. While most studies on white matter variability focus on analysis of tissue properties estimated from the diffusion data, e.g. fractional anisotropy, the shape variability of white matter tracts is much less explored. In this paper, we present a set of tools for shape analysis of white matter tracts, namely: (1) a concise geometric model of tract shapes; (2) a method for tract registration; (3) a method for deformation estimation. Our framework is useful for analysis of shape variability in white matter tracts. We demonstrate our framework by applying our methods on a dataset of 38 normally developing children of age 11 days to 8.5 years and suggest a model of canonical shape evolution on an ensemble of white matter tracts. Our framework provides a robust, quantifiable and reproducible model of changing geometric white matter shape over the course of human development that agrees with normative human head and brain growth data. Such model may improve understanding of both normal development and pathologic states and represents a novel parameter for the examination of the pediatric brain.

Title: A computational framework for closed-loop control of general anesthesia in macaques

Authors: *S. CHAKRAVARTY[1], J. A. DONOGHUE[2], M. MAHNKE[1], D. KISHNAN[4], P. L. PURDON[4,2], E. K. MILLER[1,2], E. N. BROWN[1,2,5,3,4]

Abstract: Post-operative cognitive dysfunction, particularly in the elderly, and anesthetic toxicity in children are major problems following general anesthesia (GA). A precise computerized titration of the anesthetic drug can potentially mitigate these problems. Here, we report a computational framework, developed based on initial experiments, to achieve precise control of the anesthetic state in a non-human primate GA model. In this framework, local field potentials are recorded from chronically implanted microelectrode arrays within prefrontal cortex as animals are anesthetized using intravenous propofol ($GABA_A$ agonist). We set a target anesthetic state. Then using this information, our proposed computerized closed-loop scheme automatically adjusts the drug infusion rate based on the subject's anesthetic state monitored via local field potential dynamics in the prefrontal cortex. This control scheme comprises two main steps, estimation and control, that are implemented in a cyclical manner. In the estimation step, the anesthetic state is estimated from special drug-system specific signatures present in the multi-tapered spectrogram of the local field potentials. From our initial experiments, we have identified

spectral features as candidate anesthetic markers to control. We use a state space model (SSM) to define the dynamics of the anesthetic drug transport to the brain and how it affects a selected marker. In this SSM, the state equations are based on a two-compartment linear pharmacokinetics setup comprising a central compartment (plasma) and an effect compartment (brain). The observation equation in this SSM, relating the amount of drug in the brain to the observed marker, is a Sigmoid-Emax model. This SSM paradigm allows us to implement a Kalman Filter strategy to estimate anesthetic state from the marker time-series. The parameters for this SSM strategy are estimated from preliminary data collected from macaques under a custom-designed infusion scheme. In the control step, we use a Linear Quadratic Regulator (LQR) to calculate the change in the drug infusion rate required to maintain the state at a given target value. The LQR framework allows us to the perform the estimation and control steps in sequence as well as determine optimal infusion rates that minimize a cost function penalizing the deviation of the anesthetic state and infusion rates from their respective desired values over the control interval. Our *in-silico* results indicate feasibility of validating this scheme in macaques and provide potential for analogous closed-loop control in patients requiring extended duration of anesthesia in the future.

Title: A generative model for cortical networks

Authors: *D. L. BARABASI, Z. TOROCZKAI
Physics, Univ. of Notre Dame, Notre Dame, IN

Abstract: Updated experimental efforts using hemisphere-wide retrograde and anterograde tracing have provided large-scale static data about the architecture of the cortex. Previous studies of low-density interareal connectivity have found emergent scale-free and rich club properties as indicators of network heterogeneity, however these need to be revised due to the high-density nature of the cortico-cortico wiring reported in the recent experimental studies. To understand the level of specificity and connection heterogeneity of the cortical network one needs to take an

alternative approach that is more suitable for dense, directed, spatial networks. Past work has introduced a simple core-periphery detection method based on clique distribution analysis, showing a strong core-periphery organization of the cortex in both macaques and mice when compared to appropriately chosen null-models, which was further validated using stochastic block modeling analysis. Physically, tracing experiments have revealed in both macaque and mouse brains the action of the so-called Exponential Distance Rule (EDR): an exponential decay of connection probability with distance. A prior network model based on the EDR was defined at the level of functional areas and captured many features of the experimentally obtained network, however, as we show here it fails in other measures, such as in identifying the core-periphery structure, found in experiments. Here we introduce a neuronal-level network model based on the EDR, which, given a a parcellation of the cortex into functional areas, naturally generates the interareal network. This new model now also quantitatively captures the features missed by the areal-level model and shows that the core-periphery structure emerges due both to the EDR and the distribution of area sizes and their relative positioning. These findings demonstrate that the cortical network cannot be modeled as a simple connectivity graph at the areal level, but one needs multiscale network models that are intricately tied with the functional parcellation of the cortex and the morphological properties of the cortical plate.

Hosp., Harvard Med. Sch., Charlestown, MA; [5]Ctr. for Neurorestoration and Neurotechnology, Providence VAMC, Providence, RI

Abstract: MEG/EEG are the leading methods to non-invasively record human neural dynamics with millisecond temporal resolution. However, it is extremely difficult to infer the underlying cellular and circuit level origins of these "macro-scale" signals without simultaneous invasive

recordings. This limits the translation of MEG/EEG or ECoG findings into novel principles of information processing, or into new treatment modalities for neural pathologies. As such, there is a pressing need, and a unique opportunity, to relate the "macro-scale" signals to their underlying "meso-scale" generators.
To address this need, we are building the Human Neocortical Neurosolver (HNN), an open-source neural modeling tool designed to help researchers/clinicians interpret human imaging data. HNN presents a convenient GUI to an anatomically and biophysically detailed model of human thalamocortical brain circuits, which makes it easier to generate and evaluate hypotheses of the mechanistic origin of signals measured with MEG/EEG or intracranial ECoG. A unique feature of HNN's model is that it accounts for the biophysics generating the primary electric currents underlying such data, so simulation results are directly comparable to source localized data (nano-Ampere-meters); this enables precise tuning of model parameters to match characteristics of recorded signals.
We are integrating the circuit-level modeling with the minimum-norm-estimate (MNE) source localization software, so researchers can compute MEG/EEG source estimates and test hypotheses on the circuit origin of their data in one software package. Our goal is to design HNN to be useful to researchers with no formal computational neural modeling or coding experience. Visualization plugins, which provide 3D views of model cells and their connectivity, will aid intuition on how circuit architecture can influence neocortical dynamics. We are also building resources for freely using and expanding the software through the Neuroscience Gateway Portal, and online documentation and a user forum for interaction between users and developers. We will present the initial construction of our tool and describe its use in studying the circuit-level origin of some of the most commonly measured MEG/EEG and ECoG signal: event related potentials (ERPs) and low frequency rhythms (alpha/beta/gamma).

Title: A cortical microcircuit model with heterogeneous excitatory and inhibitory neurons

Authors: *N. L. KAMIJI, R. SHIMOURA, R. F. PENA, V. L. CORDEIRO, C. ROMARO, C. C. CEBALLOS, A. C. ROQUE
Deptarment of Physics, FFCLRP, Univ. of Sao Paulo, Ribeirao Preto, Brazil

Abstract: Large-scale cortical network models often assume that the dynamic state of the network is controlled by the balance between excitatory and inhibitory synaptic inputs. Most cortical models that rely on excitation-inhibition (EI) balance have been studied in the context of random networks of leaky integrate-and-fire (LIF) neurons but recently the EI balance condition has been successfully extended by Potjans and Diesmann to a multilayered model of cortical microcircuitry. The Potjans-Diesmann (PD) model integrates experimental data from many different sources into a four-layer model with two cell types, excitatory and inhibitory, connected according to realistic layer and cell-type specific connectivity. The excitatory and inhibitory neurons of the PD model are described by the same LIF model, and a question that poses itself is whether the properties of the PD model under EI balance condition remain valid when the excitatory and inhibitory neurons become different. Here we answer this question by replacing the excitatory and inhibitory LIF neurons of the original PD model by Izhikevich regular-spiking (RS) and fast-spiking (FS) neurons, respectively, generating a heterogeneous version of the PD (hPD) model. We adjusted the synaptic parameters of the hPD model to turn it into a balanced model and studied the firing patterns of the eight cell populations under different conditions: without external input (spontaneous activity) and when the network was submitted to random input spikes applied to layers 4 and 6 to mimic thalamic inputs, as done by Potjans and Diesmann in their original work. In all cases the balanced hPD model showed similar behavior to the one presented by the original balanced PD model. In conclusion, the heterogeneous version of the Potjans-Diesmann model can be an upgrade of the original Potjans-Diesmann model to a more realistic model of the cortical microcircuit.

Title: Noise-enhanced transition from synchronized to desynchronized states in a cortical network model

Authors: *R. D. PENA[1], M. ZAKS[2], A. C. R[1]
[1]Univ. of São Paulo, Ribeirão Preto, Brazil; [2]Humboldt Univ. of Berlin, Berlin, Germany

Abstract: Neuronal activity recorded in the cerebral cortex displays complex dynamic patterns. These patterns form a continuum of states ranging from a synchronized state, characterized by low-frequency oscillation in the population firing rate and up/down switching in the single-neuron membrane potential, to a desynchronized state, characterized by a roughly constant population firing rate and irregular single-neuron firing. Being related to the instantaneous state of the brain, these regimes are separated by repeated transitions. The synchronized state is more prominent during slow-wave sleep and anesthesia while the desynchronized state is more prominent during states of wakefulness and REM sleep. The mechanisms responsible for synchronized-desynchronized transitions are not completely known and here we study the effect of synaptic noise on these transitions. We use our recently proposed random network model with mixed neuronal types (Front Comput Neurosci 8:103, 2014), which displays spontaneous network oscillations that resemble the alternation of up and down states observed in the synchronized cortical state. The model is described by deterministic equations and we add synaptic noise to it modeled by an Ornstein-Uhlenbeck process. The effect of noise was to make the network state change stochastically between synchronized and desynchronized states. Systematic analysis of firing rates, power spectra and voltage series confirms that the characteristics of the two basic states are very similar to those of desynchronized and synchronized cortical states: in the desynchronized state neurons have very low collective firing rate and are weakly correlated; in the synchronized state neurons have a collective oscillatory activity where their membrane voltages fluctuate between a hyperpolarized (down) state and a depolarized (up) state. By varying the noise intensity and using the mean duration at each state as a prevalence criterion, we observe that noise facilitates transitions from the desynchronized to the synchronized state and hinders the reverse transitions. Our results suggest that synaptic noise may be an important mechanism underlying transitions between desynchronized and synchronized states in cortical networks.

Abstract: Electrodes arrays placed subdurally on the cortical surface (electrocorticography, ECoG, using strip and grid arrays) or deeper in brain tissue (depth electrodes and stereotactic needles) are frequently deployed to study intrinsic brain activity with high spatio-temporal resolution (e.g., in epileptic patients). They are also increasingly used to inject current to modulate brain activity. Consenting subjects undergo current stimulation on different scales (e.g., standard ECoG and micro-electrocorticography, μECoG), using varying current levels and patterns to elucidate or rehabilitate brain function. However, little is known about either the optimal design or use of these systems. The project reported on in this abstract has clinical, computational, and experimental components across three sites in the US and one in Germany, collaborating synergistically to study these questions. In our clinical work, at University of Washington, we monitor current spread with high spatial and temporal fidelity to better understand tissue properties, current delivery and its effect on brain functioning, as well as to validate our computational models. Validated computational models and efficient tailored optimization methods, developed at University of Utah and Northeastern University, allow us to to optimize current in target regions-of-interest (ROIs) while constraining it in non-ROI regions for safety as well as enhanced targeting. In the German component, at University of Freiburg) we apply these models to validate and design cortical and subcortical indwelling μECoG arrays in

phantoms (Fig. 2), animals (ovine), and humans using computed patterns of low-amplitude currents delivered to specific brain ROIs. We also deploy a sensitive infrared camera to monitor induced temperature distribution. In the future we will use both in vivo ECoG and μECoG measurements of stimulation-evoked brain responses to design and assess the functional effects of current patterns and thus improve both designs and deployment of cortical arrays.

Title: Automatic labeling of cortical sulci in human fetal brains

Authors: *H. YUN[1], B. GAGOSKI[1], C. ROLLINS[2], C. ORTINAU[4], E. YANG[3], P. E. GRANT[1], K. IM[1]
[1]Newborn Med., [2]Dept. of Neurol., [3]Dept. of Radiology, Boston Children's Hosp., Boston, MA; [4]Dept. of Pediatrics, Washington Univ. Sch. of Med., St. Louis, MO

Abstract: In the human cerebral cortex, primary sulci are important anatomical landmarks for inferring cortical functional organization and their overall spatial patterns are relatively invariant across individuals[1,2]. Using spatial patterns and geometric features of the sulci, several studies have implemented automated methods for labeling sulci to analyze cortical folding pattern[3-5]. However, labeling sulci in fetal brain is still challenging, because the sulcal pattern undergoes dramatic changes during fetal stage. The aim of this study is to automatically label early primary sulci for individual fetuses based on the temporal dynamics of sulcal pattern.For labeling with temporal dynamics, we combined sulcal patterns of 9 fetal brain atlases from 23 to 31 gestational age (GA), which is crucial period for gyrification[6,7]. Sulcal regions on the templates were defined using cortical curvature maps on cortical plate surfaces, and then manually assigned to 20 anatomical labels including a non-sulcal and 19 sulcal regions. Spatial probability maps of the labels were generated by smoothing each label on the surface templates and used as prior information for individual sulcal labeling (Fig 1A). Then, the prior information was aligned to individual surfaces by 2D sphere warping[8]. To consider the temporal change of the brain, we set weights for the aligned prior information. The weight of each template was estimated by a curve, fitted on similarities of folding patterns between the individual and templates (Fig 1B). Finally, we averaged the weighed information within a sulcal region on an individual surface, and assigned one of the 20 labels with the highest average. To validate our procedure, sulcal labels were automatically assigned to 6 individual fetal brains (GA range: 24.6 - 29.6) and the results were compared with visual assessment. The labeling results were concurrent with manual assignment (Fig 1C), showing high accuracy of the automatic labeling. Our method may provide a useful tool for automatic regional analysis of the fetal brain at the primary sulcal level.

Title: Selective activation of cortical neurons by extracellular electrical stimulation

Authors: *M. KOMAROV, P. MALERBA, E. HALGREN, M. BAZHENOV
Univ. of California San Diego, LA Jolla, CA

Abstract: Brain stimulation is widely used for a number of reasons: to probe the neural system to learn about its properties, to normalize dysfunction (e.g., deep brain stimulation for Parkinsonian patients, tDCS for stroke patients), or as a method to manipulate brain activity. While the practice is widespread and scalable we still chose stimulus parameters through trial and error because of the difficulty in predicting the specific effects of electrical stimulation on brain tissue. In particular, it is not known which category of cells (if any) are going to spike due to an input, and which specific synaptic mechanisms are going to be recruited and modulated by a given stimulation protocol. Furthermore, depending on the goal of stimulation, the relevant effect could be driving cells to spike versus inducing sub-threshold changes. Empirically, stimulation can synchronize, de-synchronize, excite and/or suppress neuronal activity. But predicting these effects from biophysics and cortical anatomy has not been possible.
In this work, we develop a method that estimates the effect of the extracellular electrical stimulation on different types of cortical neurons. Our approach is based on calculation of the activation function [1], induced by the current density in the tissue under the stimulation electrode. The activation function represents the effective current across neuronal membranes. We convolve this activation with the statistical distribution of the axonal and dendritic arborizations of different cell types obtained from public databases of morphological reconstructions of cortical neurons. Combined with myelination properties, this is used to predict thedirect activation probabilities of different cortical cell types. These probabilities are then fed through a computational neural model of the cortex with realistic channel and synaptic elements, to predict the indirect effects of stimulation. Here we report the phasic effects of relatively strong and short (~200) stimulation pulses, as well as changes in baseline activity induced by weak and long stimulation. Our work predicts the selectivity of intracranial cortical stimulation across cell

types and layers, the focal activation of layer I axons due to cortical surface stimulation, and the optimal stimulation intensity capable to elicit cell activation lasting beyond the end of stimulation.

Title: A stochastic cortical microcircuit model

Authors: ***A. C. ROQUE**, N. L. KAMIJI, V. L. CORDEIRO, C. C. CEBALLOS, R. O. SHIMOURA, R. F. O. PENA, C. ROMARO
Univ. de Sao Paulo, Ribeirao Preto, Brazil

Abstract: Cortical neurons in vivo display irregular firing patterns and this stochasticity may have important consequences for network behavior. So, it is important to have stochastic network models to study the effect of noise on their dynamic activity patterns. There are basically two types of noise model for a neuron: spike generation is modeled deterministically and noise enters the dynamics via additional stochastic terms, or spike generation is directly modeled as a stochastic process. Recently, Galves and Loecherbach (J. Stat. Phys. 151, 896-921, 2013) introduced a neural model of the latter type in which the firing of a neuron at a given time is a random event with probability given by a monotonically increasing function of its membrane potential. The model of Galves and Loecherbach (GL) has as one of its components a graph of interactions between neurons. Here it is assumed that this graph has the structure of the Potjans and Diesmann (PD) cortical microcircuit model (Cereb. Cortex 24, 785-806, 2014). The PD model has four layers and two neuron types, excitatory and inhibitory, so that there are eight cell populations. The PD model replicates well the experimental distribution of spike rates across these cell populations. In this work, the leaky integrate-and-fire neurons of the original PD model

were replaced by stochastic GL neuron models, thus generating a stochastic version of the PD (sPD) model. The firing patterns of the eight cell populations of the sPD model were studied and characterized in the two-dimensional diagram spanned by the excitatory and inhibitory synaptic weights under different conditions: without external input (self-sustained activity) and when the network is submitted to random input spikes applied to layers 4 and 6 to simulate thalamic inputs, as done by Potjans and Diesmann in their original work. The average spiking behavior per cell population of the sPD model is similar to the one of the deterministic PD model, indicating that the stochastic version of the PD model is consistent with known experimental results. Therefore, the sPD model can be a useful replacement for the original PD model in studies that require comparison between stochastic and deterministic models.

Title: Sparse coding and dimensionality reduction in cortex

Authors: *E. ROUNDS[1], M. BEYELER[3], K. D. CARLSON[4], J. L. KRICHMAR[1], N. DUTT[2]
[1]Cognitive Sci., [2]Computer Sci., Univ. of California, Irvine, Irvine, CA; [3]Psychology, Univ. of Washington, Seattle, WA; [4]Sandia Natl. Labs., Albuquerque, NM

Abstract: Supported by recent computational studies, nonnegative sparse coding (NSC) is emerging as a ubiquitous coding strategy across brain regions and modalities. A combination of nonnegative matrix factorization (NMF) and sparse coding, NSC allows populations of neurons to collectively encode high-dimensional stimuli spaces using a compressed, sparse, and parts-based neuronal code. Specifically, we argue that neuronal circuits can 1) achieve sparse codes through competition, and 2) implement NMF by utilizing spike-timing dependent plasticity with homeostasis (STDPH). We applied NMF to two different datasets: 1) receptive fields in the dorsal subregion of the medial superior temporal area (MSTd), and 2) neurophysiological and behavioral recordings from rat retrosplenial cortex (RSC). In both cases, we were able to show that applying NMF to major inputs into these brain regions can result in a sparse representation

that captures important aspects of neuronal response properties of these brain regions. Furthermore, we found similar results applying STDPH to the RSC dataset. These findings support a growing body of evidence that suggests biological neurons use plasticity, such as STDPH, to produce sparse, compact stimulus representations that vastly reduce the dimensionality of their inputs.

Abstract: The ideal form of a neural-interfacing device is highly dependent upon the anatomy of the region with which it is meant to interface. Multiple-electrode Arrays provide a system which can be adapted to various neural geometries. Computational models of stimulating systems have proven useful for evaluating electrode placement and stimulation protocols, but have yet to be adequately adapted to the unique features of the hippocampus. As an approach to understanding potential memory restorative devices, a NEURON-Admittance Method model was constructed to predict the direct and synaptic response of a region of the rat dentate gyrus to electrical stimulation of the perforant path. The model comprises detailed compartmental models of 50,000 granule cells and 10,000 entorhinal cortical axons in a computer reconstruction of a 400 μm coronal slice of hippocampal tissue. A validation of estimated local field potentials against experimental recordings is presented. Further, a parametric analysis of the impact of neuronal morphometry and branching complexity on patterns of activity was performed. Beyond

deepening understanding of the hippocampal tissue system, establishment of this model provides a method to evaluate candidate stimulating devices and protocols.

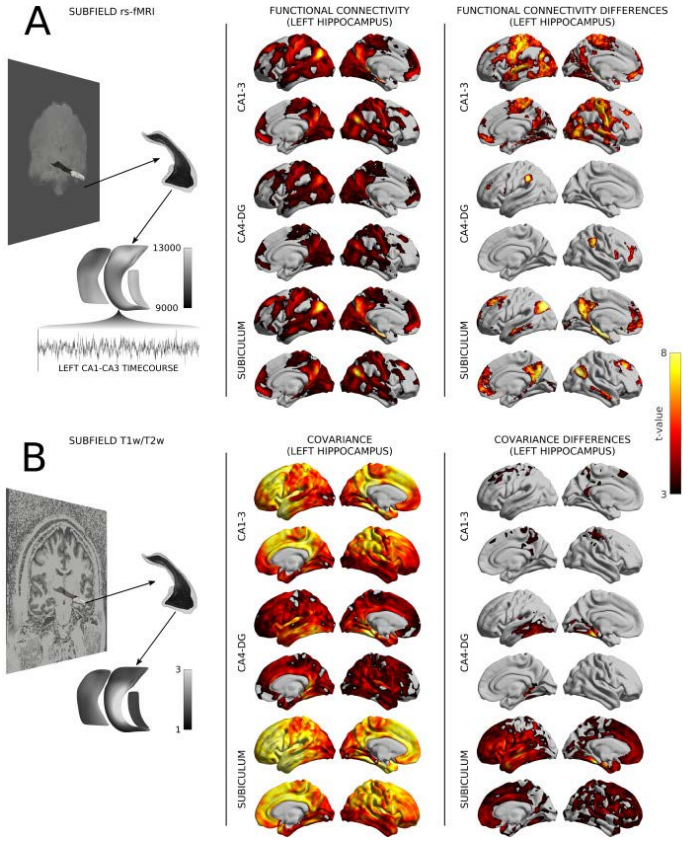
Abstract: Background. The hippocampus consists of subfields with distinct anatomic properties, thought to play different functional roles. Recent advances in magnetic resonance imaging have provided guidelines to segment subfields in-vivo, and to study their internal organization and connectivity to other regions of cortex. We provide an overview of subfield-specific networks

based on resting-state functional connectivity and covariance mapping of T1w/T2w intensity, a proxy for cortical myelin.
Methods. In 100 healthy individuals (29±4 yrs, 43 men) from the human connectome project dataset, we segmented hippocampal subfields (CA1-3, CA4-DG) and the subiculum using a surface-based algorithm. We generated surfaces running through the core of each subfield, on which we sampled resting-state fMRI signals from four 15-min scans. These signals were correlated with those of the cortical surface. We also mapped subfield-specific networks using T1w/T2w covariance analysis. We studied inter-subfield differences in connectivity using fixed-effects models and covariance differences using linear interactions.
Results. All left subfields showed bilateral functional connections to core default mode nodes, i.e., angular, medial parietal, and medial frontal cortices (Fig. A).



Functional connectivity was weakest when seeding from CA4-DG. Covariance patterns showed only modest similarity to functional networks (surface-wide correlations r=.16-.26 across subfields), highlighting mainly fronto-limbic targets (prefrontal and anterior temporal cortices; Fig. B). While subiculum covariance was higher than that of other subfields in most cortex, CA4-DG covariance showed higher covariance with fusiform areas (Fig. B).
Conclusions. Our approach provides new insights on the embedding of subfields into functional and structural networks. T1w/T2w covariance analysis may identify networks with microstructural properties resembling those of individual hippocampal subfields, but these networks may not necessarily maintain significant functional links with the subfields.

Title: Structural and dynamic properties of critical associative memory networks

Authors: *D. ZHANG[1], C. ZHANG[1], A. B. STEPANYANTS[2]
[1]Dept. of Physics, [2]Physics, Northeastern Univ., Boston, MA

Abstract: The ability of neural networks to associate successive states of network activity lies at the basis of various cognitive functions. In this study, we hypothesize that ubiquitous features of cortical network structure and dynamics develop as a result of continual memory storage. To test this hypothesis, we consider recurrent McCulloch and Pitts networks in which neurons may belong to different classes defined by their excitatory or inhibitory nature, firing probability, and robustness to noise. Learning in the network is mediated by changes in connection weights in the presence of constraints on the l1-norms of presynaptic weights of individual neurons. To determine the memory storage capacity of the network we train the network on a set of random sequences of different lengths and subsequently test the retrieval of learned memories. To retrieve a learned sequence, we initialize the network state at the beginning of the sequence and monitor memory playout. The sequence is considered to be retrieved successfully if the network states during the retrieval do not deviate substantially from the learned sequence. The maximum (critical) capacity of the network is defined as the sequence length for which the success rate in memory retrieval equals 0.5. We performed numerical simulations for networks of 400 neurons and also solved the problem theoretically in the limit of large networks by using the replica theory. The results show that critical networks have unique structural and dynamical properties which resemble those observed in many cortical systems. First, we find that, consistent with the experimental data, probability of inhibitory connections in critical networks is greater than 0.5, whereas excitatory connectivity is sparse with connection probabilities less than 0.5. Second, we find that with increasing robustness, critical networks exhibit a phase transition from networks with ordered dynamics quickly terminating in a frozen state, to networks with chaotic dynamics during which neurons exhibit irregular and correlated firing activity with average correlation coefficients in the 0.1-0.2 range. Finally, we show that the observed transition is accompanied

with the emergence of neuron clusters, existence of which is suggested by recent experimental studies. These results are consistent with the idea that cortical networks are operating in a critical state configured at the edge of order-to-chaos phase transition.

Title: Robustness to fluctuations in neural activity is reflected in the structure of critical associative memory networks

Authors: *C. ZHANG[1], D. ZHANG[2], A. B. STEPANYANTS[1]
[1]Physics, [2]Northeastern Univ., Boston, MA

Abstract: Neural networks in the brain have the ability to function reliably despite various sources of noise in synaptic transmission. In this study, we consider associative memory storage in the presence of fluctuations in generation/propagation of action potentials and spontaneous firing. We examine how the robustness in memory recall affects the memory storage capacity and structural properties of the network. Specifically, we train recurrent networks of excitatory and inhibitory McCulloch and Pitts neurons to store predefined temporal sequences of network states. Learning is carried out in the presence of sign constraints on the weights of postsynaptic connections of each neuron and homeostatic constraints on the weights of presynaptic inputs. Errors in the inputs, j, to a given neuron are described by probabilities, p_j, while errors in the neuron's output are characterized by the probability p_{out}. Each neuron in the model is required to associate noisy input patterns with correct outputs with the probability of 1-p_{out}. The latter characterizes the robustness of the network to firing fluctuations. The probability of successful learning decreases with sequence length, and at the probability of 0.5 the network is said to be at critical capacity. We use the replica theory from statistical physics [1-3], as well as numerical simulations to determine the memory storage capacity of such robust, critical networks and examine their structural properties as a function of model parameters. We compare the results of the model to known features of cortical connectivity.

Title: Basins of attraction in neural networks: A computational study

Authors: *B. ROVIRA, A. ROXIN
Ctr. De Recerca Matemàtica, Bellaterra, Spain

Abstract: The study of memory storage and retrieval with models of attractor neural networks dates back to the 1980's [5]. In such models memory is defined as a persistent state of the dynamics of the network, which is stored in the synaptic weight matrix [4]. Introduction of tools inherited from statistical physics, in particular the spin glass theory created for the study of magnets, allowed analytical study of the models [1]. In particular the capacity, defined as the maximum number of fixed points that the network is able to store, is still one of the main questions in the field [2, 7]. However, little is known about the basins of attraction of these fixed points.
We present a computational study of the basins of attraction in a network of sparse binary synapses with continuous on-line learning, similar to the Amit-Fusi model [3] but with an asymmetric learning rule, which is beneficial for performance. We study the connectivity of the network once the steady state is reached, and compare its properties with experimental data. We study the stability of the attractors under an homogeneous external input, which we use as a bifurcation parameter. To measure the basin of attraction, we test initial conditions increasingly perturbed from the attractor, measuring the hamming distance between initial condition and

intended attractor. We also study the stability of the fixed points under increasing synaptic noise, and the ability of the system to visit different attractors when drived by noise. Finally, synaptic depression dynamics are introduced to recreate hippocampal replay situations [6].
We find that the asymmetric rule increases the resilience of the model against different depression probabilities, and that the resulting connectivity has, when parameters are in their optimal values, similar properties to rat's cortical tissue. Basins of attraction can be tuned using both external input and depression probability, and the use of synaptic depression allows the system to visit stable attractors that would otherwise remain hidden.

Title: Predicting emergent sequences from network connectivity

Authors: K. MORRISON[1], C. PARMELEE[2], S. MOORE[1], *C. P. CURTO[3]
[1]Mathematics, Univ. of Northern Colorado, Greeley, CO; [2]Mathematics, Keene State, Keene, NH; [3]Mathematics, The Pennsylvania State Univ., University Park, PA

Abstract: Many networks in the brain exhibit *internally generated* patterns of activity -- that is, patterns of neuronal firing that are shaped by intrinsic properties of the network rather than by an external input. Such dynamics are believed to underlie many brain functions, ranging from central pattern generators for locomotion to emergent sequences in cortex and hippocampus. To

isolate the role of network connectivity in shaping emergent dynamics, we previously introduced the *Combinatorial Threshold Linear Network* (CTLN) model. This model has binary synapses, simple perceptron-like neurons, and uniform external input, ensuring that the emergent dynamics are controlled solely by the structure of connectivity, dictated by an underlying directed graph G. The CTLN model naturally gives rise to sequential neuronal activity, even when G is densely-connected and has no obvious chain-like architecture. This allows us to study how network connectivity shapes emergent sequences. We found that the degree profile (the set of in/out-degrees) of a graph is a surprisingly poor indicator of network dynamics; networks with matching degree profiles can have dramatically different dynamics -- including different numbers of attractors, different types of attractors (fixed point, limit cycle, or chaotic), and different sequences.
In this work, we present a sequence prediction algorithm to predict emergent sequences from a purely graph-theoretic analysis of G. The algorithm removes nodes in order to decompose graphs down to a core cycle, and then reconstructs them to arrive at a final sequence. It is tailored to oriented graphs with no sinks, as we have proven that associated CTLNs will have no stable fixed points, and it predicts both the number of dynamic attractors and the sequence of neuronal firing. The algorithm accurately predicts all emergent sequences for 142 of the 160 permutation-inequivalent oriented graphs with no sinks on n <= 5 neurons. Furthermore, we developed a new system of labeling graphs based on the decomposition rules. This taxonomy is significantly better at reflecting the types of emergent attractors, even beyond sequence prediction, allowing us to classify graphs into ``species" that display similar dynamics. We identified 19 dynamic attractor types that emerge for n <= 5 networks, and classified families of distinct non-isomorphic networks that have identical attractors. In addition to simple limit cycles, we observed more complicated periodic attractors, as well as one n=5 graph with three quasiperiodic attractors and another one with four chaotic attractors.

Title: Entropy based graph theory models of hydra regeneration

Authors: *S. BATIR, J. LOVAS, R. YUSTE
Dept of Biol. Sci. and Neuroscience, Neurotechnology Ctr., Columbia Univ., New York, NY

Abstract: Hydra vulgaris, a freshwater polyp and member of the phylum Cnidaria, is a representative of the simplest nervous systems in evolution and is also well known for its ability to reconstitute itself following traumatic damage and injury, even re-aggregating its body from a collection of dissociated cells. We are using Hydra as a preparation to both engineer its neural controllers and behavior, and to computationally model and understand its regenerative behaviour. A common assumption in the field has been that a temporal, cause-effect system can sufficiently capture the macro-scale initiation of regenerative behaviour. Here, we have chosen to instead examine time-invariant properties, applying graph theoretic approaches to interpret the evolution of a Hydra's entire neural net during reaggregation. We analyzed calcium imaging movies of transgenic GCAMP Hydra that were actively regenerating, and generated a time invariant graphical model that examines mutual information throughout multiple re-aggregation trials. The graph's vertices are defined as the fluorescent nerve net cells, and the graph's edges are defined as the mutual information across all time points. When we established a mutual information threshold, we observed an underlying, recursive geometry to an actively regenerating Hydra's nerve net. Simple network motifs repeatedly activate across all regeneration trials, recruiting surrounding network motifs in a spreading manner. We further determine underlying geometries of the network's most common motifs, and explore the graph model's balance by maximizing underlying graph entropy while minimizing enthalpy for the formation of new subgraphs within the network. Our analytical approach provides both a time invariant and interdisciplinary paradigm for describing and analyzing nerve-net mediated regenerative behaviour. Through our entropy-graph model of Hydra regeneration, we borrow organizing principles from information geometry and statistical thermodynamics to deconvolve an otherwise complex behaviour that has since eluded biologists and neuroscientists.

Title: Dynamic network analysis, an application to *C. elegans*

Authors: *V. GEORGE, F. PUPPO, G. A. SILVA
Bioengineering, UC San Diego, La Jolla, CA

Abstract: The complexity of neuronal networks makes it generally intractable to track all actualized signalling pathways. We constructed a geometric graph and analysed the resulting dynamics on that graph through the lens of refractory dynamics. As a proof of concept of our approach, we used the vast trove of C. Elegans research from Worm Atlas to construct a directed

geometric graph and to analyse the resulting dynamics supported by the connectome.
We developed a mathematical framework to analyse the temporal and spatial evolution of signalling in geometric network consisting of nodes (neurons) and edges (axons). To analyse the dynamical evolution of signals in the network we used generally prescribed values for the refractory periods and signalling speeds. For this work we developed tools which allowed us to interrogate the dynamics resulting from a single impulse input to the chemosensory ASEL neuron. Firstly, to get a network level view of the resultant activity we generated a spike raster. We then probed deeper into how the underlying graph supports network activity. Thanks to our approach, and given our access to the connectome, we were able to establish causal links between node activations. Through the capture of the causal links in the system, we established the transient and persistent dynamics supported by the connectome. Additionally, we detected cycles which maintain the persistent activity in the network. Our approach and analysis techniques serve as the basis to experimentally test activation pathways, elucidate pattern generators of the network, and begin to provide a methodology to hypothesize sub-circuits involved in certain functions based upon the prevalent signalling pathways involved in the activation of nodes of interest.
This efficient approach to analyse network dynamics which focuses on the essential signalling characteristics (signalling speeds, delays, and refractory periods) of dynamics within a neural network gives us the ability to probe the activity supported by connectomes. Our preliminary observations during the course of this work raise several theoretical and experimental questions. For example, what is appropriate stimulation protocol with which to perturb the C. Elegans network? Since in this work we focus on food stimulus, how do the patterns of activity compare to different stimuli? For example, touch response. How do gap junctions affect the network behaviour? How best to model a hybrid of spike-time and amplitude modulated networks? In addition to analysis, we also believe more work in signalling characterization of the individual neurons themselves would lead to more robust analysis.

Title: Wide-field imaging of magnetic fields from brain slice using nitrogen-vacancy centers in diamond

Authors: *M. KARADAS[1], A. M. WOJCIECHOWSKI[2], A. HUCK[2], U. L. ANDERSEN[2], N. O. DALBY[3,2], A. THIELSCHER[1,4]
[1]Electrical Engin., [2]Dept. of Physics, Tech. Univ. of Denmark, Kgs Lyngby, Denmark; [3]Dept. of Drug Design and Pharmacol., Copenhagen Univ., Copenhagen, Denmark; [4]Danish Res. Ctr. for Magnetic Resonance, Copenhagen Univ. Hosp. Hvidovre, Hvidovre, Denmark

Abstract: We explore the feasibility of wide-field imaging of magnetic fields caused by neural activity in rat brain slices with high spatial and temporal resolution using nitrogen vacancy (NV) defects in diamond. Our goal was to determine the required measurement sensitivity and resolution in space and time of the NV sensors. We simulated the magnetic fields using realistic models of pyramidal neurons in the hippocampal CA1 region that would result from evoked events generated by stimulating Schaffer collateral axons. In that setting, excitatory synaptic inputs at AMPA synapses are activated at the stratum radiatum and stratum oriens of pyramidal neurons. The thickness of the simulated brain slice was set to 400 µm, which is similar to standard hippocampus samples prepared for electrophysiological experiments. The calculation of the transmembrane potential and currents was performed using the NEURON (v7.4) software package. Then, the extracellular fields were determined in the diamond plane placed directly below the brain slice. The simulation results demonstrate: (i) The magnetic field vector has one vanishing component that is parallel to the main orientation of the CA1 cells, which is a consequence of the total net axial current density. (ii) If the stimulation is strong enough to generate population spikes in CA1, then the amplitude of the total magnetic field reaches 2.5 nT for the stratum radiatum region, and the temporal information is contained mostly within the DC-0.5 kHz bandwidth. (iii) If the stimulation does not trigger spikes, the field strength and bandwidth reduce to 0.4 nT and 150 Hz, respectively. (iv) Optimal reconstruction of the current source density requires a measurement resolution of around 10 µm. These results suggest that magnetic fields caused by neural activity may be imaged using high-purity diamond sensors with a large NV concentration, combined with a fast, high signal-to-noise ratio camera, commonly used for voltage-sensitive dye imaging.

Abstract: Behavioral tests are one of the most important tools for the study of memory and learning, which is used in animal models allowing a better understanding of the behavior of external stimuli, as well as the evaluation of drugs and their effect on the Central Nervous System (SNC).This type of test is divided into 2 large groups, the animal models of conditioned response (4-dish test, conditioning of ultrasonic vocalizations, electrical stimulation of the brain, among others) and unconditioned response (open field, high cross maze, Etc.). In this article we will discuss the Open Maze of Barnes (LAB), which is among the unconditioned response models replacing the Morris water maze avoiding the stress that the test generates on the animal. The LAB is based on the observation of specific behaviors, present in exposed animals in different situations. In these cases we try to provoke curiosity and / or fear of the animal by manipulating the environment, causing the need to hide from the source of what the specimen considers a potential danger [1] [2] [12].Since 1979, when the LAB was developed by Carol Barnes, tests were performed manually, only with the record from an observer, which recorded the data, with the objective of evaluating memory and learning mechanisms.With the development of technology and the advancement of the techniques of Artificial Vision (VA) and image processing (PI), there has been a series of applications and an infinity of uses for this type of processes, from security cameras, to Automatic processes in manufacturing companies.Thanks to the wide field of work and the flexibility of application that has today the computational processing, we decided to integrate it in the existing models for cognitive and behavioral tests.The development of our system focuses mainly on the optimization of the process involved in this type of studies, allowing a greater agility at the time of gathering and processing information and, in turn, allow the interpretation of the results in a shorter period, in addition to Be a low cost tool. Currently there is specialized software for the automation of behavioral tests, however, the cost is high, out of the economic reach of some, and in some cases work specifically with a platform with pre-established characteristics.

Title: Structural properties of a probabilistic model of neuronal connectivity in a simple vertebrate animal

Authors: *A. FERRARIO, R. MERRISON-HORT, R. BORISYUK
Plymouth Univ., Plymouth, United Kingdom

Abstract: Understanding the relationship between structure and function of neural circuits is a key problem in modern neuroscience. Although the connectivity of neuronal circuits varies considerably between individuals, functional behaviours are approximately the same, especially in the case of simple animals. This commonality in behaviour suggests that there are some fundamental principles that underlie the structure of nervous system. How can we identify these fundamental properties that are shared across individuals and allow the nervous system to function correctly?
We attempt to answer this question in the case of the hatchling *Xenopus* tadpole by defining a probabilistic model (PM) of connectivity between neurons in the animal's spinal cord. The model is derived by generalizing from multiple biologically realistic computer-generated connectomes, each representing a single individual. The model reflects properties that are shared across multiple tadpoles, and they are not biased by the individual differences. We therefore believe that the PM reflects the fundamental organisational principles of neuronal connectivity in this system. We map the connectomes generated by the PM to functional models of spiking neurons to clarify the relationship between structure of connectivity and function (swimming). We use the PM to calculate various structural measures of the whole tadpole spinal network, as well as different functional subnets (e.g. sensory pathway, central pattern generator), and compare these with known measures from other animals: C. elegans, macaque, cat and zebrafish. It is known that these networks can characterised as small-world graphs with hub structures. Similar to that we find that connectomes, corresponding to simulation of the individual tadpole, can be characterised as small-world graphs with hubs. However, this property is removed by the generalization process, as connectomes generated by the PM do not contain hubs. Since these connectomes still swim reliably, we conclude that the presence of hubs is not important for swimming.
Studying the network on one side of the tadpole spinal cord we find that this sub-network is of the small-world type and there are some similarities with C. elegans network. This result makes

an interesting link between the network structure of invertebrates and vertebrates. We calculate the spectrum of network building blocks (motifs) and identify those that are over-represented. We compare these results with similar motifs in C. elegans, macaque and cat cortex as well as the sensorimotor pathway of zebrafish. According to this analysis, the closest correspondence was between the tadpole and zebrafish.

Title: A CPG-driven neuromechanical model of forward locomotion in *C. elegans*

Authors: *E. OLIVARES[1], E. J. IZQUIERDO[1,2], R. D. BEER[1,2]
[1]Cognitive Sci. Program, [2]Sch. of informatics and Computing, Indiana Univ., Bloomington, IN

Abstract: Despite the relative simplicity of *C. elegans*, its locomotion machinery is not yet well understood. *C. elegans* locomotes in an undulatory fashion, generating thrust by propagating dorsoventral bends along its body. Two hypotheses have been proposed for the generation of these body bends: central pattern generators (CPGs) and oscillations through sensory feedback from stretch receptors. Calcium imaging studies have established that oscillatory patterns are present in ventral cord motoneurons during both forward and backward locomotion. In a recent study, we used computational modeling to demonstrate that a ventral cord CPG is feasible given the neuroanatomy and neurophysiology of the worm. We identified a repeating neural subcircuit capable of producing a pattern of neural activity that is consistent with what has been observed in the worm during backward and forward locomotion. In this study, we demonstrate that the subcircuit identified in our previous study can be interconnected as a set of repeating neural units along the ventral cord to drive forward locomotion on agar. In order to do this, we integrated the neural model with a reconstruction of a biomechanical model of the worm's body from published descriptions, with updated musculature. We used an evolutionary algorithm to fit the unknown physiological parameters of neurons, synapses and neuromuscular junctions to match the mean velocity observed in worms crawling on agar. We show that it is possible for the worm to locomote forward relying exclusively on ventral cord CPGs, without the use of stretch receptors. While the worm does use stretch receptors, our results suggest the worm is capable of producing realistic movement through multiple CPGs interconnected along the ventral cord. By running the evolutionary algorithm multiple times, we obtained not just one hypothetical solution but an

ensemble of different parameter configurations that allow the model to produce forward locomotion. Analysis of the ensemble allows us to produce testable hypotheses about the neural basis for forward locomotion in the nematode. Altogether, we provide an existence proof for forward locomotion through CPGs in an up-to-date neuromechanical model of the worm, as well as a series of testable hypotheses about its operation.

Title: *C. elegans* Neural Interactome: Interactive visualization of a full neuronal system

Authors: J. KIM[1], *E. SHLIZERMAN[2]
[1]Electrical Engin., [2]Univ. of Washington, Seattle, WA

Abstract: Both connectivity structure and dynamical biophysical processes determine the functionality of neuronal networks. We therefore develop a real-time framework, called Neural Interactome, to simultaneously visualize and interact with the structure and dynamics of such networks. Neural Interactome is a cross platform framework implemented in Python and is also a Web interface available online. It combines graph visualization with simulation of neural dynamics, or experimentally recorded multi neural time series, and allows application of stimuli to neurons for examining responses of the network. In addition, Neural Interactome supports structural changes, such as disconnection of neurons from the network (ablation feature), as typically done in experiments. Neural dynamics can be explored on a single neuron level (using a zoom feature), back in time (using a review feature) and recorded (using presets feature). We implement the framework to a model of the nervous system of *Caenorhabditis elegans (C. elegans)* nematode, and show that it can assist in studying neural response patterns associated with locomotion and other stimuli. In particular, we demonstrate how stimulation and ablation help to identify neurons, which play critical role in dynamics related to experimentally studied touch response circuit, and explore new scenarios that did not undergo extensive experimental studies.

Title: Network models of zebrafish whole-brain cell-resolution dynamics

Authors: ***M. RUBINOV**, Y. MU, D. V. BENNETT, N. VLADIMIROV, M. B. AHRENS
Janelia Res. Campus, Howard Hughes Med. Inst., Ashburn, VA

Abstract: Cell-resolution calcium-imaging data in zebrafish represent an unmatched view into vertebrate brain activity, but have been little analyzed quantitatively at the whole-brain level. We developed novel constrained factorization algorithms to analyze and model individual cell activity in these data in terms of a small number of interacting functional systems. Unlike many common dimensionality reduction algorithms, our framework produces anatomical representations of functional systems, and allows to interrogate these systems with follow-up ablation and stimulation experiments. The first step in our framework is the conversion of raw pixel time series (with dimensions: ~50 million pixels × ~10 thousand time points) into cell time series. We accomplished this with a combination of volumetric registration, four-dimensional

data storage, and constrained matrix factorization applied to contiguous blocks of these data in parallel. The resulting cell representation of whole-brain activity accurately reproduced the raw pixel time series (Figure 1 [left figure]), while reducing the size of the original data by two orders of magnitude (to ~100 thousand detected cells). We proceeded to factorize the cell time series into brain networks or systems, defined as groups of cells with similar activity. We applied non-negative matrix factorization to whole-brain cell resolution data to detect 10-100 systems, and standardized the spatial representation of these systems across multiple fish (Figure 2 [right figure]). This resulted in the delineation of spatial consensus networks and their associated time series in each fish. Finally, we devised novel nonparametric models to describe the activity of each cell in terms of a small number of overlapping functional systems. This allowed us to reduce the dimensionality of the data even further, and at the same time yielded insights on the activity of individual cells embedded in distinct systems. Together our approach allows a novel understanding of vertebrate whole-brain activity as an empirically constrained and integrated system.

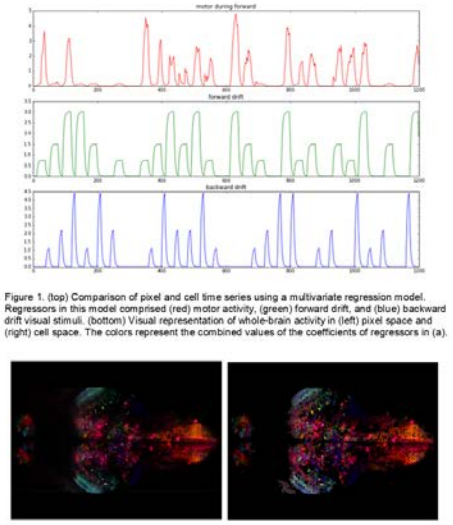

Figure 1. (top) Comparison of pixel and cell time series using a multivariate regression model. Regressors in this model comprised (red) motor activity, (green) forward drift, and (blue) backward drift visual stimuli. (bottom) Visual representation of whole-brain activity in (left) pixel space and (right) cell space. The colors represent the combined values of the coefficients of regressors in (a).

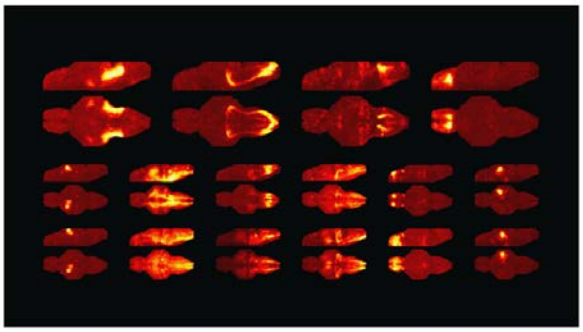

Figure 2. An illustration of 16 systems detected across 6 fish registered to a common template. These systems span the forebrain, midbrain and hindbrain, and include a combination of sensory, motor and associative areas.

Title: Multi-timescale hidden state modelling of rat behavior reveals temporal-spatial patterns

Authors: *H. SHAN, P. MASON
Dept. of Neurobio., Univ. of Chicago, Chicago, IL

Abstract: Rat locomotion in experimental contexts is widely interpreted for a variety of neuroscientific investigations, often via standardized behavioral tests (e.g. Open Field) or customized paradigms. However, analysis of behavior in these contexts largely relies on human intuition, relying on observers to design metrics or sometimes to score the behaviors themselves. We propose a framework for unbiased, quantitative investigation of rat locomotion activities, using an innovative cross-timescale hidden state discovery approach based on hidden Markov models (HMM). Our approach allows automatic and simultaneous identification of microscopic behavioral modes and macroscopic behavioral strategies. We first show that rat locomotion is computationally low dimensional and composed of stereotyped behavioral modes *at different timescales*, therefore suitable for our approach. Mode usage, and the transition between modes are functions of space and time. Importantly, modes across different timescales are connected to each other in specific patterns that suggest different low-timescale mode usage for different high-timescale locomotion strategies. In addition, the modes, the transition structure and the cross-timescales connections are sensitive to experimental manipulation. We contend that our approach can accelerate experimental investigations of rat behaviors by identifying stereotyped modes automatically and discovering how they are used by global behavioral strategies.
Experimentalists can design behavioral paradigms and metrics in analysis that are informed by stereotyped behaviors in rats. Further, these modes may be driven by distinct circuits and neural network dynamics in the nervous system, offering a way to connect behaviors to neural activities directly.

Title: Integrated neuromechanical model shows stretch-reception can generate and propagate wave responsible for forward locomotion

Authors: *E. J. IZQUIERDO[1,2], R. D. BEER[1,2]
[1]Cognitive Sci. Program, Indiana Univ., Bloomington, IN; [2]Sch. of Informatics and Computing, Indiana Univ., Bloomington, IN

Abstract: With only 302 neurons and a fully-reconstructed neural and muscle anatomy at the *C. elegans* is an ideal candidate organism to study behavior with the help of computational models. Of particular interest is understanding the neuromechanical basis of locomotion, since nearly its entire behavioral repertoire is expressed through movement. How the rhythmic pattern is generated and propagated along the body is not yet well understood. We report on the development and analysis of a model of forward locomotion that integrates known neuroanatomy, neurophysiology and body mechanics of the worm. Our model is the first to consider recent experimental analysis of the structure of the ventral cord circuitry and the effect of local body curvature on nearby motorneurons. We developed a neuroanatomically-grounded model of the ventral nerve cord subcircuit, using a neural model capable of reproducing the full range of electrophysiology observed in *C. elegans* neurons. We integrated the neural model with a biomechanical model of the worm's body from published descriptions, with updated musculature and stretch receptors. Unknown parameters were evolved using a genetic algorithm to match the speed of the worm on agar. We performed 100 evolutionary runs and consistently found electrophysiological configurations that reproduced realistic control of forward movement. The ensemble of successful solutions reproduced key experimental observations that they were not designed to fit, including the curvature profile of the body's movement, the wavelength, and frequency of the propagating wave. Analysis of the ensemble revealed forward locomotion is possible without intrinsic oscillations in either the head or the rest of the ventral nerve cord. Circuits were capable of initiating oscillations in the head using stretch reception. Similarly, circuits relied on stretch reception to propagate the dorsoventral oscillation, without the need for bistability in the motorneurons, as had been previously proposed, and with gap junctions across neural units playing only a minor role. Altogether, we provide an existence proof for forward locomotion through stretch-reception in an up-to-date neuromechanical model of the worm, as well as a series of testable hypotheses about its operation.

Title: Implementation of a query language to enable searching structured neurophysiology data

Authors: *P. JEŽEK, J. TEETERS, F. SOMMER
Univ. of California Berkeley, Berkeley, CA

Abstract: To standardize the format of contributed datasets, the Neurodata Without Borders: Neurophysiology (NWB) format was developed. The NWB format provides a standardized, yet extendable way to store neuroscience data sets. It includes a self-describing specification language that facilitates annotation of data in a unified way.
To make datasets in NWB format searchable, we developed a query engine to support searching collections of NWB files within a lab or in a repository. The query language implements basic logical, arithmetical and relational math operators. Further, the query engine contains a query parser and an NWB connector. The parser translates a query into an internal tree structure. A NWB connector was created that relates the internal representation of the query to NWB files and returns a serialized result. The NWB connector ensures an abstraction of a native HDF application interface. Technically, it is implemented on top of HDFql language that extends e. g. by filters and logical operations.
In this work we demonstrate the capabilities of the query language in a particular use case, NWB datasets in the CRCNS.org repository. CRCNS.org is a public repository for sharing neurophysiology datasets that are transferred to NWB gradually.
Our long-term goal is to provide a search engine that works across different technologies how to work with neurophysiology data.To achieve this, the query engine is implemented in a modular structure, which facilitates its adaptation to other environments, for example, other search engines and data formats. Specifically, the engine designed to be able to deal with different semantic expressivity of technologies used for neurophysiology data.

Title: Harmonization of cortical thickness measurements across scanners and sites

Authors: *N. CULLEN[1], J.-P. FORTIN[2], Y. I. SHELINE[3], R. SHINOHARA[2]
[1]Psychiatry, [2]Biostatistics and Epidemiology, [3]Univ. of Pennsylvania, Philadelphia, PA

Abstract: Introduction: With the proliferation of multi-site neuroimaging studies there is a greater need for handling non-biological variance related to the properties of MRI scanners and scan site. Such unwanted sources of bias and variability are typically included as standard confound variables, or confounders, in statistical analyses. However, non-biological confounders

typically have *a priori* unpredictable effects which may compromise the generalizability and reproducibility of results, suggesting the need for statistical methods that harmonize structural neuroimaging data across sites without compromising true biological signal.
Methods: Structural MRI images we acquired from 187 patients with major depressive disorder (MDD) at 4 different sites, with approximately even distributions of age and symptoms across sites. The ANTs cortical thickness pipeline was applied to extract cortical thickness from 102 brain regions in the OASIS template. The ComBat algorithm was applied as a pre-processing step to the cortical thickness values, after which various statistical learning tasks were carried out to understand the relationship between cortical thickness and phenotypic measures.
Results: Before Combat harmonization, median subject cortical thickness significantly differed across sites ($p = 3.3 \times 10^{11}$), particularly at one of the sites, and found 62 individual ROIs significantly associated with site after multiple comparisons. We also found that a cross-validated SVM achieved 76.6% accuracy in classifying the scanning site from their cortical thickness data alone. After applying Combat, median cortical thickness showed no difference across site, nor did any ROIs. Additionally, an SVM trained on Combat-corrected data achieved no better than random chance in classifying subjects by site. Finally, Combat improved associations between cortical thickness and age; the percentage of variation in average cortical thickness explained by age increased from 23 % to 33% before and after Combat, respectively.
Conclusions: Our results suggest that applying the ComBat algorithm to multi-site cortical thickness pipeline removes unwanted non-biological signal, increases univariate associations between regional cortical thickness and phenotypic measures, and increases the strength of out-of-sample multivariate predictions as compared to residual harmonization, adjusted residual harmonization, and the baseline of no harmonization. Most importantly, the ComBat algorithm can be seamlessly dropped into any existing pipeline as a fast and effective pre-processing step.

Title: Analyzing volumetric anatomical data with immersive virtual reality tools

Authors: *S. PAGÈS[1,2], A. HOLTMAAT[1], J. DONOGHUE[2], G. REYMOND[2]
[1]Univ. of Geneva, Geneve, Switzerland; [2]Wyss Ctr. for Bio and Neuroengineering, Geneva, Switzerland

Abstract: Recent advances in high-resolution 3D imaging techniques allow researchers to access unprecedented amounts of anatomical data of brain structures. In parallel, the computational power of commodity graphics cards has made rendering billions of voxels in real-time possible. Combining these technologies in an immersive virtual reality system creates a novel tool wherein observers can physically interact with the data. We present here the possibilities and demonstrate the value of this approach for reconstructing neuroanatomical data. We use a custom built digitally scanned light-sheet microscope (adapted from Tomer et al., Cell, 2015), to image rodent clarified whole brains and spinal cords in which various subpopulations of neurons are fluorescently labeled. Improvements of existing microscope designs allow us to achieve an in-plane submicronic resolution in tissue that is immersed in a variety of media (e. g. organic solvents, Histodenz). In addition, our setup allows fast switching between different objectives and thus changes image resolution within seconds. Here we show how the large amount of data generated by this approach can be rapidly reconstructed in a virtual reality environment for further analyses. Direct rendering of raw 3D volumetric data is achieved by voxel-based algorithms (e.g. ray marching), thus avoiding the classical step of data segmentation and meshing along with its inevitable artifacts. Visualization in a virtual reality headset together with interactive hand-held pointers allows the user with to interact rapidly and flexibly with the data (highlighting, selecting, slicing, zooming etc.). This natural interface can be combined with semi-automatic data analysis tools to accelerate and simplify the identification of relevant anatomical structures that are otherwise difficult to recognize using screen-based visualization. Practical examples of this approach are presented from several research projects using the lightsheet microscope, as well as other imaging techniques (e.g., EM and 2-photon).

Title: Open-source group feeding experimentation device (g-fed): Monitoring home cage feeding behavior in rodents

Authors: *M. A. ALI[1], K. P. NGUYEN[3], A. V. KRAVITZ[1,2]
[1]NIDDK/DEOB, Natl. Inst. of Hlth., Bethesda, MD; [2]Natl. Inst. on Drug Addiction, Natl. Inst. of Hlth., Baltimore, MD; [3]Carnegie Mellon Univ., Pittsburgh, PA

Abstract: Monitoring food intake is essential for studying eating disorders, however, current methods are either expensive and requires special caging, or cheap and inaccurate. We designed a device called Feeding Experimentation Device (FED), which is a home cage compatible food dispenser that monitors mice feeding behavior with high precision and temporal resolution. FED is cheap and easy to assemble using off the shelf components. FED has an infrared sensor that constantly monitors the presence of a food pellet, where a retrieval of the pellet triggers a motor to dispense a new one. Previously, FED logged the pellet retrieval date and time to a Secure Digital (SD) card. The data could then be analyzed and visualized using a desktop computer. Recently, we have updated FED with two new features: 1) WIFI enabled processor to send data over the internet; this allows for a real time visualization of mice feeding behavior and warning notifications if the device fails to operate, 2) a Radio Frequency Identification (RFID) system to differentiate between individual mice within a single cage for group feeding experiments. These modifications allow greater flexibility in food intake experiments with less intervention from the experimenter. G-FED is an open source, high throughput feeding device that provides instantaneous feeding analytics for group housed mice.

Title: Integrating molecular markers and gene expression in SenseLab for neuroinformatics-driven discovery

Authors: *M. SURLES-ZEIGLER[1], T. M. MORSE[3], R. A. MCDOUGAL[2], G. M. SHEPHERD[4]
[1]Ctr. for Med. Informatics, [2]Neurosci., Yale Univ., New Haven, CT; [3]Neurosci., Yale Univ. Sch. Med., New Haven, CT; [4]Dept. Neurosci., Yale Univ. Sch. of Med., New Haven, CT

Abstract: SenseLab (https://senselab.med.yale.edu/) is a collection of Neuronal, Olfactory and Disease Databases whose overall aim is to enhance experimental analysis of brain function. The

Neuronal Databases provide curated data about neurons; these include NeuronDB (https://senselab.med.yale.edu/NeuronDB/) which provides unique tools to enable users to integrate data on membrane properties, receptors, and channels in subcompartments of individual neuron types and ModelDB (https://senselab.med.yale.edu/ModelDB/) which provides published models for simulating the experimental results. To extend NeuronDB to new data, we have recently added molecular markers and gene expression data. For this purpose, we added these properties to a subset of hippocampal cells (cells of the dentate gyrus and regions CA1, CA3, and CA4), and will eventually incorporate them into cells from other brain regions within the database. To accomplish this, we are developing a process where first, Natural Language Processing techniques are applied to the PubMed API (application program interface) results to identify and download article abstracts that meet inclusion criteria after a semantic search from a corpus of related terms. These abstracts then progress to the next stage of analysis, article review. For this stage, we began with abstracts related to normal function; to be extended eventually to disease processes or treatments and developmental. During article review, molecular marker, gene expression data and the associated metadata (e.g. animal species, age, sex) are extracted from journal articles and stored in an EAV/CR (entity-attribute-value with classes and relationships) database. This data is accessible to the user via an expanded NeuronDB, and an interactive hippocampus microcircuit browser. The browser enables interoperability between the SenseLab databases' neuronal properties with links to other properties such as electrophysiological data as tracked by associated databases such as Neuroelectro (http://neuroelectro.org). Furthermore, this combined data is displayed in a new integrated graphic format called microcircuit viewer within the FunctionalMicroconnectomeDB, in which each neuron can be selectively visualized in relation to the different cell compartments and their properties within the microcircuits to which they contribute. Incorporation of molecular markers and gene expression data into the SenseLab databases will accelerate experimental and modeling research, assist in the exploration of experimental studies and models of neurons and their ion channels and receptors.

Title: Digital signal processing toolbox for real time MEG data analysis in source space

Authors: A. MOISEEV, N. PEATFIELD, S. DOESBURG, T. CHEUNG, *U. RIBARY
Simon Fraser Univ. (SFU), Burnaby, BC, Canada

Abstract: There is a growing interest in analysing MEG data in real time known as real-time MEG (rtMEG). rtMEG has potential applications in training/rehabilitation of patients using neurofeedback, brain-machine interfaces, communicating with patients with locked in syndrome, brain injury diagnostics to name a few. Recent advances in MEG instrumentation allow delivery of the MEG signal to digital signal processing (DSP) systems with sub-millisecond delay from the brain event. Earlier MEG studies showed that the brain can process sensory information in discrete time quanta as small as 12-15 ms (Joliot et al 1994). Thus to be successful, it may be crucial for rtMEG DSP system to submit its output to a feedback loop with milliseconds latency. With this performance objective in mind, we implemented a DSP toolbox to be used with the latest generation of CTF MEG electronics. In addition to basic data buffering and flow control functions, it provides on-the-fly source reconstruction using a SAM beamformer (Robinson & Vrba, 1999). To our knowledge, other existing rtMEG implementations use minimum-norm based global inverse solutions, which allow faster computations at the expense of spatial resolution. In contrast, our toolbox implements high resolution beamformer reconstruction. It was made possible by leveraging multi-threaded parallel processing capabilities of the modern computers. The software is written in C++ and runs on a general-purpose computer under a Linux OS. As an example, for an Intel 7-4820K CPU 3.7 GHz desktop it takes less than 1 ms to reconstruct amplitudes of 100 brain sources using 275 MEG channels input. The toolbox communicates with both the CTF MEG electronics and a client application using TCP-based messaging. The client may run in parallel with the toolbox on the same machine, or on a remote host. As a proof of concept, we used a retinotopic mapping experiment. We presented a subject with 9Hz flickering stimuli to map the differing portions of the visual cortex. The acquired data was replayed at 300 samples per second. We were able to localize both the fundamental and the first-harmonics with less than 50 ms latency across multiple virtual sensors. We will present results of actual rtMEG collections with several subjects based on this paradigm. Support: AMG Global Research Inc., BC LEEF, CFI, CIHR, CTF MEG, NSERC

Title: Robust estimation of calcium transients by modeling contamination

Authors: J. L. GAUTHIER[1], *A. S. CHARLES[2], J. W. PILLOW[3], D. W. TANK[1]
[2]Princeton Neurosci. Inst., [1]Princeton Univ., Princeton, NJ; [3]Psychology, Princeton Neurosci. Inst., Princeton, NJ

Abstract: Two-photon calcium imaging has enabled recording of large neural populations, but distinguishing the activity of individual neurons is not always straightforward. In densely stained tissue such as the CA1 region of mouse hippocampus, many cell bodies and processes can overlap in a small space, posing the computational challenge of demixing their signals. Automated “cell finding” methods have been developed to identify the shapes and transients of neural sources, including demixing signals from overlapping sources. These methods, however, remain susceptible to a fundamental problem: unidentified sources can produce signals that contaminate the transient estimation for identified sources. For example, if a neurite overlaps a cell body, but only the shape of the cell body was identified during cell finding, fluorescence activity in the neurite will produce an increase in the estimated fluorescence of the cell body. If unaddressed, contamination can impact scientific conclusions. For example, in one dataset collected from CA1 in an awake, behaving mouse, some pyramidal cells appeared to have multiple place fields, when in fact their time courses included activity from multiple, overlapping neurons, each of which only had a single place field. In this work, we develop an algorithm to remove such false transients. This method is based on modeling the noisy observed movies as consisting of either known sources, or a mixture of known and unknown sources (i.e. neurons or processes not detected during cell finding). We model the unknown sources as a sparse sum of Gaussian shaped dictionary elements, allowing the method to flexibly construct new sources that describe activity not accounted for by the known sources. An approximation to the maximum likelihood estimator was used to infer the activity of the known sources as well as the structure and activity of the unknown sources. This optimization reduces to an efficient and tractable modification of the LASSO procedure. We call this estimator Sparse Emulation of Unknown Dictionary Objects, or SEUDO. When applied to CA1 recordings in which some active neurons were not identified during cell finding, the performance of SEUDO was compared to manual human classification. All true transients were preserved, and false transients were either reduced in amplitude or eliminated entirely.

Title: Selective, subsecond measurement of *In vivo* hydrogen peroxide dynamics employing a double voltammetric waveform

Authors: *C. MEUNIER, E. MITCHELL, V. TOUPS, J. ROBERTS, G. MCCARTY, L. A. SOMBERS
Chem., North Carolina State Univ., Raleigh, NC

Abstract: Hydrogen peroxide (H_2O_2) is a reactive oxygen species that also serves as an important signaling molecule in normal brain function. Its concentrations fluctuate with precise spatial and temporal resolution such that functional levels can be achieved for signaling, yet unregulated H_2O_2 generation contributes to a myriad of pathological consequences due to oxidative stress. Studies aimed at elucidating these dynamics and the diverse roles that H_2O_2 plays in complex biological environments have been hindered by the lack of a method for probing dynamic H_2O_2 fluctuations in living systems with molecular specificity. Fast scan cyclic voltammetry (FSCV) at carbon-fiber microelectrodes provides a method of detecting H_2O_2 with high temporal and spatial resolution that can be used in awake and behaving animals. However, H_2O_2 variability can be masked by pH changes, which are common *in vivo*, because the voltammograms for these species overlap. A clear distinction between pure H_2O_2 and pure pH voltammograms is required for regression analysis of mixed voltammetric data. We present a novel method for removing pH contributions from complex voltammetric data. By employing two distinct potential waveforms per scan, one in which H_2O_2 is electrochemically silent and a second in which both pH and H_2O_2 are quantified. Using multivariate analysis with this waveform paradigm permits the quantified of both analytes. Thus, this work provides a powerful tool that has been used to disambiguate and evaluate spontaneous H_2O_2 fluctuations in vivo on a subsecond timescale. The data directly verify a functional relevance for dynamic H_2O_2 signaling in the dorsal striatum.

Title: Designing workflows for the collaborative management and analysis of electrophysiological data and metadata

Authors: J. SPRENGER[1,2,3], A. YEGENOGLU[1,2,3], S. GRÜN[1,2,3,4], *M. DENKER[1,2,3]
[1]Inst. of Neurosci. and Med. (INM-6), [2]Inst. for Advanced Simulation (IAS-6), [3]JARA BRAIN Inst. I (INM-10), Jülich Res. Ctr., Juelich, Germany; [4]Theoretical Systems Neurobio., RWTH Aachen Univ., Aachen, Germany

Abstract: The complexity of neuroscientific experiments and their analysis has grown to a degree where special effort and attention is required to guarantee their reproducibility. In addition, collaborations across different laboratories and countries are becoming a standard work setting, which increases the need for comprehensive documentation of data and metadata, and explicit, formal descriptions of the data analysis process. The availability of software tools that support scientists in the various steps of this process is therefore indispensable [Denker and Grün (2016) In: Brain-Inspired Computing: Brain Comp 2015, Springer]. Moreover, it is necessary to establish the workflows that link the various tools, and to develop simple interfaces for them. Here we demonstrate how such a reproducible, structured, and comprehensible workflow for an electrophysiological experiment, covering the preparation, annotation and analysis data, can be set up in a collaborative environment by the combination of multiple state-of-the-art open-source projects. The workflow features the Electrophysiology Analysis Toolkit (Elephant), which represents the central analysis resource offering methods ranging from the analysis of ensemble spike data to population signals, such as local field potentials [http://neuralensemble.org/elephant/]. Elephant is based on the generic standardized data representation for electrophysiological data provided by the Neo library [Garcia et al. (2014) Front Neuroinf 8:10]. In addition, Neo is able to interface with a range of data formats commonly used in electrophysiology. The open metadata Markup Language (odML) is used as the hierarchical structure to store metadata related to electrophysiological experiments [Grewe et al. (2011) Front Neuroinf 5:16]. Furthermore, odMLtables extends the accessibility of odML by providing an interface to a tabular metadata representation, e.g., using Excel

[https://github.com/INM-6/python-odmltables]. Finally, NIX is a newly developed scheme designed to combine electrophysiological data and metadata in a single, standardized format [https://github.com/G-Node/nix], and links the Neo and odML data models. We discuss multiple mechanisms that allow to describe the workflow itself, and show how it may be implemented, e.g., using the Collaboratory of the Human Brain Project [https://collab.humanbrainproject.eu]. While focusing on electrophysiology, many concepts of this workflow are also transferable to different types of experimental environments.

Title: Apes: Automated pipeline for EEG source reconstruction for large scale EEG analysis

Authors: *M. VIRMANI[1], N. AHUJA[2], N. PEGWAL[2], R. SHARMA[2]
[1]Dept. of Physiol., Stress & Cognitive Electro Imaging Lab. (SCEL), New Delhi, India; [2]Dept. of Physiol., Stress & Cognitive Electro Imaging Lab. (SCEL), All India Inst. of Med. Sci. (AIIMS), New Delhi, India

Abstract: Available EEG source analysis softwares lack the automation for source analysis with options of choosing multiple subjects, task conditions, method of inverse solution etc. In pursuit of fixing all the above problems with source code of openly available softwares, the focus of researchers deviates from focussing on the scientific problem to ‘how’ to do EEG data analysis. Automated Pipeline for EEG Source reconstruction (APES) aims to do away with these challenges and provide a streamlined and highly intuitive software to perform source localization with the flexibility to change and compare multiple parameters according to the need of a particular experiment. The pipeline uses MATLAB programming language and the functions of Brainstorm toolbox (which could be extended to other softwares such as Fieldtrip, EEGLAB etc.). APES has incorporated the following order of operations with a possibility to add additional operations: i) Asks user to put standard inputs: Headmodel, Channel file, Subjects EEG data, Anatomy, Choice of source algorithm ii) Extracts all the epochs for each subject’s EEG data, iii) Compute the necessary inputs for the chosen source algorithm, iv) Compute the inverse solution for each epoch, and finally, v) Compute the source waveform for each epoch of each subject. This order of operations could be repeated for any number of conditions and any number of subjects thereafter. As a test, source localization was performed using APES for extracting sources of Default Mode Network in Sternberg Working Memory experiment. APES was performed for 27 subjects, 4 conditions with ICBM152 anatomy, GSN-128 channel and a

headmodel created using Boundary Element Method (BEM). The spatial filtering technique called Beamforming was used as source localization algorithm. APES demonstrated the computation time of 2s per epoch to obtain the inverse solution, which is highly optimized when compared to multiple manual steps required in other softwares. Also it removes difficulties in repeating the similar experiment with slightly different parameters. APES has the potential to become a full-fledged EEG analysis software platform with further enhancement in the extension of the features such as preprocessing, statistical analysis, plotting etc. and using high-performance programming languages like Python/ C++. APES aims to contribute to the mission of democratizing neurotechnology by giving any hacker/ hobbyist as well as researchers to draw significant insights about how our brain works and thus advance the field of neuroscience, with utmost ease.

Title: Real-time experimental control with graphical user interface (REC-GUI) for neuroscience research

Authors: ***B. KIM**, S. KENCHAPPA, T.-Y. CHANG, L. W. THOMPSON, A. ROSENBERG
Neurosci., Univ. of Wisconsin - Madison, Madison, WI

Abstract: The accurate and precise association of neuronal activity and behavior requires the combination of real-time experimental control, stimulus rendering/presentation, as well as precisely timed measurements of electrophysiological/behavioral responses. Jointly satisfying the design specifications to achieve these distinct requirements is a challenge for experimental control systems. Towards the goal of developing a flexible solution for neuroscience research, we are spearheading a novel framework for conducting high precision experimental control using network-based parallel processing. The Real-Time Experimental Control with Graphical User Interface (REC-GUI) consists of three major components: (*i*) experimenter control, (*ii*) scripts for rendering/presenting experimental stimuli, and (*iii*) data acquisition for behavioral measurements and high-density neural recordings. At the system's core is network-based parallel

processing. Command sets are grouped into two major components: (*i*) experimental control/behavioral monitoring and (*ii*) stimulus rendering/presentation. Each group of command sets is executed on separate CPUs that communicate using internet protocols (UDP/TCP). This flexibly allows each CPU to execute command sets written in different computer languages and across different operating systems, with the only requirement being that they support network interfacing. Network-based parallel processing provides two distinct advantages: (*i*) a modular design that minimizes coding efforts (users can flexibly select the coding language) and (*ii*) high temporal accuracy of stimulus presentation and data acquisition. To demonstrate the rigor of this network-based parallel processing scheme, we implemented the following system: (*i*) experimenter control (Python GUI on Linux), (*ii*) stimulus rendering (MATLAB with PsychToolBox on Linux) and stimulus presentation (PROPixx, VPixx Technologies Inc.), and (*iii*) data acquisition (Scout Processor, Ripple Inc. on Windows). The GUI provides a customizable interface for the manipulation of experimental parameters, offering unique usability with real-time graphical feedback of behavior. We present testing results which confirm that this state-of-the-art system can support highly demanding neuroscience experiments. Because the system is modular, all software and hardware components can be easily substituted to meet specific experimental needs. Sample code and hardware configurations will be made available as a template for system customization.

Title: Particle Tracking based Motion Compensation for neuronal imaging

Authors: *W. LOSERT, S. AGHAYEE, D. WINKOWSKI, P. KANOLD
Col. of Computer Mathematical and Natural Sci., Univ. of Maryland, College Park, MD

Abstract: Calcium Imaging provides a real time view of neuronal activity with single cell resolution, with exciting possibilities for real-time readout of neuronal activity, and the potential to modulate neuronal activity with some feedback control. One challenge that prevents simple real time readout of neuronal activity from calcium imaging is jitter in the image. Since imaging is at the single neuron level, even minute shifts or rotations of the imaging field are detectable. Shifts in the location of neurons can lead to artifacts in the quantification of neuronal activity

from calcium images. Thus motion compensation is essential. We introduce a new technique to carry out Motion Compensation for Calcium Imaging that is derived from particle tracking approaches. Particle tracking based motion compensation uses only the brightest neurons that are scattered throughout an image -ten or less are generally sufficient - and tracks their position from frame to frame. This yields information on the shift in position at about ten points spread throughout in the image, which in turn is used to infer the motion and rotation of the image that best agrees with the shift of all points. This approach thus can compensate for rotational shifts unlike most other tools, and is fast enough for real time motion compensation, real time spike inference analysis, and feedback control. We validate the approach on two-photon calcium images in the superficial layers of auditory cortex of awake mice, with a simple nuclear stain as a second steady fluorescent signal that complements the genetically encoded calcium indicators.

Title: Whole mouse brain cell mapping with anatomic specificity using a standardized atlas

Authors: *N. J. O'CONNOR[1], B. S. EASTWOOD[1], S. J. TAPPAN[1], M. J. FAY[1], S. GERFEN[1], P. J. ANGSTMAN[1], C. R. GERFEN[2], J. R. GLASER[1]
[1]MBF Biosci., Williston, VT; [2]Lab. of Systems Neurosci., Natl. Inst. of Mental Hlth., Bethesda, MD

Abstract: Analyzing cellular populations within specific anatomies in brain images requires expertise in identifying neuroanatomy combined with effective cellular identification. The former typically involves a human comparing experimental images with a reference atlas and manually delineating anatomies in images for cellular population analysis. We have developed automated technology capable of reconstructing a whole brain image from serial sections, aligning this 3D brain image to a reference atlas, delineating anatomies in the experimental space, and detecting cells within these anatomies. Mapping cell populations to a standardized atlas allows researchers to objectively accumulate and compare results.
This technology includes alignment methods for assembling 3D brain images from experimental serial sections that are translated, rotated, and flipped with respect to each other. The platform

also includes registration methods for automatically matching the assembled brains to the Allen Institute for Brain Science's Common Coordinate Framework (CCF, http://mouse.brain-map.org/). Following registration, brain structures can be selected in the reference atlas and automatically delineated in the experimental 3D brain image. Newly developed cell detection methods are then performed within the delineated structures to examine population distribution. For validation, we analyzed both brightfield and fluorescent Nissl stained coronal mouse brain sections in whole slide images. Sections from these images were automatically extracted, aligned, and compiled into full resolution 3D whole-brain images (BrainMaker). The 3D brain images were then automatically registered to the Allen CCF using linear and nonlinear transform optimization. Brain structures were selected and delineated in the experimental images, and automated cell detection was applied within these structures. Validation was performed to assess the accuracy of the automated delineation and cell detection.
Here we introduce improved technology for mapping cellular populations to specific structures in reconstructed whole brain images from serial sections. This technology provides repeatable, objective measures that can be compared across experiments and laboratories. The automation of detection and anatomic mapping of cellular populations also creates the possibility of increasing the efficiency of experimental workflows.

Title: Using a probabilistic atlas to improve manual parcellation of the cerebellum

Authors: ***A. J. WORTH**[1], J. A. TOURVILLE[2]
[1]Neuromorphometrics, Inc., Somerville, MA; [2]Boston Univ., Boston, MA

Abstract: In order to develop automated methods for labeling anatomy in MRI brain scans, regions of interest (ROIs) must first be labeled manually and this must be done in a large representative sample in order to capture variability. This is a tedious task that requires considerable expertise but the overall effort can be reduced and the accuracy and reliability can be increased by using a probabilistic atlas to improve both the individual ROIs and also the labeling method.
The cerebellum was labeled in 56 T1-weighted MRI brain scans. There were 31 unique subjects, 25 of which were scanned twice and labeled blind as to which were repeat scans. We also labeled the famous high-resolution Colin27 scan. Following the Schmahmann et al. atlas, 33 regions were delineated in coronal slices: brain stem, right and left cerebellum white matter, and right, left and vermis lobules: I-IV, V, VI, CrusI (vermis "VIIAf"), CrusII, (vermis "VIIAt"), VIIb, VIIIa, VIIIb, IX, X. Identification of the relevant cerebellar sulci was done with the aid of 3D renderings of the cerebellum surface at a series of depths between the white matter and exterior surface. The iso-intensity surfaces were defined by various intensities on either side of the gray matter peak intensity found in a histogram over the cerebellum region. "Sulci lines" drawn on these surface were projected into the 3D scan volume space to identify specific sulci. "Parcellation lines" were then drawn based on the sulci lines in coronal slicess to separate the cerebellar cortex into lobes.
All labeled scans were used to create a probabilistic atlas by averaging the presence or absence of each label after a simple 3D warp to normalize the size of each cerebellum. Then, each region in each slice of every scan was compared to this atlas and an "atlas mismatch" score was calculated. In order to flush out labeling errors, large mismatch values were flagged and those outlines were examined and modified as necessary.
In our results, we describe the locations and types of errors that were found using the probabilistic atlas, and we suggest modifications to the labeling method to improve the reliability and decrease labeling time. In our initial work, we noted the lack of a reliable landmark for dividing vermis VIIAt and vermis VIIAf. According to Schmahmann et al., these regions are separated by the horizontal sulcus. This sulcus is one of the more robust landmarks on the lateral surface but rarely extends medially across the vermal surface. As such, the boundary between these two regions is often arbitrary. Reliable labeling of these areas requires either combining these two small vermis ROIs or identifying another, more robust landmark.

Title: Real-time, automatic calcium image segmentation via topology

Authors: *M. VAIANA[1], E. M. GOLDBERG[2,3], S. E. MULDOON[4]
[1]Mathematics, Univ. At Buffalo, Cheektowaga, NY; [2]Neurol., Children's Hosp. of Philadelphia, Philadelphia, PA; [3]The Perelman Sch. of Med. at The Univ. of Pennsylvania, Philadelphia, PA; [4]Dept. of Mathematics, Univ. At Buffalo, SUNY, Buffalo, NY

Abstract: We present a new method for automatic segmentation of cells from background in two-photon calcium imaging data using topological image analysis. Specifically, we classify homology cycles resulting from the persistent homology of the image complex. Our method offers the following two improvements over current methods. First, the segmentation is run on a single image instead of an entire movie. This allows a researcher to capture a single image at the beginning of a recording session and segment it immediately in real-time. Second, our method captures both neurons that fire and that do not fire. This is desirable when imaging one spatial region multiple times or over multiple sessions, as neurons which fire in one recording but not another will be registered consistently throughout the dataset. We note that, coupled with improvements in real-time motion correction, our method would allow for real-time analysis of neural dynamics.

Title: How to find candidate drugs to be repositioned for neurodegenerative disorders within a graph of globally connected machine-readable papers?

Authors: *R. GURINOVICH, A. PASHUK, E. MOROZ, Y. PETROVKIY, A. DMITRIEVSKIJ, O. KURYAN, A. TIGGRE, A. SCERBACOV
sci.AI, Tallinn, Estonia

Abstract: Drug development is a time and resource consuming process. Luckily, it produces vast amounts of knowledge in the form of laboratory notebooks, grant applications, research papers, and clinical studies reports. Whether the primary goal of the initial project was achieved or not, documented findings can still potentially contribute to future discoveries. Due to the time and economic pressures in de novo drug development, drug repositioning, enabled by this data, is a particularly valuable way of doing discovery.

To make the most from the immense size of the global research communication, research organizations require innovative methods. One of these methods is to decompose research literature to the statements, to link them in the graph and to make new research based on the resulting connections.
This is the method we apply to model a process of drugs repositioning for neurodegenerative disorders. First, we semanticize open access (OA) papers to produce their machine-readable versions through the sci.AI platform. The processed literature is then connected in the graph. The platform performs a search within the graph to find candidate drugs and therapies that might be applied for the treatment of the neurodegenerative disorders. Finally, the results of this computational method are validated against existing research reports.

Title: Automated reconstruction pipeline for oblique light sheet tomography

Authors: *J. MIZRACHI[1], A. NARASIMHAN[2], K. UMADEVI VENKATARAJU[3], P. OSTEN[4]
[1]Neurosci., Cold Spring Harbor Lab., Flushing, NY; [2]Cold Spring Harbor Lab., [3]Osten Lab., [4]Cold Spring Harbor Lab., Cold Spring Harbor, NY

Abstract: Light-sheet fluorescence microscopy (LSFM) provides volume imaging of specimens spanning from a few microns to multiple millimeters of tissue. LSFM has the advantage of high imaging speed, high dynamic range, low photobleaching and low noise. Oblique Light Sheet Tomography (OLST) is one such system tailored specifically for volumetric imaging of larger specimens. This setup combines LSFM, XYZ translation stages and a vibratome-based tissue sectioning to achieve high-speed and constant high-resolution imaging throughout large tissue volumes. In the current application of OLST, a whole mouse brain is imaged at 0.4 microns XY resolution and 2.5 microns Z spacing between oblique planes, in 14 hours.While light sheet ensures an illumination restricted in the thickness (Z of the specimen) of the imaging plane,

fluorescently labeled structures appear broader than they are due to a blur from the optical transfer function of the imaging system, including the Abbe's diffraction limit, NA of the collection objective and camera properties. This blur assumes a Gaussian shape as it comes from a point source. To overcome this constraint, an additional step of deconvolution was added before reconstruction of the image volumes. Deconvolution improves SNR of image pixels by ameliorating the effect of stray fluorescence from XY neighborhood in the illumination plane, such as source autofluorescence, camera artifact, and photon scattering within the tissue.We modelled a 3-D Gaussian point spread function designed to match that of the detected blur using the experimental beam parameters, 5 microns at the center but 20 microns near the edges, and used it for pixel-wise deconvolution. Deconvolution with our generated point spread function resulted in a significant noise reduction and narrower pixel point spread functions. Our technique, using Lucy-Richardson Deconvolution, achieves improved resolution and decreased background, as well as sharper halo-reduced images.The image transformation model used to generate the coronal section series has also been modified. Instead of aligning sections after reconstruction, we now model and apply a shear transform to shear the oblique image stack. Software for image stitching that is specifically suited for an OLST image series was also developed. These enhancements have improved reconstructed image quality and decreased processing time.

Title: Semi-automated detection and characterization of spike-wave discharges (SWDs) in a mouse model of absence epilepsy

Authors: *J. A. PFAMMATTER[1], E. P. WALLACE[3], R. K. MAGANTI[4], M. V. JONES[2]
[1]Neurosci., [2]Dept Neurosci., Univ. of Wisconsin Madison, Madison, WI; [3]Neurosci., [4]Neurol., Univ. of Wisconsin, Madison, WI

Abstract: Absence epilepsy is characterized by nonconvulsive seizures, apparent as spike-wave discharges (SWDs) on electroencephalogram (EEG) recordings, that are associated with behavioral arrests, altered consciousness, and amnesia. Detection of SWDs from EEG is traditionally done manually by clinicians and researchers. Manual detection of SWDs is time

consuming, expensive and variable both within and between scorers and between sleep stages within EEG records. These issues present a sizeable roadblock to rapid and unbiased scoring of SWDs. Here we present a semi-automated, machine learning-based method for the scoring of SWDs, implemented on 4-channel, normalized EEG records from mice with absence epilepsy (RQ: knock-ins expressing the GABA-A receptor mutation gamma2R43Q) and wild type littermates (RR). First, we train a support vector machine (SVM) to detect SWD-containing epochs (4 seconds) using a training set of example SWD- and non-SWD-containing epochs that were manually scored by human experts. This SVM uses 29 parameters calculated from EEG records and is designed to detect 'all' events that an expert human would detect at the cost of increased false positives. Automated detection of putative SWD start and stop times is performed by finding ~6 Hz patterns (the typical SWD frequency in mice) in the first derivative and the correlation between an SWD template and the EEG signals. The algorithm scores a 24-hour record in less than 5 minutes whereas manual scoring takes approximately 2-3 hours. A manual review of putative SWDs is still required at this stage, but future versions of the algorithm may only require a spot-check review. Detection of SWDs in data that were not included in training (24 hr records; 3 from 3 RQ animals, 1 from 1 RR animal) revealed a 99.78 % capture rate (of 893 events) and a 1.23 % false-positive rate (of 91065 events) compared to human scoring of the same data. Many false-positive events contain SWD-like features, detection of which scales with the frequency of true SWDs within each record. To improve the algorithm, we are pursuing analysis of the characteristics of SWDs and SWD-like events identified by the algorithm compared to those identified manually. Interestingly, numerous SWDs were found in RR animals both by human scoring and automatic detection.

Abstract: Convolutional Neural Networks (CNNs) have recently been employed with great success in image classification, and increasingly, semantic image segmentation. Despite their popularity, most approaches focus on 2D images, while most medical imaging data consists of 3D volumes. Here we apply a recently developed fully-convolutional network (U-net) architecture for semantic segmentation of human and non-human primate structural MRI voxels into gray-matter, white-matter, and cerebrospinal fluid tissue classes. We show that our model achieves state-of-the-art performance on MRI segmentation tasks, with minimal training time. We train and test our model on two datasets, a rhesus macaque T1-weighted MR images, and a publicly available dataset (MRBrainS). Macaque data were acquired with a 3T Siemens Allegra (Erlangen, Germany) using 3 elements out of a 4-channel phased array from Nova Medical Inc. (Wilmington, MA) and 0.6 or 0.5 mm^2 in-plane resolution, slice thickness: 0.6 or 0.5 mm. For the macaque dataset, ground truth was established by first warping an atlas to the structural scan using a diffeomorphic registration procedure (SyN), then hand-edited by visual inspection. For the MRBrainS dataset, ground truth was established by expert hand labeling.
Our deep convolutional architecture consisted of an expanding and contracting path, applied to 3D patches of the structural MRI volume. Each convolutional block is realized as a residual function composed of convolutions with a 3x3x3 voxel kernel followed by a skip connection consisting of an identity mapping and a summation. Between each block in the contracting path, the image is downsampled via 2x2x2 convolutions with a stride of 2. Empirical Linear Units are used throughout the network. In the expanding path, residual blocks are upsampled via a deconvolution with a stride of 2. The output of the contracting path of equal resolution is merged via a skip connection to the output of the expanding path by concatenation. In this way, detailed information from each stage of the contracting path is paired with higher-level representations. The final layer consists of 1x1x1 convolutions with a sigmoid activation indicating the probability of belonging to the segmentation mask.
Segmentation of primate neuroanatomy from MR images into tissue classes forms the basis of several measurements such as gray-matter volume or cortical surface generation. Such measurements form the core of many studies, including voxel-based morphometry and surface-based functional MRI studies. The success of learning segmentations suggests a similar approach may be viable in other imaging domains such as diffusion-weighted MR imaging.

Title: Defining and assessing the integrity of cortical layering: A quantitative approach

Authors: *A. T. KARST[1], J. BERGER[2], J. J. HUTSLER[3]
[1]Psychology, [2]Univ. of Wisconsin, Oshkosh, Oshkosh, WI; [3]Univ. of Nevada, Reno, NV

Abstract: The architecture of the human neocortex consists of cellular columns that traverse six cortical layers. Objective methods have been developed for the definition of cortical columns (Buxhoeveden, Switala, Roy, & Casanova, 2000); however, the definition of transitions between cortical layers largely relies on subjective methodology. It was the intent of the current project to create an objective method that could both identify cortical transitions between layers, and then assess the transition's integrity in Nissl stained tissue. To this end, a modified edge detection method capable of accounting for the convoluted nature of the human cortex was developed to identify the transition between cortical layers I & II. Further, after defining the cortical transition, assessment of the transition's integrity was made by obtaining a measure of sinuosity. This measure calculates the ratio of the identified transition length by the Euclidean distance of a hypothetical linear transition. This method has the potential to objectively quantify the cortical transition between layers I & II as well as assess the nature of the transition. This allows for the collection of objective data pertaining to abnormalities resulting from pathological processes involved in cortical development.

Title: Building a prototype application for visualizing neuroanatomy and quantitative cell features from the Allen Brain Atlas in virtual space

Abstract: Effective visualization of neuroscientific data can be difficult; complexity can mask trends, scale is easy to misunderstand, and highly dimensional data is challenging to present in a simple way that retains content. Virtual Reality (VR) is uniquely positioned to improve depth

and comprehensibility of data visualization. We sought to explore the use of VR for its potential to improve upon conventional presentation of complex 2D data, and to evaluate this emerging technology as a means to inspire a new cohort of scientists. A prototype application leverages data available via the Allen Brain Atlas API to integrate, browse and analyze data in an immersive virtual display environment. Key features of the application include presentation of anatomically accurate 3D brain mesh renderings paired with cell representations that can be selected and plotted in a t-SNE graph space. Implementation was done in Unity 5.x with C# and designed for the HTC:VIVE VR headset. The anatomical reference framework is the annotated adult mouse brain (Allen Mouse Common Coordinate Framework; CCF), coupled with spatially precise mappings of single neurons from visual cortex. These representations are paired with in vitro biophysical data from slice recordings and morphological neuron reconstructions, which can also be accessed in the public database online at celltypes.brain-map.org. The mouse brain volume (CCF) is the anchor of the interactive space, from which selected neurons within the brain can be explored, and the ontologically-labeled anatomy of the brain can be manipulated using natural gestures. Preliminary feedback suggests that naive users comprehend spatial and quantitative data relationships quickly and intuitively with immersive data visualization. We continue to investigate how this type of browsing experience, combined with primary data access, facilitates insight into brain function and expands knowledge by innovative experiential media.

Title: HyperTools: A python toolbox for visualizing and manipulating high-dimensional neural time-series data

Authors: *A. C. HEUSSER[1], K. ZIMAN[2], L. L. W. OWEN[2], J. R. MANNING[2]

Abstract: Data visualizations can reveal trends and patterns that are not otherwise obvious from the raw data or summary statistics. While visualizing low-dimensional data is relatively straightforward (for example, plotting the change in a variable over time as (x,y) coordinates on

a graph), it is not always obvious how to visualize high-dimensional datasets in a similarly intuitive way. Here we present HyperTools, a Python toolbox for visualizing and manipulating large, high-dimensional datasets. Our primary approach is to use dimensionality reduction techniques to embed high-dimensional datasets in a lower-dimensional space, and plot the data using a simple (yet powerful) API with many options for data manipulation (e.g. hyperalignment, clustering, normalizing, etc.) and plot styling. The toolbox is designed around the notion of data trajectories and point clouds. Just as the position of an object moving through space can be visualized as a 3D trajectory, HyperTools uses dimensionality reduction algorithms to create similar 2D and 3D trajectories for time series of high-dimensional observations. The trajectories may be plotted as interactive static plots or visualized as animations. These same dimensionality reduction and alignment algorithms can also reveal structure in static datasets (e.g. collections of observations or attributes). We present several examples using various brain imaging modalities (MEG, EEG, ECoG, fMRI) to showcase how using our toolbox to explore the brain through trajectories and low-dimensional embeddings can reveal deep insights into the structure of dynamic neural patterns.
