Title: Dissecting cytokinesis defects in the Kif20b model of microcephaly

Authors: *K. C. MCNEELY[1], J. N. LITTLE[1], N. D. DWYER[2]
[1]Cell Biol., Univ. of Virginia, Charlottesville, VA; [2]Cell Biol., Univ. of Virginia, CHARLOTTESVILLE, VA

Abstract: Neural stem cells (NSCs) must undergo polarized cell division within the ventricular zone to produce enough neurons to build the cortex. This specialized cell division must be intricately controlled to form a normal sized and layered cortex. Cytokinesis, the last step of cell division, controls the segregation of cytoplasm, membrane, and organelles to the two daughter cells through cleavage furrowing and establishment of a dense microtubule structure, the midbody. The midbody must be severed on one or both sides to finally separate the two daughter cells. Recently, cytokinesis has been implicated in cell fate determination, but the specialized mechanisms of cytokinesis in the developing brain remain unclear. We hypothesize that temporal and structural changes in cytokinesis of embryonic NSC may lead to changes in cell fate.
We previously reported a novel mouse model of microcephaly resulting from mutation of the Kinesin-6 family member Kif20b. Kif20b is a plus-end microtubule motor that localizes to the central spindle and midbody during cytokinesis. The *Kif20b -/-* mutant embryos have smaller and thinner cortices, reduced neurogenesis, and increased apoptosis. Additionally, the mutant NSC midbodies, observed at the ventricular surface, are wider, longer, and misoriented, suggesting defects in late cytokinesis.
In this work, we used both a knockdown of Kif20b in a human cell line and mouse mutant NSC cultures to study the precise role of this motor protein in cytokinesis. This work will help to elucidate the etiologies of microcephaly. Using live cell imaging and Silicone-Rhodamine Tubulin (SiR-tubulin), we found that knocking down KIF20B in HeLa cells resulted in changes in the timing of cleavage furrowing and abscission. Additionally, the midbodies of KIF20B knockdown cells showed changes in microtubule structure, supporting a role for Kif20b in midbody organization prior to abscission. To further explore the role Kif20b plays in NSC cell division we used an *in vitro* cortical NSC culture. In the NSC cultures, we found midbody shape defects including longer midbodies. Similar to the wider, longer midbodies observed *in vivo*, this supports a role for Kif20b in establishing or maintaining midbody structure. The NSC culture system also models the increased apoptosis seen *in vivo*, and shows that the apoptotic cells are

NSCs. These findings validate the *in vitro* system for studying NSC cytokinesis, and confirm a cell-autonomous role for Kif20b in NSC divisions. Currently, we are using this *in vitro* system to study detailed cytoskeletal structure and temporal dynamics of normal and abnormal cytokinesis in cerebral cortex development.

Title: Mitotically delayed Radial Glial stem cells and altered fate decisions in the developing cortex

Authors: *A. M. MITCHELL-DICK, L.-J. PILAZ, D. L. SILVER
Duke Univ., Durham, NC

Abstract: Cortical pyramidal neurons are generated in development by embryonic neural stem cells termed Radial Glial cells (RGCs). During embryonic mouse corticogenesis RGCs divide both symmetrically and asymmetrically to produce excitatory neurons, RGCs, and intermediate progenitors (IPs). Yet how individual RGCs make asymmetric and symmetric fate decisions to pattern the cortex is incompletely understood. Investigation of this process will yield insight into cognitive disorders, including microcephaly, as defects in RGC divisions can lead to microcephaly. We have recently discovered using both genetic and pharmacological models that prolonged RGC mitosis results in increased asymmetric neurogenic divisions at the expense of proliferative divisions. These models recapitulate phenotypes observed in microcephaly, namely precocious neuron generation, loss of progenitors, and apoptosis. However, despite these advances the timing and degree to which prolonged mitosis impacts embryonic neurogenesis and imparts microcephaly phenotypes *in vivo* is unknown. Therefore, we sought to develop a model of inducible pharmacological delay *in vivo* to study the effects of directly prolonging mitosis. Here, using a recently developed method to lineage trace cells in the developing cortex, we establish an *in vivo* assay for investigating pharmacological RGC mitosis delay directly impacts cell fate. We first define the kinetics by which pharmacological delay impairs progenitor mitosis. We demonstrate that delayed RGCs *in vivo* generate an increased number of immature neurons, and more apoptosis in a subset of delayed progeny. These outcomes are at the expense of Pax6+ RGCs, as we observe less newborn progenitors following delay. Our ongoing work takes an unbiased approach to examine delayed cells and their progeny in order to elucidate mechanisms

of altered fate decisions and cellular response to prolonged mitosis. This model will provide a basis for understanding the pathways and cellular behaviors that underlie cognitive developmental disorders including microcephaly.

Title: p53 deletion rescues cerebral cortex growth in a genetic model of microcephaly

Authors: J. N. LITTLE[1], *N. DWYER[2]
[1]Cell Biol., [2]Cell Biol, Univ. of Virginia Sch. of Med., Charlottesville, VA

Abstract: Growth of the cerebral cortex requires precise divisions of neuroepithelial stem cells (NSCs) that undergo both symmetric and asymmetric divisions to first expand the progenitor pool and then produce post-mitotic neurons. How this is mediated is poorly understood. One consequence of impaired NSC proliferation is microcephaly, or a small brain. In a novel mouse model for microcephaly discovered by our lab, the mutation of the kinesin Kif20b results in reduced brain size at birth. Interestingly, we found abnormalities in cytokinesis of NSCs and increased apoptosis in *Kif20b-/-* cortex. Additionally, cortical pyramidal neurons are reduced in number and show defects in polarization and morphology. During cytokinesis, daughter cells separate their cytoplasm and cleave apart. This process requires formation of a cleavage furrow that ingresses to form the midbody, the last connection between two cells before the final separation event, called abscission. NSCs undergo a polarized form of cytokinesis within the neuroepithelium that is poorly understood. In the *Kif20b-/-* cortex, NSC midbodies at the apical membrane were misshapen and misaligned. These novel phenotypes suggest delays or failures in abscission. Our hypothesis is that the loss of Kif20b causes impaired cytokinesis that results in apoptosis in a subset of NSCs, depleting the progenitor pool and impairing neurogenesis.
To test our model for the etiology of *Kif20b-/-* microcephaly, we set out to prevent apoptosis of NSCs and observe whether microcephaly could be rescued. We crossed the *Kif20b* mutant mouse line to knockouts for the pro-apoptotic *Trp53* (gene encoding the tumor suppressor p53) and *Bax*. We found that p53 deletion rescues microcephaly in *Kif20b-/-* mice, but Bax deletion does not. p53 but not Bax deletion rescued the elevated apoptosis seen in *Kif20b-/-* brains, providing

further evidence for the central role of apoptosis in *Kif20b-/-* microcephaly. In addition to rescuing brain size, deletion of p53 rescued neonatal lethality in *Kif20b-/-* mice. However, *Kif20b-/- p53-/-* mice have reduced survival after birth, with some mice dying from hydrocephalus, suggesting that brain abnormalities still remain. Current work is focused on determining 1) if the final brain structure and lamination of double mutant mice are normal, 2) the relationship between cytokinesis defects and p53 activation in *Kif20b-/-* mice and 3) the consequence of cytokinesis failure for undead NSCs and neuron daughters when apoptosis is inhibited.

Title: Symmetric cell divisions drive adult V-SVZ neurogenesis and stem cell maintenance

Authors: *K. OBERNIER[1], A. CEBRIAN-SILLA[3], M. THOMSON[2], J. PARRAGUEZ[1], J. M. GARCIA-VERDUGO[3], A. ALVAREZ-BUYLLA[4]
[2]Ctr. for Systems and Synthetic Biol., [1]UCSF, San Francisco, CA; [3]Lab. of Comparative Neurobiology, Inst. Cavanilles, Univ. de Valencia, Valencia, Spain; [4]Eli and Edythe Broad Ctr. for Regeneration Med. and Stem Cell Res., Univ. of California San Francisco, San Francisco, CA

Abstract: Neural stem cells (NSCs; B1 cells) persist in the ventricular-subventricular zone (V-SVZ) of the adult mammalian brain. B1 cells contact the lateral ventricle via a small apical ending, and blood vessels with a long basal process. B1 cells generate transient amplifying C cells that in turn give rise to young neurons that migrate to the olfactory bulb where they differentiate into interneurons. In contrast to classical views suggesting that neurogenesis and NSC maintenance are achieved by asymmetric self-renewal, we show here that B1 cells only

undergo symmetrical divisions in the adult mouse V-SVZ in vivo. The majority of B1 cells undergo symmetric consuming divisions producing C cells, which leads to a drastic decline in the number of B1 cells with increasing age. However, a subpopulation (~20-25%) of B1 cells self-renew, giving rise to two secondary B1 cells, which maintain the potential to self-renew again. Ex vivo live imaging of V-SVZ whole-mount preparations shows that during self-renewing cell divisions B1 cells maintain their basal process. Interestingly, in vivo, B1 cells also give rise to B2 cells. Similar to B1 cells, B2 cells are astrocytic and contact the vasculature, but lack the contact with the lateral ventricle. While the number of apical B1 cells is drastically reduced as mice age, B2 cells become the preponderant label-retaining cells over time. Although it is unknown whether B2 cells are neurogenic, we show that the population of secondary B (B1/B2) cells contains bona fide
stem cells as they stochastically contribute interneurons to the olfactory bulb later in life via consuming divisions. Importantly, the reactivation of secondary B cells can occur after several months, indicating that a subpopulation of self-renewing B cells is long-lived and contributes neurons to the olfactory bulb after extended periods of time.
This study identifies the cellular mechanism sustaining V-SVZ/OB neurogenesis throughout life.

Title: Mir-203 interplays with polycomb repressive complexes to regulate the proliferation of neural stem/progenitor cells

Authors: ***Z. TENG**[1], P.-P. LIU[1], G.-B. TANG[2], Y.-J. XU[3], S.-F. ZHANG[3], Y.-Q. ZENG[1], H.-Z. DU[1], C.-M. LIU[1]

Sci., Beijing, China; [2]Inst. of Zoology, Chinese Acad. of Sci., Beijing, China; [3]Intitute of Zoology, Chinese Acad. of Sci., Beijing, China

Abstract: The polycomb repressive complex 1 (PRC1) and 2 (PRC2) are two distinct polycomb group (PcG) proteins that maintaining the stable silencing of specific sets of genes through chromatin modifications. Although the PRC2 component EZH2 has been known as an epigenetic regulator in promoting the proliferation of neural stem/progenitor cells (NSPCs), its regulatory network that control this process remains largely unknown. Here we show that miR-203 is repressed by EZH2 in both embryonic and adult NSPCs. MiR-203 negatively regulates the proliferation of NSPCs. One of PRC1 components, *Bmi1*, is a downstream target of miR-203 in NSPCs. Conditional knockout of *Ezh2* results in decreased proliferation ability of both embryonic and adult NSPCs. Meanwhile ectopic overexpression of BMI1 rescues the proliferation defects exhibited by miR-203 overexpression or EZH2 deficiency in NSPCs. Therefore, this study provides the evidence for coordinated function of the EZH2-miR-203-BMI1 regulatory axis that regulating the proliferation of NSPCs.

Title: Pallial neurogenesis in Xenopus laevis

Authors: N. MORENO[1], S. JIMENEZ[2], N. VIDAL[2], D. LOZANO[2], R. MORONA[2], J. M. LOPEZ[2], *A. GONZALEZ[3]
[1]Cell Biol., Univ. Complutense, Madrid, Spain; [2]Cell Biol., Univ. Complutense of Madrid, Madrid, Spain; [3]Univ. Complutense Madrid, Madrid, Spain

Abstract: The complexity of the pallium during evolution has increased dramatically in many different respects. The highest level of complexity is found in mammals, where most of the pallium (cortex) shows a layered organization and neurons are generated during development following an inside-out order, a sequence not observed in other amniotes (birds and reptiles). Species-differences may be related to major neurogenetic events, from the neural progenitors that divide and produce all pallial cells. In mammals, two main types of precursors have been described, primary precursor cells in the ventricular zone (also called radial glial cells or apical

progenitors) and secondary precursor cells (called basal or intermediate progenitors) separated from the ventricle surface. Previous studies suggested that pallial neurogenetic cells, and especially the intermediate progenitors, evolved independently in mammalian and sauropsid lineages. In the present study, we examined pallial neurogenesis in the amphibian *Xenopus laevis*, a representative species of the only group of tetrapods that are anamniotes. The pattern of pallial proliferation during embryonic and larval development was studied, together with a multiple immunohistochemical analysis of putative progenitor cells. We found that there are two phases of progenitor divisions in the developing pallium that, following the radial unit concept from the ventricle to the mantle, finally result in an outside-in order of mature neurons, what seems to be the primitive condition of vertebrates. Gene expressions of key transcription factors that characterize radial glial cells in the ventricular zone were demonstrated in *Xenopus*. In addition, although mitotic cells were corroborated outside the ventricular zone, the expression pattern of markers for intermediate progenitors differed from mammals.

Title: Nox4 participates in damage-induced proliferation of neural stem cells and subsequent restoration of recognition memory in the hippocampus

Authors: *Y. YOSHIKAWA[1], T. AGO[1], J. KURODA[1], Y. WAKISAKA[1], H. NAKASHIMA[2], K. NAKASHIMA[2], T. KITAZONO[1]
[1]Dept. of Med. and Clin. Sci., Grad. Sch. of Med. Sciences, Kyushu Univer, Fukuoka-Shi, Japan; [2]Dept. of Stem Cell Biol. and Medicine, Kyushu Univ., Fukuoka, Japan

Abstract: Purpose: It is known that reactive oxygen species (ROS) participate in growth regulation of neural stem cells (NSCs) and in hippocampus-associated learning and memory. However, the origin of ROS linking to these functions remains unknown. We found that Nox4, a ROS-producing NADPH oxidase family protein, is expressed in primary cultured NSCs and in Sox2-positive NSCs in the subventricular zone and in the subgranular zone (SGZ) of the hippocampus *in vivo*. In the present study, we investigated the roles of Nox4 in NSCs *in vitro* and *in vivo*.
Method: NSCs were prepared from telencephalons of pregnant ICR mouse embryos at E14.5. We overexpressed Nox4 in cultured NSCs by using lentivirus. We assessed proliferation of NSCs by MTT assay *in vitro* and by incorporation of 5-ethynyl-2’-deoxyuridine (EdU) *in vivo*.

Hippocampal neuronal damages were induced by intraperitoneal administration of trimethyltin (TMT) (2.1 mg/kg). Recognition memory was assessed by a novel object recognition (NOR) test. **Results:** Basic fibroblast growth factor (bFGF) significantly induced the phosphorylation of Akt and increased the proliferation of the cultured NSCs. Nox4 inhibitors, VAS2870 or GKT137831, as well as LY294002, an inhibitor of PI3K upstream of Akt, attenuated the bFGF-induced proliferation of the NSCs in a dose-dependent manner. Lentivirus-mediated Nox4 overexpression increased the production of H_2O_2, the phosphorylation of Akt, and the proliferation of the NSCs, while the enhanced proliferation was canceled by the presence of the Nox4 inhibitors. The differentiation into neurons or astrocytes was not different between cultured NSCs prepared from Nox4-deficient mice and those from wild-type littermates. Although the hippocampal development was apparently normal, the proliferation of NSCs in the SGZ in response to TMT-induced hippocampal neuronal damages was significantly attenuated in Nox4-deficient mice. A NOR test demonstrated that functional restoration of recognition memory after TMT-induced hippocampal neuronal damages was significantly attenuated in Nox4-deficient mice, compared with wild-type littermates.
Conclusion: Nox4 participates in the proliferation of NSCs both *in vitro* and *in vivo*. Nox4-mediated proliferation of NSCs in the SVZ of the hippocampus may be involved in post-damage functional restoration of recognition memory.

Title: HIV-1 Tg26 transgenic mice exhibit early and late neurogenic deficits, which correlate with neurocognitive dysfunction

Authors: *R. PUTATUNDA, M. CURTIS, Y. ZHANG, T. ZHANG, X. XIAO, M. XIN, F. LI, D. PRATICO, M. F. BARBE, W. HU
Pathology and Lab. Med., Lewis Katz Sch. of Med. At Temple Univ., Philadelphia, PA

Abstract: Mild to moderate forms of HIV-1 associated neurocognitive disorders (HAND) continue to afflict HIV-1 infected patients even in the era of the combined antiretroviral therapy.

Recently, compromised adult neurogenesis has been shown to be an underlying substrate for HAND. Not only is HIV-1 capable of infecting neural stem cells (NSCs) *in vitro* and *in vivo*, the viral proteins Tat or gp120 have been shown to individually inhibit NSC proliferation and neuronal differentiation. However, no studies have characterized whether and how the combined viral proteins from latent HIV-1 reservoirs affect the early and late stages of neurogenesis, and correlated these changes with neurocognitive function. To this end, we performed *in vitro* and *in vivo* studies using HIV Tg26 transgenic mice expressing 7 of the 9 HIV-1 viral proteins. RT-qPCR analysis validated the presence of the Gag, Env, and Tat transcripts in the neurogenic zones. *In vitro* stemness assays revealed that Tg26 mouse NSCs were unable to form as many primary and secondary neurospheres as wild-type (WT) mouse NSCs. Additionally, i*n vitro* differentiation assays revealed that Tg26 mouse NSCs were not only unable to differentiate as efficiently into neurons as WT mouse NSCs, but they generated more astrocytes. These proliferative and differentiative effects were confirmed by immunohistochemistry in the dentate gyri of WT and Tg26 mice. Retroviral-eGFP labeling demonstrated that the newborn neurons in the dentate gyri of adult Tg26 mice had initial dendritic arborization deficits, as well as a slightly shorter dendritic length. Finally, Barnes Maze analysis revealed spatial memory acquisition and long term memory retention deficits in Tg26 mice. In conclusion, Tg26 mice exhibit early and late neurogenic deficits, which correlate with neurocognitive dysfunction. (This work was partially supported by a Ruth L. Abstract: Over 90% of glioblastoma (GBM), the most common and lethal brain cancer in adults, develop rapidly with clinical evidence of lower-grade gliomas, thus also known as primary/de novo GBM. Due to rapid clinical course, little or no evidence is available on the existence of less aggressive or proliferative glioma precursor cells during early stages of primary GBM pathogenesis. Whether a therapeutic strategy can be developed to treat highly aggressive primary GBM at early stages remains unknown. Recent characterization of spatiotemporal genomic architecture of primary GBM suggests a clinically unobserved common ancestor (CA) with a less aggressive phenotype that could remain latent for decades. This CA generates genetically highly divergent subclones, seeding pre-therapy multifocal and/or post-therapy distally recurred GBMs. Here we developed mouse models of malignant gliomas/GBMs driven by single *p53* mutations, recapitulating this unique branched evolutionary pattern. We show a CA-derived malignant gliomas/GBMs, seeding multiple regions via two distinct evolutionary patterns. In the brain parenchyma, highly proliferative gliomas underwent whole-genome doubling with unstable sub-tetraploid/4N genomes, loss of chromosome 19/*Pten* and PI3K/Akt activation. However, relatively quiescent glioma cells with near-diploid/2N genomes and normal *Pten* were maintained in the subventricular zone (SVZ) stem-cell niche. Akt inhibition by *Rictor*/mTORC2 deletion blocked glioma distant dissemination from the SVZ stem-cell niche. Thus, our study identifies the closest descendants of evolutionarily unobserved localized CAs located in the SVZ, generating highly proliferative and migratory multifocal GBMs at distant locations in an mTORC2/Akt-dependent manner. Further, our study delineates a complex branched pattern of clonal evolution from neural stem cells in the SVZ to highly proliferative and migratory GBM cells in the distant locations of the brain parenchyma.

Abstract: Throughout life, the process of neurogenesis continues in two specific regions of the adult brain: the dentate gyrus of the hippocampus and the subventricular zone of the lateral ventricles. The neurogenic capacity of the hippocampus is dependent on the existence of a population of radial glia-like cells (RGLs) that act as neural stem cells. However, the underlying mechanisms regulating RGL activation throughout life have not been fully elucidated. The inhibitory neurotransmitter GABA, acting via $GABA_A$ receptors, regulates multiple stages of adult neurogenesis including neural progenitor proliferation, migration, neuronal maturation, synaptic integration and survival. The mode of GABA action depends on intracellular chloride levels, which are determined by the differential expression of chloride importers NKCC1 and KCC2. NKCC1 is predominantly expressed in neural precursor cells and drives Cl^- influx. The role of the chloride importer NKCC1 in the activity of RGLs from the dentate gyrus remains unknown. Therefore, we used a novel inducible transgenic mouse model for specific NKCC1 knock-out ($NestinCreER^{T2}/NKCC1^{fl/fl}$/tdTomato mice) in $nestin^+$RGLs. Our data show that NKCC1 knockout strongly promotes the expansion of the RGL neural stem cell population in the adult and aged hippocampal dentate gyrus. Detailed morphometric analysis of RGLs indicated an increase in the cellular complexity as shown by changes in length, width, and surface of the cells in adult and aged mice. Our study shows for the first time that the self-renewal capacity of RGLs in the adult and aged hippocampal dentate gyrus is strongly modulated by the chloride importer NKCC1. Understanding the underlying mechanisms of neural stem cell activation throughout life is important to restitute the stem cell pool and generate new neurons, thereby improving the cognitive function during aging.

Title: Serotonin receptor mechanism regulating adult neural stem cells in the mouse hippocampus

Authors: *A. J. CROWTHER[1], J. SONG[2]
[1]Univ. of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Univ. of North Carolina, Chapel Hill, Chapel Hill, NC

Abstract: Antidepressants targeting the serotonin system are commonly ineffective for 40% of patients with unclear causes. Adult hippocampal neurogenesis may be a critical substrate of successful treatment response. Animal models of depression have reduced hippocampal neurogenesis that is reversed by antidepressants. Furthermore, neurogenesis is required for specific behavioral responses to SSRIs in animal models. However, most previous studies employ systemic broadly-acting drugs or complete removal of neurogenesis through genetic approaches or focal irradiation. Circuit and cell-type specific postsynaptic effects of antidepressants are not well understood. We take a circuit-based approach in combination with cell-type specific conditional genetics to investigate serotonin receptor mechanisms controlling two critical stages of neurogenesis, stem cell fate choice and proliferation of neural progenitors. We demonstrate that selective 5-HT1A receptor deletion in adult neural stem cells leads to increased glial differentiation of stem cells, whereas its deletion in neural progenitors leads to increased proliferation. Furthermore, chemogenetic activation of 5HT circuitry leads to increased quiescence of neural stem cells in the dentate gyrus. Our studies establish a novel activity-dependent mechanism by which early hippocampal neurogenesis is regulated by 5-HT.

Title: Quantification of efficiency for understanding larval zebrafish fine motor control development and modulation

Authors: *S. WAHLSTROM-HELGREN, A. BOWMAN, K. VANPELT, M. A. MASINO
Neurosci., Univ. of Minnesota, Minneapolis, MN

Abstract: During free-swimming, larval zebrafish perform a lateral undulation that translates into fluid motion around the fish to propel it forward. This transformation of lateral movement to forward motion is performed with a given efficiency, which is dependent on the coordination of strength and timing of the muscle groups. Therefore, a quantification of this transformation can be used to assess refinement of fine motor control during development or to determine the effects of perturbations to the locomotor circuitry. Here, we tested the hypothesis that larval locomotion becomes more efficient as development proceeds—less lateral undulation is required to move the same distance because of increased coordination and strength of the muscle groups. In this study, we utilized high-speed video (210 frames per sec) recordings, Ctrax software (an open-source

tracking software), and physics first principles to study how this transformation occurs during development, and how the transformation can be perturbed by modulatory neurotransmitters. Specifically, we quantified and correlated the power produced by the undulation and the power of the forward movement of the fish. As predicted, we found that the power measures became more strongly correlated and the variance was reduced across developmental stages (3 days post-fertilization (dpf) to 7dpf). Previous work in the lab showed that between 3dpf and 4dpf a switch in swimming behavior occurs where swim episodes significantly decreased in duration. Furthermore, blockade of dopamine 4 receptors (D4Rs) can reverse this switch in the 4dpf and older larvae. Therefore, we asked if/how the power measures were altered in the presence of a D4R antagonist when applied to post-switch (5dpf) larvae. We found that the correlation between the power measures increased and the variance was reduced. Interestingly, D4R antagonism increased the efficiency of the transformation; correlation higher and variance lower. In conclusion, we have established a novel method to quantify the efficiency of the free-swimming larval zebrafish locomotor pattern, which can be applied to systematically examine the effects of various modulated states of the locomotor circuitry.

Title: Motor control of swimming is developmentally refined in larval zebrafish

Authors: *M. A. MASINO, K. VANPELT, A. BOWMAN, S. WAHLSTROM-HELGREN
Neurosci., Univ. of Minnesota, Minneapolis, MN

Abstract: Fine motor skills are acquired throughout development. In zebrafish, we expect that the acquisition of fine motor control during larval development is reflected in the swimming locomotor pattern and that this control can be quantified by examining various properties of the locomotor pattern. Previous work from the lab has shown a developmentally-mediated switch in swim episode duration (decrease) and frequency (increase) that occurs in larvae between 3dpf (days post-fertilization) and 4dpf. We hypothesize that other swim properties—i.e. maximum forward velocity, distance traveled per episode, and tail-beat frequency—will also be refined as fine motor control develops. Using high-speed (210 frames per sec) video recordings, we tracked swimming zebrafish larvae with Ctrax (an open source tracking software) across developmental

stages to encompass both the pre- and post-switch states, at 3dpf, 5dpf, and 7dpf. Swim episodes were identified with an in-house MatLab script and the properties of interest measured. The magnitude of all three measures decreased and the variance reduced as the larvae progressed from 3dpf to 7dpf reflecting the development of fine motor control. Our previous work showed that the application of a dopamine 4 receptor (D4R) antagonist to 4dpf larvae (post-switch) reversed the locomotor pattern from frequent, short episodes to infrequent, long episodes. Therefore, to determine the effects of D4R antagonism on the properties of interest we applied the D4R antagonist to 5dpf (post-switch) larvae. Interestingly, we found that all three measures decreased in a manner similar to that of the behavior of the untreated 7dpf larvae. This result was both unexpected and interesting because the blockade of the D4Rs does not simply revert the swimming pattern to a pre-switch state, but instead influences episode duration and episode frequency towards the pre-switch state while the other properties--maximum forward velocity, distance traveled per episode, and tail-beat frequency--become further refined. Future work will focus on understanding the underlying mechanism of dopamine action onto D4Rs to effect these behavioral properties.

Abstract: GABA mimicry and NMDA antagonistic reagents including alcohol and analgesic agents induce neurodegeneration in the developing brain. The developmental exposure to those agents increases the risks of neurological and psychiatric diseases. Therefore understanding the underlying molecular mechanisms is crucial for developing potential interventions for such acquired neuropsychiatric conditions. Here we show that the lack of primary cilia in the developing cerebral cortex augmented alcohol's effects that reduce/degenerate dendritic arborization through excessive fragmentation of cytoskeletal proteins by activated caspase-3. Consistently, microglial accumulation and activation were enhanced in the cilia-deficient mice exposed to ethanol. In the cilia-deficient cortical neurons, we found reduced activation of IGF receptors, while phosphorylation of S6, a downstream of mTOR signaling, was increased. Notably, the loss of protection of cortical neurons in the lack of primary cilia was rescued by administration of Akt agonist to the alcohol-exposed mice. These results suggest a mechanism of neuroprotection by IGFR-Akt signaling that requires the primary cilia. Therefore enhancing such cilia-mediated intrinsic protective mechanisms may become a potential intervention for acquired brain injury during brain development and the associated neurobehavior problems.

Title: Multiple functions of Ldb1 in dorsal telencephalic development

Authors: *V. J. KINARE[1], H. PADMANABHAN[2,3,4], G. GODBOLE[2], Z. KHATRI[2], U. MAHESHWARI[2], B. MURALIDHARAN[2], S. P. TOLE[2]
[1]Sophia Col. For Women, Mumbai, India; [2]Dept. of Biol. Sci., Tata Inst. of Fundamental Res., Mumbai, India; [3]Dept. of Stem Cell and Regenerative Biol., [4]Ctr. for Brain Science, and Harvard Stem Cell Inst., Harvard Univ., Cambridge, MA

Abstract: Ldb1 (LIM Domain Binding Protein 1) is a transcriptional cofactor which interacts with various LIM-HD, Lmo, Otx and bHLH proteins, many of which are known regulators of telencephalic development (Mangale et al., 2008; Zhao et al., 1999; Johanssen et al., 2013) . In order to study role of Ldb1 in regulating telencephalon morphogenesis and to circumvent early embryonic lethality (Mukhopadhyay et al., 2003), we used a floxed *Ldb1* line in conjunction with different Cre drivers known to act during early telencephalic development.
Surprisingly, we found that these drivers recombine the floxed *Ldb1* locus with different degrees of efficiency in the embryonic mouse dorsal telencephalon. While *Foxg1Cre* deletes *Ldb1* from the entire dorsal and ventral telencephalon by embryonic day (E) 12.5, *Emx1Cre*, which acts only in the dorsal telencephalon, displays efficient floxing medially, and less efficient floxing laterally by this stage. These differential effects are specific to the floxed *Ldb1* locus, since a standard floxed *Ai9* reporter line displays efficient floxing appropriate for each Cre line by E12.5. With time, however, the floxing efficiency at the Ldb1 locus appears to improve, such that by E15.5, there is no medio-lateral difference in the case of *Emx1Cre*. Therefore, our results suggest caution in interpreting the effects of conditional loss of Ldb1, since the actual recombination of the gene may not have occurred at the expected time point as assessed by the floxing of reporter lines.
Loss of Ldb1 using *Foxg1Cre* recapitulates many of the phenotypes seen in Lhx2 loss of function brains, while also exhibiting some unexpected and novel phenotypes. Loss of Ldb1 using *Emx1Cre* causes efficient recombination in the hippocampal primordium, and profoundly disrupts hippocampal development. We were able to rescue the hippocampal defects using a chimeric *Ldb1-Lhx2* construct, demonstrating that an Ldb1-Lhx2 complex is the active complex critical for the regulation of hippocampal specification and neurogenesis. Therefore, the functional partner for Ldb1 in hippocampal development appears to be Lhx2.

Title: Hypothalamic Ptf1a is required for sexual differentiation of the brain and behavior

Authors: *T. FUJIYAMA[1,2], S. MIYASHITA[2], Y. TSUNEOKA[3], M. NAGAOKA[2], M. KAKIZAKI[1], S. KANNO[1], Y. ISHIKAWA[1], Y. KAWAGUCHI[4], Y. YANAGAWA[5], M. A. MAGNUSON[6], Y.-I. NABESHIMA[7], M. YANAGISAWA[1], H. FUNATO[3], M. HOSHINO[2]

Abstract: The brain has sexual differences in structure and function, which are determined during the critical period (from embryonic day 16 to P8 in mice) by the sex steroid hormonal milieu. However, it remains unknown how the developing brain acquires the ability to respond to the gonadal hormones before the critical period. *Pancreas transcription factor 1a (Ptf1a)* is expressed in the developing brain and known to be required for the proper maturation of the cerebellum, brain stem and spinal cord. Although the preoptic area and ventral diencephalon are only regions where *Ptf1a* is expressed in the developing forebrain, the role of *Ptf1a* in these regions is largely unknown. Here we report that hypothalamus-specific *Ptf1a*-deficient (cKO) mice (*Nkx2.1-Cre; Ptf1a-flox*) exhibited abnormalities in sexually-biased behaviors such as mating, aggression and parenting. *Ptf1a* cKO mice also showed maldevelopment of gonadal tissues in both sexes. Histological examination revealed that sexual differences in hypothalamic gene expressions of *Ptf1a* cKO mice were different from those of control mice. We did not detect any overt changes in the hypothalamic structures in *Ptf1a* cKO mice nor an increased cell death in the hypothalamus of *Ptf1a*-null mice. Next, we performed microarray analysis using FACS-sorted cells expressing *Ptf1a*-YFP from E14 brains, which showed a significant decrease in *Kiss1* gene expression. We confirmed a decreased *Kiss1* mRNA in adult *Ptf1a* cKO mice using quantitative PCR. In addition, *Kiss1*-positive cell numbers in the anteroventral periventricular (AVPV) and arcuate nucleus (ARN) were markedly decreased in both sexes. Since the *Kiss1* gene encodes kisspeptin that is required for sexual maturation and directly regulates the release of gonadotropin releasing hormone (GnRH) from the anterior pituitary, the current results suggest that hypothalamic *Ptf1a* is required for sexual differentiation of the brain and gonadal tissues via proper kisspeptin expression.

Title: Cell-type-specific alternative splicing controls cerebral cortex development

Authors: *X. ZHANG[1], X. WU[2], M. CHEN[1], J. FAN[3], D. BLACK[4], D. V. KHARCHENKO[3], P. A. SHARP[2], C. A. WALSH[5]

Abstract: Alternative splicing is widespread in the brain but its role in regulating neural progenitor cell (NPC) fate remained an open question. Using single cell RNA-Seq and mouse reporter lines, we studied NPCs and neurons purified from the developing mouse and human cerebral cortices, and uncovered hundreds of alternatively spliced exons that preferentially affect cytoskeletal proteins. We demonstrated that Ptbp1 and Rbfox proteins antagonistically regulate the NPC-to-neuron transition by regulating a group of neuron-specific exons. While Ptbp1 maintains apical progenitor lamination through suppressing a poison exon of *Flna* in NPCs, Rbfox proteins promote neuronal differentiation by switching Ninein from a centrosomal splice form in NPCs to a non-centrosomal isoform in neurons. We further identified a deep intronic human mutation within a PTBP1 binding site that disrupts normal skipping of the FLNA poison exon in NPCs and causes a brain-specific malformation. This study indicates that cell-type-specific alternative splicing controls neurogenesis in the developing cerebral cortex.

Title: Thalamic and behavioral repercussions following cortex-specific deletion of Emx2

Authors: S. I. AKHIDENOR[1], N. A. CASTRO BORJAS[1], A. K. SWEDZINSKI[1], K. M. HIXSON[1], A. MACGREGOR[1], A. B. ZEMBRZYCKI[2], *A. M. STOCKER[1]

Abstract: The mammalian cortex is comprised of several primary sensory areas, which receive information from the periphery relayed through the appropriate sensory specific thalamic nuclei. The developmental process through which the neocortex is subdivided into distinct functional areas is called area patterning. Studies investigating intrinsic area patterning mechanisms have shown that transcription factors are expressed in different mediolateral and rostrocaudal gradients by cortical progenitors during early corticogenesis, which specify positional/areal identities. Previous research exploring cortex-specific deletion of Pax6 revealed top-down plasticity in the thalamus. More specifically, a genetic driven reduction of the primary somatosensory area subsequently caused a reduction in the somatosensory thalamic nucleus (ventral posterior). Previous research has shown that a cortex-specific deletion of Emx2 causes a decrease in posterior area size, particularly the visual areas. To determine if top-down plasticity is present in the visual system following area patterning changes, we examined the size of specific thalamic nuclei following cortex-specific Emx2 deletion (mediated by Emx1 driven Cre-recombinase). We observed no changes in dorsal lateral geniculate size (the visual thalamic nucleus) in Emx2 mutants. In contrast, we observed a significant reduction in the size of the reticular thalamic nucleus. However, this reduction was not apparent until the end of the critical period. We also observed behavioral changes that mirrored the timeline of the anatomic changes in the reticular thalamic nucleus. These results indicate top-down plasticity does occur in the visual system, but via mechanisms distinct from those found in the somatosensory system.

Title: Postmitotic subdivision of the contralateral medial vestibulospinal tract by specific expression of transcription factors

Authors: *A. LUNDE[1], B. W. OKATY[2], S. M. DYMECKI[3], J. C. GLOVER[1]
[1]Univ. of Oslo, Oslo, Norway; [2]Genet., [3]Harvard Med. Sch., Boston, MA

Abstract: The vestibulospinal system is a collection of brainstem to spinal cord projection neurons residing in the vestibular nuclei, and helps animals ranging from agnathans to humans to maintain proper balance and posture. These neurons can be classified into three distinct groups according to their projection pattern and rhombomeric origin. Fate mapping has demonstrated that the ipsilateral lateral vestibulospinal tract (LVST) group derives from rhombomere (r)4, the ipsilateral medial vestibulospinal tract (iMVST) derives from r6, and the contralateral medial vestibulospinal tract (cMVST) group derives from r5 and part of r4 (Di Bonito et al., 2015; Diaz, Puelles, Marin, & Glover, 1998).
To investigate the combinatorial pattern of rhombomeric origin and downstream transcription factor expression in the cMVST neurons, we combined retrograde fluorescent tracing with immunohistochemistry in wild type and r4-Hoxb1-YFP (r4 lineage specific) mouse embryos. We found that r4-derived cMVST neurons express Lbx1 post-mitotically, while the r5-derived component of cMVST neurons is void of Lbx1. Preliminary data suggests that Evx2 has the opposite expression pattern, with r4-derived cMVST neurons being Evx2-negative and r5-derived cMVST neurons being Evx2-positive. Several other transcription factors appear to be quantitatively modulated by rhombomeric origin as assessed by immunostaining intensity.
Thus, the cMVST is subdivided post-mitotically into different transcription factor-specific domains according to rhombomeric origin, suggesting functional subdivisions in the control of neck musculature by the vestibulospinal system.

Title: Regression of the intrinsic activation properties of Renshaw cells during the early phase of the spinal cord network development

Authors: *P. LEGENDRE[1], J. BOERI[1], H. LE CORRONC[1], B. LE BRAS[1], C. MOUFFLE[1], J. MANGIN[1], P. BRANCHEREAU[2], A. CZARNECKI[1]
[1]INSERM U1130/CNRS UMR 8246, UPMC UM CR18,, Paris, France; [2]Univ. Bordeaux & CNRS - INCIA UMR 5287, Pessac Cedex, France

Abstract: Context: As in many central nervous system areas, the embryonic spinal cord (SC) generates spontaneous rhythmic synchronized neural activity (SNA). SNA is essential for the development of neuronal networks. In the mouse embryonic SC, SNA emerges at the onset of synaptogenesis (E12.5 to E14.5) and then disappears when the first locomotor networks become functional (after E15.5). SNA is characterized by the periodic occurrence of giant depolarizing potentials (GDPs) in motoneurons (MNs), mainly due to the massive release of GABA. Among the several SC GABAergic interneurons (INs), the V1 INs are one of the first INs projecting onto MNs at the onset of SNA. But how the intrinsic activation properties of these INs develop and consequently control GDPs remain open questions. Aim: To address this issue, we analyzed the development of the intrinsic activation properties of V1 INs and of MNs between E12.5-E14.5. Methods: MNs and V1 INs recorded using whole-cell patch-clamp in the SC open-book preparation. Results: At E12.5, V1 INs identified by FoxD3 and calbindin (Renshaw cells), displayed various firing patterns. Cluster analysis revealed that this heterogeneity reflects different regimes of intrinsic activation properties that can be classified as single-spiking, repetitive-spiking or sodium-dependent plateau potential regime. To the contrary, MNs displayed only single-spiking or repetitive-spiking regimes. We discovered that regimes of intrinsic activation properties of V1 INs and MNs depend on the ratios of the persistent sodium current (INaP) versus the delayed voltage-dependent potassium currents (IKdr). Blockade of INaP with riluzole convert plateau potential or repetitive-spiking into single-spiking cell while reduction of IKdr convert single-spiking into plateau potential or sustained-firing regimes. MNs intrinsic excitability develops in a classical way between E12.5 and E14.5, with an increase in the proportion of MNs firing repetitively at E14.5. To the contrary, V1 INs lose their ability to generate repetitive-spiking or plateau potential at E14.5 related to a decrease in the gNaP/gKdr

ratio. This regression in V1 INs intrinsic activation properties is transitory since these INs are able to fire repetitively at later developmental stages.

Title: MacBrainResource: Collection of slides and tissues enables study of non-human primate development and architecture

Authors: *L. D. SELEMON, A. DUQUE
Dept Neurosci., Yale Univ. Sch. Med., New Haven, CT

Abstract: A macaque brain tissue resource (MacBrainResource), designed for the study of developmental neurobiology, neurocytology and neuroanatomy is now available to the neuroscience community at large. The mission of this newly NIH-supported resource is to facilitate access to non-human primate brain slides, fixed and frozen tissue and EM blocks produced by decades of study in the laboratories of Drs. Pasko Rakic and Patricia S. Goldman-Rakic at Yale University. MacBrainResource includes an extensive collection of ^{3}H-thymidine labeled brain slides for the study of neurogenesis (Set 1). To generate this collection, ^{3}H-thymidine was injected into pregnant rhesus monkeys for uptake into fetal brains ranging in age from near conception (E29) to the end of gestation (E165), and into postnatal monkeys as well. Survival times varied from 1 hour to days, months, and years so that the place and time of origin, kinetics of proliferation and rate of migration of various classes of neurons and their settling patterns can be studied. Serial sections throughout the entire brain were cut generally at 20 μm thickness, and every 20th section was developed autoradiographically and Nissl counterstained. Only limited regions of the brain have been studied for the time of neuron origin, leaving the vast majority of cell populations available for analysis and publication. Unstained, intermediate sections were collected as well; these could be utilized for developmental studies via the application of new methods. Slides may be accessed on site at Yale or remotely via electronic images uploaded to the website, MacBrainResource.org, by request. Other available material includes autoradiographically labeled slides from brains with ^{3}H-amino acids injections for anterograde tract-tracing (Set 2), slides from animals with prenatal or postnatal lesions (Set 3), slides prepared for stereological analysis from adult monkeys that had been fetally irradiated and

corresponding control sham-irradiated and non-irradiated animals (Set 4), and EM blocks of multiple brain regions at all ages of development (Set 5). MacBrainResource affords neuroscientists worldwide a means to address questions about non-human primate development and structure that are pertinent to contemporary issues in basic neurobiology and human disease. Moreover, access to archived brain materials will enable researchers to perform *de novo* non-human primate research without the need to sacrifice any additional animals.

Title: Small molecules instruct rod photoreceptor progenitor fate or permit cone photoreceptor progenitor fate from mammalian retinal stem cells

Authors: *J. J. BELAIR-HICKEY[1], S. KHALILI[1], B. G. BALLIOS[2], K. N. GRISÉ[1], B. L. K. COLES[1], V. WALLACE[3], G. BERNIER[4], D. VAN DER KOOY[1]
[1]Mol. Genet., [2]Ophthalmology and Vision Sci., Univ. of Toronto, Toronto, ON, Canada; [3]Vision Sci. Res. Program, Toronto Western Res. Inst., Toronto, ON, Canada; [4]Stem Cells and Developmental Biol., Hôpital Maisonneuve-Rosemont, Montreal, QC, Canada

Abstract: The adult mammalian eye contains a rare population of quiescent retinal stem cells (RSCs) within the pigmented ciliary retinal margin having the ability to self-renew and give rise to all cell types of the retina *in vitro*. When plated at a clonal density a single RSC will divide to produce a free-floating sphere colony of ~3000-5000 cells, of which the majority are either retinal pigmented epithelial (RPE) progenitors or non-pigmented neural retinal (NR) progenitors. Here we report the isolation of lineage restricted photoreceptor progenitor cells derived from murine RSCs, allowing for the production of pure populations of photoreceptors *in vitro*. When RSC-derived NR progenitors were plated at a single-cell per-well density and exposed to COCO (a secreted multifunctional inhibitor of BMP / Wnt / TGFβ signalling pathways) for 45 days, nearly all of the clones were 100% positive for cone-arrestin and s-opsin (markers of mature post-mitotic s-cone photoreceptors). Furthermore, COCO needed to be present throughout the entire differentiation period to induce cone photoreceptor fate. These data suggest that the inhibition of these three major signalling pathways is acting to cause NR progenitors to default towards an s-cone photoreceptor fate, a concept that has been proposed for cone developmental *in vivo*. In contrast, when single non-pigmented NR progenitors were exposed to taurine +

retinoic acid (T/RA) for 40 days, all clones contained 100% rhodopsin positive cells (a marker of post-mitotic mature rod photoreceptors). Unlike COCO, however, T/RA does not need to be present throughout the entire differentiation period, and can be removed during later time-points while still producing enriched rod photoreceptor clones. This indicates that, unlike cone photoreceptor development, T/RA is acting in an instructive manner to bias NR progenitors towards a rod lineage-restricted cell fate. In both cases, the size and survival of clones was no different compared to NR progenitors exposed to a pan-retinal differentiation condition in 1% FBS, arguing against COCO or T/RA having a selective survival effect on photoreceptor lineage restricted progenitor cells. In addition to murine eyes, RSCs can also be isolated from both human donor eyes and human pluripotent stem cells. The ability to derive cone or rod lineage-restricted progenitors from these sources provides potentially inexhaustible sources of rods and cones for therapeutic applications, as well as a developmental system to study the molecular identity of photoreceptor lineage-restricted progenitors in a human context.

Title: Characterization of transcription factor expression during retinal development in gallus gallus

Authors: B. KABLE[1], *S. A. GEORGI[2]
[2]Biol. Sci., [1]York Col. of Pennsylvania, York, PA

Abstract: During retinal development, a group of multipotent progenitor cells give rise to six types of neurons and one type of glia in a conserved order, with ganglion cells being produced first, and Müller glia last. While numerous transcription factors that control this process have been identified and characterized, the details by which these genes regulate the process of cellular differentiation is still unclear. It is likely that many of these transcription factors represent only the first steps of the genetic cascades of differentiation, and that there are additional transcription factors that play a role in activating or repressing the genes necessary to convert a retinal progenitor cell into a functional neuron or glial cell. In previous studies (Georgi and Reh 2010) we performed a conditional knockout (CKO) of Dicer, an enzyme required for microRNA biogenesis, and observed that retinal progenitor cells did not produce late cell types.

This suggested they were arrested in an early competence state, and to determine genetic changes that might underlie this phenotype we performed a microarray of Dicer CKO retina (La Torre et al. 2013). We hypothesize that those genes that decreased on the microarray are involved in the generation of late cell types. Interestingly, on this list were numerous transcription factors whose expression and function in the retina has not yet been characterized. The aim of this study is to provide initial characterization of the expression of these unstudied transcription factors during chicken retinal development using qPCR and immunohistochemistry. Our data support our hypothesis that these transcription factors play a role in late retinal development, and provide a foundation for future studies into the specific developmental function of these genes.

Title: Comparative analysis of cone and horizontal cell restricted progenitors and multipotent progenitors in the vertebrate retina

Authors: *D. F. BUENAVENTURA[1,2], M. GHINIA[1], M. EMERSON[1]
[1]City Col. of New York, New York, NY; [2]Biol., CUNY Grad. Ctr., New York, NY

Abstract: Every cell type in the vertebrate retina is derived from multipotent retinal progenitor cells (RPCs). Current evidence suggests that some RPCs are molecularly restricted to produce only certain cell types. Little is known about how many types of restricted RPC populations exist or what distinguishes them molecularly from multipotent RPCs. The ThrbCRM1 regulatory element is activated by OC1 and OTX2 and drives reporter expression in one type of restricted RPCs that preferentially generate cones and horizontal cells. RNAseq of the ThrbCRM1+ cell population shows an upregulation of cone and HC-specific transcripts and downregulation of traditional multipotent progenitor markers. Further characterization of the ThrbCRM1+ premitotic subpopulation in the chicken retina at E5 suggests that OC1/OTX2+ progenitors downregulate multipotent markers VSX2/LHX2/PAX6 at different rates during the restriction process and become spatially segregated from the remaining multipotent progenitor population. At E6, our analysis indicates that a subset of OTX2/OC1+ RPCs remain apically and begin to upregulate a photoreceptor-specific marker, while another subset downregulate OTX2+ but maintain OC1 expression and migrate to the basal retina for another mitotic event. Therefore, our

data suggests that cone and HC progenitors at E5/E6 exhibit a different molecular signature and behavior than LHX2/VSX2/PAX6+ proliferating multipotent progenitors.

Title: D-serine modulation of glutamatergic transmission disrupts retinotectal input convergence in the developing visual system

Authors: *M. VAN HORN, E. S. RUTHAZER
Neurol. and Neurosurg., McGill Univ., Montreal, QC, Canada

Abstract: N-methyl-D-aspartate receptor (NMDAR) activation is essential for establishing and maintaining precise neural circuit refinement. The gliotransmitter D-serine is a co-agonist for NMDARs and modulates synaptic transmission and plasticity mediated by this receptor. Here we investigated the role D-serine plays in modulating synaptic transmission and axonal remodeling in the developing visual system of the Xenopus tadpole. We find that D-serine is an endogenous co-agonist of the NMDAR that is normally present below saturating levels and show that glutamate receptor activation can evoke endogenous D-serine release, which promotes glutamatergic synapse maturation and stabilizes axonal structural and functional inputs. Here, to test the functional consequence of chronic enhancement of NMDAR currents by exogenous D-serine, we performed whole-cell recordings in vivo while presenting patterned visual receptive field mapping stimuli in control animals and in animals raised in D-serine for 48 h. Each location in a 7 by 7 grid of visual subfields was illuminated at random to map out the synaptic currents evoked by subfield illumination. Responses evoked after the illumination of the light (ON) as well as the extinction of the light (OFF) were analyzed. Consistent with previous studies, we found that OFF responses were typically larger than corresponding ON responses in control animals, as indicated by the mean OFF/ON peak response ratio of 1.74 ± 0.27. In contrast, ON and OFF responses from cells recorded from animals raised in D-serine were more closely matched (OFF/ON ratio: 0.83 ± 0.08). Interestingly, a comparison of the sum of responses across all subfields revealed that the overall response is greater in D-serine animals and a comparison of the size of the receptive field shows that the ON response is significantly larger in the D-serine

animals. Taken together these results suggest that D-serine exposure promotes a non-specific strengthening of retinal ganglion inputs leading to a more divergent receptive field map. Overall, these findings positively implicate NMDAR-mediated neurotransmission in developmental synapse maturation and the stabilization of axonal inputs and reveal a potential role for D-serine as an endogenous modulator of neural circuit refinement.

Title: The role of purinergic receptors in early neural calcium activity

Authors: *S. BRACERO, L. G. YI, S. PAUDEL, M. S. SAHA
The Col. of William and Mary, Williamsburg, VA

Abstract: Although calcium plays an essential role as a signaling molecule during neural development, very little is known about what triggers the observed dramatic fluctuations. The purinergic receptors are a large family of highly conserved proteins that bind purines such as ATP and have been implicated as mediators of calcium activity and cell proliferation during early neural development. Here we have cloned members of the purinergic receptor family in an attempt to determine if they are mediating the widespread calcium activity that occurs throughout gastrula and neurula stages of development. In particular, the Y family G protein-coupled purinoreceptor P2RY11 was cloned and characterized in *Xenopus laevis* during embryonic development. Expression of this receptor was observed starting at the early neurula stage in the posterior tip, and in the tailbud of early tailbud stage embryos, which has never before been observed. Expression was also observed in the developing notochord, which is consistent with previous reports on the expression of P2RY11. Due to its temporally and spatially restricted expression patterns, the role of P2RY11 in tailbud regeneration was investigated through amputation experiments. P2RY11 was not expressed in response to tail amputation. Given these results, P2RY11 is likely involved in the formation of the tailbud during development, but is not responsible for its proliferative and regenerative abilities. However, calcium imaging of tailbud cells in the presence and absence of NF-157, a P2RY11 antagonist, revealed that P2RY11 may mediate high frequency, low amplitude calcium spiking and that

P2RY11 may be involved in early neural patterning. Here we report the expression patterns of P2RY11 and other purinergic family members in neural development.

Title: Effects of neonatal hyperoxia on the critical period of postnatal development of neurochemical expressions in brain stem respiratory-related nuclei in the rat

Authors: L. MU[1], T. MICHALKIEWICZ[2], G. G. KONDURI[2], M. HODGES[3], *M. T. WONG-RILEY[4]
[1]Cell Biology, Neurobio. and Anat., [2]Pediatrics, [3]Physiol., [4]Med. Col. of Wisconsin, Milwaukee, WI

Abstract: We have identified a critical period of postnatal respiratory development in the rat at postnatal days P12-13, when inhibitory influence dominates and when the response to hypoxia is at its weakest. This critical period has significant implications for Sudden Infant Death Syndrome (SIDS), the cause of which remains unclear. One of the known risk factors for SIDS is prematurity. A common intervention used in premature infants is exposure to hyperoxia, which, if prolonged, can alter the ventilatory response to hypoxia and induce sustained inhibition of lung alveolar growth and pulmonary remodeling. The goal of the present study was to determine if neonatal hyperoxia causes neurochemical changes in brain stem respiratory-related nuclei. Sprague-Dawley rats of both sexes were exposed to 90% oxygen from the day of birth (P0) until P10. They were then euthanized at 4 time points: P10 (immediately after hyperoxia and before the critical period), P12 (during the critical period), P14 (immediately after the critical period), and P17 (a week after the cessation of hyperoxia). Control animals were exposed only to room air. Brain stems of all animals were processed for cytochrome oxidase histochemistry and neurochemical immunohistochemistry followed by optical densitometry of reaction product within single neurons of respiratory-related hypoglossal nucleus, pre-Bötzinger nucleus, the ventrolateral subnucleus of nucleus tractus solitarius, and brain stem raphé nuclei, as well as in the non-respiratory cuneate nucleus (CN). In agreement with our previous findings, levels of cytochrome oxidase, brain-derived neurotrophic factor (BDNF), TrkB (high-affinity receptor of BDNF), and several proteins governing serotonergic functions (5-HT_{1A} and $_{2A}$ receptors, 5-HT synthesizing enzyme tryptophan hydroxylase [TPH], and serotonin transporter [SERT]) all fell

during the critical period (P12) in control animals. However, in hyperoxic animals, the levels of these neurochemicals fell at P14 and not at P12. Thus, neonatal hyperoxia appears to delay but not eliminate the critical period of postnatal development in multiple brain stem respiratory-related nuclei, but not in non-respiratory cuneate nucleus of the brain stem. (Supported by Children's Hospital of Wisconsin Research Institute)

Title: Meningeal lymphatics control brain immune surveillance and play key role during neuroinflammation

Authors: *A. LOUVEAU[1], J. HERZ[2], M. ALME[2], G. HEROD[2], J. SETLIFF[2], K. VIAR[2], S. DA MESQUITA[2], I. SMIRNOV[4], R. CAO[2], S. HU[2], G. OLIVER[5], J. KIPNIS[3]

Abstract: The central nervous system (CNS) is considered an immune privilege organ, primarily due its lack of lymphatic system. Contrary to the parenchyma, the meninges have recently been shown to harbor a conventional and functional lymphatic system capable of draining cerebrospinal fluid (CSF). Here we demonstrate that the meningeal lymphatic system extends initial buttons to the sub-arachnoid space (SAS) enabling circulation of macromolecules and immune cells from the CSF/meningeal compartments into the cervical lymph nodes. Using both photoconversion approach and exogenously labeled immune cells, our results show that the CCR7-CCL21 pathway is the primary driver of cell drainage from the CSF/meningeal compartments. Furthermore, we demonstrate, using genetic, surgical and chemical approaches that the meningeal lymphatic route is the main route for immune cells circulation. We could not

confirm the role of nasal route in immune cell recirculation, as has been previously suggested. The meningeal lymphatics have a unique transcriptomic profile preventing them to morphologically respond to local neuroinflammation. Nevertheless, their ablation results in delayed and ameliorated clinical symptoms in an animal model of multiple sclerosis (experimental autoimmune encephalomyelitis; EAE). Interestingly, analysis of T cells in mice with ablated lymphatic suggests a failure of activation and acquisition of proper encephalitogenic program to reach the CNS and cause pathology. These results suggest that meningeal lymphatic vasculature plays a central role in the generation and maintenance of the immune responses towards the CNS-derived antigens, notably by modulating the licensing of peripheral encephalitogenic T cells in the cervical lymph nodes. The meningeal lymphatic vasculature might therefore represent a therapeutic target for modulation of the immune responses directed towards the CNS.

Title: Suppression of BIM upregulation and apoptotic death by chronic depolarization of NGF-deprived sympathetic neurons

Authors: A. A. ALSHAMRANI, *J. L. FRANKLIN
Univ. of Georgia, Athens, GA

Abstract: Survival of developing sympathetic neurons is determined by the availability of nerve growth factor (NGF) at the time of innervation of their target organs. NGF-deprived sympathetic neurons in cell culture die by apoptosis within 48-72 h after deprivation, a hallmark of which is the upregulation of BH3-only pro-apoptotic proteins. Chronic depolarization induced by elevated potassium concentration promotes the survival of these cells and that of many other types of neurons in culture and is thought to be a model for the role of electrical activity in promoting neuronal survival during the development of the nervous system. Suppression of apoptosis by chronic depolarization is mediated by a sustained rise of cytoplasmic free Ca_2^+ concentration. Little is known about how this Ca_2^+ increase blocks apoptotic death. Here we report, that in NGF-deprived sympathetic neurons from mouse superior cervical ganglia (SCG), incrementally

increasing K^+ concentrations induced a concentration-dependent enhancement of survival, with 40 mM as the optimal survival-promoting concentration. Both NGF and 40 mM K^+ rescued NGF-deprived SCG neurons over the same time course, suggesting that they may activate or inhibit the same survival or apoptotic pathways, respectively. Immunoblot experiments revealed that, unlike NGF-deprived neurons, chronically depolarizing these neurons with 40 mM K^+ for 12, 24, 48 h caused a complete suppression of the upregulation of the BH3-only pro-apoptotic protein BIM but not other BH3-only proteins. We are investigating whether suppression of BIM upregulation is a major mechanism by which chronic depolarization promotes survival of sympathetic neurons in culture.

Title: Adult neurogenesis in the nucleus accumbens of the rat

Authors: *J. S. SNYDER[1], J. YANG[1], D. R. SEIB[2]
[1]Dept. of Psychology, [2]Dept. of Psycholgy - Snyder Lab., Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Adult neurogenesis is well-characterized in the hippocampus and subventricular zone-olfactory bulb. Despite numerous reports, the idea of widespread adult neurogenesis remains controversial. The striatum is one region where neurogenesis has been identified, but the magnitude and temporal characteristics of neuron addition has not been studied in detail. Here, we characterized the phenotype and survival timecourse of adult-born neurons in the nucleus accumbens, a part of the ventral striatum involved in reward and reinforcement-related behaviors. Young adult male and female rats (8 weeks old) were treated with the BrdU to label newborn cells and then brains were collected 1, 2, 4, 8 or 16 weeks later. BrdU+ cells were quantified in both the core and shell regions of the nucleus accumbens, and were examined immunohistochemically for calbindin and calretinin expression, two markers of GABAergic interneuron populations. The total number of BrdU+ cells was greatest at 1 week post-injection and steadily declined thereafter. No BrdU+ cells showed co-labelling for calbindin but approximately 2-3% expressed calretinin at the 4 and 8 week time points. Few BrdU+calretinin+ neurons remained at 16 weeks, possibly because neurons have died, matured into a different GABAergic neuron phenotype, or migrated elsewhere. In follow up experiments we are

examining whether accumbens neurogenesis can be increased by exercise, which robustly increases adult neurogenesis in the hippocampus, and whether newborn accumbens neurons derive from a GFAP+ precursor (likely in the subventricular zone), using GFAP-TK rats. Collectively, our findings suggest that adult neurogenesis is more widespread than is generally appreciated. Specifically, our data identify adult neurogenesis as a novel form of plasticity in the nucleus accumbens that may contribute to reward and reinforcement-related behaviors, many of which are disrupted in psychiatric disorders.

Title: Developmental formation of perineuronal nets in the mouse hippocampal CA2 area

Authors: *A. NOGUCHI[1], N. MATSUMOTO[1], H. TAMURA[2], Y. IKEGAYA[1]
[1]The Univ. of Tokyo, Tokyo, Japan; [2]L-StaR, Hoshi Univ., Tokyo, Japan

Abstract: Perineuronal nets (PNNs) are extracellular macromolecules that consist of several components, including chondroitin sulfate proteoglycans, hyaluronan, and tenascin-R. PNNs exist mostly around inhibitory interneurons, such as parvalbumin-positive interneurons, and are also present around excitatory neurons in several other brain regions than the hippocampus, preventing plasticity in these neurons. A recent report showed that PNNs are also distributed around excitatory pyramidal cells in the CA2 subarea of the mouse hippocampus and suppress excitability and plasticity of these neurons. However, the postnatal development of PNNs in the hippocampal CA2 subregion has not been well understood yet. In the present study, using immunohistochemical method, we focused on aggrecan, one of the chondroitin sulfate proteoglycans as a main component of PNNs, and found aggrecan expression in the pyramidal cell layer of the putative CA2 subregion at as early as postnatal-day 5 (P5), before the appearance of the CA2 subregion at P14, defined by regulator of G protein signaling 14 (RGS14), a CA2 marker protein. In the process of the investigation about the postnatal development, we also demonstrated that aggrecan immunoreactivity was stronger in the anterior sections of the CA2 subregion than the posterior sections and that the exclusive expression of aggrecan in the putative CA2 subarea started to appear in the most anterior section. These results

suggest that there might be some functional difference in the CA2 subarea along the anterior-posterior axis.

Title: Newly generated cells in adult turtles are not GABAergic

Authors: *J. E. ALOUIDOR[1], A. S. POWERS[2]
[1]Neurosci., Stony Brook Univ., East Setauket, NY; [2]Psychology, Stony Brook Univ., Stony Brook, NY

Abstract: Gamma-aminobutyric acid (GABA) is the major inhibitory neurotransmitter in the adult vertebrate brain. As in many nonmammals, widespread adult neurogenesis occurs in the telencephalon of turtles. We studied whether the new cells are GABA-positive. Although they have been shown to be mainly neurons, nothing is known about the neurotransmitter used in the new cells in turtles. Furthermore, the neurotransmitter that regulates the different steps of adult neurogenesis specifically in turtles is unknown. While previous studies had demonstrated the presence of GABAergic cells in different regions of the turtle brain, this study aimed at determining whether GABAergic neurons are present in regions of neurogenesis in turtles, and whether GABA is present in the newly generated cells. Four adult painted turtles (*Chrysemys picta)* were kept under standard conditions and fed a standard diet. They were given 9 injections of BrdU (50 mg/kg) over a three-week period and euthanized 6 weeks after the first BrdU injection by an overdose of anesthetic and transcardial perfusion. The brains were cryoprotected and sectioned at 40 um. Some sections were stained with standard immunohistochemistry to determine the presence of GABAergic neurons. Other sections were stained with standard double immunofluorescence staining methods to determine whether the newly generated cells are GABAergic. As in previous studies, adult neurogenesis was seen near the lateral ventricles of the telencephalon in turtles. Moreover, our immunohistochemical technique revealed GABA-positive cells in similar regions near the lateral ventricles of the turtle telencephalon, with some revealing potential cell axons. Co-expression of GABA-positive cells with BrdU-positive cells was not observed, however, suggesting that none of the newly generated cells are GABAergic. GABAergic cells were found instead to be in close proximity to and sometimes even surrounding the newly formed cells. This finding shows continuity with mammals, where the new cells in the hippocampus are not GABAergic. A demonstration of continuity like this is consistent with the idea that GABA, as suggested in mammals, plays a key regulatory role in the formation and

synaptic integration of the newly synthesized cells; however, further studies are needed to support this hypothesis in turtles. Determining the neurotransmitter that regulates adult neurogenesis activities in turtles or the neurotransmitter used in the new cells could help to clarify why there is widespread neurogenesis in nonmammals compared to observed limited neurogenesis in mammals.

Title: Cell proliferation in the hindbrain of semi-intact *In vitro* preparations of Xenopus laevis tadpoles

Authors: V. SCHWARZ[1], R. SANCHEZ-GONZALEZ[2], J. NINKOVIC[2,3], *H. STRAKA[1]
[1]LMU Munich - Biocenter Martinsried, Planegg, Germany; [2]Inst. of Stem Cell Res., Helmholtz Ctr. Munich, Munich, Germany; [3]Biomed. Ctr., LMU Munich, Munich, Germany

Abstract: The considerable body growth during larval development in fish and amphibians is accompanied by an equally extensive increase in brain size and number of neuronal and non-neuronal elements. The continuous growth of the brain in anamniotes is to large extent achieved by an ongoing neurogenesis, as well as an increase in non-neuronal supporting cells and vascularization. Despite the vast amount of data on embryonic brain development, relatively little is known about cell proliferation at later ontogenetic stages. This prompted us to visualize cell proliferation in the hindbrain of *Xenopus laevis* tadpoles. Experiments were performed on semi-intact *in vitro* preparations at stage 50-52 and exploited a Bromodeoxyuridine (BrdU)-based identification of newborn cells and pursuit of the cells for up to 5 days after isolation of the preparation. BrdU-labeled cells were identified after tissue fixation, serial sectioning of the brain into 30 µm cross-sections and fluorescent antibody staining. This allowed determining site(s) and amount of cell proliferation, rate and extent of cell migration and fate over several days. Immunohistochemistry with antibodies against neuronal (HuC/D) and glial/progenitor markers (Sox10, Vimentin) was used to determine cellular profiles. Initial experiments indicated that incubation of tadpole preparations for 30 min in 5 mMol BrdU containing Ringer solution was optimal for a reliable labeling of proliferating cells. Following 30 min BrdU pulse labeling and

immediate fixation of the tissue, 30-50 newborn cells per section were predominantly encountered at the ventricular surface throughout the rostro-caudal extent of the hindbrain, although with rhombomere-specific regional differences in cell numbers. Following immediate fixation after BrdU pulse labeling, newborn cells were located within the epithelial layer but showed a ventro-lateral dispersion with increasing survival times up to 48 hours after pulse labeling. This migratory behavior, although limited in extent to ~50 µm, differed between cells and was generally larger for newborn cells medial to the sulcus limitans. Thus, rather than a homogeneous migratory wave, newborn neurons spread actively or were passively pushed from the proliferation zone at a differential rate. Immunohistochemistry of cellular profiles will determine cell fates, identify neuronal precursors and their insertion into defined circuitries with longer survival times. Moreover, the use of isolated *Xenopus* preparations for such an *in vitro* approach allows pharmacological manipulations of neurogenesis and subsequent migration, as well as the study of lesion-induced cell proliferation.

Title: The effect of exercise on neurogenesis in the green anole lizard brain

Authors: C. A. FOLEY[1], J. J. RODDICK[1], E. C. MAGNUSON[2], A. Z. WANG[2], J. F. HUSAK[2], *R. E. COHEN[3]
[1]Minnesota State University, Mankato, Mankato, MN; [2]Univ. of St Thomas, St Paul, MN; [3]Biol. Sci., Minnesota State Univ. Mankato Dept. of Biol. Sci., Mankato, MN

Abstract: Previous studies in mammals have shown that exercise promotes neurogenesis in the hippocampus, but not much is known about how exercise impacts neurogenesis in reptiles. The hippocampus is responsible for behaviors such as spatial learning and memory, and is a major site of neurogenesis in the adult brain. The hippocampus also exhibits high levels of brain-derived neurotrophic factor (BDNF) and exercise has been associated with an upregulation of BDNF in the hippocampus. The green anole lizard (*Anolis carolinensis*) is an ideal model organism for studies of neuroplasticity due to dramatic seasonal changes in reproductive and aggressive behaviors, circulating steroid hormone levels and brain morphology. We examined how exercise impacts neurogenesis in the dorsal cortex (DC) and medial cortex (MC), the reptilian homolog of the hippocampus. To do that, two cohorts of adult breeding male lizards were injected subcutaneously with BrdU (50 mg/kg) once per day for five days prior to

treatment. The exercise group underwent forced exercise on a treadmill for 30 minutes/day for three weeks. The control group was handled and put back in the cage every day for three weeks. Two hours prior to sacrifice an additional bolus of BrdU was injected to mark newly proliferating cells. Tissue was collected, frozen and cryosectioned. An immunohistochemistry was performed for BrdU and Hu (neuronal marker), and double positive cells were counted in the DC and MC to examine the effects of exercise on new neuron integration. We also counted BrdU positive cells in the dorsal section of the subventricular zone to quantify neuronal progenitor cell proliferation between the two treatments. We will determine whether exercise impacts neurogenesis in the hippocampus and progenitor cell proliferation in the subventricular zone in reptiles, as it does in mammals. We also plan to utilize in situ hybridization to measure BDNF levels in the brain.

Title: Neural progenitor cells in cerebral cortex of epilepsy patients do not originate from astrocytes expressing GLAST

Authors: *M. PEKNA, M. CHEN, T. PUSCHMANN, U. WILHELMSSON, C. ÖRNDAL, K. MALMGREN, B. RYDENHAG, M. PEKNY
Univ. of Gothenburg, Gothenburg, Sweden

Abstract: Adult neurogenesis in human brain is known to occur in the hippocampus, the subventricular zone, and the striatum. Neural progenitor cells (NPCs) were reported in the cortex of epilepsy patients, however their identity is not known. Since astrocytes were proposed as the source of neural progenitors in both healthy and diseased brain, we tested the hypothesis that NPCs in the epileptic cortex originate from reactive, alternatively, de-differentiated astrocytes that express glutamate aspartate transporter (GLAST). We assessed the capacity to form neurospheres and the differentiation potential of cells dissociated from fresh cortical tissue from patients who underwent surgical treatment for pharmacologically intractable epilepsy. Neurospheres were generated from 57% of cases (8/14). Upon differentiation, the neurosphere cells gave rise to neurons, oligodendrocytes and astrocytes. Sorting of dissociated cells showed that only cells negative for GLAST formed neurospheres. In conclusion, we show that cells with

neural stem cell properties are present in brain cortex of epilepsy patients, and that these cells are not GLAST-positive astrocytes.

Title: Investigating homeostatic regulation of developmentally-born neurons following manipulations of adult neurogenesis in the dentate gyrus

Authors: ***S. P. CAHILL**[1], *S. P. CAHILL[1], A. MARTINOVIC[2], J. COLE[2], J. S. SNYDER[3]
[1]Dept. of Psychology, Univ. of British of Columbia, Vancouver, BC, Canada; [2]Univ. Of British Columbia, Vancouver, BC, Canada; [3]Dept. of Psychology, Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Adult-born neurons contribute significantly to the synaptic circuitry in the dentate gyrus (DG) and play an important role in the cognitive and emotional functions of the hippocampus. An outstanding question is whether postnatal neurogenesis leads to continued growth in the DG or whether the addition of adult-born neurons is balanced by death of developmentally-born neurons. We have recently found that developmentally-born neurons die in early adulthood, unlike adult-born cells, which are known to remain stable (after reaching maturity). While adult-born neurons have enhanced plasticity and unique circuitry during their immature stages, many reports indicate that they may become functionally equivalent to neurons born in early postnatal development once they have reached maturity. These data collectively suggest that adult neurogenesis may serve to directly replace lost developmentally-born cells. Whether there is a causal, homeostatic relationship between numbers of developmentally-born and adult-born neurons remains unknown. We aimed to test this hypothesis by directly manipulating the adult-born neuronal population and examining how this impacts the number of surviving developmentally-born neurons in the DG. Male rats were injected with the mitotic marker BrdU at postnatal day 6, the peak of DG neuron birth, followed by either neurogenesis-promoting or suppressing treatments administered from 2 until 6 months of age. To suppress

adult neurogenesis we used transgenic GFAP-TK rats; at the end of treatment adult neurogenesis was reduced by 69%, as measured by doublecortin immunohistochemistry (IHC). To enhance adult neurogenesis, we subjected rats to alternating 4-week blocks of running and memantine, an NMDA antagonist, which we have found produces sustained increases in adult neurogenesis by 28% as measured by doublecortin IHC. According to a homeostatic relationship, we predict that supressing adult neurogenesis will increase survival of developmentally-born cells; conversely, we predict that increasing adult neurogenesis will reduce survival of developmentally-born cells. Finally, independent of changes in cell number, prolonged reductions or enhancements of adult neurogenesis may alter recruitment of DG neurons during learning experiences. To this end, all rats were exposed to a novel environment prior to the end of the experiment, to measure experience-driven expression of immediate-early genes in developmentally-born DG neurons. Collectively, these data will clarify whether there are interactions between neurons born at different stages of development, which may shape how information is retained in the hippocampus.

Title: Quantitative analysis of kynurenine II aminotransferase (KAT II/AADAT) gene in the rat brain reveals high expression in the Subventricular Zone, the rostral migratory stream and the corpus callosum

Authors: *L. H. TONELLI[1], C. SONG[2], C. VAUGHN[2], K. MURPHY[3], G. HOFFMAN[3], R. SCHWARCZ[4], S. CLARK[2]
[1]Univ. of Maryland Baltimore, Baltimore, MD; [2]Univ. of Maryland, Baltimore, MD; [3]Morgan State Univ., Baltimore, MD; [4]Maryland Psychiatric Res. Center, Univ. of Maryland, Catonesville, MD

Abstract: Kynurenic acid, a metabolite of the kynurenine pathway of tryptophan degradation, acts as an endogenous antagonist of alpha7 nicotinic and NMDA receptors and has been implicated in a number of neurophysiological and neuropathological processes including cognition and neurodegenerative events. Kynurenine aminotransferase II (KAT II/AADAT), the

enzyme that appears to be responsible for the formation of the majority of neuroactive kynurenic acid in the brain, has therefore raised significant interest. Using immunohistochemistry, this enzyme has been localized primarily in astrocytes throughout the adult rat brain (Guidetti et al., 2007), but further detailed neuroanatomical studies have not been conducted so far. In the present study, we employed quantitative *in situ* hybridization with radioactive riboprobes to analyze the relative expression of KAT II mRNA in the brain of adult, male rats, both in normal conditions and 6 hours after the administration of lipopolysaccharide (LPS; 2 mg/kg, ip). Specific hybridization signals for KAT II were detected, with the highest expression in the subventricular zone (SVZ), the rostral migratory stream and the floor of the third ventricle, followed by the corpus callosum and the stratum lacunosum moleculare (SLM) of the hippocampus. This pattern of mRNA expression was paralleled by differential protein expression, determined by serial dilutions of antibodies (up to 1:1 million) and was confirmed to be primarily astrocytic in nature. The mRNA signal in the SVZ and SLM was substantially increased by the LPS treatment without detectable changes elsewhere. These results demonstrate that KAT II is expressed in the rat brain in a region-specific manner and that gene expression in the SVZ and SLM is sensitive to inflammatory processes suggesting a so far unrecognized role for kynurenic acid in the brain's germinal zone.

Title: Oligodendrocyte progenitor cells of the adult mouse suprachiasmatic nucleus may be a source of new neurons

Authors: D. H. BELIGALA, A. DE, H. J. MCQUILLEN, *M. E. GEUSZ
Dept. of Biol. Sci., Bowling Green State Univ., Bowling Green, OH

Abstract: Studies have suggested that oligodendrocyte progenitor cells (OPCs) can give rise to new neurons in the hypothalamus of adult mice. Nascent neurons alter neuronal circuits and could provide flexibility in the timing of the circadian clock in the suprachiasmatic nucleus (SCN) of the hypothalamus. Studies have not addressed whether ongoing or episodic OPC activity influences circadian clock functions. The aim of this study was to identify and confirm in vitro differentiation of OPCs from juvenile and adult mouse SCN. To limit the cultures to SCN cells, the optic chiasm and ependymal cell layer of the third ventricle were surgically removed from tissue explants trimmed from brain sections. Explants were placed in NeuralX medium

designed for OPC culture, which contained fibroblast growth factor-2, platelet-derived growth factor-AA (PDGF-AA), and GS22 supplement. By 4 days, explants attached to cell culture dishes and produced cells migrating from the edges and proliferating. Explants were removed after 11 to 25 days in culture. Immunocytochemistry and confocal microscopy was used to identify markers for OPCs (Olig2, PDGF receptor-α, and NG2), oligodendrocytes (myelin basic protein), neuroblasts (doublecortin), immature neurons (Class III-β tubulin), and mature neurons (NeuN). Cultures were enriched in cells expressing Olig2 (74.9%) and PDGFR-α (87.6%), along with fewer NG2-positive cells (7.19%). In a separate group, explant removal was followed by a medium exchange to BrainPhys supplemented with SM1 to determine whether the cultures can differentiate into neurons. After 4-5 days, the cell monolayer was rearranged into cell clusters, and the number of cells expressing neural markers increased: doublecortin (1.82-fold), class III-β tubulin (16.3-fold), NeuN (26.9-fold). After inducing differentiation, over 55% of the cells expressed Class III-β tubulin and 27% expressed NeuN. Myelin basic protein expression showed a 3.84-fold increase in the BrainPhys medium, suggesting a subset of OPCs differentiated into mature oligodendrocytes. These results indicate the potential for mature SCN tissue to form additional neurons, and it suggests a mode of possible plasticity within SCN neural circuits to provide adaptive or developmental changes in circadian rhythms.

Title: CreER^{T2} mediated genetic recombination in adult murine neural stem and progenitor cells is induced by tamoxifen delivered via voluntary chow consumption

Authors: *B. SMITH[1,2], E. D. KIRBY[2,3,4,5]
[2]Dept. of Psychology, [3]Dept. of Neurosci., [4]Chronic Brain Injury Initiative, [5]Behavioral Neuroendocrinology Group, [1]The Ohio State Univ., Columbus, OH

Abstract: The tamoxifen (TAM)-sensitive Cre recombinase (CreER^{T2}) system has produced robust temporal control of genetic recombination in a variety of in vivo mouse models. Use of cell-specific expression of TAM-sensitive CreER^{T2} has become increasingly common in the field of adult neurogenesis as a technique for manipulating gene expression in neural stem and

progenitor cells (NSPCs) in adulthood. For example, the nestin promoter, which is selectively active in adult NSPCs, has been successfully used to drive CreER^{T2} expression and thereby genetic recombination of LoxP-flanked sites in NSPCs in the subgranular zone (SGZ) of adult NestinCreER^{T2} mice. Intraperitoneal injection of TAM in adult NestinCreER^{T2} mice is currently the standard method of TAM administration. Oral gavage has also been used previously. However, both TAM injections and oral gavage can be stressful for mice and are time and labor intensive for experimenters. Use of TAM mixed with chow has recently emerged as an efficient, low stress method for delivering TAM to tissues outside the brain. The efficacy of voluntary TAM consumption via chow for recombination in NSPCs has yet to be assessed. We therefore investigated the efficacy of TAM administered in a custom diet for inducing CreER^{T2} mediated recombination in NSPCs in the SGZ of adult mice. Nestin-CreER^{T2} mice were crossed with a commonly used Cre-sensitive reporter mouse, R26R-STOP-EYFP. Double mutant offspring (age 7-9 weeks) were provided a free feeding diet of Teklad Global 16% Protein Rodent Diet with 0.5g/kg of TAM. Following 1, 2, or 3 weeks of diet treatment, the mice were perfused and free floating immunohistochemistry was used to quantify efficiency and specificity of genetic recombination in NSPCs of the hippocampus. Our findings show that TAM chow effectively induces recombination in NSPCs, resulting in robust reporter expression. The highest rate of recombination was achieved with the 3 week treatment of TAM diet, whereas shorter treatments resulted in less recombination. Our findings demonstrate an alternative method for inducing TAM-mediated genetic recombination of LoxP-flanked sites in adult mouse NSPCs that reduces both stress for mice and experimenter labor compared to the field standard of intraperitoneal injections. Use of chow to deliver TAM could be particularly effective in models where animal stress or handling are of concern or where high rates of recombination following long-term TAM exposure are necessary.

Title: Family Nurture Intervention in preterm infants increases early development of cortical activity and independence of regional eeg power trajectories

Authors: *M. MYERS, M. G. WELCH, P. G. GRIEVE, J. ISLER, R. STARK, J. BARONE
Pediatrics, Columbia Univ. Med. Ctr., New York, NY

Abstract: Aim: Premature delivery and maternal separation during long-term hospitalization increase infants' risk for neurodevelopmental disorders. A randomized controlled trial comparing standard NICU care with Family Nurture Intervention (FNI) demonstrated improvement across multiple mother and infant domains; these findings included increased EEG power in the frontal polar region at term age and greater independence of EEG power (decreased coherence) within and between frontal regions. Herein, we extend this analysis to include brain-wide cortical activity. **Methods:** EEG power data was assessed to quantify developmental trajectories of brain-wide cortical activity at all EEG frequencies and in both sleep states. **Results:** FNI significantly increased developmental rates of change in EEG power from 35 to 40 weeks at most frequencies over the entire cortex, with greater regional independence in those rates of change. **Conclusions:** The present study, taken with our prior EEG findings, strengthen the conclusion that facilitating co-regulation and emotional connection between mother and infant with FNI promotes cerebral cortical development of preterm infants. Importantly, this study's term frontal EEG power and brain-wide developmental change findings indicate that term-age EEG and preterm EEG may provide biomarkers for developmental risk in preterm infants as well as a proximal marker of efficacy of early intervention.

Title: Experience-dependent regulation of Cajal-Retzius cell networks in the developing and adult mouse hippocampus

Authors: *G. MACCAFERRI[1], S. K. LEE[1], T. I. NEBLETT[1], G. M. RUNE[2], M. ANSTÖTZ[1,2]
[1]Dept Physiol, Northwestern Univ., Chicago, IL; [2]Inst. for Neuroanatomy, University/University Hosp. Hamburg, Hamburg, Germany

Abstract: In contrast to their near-disappearance in the adult neocortex, Cajal-Retzius cells have been suggested to persist longer in the hippocampus. A distinctive feature of the mature hippocampus, not maintained by other cortical areas, is its ability to sustain adult neurogenesis. Here, we have investigated whether environmental manipulations affecting hippocampal

postnatal neurogenesis have a parallel impact on Cajal-Retzius cells. We used multiple mouse reporter lines to unequivocally identify Cajal-Retzius cells and quantify their densities during postnatal development. We found that exposure to an enriched environment increased the persistence of Cajal-Retzius cells in the hippocampus, but not in adjacent cortical regions. We did not observe a similar effect for parvalbumin-expressing interneurons, which suggested the occurrence of a cell type-specific process. In addition, we did not detect obvious changes either in Cajal-Retzius cell electrophysiological or morphological features, when compared to what previously reported in animals not exposed to enriched conditions. However, optogenetically-triggered synaptic output of Cajal-Retzius cells onto local interneurons was enhanced, consistent with our observation of higher Cajal-Retzius cell densities. In conclusion, our data reveal a novel form of hippocampal, cell type-specific, experience-dependent network plasticity. We propose that this phenomenon is required for the correct regulation of enrichment-dependent enhanced hippocampal postnatal neurogenesis.

Title: Enhancing plasticity rescues social behavioral deficits in Pten haploinsufficient mice

Authors: *A. E. CLIPPERTON-ALLEN, A. ZHANG, O. S. COHEN, D. T. PAGE
Neurosci., The Scripps Res. Inst., Jupiter, FL

Abstract: *Pten* germline haploinsufficient (*Pten*$^{+/-}$) mice, which model macrocephaly/autism syndrome, show deficits in social behaviors, as well as early brain overgrowth and cortical-subcortical hyperconnectivity. Previous work in this model has indicated that altered neuronal connectivity may be a substrate for social behavioral deficits. We hypothesized that exposing *Pten*$^{+/-}$ mice to environmental enrichment after brain overgrowth has occurred may facilitate adaptation to abnormal “hard-wired” connectivity through enhancing synaptic plasticity. To test this hypothesis, wild type and *Pten*$^{+/-}$ mice were reared from weaning under either standard (4-5 mice per standard-sized cage, containing only bedding and nestlet) or enriched (9-10 mice per large-sized cage, containing objects for exploration and a running wheel, plus bedding and

nestlet) conditions for 35 days. Adult mice were then tested using several social and non-social assays in which *Pten*$^{+/-}$ mice display deficits. Environmental enrichment rescued sex-specific deficits in social approach behavior in *Pten*$^{+/-}$ mice, but did not rescue other non-social deficits in these animals. Ongoing experiments are examining the effects of environmental enrichment on network activity in brain areas important for processing social information and on the expression of genes related to synaptic plasticity. Together, our results indicate that environmental enrichment can rescue social behavioral deficits in *Pten*$^{+/-}$ mice, possibly through a synaptic plasticity mechanism.

Ctr., Heidelberg, Germany; [7]Mt Sinai Sch. Med., New York, NY

Abstract: Abstract:
Social behavior deficits are a core symptom in autism spectrum disorder (ASD), which up to date have no pharmacological treatment. The hypothalamic oxytocin (OXT) system is a well-known modulator of social behavior, which brought interest in using the OXT peptide to treat social behavioral deficits. Our studies in a rat model for ASD, the *Shank3*-deficient rat, demonstrated that intracerebroventricular OXT administration ameliorates synaptic plasticity, attentional and social memory deficits. Clinical trials of OXT in ASD produced equivocal results raising

questions about (1) whether this equivocally is driven by the heterogeneity in ASD, where some ASD subgroups may benefit better than others and (2) if the efficacy of OT treatment is dependent on the functionality of the OXT system and/or is sensitive to specific developmental window. Addressing these questions is challenging due to the lack of predictive biomarkers and the lack of sufficient and diverse postmortem samples to determine how OXT-system is affected in different ASD subjects. Genetic animal models with mutations in ASD-associated genes are powerful tool to help overcome these limitations, yet to date only few studies have employed these models to tackle the limitations in clinical studies. Our study is focused on examining the effect of ASD-associated mutations on the integrity and functionality of the OXT hypothalamic system and on assessing the effect of OXT treatment on behavioral deficits during different developmental stage. For this purpose, we are using two rat models with mutations in ASD-associated genes with relatively common and high penetrant in ASD and intellectual disability: (1) the *Shank3*-deficient rat model with a mutation in the *Shank3* gene, which is implicated in Phelan McDermid syndrome (PMS) and (2) the *Fmr1*-rat model with a mutation in the *Fmr1* gene, which is implicated in Fragile X syndrome (FXS). Our characterization of the OXT neurons in the hypothalamic periventricular nucleus (PVN) of *Shank3*-knockout rats revealed increased OT immunoreactivity and dendritic swelling, suggesting that OXT release is impaired. In *Fmr1*-rats, we found decreased numbers of OXT neurons in the PVN. Our findings suggest that the OXT system may be impaired in subset of individuals with ASD (i.e., with PMS and FXS) and imply that treatment with OXT may be beneficial in these individuals, where the integrity of the OXT system could be potentially disturbed.

Title: Uncovering the role of long non-coding RNAs (lncRNAs) in autism spectrum disorders using integrated transcriptomic approaches

Authors: N. J. FRANCOEUR[1], M. J. GANDAL[3], K. A. SARPONG[1], J. S. JOHNSON[1], P. SKLAR[1], H. VAN BAKEL[2], D. H. GESCHWIND[3], *D. PINTO[1]

[1]Psychiatry, and Genet. and Genomic Sci., [2]Genet. and Genomic Sci., Icahn Sch. of Med. At Mount Sinai, New York, NY; [3]UCLA, Los Angeles, CA

Abstract: The contribution of non-coding genomic elements remains largely unexplored in autism spectrum disorders (ASD). LncRNAs are increasingly recognized for their role in transcription regulation, and likely contribute to transcriptome dysregulation in ASD.
We are applying a combination of short-read and long-read RNA-Seq, with and without lncRNA capture to unveil the role of lncRNAs in ASD. As lncRNAs are poorly represented in standard RNA-Seq experiments, we used capture RNA-Seq (Capture-Seq) to quantify lncRNA expression in postmortem prefrontal cortex and cerebellum tissue in a cohort of 40 ASD and control samples. We additionally combined full-length isoform sequencing (Iso-Seq) with capture (Capture-IsoSeq) to build a comprehensive map of brain-expressed lncRNAs.
The enrichment by Capture-Seq increased the lncRNA fraction of our RNA-Seq datasets from 5% to 57%. We identified 28 differentially expressed (DE; FDR<0.05) lncRNAs and transcripts of unknown coding potential (TUCPs) in ASD samples compared to controls. A “guilt-by-association” analysis further revealed genes under putative cis-regulation of DE-lncRNAs that are implicated in pathways dysregulated in ASD. Finally, Capture-IsoSeq profiling identified ~3,600 novel multiexonic lncRNA/TUCP isoforms expressed in prefrontal cortex. We have identified many DE lncRNA/TUCP transcripts in a cohort of 40 ASD and control samples from two different brain regions as a first step towards understanding the role of lncRNAs in ASD etiology.
In summary, capture enriched sequencing substantially improves our ability to profile lncRNA expression and reconstruct poorly annotated lncRNA isoforms.

Title: mTORC2 dysfunction underlies the neuronal physiological and behavioral abnormalities in Pten-deficient mouse model of autism

Authors: *C.-J. CHEN[1], M. SGRITTA[1], R. D. LUCERO[2], J. L. NOEBELS[2], M. COSTA-MATTIOLI[1]
[1]DEPT OF NEUROSCIENCE, [2]DEPT OF Neurol., BAYLOR COLLEGE OF MEDICINE, Houston, TX

Abstract: Autism Spectrum Disorder (ASD) is one of the most common neurological disorders characterized by abnormal social behavior, deficits in communication, restricted/repetitive stereotype behaviors and, often, intellectual disability. In addition, epilepsy is also common in ASD patients. The mechanistic target of rapamycin (mTOR) acts as a highly conserved signaling hub that integrates neuronal activity and a variety of synaptic inputs. Loss-of function mutations in phosphatase and tensin homolog (PTEN), a negative regulator of mTOR signaling, were associated with syndromic ASD. While PTEN-deficiency leads to the hyperactivation of both mTOR complexes (mTORC1 and mTORC2), it is generally believed that dysregulation of mTORC1-mediated protein synthesis leads to ASD phenotypes. However, most of the evidences supporting a role for mTORC1 in ASD-like phenotypes relied on the chronic pharmacological inhibition of mTOR by rapamycin, which blocks the activity of both mTORC1 and mTORC2 in brain. To investigate the selective involvement of mTOR complexes in PTEN-associated ASD, we generated mice lacking PTEN, PTEN and Raptor (defining component of mTORC1), or PTEN and Rictor (defining component OF mTORC2) in the forebrain. Mice lacking Pten in the forebrain showed up-regulation of both mTORC1 and mTORC2 activities, exhibited ASD-like behavior, seizures, hyper-excitability in hippocampal neurons, and they died between 7-8 weeks of age. Surprisingly, genetic inhibition of mTORC1 had no effect on PTEN induced pathology. By contrast, genetic inhibition of mTORC2 in PTEN-deficient mice prolonged their lifespan, ameliorated seizure activity, normalized neuronal excitability, and restored cognitive and social behaviors. The changes in neuronal function in Pten-Rictor deficient mice were accompanied by restoration of Akt-mediated glucose metabolism, which was disrupted in the Pten-deficient brain. Our study not only provides advances in the understanding of the role of different mTOR complexes in ASD, but also suggests potential new mTORC2-based treatment for ASD and related neurodevelopmental disorder.

Title: Loss of the sulfate transporter Slc13a4 impairs social interactions and adult neurogenesis in mice

Authors: *Z. ZHANG[1,2], M. PIPER[1], P. DAWSON[2], D. SIMMONS[1,2]
[1]The Univ. of Queensland, SBMS, Brisbane, Australia; [2]Mater Res. Inst., Brisbane, Australia

Abstract: SLC13A4 is a sodium-dependent sulfate transporter which is primarily expressed in the placenta and brain. During our earlier investigations of placental *Slc13a4* function, we observed that *Slc13a4* haploinsufficiency caused abnormal maternal behaviours, resulting in a postpartum loss of pups. In the current study, we investigated potential reasons underlying this phenomenon. We, and others, found *Slc13a4* gene expression to be predominately restricted to the choroid plexus (ChPs) and pia mater of the brain, suggesting a role in regulating sulfate levels in the brain. We then localized SLC13A4 protein to the basolateral membrane of ChP epithelium, consistent with a role in sulfate uptake from the blood. Tail vein injections of ^{35}S-labelled sulfate corroborate this hypothesis, as *Slc13a4*$^{+/-}$ mice uptake ~50% less $^{35}SO_4^{2-}$ into the brain than wildtype controls. Abnormal maternal behaviours usually occur along with other impaired behaviours. Initial behavioural, motor and metabolic tests did not reveal differences between*Slc13a4*$^{+/+}$ and *Slc13a4*$^{+/-}$ animals, including olfactory discrimination, forced swim test, hanging wire test, food and water intake, and body weight and fat composition. However, we did observe profound defects in social interaction (separate reunion test and intruder test) and social memory, commonly seen in animal models of autism spectrum disorders (ASDs). Some of ASDs mouse models and human autism patients also display alterations in neurogenesis; we performed BrdU injections in 10-12-week old adult mice and observed an increase in neural stem cell proliferation within the subventricle zone (SVZ). We then deleted *Slc13a4* only in adult mice (~10 weeks of age), by crossing *Slc13a4*$^{flx/flx}$ with the UBC-Cre-ER^{T2} deleter line, and found that none of these phenotypes developed, suggesting a developmental origin to the phenotypes we observed previously. Indeed, when we deleted *Slc13a4* at postnatal day 7, *Slc13a4*$^{+/-}$ mice developed all the deficits in social interaction and altered neurogenesis at 12 weeks of age. Therefore, SLC13A4 activity appears to be essential during an earlier developmental window in order to prevent the onset of social interaction and neurogenesis impairments in later adult life. In summary, our current findings regarding SLC13A4 function highlights the critical role of *Slc13a4* activity in regulating animal behaviour and promoting a proper microenvironment which is essential for homeostasis of adult neurogenesis during postnatal development. Disruption of *Slc13a4* during this critical window appears to promote the development of autism-like phenotypes in adults.

Title: The role of Ras pathway in social and communication behaviors in Nf1 mice

Authors: *J. L. LUKKES[1], J. PATEL[1,4], M. M. HAULCOMB[6,1], D. NEWKIRK[6], A. R. ABREU[1], S.-J. PARK[7,2], D. CLAPP[7,2], A. I. MOLOSH[1,5], A. SHEKHAR[3,5,1]

Sch. of Med., Indianapolis, IN

Abstract: Neurofibromatosis type 1 (NF1) is a common human genetic disorder caused by a loss-of-function mutation in one copy of the NF1 gene (*NF1*$^{+/-}$). A majority of children with NF1 suffer from some learning or cognitive difficulties with a third associated with autism spectrum disorders (ASD). Recent studies have also reported that a significant number of children with NF1 demonstrate disruptions in communication that are independent of their attention and learning problems. The NF1 gene encodes neurofibromin, a p21 Ras GTPase-activation protein (GAP), and its activity is mediated by its GAP domain. Isoform 1 of the NF1 gene expresses the full length NF1 transcript. One particular splice variant, exon 23a, adds 21 amino acids in the NF1 GAP region and weakens its ability to control Ras signaling. We have previously demonstrated that deletion of a single *Nf1* allele (*Nf1*$^{+/-}$) in male mice leads to hyperactivation of Ras pathway associated with deficits in social memory. However, little is known about the role of Ras hyperactivation within key neural networks in regulating communication and stereotypical behaviors. To further characterize the behavioral phenotype of *Nf1*$^{+/-}$ male mice and to determine the role of of Ras hyperactivation in ASD phenotypes, we compared wildtype (WT), *Nf1*$^{+/-}$, *23a*$^{+/+}$, and *23a*$^{+/+}$/*Nf1*$^{+/-}$ mouse strains that were bred from a C57BL/6J background to examine differences in female-induced ultrasonic vocalizations (USVs), social preference behavior in a three-chambered apparatus, and stereotypic rearing. We also mapped

the neural networks involved in these behaviors by examining the differential activation pattern of pERK immunoreactivity within neuronal cells in WT compared to *Nf1*$^{+/-}$, *23a*$^{+/+}$, and *23a*$^{+/+}$/ *Nf1*$^{+/-}$ mice. Female-induced USVs were disrupted in *Nf1*$^{+/-}$, *23a*$^{+/+}$, and *23a*$^{+/+}$/ *Nf1*$^{+/-}$ compared to WT mice. Insertion of exon 23a did not affect social preference compared to WT, however *23a*$^{+/+}$/ *Nf1*$^{+/-}$ mice exhibited significant short- and long-term social deficits. Furthermore, *Nf1*$^{+/-}$ mice demonstrated increased duration and frequency of rearing in a novel test cage compared to WT animals. Similar to the Ras increases observed in the BLA, increased pERK immunoreactivity was noted in the prefrontal cortex of *Nf1*$^{+/-}$ mice compared to WT. Our results suggest the importance of the Ras pathway in social but not in communication behaviors. Our data also provide additional information about the neural circuits and mechanisms relevant to other forms of Ras-and synaptopathy-induced ASD syndromes and important leads to developing deficit-specific therapies for NF1 children.

Title: Deletion of semaphorin 3F in interneurons is associated with decreased GABAergic neurons, autism-like behavior, and increased inflammation and oxidative stress

Authors: R. JAGADAPILLAI[1], Z. LI[2], *E. GOZAL[3], G. N. BARNES[4]
[1]Pediatrics, PRI, Univ. of Louisville, Louisville, KY; [2]Neurol., Vanderbilt Univ., Nashville, TN; [3]Pediatrics, Pharm & Tox, Physiol., Dept of Pediatrics PRI / Univ. of Louisville, Louisville, KY; [4]Dept Neurology, Dept. of Pediatrics PRI, Univ. of Louisville Sch. of Med., Louisville, KY

Abstract: The neuropathology of all neural circuits in ASD are dependent on changes in functional connectivity via the excitation/inhibition (E/I) ratio, that impact routine neurotransmission, synaptic plasticity, and network function. We were the first to publish an extensive investigation of an animal model of autism and epilepsy (Barnes et al., 2009). The semaphorin/neuropilin gene family, an ASD associated set of genes, are guidance cues that control processes and cell motility in a wide variety of tissues. In the developing brain, these cues control interneuron migration/cell numbers, regulate neurite outgrowth (axon/dendrite), and control both GABA/excitatory synaptogenesis. Several groups, including our own, have noted

behavioral phenotypes consistent with autism in both the semaphorin 3F (Sema 3F) and neuropilin 2 (NRP2) knockout mice. Similar to NRP2 KO mice, the interneuron specific but not excitatory neuron specific knockout of Sema 3F had decreased Parv+ and NPY+ interneurons and increased epileptogenesis with decreased social behaviors and increased repetitive behaviors compared to wild type littermates. We aimed to determine whether semaphorin 3F KO mice also presented with brain inflammation and oxidative stress that could be associated with ASD-like behavior. The significant increase in immunoreactivity of Iba1, a microglial marker, and of oxidative stress markers (DHE, 4HNE, iNOS, and 3-nitrotyrosine) suggest increased inflammation and oxidation products both within the glia and neurons of the interneuron specific Sema 3F KO mouse. Thus, although this is a single ASD associated gene KO mouse, these data strongly suggest that genetic mouse models of autism with markers of inflammation will be an excellent tool to investigate the role of genomics, environmental factors influencing the immune system (metals, obesity), clinical endophenotypes, and metabolic conditions. Most importantly, these models and others can define molecular mechanisms influencing the interactions among organ systems contributing to ASD brain dysfunction.

Abstract: Objectives: The objective of this study is to examine *de novo* genetic variants of autism spectrum disorder (ASD) and to explore their characteristics using network analyses. **Methods:** The probands with ASD and their biological parents were recruited. We ascertained diagnosis based on DSM-IV-TM criteria, using Autism Diagnostic Observation Schedule and

Autism Diagnostic Interview - Revised. We selected probands with typical phenotypes in all domains and with nonverbal or phrase speech level of language. In the pilot phase, we performed whole exome sequencing (WES) with minimum 50x for 13 families. In the extended phase, additional WES was performed for 38 families, at least 100x depth and high-coverage pooled sequencing for their parents (250 million paired-end reads for mothers and 236 million for fathers). All the sequence reads were mapped onto the human reference genome (hg19 without Y chromosome). We used BWA, Picard, GATK (McKenna, Aaron, et al., 2010) and in-house custom annotation pipeline for variants discovery. We selected *de novo* mutation candidates from each proband which are not detected in two pooled samples and pathogenic variants. For validation, Sanger sequencing was applied on ABI 3730 or Sequenom MassARRAY system (Sequenom, Inc., San Diego, CA). Network analyses was performed using pathway studio (RELX, 2016) and ingenuity pathway analysis (Quiagen, 2017). Connectivity map was generated with reference to previously known candidate genetic variants of ASD.
Results: Fifty one subjects with ASD (4 females, 77.56±31.22 months, IQ 60.04±14.79) and their families were included. Forty four *de novo* variants from 46 families are validated. Clinical variables did not show significant differences between subjects with and without *de novo* variants. KCTD9, HAX1, IWS1, NFKB1, RUFY1, ATXN1, SCAL25A13, PFKP RNH1, RASAL1, SNF8, ELL, PPP1R16B genes were revealed to interact with previously known ASD risk genes. In the network analyses, *de novo* variants are involved in the gene networks related to hereditary disorder, developmental and neurological disorder, neuronal injury and abnormalities, and nervous system development and function.
Conclusions: In the WES of family samples of ASD, we observed novel *de novo* variants which are assumed to contribute to development of ASD with relatively low functioning.

Title: ASD-associated behavioral traits and dopaminergic abnormalities in the SERT G56A mouse

Authors: *G. E. DICARLO[1], K. E. BUNDSCHUH[1], M. T. WALLACE[2]
[2]Hearing and Speech Sci., [1]Vanderbilt Univ., Nashville, TN

Abstract: Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder characterized by deficits in social communication and interaction and by patterns of restricted interests and repetitive behaviors. Moreover, nearly 90% of individuals with ASD experience some alteration in sensory function. One key brain region for the integration of information related to social communication, and for the elaboration of sensorimotor behaviors, is the striatum. The striatum is highly enriched in both dopaminergic and serotonergic projections, and recent work has suggested an altered developmental trajectory of the striatum in individuals with ASD. While both serotonergic and dopaminergic dysfunction have been implicated in ASD and these two neurotransmitter systems are known to interact at the cellular level, little work has focused on understanding how dysfunction in one of these neurotransmitter systems cascades into dysfunction of the other. In this study, we used a mouse expressing an ASD-associated point mutation in the serotonin transporter (SERT) to determine the impact of this mutation on striatal dopaminergic function. This mutation, a glycine to alanine substitution at site 56 (SERT G56A), is known to increase the firing rate of serotonergic neurons, to increase the sensitivity of type 1A and 2A serotonin receptors, and to enhance the rate of serotonin clearance from the extracellular space. In addition to previous work showing altered social communication and repetitive behaviors in these animals, our current work demonstrates early-life deficits in social preference and communication as well as altered maternal care towards animals homozygous for this mutation. To probe the effect of this mutation on the dopaminergic system, we measured expression levels of the dopamine transporter (DAT) and the concentration of dopamine in the striatum of mice homozygous for the SERT G56A mutation. We found that SERT G56A homozygous animals exhibit a significant reduction in expression of the dopamine transporter (DAT) in the striatum when compared to wild-type littermates, without change in the concentration of dopamine or its metabolites in the striatum. To explore anatomical correlates of these findings, we performed *ex vivo* diffusion kurtosis imaging studies, which suggested microstructural abnormality in the striatum of the SERT G56A mice. This works provides evidence for striatal dopaminergic dysfunction as the result of an ASD-associated mutation in the serotonin system and supports future research directed toward uncovering the role of dopaminergic dysfunction in ASD.

Title: Resting-state functional connectivity in homozygous Cntnap2 knockout mice

Authors: *K. Y. CHOE[1], M. SAFRIN[2], N. G. HARRIS[3], D. H. GESCHWIND[2]
[1]Neurobio., [2]UCLA, Los Angeles, CA; [3]Neurosurg., Dept. Neurosurgery, UCLA, Los Angeles, CA

Abstract: Neuroimaging studies in individuals diagnosed with autism spectrum disorders (ASD) have repeatedly reported aberrant neural connectivity, including decreased long-range and increased short-range functional connectivity. Understanding the mechanistic basis for these changes warrants the use of animal models with strong construct and face validity. Mice lacking Contactin-Associated Protein-Like 2 (Cntnap2), a highly penetrant major gene form of ASD, display the core behavioral phenotypes of ASD (Penagarikano et al., 2011). A recent report has demonstrated reduced local and long-range prefrontal functional connectivity in these mice (Liska et al., 2017). To assess disruptions at a whole brain network level, we performed high field (7 Tesla) resting-state functional magnetic resonance imaging, 2000/19ms repetition and echo time for 5 mins, in dexmedetomidine-sedated wild-type (WT, n=20) and Cntnap2 knockout (KO, n=24) male and female mice. Global network connectivity measures were calculated over a 5-50% network density range, using the network-based statistic approach (Zalesky et al., 2010). Compared to WT controls, we observed subtle trends toward reductions (~10-15%) in global efficiency, mean local efficiency, and mean clustering coefficient in KO mice. These results suggest both global and local decreases in functional connectivity. No genotype differences were found in characteristic path length and modularity. To determine the brain regions that may underlie this altered global connectivity, we analyzed functional connectivity at the regional level, defined by a modified, 3D Allen mouse brain parcellated atlas (23 bilateral regions, 64 in total). At 35% network density, we found significantly lowered ($p<0.05$) functional connectivity in KO mice in association areas, piriform cortex and dorsal peduncular areas (vs. WT: -22.4±7.2%, -26.8±7.0%, -18.4±5.0%, respectively). These results, while preliminary, are consistent with previous observations, and highlight potential parallels between functional connectivity alterations in Cntnap2 KO mice and in individuals with ASD. We are now extending these pilot data to validate the generalizability and reproducibility of these results.

Title: Dip2a mutant mice and gene expression pattern

Authors: *J. MA[1], L. ZHANG[2], Y. WANG[1], C. SU[1], Y. ZHENG[2], X. ZHU[1]
[1]Inst. of Genet. and Cytology, Jilin, China; [2]Transgenic Res. Ctr., Jilin, China

Abstract: Disconnected (disco)-interacting protein 2 homolog A (DIP2A) is a member of the DIP2 protein, which is evolutionarily conserved in organisms from *C. elegans* to humans. DIP2A is firstly identified and characterized in *Drosophila* and interacted with the transcription factor *disco*. Recently, studies on autism spectrum disorder (ASD) patient using copy-number variants (CNV) analysis have pointed out that *Dip2a* is a risk factor for ASD occurrence. Patients with a ~3-Mb terminal deletion of chromosome 21p22.3, including *Dip2a*, showed substantial susceptibility to ASD. These data provided strong evidence for *Dip2a* mutations in various cognitive and social defects. However, roles of DIP2A in mammalian are still obscure. Thus clarifying the functions of DIP2A in neurodevelopment could provide new insights for ASD nosogenesis. To investigate DIP2A function and expression in mouse brain, two mouse models were generated using CRISPR/Cas9 technology, including an entire *Dip2a* gene deletion mutant model (about 65kb) and a β-galactosidase (lacZ) reporter gene knock-in mouse model. Our preliminary results showed the mutant mice were fertile with no obvious phenotypic difference, including life span and body weight. More characterization work is underway to study the impact of *Dip2a* deletion on neuronal development. Using lacZ staining analysis we found DIP2A is broadly expressed in neuronal, reproductive and vascular tissues, as well as in heart, kidney, liver and lung, which are all derived from ectoderm in mouse embryo. A further investigation in brain tissue showed DIP2A is highly expressed in cortex, hippocampus and thalamus, including amygdala, which are the regions rich of projection neuron soma. In comparison, its expression in the striatum was low, where are mostly nerve fibers. Then, we co-immunostained lacZ with a variety of cell type-specific markers in *Dip2a*$^{lacZ/+}$ mice to investigate its expression in different neuron developmental stages. DIP2A was only detected in in part of immature neurons and all mature neurons, but not in the neuroblasts, type 1 or type 2 radial glia-like cells as well as astrocytes. Collectively, these data suggest that DIP2A is likely to function in projection neuron maturation.

Title: A mouse model of the human 15q13.3 microdeletion syndrome (Df(h15q13)/+) with reduced alpha7 nAChR expression exhibits no deficits in hippocampal excitatory transmission and activity-regulated gene expression

Authors: *K. A. REES[1], A. A. HALAWA[1,2], D. CONSUEGRA GARCIA[1,3], W. H. GRIFFITH[1], U. H. WINZER-SERHAN[1]
[1]Dept. Neurosci. & Exp. Therap., Texas A&M Univ. Hlth. Sci. Ctr., Bryan, TX; [2]Dept. of Forensic Med. and Toxicology, Mansoura Univ., Elmansoura, Egypt; [3]Univ. del Este, Carolina, PR

Abstract: The 15q13.3 microdeletion syndrome is associated with high risk for epilepsy, intellectual disability, schizophrenia, autism spectrum disorder (ASD), and ADHD. However, there is incomplete penetrance, and the phenotype is heterogeneous. Most human carriers have a heterozygous deletion which encompasses seven genes: CHRNA7, FAN1, MTMR10, OTUDA7A, TRPM1, and KLF13. The alpha7 nicotinic acetylcholine receptor (α7 nAChR) subunit, encoded by CHRNA7, is involved in excitatory synapse formation, and haploinsufficiency of the CHRNA7 is believed to be causative for most of the behavioral phenotypes in human carriers. A translationally relevant mouse model with a homologous deletion on the mouse chromosome 7qC, Df(h15q13)/+ was recently created (Fejgin et al. 2014), which displays behavioral features of the 15q13.3 syndrome. In this study, we used wild-type (WT) and heterozygous (HT) male and female Df(h15q13)/+ mice to test the hypothesis that HT mice have reduced excitatory transmission in the hippocampus, and altered basal expression of activity-regulated genes. Using receptor autoradiography, we first quantified the numbers of α7 nAChR binding sites in cortex and hippocampus, which were decreased by ~50% in the HT compared to the WT mice (n=8, $p<0.001$). To determine differences in the neurophysiology, young adult male and female WT and HT mice were used for recordings of field excitatory postsynaptic potentials (fEPSPs). Hippocampi were removed, and transverse 450 µm slices were cut from the middle third of each hippocampi. EPSPs were evoked via a bipolar stimulating electrode placed in Schaeffer collaterals with dendritic fEPSPs recorded in the stratum radiatum. Input/output (I/O) curves were generated by increasing stimulation intensities, and the slope of the dendritic response was measured. Analysis revealed that there was no significant difference between genotype in either male or female mice in the slope of the I/O curves (n=4-7), and no difference was detected in long-term potentiation (LTP) after theta-burst stimulation (n=3-6). Thus, no significant difference in excitatory transmission was found in the hippocampus between WT and HT mice. Furthermore, there was no significant difference between WT and HT mice (n=4) in basal mRNA expression of the activity-regulated genes Arc, BDNF, c-Fos, Egr-1 and Npas4, as determined by in situ hybridization. In summary, despite significantly decreased expression of α7 nAChR binding sites, there was no apparent alteration in hippocampal neurophysiology in terms of fEPSPs or LTP, or in expression of activity-regulated genes in mice with a heterozygous deletion.

Title: MTOR signaling modulates migration of cortical interneurons in the LgDel model of 22q11.2 DS

Authors: *E. M. PARONETT[1], D. W. MEECHAN[2], C. A. BRYAN[2], E. A. RADIN[2], A.-S. LAMANTIA[2], T. M. MAYNARD[2]
[2]PHARMACOLOGY AND PHYSIOLOGY, [1]George Washington Univ., Washington, DC

Abstract: Disruptions in interneuron connectivity have been identified as a key pathological target in several behavioral disorders, including autism and schizophrenia. We have previously shown in a mouse model of 22q11.2 Deletion Syndrome (22q11.2 DS), a neurodevelopmental syndrome strongly associated with autism and schizophrenia, that the migration of interneurons into the cortex is delayed and disrupted, leading to an aberrant distribution of interneurons in the cortex. This disruption in interneuron migration is due to dysregulated signaling via the Cxcr4 cytokine receptor, which has been shown to act via modulation of the mammalian target of rapamycin (MTOR) signaling pathway in several models of cell motility. We have used a conditional genetic approach to disrupt MTOR signaling in both LgDel and WT mice, by using a Dlx5/6-Cre line to specifically ablate either the MTOR-repressor Tsc2, or Mtor itself, in interneuron precursors. We found that heterozygous loss of Mtor amplifies the migration defects normally observed in the LgDel cortex, with compound LgDel;$Mtor^{+/-}$interneurons showing disorganized distributions. In contrast, when the LgDel mutant is complemented with an mTOR "gain of function" mutation (LgDel;$Tsc2^{+/-}$), few interneurons enter the cortex at E14. Additionally, signaling intermediates downstream of MTOR appear to have altered expression in the LgDel cortex. Thus, MTOR signaling appears to be disrupted in the cortex of the LgDel mouse model, leading to altered neuronal circuitry. MTOR signaling is itself implicated in behavioral disorders such as autism, and multiple genetic syndromes with autism-like behavioral consequences have been described that involve Mtor and its interacting partners. Therefore, it is possible that this signaling mechanism may be a point of convergence between 22q11.2 DS and other, genetically distinct forms of syndromic behavioral disorders.

Title: Deficient of autism susceptibility gene Protocadherin 9 leads to abnormalities in vestibular response and emotional behavior in mice

Authors: *S. HIRANO[1], T. FURUSE[2], S. WAKANA[2], S. NAGAO[3], M. KUDOH[3], Y. SATO[1], K. OKANO-IMAI[1], K. YOSHIZAWA[4]
[1]Lab. Cell Biol., Kansai Med. Univ., Hirakata City, Japan; [2]Technol. and Develop. Team for Mouse Phenotype Analysis, RIKEN, Tsukuba, Japan; [3]Lab. for Motor Learning Control, RIKEN BSI, Saitama, Japan; [4]Lab. Environ. Sci., Dep. Food Sci. Nut., Mukogawa Women's Univ., Nishinomiya, Japan

Abstract: Protocadherins constitute the largest family of cadherin superfamily genes. Protocadherin 9 (Pcdh9) is reported to be an autism susceptibility gene (Marshall et al. 2008). In mouse, Pcdh9 is expressed in various parts of the developing nervous system including the oculomotor and vestibular systems (Asahina et al. 2012). To determine the roles of Pcdh9 in the nervous system, we generated a Pcdh9 knock-out (Pcdh9-KO) mouse line (established by RIKEN CLST LARGE), and analyzed its histology, vestibular function, and behavior.
No significant morphological abnormalities were detected in any tissues including the liver, stomach, intestine, heart, kidney, lung, etc. in Pdh9-KO mice through analysis of general histology with HE staining, although their body weight was low. The gross morphology of the

brain and major neural tracts of Pdh9-KO mice visualized with the anti-neurofilament antibody was normal.
Then, we examined roles of Pdh9 in neural functions. We tested the vestibular response of Pcdh9-KO mice, as reported in the previous study of Shutoh et al. (2006). Gains of the horizontal optokinetic response, but not those of the horizontal vestibular-ocular reflex, were significantly reduced compared with those of wild-type mice. Second, we tested the behavior of Pcdh9-KO mice systematically using protocols of the Japan mouse clinic (RIKEN BRC), which includes light/dark transition test, open-field, Crawley's three chamber test, Home-cage activity test, Y-maze test, fear conditioning test, and pre-pulse inhibition test (http://ja.brc.riken.jp/lab/jmc/mouse_clinic/en/business/pipeline.html). In the open-field test, Pcdh9-KO mice had a tendency to stay in the peripheral zone and to travel longer distances. In Crawley's three chamber test, Pcdh9-KO mice showed a tendency to avoid a novel object, although their social interaction with stranger mice was normal. In the home-cage activity test, activity of Pcdh9-KO mice was higher than that of wild-type mice during the light period. These results suggest that emotionality of the Pcdh9-KO mice was enhanced compared with wild-type mice. Taken together, we suggest that Pchd9 may be involved in neural functions underlying vestibular response and emotional behavior.

Title: Altered prefrontal anatomy and functional connectivity in mice lacking autism-associated gene Shank3

Authors: ***M. PAGANI**[1,2], C. ROBOL[1], R. GOMOLKA[1], A. LISKA[1,2], A. GALBUSERA[1], A. AKSIUTO[1], A. GOZZI[1]
[1]Functional Neuroimaging Laboratory, CNCS, Inst. Italiano di Tecnologia, Rovereto, Italy; [2]Ctr. for Mind and Brain Sci., Univ. of Trento, Rovereto, Italy

Abstract: Mutations in postsynaptic scaffolding protein Shank3 have been strongly implicated in 22q13 deletion syndrome (Phelan-McDermid syndrome) as well as other non-syndromic

forms of autism spectrum disorder (ASDs). A number of recent reports have investigated basal ganglia function in mouse lines harboring Shank3 mutations, revealing specific striatal circuit impairments underlying self-injurious repetitive grooming exhibited by these mutants. However, Shank3 mutations in humans are often associated with intellectual disability and cognitive impairments, suggesting that functional alteration in Shank3 could affect extra-striatal brain substrates such as high order cortical regions.
To probe this hypothesis, we used structural and functional MRI to obtain an unbiased mapping of cortical anatomy and connectivity in mice harboring Shank3B mutation ($Shank3B^{-/-}$). High resolution morpho-anatomical mapping using voxel based morphometry in Shank3B mutants revealed broad and prominent reductions in gray matter volume in prefrontal areas and lateral associative cortical regions of the mouse brain. In keeping with the gray matter reductions, regionally unbiased resting-state fMRI (rsfMRI) connectivity mapping revealed local and global connectivity reductions in prefrontal and anterior cingulate regions. This effect was associated with reduced long-range connectivity in midline integrative areas of the mouse default mode network. No overt genotype-dependent alterations in white macrostructure or fiber-organization were observed, as documented by DTI-based fractional anisotropy mapping, and tractographic analyses. We are currently performing prefrontal retrograde mapping to probe the role of altered mesoscale wiring in the observed functional connectivity alterations. Overall, our results suggest that Shank3 mutations can affect higher-order cortical activity via trophic and functional downregulation of prefrontal areas, and serve as a plausible neuro-functional correlate for the cognitive impairments observed in Shank3-associated ASD.

Title: A zebrafish model of epilepsy and autism spectrum disorders: Investigating the function of scn1lab

Authors: *C. SAKAI[1], F. ABBAS[1], S. IJAZ[1], M. GHOSH[2], J. RIHEL[2], E. J. HOFFMAN[1]
[1]Yale Univ., New Haven, CT; [2]Univ. Col. London, London, United Kingdom

Abstract: Human genetics studies have identified a number of genes that are strongly associated with both autism spectrum disorders (ASD) and epilepsy, including *SCN1A* and *SCN2A*. To gain insights into basic neurodevelopmental mechanisms involving these genes, we disrupted the function of the zebrafish paralog, *scn1lab*, which is 77% and 79% identical to *SCN1A* and *SCN2A*, respectively. Previously, we showed that zebrafish mutants of the ASD and epilepsy risk gene, *CNTNAP2*, display fewer forebrain GABAergic neurons, seizure sensitivity, and nighttime hyperactivity. Using pharmaco-behavioral profiling, we found that drugs with estrogenic activity rescue the *cntnap2* mutant behavioral phenotype. Here, we hypothesized that zebrafish *scn1lab* mutants might display similar phenotypes as *cntnap2* mutants. To test this, we generated two mutant lines lacking *scn1lab* function and performed structural and behavioral assays. These studies found that homozygous *scn1lab* mutants display a 25% reduction in brain area and a significant decrease in GABAergic neurons in the forebrain and hypothalamus compared to wildtype siblings [50% and 25% reduction, respectively, $p<0.0006$]. Homozygous mutants also display a 4-fold increased response to drug-induced seizures, consistent with attenuated GABAergic signaling. Further, using high-throughput behavioral profiling, we found that mutants display daytime hypoactivity and nighttime hyperactivity, in addition to altered responses to visual startle stimuli. Using pharamaco-behavioral profiling, we found that serotonin receptor antagonists, anticholinergic compounds, and adrenergic receptor agonists correlate with the mutant phenotype, and identified estrogens, nicotinic acetylcholine receptor agonists, and anti-inflammatory compounds as anti-correlating. These anti-correlating compounds may have the potential to rescue the mutant activity phenotypes, which we will test in future experiments. Together, these studies begin to identify common mechanistic pathways for further investigation in ASD and epilepsy.

Title: Multi-group cross-sectional study of a mouse model of TS reveals select neurobehavioral alterations for future preclinical studies

Authors: *S. SORIANO, S. HAO, S. VEERARAGAVAN, Z. WU, B. P. VICARI, C. S. WARD, J. TANG, R. C. SAMACO
Baylor Col. of Medicine/Jan and Dan Duncan NRI, Houston, TX

Abstract: Tuberous Sclerosis (TS) is a dominantly inherited genetic disorder caused by heterozygous mutations in either *TSC1* or *TSC2*, affecting multiple physiological systems. A spectrum of neurobehavioral features are highly prevalent in TS and include autism and impaired memory. Mouse models with mutations in either *Tsc1* or *Tsc2* have been reported to recapitulate features of TS, including impairments in behavior and cognition. Therapeutic intervention targeting the mTOR pathway holds great promise in improving the neurological symptoms associated with TS. However, in preparation for the possibility that mTOR inhibition is either incomplete or insufficient for therapeutic benefit, novel interventions independent of mTOR signaling must be identified. To this end, we focused our efforts on identifying the most robust and reproducible preclinical outcome measures in male and female mice lacking one copy of *Tsc2*. Our cross-sectional experimental design consisted of four cohorts tested at specific ages for select behavioral assays, in addition to an additional cohort of animals tested in a behavioral test battery. Moreover, given the recent concerns and issues related to the reproducibility of behavioral features in mouse models of ASD/IDD, our animals were tested across two different facilities by independent laboratories, and incorporating definitive ages and sexes ensured the rigor of these studies. The behavioral domain that is consistently altered in *Tsc2* mice across these studies and concordant with historical studies is abnormal aversive and spatial learning and memory. Furthermore, we confirmed that *Tsc2* mice displayed normal anxiety-like behavior, motor coordination, sociability and pain nociception, consistent with previous findings. *Tsc2* mice also demonstrated normal performance in several behavioral tests that have not been performed by other groups. In contrast, the single discrepant data that we found thus far was a female-specific difference in spontaneous exploratory activity uncovered by our groups compared with other published studies likely due to differences in factors such as age and methodology. Taken together, the results from these large-scale replication studies suggest that there is value in studying TSC2 deficiency to model select neurobehavioral features of the human condition that may serve as potential preclinical outcome measures but strengthen the need to further develop alternate approaches and/or models as useful *in vivo* tools to address the constellation of symptoms in TS.

Title: Development of a CRISPR-mediated molecular rescue of Pitt Hopkins Syndrome, a monogenetic autism spectrum disorder

Authors: B. MAYFIELD[1], J. F. BOHLEN[1], G. R. HAMERSKY[1], R. A. GALLO[1], *B. J. MAHER[1,2,3]

Abstract: Pitt Hopkins Syndrome (PTHS) is a monogenetic autism spectrum disorder, resulting from various mutations to one copy of transcription factor 4 (TCF4). TCF4 is a basic helix-loop-helix transcription factor that has vital importance in neuronal migration and cortical development. While the exact molecular function and downstream effects of TCF4 are still largely unknown, the behavioral and medical deficits are clearly visible in patients having only a single copy of the gene. Here, we are attempting to use clustered regulatory interspaced short palindromic repeats (CRISPR) technology as a form of *in utero* gene therapy to encourage normal cortical development in a mouse model of PTHS. A CRISPR with dead Cas9 nuclease activity fused to a VP64 protein was shown to be effective at upregulating gene transcription (CRISPR/dCas9-VP64). We transfected mouse N2A cells and human HEK293 cells with CRISPR/dCas9-VP64 plasmid and tested a variety of guide RNAs (sgRNAs) that targeted different regions of the TCF4 promoter for efficacy in boosting TCF4 expression. We identified several sgRNAs that significantly increased expression of endogenous TCF4 transcript and protein. Next, we cloned the CRISPR/dCas9-VP64 construct and sgRNA into a single lentiviral vector. The effectiveness of this viral vector at boosting TCF4 expression is currently underway. Ultimately, we plan to test this viral vector for effectiveness at rescuing cellular and behavioral deficits observed in a mouse model of PTHS. We plan on performing *in utero* viral injection into the ventricles of developing mouse embryos (E12.5), a development timepoint just prior to the onset of TCF4 expression in the developing cortex.

Title: Potential role of sema6A in autism spectrum disorder

Authors: K. V. MENZEL[1], *C. PLACHEZ[2]
[1]Hussman Inst. for Autism, Baltimore, MD; [2]Hussman Inst. For Autism, Baltimore, MD

Abstract: During brain development, a multitude of neuronal networks form as neurons find their correct position within the brain and send out axons to synapse onto specific targets. Altered neuronal connectivity within these complex networks has been reported in Autism Spectrum Disorder (ASD), leading to alterations in brain function and multisensory integration. Semaphorins (also referred to as Semas), a large protein family of 20 members, have been shown to play an important role in neuronal circuit formation, and have been implicated in the etiology of ASD. This study focuses on the role of Sema6A, one of these family members, during brain development. Human studies have reported impaired thalamo-cortical connectivity in ASD (Nair et al. 2013), and Sema6A mutant mice display improper thalamo-cortical connections (Little et al., 2009). Moreover, ASD human brains display disorganized cerebellar granule cells (Wegiel et al., 2010; Blatt, 2012) and Sema6A has been shown to play a role in the migration of these granule cells (Kerjan et al., 2005). Taken together, these findings suggest that Sema6A may be an attractive candidate to study an underlying cause of ASD during brain development. Excitation/Inhibition balance is also affected in ASD (Hussman, 2001; Blatt et al., 2001; Gao and Penzes 2015), therefore, this study is investigating the contribution of Sema6A toward GABAergic interneuron migration during brain development. Our preliminary data demonstrates that Sema6A mutant mice display a reduction of parvalbumin immunostaining in the thalamus and cerebellum, whereas calbindin immunostaining is reduced in the hippocampus. These results suggest a potential role of Sema6A in interneuron migration during brain formation. The present study will further investigate how the loss of Sema6A could impact the formation of neuronal networks.

Title: Deletion of the autism-related gene neurexin II (Nrxn2) causes alterations to the structure of the social brain as measured by DT-MRI and CLARITY

Authors: *J. DACHTLER[1], E. PERVOLARAKI[2], A. TYSON[3], F. PIBIRI[1], R. J. RODGERS[2], C. LEVER[1], S. J. CLAPCOTE[2], L. ANDREAE[3]
[1]Durham Univ., Durham, United Kingdom; [2]Univ. of Leeds, Leeds, United Kingdom; [3]King's Col. London, London, United Kingdom

Abstract: It is becomingly clear that many of the genetic mutations thought to be implicated in autism cluster upon proteins relating to synaptic signaling. A family of presynaptic proteins that have garnered recent interest have been the neurexins (NRXNs). Neurexins are encoded by three genes (*NRXN1, 2* and *3*) and convey a functional role in GABAergic and glutamatergic synaptic transmission. Given the reports of *NRXN2* deletions in autism, we recently studied a mouse model that lacked αNrxn2 to provide causal evidence that the loss of Nrxn2 resulted in ASD-like behaviors. We found that social approach and social recognition was impaired in mice with a homozygous deletion (KOs) of αNrxn2. To explore whether the loss of αNrxn2 changes the microstructure of brain regions associated with social behavior, we scanned fixed brains of wild-type (n=6) and αNrxn2 KO (n=6) mice in a 9.4T spectrometer using a diffusion tensor MRI (DT-MRI) protocol (TE: 35 ms, TR: 700 ms, 12 signal averages). The ex vivo mouse brain 3D diffusion-weighted images were then analyzed for fractional anisotropy (FA), apparent diffusion coefficient (ADC), radial diffusion (RD) and axial diffusion (AD). Our analysis focused upon the hippocampus, amygdala, anterior cingulate cortex (ACC) and the orbitofrontal cortex (OFC). We also examined diffusion properties of tracts between the amygdala and hippocampus, and amygdala and orbitofrontal cortex. The same ex vivo brains were then sectioned focusing on the same brain regions and were cleared using the CLARITY procedure. Sections were stained for neurofilament and DAPI and imaged by confocal microscopy. Cell nuclei and fibres were segmented, and for each ROI, cell density, fibre density and anisotropy index were calculated.

We report that the loss of αNrxn2 causes FA changes to the anterior (p=0.037), posterior (p=0.007) and basolateral amygdala (p=0.031), as measured by DT-MRI. The ADC of the dentate gyrus of the anterior (p=0.002) and posterior (p<0.0001) hippocampus was increased. The OFC had significantly increased AD (p=0.008) and RD (p=0.002). We also found significantly increased RD of OFC to amygdala tracts (p=0.0005). Using the same tissue, cell counting from CLARITY-treated tissue revealed no significant cell density differences from any brain region tested. However, neurofilament staining found significant increases to anisotropy index in the amygdala (p=0.02), orbitofrontal cortex (p=0.04) and the ACC (p=0.003). These results suggest that deletion of αNrxn2 causes discrete changes to the microstructure of the social brain that can be detected by both DT-MRI and CLARITY without gross morphological changes to cell density.

Title: The architecture and development of the axon initial segment (AIS) in an autistic mouse model

Authors: *M. A. ALSHAMMARI[1], M. R. KHAN[1], K. A. ALHOSAINI[1], R. ALI[2], M. BOUDJELAL[2], T. K. ALSHAMMARI[1]
[1]Pharmacol. and Toxicology, Col. of Pharmacy, King Saud Univ., Riyadh, Saudi Arabia; [2]Med. Res. Core Facilities & Platforms, King Abdullah Intl. Med. Res. Ctr., Riyadh, Saudi Arabia

Abstract: The axon initial segment (AIS), a specific region for action potential initiation in neurons, is a critical determinant of neuronal excitability. Growing evidence indicates that the appropriate recruitment of the AIS macrocomplex is essential for synchronized firing. However, any disruption of the AIS structure is linked to the etiology of multiple disorders, including autism spectrum disorder (ASD), a disease characterized by deficits in social communication, stereotyped behaviors, and very limited interest. Until now, a complete understanding of the molecular elements that lie at the basis of AIS in ASD has remained elusive. Here, we examine the AIS structure at different developmental time points in the BTBR T+ Itpr3tf/J mouse model, a valid model that exhibits behavioral, electrical, and molecular features of autism, compare to the C57/B6 wild-type control mouse. By using Western blot studies and high-resolution confocal

microscopy, our data suggest a disruption of the expression of AIS markers such as ankyrin-G and fibroblast growth factor 14 (FGF14) in BTBR compare to the wild-type control mice. Ongoing studies are evaluating the impact of inositol 1,4,5-trisphosphate receptors 3 (IP3R), a critical receptor for maintaining calcium homeostasis in neurons, in the functional integration of voltage-gated sodium channel Nav1.6 in the cortical pyramidal neurons of BTBR mice at different developmental time points. Our results may provide evidence of previously undescribed mechanisms that play a role in the pathogenesis of ASD.

Title: Mouse Models show that Cerebellar Networks are altered in Autism

Authors: *J. ELLEGOOD[1], Y. YEE[1], R. HENKELMAN[1], P. TSAI[2], J. P. LERCH[1]
[1]Mouse Imaging Ctr., Hosp. For Sick Children, Toronto, ON, Canada; [2]Neurol., UT Southwestern, Dallas, TX

Abstract: Background - Over the past 7 years, we have established a large cohort of mouse models related to autism. This allows for investigation of a large autism population in the mouse, which can be also viewed as representative of idiopathic autism. Therefore, differences in networks or regions across autism can be determined. The cerebellum has been frequently found to be different in autism and autism related disorders (see reviews by Tsai, 2016, Hampson and Blatt 2015, and D'Mello and Stoodley 2015), so the question we asked was: Can we detect cerebellar differences across our model autistic population? **Objectives** - To assess differences in the cerebellum and cerebellar networks across multiple autism mouse-lines to determine any commonalties or differences shared across the population. **Methods** - The data used in this study was accumulated from 44 different autism mouse-lines and included greater than 60 genotypes and over 1500 mice. *MRI Acquisition* - A multi-channel 7.0 Tesla MRI was used to acquire anatomical images of the brain. A T2-weighted, 3-D fast spin-echo sequence was used that yielded an image with 56 μm isotropic voxels (3D pixel) in ~14 h. *Data Analysis* - To visualize and compare any differences the images are registered together. The goal of the registration is to

model how the deformation fields relate to genotype, wild-type (WT) vs. autism mutant (Lerch et al., 2008). Volume differences are then calculated across the cerebellum in individual voxels or for 39 different cerebellar regions and their corresponding network (Steadman et al. 2014). **Results** - Overall, the cerebellum as a whole was one of the most affected regions across the brain (Ellegood et al. 2015). In addition to the cerebellum as whole, we examined the cerebellar cortex, hemispheres, vermis, and deep cerebellar nuclei (DCN). Out of those five regions only the DCN, the outputs of the cerebellum, were significantly smaller in the autism group (t-value of -4.26). Therefore, we further examined the projections from the DCN using anatomical covariance to assess the structural connectivity (Evans, 2013). The connectivity was measured between the DCN and the cerebellar cortex, thalamus, pontine nucleus, and the cortex, and was altered only between the DCN and cortex in the autism models when compared to the WT. **Conclusions** - Using anatomical covariance to assess structural connectivity in the mouse models of autism has revealed an alteration in the connectivity between the DCN and the cortex. This alteration preferentially affects the somatosensory, visual and association corticies. Further investigation is warranted to determine the underlying cause of this difference.

Title: Characterization of ankyrin mutations associated with autism spectrum disorder

Authors: *J. GARZA[1], T. L. PETRYSHEN[2]
[1]Ctr. for Human Genet. Research, Psychiatry, [2]Psychiatry, Ctr. for Genomic Med., Massachusetts Gen. Hosp., Boston, MA

Abstract: Recent large-scale genomic studies have identified candidate genes involved in synaptic transmission that are highly associated with autism spectrum disorder (ASD), including ANK2 and ANK3. Loss of function missense mutations were associated with autistic patients. The goal of this project is to functionally characterize de novo loss of function mutations in ankyrins and identify their contribution to ASD. A CRISPR/Cas9-based approach was used to transcriptionally repress ankyrin in a cell model. Fourteen sgRNA and one non-targeting control

sgRNA were designed and screened for efficiency of transcriptional repression. Ankyrin levels were measured by qPCR. Tubulin polymerization and end-binding protein 3 expression were evaluated using Western blot. Furthermore, CRISPR/Cas9 was also used to induce point mutations within the Ank2 gene. Fourteen sgRNA were designed upstream of the transcriptional start site of Ank3. Four sgRNA transcriptionally repressed Ank3b, however three of these had off-target effects whereas a single sgRNA had specificity for Ank3b. The expression of Ank3b was reduced to approximately half of control levels after CRISPR-mediated repression. As a result of Ank3 repression, tubulin polymerization was impaired, suggesting that microtubules were destabilized. The protein expression of end-binding protein 3 (EB3) was evaluated after transcriptional repression of Ank3 and resulted in a significant increase in EB3 levels. These results indicate transcriptional repression of ankyrin destabilizes microtubules which induces neuronal dysfunction that may be associated with ASD. These data will provide a better understanding of the genetic factors underlying ASD.

Title: An autism-susceptibility candidate gene controls variability of escape responses in larval zebrafish

Authors: *U. JHA[1], I. KONDRYCHYN[1], V. KORZH[2], V. THIRUMALAI[1]
[1]Natl. Ctr. For Biol. Sci., Bangalore, India; [2]Intl. Inst. of Mol. and Cell Biology,, Warsaw, Poland

Abstract: The autism susceptibility candidate 2 gene (AUTS2) is associated with multiple neurological disorders including autism spectrum disorders and intellectual disabilities. However, apart from a few findings suggestive of a regulatory role, the function of this gene remains unknown. We set out to determine the function of auts2 in neural development and circuit function using larval zebrafish (*Danio rerio*). We identified four auts2 paralogs in zebrafish: auts2a, auts2b, fbrsl1 and fbrs. Of these, auts2a is located on chromosome 10 and codes for a protein with 1278 amino acids residues. Expression of auts2a was seen widely in the

central nervous system with prominent expression in the hindbrain. At 14 hours post fertilization (hpf), auts2a is strongly expressed in rhombomere 4 - the place where Mauthner neurons, that trigger escape response, are located.
To test the function of auts2a in neural circuit assembly, we induced mutations in the auts2a locus using transcription activator-like effector nucleases (TALEN). We isolated several alleles with loss of function due to frame-shift mutations leading to premature stop codons. Mutant fish showed normal gross morphology and development and were fertile. Escape response is critical for survival, is stereotyped, and the underlying circuit is well-characterised. Therefore, we evaluated escape response in auts2a mutants as a tool for investigating the role of auts2a in circuit development and behavior. The latency to trigger an escape response was longer in auts2a mutants compared to wildtype. Further, the variability of latency was also higher compared to the tightly regulated short latencies in wild type fish and heterozygotes. We also observed greater proportions of no response trials and ipsilateral responses in auts2a mutants compared to wild type fish and heterozygotes. Lastly, these defects were exacerbated when stimuli were applied to the tail than in trials when the stimuli were applied to the head, hinting at defects in Mauthner neurons. Our next steps focus on looking at calcium activity profile of Mauthner and its homolog to get mechanistic insights into these behavioural defects. Our study on auts2 genes may further reveal general principles in how variability, a fundamental aspect of behavior, arises.

Title: FOXG1 overexpression and epigenetic landscape in a human iPSC-derived forebrain organoid model of severe, macrocephalic autism spectrum disorder

Authors: *N. NOLAN[1], J. MARIANI[1], F. WU[1], A. ABYZOV[3], F. M. VACCARINO[1,2]
[1]Child Study Ctr., [2]Neurosci., Yale Univ., New Haven, CT; [3]HSR, Harwick 3-12, Mayo Clin., Rochester, MN

Abstract: Autism Spectrum Disorder (ASD) is a highly heritable developmental disorder which, in severe cases, is associated with cortical overgrowth, macrocephaly, and excitatory/inhibitory neuronal imbalance. Using an organoid model of forebrain development, we previously

implicated FOXG1, a transcription factor involved in early forebrain patterning, in contributing to the ASD phenotype in four families of macrocephalic ASD patients with no known ASD-associated mutations (Mariani et al., Cell 2015). This phenotype included a transient increase in cell proliferation, overproduction of GABAergic neurons, and neurite/synaptic overgrowth. RNA-seq studies and gene network analyses also showed that FOXG1 is upregulated as well as co- expressed with other transcription factors and cell fate determinants in ASD patients' forebrain organoids. Increased FOXG1 activity may explain some features of ASD pathophysiology, fitting with FOXG1's known role in cortical growth and GABAergic neuronal development. We showed that FOXG1 shRNA knockdown normalized both expression of several GABAergic neuron-associated genes and GABAergic neuron overproduction in ASD-derived organoids. However, to what extent FOXG1 upregulation is sufficient to generate the ASD organoid phenotype, and the details of the FOXG1 regulatory network in health and disease, remain unclear. Furthermore, the epigenetic landscape of ASD is not well understood, particularly in regard to FOXG1. ASD-derived organoids show increased FOXG1 expression but without mutations in the FOXG1 sequence or upstream promoter regions, suggesting that epigenetic or distal regulatory changes might contribute to FOXG1 overexpression. To answer these, we use an inducible system to overexpress FOXG1 in wild-type organoids from ASD patients' fathers and unrelated, age-matched controls. Comparisons using RNA-seq, ChIP- seq, immunocytochemistry, and neuronal phenotype analyses are used to examine the extent to which FOXG1 overexpression alone recapitulates the ASD transcriptomic and neurophenotypic changes seen in organoids derived from ASD probands. Second, by performing histone ChIP-seq analyses on organoids derived from ASD patients and their unaffected fathers at time points corresponding with early forebrain development, and then intersecting these regulatory regions with gene variants associated with ASD in large cohorts of families (from MISSNG and SFARI datasets), we explore the dynamic developmental epigenetic landscape of our ASD cohort, including potential genetic and/or epigenetic causes for the previously detected transcriptome alterations such as the overexpression of FOXG1.

Abstract: With antibody-based therapeutics emerging as a promising treatment for central nervous system (CNS) disorders, characterizing antibody distribution in the brain microenvironment will be critical for successful translation. Immunoglobulin G (IgG) antibody distribution is expected to be influenced by binding to a variety of endogenous Fc receptors. Fc receptors, present on immune and non-immune cells, bind to the crystallizable fragment (Fc region) of immunoglobulins throughout the body. Surprisingly, the expression of these receptors in the CNS has not been well described. Here, we have used immunohistochemistry to investigate the distribution of two Fc receptors in the brain - the inhibitory Fc gamma receptor (FcγRIIb) and the neonatal Fc receptor (FcRn). The expression of these receptors was studied at the nasal epithelia (olfactory and respiratory), trigeminal nerve, lymph nodes, brain, dura and spinal cord. FcγRIIb is an inhibitory receptor that binds to IgG with low affinity ($K_d \sim 10^{-6}$ M). We observed that FcγRIIb expression was relatively high at the cerebrospinal fluid (CSF) - brain interfaces. Immunoreactivity co-localized with surface astrocytes and also possibly leptomeningeal cells. Intriguingly, the distribution of centrally applied (intranasal or intrathecal administration) IgG appears to be restricted at locations with high FcγRIIb expression, suggesting that reversible binding may be limiting CNS distribution of IgG. The neonatal Fc receptor (FcRn) only binds IgG with high affinity in slightly acidic environments (pH ~ 6.5) such as endosomes/lysosomes and mucus layers overlying certain epithelia, with much weaker binding affinity in most other physiological compartments (pH ~ 7.4), e.g., blood and CSF. In the brain microenvironment, FcRn appears to be expressed by brain endothelial cells and has been thought to play some role in the clearance of IgG from the brain. Our data suggests that FcRn is prominently expressed by cells around the perivascular space and the sub-arachnoid space as well as at CSF-facing interfaces (e.g., ventricular surfaces, choroid plexus epithelial cells and their associated stroma). We also observe FcRn expression in the olfactory epithelia. We hypothesize that FcRn binding may be an important influence on the uptake and transport of IgG administered via the CSF or intranasally. Overall, our findings may potentially inform the engineering of antibody therapeutics for more efficient distribution within the CNS as well as

provide new insights into the physiological factors influencing the distribution of endogenous IgG.

Title: Increasing selective hip-knee control of infants at high risk for cerebral palsy: A feasibility study

Authors: *B. A. SARGENT, K. HAVENS, N. MARCIONE, C. J. WINSTEIN, L. FETTERS
USC, Los Angeles, CA

Abstract: Background. Infants with brain insults are at high risk for cerebral palsy (HRCP) and have reduced selective hip-knee control. We developed an in-home intervention to encourage selective hip-knee control that uses a Microsoft Kinect to track an infant's leg movements and activate an overhead infant mobile based on specific kicking actions. The purpose of this study is to determine: (1) the feasibility of the in-home mobile intervention, (2) if infants at HRCP and infants with typical development (TD) learn the contingency between leg movement and mobile activation, (3) if both groups increase selective hip-knee control when activating the mobile compared to spontaneous kicking. **Methods**. Six infants at HRCP and 12 infants with TD at 3½-months corrected-age participated in the study. Each infant participated in an 8-10 min/day, 5 day/week, 6-week mobile intervention. On the first day of each week, the spontaneous kicks of each infant were assessed for 2-min, followed by 8-min of the infant playing with a mobile that activated based on specific kicking actions. For the next 4 days, the infant played with the mobile for 8-min each day. At the end of 6-weeks, parents answered questions about feasibility.

Learning was assessed weekly based on an increase in the proportion of time that the infant demonstrated the reinforced leg actions (RLA) when playing with the mobile compared to spontaneous kicking. Selective hip-knee control was assessed weekly based on a decrease in the hip-knee correlation coefficient (CC) of kicks that activated the mobile compared to spontaneous kicking. **Results**. Feasibility: Parents stated infants were happy during the majority of sessions and the in-home intervention was easy to implement. Adherence was 93-100%. Learning: All infants learned that their leg action activated the mobile: infants with TD met the individual learning criteria for a median of 5 weeks (range 3-6), and infants at HRCP met the criteria for a median of 3 weeks (range 2-4). For 4 of 6 weeks, the group with TD demonstrated a significant increase in RLA when activating the mobile (21.4±1.3%) compared to spontaneous kicking (9.8±2.0%, $p<0.0001$). Selective hip-knee control: For 5 of 6 weeks, the group with TD demonstrated a significant decrease in hip-knee CC when activating the mobile (0.32±0.08) compared to spontaneous kicking (0.59±0.08, $p<0.0001$). **Conclusions/Significance**. The mobile intervention is feasible. Preliminary data supports that infants with TD and HRCP are learning that their leg actions activate the mobile, and infants with TD demonstrate more selective hip-knee control when activating the mobile compared to spontaneous kicking.

Title: ERK-mediated phosphorylation of Egr1-3 coregulator NAB2 at multiple sites

Authors: K. M. ABT[1], N. A. BERRY[1], S. KLETSOV[1], T. T. EDWARDS-GRANT[1], J. W. TULLAI[2], *K. W. ADAMS[1]
[1]Biol. Sci., Bridgewater State Univ., Bridgewater, MA; [2]Dept Biol, Boston Univ., Boston, MA

Abstract: The early growth response (Egr) family of transcription factors comprises five members, Egr1-4 and Wilms Tumor 1 (WT1), which play roles in various cell behaviors including proliferation, apoptosis, and differentiation in a cell type- and stimulus-specific manner. Roles for Egr1-3 are particularly well-documented in the nervous system. Egr1 and 3 contribute to learning and memory through regulation of genes that mediate synaptic plasticity and long-term potentiation. Egr2 controls hindbrain development through regulation of *Hox* gene

expression and drives peripheral nerve myelination through, at least in part, activation of the gene encoding myelin protein zero in Schwann cells. Egr1 and 2 also contribute to transcriptional network that drives neuronal differentiation of PC12 cells. However, the mechanisms that regulate Egr1-3 activities in the nervous system are not fully understood. One mechanism of regulation involves protein-protein interactions with co-regulators NAB1 and 2 through a conserved R1 domain in Egr1-3. Most reports demonstrate that NABs repress Egr1-3 transactivation activity when bound, however, NABs can also enhance transactivation in a target gene-specific manner. The mechanisms controlling the effect of NABs on Egr activities are not clear. Here, we provide evidence that NAB2 regulation may involve its phosphorylation at several sites by ERK. Using PC12 cells as a model system, our data demonstrate that nerve growth factor (NGF) induces a NAB2 mobility shift in SDS-PAGE within 10 minutes of treatment. The mobility shift was reversed when lysates from NGF-treated cells were treated with lambda phosphatase, suggesting the shift is due to phosphorylation. Inhibition of ERK signaling during NGF treatment blocked the mobility shift, while recombinant ERK phosphorylated recombinant NAB2 in an *in vitro* kinase assay, together indicating that direct phosphorylation of NAB2 by ERK may be responsible for the NAB2 mobility shift in response to NGF. Nine potential ERK phosphorylation sites were identified in NAB2, which were mutated individually to alanine within a NAB2 expression construct to evaluate phosphorylation at those sites based on their mobility in SDS-PAGE. Of the nine mutants, three exhibited clear changes in NAB2 mobility, which were additive in double and triple mutants for those sites. Ongoing experiments are evaluating the effect of NAB2 phosphorylation on its localization and regulation of Egr1-3.

Title: Atypical postnatal development of feedback excitatory and local inhibitory circuits in layer I of prefrontal cortices in autism

Authors: *I. TRUTZER[1], B. ZIKOPOULOS[2]
[1]Neurosci., [2]Boston Univ., Boston, MA

Abstract: Layer I of the cortex appears early in development and is composed of glia and limited neurons dispersed among dendrites and axons. The neurons in layer I direct the patterning of cortical lamination in mammals, including humans. In adulthood, layer I contains few, overwhelmingly inhibitory, neurons. Dendrites of excitatory pyramidal neurons from the deep cortical layers terminate in this layer, where they receive synapses from feedback projections that modulate cortical function. The balance of excitation-inhibition in this layer is therefore integral for proper cortical information processing. Despite the unique role of layer I, little is known about the postnatal development of this layer. In order to study the excitatory-inhibitory balance in this layer through postnatal development, we studied the distribution of distinct classes of inhibitory neurons and the density of myelinated axons in layer I of prefrontal cortices in typically developing children and adolescents. We compared our findings with data from children and adolescents with autism, a disorder characterized by an imbalance in excitation and inhibition in the brain. Inhibitory neurons are categorized by their expression of calcium binding proteins. Neurons that express calretinin (CR) and calbindin (CB) exert modulatory inhibition on their targets, while those that express parvalbumin (PV) are strongly inhibitory. CR-expressing neurons have been observed in layer I in prenatal and adult tissue. Neurons expressing CB and PV are not present in layer I in the neurotypical adult brain. We report that in addition to CR-expressing neurons, PV- and CB-expressing neurons are found in layer I of PFC in neurotypical children and adolescents. In autism, children and adults have CB, PV, and CR-expressing neurons in layer I in LPFC and ACC. In LPFC, children with autism have a sharp reduction in the density of dis-inhibitory CR-expressing neurons during adolescence. In this same region, children with autism have a steeper increase in the proportion of small axons, representative of short-range pathways, compared with neurotypical children. In ACC, children with autism have increased density of PV-expressing neurons in adolescence relative to neurotypical children; feedback pathways in this area are heterogeneous, in line with the widespread connectivity of this area. The observed changes in cortical structure, including the appearance of strongly inhibitory PV neurons in layer I and reduction of dis-inhibitory CR-expressing neurons in adolescence, along with changes in feedback excitatory pathways, likely have significant implications for the efficiency of cortical processing in these areas.

Title: Common laminar distribution and density of synapses and axons in prefrontal cortices in humans and non-human primates

Authors: *M. GARCIA-CABEZAS[1], I. TRUTZER[2], H. BARBAS[3], B. ZIKOPOULOS[3]
[1]Hlth. Sci. (Neural Systems Lab), Sargent College, Boston Univ., Boston, MA; [2]Neurosci., [3]Boston Univ., Boston, MA

Abstract: The anterior cingulate cortex (ACC) and lateral prefrontal cortex (LPFC) communicate in a prefrontal attention network in humans. The coordinated activity of these cortices is necessary for switching attention, and may be involved in decision making and encoding of emotional responses. Excitatory synaptic connections between ACC and LPFC have been characterized in rhesus macaques, where axons from ACC mainly target the upper layers (1, 2, and upper 3) of LPFC, which is typical of feedback pathways, while axons from LPFC mainly target the middle layers (lower 3 through upper 5) of ACC, typical of feedforward pathways. Disruption of connections and local signal processing of ACC and LPFC could lead to behavioral symptoms of attentional regulation, seen in disorders such as autism spectrum disorders (ASD). Studies have characterized the structure of long- and short-range pathways in the white matter to characterize structural connectivity between brain regions. In order to expand on these analyses, it is necessary to study the intercortical structure of connected brain areas to identify possible changes in the distributions of axons or synapses that could represent changes in specific classes of pathways. We quantitatively analyzed the density of synapses and axons in the individual cortical layers of these two areas in adult rhesus macaque brains, and compared the results with the laminar density of myelinated axons in adult humans. The relative density of each synapse type differs between the different cortical layers and areas, and influences the regulation of specific types of pathways. We also correlated the axon density of different cortical layers in rhesus macaque and human brain tissue with the goal to determine if the rhesus monkey can be used as a primate model system. We determined that the density of axons is highest in the deep cortical layers and lowest in Layer II, while synapse density shows the opposite trend. ACC (area 32) has fewer myelinated axons, especially in the deep layers, and a higher density of synapses in adult monkeys when compared to LPFC (area 46). The densities of axons in the different cortical layers follow similar trends in rhesus and human subjects. These findings serve as a basis to understand important developmental processes that influence neural circuit structure.

Title: ITGB3 gene promoter variants influence 5-HT blood levels by modulating the externalization of the platelet 5-HT transporter in Autism Spectrum Disorder

Authors: *A. M. PERSICO[1,2], S. GABRIELE[3], M. CANALI[3], C. LINTAS[3], R. SACCO[3], C. GREGORJ[3]
[1]Unit of Child and Adolescent Psychiatry, Univ. of Messina, Messina, Italy; [2]Mafalda Luce Ctr. for Pervasive Developmental Disorders, Milan, Italy; [3]Univ. Campus Bio-Medico, Rome, Italy

Abstract: Genetic factors contribute significantly to autism spectrum disorder (ASD). The *ITGB3* gene, located on human chr. 17q21.32, encodes integrin beta 3, the beta subunit of the platelet membrane adhesive protein receptor complex GPIIb/IIIa. Integrin beta 3 interacts with the serotonin transporter (SERT), encoded by the *SLC6A4* gene, regulating its trafficking on the plasma membrane of platelets and serotonin (5-HT) uptake in synapses. *ITGB3* and *SLC6A4* were both identified as quantitative trait loci (QTLs) for 5-HT blood levels, known to be elevated in 20-30% of ASD patients (Gabriele et al., Eur Neuropsychopharmacol 24:919, 2014). The *rs2317385* G allele in the *ITGB3* promoter region is significant associated with 5-HT blood levels in 293 Italian ASD families (Napolioni et al., Eur J Hum Genet 19:353, 2011). To identify functional *ITGB3* variants contributing to elevate 5-HT blood levels, we sequenced the *ITGB3* promoter region, exons and exon-intron junctions in twenty individuals selected on the basis of known genotypes. Six SNPs were identified, all located in the *ITGB3* promoter region and in tight linkage disequilibrium with *rs2317385*, defining four haplotypes. Each haplotype was cloned into pGL4.10, transfected into hematopoietic (K-562 and HEL 92.1.7) and neuronal (N2A) cell lines, and analyzed by luciferase assay. A significant increase in *ITGB3* promoter activity and differential allelic effects were detected after differentiation into megakaryocytes both in K-562 and HEL 92.1.7, but not in N2A cell lines, with the *rs55827077* C allele associated with greater luciferase activity ($P<0.05$), as predicted. This same allele was associated with elevated 5-HT blood levels in 176 ASD patients ($P=0.01$), with significantly greater amounts of platelet integrin beta 3, as assessed by western blotting ($P=0.02$), and with increased SERT externalization on the platelet plasma membrane ($P=4.05 \times 10^{-11}$). These results support cell type- and differentiation-specific effects of *ITGB3* promoter activity exerted by common genetic variants linked to hyperserotoninemia in autism.

Title: Key role of BET-controlled gene networks in autism

Authors: *J. SULLIVAN[1], A. BADIMON[1], P. AYATA[1], U. SCHAEFER[2], M. DUFF[1], R. K. PRINJHA[3], A. SCHAEFER[1]
[1]Icahn Sch. of Med. At Mount Sinai, New York, NY; [2]Rockefeller Univ., New York, NY; [3]GlaxoSmithKline, Birmingham, United Kingdom

Abstract: Autism Spectrum Disorder (ASD) is a group of complex neurodevelopmental disorders that are characterized by social impairment and repetitive behaviors. There is no known single cause for ASD, but it is clear that there are strong genetic and environmental components to the development of the disorder. Recent whole-exome sequencing studies confirmed synaptic dysfunction as a central mechanism in the disease pathology but also surprisingly implicated a group of transcriptional regulators. This suggests the possibility of a novel, epigenetic mechanism underlying ASD where disruptions in gene transcription lead to abnormal neuronal development and circuit formation. To address the contribution of transcriptional dysregulation as the cause of ASD-like phenotypes, we used a novel pharmacological approach to temporarily inhibit transcription during postnatal brain development. In collaboration with GlaxoSmithKline, we developed a brain-permeable inhibitor, I-BET858, of the bromodomain and extraterminal domain-containing proteins (BETs) which regulate the elongation phase of transcription. We found a surprisingly selective impact of BET inhibition on synaptic functional genes. These I-BET858-sensitive genes are characterized by their extended length which may explain their selective sensitivity. Many of the I-BET858-sensitive genes have also been linked to ASD in humans, suggesting the key role of the BET-controlled gene network in the disorder. Finally, we found that pharmacological inhibition of BET-dependent transcription during postnatal brain development led to the development of an autism-like phenotype in mice. These findings

illustrate that transcriptional dysregulation can directly impair brain development, supporting the existence of an epigenetic mechanism underlying Autism Spectrum Disorder.

Title: Serotonergic axons appose angiogenic blood vessels in autism temporal cortex: An immunocytochemical study in postmortem human brains

Authors: *K. N. MANGAR, E. C. AZMITIA, X. F. JIA
Dept. of Biol., New York Univ., New York, NY

Abstract: Serotonin (5-HT) axons have long been associated with the normal brain vasculature. Increased serotonin axons (Azmitia et al., 2011b) and increased angiogenic blood vessels (Azmitia et al., 2016) have been demonstrated in the autism brain. Studies also showed that increasing brain 5-HT with serotonin specific reuptake inhibitors (SSRIs) results in hippocampal angiogenesis in rats (Warner-Schmidt and Duman, 2007) and in humans (Boldrini et al., 2012). Additionally, 5-HT is a crucial driving force of tumor angiogenesis (Zamani and Qu, 2012; Qin et al., 2013). In this study, we focused on 5-HT transporter-immunoreactive (5-HTT-IR) axons and nestin-IR proliferating pericytes on blood vessels to explore for an anatomical association between these axons and blood vessels in the autism brain. The present work used postmortem brain tissues from 3 age groups of ASD donors (2.8 - 10 years; 10.1 - 20 years; 20.1 - 29 years) and their age matched controls (2.1 - 30 years). Brain hemispheric sections of the temporal cortex were labeled with mouse monoclonal nestin (Millipore), a marker of proliferating blood vessels; rabbit polyclonal Ulex Europaeus Agglutinin 1(UEA-1) lectin, a marker of mature blood vessels, (Vector Laboratories, CA); and mouse monoclonal serotonin transporter (5-HTT) (MAb Technologies, GA), a marker of serotonin axons. These primary antibodies were used in single and double immunocytochemistry. Double immunolabeling with UEA-1 and 5-HTT confirmed prior observations of serotonin axons innervating mature endothelial cells in normal brains**.** This relationship is also present in autism brains of all ages. Double labeling with nestin and 5-HTT in autism brains showed extensive labeling of 5-HTT-IR axons on blood vessels covered with nestin positive proliferating pericytes throughout the temporal cortex. Many axons were seen

contacting proliferating pericytes all along the entire blood vessel. This strong interaction was visible in all 3 age groups. However, the 5-HTT-nestin relationship was not observed in control brains as nestin expression is high only in early development (<2 years) and in angiogenic vessels but not in mature vessels of normal brains. This close apposition of 5-HTT-IR axons to nestin-IR positive pericytes illustrates a crucial association in the angiogenic autism brain further suggesting that 5-HT contact may drive angiogenesis and pericyte proliferation in autism patients. This could be a new therapeutic target for drug intervention in autism patients by blocking the 5-HT pathway.

Title: Segregated expressions of autism risk genes Cdh 9 and Cdh 11 in autism-relevant regions of developing cerebellum

Authors: *C.-L. WANG[1], Y. WANG[1], X. YUAN[2]
[1]Hussman Inst. For Autism, Baltimore, MD; [2]Hussman Inst. for Autism, Baltimore, MD

Abstract: Recent genome wide association studies (GWAS) and whole genome sequencing (WGS) have highlighted type II cadherins as risk genes for Autism Spectrum Conditions (ASC). To understand how these cadherins may be linked to the morphogenesis of autism-relevant brain regions, we carried out *in situ* hybridization (ISH) to examine the mRNA expression profiles of two autism-associated genes Cdh9 and Cdh11 in developing mouse brains. We found that during the first postnatal week both genes are expressed at a high level but in distinct sub-populations of Purkinje cells of the cerebellum, a frequently targeted area in autism. As development proceeded, the expression of Cdh9 and Cdh11 both declined and maintained at a low level in adulthood in the mouse brain. Interestingly, developmental expression of Cdh11 was largely confined to areas that mediate high cognitive functions of the cerebellum in the adult, including the dorsal lobules of the vermis and the lateral hemisphere equivalent to the Crus I and Crus II areas in human, and these areas are known to be highly vulnerable in ASC. Careful examination of adjacent sagittal sections showed that the two genes are expressed largely in a complementary pattern with sharp boundaries. In particular, in the lobules 6/7 of the vermis, Cdh11 expressing area was confined to the central part, flanked by the Cdh9 expressed area. The Purkinje cell marker calbindin also exhibited differential expression in an area-specific manner. Interestingly, the high Cdh11

expression in the central part of the lobe 6/7 was associated with a very low expression of calbindin in the same area, whereas in the flanking area of high Cdh9 expression, calbindin was expressed at a much higher level. In lateral area of the cerebellar hemisphere, a similar segregated expression pattern of Cdh9 and Cdh11 was observed, also with an inverse correlation between the expression of Cdh11 and calbindin. Our results revealed a clear segregation of two autism risk genes Cdh9 and Cdh11 with regard to their expression in Purkinje cells, raising the possibility that these two genes may exert different but correlated functions in orchestrating the postnatal development of cerebellar circuitries that are closely relevant to cognitive functions. Importantly, the very low calbindin level in the Cdh11-high domains suggests that Cdh11 may regulate the delayed maturation of Purkinje cells in areas associated with cognitive functions of the cerebellum.

Title: Altered HDAC4 localization in a mouse model of maternal immune activation

Authors: P. COIRO, L. BERGDOLT, Y. JUNG, *A. DUNAEVSKY
Developmental Neurosci., Univ. of Nebraska Med. Ctr., Omaha, NE

Abstract: Infections during pregnancy are associated with increased risk of psychiatric disorders in offspring, including autism spectrum disorder and schizophrenia. The viral mimic Poly(I:C) is often used in rodent models of maternal immune activation (MIA). We and others have previously shown altered cytokine expression and synapse number in brains of mouse MIA offspring that were associated with altered behaviors. Here we investigated the molecular mechanisms that might mediate the reduced number of synapses observed in MIA offspring. Specifically, we have tested the hypothesis that MIA induces epigenetic changes in the fetal brain which involve the nuclear translocation of the histone deacetylase HDAC4, resulting in a long-lasting impact on synaptic structures. We report that in neurons of MIA offspring, both in culture and in vivo, there is nuclear accumulation of HDAC4, which belongs to class IIa HDACs and is mainly cytoplasmic in basal conditions. This altered subcellular localization is associated

with a reduction of phospho-HDAC4 that is necessary for the nuclear export. In MIA offspring we also find activation of extracellular signal-regulated kinase ERK1/2 that has been shown to be activated by cytokines and lead to nuclear translocation of HDAC4. Nuclear accumulation of HDAC4 was correlated with a reduction in number of spines. Moreover, HDAC4 makes a complex with another class I HDAC, HDAC3, resulting in a total reduction of the acetylation of Histone H3. Finally, using a specific inhibitor for HDAC4, we were able ameliorate the reduction in number of spines in cultured neurons from MIA offspring. Current efforts are underway to determine if postnatal administration of HDAC4 inhibitor can ameliorate the behavioral impairments associated with MIA.

Abstract: We show for the first time that diminished dosage of genes deleted in 22q11 Deletion Syndrome (22q11DS), which is associated with autistic spectrum disorders (ASD) and schizophrenia (Scz), results in cortico-cortical under-connectivity. Mapping of cortical projections in the *LgDel* 22q11DS mouse model reveals under-connectivity between the medial frontal cortex and other cortical association areas.
These changes are reflected in eletrophysiological responses measured in the *LgDel* medial frontal cortex following stimulation from other cortical areas. Furthermore, the dendritic and

axonal growth of the layer 2/3 projection neurons (PNs) that make the majority of cortico-cortical connections are dysmorphic. *In vivo* and *in vitro*, dendritic length and complexity as well as axon length is reduced in *LgDel* Layer 2/3 projection neurons (PNs). Using scanning electron microscopy with back-scatter detection to resolve individual synapses, we found a significantly diminished frequency of synaptic contacts on the dendrites of identified layer 2/3 PNs. The synaptic contacts that remain on LgDel layer 2/3 PN primary dendrites and in the adjacent layer 2/3 neuropil have reduced numbers of synaptic vesicles in presynaptic processes as well as decreased thickness and size of post-synaptic densities. We also observed hallmarks of cellular stress in these neurons that include distended mitochondrial cristae-indicative of altered reactive oxygen species (ROS) levels. Disrupted function of a 22q11 mitochondrial gene, *Txnrd2*, recapitulates these phenotypes. *Txnrd2* over-expression in *LgDel* restores WT ROS levels as well as synapse, dendrite and axon growth *in vitro*. Targeted, sparse recombination of one mutant allele of *Txnrd2* (*Txnrd2*$^{+/fl}$) using a Cux2:CRE^{ERT} driver in layer 2/3 PNs *in vivo* recapitulates, at comparable magnitudes, the dendritic growth deficits seen in the *LgDel*. The antioxidant, N-acetyl cysteine (NAC), also reverses these changes in *LgDel*, *Txnrd2*-depleted and *Txnrd2*$^{+/-}$ layer 2/3 PNs in vivo. Finally, preliminary work suggests that some behavioral deficits seen in LgDel mice may be partially or completed reversed by NAC treatment from birth onward. Thus, *Txnrd2*-dependent redox regulation underlies cortico-cortical under-connectivity in a genetically valid mouse model of 22q11DS. Our data establishes under-connectivity as a consequence of a genomic lesion associated with ASD and Scz, and related cortical circuit disorders and suggests a new, safe therapeutic approach for ameliorating cortical circuit pathogenesis and behavioral deficits in neurodevelopmental disorders.

Title: Distinct changes in striatal glutamate efflux during grooming behavior in the BTBR mouse model of autism

Authors: *J. T. DUNN, R. OCAMPO, M. E. RAGOZZINO
Psychology, Univ. of Illinois At Chicago, Chicago, IL

Abstract: Restricted interests and repetitive behaviors (RRBs) comprise a core symptom domain of autism spectrum disorder (ASD). Such behaviors exist in both cognitive forms (e.g. insistence on sameness) as well as compulsive-like motor behaviors (e.g. repetitive hand movements, body rocking). One prevalent hypothesis related to the neuropathophysiology underlying the ASD behavioral phenotype suggests that an imbalance of excitation and inhibition exists within a cortico-basal ganglia-thalamo-cortical circuit. More specifically, dysfunction of this circuit may stem from altered cortico-striatal glutamatergic transmission. Mouse models of ASD such as the BTBR T+Itpr3tf/J (BTBR) mouse model of idiopathic autism offer an opportunity to explore this hypothesis, as they have previously been shown to engage in repetitive self-grooming behavior representative of compulsive-like RRBs observed in ASD. Through the use of glutamate biosensors (Pinnacle Technology Inc., Lawrence, KS), we were able to assess real-time changes in glutamate concentration within the dorsomedial striatum while BTBR mice and C57BL6/J (B6) control mice engaged in self-grooming behavior. Grooming behavior was measured across a 10 minute testing period in a clear, plastic container. The testing period was video recorded by a camera synced to the glutamate signal produced by the implanted biosensor. As previously reported, BTBR mice demonstrated elevated self-grooming behavior compared to B6 controls. Interestingly, preliminary data indicate that while a decrease in glutamate concentration was observed during bouts of grooming in B6 control mice, an increase in BTBR dorsomedial striatum glutamate concentration was observed during self-grooming behavior. These preliminary findings suggest that both the direction and magnitude of changes in glutamate concentration within the striatum may be key in understanding the driving factors of RRBs in ASD.

Title: Altered nucleus accumbens activity as a shared neural circuit defect for autism-related behaviors

Authors: *M. F. DAVATOLHAGH[1], K. CHOI[1], J. LYNCH[2], T. O'BRIEN[1], T. ABEL[2], M. V. FUCCILLO[1]

Abstract: Autism spectrum disorders (ASD) are neurodevelopmental abnormalities characterized by impairments in two core domains: social interaction/communication and repetitive, stereotyped behaviors. While candidate gene approaches have revealed a growing number of genes implicated in ASD, it has been difficult to investigate pathophysiological mechanisms due to the polygenic nature of the disease. One potential approach is to identify specific neural circuits that mediate ASD-associated behaviors. Studies have implicated the nucleus accumbens as a brain region whose dysfunction has been attributed to deficits in both social reward and motor control. We hypothesize impaired synaptic transmission in the nucleus accumbens as a recurring neural circuit defect that mediates motor abnormalities associated with ASD. To examine ASD-related motor behaviors we used the accelerating rotating rod (rotarod) as a measurement of the formation of repetitive motor routines, correlating learning rate and stereotyped motor output. As the enhanced rotarod phenotype has been demonstrated across multiple mouse models, we will employ this task as a behavioral "endophenotype" in our attempt to uncover a common neural circuit abnormality in genetic models for ASD. We have confirmed that both Neurexin-1α and 16p11.2$^{del/+}$ ASD-associated genetic models have increased learning rate on the rotarod. To examine global synaptic changes onto neurons in the nucleus accumbens, whole-cell voltage-clamp recordings were performed. Preliminary results suggest that both Neurexin-1α and 16p11.2$^{del/+}$ animals have significant alterations in synaptic transmission within the nucleus accumbens. Together, these findings provide further evidence for altered activity in the nucleus accumbens in autism etiology. Future experiments will explore accumbal physiological alterations *in vivo* during rotarod learning in an attempt to understand whether mutation-associated synaptic changes are driving repetitive motor output in these two genetic models.

Title: Autism Spectrum Disorders may be caused by developmental dysregulation of polyamine metabolism

Authors: *A. J. SOKOLOFF
Dept Physiol, Emory Univ., Atlanta, GA

Abstract: Heritability of Autism Spectrum Disorders (ASD) is likely overstated because of the uncertain genetic significance of monozygotic twin (MZ) studies due to monochorionic

placentation in most MZ pregnancies. To identify non-genetic biological processes that can cause ASD, studies were searched in Pubmed by key words “maternal autism risk factors” (M-ASD-RF), “gestational autism risk factors” (G-ASD-RF), “autism neural phenotype” (ASD-NP), “autism neuroanatomy” and by manual search of developmental literature to identify metabolic pathways linking RF and NP. Despite differences by study, likely M-RF for increased ASD were autoimmune disease, diabetes (M,G), infection, intestinal disorders, obesity, elevated sex steroids, short and long inter-birth interval, thyroid peroxidase auto-antibody and vitamin D deficiency. Likely G-RF for increased ASD were hypoxia, ischemia, pre-eclampsia, preterm birth and preterm small for gestational age, term large for gestational age, and exposure to valproic acid and some environmental toxins. Equivocal RFs, e.g., SSRI, smoking, were not considered. NPs with the most common penetrance were evaluated (cerebellar hypo/hyperplasia, Purkinje dysgenesis; cerebral overgrowth, variation in neuronal migration and connectivity, cortical dysgenesis; amyloidosis). A review of >5,000 peer-reviewed studies in human and non-human in vivo and in vitro systems revealed that a single pathway, polyamine metabolism (PA), connected increased ASD-RF to ASD-NP. The conclusion that developmental PA dysregulation (PA-DYS) causes ASD was supported by robust PA in factors with decreased ASD risk (thyrotoxosis, preconceptual/early-G folic acid). I conclude that developmental PA-DYS causes ASD. PA is essential for fundamental cellular (e.g., transcription, translation, cell-cycle) and neurodevelopmental (e.g., neurogenesis, differentiation, migration; axogenesis; synaptogenesis) processes; thus neural consequences of PA-DYS can be variable by timing, localization, mode (e.g., synthesis, catabolism) and molecular interactions of PA-DYS. Such variability in PA-DYS may explain differences in ASD-NP and may underlie temporal windows of certain RFs. Because PA is essential for placenta vascular, immune and hormonal function, placenta modification by PA-DYS can substantially impact ASD-NP. Requirement of PA in DNA repair suggests that many de novo mutations in ASD are correlative of PA-DYS and not causal of ASD. These findings suggest that PA biomarkers may enable identification of some at-risk pregnancies and infants, and restoration of PA homeostasis may mitigate some fraction of ASD risk.

Title: Density of cannabinoid receptors of autistic rat after musical stimulation

Authors: *D. MONJE[1], J. MANZO[2]
[1]CENTRO DE INVESTIGACIONES CEREBRALES, UNIVERSIDAD VERACRUZANA, XALAPA, Mexico; [2]Univ. Veracruzana, Xalapa, Ver. Mexico, Mexico

Abstract: Endocannabinoids are involved in several processes related to activities such as learning and memory. In autism, it has been seen that the alteration in cannabinoids has an impact on the manifestation of symptoms such as response to social reward and anxiety. But there are no pharmacological treatments to reverse these effects. Therefore, defining strategies to recover the changes in the cannabinoids of the autistic brain is fundamental. This work started from this premise. Musical stimulation in various animal models has shown positive effects on neurorehabilitation. In autism, these effects are beginning to appear. We have been working on the role of the cerebellum in the learning and motor control of Wistar rats, and documented the fluctuation of cannabinoid receptors in subjects with normal development. In this study we analyzed the modification of these receptors in an autism model, to determine the effect of musical stimulation on their density in the cerebellum. We worked with a postnatal model of autism, which is produced by injecting a dose of 400 mg / kg of valproic acid at PN10 day. From day PN1 to PN30, subjects received musical stimulation daily for one hour, with Mozart sonatas, at an intensity of 70dB. Then, the cerebellar fluoculous were obtained to be analyzed by immunohistochemistry for CB1 receptors. The results showed that the density of CB1 receptors does not change significantly in the autistic subjects, but the subjects with musical stimulation present a smaller variability between them. This information reveals that the system of cannabinoids in the cerebellum of control and autistic subjects is similar and respond in the same way to musical stimulation. Title: The Intelectual disability gene CC2D1A regulates subcellular localization of AKT signaling in neurons

Authors: *P. A. MUÑOZ LLANCAO, A. W. OAKS, E. J. FARROW, M. C. MANZINI
GW Inst. for Neuroscience, Dept. of Pharmacol. and Physiol., The George Washington Univ., Washington, DC

Abstract: Intellectual Disability (ID) and Autism Spectrum Disorder (ASD) are common neurodevelopmental disorders, in which many signaling molecules are mutated or dysfunctional, stressing a critical role for intracellular signaling in cognitive development. In this context, mutations in the CC2D1A (coil-coiled and C2-domain containing 1A) gene has been shown that cause a spectrum of phenotypes including non-syndromic ID, ASD and seizures. CC2D1A has the structure of a scaffold characterized by four DM14 domains, protein-binding domains unique to this protein and its homolog CC2D1B. Through these domains, CC2D1A interacts with a variety of signaling proteins (e.g AKT, PKA, and NF-κB pathway) involved in transcription, endosomal signaling, and membrane trafficking modulation.
Our hypothesis is that CC2D1A controls AKT signaling by targeting it to specific subcellular regions promoting localization of signaling events. We find that AKT signaling is altered in both non-neuronal cell lines (HEK293) and primary neurons when CC2D1A is overexpressed or removed. Using immunocytochemistry, we detected active/phosphorylated Akt (pT308) in conjunction with recycling endosomes following CC2D1A overexpression in HEK293 cells. To determine whether overexpression of CC2D1A changes the subcellular distribution of active AKT, we used Förster resonance energy transfer (FRET) biosensor for AKT activity, Eevee-iAkt. We then performed fluorescence lifetime imaging (FLIM) in HEK293 cells to validate the FRET signal. We found that overexpression of CC2D1A lead an increased in FRET emission at the plasma membrane of the cells and at the endolysosomal machinery.
One important function of AKT in neurons is downstream of brain derived neurotrophic factor (BDNF), which is critical for neuronal differentiation, function and plasticity. Analysis in cortical neurons generated from Cc2d1a knock-out embryos showed an enhancement in AKT activation following BDNF treatment. In parallel, AKT phosphorylation is increased in lysates from the brain of adult Cc2d1a-deficient animals. We are now evaluating AKT activity by FRET in primary neurons from wild type and Cc2d1a KO mice following BDNF treatment, to analyze where activated AKT is localized in the cell body and dendritic arbor.
Taken together our result show that CC2D1A regulates the subcellular localization of AKT signaling at the plasma membrane and endolysosomal vesicles. This function may regulate intracellular signaling response downstream of BDNF controlling neuronal differentiation and leading to intellectual disability when disrupted.

Abstract: Disruption in neural migration and/or defective morphological maturation can lead to brain malformations with functional consequences on proper wiring of the neuronal network, as already described in neurodevelopmental disorders such as Autism Spectrum Disorders (ASD). Common knowledge indicates cell-adhesion molecules (CAMs) and Receptor tyrosine kinases (RTKs) as essential for proper neural migration and spine maturation. Moreover, ERK and AKT are convergent signaling pathways downstream to many RTKs and highly implicated in autism. Here, we identified three proteins (previously associated to ASD), which possibly form a multiprotein complex that regulates ERK and AKT signaling, cortical development and core behaviors related to autism. In particular, by *in utero* electroporation coupled with RNA interference (siRNA), we downregulated alternatively the expression of CAMs Neuronal Growth Regulator 1 (Negr1) and Protocadherin 19 (PCDH19), as well as the RTK Fibroblast Growth-Factor Receptor 2 (FGFR2) in late-born pyramidal neurons migrating to the superficial layers of the neocortex. We found that all three siRNA manipulations caused ectopic positioning of neurons concentrated at the border between layer 5 and layer 4 in the somatosensory cortex and reduced spine density. In agreement with association of Negr1, FGFR2, and PCDH19 to autism, we found that their downregulation in the somatosensory cortex resulted in a decreased number of ultrasonic vocalizations in pups, increased pain threshold and decreased social interactions in juvenile animals. Interestingly, we found that Negr1, FGFR2 and PCDH19 physically interact with one another and that Negr1 modulates FGFR2-ERK and AKT signaling by decreasing FGFR2 degradation from the plasma membrane *in vitro*. Accordingly, FGFR2 overexpression rescues all anatomical and behavioral defects observed upon Negr1 knock-down. Finally, the above findings were confirmed by the defective cortical layering and behavior in Negr1 knock out mice. These data suggest that the Negr1/FGFR2/PCDH19 complex, is necessary for proper

cortical development, as well as for core behaviors related to ASD by possibly activating ERK/AKT.

Title: A sex difference in oxytocin-expressing cells and serotonin receptors in the paraventricular nucleus after developmental serotonin exposure

Authors: *K. WAGNER, S. L. ZUP
Psychology, Univ. of Massachusetts Boston, Boston, MA

Abstract: The developmental hyperserotonemia (DHS) model of Autism Spectrum Disorder (ASD) utilizes perinatal administration of serotonin (5HT) agonist 5-methoxytptamine (5-MT) to mimic the elevated blood 5HT levels observed in many ASD individuals. DHS produces behavioral and brain morphological changes relevant to ASD, such as dysregulation of oxytocin (OXT)- a hormone implicated in social behavior regulation. 5HT can influence OXT release via its receptors 5-HT_{1A} and 5-$HT_{2A,}$ which co-localize in OXT+ cells in the paraventricular nucleus (PVN) of the hypothalamus. Thus, DHS may induce abnormal social behavior by acting during development to decrease the number of OXT+ cells and/or the likelihood of OXT+ cells to release OXT into circulation. The most parsimonious mechanism of 5HT action would be via alteration of 5HT receptors on OXT+ cells. In addition, there are pronounced sex differences in both developmental 5HT regulation and ASD diagnosis, suggesting that 5HT may alter OXT differently between males and females. Despite this, most DHS studies are only performed in males. We directly compared the number of OXT+ cells and percentage of OXT+ cells expressing $5HT_{1A}$ and $5HT_{2A}$ receptors between adult male and female DHS rats. We report sex differences in the number of OXT+ cells as well as their expression of 5HT receptors in the PVN. In agreement with previous findings, adult DHS males had fewer OXT+ cells than controls. Adult DHS females, however, had the same number of OXT+ cells as controls. Both DHS males and females had a lower percentage of OXT+ cells expressing excitatory $5HT_{2A}$ receptors than controls, but only DHS females had a higher percentage of OXT+ cells expressing inhibitory $5HT_{1A}$ receptors. This expression pattern suggests that females, but not males, can regulate 5HT receptors after DHS in a manner that promotes OXT+ survival and functional

efficiency. These data are especially interesting in light of previous findings that juvenile DHS males, but not females, have a 5HT receptor profile that favors excitability in the PVN. We hypothesize that DHS leaves OXT+ cells in males vulnerable to over-excitation and cell death, whereas females can compensate to thus produce the appropriate number of OXT+ cells by adulthood.

Title: Differential alternative splicing in superior temporal gyrus of autism spectrum disorder brains

Authors: B. STAMOVA[1], B. P. ANDER[2], A. OMANSKA[3], M. DUROCHER[2], F. SHARP[2], *C. M. SCHUMANN[3]
[1]Neurol., Univ. of California, Davis Sch. of Med., Sacramento, CA; [2]Neurol., [3]Psychiatry and Behavioral Sci., UC Davis MIND Inst., Sacramento, CA

Abstract: Objectives: Gene expression studies in postmortem brain in Autism Spectrum Disorders (ASD) have revealed dysregulated immune and neuronal networks, and implicated differential alternative splicing (DAS). Thus, we investigated DAS and the co-expression structure in the superior temporal gyrus (STG) of brains of ASD subjects compared to typically developing controls (TD). STG is an association cortex involved in social, speech, and face perception, joint attention, and implicated in ASD. **Methods:** RNA libraries from 45 subjects (16 ASD, 14/2 M/F; 29 TD, 23/6 M/F) were sequenced to 40M 2×150 bp reads. DAS was assessed using Log-normal with shrinkage models and a Gene-Specific algorithm, considering Diagnosis, Sex and Age. DAS was considered significant with |Fold-Change| >1.2, and FDR-corrected $p<0.3$ (nominal $p<0.01$). Weighted Gene Co-expression Network Analysis (WGCNA) was performed on gene-level expression to define modules of co-expressed genes in TD and ASD (unsigned networks; preservation Z-statistics). **Results:** 330 genes showed DAS in ASD vs. TD considering both sexes: 795 in ASD-Male vs. TD-Male, and 41 in ASD-Female vs. TD-Female. Genes with DAS were over-represented in immune and neurotransmitter pathways, some of which have previously been implicated in ASD. There was no significant age difference between ASD (Average age: 30 years, range 9-56)) and TD (Average age: 25.2, range 5-68) groups. There was significant overlap with ASD-implicated genes with all ASD vs. TD (33 genes,

p=1.3E-06) and ASD-Male vs TD-Male (81 genes, p=7.9E-15) DAS gene lists. Among them, the RBFOX2-12 transcript was down-regulated in ASD-Male. RBFOX2 (RNA Binding Protein, FOX1 Homologue 2) regulates alternative splicing in the nervous system and is homologous to FOX1 (A2BP1), a neural-specific splicing regulator reported to be down-regulated in ASD brain (Voineagu et al, 2011). There was a significant overlap with our all ASD vs. TD (9 genes, p=0.004) and ASD-Male vs. TD-Male (32 genes, p=4.1E-12) gene lists when compared to the 196 genes with FOX1-dependent DAS identified by Voineagu et al. WGCNA revealed perturbation in co-expression in several modules and a number of ASD-implicated genes were hub genes in modules with low preservation, potentially affecting nervous system development and function (MECP2, PTEN, MAPK1, DYRK1A, DOCK4, GNAS), such as potentiation of synapse, quantity of neurons, dendritic branching and prepulse inhibition. **Conclusions:** There is differential alternative splicing in the STG region of ASD brains which is modulated by age and sex. WGCNA also revealed hub genes which have been implicated in ASD.

Title: Altered excitatory-inhibitory ratio preserves circuit excitability in FMR1, CNTNAP2, 16p11.2 deletion, and Tsc2 mouse models of autism

Authors: *T. LANGBERG[1], M. W. ANTOINE[2], P. SCHNEPEL[3], D. E. FELDMAN[4]
[1]Univ. of California, Berkeley, Berkeley, CA; [2]Miller Inst. for Basic Res. in Sci., Univ. of California Berkeley, Berkeley, CA; [3]Mol. and Cell Biol., Univ. of California Berkeley Dept. of Mol. and Cell Biol., Berkeley, CA; [4]Molec & Cell Biology; Helen Wills Neurosci Inst., UC Berkeley, Berkeley, CA

Abstract: Distinct genetic forms of autism are widely hypothesized to share a common circuit basis in increased excitation-inhibition (E-I) ratio in cerebral cortex, causing hyperexcitability and excess spiking. We tested this hypothesis by comparing synapse and circuit physiology in L2/3 of somatosensory cortex in four transgenic mouse models of autism ($CNTNAP2^{-/-}$, $FMR1^{-/y}$, 16p11.2 deletion, $Tsc2^{+/-}$). All strains showed reduced L4-evoked IPSCs in L2/3 pyramidal cells coupled with a more moderate and variable reduction of EPSCs, thus increasing E-I ratio versus wild types. mIPSCs and mEPSCs showed only modest or inconsistent changes in autism

genotypes. Remarkably, reductions in evoked IPSCs and EPSCs were quantitatively matched to drive stable—not increased—peak synaptic potentials relative to wild type. This suggests that the L2/3 network may have normal, not enhanced, excitability. Consistent with this prediction, spontaneous network-driven spiking in L2/3 of active slices was normal in autism models, except for elevation in CNTNAP2$^{-/-}$ mice. To test whether these synaptic changes alter circuit excitability in vivo, we recorded whisker-evoked spiking in L2/3 of the CNTNAP2, FMR1, and 16p11.2 strains under urethane-anesthesia. Regular-spiking (RS, presumed excitatory) units showed increased spontaneous firing only in CNTNAP2$^{-/-}$ mice. Whisker-evoked RS unit firing was normal in CNTNAP2$^{-/-}$ and 16p11.2 deletion mice, and was reduced in FMR1$^{-/y}$ mice. Sensory tuning was unchanged in all genotypes, except for reduced tuning preference for the columnar whisker in FMR1$^{-/y}$ mice. Thus, excitability and sensory processing in L2/3 of autism strains was remarkably normal, despite the substantial reduction in L4-L2/3 inhibition. We hypothesize that inhibitory weakening in autism mutations contributes to homeostatic stabilization of net synaptic drive, rather than driving circuit hyperexcitability, at least for low-frequency stimuli.

Title: Decreased spontaneous network activity in a mouse model of Pitt-Hopkins Syndrome, a rare form of autism spectrum disorder (ASD)

Authors: *H.-Y. CHEN, G. R. HAMERSKY, S. C. PAGE, B. J. MAHER
Developmental Electrophysiology, Lieber Inst. For Brain Develop., Baltimore, MD

Abstract: Pitt-Hopkins Syndrome (PTHS) is a rare form of autism spectrum disorder (ASD) that is caused by de novo mutation in one copy of the transcription factor 4 (TCF4) gene. This gene belongs to type 1 basic helix-loop-helix (bHLH) transcriptional factor family and is able to form homodimer or heterodimer with other members in this gene family for gene regulation in a tissue specific manner. Using a mouse model of PTHS that produces a truncated TCF4 protein (TCF4+/tr), we previously reported that medial prefrontal pyramidal neurons display intrinsic

excitability deficit that are partially due to ectopic upregulation of SCN10a (Rannals et al., Neuron 2016). Here, we ask whether these cellular level excitability deficits have any impacts on synaptic transmission and network activity. We studied spontaneous neurotransmission with whole-cell patch clamp and network activity using Ca2+ imaging in acute prefrontal brain slices. We observed that TCF4+/tr neurons showed decreased frequency and amplitude of spontaneous excitatory synaptic currents (sEPSCs) onto pyramidal neurons. However, this effect was abolished in the presence of TTX suggesting that it was dependent on the generation of spontaneous action potentials. We also observed a significant reduction in the frequency of spontaneous inhibitory currents (sIPSCs) onto these pyramidal neurons. Similarly, this effect was sensitive to application of TTX, suggesting a dependence on the generation of spontaneous action potentials. To test for a generalized deficit in spontaneous action potentials in the prefrontal cortex of this PTHS mouse model Ca2+ imaging experiments are ongoing. These results herein together with intrinsic excitability deficit suggests pyramidal cells in this PTHS mouse model have an overall decrease in their ability to generate spontaneous action potentials and this leads to a generalized decrease in network activity. We hypothesize these excitability deficits in prefrontal cortical networks represent pathophysiology in PTHS that may underlie cognitive deficits observed in this patient population.

Title: Understanding interneurogenesis in a novel model of neonatal brain injury

Authors: *H. LACAILLE[1], C. M. VACHER[1], A. PENN[1,2]
[1]Ctr. for Neurosci., Children's Natl. Hlth. Syst., Washington, DC; [2]Neonatology, Fetal Med. Inst., Washington, DC

Abstract: Preterm birth is a leading cause of neonatal encephalopathy that can lead to long-term neurological impairment. Maternal immune activation (MIA), seen in 85% of extremely preterm births, and extreme prematurity itself has been implicated in the resulting neurodevelopmental disorders. A common feature of these disorders is an imbalance between neuronal excitation and inhibition, mediated by developmental alterations of GABAergic interneurons, especially in the prefrontal cortex (PFC). Interneurons are generated through late gestation and mature after birth; increasing evidence suggests that abnormal interneuron development after preterm birth is a critical mechanism underlying cortical dysfunction. To test our hypothesis that alterations in GABAergic interneurons play a key role in preterm encephalopathy and its long-term functional

consequences, we developed a novel pre-clinical model combining mild pre- and postnatal insults: LPS exposure in late rodent gestation (MIA, modeling prenatal infection/inflammation) followed by postnatal chronic sublethal hypoxia (CSH, modeling poor lung function of preterm birth). Using GAD65-GFP transgenic mice to mark GABAergic interneurons, PFC development was assessed. Independently, MIA or CSH lead to transient or limited interneuron disruption. We previously reported that prenatal LPS exposure alone altered progenitor proliferation in the ganglionic eminence, plus migration and survival of these cells at embryonic day E17.5; however, significant rebound recovery appeared to occur. In contrast, sequential use disrupted multiple maturational steps, permanently altering cortical GABAergic circuits, while leaving the majority of NeuN+ excitatory neurons intact. At postnatal day 30 (P30), there was significant loss of GFP+ cells, reflecting loss of multiple interneuron subtypes (parvalbumin, somatostatin, NPY, calbindin, calretinin) in the PFC. Further investigations are focused on deciphering the mechanisms of interneuron loss and the potential for recovery at later developmental stages. Understanding alteration of interneuron populations after neonatal injuries is a critical step in developing targeted therapies to prevent the cortical dysfunction associated with extremely preterm birth.

Title: Differences in lumbar motor neuron pruning in an animal model of early onset spasticity

Authors: *J. E. BRANDENBURG[1,2], H. M. GRANSEE[3], W. Z. ZHAN[4], M. J. FOGARTY[4], G. C. SIECK[4,3]
[1]Dept. of Physical Med. and Rehabil., [2]Pediatric and Adolescent Med., [3]Anesthesiol., [4]Physiol. & Biomed. Engin., Mayo Clin., Rochester, MN

Abstract: Spastic Cerebral Palsy (sCP) is the most common motor disability of childhood with spasticity being the most common sign and ambulation always affected. Despite sCP being poorly predicted by brain imaging, the focus of research has remained on the brain being the driver of the motor impairment and spasticity. By contrast, motor neurons (MNs), via the motor unit and neurotransmitter signaling, are the ultimate target of most clinical therapeutic spasticity treatments in sCP, are the final common output of motor control, and are poorly understood in sCP. MN development in sCP is a critical knowledge gap as the late embryonic and postnatal

periods are not only when the supposed brain injury occurs in sCP, but is a critical time for spinal cord neuromotor development. Therefore, using an animal model of early onset spasticity (*Spa* mouse [B6.Cg-*Glrb*^{spa}/J] with a Gly receptor mutation), we have focused our work on evaluating lumbar MN and motor unit physiology. Similar to previous work in other glycine mutants, we hypothesized that *Spa* mice will have decreased lumbar MN pruning (i.e. a greater number of MNs) with MNs having a smaller somal size. 5-9 week-old *Spa* (Glrb$^{-/-}$) and wildtype (Glrb$^{+/+}$) mice from our *Spa* mouse colony underwent unilateral retrograde labeling of the tibialis anterior (TA) muscle MNs (L2-L4 innervation) via nerve dip of the peroneal nerve. Three days following nerve dip, mice were euthanized, perfused with 4% paraformaldehyde and lumbar spinal cord excised and processed for longitudinal cryosectioning (70-100 µm) and prepared for confocal imaging. Absolute lumbar TA MN counts were obtained using mosaic images of adjacent serial sections, with *Spa* mice having 60% fewer MNs compared to wildtype mice (P<0.01). Somal size measurements were obtained using ImageJ with *Spa* mice having a ~34% reduction compared to wildtype mice (P<0.01). MN pruning and somal size is clearly abnormal in early onset spasticity and is contrary to our hypothesis. Our work now has a two-fold focus. One, as previous work has been in fetal mice; we are exploring MN pruning and somal size in fetal *Spa* and perinatal mice to further understand the timing of the MN pruning. Two, we also propose that these gross alterations in MN pruning may underpin the impaired neuro-motor transmission and force generation in this model of sCP, which are a focus of other ongoing studies.

Title: Investigating the neural mechanisms that underlie neurodevelopmental disorders associated with EHMT1

Authors: *M. ADAM[1], N. HAAN[2], T. HUMBY[3], A. R. ISLES[1]
[1]MRC CNGG, [2]Neurosci. and Mental Hlth. Res. Inst., [3]Sch. of Psychology, Cardiff Univ., Cardiff, United Kingdom

Abstract: *Euchromatic Histone Methyltransferase 1 (EHMT1)* encodes a histone methyltransferase of critical importance for heterochromatin formation and gene silencing.

Haploinsufficiency of *EHMT1* is the primary cause of Kleefstra Syndrome. Additionally, CNVs spanning *EHMT1* have also been associated with Autism spectrum disorder (ASD) and schizophrenia. Further genetic studies have also linked *de novo* mutations affecting *EHMT1* to developmental delay more generally. The severity and breadth of neurodevelopmental phenotypes associated with changes in *EHMT1* dosage are a strong indication of the central importance of this gene. However, a clear understanding of its role in the development and function of the brain is still lacking. Work in our lab showed that *Ehmt1*$^{+/-}$ mouse embryonic stem cells (ESCs) could be differentiated into biochemically normal neural progenitor cells but in significantly reduced numbers, suggesting a neurogenic component to *EHMT1*. Here we aim to explore the role of *Ehmt1* in the brain further, using both a cellular and animal model approach. We have established a novel conditional heterozygous knockout *Ehmt1* mouse line by crossing a floxed *Ehmt1* mouse line with a D6-Cre mouse line leading to forebrain specific deletion mouse model (*Ehmt1*$^{D6cre/+}$). To discern whether haploinsufficiency of *Ehmt1* leads to altered neurogenesis using BrdU on sectioned brain samples from adult *Ehmt1*$^{D6cre/+}$ knockouts and *Ehmt1*$^{flx/+}$ littermate controls. Initial data suggests a trend towards an increase in proliferation in the adult *Ehmt1*$^{D6cre/+}$ compared to the *Ehmt1*$^{flx/+}$ littermate controls. We are now going on to assess survival and differentiation rates differences in these mice. Additionally, these *ex vivo* data was complemented by analysis of primary cell cultures derived from *Ehmt1*$^{D6cre/+}$ brain. Analyses of the neuronal phenotypes found that *Ehmt1*$^{D6cre/+}$ cells showed impaired maturation compared to WT controls, with a significant reduction in DCX+ cells. To complement these findings, RNA-Seq analysis on the primary cell cultures will be undertaken. Finally, the functional consequence of *Ehmt1* haploinsufficiency in the brain has been assessed using behavioural tasks of relevance to the associated neurodevelopmental disorders and/or linked to neurogenesis. We demonstrate that *Ehmt1*$^{D6cre/+}$ knockouts have deficits in sensorimotor gating using the acoustic startle task, and impaired learning and memory using the novel object recognition task and 1-choice serial reaction time task. Taken together, these data provide insight into the neural mechanism that underlie the neurodevelopmental disorders associated with *EHMT1* mutation.

Inst., Boston, MA

Abstract: Eye movements are controlled by distinct motor nuclei in the brainstem that have differential vulnerability to disease. In some congenital cranial dysinnervation disorders (CCDDs), specific subsets of ocular motor neurons (OMNs) show dysinnervation, while other motor neuron (MN) subtypes are unaffected. In contrast, OMNs continue to function until late in the course of Amyotrophic Lateral Sclerosis (ALS), while spinal and other brainstem MNs degenerate. We aim to define developmental gene expression variations among these populations and generate a toolbox of genetic markers to help study these disorders. We used *Islet-1:GFP* and *Hb9:GFP* mice to isolate seven distinct MN pools on embryonic days E10.5 and E11.5 via microdissection and fluorescence-activated cell sorting (FACS): three ocular motor cranial nuclei (CN) affected in CCDDs but preserved in ALS (CN3, CN4, CN6), and four MN types that are affected in ALS as well as in a subset of CCDDs (CN5, CN7, CN12, and spinal motor neurons). RNA-seq analysis was performed on each. Single cell RNA-seq was also done on CN3 and CN4 MNs. Gene expression was validated with database analysis, in situ hybridization, and evaluation of mouse Cre reporter lines. Birthdates of the OMN populations were analyzed via BRDU/EdU injections on different days of development (E8.5-E11.5). RNA-Seq analysis was performed with Genesifter (pooled samples) or SEURAT (single cell data). Each MN population showed unique gene expression patterns, including novel markers of OMNs. Some CN3 subpopulations may correspond to spatially distinct subnuclei and/or temporally distinct populations that are selectively affected in some CCDDs. Overall, these data uncover distinct developmental gene expression patterns and markers of the various cranial motor neurons that provide new tools to study their selective vulnerability in the CCDDs.

Title: Alteration of functional cortical connectivity in a rat model of subcortical band heterotopia

Authors: *V. PLANTIER, F. MARTINEAU, F. WATRIN, E. BUHLER, J.-B. MANENT, I. BUREAU, A. REPRESA
INSERM, Marseille Cedex 09, France

Abstract: Subcortical band heterotopia (SBH) occurs when neocortical neurons fail to migrate to the correct location and accumulate in the subcortical white matter, close to the lateral ventricle. SBH in humans is associated with mental retardation and intractable epilepsy. The syndrome is mainly related with mutations in the doublecortin (DCX) gene. Previous investigations on a rat model of SBH, the DCX-KD rat, suggest that most interictal-like discharges originate in the normotopic cortex and propagate then to the SBH (Petit, Jalabert *et al.* 2014). In addition to this, cortical neurons overlying the heterotopia were shown to exhibit a massive increase of ongoing glutamatergic synaptic currents (Ackman *et al.*, 2009). We therefore postulate that neuronal networks in normotopic cortex experience a significant remodeling that would contribute to the development of clinical manifestations. To evaluate this hypothesis, wistar rats underwent an *in utero* injection/electroporation at E16 of shRNA constructs targeting DCX to generate a SBH, close to the barrel cortex. Two weeks after birth, the functional connectivity to layer II/III in barrel field cortex was investigated using laser scanning photo stimulation of caged glutamate combined with local field and whole-cell patch clamp recordings. Physiologically, barrel cortex circuits are organized in functional columns spanning multiple layers (L1-L6). Our data clearly show network alterations in the DCX rat model, that diverge depending of the position of the barrel analyzed either above or adjacent to the SBH. In the barrels adjacent to the malformation, the column organization was disturbed and the layer II/III received strong excitatory inputs from layers II/III/IV/V and VI compared with control rat barrel cortex. The inhibitory inputs from the same layers to layer II/III were also increased but to a lesser extent signifying a hyperexcitability of this cortical network in SBH-rats. In contrast to this, the barrels placed directly over the heterotopia displayed a dramatic reduction of the excitatory inputs from layers IV to layer II/III while inhibitory inputs were apparently not modified. These results strongly suggest that the presence of band heterotopia associates a significant reorganization of the normotopic cortex network that would impair the normal operation of somatosensory cortex.

Abstract: More than 25,000 extremely preterm infants (EPIs) (children born before 28 gestational weeks [GWs]) are born annually in the United States (approximately 0.6% of all births), and this number is increasing by 7% a year. Although the survival rate of extremely preterm infants has improved, many survivors (25% to 50%) develop cognitive impairment in later life. The reason why cognitive impairment is a common neurological outcome following brain injury in EPIs remains unknown. Moreover, EPIs are more likely to have psychiatric disorders, such as autism spectrum disorders (ASD) and attention-deficit/hyperactivity disorder

(ADHD). In this study, we investigated whether altered neuronal migration might be involved in the pathogenesis of the cognitive impairment that often develops later in EPIs with brain injury. We examined the developing human neocortex and confirmed that neuronal migration continues beyond 23 GWs, the gestational age at which the EPIs are born. We observed larger numbers of ectopic neurons in the white matter in human EPIs with brain injury. To investigate whether preterm brain injury affects neuronal migration, we established a mouse model of EPIs with brain injuries by producing ischemic brain damage in mouse embryos with the occlusions of the maternal uterine arteries and analyzed cortical development. The mice showed delayed neuronal migration, ectopic neurons in the white matter, altered neuronal alignment, and abnormal cortico-cortical axonal wiring. Similar to human EPIs brain injury, the surviving mice exhibited cognitive deficits. These findings suggest that altered neuronal migration by brain injury contribute to the subsequent development of cognitive impairment in EPIs.

Title: Effect of bilateral asymmetry on neuronal connectivity and behavior

Authors: *P. HAN[1], M. D. MERSHA[2]
[2]Biol., [1]Delaware State Univ., Dover, DE

Abstract: Animal body plans tend to display external symmetry; however, their internal organs can be anatomically and/or functionally asymmetrical. Visceral organs such as liver, pancreas, lungs etc. show anatomical asymmetry in a bilateral fashion. Left and right cerebral hemispheres are functionally asymmetric and small deviations have been correlated with pathologies such as schizophrenia and bipolar disorders. Bilateral asymmetry is genetically and developmentally defined as a third axis besides the anterior/posterior and dorsal/ventral axes. We are using *Caenorhabditis elegans* as a model to study the molecular genetic bases of left/right (L/R)

asymmetry. Externally *C.elegans* is predominantly symmetrical but the animal displays clear bilateral asymmetry in the viscera in terms of the gut and gonad placement. In addition, certain neuronal pairs also show asymmetry such as the left and right neurons of the AWC neuronal pair. Mutants affecting early development and spindle orientation have been reported to result in bilaterally reversed embyos, and deletion of a Gα protein coding gene expressed at the 4-6 cell stage has been shown to yield up to 50% sinistral worms. We are looking at initial or early symmetry-breaking steps by recording the rate of sinistral embryos, lethality rates, and the behavior of surviving adults. Our results with various mutants show that surviving adults are impaired in both associative and non-associative learning. We are currently focusing on whether the reversed asymmetry directly correlates with the observed effects on behavior, and mapping potentially atypical neuronal circuits.

Title: An optogenetics based approach for elucidating how high frequency stimulation at the subthalamic nucleus suppresses excessive self-grooming in autism-like mouse models

Authors: *A. STEPANIAN[1], S. ADHIKARI[1], A. D. CHANG[1], J. S. CHUNG[1], V. A. BERGES[1], G. Y. FRIDMAN[2], J. M. BARABAN[3], I. M. RETI[1]
[1]Dept. of Psychiatry and Behavioral Sci., [2]Dept. of Otolaryngology, [3]Solomon H. Snyder Dept. of Neurosci., Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: Approximately one quarter of individuals with an autism spectrum disorder (ASD) display self-injurious behavior (SIB) ranging from head banging to self-directed biting and punching. Electroconvulsive therapy (ECT) can yield up to 90% suppression of SIB frequency; however, these patients typically require frequent maintenance ECT to sustain the improvement gained during the acute course. Long-term consequences of such frequent M-ECT started as early as childhood in some cases are unknown, and there is a need for alternative forms of

chronic stimulation for these patients.
It has been shown that high frequency stimulation at the subthalamic nucleus (STN-HFS) significantly suppresses excessive self-grooming in *Shank3B*$^{-/-}$ mice. Since STN-HFS stimulates both neurons at the STN and fibers of passage that pass adjacent to this nucleus, it is unclear which pathways mediate the acute and persistent suppression of excessive self-grooming by STN-HFS. As it would be important to distinguish between these two mechanisms before considering invasive or non-invasive neuromodulation for patients, we are utilizing an optogenetics-based approach to help determine which pathways mediate the response. We are conducting electrophysiological studies optically stimulating mice at the STN that have been light sensitized by injection of channelrhodopsin (ChR) in the STN or cortical regions that send fibers of passage adjacent to the STN.
Field recordings at the STN with stimulation at 5Hz intervals (5mW, 2ms for 3s) demonstrate near complete spike entrainment at up to 15Hz, before falling at higher frequencies. Using the same stimulation parameters, we evaluated the response to continuous optical stimulation at 15Hz for an hour, and observed almost 100% spike entrainment for the entire duration of the test (n=3).
For fibers of passage, mice were injected in M2 with ChR and 3 weeks later field recordings were made at M2 in response to optogenetic activation at STN. We firstly conducted "collision tests" to demonstrate that the selected field at M2 contains neurons that project to fibers of passage adjacent to the STN. Field recordings at M2 at 5Hz intervals (5mW, 2ms for 3s) demonstrate near complete spike entrainment at up to 8Hz, before falling at higher frequencies. We observe nearly 100% spike entrainment to one hour of continuous optical stimulation at 7 Hz.
We will use this data to guide stimulation parameters for ongoing behavioral experiments, where animals will receive fiber optic implants at either light sensitized STN or M2 (to stimulate fibers of passage). A self-grooming assay will be employed to quantify changes in self grooming following bouts of stimulation.

Title: Mapping the neural circuitry of restricted repetitive behavior: Multimodal neuroimaging in an animal model

Authors: *M. H. LEWIS[1], ***M. H. LEWIS**[1], B. J. WILKES[2], C. BASS[2], H. KORAH[2], M. FEBO[1]
[1]Psychiatry, UF Col. of Med., Gainesville, FL; [2]Psychology, Univ. of Florida, Gainesville, FL

Abstract: Restricted, repetitive behavior is diagnostic for autism spectrum disorder (ASD) and a prominent feature of other neurodevelopmental disorders. Our lab utilizes an inbred mouse strain (C58) that exhibits robust repetitive motor behavior phenotype (vertical jumping, backward somersaulting). Previous histochemical work from our lab suggests that alterations in basal ganglia circuitry mediate the expression of this repetitive behavior. Neuroimaging studies in ASD also support the role of altered basal ganglia circuitry in repetitive behavior, but also suggest that the cerebellum may be involved. In order to further investigate the role of basal ganglia and cerebellar circuitry alterations in repetitive behavior, we performed *ex vivo* magnetic resonance imaging (MRI) and diffusion tensor imaging (DTI) on C58 mice (n=10) and C57BL/6 controls (n=10) reared in standard housing conditions. We performed whole brain voxel-based morphometry (VBM), as well as targeted investigations of volume and fractional anisotropy (FA) in the basal ganglia and cerebellum. We also performed probabilistic tractography to assess intra-basal ganglia connectivity. As with prior work in our lab, we found high rates of repetitive motor behavior in C58 mice, with little such repetitive behavior exhibited by C57BL/6 control mice. Consistent with our hypothesis of indirect pathway dysfunction, to date we have found significant alterations in basal ganglia morphology among C58 mice, including smaller volumes of the globus pallidus and subthalamic nucleus, as well as reduced FA in WM fiber tracts within the basal ganglia. These findings provide novel evidence for alterations in basal ganglia morphology in the C58 animal model of repetitive behavior, and are consistent with human neuroimaging findings of altered basal ganglia morphology in relation to repetitive behavior in ASD.

Title: Hippocampal-specific ampa receptor dysregulation in cdkl5 ki mice

Authors: *M. YENNAWAR[1], R. WHITE[2], F. E. JENSEN[2]
[1]Pharmacol., [2]Neurol., Univ. of Pennsylvania, Philadelphia, PA

Abstract: CDKL5 disorder is a rare neurological disease where patients develop severe seizures, followed by intellectual disability and autistic behaviors. It results from loss-of-function mutations in the gene for cyclin-dependent kinase-like 5 (CDKL5). There are several mouse models of CDKL5 disorder where mice exhibit autistic-like behaviors but not spontaneous seizures. In our investigation of the CDKL5 knock-in (KI) mouse, we previously reported that the mice have deficits in learning, memory and social interaction, as well as motor neuron dysfunction. We now show that adult CDKL5 KI mice have a significantly lower seizure threshold than WT littermates after being administered a subthreshold dose of pentylenetetrazol (n=10, p=0.0099). To investigate the molecular changes underlying the hyperexcitability in CDKL5 KI mice, we performed Western blot analysis of membrane-bound proteins that regulate the excitatory-inhibitory (E-I) balance. We found that the ratio of AMPA receptor subunits GluA2:GluA1 is significantly lower in CDKL5 KI hippocampus compared to WT littermates (n=10, p= 0.0048), and is driven by decreased levels of GluA2 (n=14, p=0.0129). There were no significant changes in NMDA receptor or $GABA_A$ receptor subunits. Decreased GluA2:GluA1 is consistent with the literature of E-I imbalance and suggests that there is an increase in the number of GluA2-lacking, Ca^{2+} permeable (CP) AMPA receptors at the membrane. Increased levels of CP-AMPARs cause alterations in Ca^{2+} homeostasis, and may result in hyperexcitability and altered plasticity. Ongoing electrophysiology experiments are being performed to elucidate the functional consequence of dysregulated AMPA receptors in CDKL5 KI mice. These novel results indicate that molecular changes in the hippocampus of CDKL5 KI mice may underlie the lowered seizure threshold and hippocampal-specific behavioral abnormalities observed in these mice.

Title: Oxidative stress and mitochondrial dysfunction in TALLYHO/JngJ mice - a common link between type 2 diabetes, obesity and Alzheimer's disease

Authors: *J. S. BHATTI[1,2], K. THAMARAI KANNAN[3], P. REDDY[1]
[1]Garrison Inst. on Aging, Texas Tech. Univ. Hlth. Sci. Ctr., Lubbock, TX; [2]Biotech. and Bioinformatics, Sri Guru Gobind Singh College, Sector 26, Chandigarh, India; [3]Texas Tech. Univ., Lubbock, TX

Abstract: Recent studies linked the high prevalence of type 2 diabetes mellitus (T2DM) and obesity with the risk of dementia and Alzheimer's disease (AD). However, the molecular mechanisms linking T2DM and AD are unknown. The present study was aimed to study the biochemical and mitochondria/oxidative stress biomarkers in a mouse model of T2DM, TALLYHO/JngJ (TH). Age and sex matched, SWR/j mice were used as non-diabetic and non-obese control mice. We studied the development of T2DM and obesity in TH mice at 8, 16 and 24 weeks of age by measuring body weight, glucose tolerance, insulin tolerance, and triglyceride levels in TH and SWR mice. Oxidative stress and mitochondrial markers were studied after the development of T2DM in TH and control mice. Compared with age- and sex-matched control mice, both male and female TH mice were significantly heavier, and hyperinsulinemic. The hyperinsulinemia was more prominent in male TH mice than female TH mice. Plasma glucose levels progressively increased with age in male TH mice resulting in type 2 diabetes, while female TH mice remained normoglycemic throughout the study. Interestingly, male TH mice demonstrated a severe increase in plasma triglyceride levels in the pre-diabetic stage that was maintained throughout the study. Oxidative stress and mitochondrial dysfunction were observed in diabetic male mice compared to control, female TH mice. The histopathological examinations show that both the male and the female TH mice had enlarged pancreatic islets compared to control mice. In conclusion, these findings suggest that insulin resistance, hypertriglyceridemia and hyperglycemia causes oxidative stress which then leads to mitochondrial dysfunction in TH mice. Based on these observations, we conclude that TH mice can be used as a relevant model to study the molecular links between type 2 diabetes and Alzheimer's disease.

Title: Decreased rates of cerebral protein synthesis measured *In vivo* in a mouse model of tuberous sclerosis complex: Influence of recycling of amino acids derived from protein breakdown

Authors: R. M. SARE[1], T. BURLIN[1], T. HUANG[1], *D. PICCHIONI[2], C. B. SMITH[1]
[1]Section on Neuroadapatation and Protein Metabolism, Natl. Inst. of Mental Hlth., Bethesda, MD; [2]Intramural Res. Program, NIH, Bethesda, MD

Abstract: Tuberous Sclerosis Complex (TSC) is an autosomal dominant neurogenetic disorder affecting 1 in 6,000 people. TSC usually has effects on the central nervous system manifested by a high incidence of seizures, intellectual disability, and autism. TSC is caused by mutations in either *TSC1* or *TSC2*, which encode for proteins that form a complex and interact with a small GTP-binding protein, RHEB, to inhibit mammalian target of rapamycin complex 1 (mTORC1). mTORC1 is a central regulator of ribosomal biogenesis and translation initiation. We investigated the effects of *Tsc2* haploinsufficiency ($Tsc2^{+/-}$) on regional rates of cerebral protein synthesis (rCPS) measured *in vivo* by means of the L-[1-^{14}C]leucine method. This method is based on the quantitative autoradiographic determination of the amount of labeled product formed (labeled protein) divided by the integrated specific activity of the tissue leucine pool for protein synthesis. There are two possible sources of leucine in the precursor pool: plasma and protein degradation. In this method, the fraction of leucine derived from arterial plasma (lambda) is included in the calculation. In our initial evaluation, we assumed that the value of lambda was unchanged in $Tsc2^{+/-}$ mice, and with this assumption, we found diminished rCPS in freely-moving, awake, male $Tsc2^{+/-}$ mice at 3 months of age. To confirm the validity of this unexpected decrease, we measured lambda in a separate series of WT and $Tsc2^{+/-}$ mice. In the $Tsc2^{+/-}$ animals, the value of lambda is higher compared with WT mice indicating that in $Tsc2^{+/-}$ mice a greater fraction of the precursor pool comes from plasma and a smaller fraction comes from protein breakdown. This substantiates the changes in rCPS that we observed and suggests that the rates of both protein synthesis and protein degradation are decreased. Our results indicate a complex role of mTORC1 in the regulation of cerebral protein synthesis.

Title: Evaluating the role of cohesin complex proteins in memory and learning

Authors: *K. A. EDWARDS[1], B. Z. KACSOH[1], M. B. HOPPA[2], G. BOSCO[1]
[1]Mol. and Systems Biol., [2]Biol., Dartmouth Col., Hanover, NH

Abstract: Mutations in proteins that organize chromatin are often found in neurological diseases, such as Cornelia de Lange Syndrome (CdLS). However, the mechanisms linking chromatin organizers to neurological defects remain unclear. CdLS patients present with microcephaly, intellectual disability, and memory deficits caused by heterozygous loss-of-function mutations in the genes encoding the cohesin complex proteins and the protein that loads cohesin onto chromatin, Nipped-B (NipB). These proteins function together in regulating chromatin structure and gene transcription. Our objective is to determine how cohesin and cohesin-related proteins regulate memory, learning and social behavior in *Drosophila*. In a non-associative social learning and memory paradigm, we can measure how mutations in cohesin or NipB are able to remember and learn. We found that mutations in SMC1, a cohesin protein, impaired memory formation while flies with mutations in NipB have impaired memory retention. Additionally, flies with mutations in Rad21, another cohesin protein, are unable to learn while flies with mutations in SMC1 and NipB have an impaired ability to learn. We are continuing to investigate these phenotypes to evaluate how cohesin and cohesin-related proteins influence memory and learning in adult organisms.

Title: Hyperactivation of ERK/MAPK leads to altered cortical projection neuron outgrowth, reduced activity dependent gene expression, and motor learning deficits

Authors: *G. R. BJORKLUND[1], L. T. HEWITT[2], K. NISHIMURA[1], J. M. NEWBERN[1]
[1]Arizona State Univ., Tempe, AZ; [2]Inst. for Neurosci., Univ. of Texas Austin, Austin, TX

Abstract: A series of well-defined genetic mutations found within the RAS/RAF/MEK/ERK (ERK/MAPK) pathway are the source of syndromes collectively known as RASopathies. A majority of these syndromes result in the upregulation of ERK/MAPK signaling and are linked to intellectual disability and developmental delay. However, it is unknown whether altered cortical connectivity and abnormalities in axonal development contribute to these neurological defects. Additionally, cortical layer and neuron type specific effects on developmental connectivity, motor function, and learning have yet to be investigated fully. Here, we have used a conditional genetic approach to hyperactivate the ERK/MAPK pathway in glutamatergic neurons of the developing mouse cortex. We have found that constitutive activation of MEK1 in glutamatergic neurons across all cortical layers leads to reduced corticospinal elongation and learning deficits in rotarod and skilled reaching and grasping tasks. Moreover, our data indicates this coincides with a reduction in activity-dependent Arc and c-Fos expression throughout the motor cortex. Our experiments will examine whether these behavioral deficits are also linked to altered corticostriatal or callosal projection neuron outgrowth. We have additionally tested whether the changes in axonal outgrowth are due to layer 5 autonomous effects of constitutively active MEK1 using Rbp4:Cre mice. Importantly, we find that the alteration in corticospinal connectivity is indeed layer 5 autonomous. These mutants also exhibit a significant reduction in corticostriatal and callosal innervation. We have not found that these axonal outgrowth phenotypes coincide with changes in rotarod performance and are currently assessing skilled reaching and grasping and activity dependent gene expression. This data suggests that motor learning deficits are not due solely to hyperactivation of ERK/MAPK in glutamatergic neurons in layer 5. Nonetheless, our data demonstrates an important layer 5 autonomous role for MEK1 hyperactivation in modulating long-range axonal connectivity. These findings may provide insight into candidate pathological mechanisms that drive neurological defects in RASopathies.

Title: Ranbp1 haploinsufficiency contributes to cranial neural crest anomalies in 22q11.2 DS

Authors: *T. M. MAYNARD, E. M. PARONETT, C. A. BRYAN, J. A. SABATINO, B. A. KARPINSKI, A. FERNANDEZ, A. S. LAMANTIA
Pharmacol. and Physiol., George Washington Univ., Washington, DC

Abstract: 22q11.2 Deletion Syndrome (22q11 DS) is a neurodevelopmental disorder that impacts 1 in 4,000 live births. Craniofacial anomalies, including cleft palate and other structural defects of the palate, as well as defects in sensory/motor coordination that impair speech and swallowing, are apparent in most individuals carrying with 22q11.2 deletions. We have found that *Ranbp1*, a 22q11.2 DS candidate gene, is a key regulator of multiple aspects of craniofacial development. Mice with homozygous null mutations of *Ranbp1* have a severe, strongly penetrant cleft palate phenotype, with a complete failure of palatal closure, and a concomitant failure to form key neural-crest derived palatal bone structures including the palatal processes of the maxilla and premaxilla. Conditional neural-crest specific knockout of *Ranbp1* yields a highly-penetrant but less-severe phenotype: *Wnt1*-Cre::*Ranbp1* null embryos have closed but highly dysmorphic palatal structure. *Ranbp1* mutation also disrupts the formation of the trigeminal ganglion, mirroring anomalies we have observed in the *LgDel* mouse model of 22q11 DS. Heterozygous *Ranbp1* mutants display a more subtle and variable phenotype: heterozygous mutants show a delay in palatal shelf elevation/extension, as closure appears to be complete in most by E15.5. This delay appears to prefigure minor anomalies in palatal bone structure that are apparent at E17.5, and is accompanied by other subtle craniofacial anomalies. Thus, *Ranbp1* appears to be the first 22q11.2 candidate gene that is able to heterozygously compromise palate formation, as well as disrupt the development of other craniofacial structures, possibly by disrupting the function of key craniofacial signals that pattern the cranial neural crest.

Title: Latrophilin 3: A mouse model of attention deficit hyperactivity disorder

Authors: *N. MORTIMER[1,2], M. RIBASES[1], J. RAMOS-QUIROGA[1], K. LESCH[2], O. RIVERO[2]

[1]Psychiatry, Mental Hlth. and Addiction, Vall D'Hebron Res. Inst. (VHIR), Barcelona, Spain; [2]Dept. of Psychiatry, Psychosomatics and Psychotherapy, Univ. of Würzburg, Würzburg, Germany

Abstract: Attention Deficit Hyperactivity Disorder (ADHD) may be defined as a chronic condition marked by persistent inattention, hyperactivity and sometimes impulsive behaviour. ADHD begins in childhood and persists into adulthood in up to two thirds of cases. Animal models are essential for understanding this disorder. Multiple polymorphisms in the *LPHN3* gene have been repeatedly linked with an increased risk of ADHD, making it an attractive target for modelling in genetically modified organisms. Latrophilin 3 is produced by neuronal cells, localised at synapses and has putative roles in neuronal migration and synapse development. *Lphn3*-deficient mice may incorporate some key attributes of ADHD. Promisingly, previous studies in *Lphn3* -/- mice have reported increased locomotive activity and altered gene expression of dopaminergic and serotoninergic receptors and transporters.

In this study we examine the characteristics of *Lphn3*-deficient mice in multiple behavioural domains. 19 *Lphn3* -/- mice, 20 *Lphn3* +/- mice and 29 *Lphn3* +/+ mice were tested in the open field (OF), light dark box (LDB), object recognition (OR) and Barnes Maze (BM) tasks for respective abnormalities in locomotive activity, anxiety level, recognition memory and spatial memory. A subgroup of *Lphn3* -/- and *Lphn3* +/+ were tested in the social interaction (SI) and resident intruder (RI) paradigms for alterations in sociability and aggression. *Lphn3*-deficient mice's movement parameters were tested in the novel Gaitlab System.

The OF Test has confirmed the increased *Lphn3* -/- locomotive activity phenotype (one way ANOVA p=0.0001). Contrasting this increased horizontal locomotive activity is a drastically reduced rearing activity (one way ANOVA p=0.0001). A reduction in recognition memory of *Lphn3* -/- mice was observed in the OR task (one way ANOVA p=0.004) along with reduced spatial memory and learning ability in the BM test (two-way repeated measures ANOVA p=0.0039). In the RI paradigm *Lphn3* -/- mice displayed dramatically reduced aggression levels with a complete absence of attacks in the 8 null mice tested (Fisher's Exact Test p=0.0007). Despite this reduction in aggression, initial analysis of *Lphn3* +/+ and -/- mice in the SI task has not revealed any significant differences in sociability or social memory. Movement analysis described altered limb positioning of *Lphn3* -/- mice in comparison to *Lphn3* +/+ mice. *Lphn3* +/- mice were not found to be significantly different from WT mice in any of the behavioural paradigms chosen for study.

These findings confirm the Lphn3 null mouse as a promising model of ADHD, which is currently being further expanded upon by molecular analysis including RNA-sequencing.

Title: Ablation of Arx in mature GABAergic interneurons impaired network function via dysfunction of calcium extrusion and sequestration mechanisms in the mouse hippocampus

Authors: *D. J. JOSEPH[1], A. J. MCCOY[1], R. RISBUD[1], E. D. MARSH[1,2]
[1]Pediatrics Neurol., Children's Hosp. of Philadelphia, Philadelphia, PA; [2]Neurol., Perelman Sch. of Med. at the Univ. of Pennsylvania, Philadelphia, PA

Abstract: Transcription factors (TFs) establish the molecular codes that regulate early developmental stages of GABAergic interneurons. The Aristaless Related homeobox (*Arx*) protein is a TF within such regulatory network controlling interneuron development. However, *Arx* remains expressed in mature interneurons, suggesting a divergent, yet unknown, function. We previously showed that postnatal ablation of *Arx*, in interneurons, impaired long term plasticity (LTP) in the hippocampus. Preliminary investigation into the molecular mechanisms mediating these effects suggest a dysregulation in homeostatic basal Ca^{2+} levels. Here, we further investigated the molecular pathways involved in this dysregulation of basal Ca^{2+} levels. To temporally control *Arx* expression, we crossed a floxed *Arx* mouse ($Arx^{fl/fl}$) with a tamoxifen (Tam) inducible Cre^{ER}- mouse, resulting in complete loss of *Arx* 30 days after Tam injection. We reasoned that if changes in homeostatic Ca^{2+} levels is the main factor limiting LTP expression, then elevation of external Ca^{2+} or chelation of excess intracellular Ca^{2+}, or activation of Ca^{2+}extrusion and sequestration pumps could reverse these deficits and rescue LTP. Thus, we recorded field excitatory postsynaptic potentials (fEPSPs) at CA1 synapses in response to Schaffer collaterals (SC) stimulation in $Arx^{+/y}$ and $Arx^{-/y}$; Cre^{ER} mice in normal recording solution, in high extracellular Ca^{2+}, in BAPTA-AM, or in the plasma membrane Ca^{2+}-ATPase pump (PMCA) agonist Phosphatidylinositol 4,5-bisphosphate (PIP2). To measure LTP, baseline fEPSPs were recorded for 30 min in normal solution with last 10 min of recordings in presence or absence of the aforementioned drugs and post-tetanus fEPSPs were recorded in normal conditions.
Our results show that $Arx^{-/y}$; Cre^{ER} mice had reduced LTP and confirmed our preliminary observation that perfusion with higher external [Ca^{2+}] during induction partially restored CA1 LTP to $Arx^{-/y}$ slices. This rescue of LTP in $Arx^{-/y}$ slices was also noted when Ca^{2+} influx was partially blocked by reducing the extracellular Ca^{2+}/Mg^{2+} ratio. BAPTA-AM completely restored

LTP to *Arx*$^{-/y}$ slices. Preliminary results show that pre-application of PIP2 completely restored CA1 LTP in these *Arx*$^{-/y}$ slices. Finally, direct activation of CaMKII in *Arx*$^{-/y}$ slices rescued LTP deficits in 60% of the slices tested.
Our results suggest that postnatal loss of *Arx* elevated postsynaptic Ca^{2+} levels due to impairments of Ca^{2+} extrusion pumps to ultimately limit SC-CA1 LTP. These data suggest that modulation of Ca^{2+} buffering capacity or PMCA pump activity may be temporally targeted for therapy in patients with *Arx* mutations and more broadly in epilepsy.

Title: CASK haploinsufficiency produces developmental retinal ganglion cell pathology and optic nerve hypoplasia

Authors: *A. KERR, C. LIANG, K. MUKHERJEE, M. A. FOX
Virginia Tech. Carilion Res. Inst., Roanoke, VA

Abstract: Optic Nerve Hypoplasia (ONH) is currently the leading cause of childhood blindness in developed nations and its prevalence has been rising steadily over the past decades. Despite its prevalence, we know little about the genetic, molecular, or cellular mechanisms underlying ONH. A previous study described ONH in a cohort of patients with mutations in the X-linked gene CASK. CASK encodes a membrane-associated guanylate kinase (MAGUK) protein with well-established roles in neural development and synaptic function. In addition to ONH, CASK mutations are associated with microcephaly with pontine and cerebellar hypoplasia (MICPCH), X-linked intellectual disability (XL-ID), and autism spectrum disorder. Our previous studies demonstrated that heterozygous deletion of CASK in female mice recapitulate many of the phenotypes observed in patients with CASK mutation, including ONH. Thus, heterozygous CASK mutant mice represent a novel model to gain mechanistic insight into the development and pathogenesis of ONH. Here, we sought to use this model to assess changes in the subcortical visual system in CASK(+/-) mice and, as expected, our results demonstrate that fewer retinal axons are present in the developing optic nerve of CASK(+/-) mice. However, it is important to note that reduced optic nerve (ON) size and retinal axon number are not observed at birth, but

emerge during perinatal development. Accompanied with changes in the ON, we observed reduced retinogeniculate connectivity and a reduction in retinal ganglion cells (RGCs) in these mutants. These are the first results to demonstrate a role for CASK in the development of the subcortical visual development, and they demonstrate that disruption in CASK signaling represents a novel model for investigating mechanisms underlying ONH. For example, we are now using conditional approaches to delete CASK in specific population of cells in the retina, ON, and brain to elucidate cellular mechanisms underlying ONH.

Title: Defective heterochromatin remodeling due to Nde1 loss leads to nuclear architecture aberration of cortical neurons

Authors: *Y. FENG, *Y. FENG, ***Y. FENG**, A. LANCTOT, Y. GUO
Dept. of Neurol. and Ctr. for Genet. Med., Northwestern Univ. Sch. of Med., Chicago, IL

Abstract: The *NDE1* gene encodes a scaffold protein essential for CNS development. Homozygous loss of *NDE1* results in extreme microcephaly and profound mental retardation, while single nucleotide mutations and copy number variants of its locus 16p13.11 are linked to a wide range of neuro-developmental disorders, suggesting that NDE1 aberrance may underlie polymorphic genetic variations and heterogeneous impairments of brain function. Using murine models of Nde1 mutation, we identified a pivotal role of Nde1 in maintaining the genome stability of cortical neural progenitors through facilitating DNA replication and de novo epigenetic modification of the constitutive heterochromatin. We showed that cerebral cortical neurogenesis is concomitant with substantial heterochromatin compression that was compromised by Nde1 deficiency, leading to high levels of DNA double strand breaks in neural progenitors and profound nuclear architecture aberrations in cortical neurons. The genome and epigenome defects in Nde1 deficient neurons were heterogeneous and shared the hallmarks of malignant transformation and degeneration. These results demonstrate that NDE1-depedndent heterochromatin remodeling is indispensable for chromosome structure and genome integrity of cortical neurons.

Title: Functions of ERK/MAPK signaling in GABAergic neuron development and identity

Authors: *M. HOLTER[1], G. R. BJORKLUND[1], S. A. SHAH[1], J. D. NICHOLS[2], J. S. MARTINEZ[1], T. R. ANDERSON[3], J. M. NEWBERN[1]
[1]Sch. of Life Sci., Arizona State Univ., Tempe, AZ; [2]Salk Inst. for Biol. Studies, La Jolla, CA; [3]Univ. of Arizona-College of Med. Phoenix, Phoenix, AZ

Abstract: Perturbations to ERK/MAPK signaling give rise to a family of developmental syndromes, collectively termed RASopathies. Patients with RASopathies exhibit a range of neurological symptoms that include intellectual disability, motor delay, and seizures. Cortical GABAergic neurons are thought to contribute to abnormal neurological function, however, the function of canonical ERK/MAPK signaling in GABAergic neuron development remains poorly understood. To address these questions, we developed transgenic mouse models to induce gain-of- or loss-of-function ERK/MAPK signaling specifically in mouse GABAergic neurons. Our data shows that gain-of-function ERK/MAPK signaling in GABAergic neurons led to the selective loss of fast-spiking parvalbumin-positive GABAergic neurons in the adult mouse cortex. Interestingly, we observed reduced GABAergic neuron number in late embryonic stages of mouse brain development. Studies are underway to determine whether this loss is due to altered GABAergic neuron migration from the ganglionic eminences or early cell death of immature neurons. To reverse GABAergic neuron loss, pharmacological normalization of ERK/MAPK signaling with the MEK inhibitor, PD0325901, is being evaluated. Surprisingly, loss-of-function ERK/MAPK mutations did not yield a comparable degree of GABAergic neuron loss. However, high throughput sequencing of RNA immunoprecipitated from cortical GABAergic neurons harboring mutations to induce loss-of-function ERK/MAPK signaling revealed changes in the expression of various genes important for neuronal differentiation. Whole-cell patch clamp of GABAergic neurons in the juvenile loss-of-function cortex indicated altered physiological properties in fast-spiking neurons that may be explained by changes in connectivity. To fully appreciate these physiological alterations, we have conducted 3D morphological reconstructions to further examine the functional role of ERK/MAPK in GABAergic neuron dendritic outgrowth and activity dependent neuronal development. Continued study of ERK/MAPK signaling in GABAergic neurons will better our understanding

of GABAergic neuron development and mutation specific aspects of RASopathy neuropathogenesis.

Title: Caspar-positive area decrease and dendritic morphological change in the sensorimotor cortex are related to motor coordination dysfunction in neonatal white matter injury model rat

Authors: *Y. UEDA[1], Y. BANDO[2], S. MISUMI[1], A. ISHIDA[1], H. HIDA[1]
[1]Nagoya City Univ. Grad Sch. Med. Sci., Nagoya-Shi, Japan; [2]Asahikawa Med. Univ., Asahikawa-Shi, Japan

Abstract: We established a neonatal white matter injury (WMI) model (Mizuno et al, Neonatology, 2008). The model has slight difficulty in motor coordination without neuron cell loss, which accompanied with oligodendrocyte progenitor cell loss and dysmyelination in the sensorimotor cortex (Misumi et al, Cell Transplantation, 2016). To clarify a question why the motor deficits are induced in our model with no apparent neuron loss, we focused on the histological changes in the sensorimotor cortex. The model was made by right common carotid artery occlusion followed by 6% oxygen for one hour in P3 Wistar rat. Coronal sections in the hindlimb motor cortex (M1) were prepared from adult model rat and processed for the immunostaining. We used contactin associated protein 1 (Caspr) antibody to detect dysmyelination and Golgi-staining to see dendritic morphological alterations. Caspar staining revealed that the positive particle was usually detected as twin-dots and the number of Caspr positive particles was decreased in the H-I side cortex, where less staining of myelin basic protein was shown in our previous data. Golgi-staining revealed that the neurite morphology was different between H-I side and contralateral side. Furthermore, the more dendritic extension was observed in the H-I side of the cortex. These data suggest that the slight difficulty in motor

coordination with no obvious neuron loss in a neonatal WMI model was probably related to less number of Caspr particles and altered dendritic extensions in the H-I sensorimotor cortex.

Abstract: Bipolar disorder, schizophrenia, autism, and intellectual disability are complex neurodevelopmental disorders that debilitate approximately 2.6%, 1.1%, 1.5%, and 1.0% of individuals in the United States, respectively, and millions more worldwide. For each disorder, genetic and environmental risk factors disrupt normal cognition and alter neuronal connectivity, as exemplified by alterations in dendrite and dendritic spine structure. Studies in diverse model organisms have described important roles for the 330 kDa triple functional domain (TRIO) protein in the regulation of dendrite, dendritic spine, and synapse development and function. TRIO mRNA is alternatively spliced, generating isoforms containing combinations of 2 guanine nucleotide exchange factor (GEF) domains and 1 putative kinase domain. A targeted search of the literature reveals that the *TRIO* gene has a significant number of neurodevelopmental

disease-associated *de novo* mutations. A majority of the *de novo* mutations are found in the first GEF domain (GEF1), which activates Rac1, a small GTPase. To determine the impact of these *de novo* mutations and other rare disease-associated variants on TRIO function, we expressed wild type and mutated TRIO protein in HEK293 cells and used a Rac1 biosensor to assay its Rac1 GEF activity. We discovered that 2 TRIO GEF1 mutants had significantly decreased ability to activate Rac1, compared to wild type. To study the behavioral impact of damage to one TRIO allele, we created mice heterozygous for *Trio* deletion in excitatory neurons of the cortex and hippocampus. These mice along with sex-matched, wild type littermates were evaluated using a variety of behavioral tests. Mice heterozygous for *Trio* in excitatory neurons exhibit increased anxiety-like behavior, decreased locomotor activity, and deficits in sociability. Western blot analysis of cortical extracts demonstrated that levels of Trio protein were reduced to approximately half of wild type levels in the heterozygotes. In summary, disease-associated *de novo* mutations decrease TRIO's GEF activity toward Rac1, and haploinsufficiency of *Trio* in excitatory neurons produces deficits with close parallels to neurodevelopmental disorders.

Abstract: Background: Deletions of chromosomal loci that include the *Crk* and *Crkl* genes, *coding for signaling adapters,* have been linked to syndromes that may manifest with abnormal brain development, intellectual disability and seizures but also non-neurological symptoms. *Crk* may be part of the 17p13 deletion seen in Miller-Dieker syndrome (MDS), while *Crkl* is included in the deleted 22q11.2 region in DiGeorge syndrome (DGS). The contribution of *Crk* genes to the neurological phenotypes of these syndromes has not been fully investigated in mouse models.
Objective: To determine if *Foxg1*^{Cre}-driven deletion of *Crk* /*Crkl* in mouse telencephalon results in neurodevelopmental defects and increased seizure susceptibility, as seen in MDS and DGS.
Methods: Foxg1^{Cre}-driven deletion of Crk and CrkL was done in *Crk*^{flox} and *Crkl*^{flox} male and female mice. Littermate control and *Crk*+/-; *Crkl*+/- mice were compared blinded to genotype. Body weights, surface righting time (SRT) and open field activity (OFA) were scored between PN3-19. Barnes Maze test of visuospatial learning and memory was done between PN16-19. Two-hour video-monitoring sessions (PN4-5) were scored for spasms. Separate cohorts were monitored with epidural video-EEG for spontaneous seizures.
Results: *Foxg1*^{Cre}-driven *Crk*+/-; *Crkl*+/- mutants had slower weight gain rates (0.20g/d, n=5) than controls (0.28 g/d, n=20) (P=0.01) and higher failure rates in OFA (60% vs 42.8%, P=0.006) and NG (21.3% vs 9.7%, P=0.004). *Crk*+/-; *Crkl*+/- mutants (n=5) had higher failure rates in the Barnes maze test than controls (n=20) (P=0.02). There were no genotypic differences in the frequency of behavioral spasms between PN4-5. Increased threshold to clonic (P=0.03, median test), but not tonic, flurothyl-induced seizures was noted in PN36-39 *Crk*+/-; *Crkl*+/- (n=4) compared to controls (n=20). Video-EEG monitoring revealed disorganized background (2/2), focal frontal epileptic discharges (2/2) and frontal-onset spontaneous seizures (1/2) in the *Crk*+/-; *Crkl*+/- mice but not in controls (n=4).
Discussion: Conditional *Foxg1*^{Cre}-driven *Crk*+/-; *Crkl*+/- loss in mouse telencephalon could lead to neurodevelopmental, visuospatial learning defects. Although no increased susceptibility to flurothyl seizures was seen, *Crk*+/-; *Crkl*+/- showed spontaneous focal epileptic discharges and/or seizure suggesting a trend towards epilepsy phenotype.

Title: Social isolation during the critical period reduces synaptic and intrinsic excitability of a subtype of pyramidal cell in mouse prefrontal cortex

Authors: *H. YOSHINO[1], K. YAMAMURO[1], Y. OGAWA[2], M. MAKINODAN[1], M. TORITSUKA[1], K. OKAMURA[1], Y. NISHIHATA[1], Y. YAMAGUCHI[1], S. KIMOTO[1], M. YAMASHITA[3], G. CORFAS[4], T. KISHIMOTO[1]

Abstract: Juvenile social experience is crucial for the functional development of forebrain regions, especially the prefrontal cortex (PFC). We previously reported that social isolation for two weeks after weaning induces prefrontal cortex dysfunction and hypomyelination. However, the effect of social isolation on physiological properties of PFC neuronal circuit remained unknown. Since hypomyelination due to isolation is prominent in deep-layer of medial PFC (mPFC), we focused on two types of layer-5 pyramidal cells in the mPFC: prominent h-current (PH) cells and non-prominent h-current (non-PH) cells. We found that a two-week social isolation after weaning leads to a specific deterioration in action potential properties and reduction in excitatory synaptic inputs in PH cells. The effects of social isolation on PH cells, which involve reduction in functional glutamatergic synapses and AMPA/NMDA charge ratio, are specific to the two weeks after weaning and to the mPFC. We conclude that juvenile social experience plays crucial roles in the functional development in a subtype of layer-5 pyramidal cells in the mPFC. Since these neurons project to subcortical structures, a deficit in social experience during the critical period may result in immature neural circuitry between mPFC and subcortical targets.

Abstract: Dysfunctions of thalamo-cortical networks are implicated in schizophrenia. In the neonatal ventral hippocampal lesion (NVHL), a heuristic animal model of schizophrenia, brain oscillation changes similar to those of schizophrenic patients have been reported. The aim of this study was to analyze the effects of short-term deep brain stimulation (DBS) in the thalamic reticular nucleus on electroencephalographic (EEG) activity in the NVHL. Male and female Sprague-Dawley rats were used and the model was prepared by excitotoxicity damage of the ventral hippocampus on postnatal day 7 (PD-7). Chronic bilateral stainless steel electrodes were implanted in the TRN, thalamic dorsomedial nucleus and prelimbic area at PD-90. Rats were classified as follows: sham and NVHL groups, both groups received bilateral DBS in the TRN for 60 min (100 Hz, 100 µs pulses, 200 µA). All animals showed a sudden behavioral arrest accompanied by widespread symmetric bilateral spike-wave discharge, this activity was affected by DBS-TRN. Additionally, the power spectra of 0.5-100 Hz and the coherence of 0.5-4.5 and 35-55 Hz frequencies were modified by DBS-TRN. Our results suggest that DBS in the TRN may modify functional connectivity between different parts of the thalamo-cortical network. Additionally, our findings may suggest a beneficial effect of DBS-TRN on some preclinical aberrant oscillatory activities in a neurodevelopmental model of schizophrenia.

Title: Abnormal craniofacial and neural development in glycosyltransferase mutant zebrafish recapitulates CDG-Ij patient phenotypes

Authors: *L. N. LUDERMAN[1,2,3], E. W. KNAPIK[5,4,2]
[2]Vanderbilt Brain Inst., [3]Program in Developmental Biol., [4]Vanderbilt Genet. Inst., [1]Vanderbilt Univ., Nashville, TN; [5]Dept. of Medicine, Div. of Genet. Med., Vanderbilt Univ. Med. Ctr., Nashville, TN

Abstract: Glycosylation is an important co-translational and post-translational modification required for protein function, such as recognition by ER quality control machinery, binding, structural and metabolic activity. Due to the prevalence and necessity of glycoproteins for normal cellular function, defects within the N-glycosylation pathway result in disruptions in development and function of multiple organ systems, including the nervous, skeletomuscular, respiratory and visual systems. Mutations in over 30 genes involved in N-glycosylation of proteins have been identified as genetic causes of a group of diseases known as congenital disorders of glycosylation (CDG). CDG-Ij is caused by mutations within the *DPAGT1* gene encoding the first glycosyltransferase (GlcNAc-1-P transferase) of the N-glycosylation pathway. CDG-Ij patient symptoms include microcephaly, dysmorphic face, hypotonia, mental retardation, seizures, and exotropia. Recently, clinical studies on CDG-Ij patients have added new phenotypes to the disease spectrum to include neuromuscular phenotypes, although additional studies are needed to understand the full pathology of the disease. Prior work in our laboratory identified a mutant zebrafish line, *stumpf* (*stp*^{m365}), that carries a point mutation in a highly-conserved domain of Dpagt1. Zebrafish *stumpf* mutant phenotype includes malformed craniofacial skeleton and defects in neural tissue development, similar CDG-Ij patient phenotypes. Using both molecular and imaging techniques, the *stumpf* zebrafish mutant provides a unique vertebrate model system to study the mechanism of CDG-Ij and the disease phenotypic spectrum.

Title: Neurosteroids abnormalities in a murine two-hit model of suicide-related behaviors in a schizophrenia-like context

Authors: *C. MAURICE-GÉLINAS[1], J. DESLAURIERS[2], O. HUBERT[1], P. SARRET[1], S. GRIGNON[1]

[1]Univ. De Sherbrooke, Sherbrooke, QC, Canada; [2]Psychiatry, Univ. of California San Diego, LA Jolla, CA

Abstract: Suicide risk in patients with schizophrenia is roughly 5 times more frequent than in the general population. At odds with other clinical conditions, suicidal behaviour in schizophrenia patients does not seem to involve serotoninergic abnormalities, and its pathophysiology remains obscure. One cue to a better understanding might come from the suicide-preventing effects of clozapine, an antipsychotic with superior efficacy and specific neurochemical properties, including modulation of neurosteroid (NS) levels (e.g., allopregnanolone, a NS with known effects on GABA-mediated transmission).We recently characterized a Two-Hit murine Model of Suicide-related behaviors (SRB) in a schizophrenia-like context (THMS). In this model, pregnant C57BL/6 mice are injected with 20 mg/kg of polyinosinic/polycytidylic acid (PolyI:C) at gestational day 12 and their offspring are submitted to social isolation (SI) from postnatal days 21 to 53. In this THMS, clozapine normalized prepulse inhibition, aggressiveness, impulsivity and anxiety-like behaviours. Of note, the NS synthesis inhibitor finasteride increased aggressiveness in THMS mice and antagonized clozapine effects on locomotion, suggesting NS involvement in SRB and clozapine effects in this model.Methods: As a second step to ascertain biological explanation for these behaviors, we assessed the levels of 5-alpha-reductase (5α-reductase), $GABA_A$ subunits, translocator protein (TSPO) and cholesterol side-chain cleavage (p450scc) by qPCR or western blot (WB) analysis in animals subjected to the THMS and/or to subacute clozapine treatment. Results: qPCR analysis and WB analysis of $GABA_A$ delta subunit levels revealed no difference across conditions or treatment. Likewise, no changes in $GABA_A$ alpha4 subunits, 5α-reductase 1 and 2 levels were observed, although WB analysis of overall $GABA_A$α subunits ($GABA_A$α1-6) showed main effects of condition ($p<0.05$) and finasteride ($p<0.05$). Interestingly, gestational inflammation elicited by polyI:C inhibited the stress-induced increase in TSPO and p450scc mRNA levels. Indeed, in the prefrontal cortex and striatum, there was an increase in TSPO expression (+34% and +49%, respectively, $p<0.05$) and p450scc (+65% and +71%, respectively, $p<0.05$) in animals subjected to SI. However, in mice exposed to both conditions (prenatal polyI:C and SI), there was no elevation of TSPO levels and p450scc. Conclusion: Altogether, these results suggest that the THMS is associated with significant modifications of NS signaling. Yet, clozapine effects in this context do not seem to involve prominent changes of TSPO/p450scc levels, nor modulation of $GABA_A$ levels.

Title: The thalamus reticularis nucleus is susceptible to redox dysregulation

Authors: *P. STEULLET[1], J. CABUNGCAL[2], M. R. CUENOD[3], K. Q. DO[4]
[1]Ctr. For Psychiatric Neuroscience, CHUV, Lausanne-Prilly, Switzerland; [2]Dept. of Psychiatry, Univ. Hosp. of Lausanne, Lausanne-Prilly, Switzerland; [3]Ctr. for Psychiatric Neurosci. - Lausanne Univ. Hosp., Prilly-Lausanne, Switzerland; [4]Ctr. for Psychiatric Neurosci., Prilly-Lausanne, Switzerland

Abstract: Oxidative stress is a convergent mechanism affecting prefrontal parvalbumin-expressing interneurons in many animal models carrying genetic and/or environmental risks relevant to schizophrenia. Here, we examined the vulnerability to redox dysregulation of the thalamic reticularis nucleus (TRN), a region consisting of GABAergic neurons, whose vast majority express parvalbumin. Via their inhibition of thalamo-cortical neurons, TRN cells modulate thalamo-cortical communication, which is abnormal in high-risk individuals and schizophrenia patients. Recently, Berretta and colleagues found reduced parvalbumin-immunoreactive (PV-IR) cells and abnormal perineuronal nets in the TRN of schizophrenia patients. We assessed the morphological integrity and function of TRN cells in an animal model of redox dysregulation induced by low glutathione content (*Gclm* KO mice). Oxidative stress was present in TRN of KO mice, from childhood on. The oxidative stress was more prominent in TRN than in other thalamic nuclei. In all ages investigated (postnatal, days 20, 40, 90), there was reduced number of PV-IR cells in KO as compared to WT mice. Likewise, the extracellular perineuronal net surrounding PV-IR cells was altered. The firing pattern and physiological properties of TRN cells recorded in-vitro were also altered in KO mice. During spontaneous activity, less TRN cells generated bursts of action potentials in KO as compared to WT mice. The membrane potential of the TRN cells had to be more hyperpolarized in KO than in WT mice in order to produce depolarization-evoked bursts of action potentials. This indicates that TRN cells are less inclined to fire in bursting mode in KO as compared to WT mice. On the other hand, the fast-spiking tonic firing mode of TRN cells in KO was not altered. Thus, the TRN is highly vulnerable to redox dysregulation and prone to oxidative stress early during development. These data suggest that redox dysregulation could be one mechanism by which the TRN could be affected during the progression of the disease, leading to inappropriate thalamo-cortical communications and affecting for instance sleep spindles as well as selective attention.

Title: Unique connectivity within the necklace subsystem suggests a novel function in olfactory processing

Authors: *T. TAN, K. DRUMMEY, N. BHAGAT, W. GILLIS, J. KATON, K. MESSEMER, C. DIXON, J. NGUYEN, S. R. DATTA
Neurobio., Harvard Med. Sch., Boston, MA

Abstract: Animals have evolved a number of anatomically and molecularly distinct olfactory subsystems to detect and appropriately respond to environmental stimuli. Canonical mammalian olfactory pathways are defined by populations of olfactory sensory neurons (OSNs) that reside within specific zones of the nasal epithelium, project to a small number of specific glomeruli in the olfactory bulb (OB), and synapse onto second-order neurons that route information to a set of higher-brain structures. The GCD “necklace” subsystem exhibits atypical anatomical organization in the periphery, with OSNs located within isolated “cul-de-sacs” of the nasal epithelium; these neurons project axons to a seemingly interconnected string of glomeruli encircling the caudal OB. However, further details about the anatomical architecture of this olfactory subsystem are absent, due in large part to the relative inaccessibility of this subsystem *in vivo* compared to other olfactory systems. To better query the organizational logic of the necklace subsystem, we developed a novel surgical preparation to expose the mouse necklace subsystem *in vivo*. Using this preparation – which provides us unprecedented access to this atypical olfactory system – we performed anatomical tracing to and from individual necklace glomeruli to identify the organizing principles by which this subsystem processes olfactory information. We observe that a single glomerulus is innervated by OSNs that are spread across multiple cul-de-sacs in the epithelium, suggesting that each glomerulus redundantly “pools” olfactory information from across the epithelium, rather than “tiling” physical olfactory space in the nose. Together with earlier results from our laboratory showing that – in stark contrast to other mammalian olfactory systems – each necklace OSN expresses multiple chemoreceptors, our results suggest that the necklace system is built to integrate diverse chemical signals,

suggesting a fundamentally distinct functional role for the necklace subsystem in mediating olfactory driven behaviors.

Title: A deep learning pipeline for studying olfactory bulb molecular anatomy at genomic scale

Authors: *J. B. CASTRO[1], A. ANDONIAN[2], D. PASELTINER[2]
[1]Psychology, [2]Bates Col., Lewiston, ME

Abstract: The olfactory bulb (OB) receives molecularly heterogeneous and topographically organized sensory inputs. While the zonal organization of the OB's inputs is well established, we understand comparatively less about whether this organization is maintained, elaborated, or discarded in the bulb's intrinsic circuitry. To understand the bulb's genomic anatomy -- especially the possible molecular heterogeneity of its mitral cells -- we have registered thousands of in-situ-hybridization (ISH) experiments from the Allen Brain Atlas (ABA) to a set of common OB templates. Doing this at scale requires robust and automated tissue classification for groupwise registration. Here, we describe our use of convolutional neural networks to classify OB sections from the ABA in both supervised and unsupervised contexts. We observe expert-level classification of tissue sections, with accuracy approximately equal to the reproducibility of human-raters (~85% on a 6-class classification task). In preliminary analyses in which we have performed non-negative-matrix factorization based dimensionality reduction on 1,000 registered data sets, we find that gene expression in the mitral cell layer is well-described by 3 non-overlapping spatial modes that explain >90% of expression variance. Intriguingly, two of these modes strongly resemble the dorsal and ventral domains of the bulb defined by OCAM labeled inputs, suggesting that the topographic specialization of bulbar inputs may also be evident in second-order olfactory system neurons.

Title: Loss of cilia on granule cells alters olfactory bulb morphology

Authors: *J. MCINTYRE, A. K. PARKER
Neurosci., Univ. of Florida, Gainesville, FL

Abstract: Olfactory sensory neurons (OSNs) project axons into the olfactory bulb (OB), where they form synapses with mitral cell dendrites in glomeruli. The activation pattern of glomeruli, and associated mitral cells underlie odor coding in the OB. Within this network are interneurons that shape synaptic input from OSNs as well as activity of mitral cells. Glomerular activity also depends on innervation from higher brain regions that supply modulation to the synaptic circuits. For example, neurons in the OB can be modulated by neural hormones associated with hunger and satiety. An unexplored mechanism of neural modulation involves primary cilia, evolutionarily conserved organelles, the function as signaling centers for numerous extracellular cues and several neuromodulatory G-protein coupled receptors (GPCRs) are localized to neuronal primary cilia. The role of neuronal cilia, and the GPCRs enriched in them, however remains unclear. Recent data suggests neuronal cilia regulate dendritic growth and branching patterns as well as agonist induced activity. The goal of this study is to identify neuromodulatory GPCRs within cilia of neurons in the OB and to determine a role for these organelles. Using in situ hybridization and immunohistochemistry we have identified the expression and localization of several neuromodulatory GPCRs in distinct OB neuronal populations. mRNAs for several GPCRs including GPR161, somatostatin receptor type 3 (SSTR3), and melanin-concentrating hormone receptor (MCHR1) were expressed in neurons in the OB. IHC for SSTR3 revealed localization to cilia on mitral cells and granule cells but absent from periglomerular interneurons. In contrast MCHR1 localized to a subset of periglomerular interneurons and granule cells but not mitral cells. Granule cells typically only expressed either SSTR3 or MCHR1, but in a subset of cells they were co-localized. The localization of SSTR3 and MCHR1 to largely interneurons suggests a role for their regulation of granules cells in response to neuromodulators in order to shape olfactory processing. To investigate a potential function of cilia on mature granule neurons, we used Gad2^{ires}Cre mice to selective knockout of the ciliary gene *Ift88*. Loss of *Ift88* resulted in widespread loss of cilia on granule cells. While at 3 weeks of age no morphological changes were seen, at 6 weeks of age, the OB of knockout mice was noticeably disorganized and the glomeruli were significantly smaller. Additionally, innervation by OSN axons and

dopaminergic neurons was decreased. These results indicate that cilia on mature interneurons are important for their function and the maintenance of the OB.

Title: Spatial and functional connectivity of perinatal and adult-born granule cells in the mouse olfactory bulb

Authors: *M. PALLOTTO, K. L. BRIGGMAN
Natl. Inst. of Hlth., Bethesda, MD

Abstract: Granule cells (GCs) are the main GABAergic interneurons of the olfactory bulb (OB). They are produced from birth to adulthood and inhibit the activity of mitral and tufted cells (M/TCs), with whom they make dendro-dendritic synapse. MCs and TCs are functionally distinct cell types and process different aspects of olfactory information, forming two different sub-circuits. The role of GCs in the OB has been extensively investigated. However, whether the time of birth of these interneurons contributes differently to the inhibition of MC and TC output neurons is unknown.
The aim of this work is to investigate, in adult mice, the functional connectivity of GCs with MCs and TCs as a function of the time of birth of GCs and their developmental stage.
We use Pdch::CRE transgenic mice, in which injections of a light activated ion channel, fl-ChETA AAV, allow expression specifically in M/TCs. In OB slices, whole field light stimulation elicits axon potentials in MCs. Using a micro-mirror device (DMD), we are able to selectively light-activate specific M or TCs with high temporal and spatial resolution. In the same mouse, we inject a combination of AAV vectors encoding calcium indicators (GECIs: GCaMP6s or Ruby-GCaMP6s) at postnatal day 2 (p2) or p30 to label and identify perinatal GCs and both immature and mature adult-born GCs. Preliminary data show that both perinatal and adult-born GCs respond to a variety of light stimuli including specific combinations of M and TCs. We are in the process of mapping the spatial distribution of responsive GC cell bodies relative to the distance from the stimulus location (M or T cell bodies).
Lastly, to validate these data we are collecting a 3D volume using serial block-face EM of a mouse injected with AAV of three different colors (GFP, RFP or cerulean) at different time points (p2, p30 and p50). Altogether, these experiments will help us to investigate the specificity of functional connectivity between MCs, TCs and adult-born and perinatal born GCs, and help us to understand better the connectivity among OB neurons and the role of adult generated neurons.

Abstract: Motherhood is accompanied by new behaviors aimed at ensuring the survival and wellbeing of the offspring. Newly appearing maternal behaviors are most likely associated with alterations in neuronal circuits that would in turn affect odor coding. The olfactory bulb (OB), the first central processing center in olfaction, serves as an essential computational hub for odor coding. We recently discovered that motherhood was accompanied by an increased inhibitory drive onto Mitral\Tufted (M/T) cells - the projection neurons of the OB. To study circuit motifs associated with this increased inhibition, we studied the presynaptic connectivity landscapes of M/T cells in naïve mice and mothers using monosynaptic rabies trans synaptic tracing. We targeted M/T cells by using a cre-dependent version of rabies virus injected into the tbet-cre mouse line. Rabies tracing revealed both local as well as long range synaptic inputs on M/T cells, which was then quantified in naïve mice and mothers. While local pre-synaptic landscapes of M/T cells in mothers were stable, several long-range landscapes were dramatically plastic. Specifically, the number of inputs per M/T cells from the piriform cortex (PCx) increased two-fold. These data suggest that feedback connections into the OB have a central role in re-shaping M/T responses following motherhood and signifies the PCx-to-M/T as a central circuit motif for parental plasticity.

Title: Biphasic functions for the GDNF-Ret signaling pathway in chemosensory neuron development and diversification

Authors: *C. R. DONNELLY[1], A. SHAH[2], C. MISTRETTA[2], R. M. BRADLEY[2], B. A. PIERCHALA[2]

Abstract: The development of the taste system relies on the coordinated regulation of cues that direct the simultaneous development of both peripheral taste organs and innervating sensory ganglia. However, the underlying mechanisms remain poorly understood. In this study, we describe a novel, biphasic function for the glial cell line-derived neurotrophic factor (GDNF) in the development and subsequent diversification of chemosensory neurons within the geniculate ganglion (GG). GDNF, acting through the receptor tyrosine kinase, Ret, regulates the expression of the chemosensory fate determinant Phox2b early in GG development. *Ret*$^{-/-}$ mice, but not *Ret*$^{fx/fx}$; *Phox2b*-Cre mice, display a profound loss of Phox2b expression with subsequent chemosensory innervation deficits, indicating Ret is required for initiation of Phox2b, but not its maintenance. Ret expression is extinguished perinatally, but re-emerges postnatally in a subpopulation of large-diameter GFRα1+ GG neurons expressing the mechanoreceptor marker NF200. Intriguingly, we observed that ablation of these neurons in adult *Ret*-Cre/ER^{T2}; *Rosa26*$^{LSL\text{-}DTA}$ mice caused a specific loss of tactile but not chemical or thermal electrophysiological responses. Overall, the GDNF-Ret pathway exerts two critical and distinct functions in the peripheral taste system: embryonic chemosensory cell fate determination and the specification of lingual mechanoreceptors.

Title: Regulation of deep short axon cells (dSACs) in the olfactory bulb as part of a microcircuit involving the gut hormone, glucagon-like peptide-1 (GLP-1)

Authors: *Z. HUANG[1], N. THIEBAUD[2], D. A. FADOOL[3]
[1]Biol. Sci., FSU, Tallahassee, FL; [2]Dept. of Biol. Sci., [3]Prog in Neurosci & Molec Biophys, Florida State Univ., Tallahassee, FL

Abstract: Glucagon-like peptide-1 (GLP-1) and its analogues are promising drug candidates for treating type 2 *diabetes mellitus* given their important role in peripheral glucose metabolism. The recent development of a transgenic reporter for preproglucagon allowed us to previously identify GLP-1 in deep short axon cells (dSACs) and the expression of GLP-1 receptor in downstream mitral cells (MCs) of the olfactory bulb (OB). GLP-1 modulation of MCs was dependent upon potassium channel Kv1.3. While optogenetic analysis of this circuit has been performed, endogenous activation of the dSACs circuit is unknown. Herein, we used an *in vitro*, brain slice approach to investigate the GLP-1 dSACs activation. Juvenile mice (P20 to P45) of both sexes were used to examine the involvement of centrifugal projections from higher brain areas including serotonergic, cholinergic, and noradrenergic afferents. Bath application of serotonin (40 µM, n = 4) and norepinephrine (100 µM, n = 4) had no effect on the evoked firing frequency. Acetylcholine (ACh; 100 µM), however, led to either inhibition or excitation of GLP-1 dSACs. For inhibition, ACh induced a small outward current (5.1 ± 1.8 pA, n = 9) recorded by voltage-clamp when dSACs were held at −70 mV. When injecting a small current in current-clamp mode, ACh delayed the latency to first spike (control: 253 ± 30 ms, ACh: 396 ± 4 ms; n = 2). For excitation, bath application of ACh resulted in 2.1 ± 0.6-fold increase in firing frequency (n = 19). Previous evidence has shown that GLP-1 neurons in the NTS can be modulated by metabolic-related hormones such as leptin and cholecystokinin (CCK). We found that GLP-1 dSACs could be modulated by CCK, but not by leptin. Bath application of CCK (0.8 µM) led to either cessation of firing (n = 7) or an increase in firing of 1.8 ± 0.3-fold (n = 10). When we switched the bath glucose concentration from 22 mM to 1 mM, a subset of GLP-1 dSACs (6 of 16 tested cells) demonstrated a 1.2 ± 0.4-fold increase in firing frequency that was accompanied by a 1-2 mV depolarization. Lastly, mice were injected intraperitoneally (200 nmol/kg) with the GLP-1 analogue exendin-4 or control saline and tested 30 minutes post injection in a habituation-dishabituation odor test. Mice receiving exendin-4 failed to significantly dishabituate, demonstrating impaired ability to discriminate the odor ethyl octanoate from ethyl hexanoate (control: 2.2 ± 1.2 new/old odor explore time ratio, n = 11; exendin-4: 0.7 ± 0.5 ratio, n = 7). Our data support that GLP-1 dSACs are differentially modulated by the neurotransmitter ACh and the metabolic hormone CCK. Some GLP-1 dSACs are glucose sensitive and *in vivo* application of GLP-1 analogue dampens the discrimination of odors.

Title: Spine fluctuations and adult neurogenesis jointly rewire the olfactory network and reshape sensory processing

Authors: *H. RIECKE, J. H. MENG, J. PARK
Engg. Sci. & Applied Mathematics, Northwestern Univ., Evanston, IL

Abstract: The mammalian olfactory system exhibits profound structural plasticity. While large numbers of new granule cells enter the olfactory bulb even in adult animals and form reciprocal synapses with the mitral cells, the spines of the reciprocal synapses of young and old granule cells exhibit highly dynamic turnover. In addition, the granule cells are the targets of extensive centrifugal projections that originate in part in cortical areas. What do these mechanisms contribute to olfactory processing? How do they complement each other? We address these questions using computational modeling.
In recent work on spine fluctuations we have shown that the experimentally observed age-dependence of spine stability can arise from a Hebbian mechanism that stabilizes synapses connecting strongly active cells. Through the resulting restructuring the bulbar network learns to enhance differences between very similar odors [1].
Here we first show that adult neurogenesis alone is sufficient to restructure the bulbar network such that after learning most mitral cells are significantly more strongly adapted to the learned, familiar odor than to a novel odor, as has been observed experimentally [2]. Upon familiarizing the bulbar network with a pair of very similar odors the differences between the bulbar representations of these odors are enhanced, while learning a pair of dissimilar odors reduces their differences, in qualitative agreement with recent experiments [3]. This difference in network evolution also manifests itself in the number of model mitral cells whose odor responses contribute to the differentiation of the odors compared to those that do not [3].
We then investigate a model that combines spine fluctuations and adult neurogenesis, addressing how each contributes to the speed of adaptation and to the network's ability to adapt to completely novel odors. The apical synapses between granule and mitral cells develop much later than the proximal synapses that receive centrifugal inputs. We investigate to what extent this enhances the odor-specificity of the network structure and its odor processing.

Title: Investigating the subtype-specific connectivity of periglomerular cells in the mouse olfactory bulb using correlative serial block-face electron microscopy

Authors: *K. FULTON[1,2], K. L. BRIGGMAN[1]
[1]Neurosci., NIH, Bethesda, MD; [2]Neurosci., Brown Univ., Providence, RI

Abstract: A dense reconstruction of synaptic connectivity requires high-resolution 3D electron microscopy (EM) data. However, EM data alone typically lacks functional information about the neurons in the data. One way to add functional information to an EM dataset is to fluorescently immuno-label tissue for specific functionally relevant proteins and to optically image the distribution of proteins prior to preparing the tissue for EM. Unfortunately, current immunohistochemistry protocols rely on detergent permeabilization, which significantly compromises tissue ultrastructure and renders such protocols incompatible with high quality EM. We recently showed that preservation of extracellular space (ECS) improves access for antibodies with minimal detergent permeabilization (Pallotto and Watkins et al., 2015). We have utilized the ECS preservation in acutely fixed sections and developed a permeabilization-free immunolabeling protocol compatible with serial block-face scanning electron microscopy (SBEM), which permits deep antibody penetration and preserves ultrastructure integrity. SBEM, in combination with immunofluorescent labeling of neuron subtypes in the same piece of tissue, allows us to correlate the morphological and physiological properties of neurons through a dense reconstruction of the synaptic connectivity.
We are utilizing this approach to investigate the differences in synaptic connectivity between neurochemically-distinct periglomerular cell (PGC) subtypes and olfactory bulb (OB) principle neurons, mitral (MCs) and tufted cells (TCs), to understand if PGC subtypes have functionally distinct roles in odor processing. Recent work demonstrated that PGCs differentially modulate the spatiotemporal dynamics of MCs and TCs, which results in antiphase coupling of the MCs and TCs relative to the sniff cycle. Specific connectivity between principle neurons and PGC subtypes would imply heterogeneity in the roles of PGC subtypes modulating olfactory information. However, due to the complexity of the circuit, it has been difficult to study the functional connectivity using standard recording methods. As a result, the functional roles of the

PGC subtypes remain unknown due to a lack of knowledge about how they connect to MCs and TCs. Understanding the connectivity of PGC subtypes with MCs and TCs will be important for future investigations into the subtype-specific involvement in regulating mitral versus tufted cell activity in the OB. Finally, this experiment will challenge the canonical view of olfactory bulb circuitry by potentially revealing previously unidentified wiring specificity underlying OB computations.

Title: Communication between two brain hemispheres: The wiring of bilateral local interneurons in *Drosophila* olfactory system

Authors: *S.-H. LIN, H.-J. LIN, H.-H. CHANG, K.-T. TSAI, Y.-H. CHOU
Inst. of Cell. and Organismic Biology, Academia Sinica, Taipei, Taiwan

Abstract: How two brain hemispheres communicate to each other and to what extent is largely unknown. Understanding how neurons wire to connect two brain hemispheres is essential to know how information is communicated between them. Olfactory local interneurons(LNs) provide horizontal connections inside the antennal lobe(AL), the first olfactory processing center in *Drosophila* olfactory system, and are essential for neural computation and information processing. Our previously work demonstrated that there are unilateral LNs with process restricted in one AL and bilateral LNs that innervate both ALs. Compared to unilateral LNs, the properties of bilateral LNs are largely unknown. Here we characterize bilateral LNs at single-cell resolution by Mosaic Analysis with a Repressible Cell Marker (MARCM), and simultaneously explored their neurotransmitter identities and birth timing. We systematically analyzed all bilateral LNs born in sixteen consecutive twelve-hour time windows covering larval and pupal development and obtained >1078 single cell clones. We found these bilateral LNs have either roughly symmetric or asymmetric innervation patterns in the ipsilateral and contralateral AL. Their morphologies are also highly diverse and likely with certain degree of variability. We are scoring individual bilateral LNs' arborization patterns, and analyzing their synapse distributions and neurotransmitters profiles. Our work will allow us to address whether there is any correlations between bilateral LNs' innervation pattern, neurotransmitters, and /or birth timing.

We will then focus on several types of bilateral LNs to investigate their development and potential biological functions.

Title: Serotonergic modulation differentially targets distinct network elements within the antennal lobe of *Drosophila melanogaster*

Authors: *T. R. SIZEMORE, A. M. DACKS
Dept. of Biol., West Virginia Univ., Morgantown, WV

Abstract: Neuromodulation confers flexibility to anatomically-restricted neural networks so that animals can properly respond to complex internal and external demands. However, determining the mechanisms underlying neuromodulation is challenging without knowledge of the functional class and spatial organization of neurons that express individual neuromodulatory receptors. Here, we describe the number and functional identities of neurons in the antennal lobe of *Drosophila melanogaster* that express each of the receptors for one such neuromodulator, serotonin (5-HT). Although 5-HT enhances odor-evoked responses of antennal lobe projection neurons (PNs) and local interneurons (LNs), the receptor basis for this enhancement is unknown. We used endogenous reporters of transcription and translation for each of the five 5-HT receptors (5-HTRs) to identify neurons, based on cell class and transmitter content, that express each receptor. We find that specific receptor types are expressed by distinct combinations of functional neuronal classes. For instance, the excitatory PNs express the excitatory 5-HTRs, while distinct classes of LNs each express different 5-HTRs. This study therefore provides a detailed atlas of 5-HT receptor expression within a well-characterized neural network, and enables future dissection of the role of serotonergic modulation of olfactory processing.

Title: Keystone relationships of transmitter co-expression predict patterns of local interneuron heterogeneity

Authors: *K. M. LIZBINSKI[1], G. F. MARSAT[1], A. M. DACKS[2]
[1]Biol., [2]Dept. of Biol., West Virginia Univ., Morgantown, WV

Abstract: Heterogeneity in individual neural properties provides a network with multiple coding strategies resulting in greater resolution for information processing. However, the organizing principles that support heterogeneity within a neural class are often poorly understood. Here, we focus on a highly heterogeneous population of local interneurons whose traits co-vary seemingly at random. We systematically determine the co-expression of neuropeptides and GABA by local interneurons (LNs) in the olfactory system of the moth, *Manduca sexta* and find that the high degree of neuropeptide co-expression appears random on a neuron by neuron basis. Using a computational model, we demonstrate that neuropeptides are co-expressed in a specific, non-random pattern, and that deterministic, keystone relationships explain the overall heterogeneity of transmitter co-expression. Olfactory receptor neurons, LNs and projection neurons all expressed four of five neuropeptide receptors and the $GABA_B$ receptor, suggesting that LN activation influences multiple stages in olfactory processing. Tachykinin exhibited “all-or-none” co-expression with other neuropeptides and the tachykinin receptor was not expressed by LNs, suggesting that tachykinergic LNs are functionally distinct from other LN types. Our data demonstrates that the role of LN subtypes are finely tuned by the expression of specific subsets of neuropeptides and that the influence of peptidergic signaling by LNs likely influences multiple stages of olfactory processing.

Title: Ephrin-A/EphA signaling guides embryonic gustatory and somatosensory lingual afferents

Authors: K. DOSHI[1], N. HOSHINO[1], J. HWANG[1], R. W. TREFFY[2], *M. W. ROCHLIN[1]
[1]Dept Biol, Loyola Univ. Chicago Dept. of Biol., Chicago, IL; [2]Univ. of Illinois Chicago, Chicago, IL

Abstract: Ephs and ephrins are cell surface molecules that act as ligands and receptors for one another, initiating signaling cascades that can cause repulsion, arborization, or growth promotion of axons. They are known to have important roles in axon pathfinding and targeting throughout the nervous system, but little is known of their roles in the innervation of gustatory papillae. There are two classes of Ephs and ephrins: ephrin-As are lipid-linked proteins that interact predominantly with EphAs, whereas ephrin-Bs are transmembrane proteins that interact predominantly with EphBs. At the time that gustatory axons are penetrating fungiform papilla epithelium in rats and mice, anti-ephrin-A3 and anti-ephrin-A1 label the lingual epithelium broadly, but the labeling is less intense in gustatory epithelium, particularly the area traversed by gustatory axons. In situ hybridization results support these findings. Anti-EphA5 and -EphA7 label afferents within nascent fungiform papillae. Using stripe assays, we show that ephrin-A-Fc and EphA-Fc fusion proteins repel geniculate (gustatory) and trigeminal (somatosensory) ganglion neurites dose dependently in vitro. Together, these data are consistent with a guidance role for ephrin-As and potentially EphAs during pathfinding and targeting of gustatory and somatosensory axons in the tongue. Intriguingly, ephrin-A3 repels E18 rat-derived geniculate neurites with significantly greater potency than trigeminal neurites. This raises the possibility that ephrin-A signaling corrals gustatory afferents into the center of fungiform papilla epithelium, where the taste bud will form, and segregates them from the less ephrin-A-sensitive somatosensory afferents that supply the surrounding papilla epithelium. Ephrin-B2 is also expressed along the dorsal lingual epithelium, albeit later than ephrin-A1 and -A3, after axons penetrate the epithelium; and ephrin-B-Fcs are repellent in vitro. Combining intermediate concentrations of ephrin-A-Fcs and ephrin-B-Fcs in the same stripe results in additive repellent effects. Preliminary results from triple knockout mice lacking ephrin-A1, -A3 and -A4 suggest that normal innervation depends on ephrin-A signaling.

Title: Cell loss in the rat geniculate ganglion following neonatal chorda tympani transection

Authors: *L. J. MARTIN[1], K. K. SAMSON[2], S. I. SOLLARS[1]
[1]Univ. of Nebraska At Omaha, Omaha, NE; [2]Univ. of Nebraska Med. Ctr., Omaha, NE

Abstract: Outcomes following injury often differ drastically depending on the age during insult. The rat chorda tympani (CT) taste nerve regenerates following transection, unless denervation occurs at or prior to postnatal day ten (P10). We recently found that this lack of regeneration is associated with a dramatic loss of CT terminal field volume in the brainstem 50 days after injury, suggesting that early transection causes CT cell loss. To determine whether cell death can explain the decrease in terminal field after early CT injury, we counted cells in the geniculate ganglion 50 days following CT transection in neonatal (P5) or adult (P50) rats. Adult rats undergoing CT transection were used as controls since there is little to no CT cell or terminal field loss in these animals (Reddaway et al., *J. Comp. Neurol.* 2012, *520* (11), 2395-2413) and transection allows the application of a neural tracer. Female neonatal or adult Sprague-Dawley rats were anesthetized with Brevital, and the CT was assessed through an incision in the neck before being cut. To differentiate CT cells from other geniculate ganglion sensory cells, the nerve was labeled with the long-lasting tracer DiI. After cutting the CT, crystals of DiI (1,1'-Dioctadecyl-3,3,3',3'-Tetramethylindocarbocyanine Perchlorate) or a DiI paste was placed on the cut portion of the nerve. Fifty days after the nerve transection and label, rats were perfused and a portion of the facial nerve was extracted with the geniculate ganglion and greater superficial petrosal nerve attached. Tissue was cut into 10 μm sections using a cryostat. An epifluorescent microscope was used to identify DiI-labeled CT cell bodies in the geniculate ganglion which were traced using Neurolucida (MBF Bioscience). Tissue was stained with cresyl violet, and the total number of ganglion cells was determined by counting cells with a visible nucleolus. Results show that there are significantly fewer ganglion cells in rats that received CT transection at P5 compared to P50 ($t(4) = 3.232$, $p < .05$). On average, there were 278 fewer ganglion cells in the early cut animals, indicating that a large portion of CT cells die following early CTX. This finding suggests that the substantial loss of CT terminal field after early denervation is caused by CT cell death. Additionally, the maintenance of many, but not all, CT cells appears to be dependent on nerve integrity during postnatal development. We are currently assessing the

number of DiI-labeled cells to determine whether ganglion cell loss is limited to chorda tympani cells, or if adjacent gustatory or somatosensory cells are impacted as well.

Title: Altered migration of inhibitory interneurons in a mouse model of intellectual disability

Authors: A. MASET[1], L. GALLA[2,1], *C. LODOVICHI[2,1,3]
[1]Venetian Inst. of Mol. Med., Venetian Inst. of Mol. Med., Padova, Italy; [2]Neurosci. Inst. CNR, Neurosci. Inst. CNR - Fondazione, Padova, Italy; [3]Armenise Harvard CDA, Padova, Italy

Abstract: Oligophrenin1 (OPHN1), a X-linked gene associated to intellectual disability, encodes a Rho-GTPase activating protein that is thought to regulate several developmental processes including axon outgrowth, dendritic maturation and cell migration. How OPHN1 could affect circuit formation and function leading to cognitive dysfunction remain obscure. Neuronal migration is one of the fundamental process that underlies proper assembly and function of neuronal circuits. Migration occurs mostly during embryonic life although it persists in the sub-ventricular zone (SVZ), in adulthood. Neuronal precursors generated in the SVZ, migrate along the rostral migratory stream (RMS) to reach the olfactory bulb (OB), where they become mature interneurons. To understand the impact of OPHN1 on cell migration, we employed a line of mice expressing a null mutation of OPHN1. By combining birthdating experiments and lentiviral vectors to labels progenitors in the SVZ, we found that the progression, the morphology and the directionality of migrating cells is deeply perturbed in OPHN1 ko mice. To investigate the mechanism underlying altered cell migration, we performed time-lapse of migrating neuroblasts, *in vivo*, testing compounds that have been shown to modulate cell migration, such as GABA. GABA is abundantly present in the rostral migratory stream. It is produced by migrating neuroblasts and is known to modulate rate of migration acting on neuronal precursor in a paracrine-autocrine manner. We found that the response to GABA of migrating neuroblasts was deeply altered in OPHN1 KO mice.

Title: Interneuron migration and synaptic integration in Lis1 mutant mice

Authors: *T. G. EKINS[1,2], J. A. D'AMOUR[1], C. J. MCBAIN[1]
[1]NIH/NICHD, Bethesda, MD; [2]Brown Univ., Providence, RI

Abstract: Classical lissencephaly is a neuronal migration disorder caused by PAFAH1B1 (Lis1) haploinsufficiency and is characterized by developmental delays, agyria, mislamination of brain structures and epilepsy. In the current study we investigate the consequences of lis1 haploinsufficiency at the cell and circuit level. To this end, we have utilized lis1 heterozygous (lis1+/-) and a lis1 conditional knock-out mouse lines (Lis1fl/+). The latter was crossed to several cre lines to conditionally delete one copy of lis1 selectively in pyramidal cells (Emx1-Cre), all interneurons (INTs; Dlx5/6-Cre) or a subset of INTs that are derived from the medial ganglionic eminence (Nkx2.1-Cre). Emx1-Cre heterozygous deletion of lis1 resulted in heterotopic banding similar to the lis1+/- mouse, while Nkx2.1-cre heterozygous deletion did not result in heterotopic banding. We observed that by late adolescence, the same number of parvalbumin+ interneurons, somatostatin+ INTs, and reelin+ INTs are present in CA1 for all of the previously listed genetic lines. However, within CA1, these INT populations were shifted to more superficial regions away from stratum oriens and towards stratum radiatum across. These results suggest that INTs reach the hippocampus in normal numbers but are mislocated along the radial axis, suggesting that the second phase of INT migration (radial migration) is disrupted in lis1 mutant mice. Interestingly, this is true for lines where only PCs lack lis1, and where only INTs lack lis1, suggesting that both expression of lis1 in INTs and PC somatic position are necessary for proper migration of interneurons. To further study this phenomenon, we will use a tamoxifen inducible Nkx2.1-cre line crossed to Lis1fl/+ mice at various embryonic time points (e12-e17) to closely follow the tangential and radial migration of small groups of INTs into the hippocampus. Subsequently we will isolate the time point where the most radial migration of INTs occurs and image this migration in real-time using live slices from embryonic mice. In addition, to investigate how migration deficits may affect hippocampal connectivity we will perform electrophysiological analyses in lis1 mice to assess the intrinsic physiology, functional properties and synaptic integration of INTs within hippocampal networks. We anticipate that our study will reveal the circuit deficits relating to INT function that may underlie the increased propensity for epileptic episodes that is described in lissencephaly.

Title: A role for Med12 and Wnt signaling in regulation of oxytocin expression

Authors: *E. D. SPIKOL, E. GLASGOW
Dept. of Oncology, Georgetown Univ., Washington, DC

Abstract: The neuroendocrine system controls homeostasis, metabolism, mood and sexual behaviors. Disruptions in its development and regulation are associated with congenital abnormalities and neuropsychiatric disorders, necessitating a more thorough understanding of molecular control of neuroendocrine cell populations. Reduced oxytocin is a feature of Prader-Willi syndrome, a neurobehavioral disorder characterized by dysregulated social behavior and insatiable appetite. Here, we find that oxytocin expression is eliminated in med12 mutant embryos, while upstream regulators remain intact. Med12 is a regulatory component of the Mediator complex, which facilitates interaction between gene-specific transcription factors and general transcription machinery. Since Med12 was shown to transduce Wnt-signaling, and Wnt-signaling is known to influence patterning of the hypothalamus, we hypothesized that disruption of Wnt-signaling was responsible for lost oxytocin expression in med12 mutants. Indeed, we found that Med12 is largely epistatic to Wnt-signaling, thus confirming a role for Med12 in Wnt-signaling during zebrafish development. However, we also found that oxytocin expression was reduced in apc mutants, which have overactive Wnt-signaling, and unchanged in embryos treated with Wnt inhibitors. These surprising results indicate that the role of Med12 in oxytocin expression is independent of Wnt-signaling. Additionally, suppression of Wnt-signaling appears to be required for oxytocin expression. Using a chemical Wnt activator, we found that sensitivity of oxytocin cells to overactive Wnt signaling aligns with the earliest recorded oxytocin expression, around 30 hours post-fertilization. We hypothesize that a transient Wnt-repressive center is required for oxytocin cell and hypothalamic development. A more complete understanding of the molecular control of oxytocin expression is especially relevant given the increasing appreciation for the role of oxytocin in social behavior and mental health.

Title: Effects of prenatal alcohol exposure in rats on corticotropin-releasing factor type 1 receptor expression throughout the limbic system and hypothalamus

Authors: *S. BOUQUIN[1], C. R. OLGUIN[1], J. WAGNER[2], D. D. SAVAGE II[3], N. PENTKOWSKI[2]

Abstract: Prenatal alcohol exposure (PAE) detrimentally affects the development of numerous biological systems. Previous work indicates that animals with a history of PAE exhibit normal basal corticosterone levels, yet are stress hyper responsive, which may result from alterations in the corticotropin-releasing factor (CRF) signaling system. CRF controls the hypothalamic-pituitary-adrenal (HPA) axis response to stress via actions at two G protein-coupled receptors, termed CRF_1 and CRF_2. Chronic stress over activates the HPA axis, which in turn, increases CRF production and increased expression of CRF_1. Previous studies using CRF knockout mice indicate differential involvement of CRF_1 and CRF_2 in mediating stress. After exposure to chronic stress, CRF_1 knockout and double knockout mice were resistant to the negative effects of stress, while CRF_2 knockout mice exhibited heightened anxiety and sensitivity to stress. It has been proposed that CRF_1 and CRF_2 work in conjunction as a negative feedback loop, with CRF_1 acting as the excitatory mechanism and CRF_2 acting as the inhibitory mechanism. While evidence indicates that PAE increases both HPA responsivity and CRF levels, it is still unclear whether or how PAE affects basal CRF receptor expression. This study examined the effects of PAE on CRF_1 expression in key brain regions related to cognition and stress responsivity (hippocampus, hypothalamus, prefrontal cortex and amygdala). Adult Long-Evans rats (n=29) from either PAE litter dams (n=14) or saccharin litter dams (n=15) were perfused with 4% paraformaldehyde, and the brains were removed, cryoprotected, sectioned and processed for CRF_1 expression. Overall, no statistically significant differences in CRF_1 levels were observed between PAE and control animals. In the prefrontal cortex and hypothalamus, both control and PAE males had higher CRF_1 levels compared to females. However, in the hippocampus, both control and PAE females had higher CRF_1 levels compared to males. These results indicate sex differences in brain regions affected by PAE.

Title: Hippocampal dentate gyrus impairments in Gnb5 heterozygous mice

Authors: *A. AWE, J. ZHANG, M. PANDEY, P. ADIKARAM, W. F. SIMONDS
Natl. Inst. of Diabetes and Digestive and Kidney Dis., NIH, Bethesda, MD

Abstract: Gβ5 is a structurally divergent isoform of the Gβ protein family that is encoded by *Gnb5*. Gβ5 in combination with the R7 subfamily of regulator of G-protein signaling (R7-RGS) proteins and the R7-RGS binding protein regulate G-protein coupled receptor signaling in the brain by accelerating inactivation of $G\alpha_{i/o}$ subunits. Homozygous knockout of *Gnb5* in mice results in alterations in motor learning capacity and structural abnormalities in the brain, including in the hippocampal dentate gyrus (DG), a structure essential to memory formation and spatial navigation. Furthermore, homozygous loss of function mutations in *GNB5* in humans results in a recently-described cognitive disability and unique neuropsychiatric phenotype characterized by motor and speech delays, and attention deficits. However, although roughly 2% of the human population is heterozygous for damaging *GNB5* mutations, little is known about potential impairments in mice or humans heterozygous for *Gnb5* loss of function mutations. This study investigates possible hippocampal DG impairments in $Gnb5^{+/-}$ mice and any associated functional consequences. Employing cresyl violet and immunohistochemistry staining techniques, we investigated possible alterations to the structural organization of the DG and perturbations in cell composition of the DG hilus. We show that $Gnb5^{+/-}$ mice develop lateralized abnormalities of left versus right DG hilus area that were not observed in *Gnb5* wild-type mice. Further, we observe a more pronounced abnormality in left hilus area than the right hilus. We find that $Gnb5^{+/-}$ mice also display perturbations in DG hilus cell composition affecting both neurons and glia. These findings demonstrate that *Gnb5* heterozygous mice have distinct structural and compositional abnormalities in the hippocampus that may result in altered dentate gyrus functions pertaining to memory formation and spatial navigation.

Title: Experimental demyelination and synaptic development in the olfactory peduncle

Authors: L. COLLINS, E. VOGT, *P. C. BRUNJES
Dept Psychol, Univ. of Virginia Dept. of Psychology, Charlottesvle, VA

Abstract: The olfactory forebrain is interconnected through two large white matter tracts: the lateral olfactory tract (LOT) transfers information from the olfactory bulb to the ipsilateral olfactory cortex while the anterior commissure (AC) interconnects the left and right olfactory cortices. We assessed if these tracts are susceptible to experimental demyelination and, if so, whether they might have the capacity to remyelinate, as suggested by their proximity to the to the subventricular zone. Lysolecithin-induced demyelination and remyelination was examined at multiple post-injection times with electron microscopy. Significant demyelination was seen 7 days post-injection (dpi) and evidence of remyelination was observed by 21dpi in both tracts. The findings indicate that the olfactory system could be an important model for studies of myelin regulation. A second group of studies was prompted by our previous work showing that the tracts develop differently, with the LOT myelinating 2-3 days earlier than the AC. The anterior olfactory nucleus (AON) may reflect the largest effects of these developmental changes as it is the first area to receive information from the LOT and it provides most of the axons that cross in the AC. Four parallel studies were performed to understand general synaptic development in pars lateralis of the AON. First, regional differences in the development of excitatory (VGLUT1 and VGLUT2) and inhibitory (VGAT) terminals were measured. Both VGLUT1 and VGAT endings were very dense. VGLUT1 was evenly spread through all layers while VGAT staining was highest in superficial Layer 1. VGLUT2 synapses were sparse and concentrated just beneath the LOT. Second, perineuronal net staining was observed as early as P5. Brevican was found primarily around pyramidal cell bodies and aggrecan on apical dendrites. Third, an examination of early vascular development indicated that vessel caliber decreases from P5-P30 while density remains the same. Finally, we made a detailed analysis of the terminations of axons coursing through the AC and synapsing in the contralateral AON. Axons were visualized by injections of fluorescent AAV into the right AON. Consistent with previous reports most contralateral labeling occurred in layer 2 of pars lateralis, with progressively less in dorsalis, ventroposterior, and medialis. Reconstructions indicate that contralateral axons are simple with few branch points. Electron microscopic analyses to localize synaptic sites are presently underway.

Title: Coordinated electrical activity in the olfactory bulb gates the oscillatory entrainment of entorhinal networks in neonatal mice

Authors: ***S. GRETENKORD**, J. K. KOSTKA, H. HARTUNG, A. MINIER-TORIBIO, I. L. HANGANU-OPATZ
Developmental Neurophysiol., Univ. Med. Ctr. Hamburg-Eppendorf, Hamburg, Germany

Abstract: Olfactory inputs from the environment are critical for the survival of newborn mice, but their impact on the development of higher cognitive functions and the limbic system is poorly understood. In contrast to the other sensory systems, which are underdeveloped during the early postnatal period, olfaction reaches full maturity already during intrauterine life and controls mother-offspring interactions. It is, however, still unknown whether early olfactory inputs drive the development of limbic networks. Here, we aim at understanding the structural and functional principles underlying the connectivity and communication between the olfactory bulb (OB) and lateral entorhinal cortex (LEC) - the gatekeeper of limbic circuitry -, during neonatal development. For this, we combine tracing of long-range OB-LEC connectivity with extracellular and patch-clamp recordings from the OB mitral cell layer and LEC in vivo, as well as pharmacological and optogenetic silencing of the OB. We show that discontinuous oscillations with main frequency within the theta band (4-12 Hz) accompany the respiration-related activity in the OB of neonatal mice. They time the firing and synaptic activity of mitral cells. The coordinated activity provides tight coupling by synchrony and directed interactions between OB and LEC. This functional communication relies on early emerging axonal projections of mitral cells to LEC. These findings elucidate the structural and physiological signature of OB-to-LEC communication during early development. Taking into account that LEC drives prefrontal-hippocampal networks during the neonatal period, coordinated activity in the OB might facilitate the maturation of limbic circuitry.

Title: Differential transcription factor expression in two medial amygdala neuronal subpopulations is implicated in components of innate behavioral responses

Authors: *J. E. LISCHINSKY, M. GOODRICH, M. J. HERRERO, J. G. CORBIN
Children's Natl. Med. Ctr., Washington, DC

Abstract: Innate behaviors such as mating and aggression are essential for the propagation of species. The medial amygdala (MeA) is part of the limbic system and is one of the main processing centers for instinctive behavioral cues as it is only two synapses away from olfactory sensory neurons in the vomeronasal organ. Previous work from our laboratory has shown that expression of two transcription factors, Dbx1 and Foxp2, marks two distinct MeA progenitor populations destined to generate two distinct mature subpopulations as defined by molecular and electrophysiological criteria. Furthermore, these populations are both activated during mating and aggressive social behavioral cues, with the latter in a sex-specific manner. In contrast to activation by social cues, *Dbx1*-derived and Foxp2+ neurons are not activated during exposure to non-social cues such as predator odor, which activates another developmentally defined MeA subpopulation. Thus, social versus non-social amygdala responses are predicted by patterns of transcription factor expression at the progenitor stage and may be engaged during different subcomponents of olfactory-driven innate behaviors.

Abstract: *FOXP2*, a transcription factor previously identified as a 'language gene', regulates a variety of autism-linked genes in the cerebral cortex and striatum (e.gs. *Auts2*, *CNTNAP2*, *CTBP1*, *FMR1*, *MET*, *Pax6*, *Plaur* and *SRPX2*). Moreover, *FOXP2* has a score of 3 (suggestive evidence) on the AutDB/SFARI autism scale. However, little is known about the role of FOXP2 in the amygdala, a key part of the limbic system involved in social function. Our recent work revealed that Foxp2+ neurons in the medial amygdala (MeA) are activated by innate reproductive and aggressive behaviors, two social behaviors modulated by olfactory input (Lischinsky *et al.*, *eLife* 2017). Based on these findings we next sought to investigate the identity of Foxp2+ neurons in the MeA and to study how Foxp2 is mechanistically linked to mouse amygdala development and social function. Exploring the identity of MeA Foxp2+ cells in mice, we find that Foxp2+ neurons express several markers related with neuronal development and social behavior. Moreover, RNAseq analysis of FACs sorted Foxp2+ cells revealed high expression of autism-risk genes within this population. Our present data provides a set of indicators for functionally assessing *Foxp2*-driven mechanisms in early development, and amygdala-related social behaviors in adult mice. Deciphering such mechanisms in the amygdala may help to better understand the underlying genetic mechanisms mediating social dysfunction in autism.

Univ., Portland, OR; [7]Section on Integrative Neuroimaging, NIH, Bethesda, MD; [8]Dept. of Psychiatry, Univ. of North Carolina, Chapel Hill, NC

Abstract: Early life stress, including adverse caregiving experiences, is a major risk factor for psychopathology, and social and cognitive deficits. How maltreatment affects neurobehavioral development is not well understood and challenging to disentangle from heritable factors. This study utilized a well-established nonhuman primate model of spontaneous maternal maltreatment (MALT) leading to infant distress. In this model, the highest rates of abuse and rejection co-occur with rapid brain development and limbic maturation, leading to long-term effects on socioemotional behavior, and alterations in amygdala (AMYG) and white matter development. To disentangle the effects of experience from inheritance we used a unique cross-fostering design with random assignment of infants to control or maltreating foster mothers. This study delves into neurodevelopmental alterations underlying behavioral and stress outcomes, focusing on AMYG functional connectivity and structural development in the juvenile period. We collected (1) structural MRI in 42 infant rhesus (20 Control (11 F, 9 M), 22 MALT (8 F, 14 M)) during infancy (2 wks, 3, 6 mo) and juvenile period (12, 18 mo), and (2) resting state functional MRI to examine AMYG functional connectivity (FC) in a subset (13 MALT (6 F, 7 M) and 13 Controls (7 F, 6 M)). We have reported weaker prefrontal cortex-AMYG FC in MALT during development - we extend these studies to examine alterations in AMYG FC to other regions, performing a voxel-wise AMYG seed-based FC analysis at the group level. Stronger positive FC was found in MALT with regions regulating fear and processing socioemotional stimuli: right-left AMYG FC, periamygdaloid ctx, piriform ctx and superior temporal gyrus; brainstem- locus coeruleus, laterodorsal/dorsal tegmental areas, parabrachial complex, Inferior cerebellar peduncle and spinal vestibular nuclei. Stronger negative FC detected with the cerebellum in MALT (all results $p<0.005$, cluster threshold >2 voxels, uncorrected for multiple comparisons). Stronger FC between these regions in MALT suggest increased processing of socioemotional

stimuli, especially related to fear-learning. Fear-potentiated startle studies in these animals, now adolescents, are consistent with this interpretation - MALT show elevated fear potentiated startle, and impaired discrimination of fear and safety cues, suggesting impaired fear regulation. Our group reported larger AMYG volumes in MALT during adolescence associated with increased emotional reactivity - we are extending these studies to examine the emergence of these effects on total brain, gray and white matter, cortical, and hippocampal and AMYG volumes.

Title: Impact of pre-weaning high fructose diet on basolateral amygdala development and socioemotional behavior

Authors: *C. E. BARRETT, A. MENIGOZ, C. BATTERMAN, J. GUO, D. G. RAINNIE
Dept. of Psych. and Beh. Disorders, Emory Univ., Atlanta, GA

Abstract: Type 2 diabetes mellitus (T2DM) is now at epidemic proportions in the US population, with ~10% of the population having T2DM and 35% with pre-diabetic metabolic disorder. The incidence of T2DM in children has risen by > 30%, together with a parallel increase in co-morbid psychological disorders. Children with T2DM are at increased risk of psychiatric disorders, suggesting commonalities in environmental etiology and neural circuitry early in development. Aberrant activity of basolateral amygdala (BLA) principal neurons is thought to be critically involved in the pathophysiology of psychiatric disorders, many of which emerge early in life. We hypothesized that pre-weaning exposure to a high fructose diet (pw-HFrD) would disrupt normative development of BLA principal neurons and be associated with behavioral abnormalities. We examined socioemotional behavior (n=12 males, 12 females per diet group) and single cell BLA gene expression across development in pw-HFrD and control rats. Pw-HFrD lead to a behavioral profile of hyperactivity and increased risk taking as evidenced by increased distance traveled in the open field in males ($p=0.041$), reduced time spent immobile in a forced swim test in both males ($p=0.03$) and females ($p=0.02$) and increased time

in the open zones of an elevated-O maze in males (p=0.001) and females (0.013). pw-HFrD males also displayed reduced startle amplitudes (p=0.018), and females displayed enhanced social interaction time in a social preference test (p=0.0062). Pw-HFrD animals also displayed alterations in genes involved in metabolic regulation in BLA principal neurons. pw-HFrD causes premature expression of insulin and insulin-like growth factor receptor (Igfr) mRNA prior to weaning and abnormally high levels of Igfr mRNA even after weaning. pw-HFrD also causes significant and long-lasting changes to the expression of mRNA for Ampk subunits and other components of the AMPK signaling cascade. Significantly, we have shown that intracellular manipulations of the AMPK pathway regulates electrophysiological properties of BLA principal neurons, and that local AMPK manipulations in vivo alter anxiety-like behavior. Hence, we would predict that disruptions of this pathway during key periods of development resulting from a pw-HFrD would likely result in long-lasting and deleterious effects on emotional processing in the extended amygdala. Uncovering disruptions in metabolic pathways shared between juvenile-onset diabetes and affective disorders may be a crucial step in developing new therapeutic strategies effective at improving the physical and psychological health of those suffering from these metabolic disorders.

Title: Immunohistochemical characterization of the rat habenulo-interpeduncular tract during postnatal development

Authors: A. KUMAR, B. VREELAND, *S. E. MCCALLUM
Dept. of Neurosci. and Exptl. Therapeut., Albany Med. Col., Albany, NY

Abstract: The habenulo-interpeduncular pathway (Hb-IPN) serves as a relay station, linking limbic forebrain and midbrain/hindbrain regions, and has emerged as a key circuit in the regulation of nicotine reinforcement, dependence and withdrawal. Major transmitter systems in this pathway include acetylcholine, substance P and glutamate. Recently, expression of the orphan G-protein-coupled receptor, GPR151, has also been identified in this pathway, however a specific function for this receptor is not known, nor has an endogenous ligand been identified. This protein is unique in that it is restricted to the Hb-IPN, a pattern that is highly conserved across multiple species (Broms, et al., Comp. Neurol., 2015). Moreover, genetic deletion of GPR151 causes multiple behavioral deficits in mice and attenuated responses to nicotine

(Kobayashi et al., Front. Behav. Neurosci, 2013).
In this study, we sought to characterize the Hb-IPN pathway throughout postnatal development, using immunohistochemistry. Brains from male and female rats of different ages (postnatal days 2, 5, 8, 14, 21, 35 and adult) were processed for immunohistochemistry and, using confocal microscopy, patterns of GPR151 expression were characterized in the Hb and the IPN. In addition, co-localization of GPR151 with major neurotransmitters abundant in the Hb-IPN (acetylcholine, substance P, and glutamate) was evaluated at the same time points.
Preliminary results reveal differences in GPR151 expression in the Hb-IPN throughout postnatal development. In early postnatal brain (P2), GPR151 expression in the medial habenula (MHb) is localized to the dorsomedial subregion, but emerges in the ventral MHb by P8 and through adulthood. In co-localization studies, differences between early postnatal and adult brain have been observed. Most importantly, little to no co-localization with choline acetyltransferase (ChAT) was observed in the MHb of P2-P8 animals compared to more extensive co-localization of GPR151 and ChAT in the adult MHb. The expression of GPR151 in the lateral habenula (LHb) is higher in brains of P2-P8 rats compared with older rats, but is generally abundant in this region throughout each stage of postnatal development. Consistent with previous findings, (Broms et al., 2015), we found that GPR151 was localized to axons and not found in cell bodies. Despite having no known ligand, GPR151 is a promising pharmaceutical target for multiple conditions, ranging from mood disorders to nicotine addiction. Furthermore, since GPR151 is present in rodent brain as early as E16.5 (Quina et al., J. Neurosci., 2009), it may play a role in mediating developmental responses following prenatal nicotine exposure.

Title: Neural crest derived chromatophores in red-eyed tree frogs

Authors: *P. SANGUANVICHAIKUL[1], A. NKETIAH[2], M. DE BELLARD[3]
[1]biology, California State Unversity Northridge, Panorama City, CA; [3]biology, [2]California State University, Northridge, Northridge, CA

Abstract: The Red-Eyed Tree Frog has striking skin colors that allows it to select mates. Skin coloration comes from neural crest stem cells that give rise to melanocytes and chromatophores. Although chromatophores had been studied in other organisms like chameleons and fish, their

location and phenotype has not been studied in these tree frogs. The purpose of this study is to develop skin histology methods and identify neural crest derived cells. For this, we used immunofluorescence to label different cells within the skin. Thus, we were able to identify poison and mucous glans as well as other neural crest derived cells in the skin of adult frogs. We are beginning to collect similar samples from tadpoles and froglets. We plan to continue mapping the histology during the different stages of development and eventually cell cultures. By doing so, we can follow the development of melanocytes and chromatophores.

Abstract: Aniridia is a congenital and progressive disorder affecting approximately 1 in 83,000 live births. Although the disorder is most well known for its ocular phenotypes, the condition has several other abnormalities, which are only recently emerging as prominent features of the disorder. These include neural, sensory, cognitive, and auditory processing deficits. Development of aniridia in humans is predominately caused by heterozygous loss-of-function mutations in the *PAX6* gene, a highly conserved transcription factor critical for normal eye and brain development. Previous studies of patients with aniridia using magnetic resonance imaging (MRI) have shown changes in interhemspheric connectivity and grey matter volume. Our lab has

utilized 3T MRI to show structural changes in the brains of aniridia patients as compared to their *PAX6*-normal comparisons. Consistent with other reports, we found reductions to major fiber tracts such as the anterior commissure, posterior commissure, and optic chiasm in addition to lack of or reduction of the pineal gland. The cellular basis for these changes are not well understood. To better understand the role of *PAX6* in brain development and adult brain function we have turned to the rodent model of aniridia, *Small eye*, where we can utilize a variety of tools to assess *Pax6* expression and the neural consequences of mutations in the brain. The current study employed MRI using a 7T Agilent system to acquire structural brain images using 3D T2 weighted fast spin echo sequences, histological examination, *Pax6* transgenic mouse lines, histological examination, and tissue clearing of the adult brain to examine the consequences of loss of one functional copy of the *Pax6* gene. Results indicate that the effect of *Pax6* mutations on discrete brain structures such as the anterior commissure and optic chiasm are conserved from mice to humans. Furthermore, our imaging of transgenic brains using clearing methods has allowed us to develop a novel analysis comparing adult *Pax6* expression directly with structural changes in *Small eye* heterozygous mice. Collectively, these data allow us to visualize the overlap between adult *Pax6* expression and structural brain variants, and provide new hypotheses regarding the effects of early versus adult *PAX6* haploinsufficiency in the mammalian brain. Implementation of this approach also provides a novel platform for investigating the link between gene expression and neural structure and connectivity, with broad applications for neurogenetic research.

Title: Gender Differences of axonal density in the Rat Corpus Callosum

Authors: *D. J. AL QATTAN[1], L. ALZGHOUL[2], M. ELBELTAGY[3], A. AL-SHATARAT[3]
[1]Pathology, [2]Dept. of Physiol. and Biochem., The Univ. of Jordan, Amman, Jordan; [3]Dept. of Anat., The university of Jordan, Amman, Jordan

Abstract: Sexual dimorphism exists at all levels of the nervous system, from genetic, anatomical, and system levels. These sex differences could underlie gender-related differences in behavior and neuropsychological function, as well as, the sex differences in the prevalence of

various mental problems such as autism, attention deficit, and schizophrenia. The corpus callosum (CC) is the largest of the brain commissures, which connects the cerebral cortices of the two hemispheres, and provide interhemispheric connectivity for information transfer and processing between cortical regions. Alteration in the axonal density of CC will alter interhemispheric connectivity and commonly documented in several psychiatric disorders. The CC consists of myelinated and unmyelinated axons, glial cells, and blood vessels. Several functional studies have reported that CC function is associated with its axon density and myelination properties. The sexual dimorphism in the axonal content of the CC has always been controversial; hence, the aim of this study was to analyze the differences in axons density of the CC between male and female rats. To assess that, five pairs of adult male and female rats were perfused and the CC was sectioned. Then four sections from different subregions of the corpus callosum that represent the genu, anterior body, posterior body, and splenium of the CC were stained and electron microscopic images were captured using stereological guidelines. Later, the axons density for each subregion is calculated and compared between males and females. Our preliminary findings of the present study indicated region specific differences in the myelinated, unmyelinated or the ratio of myelinated/total axons in the CC between male and female rats.

Title: Structural and functional brain changes due to activity-dependent myelination

Authors: *R. T. REUSCH[1], A. RIGODANZO[1], C. SHERWOOD[3], K. A. PHILLIPS[2]
[1]Neurosci., [2]Psychology, Trinity Univ., San Antonio, TX; [3]Anthrop., George Washington Univ., Washington, DC

Abstract: Changes in white matter organization and reorganization of functional connectivity networks are hypothesized to result from activity-dependent myelination. We used non-invasive diffusion weighted imaging and resting-state fMRI to identify structural and functional brain changes associated with time engaged in motor learning. Ten socially housed capuchin monkeys (*Cebus apella*), naïve to prior fine motor tasks, participated in the 12-week experiment. Five monkeys (male $n = 3$) trained daily on a fine motor task (Peg Board) for 8 weeks followed by 4 weeks of continued once-a-week practice; the control condition of five monkeys (male $n = 2$) did

not engage in a fine motor task. Neuroimages were collected from all monkeys at three time points: baseline, 8 weeks, and 12 weeks. Tract based spatial statistics will be used to evaluate changes in the white matter underlying the intraparietal sulcus. Seed-based analysis approach will evaluate changes in the resting-state connectivity visuospatial and sensorimotor networks. We hypothesize that subjects will show an increase in 1) structural integrity of myelin (quantified by fractional anisotropy, FA) and 2) strength of associated functional networks after engaging in motor learning. Furthermore, we expect changes in FA and functional networks are positively correlated with each other.

Title: Lack of vagal parasympathetic innervation of the spleen in different strains of rats

Authors: *G. CANO, S. HERNAN, A. F. SVED
Univ. of Pittsburgh Dept. of Neurosci., Pittsburgh, PA

Abstract: Activation of splenic sympathetic nerves plays an important role in the anti-inflammatory responses orchestrated by the spleen in rodents. Nevertheless, an alternative mechanism has been proposed in which vagal parasympathetic nerves innervate the spleen and have anti-inflammatory actions. This route is controversial because only sympathetic innervation of the spleen has been documented. It has been proposed that the spleen receives direct vagal parasympathetic innervation exclusively at its tips (apparently missed in previous tracing studies). To explore this possibility, we injected two recombinants of the viral transneuronal tracer Pseudorabies virus that express RFP (PRV-614) and GFP (PRV-152) simultaneously into the tips of the spleen (2 ul each), or in the tip and main body of the spleen (4 ul), respectively. To examine if there were anatomical differences in the spleen innervation among different rat strains or vendors, we used Sprague-Dawley rats from two vendors, and Long-Evans rats. Rats were perfused after several specified survival times, and brains and spinal cords removed and processed immunohistochemically to detect both viruses.
Macroscopically, we observed a fiber-like structure in the upper tip of the spleen (very prominent in Harlan Sprague-Dawley rats), which runs independently of the vasculature and ends on the stomach surface. This structure is most likely the equivalent of the gastrosplenic

ligament in humans. Microscopically, early infection was observed in sympathetic preganglionic neurons (SPNs) located in the intermediolateral cell column (IML) of the spinal cord (T_{3-12}). The majority of infected SPNs were single infected, though some double infected SPNs were observed in IML clusters. At intermediate survival times, infected neurons appeared in other spinal groups, as well as in brain regions containing neurons known to innervate the IML, such as the paraventricular hypothalamic nucleus, A5 group, rostroventrolateral medulla, ventromedial medulla and caudal raphe nucleus. The majority of brain infected neurons were double infected. At longer survival times, infected neurons appeared in additional brain regions and were mostly double infected. There were no infected neurons in the dorsal motor nucleus of the vagus at any survival time analyzed in any rat strain tested, demonstrating the lack of vagal parasympathetic innervation at the tips of the spleen as previously proposed. Our anatomical results suggest that the effects of vagal stimulation on splenic function in rats are not mediated by direct vagal innervation of the spleen, but most likely by an alternative indirect mechanism that needs to be elucidated.

Abstract: Organisms have developed physiological and behavioral strategies to survive environmental extremes, such as changes in temperatures, food shortages, and precipitation. In temperate regions, the honey bee, *Apis mellifera*, has the capacity to survive the low temperatures during winter producing bees called “winter bees”. For this study we specifically examined whether the *A. mellifera* uses similar strategies to cope with the stress of low food availability and lower night temperatures in the tropics. To test the hypothesis that “winter bee” physiology is a general response to adverse conditions, we examined bees in Puerto Rico, a tropical island with relatively warm temperatures year-round. Yet in dry and wet seasons there occurs changes in food availability (plants blooming changes over the year). We have demonstrated that genetically distinct, Africanized bees in Puerto Rico demonstrate a decrease in

the colony brood amounts with reduced temperature (75 degrees F vs 90 degrees F in wet season), and reduced flowering of forage plants (15% in bloom from November to February). We also examined individual characteristics associated with winter bees such as high longevity under adverse conditions. We examined in Puerto Rican bee's expression of physiological traits and genes that are correlated with overwintering bees in the temperate zone.

Title: The cooperation between Tip60 HAT activity and transcription factories in activity-dependent genome reorganization

Authors: *A. KARNAY[1], F. ELEFANT[2]
[1]Dept. of Neurobio. and Anat., Drexel Univ. Col. of Med., Philadelphia, PA; [2]Dept. of Biol., Drexel Univ., Philadelphia, PA

Abstract: Coordinated transcription of genes within mammalian nuclei in response to external stimulus is a dynamically orchestrated process involving the interplay between epigenetics-mediated chromatin remodeling and RNA polymerase-mediated transcription. Recently, the potential for an additional layer of regulation has emerged in which active, co-regulated genes converge and relocalize within specialized nuclear subcompartments enriched in hyperphosphorylated RNAPII and transcriptional regulatory proteins thereby mediating efficient, co-regulated gene transcription. While these nuclear 'hot spots' known as transcription factories (TFs) have been demonstrated in other cell types, its presence in hippocampal neurons and its role in activity-dependent transcriptional control within the brain remains relatively unexplored. Furthermore, while previous findings indicate a functional relevance of histone acetylation in activity-dependent gene expression, the full array of HATs involved in this process remain to be determined. To gain insight into this process, we utilized rat hippocampal cells and analyzed Tip60 histone acetyltransferase (HAT)-mediated histone acetylation changes in known co-regulated cognition-associated genes before and after extracellular stimulation. Our findings thus far show that Tip60 shuttles into the nucleus following external stimulation and associates with genes with well characterized roles in synaptic plasticity to induce their co-activation. We are currently characterizing potential changes subcellular nuclear localization and interaction between these genes and transcription factories before and after stimulation-induced expression using FISH analysis. Our findings should provide fundamental insights into a new physiological

gene expression paradigm governing transcriptional activation of co-regulated genes within neuronal nuclei in response to external stimuli and how disruption of this process may contribute to the etiology of neurodegenerative disease.

Title: Generation of neocortical oscillations in isolated brain slices

Authors: B. A. DAGNE[1], N. S. CAYLA[1], S. W. EVANS[2], *B. MACIVER[3]
[1]Anesthesia, Stanford, Stanford, CA; [2]Neurosci., Stanford Univ., Mountain View, CA; [3]Anesthesia, Stanford Univ., Stanford, CA

Abstract: Introduction: The electroencephalogram (EEG) is a commonly used measure of electrical activity in the brain. Synchronous rhythmic activity and modulations of such oscillations with behavior has been useful for understanding complex processing of stimuli in the brain. *In vitro* studies have played an important role in helping us to better understand how these rhythms are generated. Different frequencies of oscillatory activity have been induced in rodent neocortical slices by pharmacologically mimicking cholinergic inputs to the cortex.
Methods: Micro-EEG were recorded from 400 µM-thick rat brain slices submerged in artificial cerebrospinal fluid (ACSF) by placing stimulating electrodes in white matter and recording electrodes in layers II/III of the neocortex in OC2mm cortex. We stimulated cortical neurons electrically to drive thalamic and cortical inputs; and chemically by adding combinations of carbachol (cholinergic agonist), bicuculline (competitive antagonist of $GABA_AR$), and kainate (agonist of non-NMDA glutamatergic receptors), which variably activated glutamatergic or cholinergic pathways. Also, 2-amino-5-phosphonovaleric acid (APV, an NMDA receptor antagonist) was used to tease apart glutamatergic mechanisms.
Results: *In vivo*-like theta oscillations were produced in the slices by mimicking cholinergic and GABAergic inputs with combined applications of carbachol, and bicuculline. Also, activating glutamatergic inputs through the addition of kainate and carbachol also produced theta oscillations without involving any GABAergic disinhibition. Lowering magnesium concentrations in the ACSF increased NMDA-gated glutamate inputs and this produced even

more robust theta oscillations. Finally, the necessity of NMDA stimulation was shown when APV was added to reversibly block the oscillations produced by any combination of agents. **Conclusions:** This project provides a pharmacological survey of agents for creating EEG oscillations in the neocortical slices. Application of drugs influencing glutamatergic and cholinergic receptors can stimulate oscillatory activity in the neocortex. Moreover, it is possible to induce theta oscillations without disturbing GABA activity, by co-activating kainate receptors. This will be useful to study drugs that involve effects on GABAergic inhibition.

Title: Estradiol and dihydrotestosterone regulation of "muscle" genes during sexual differentiation of neural structures

Authors: K. CLEMENTS, *S. L. PETERSEN
Life Sci. Labs., Univ. of Massachusetts Amherst, Amherst, MA

Abstract: Hormonal regulation of neural development contributes to sexual dimorphism of brain structures and functions that become apparent in adulthood. According to existing dogma, perinatal males are exposed to testosterone released by the developing testes, and estradiol (E2) derived from testosterone is the hormone that controls sexual differentiation. Two examples of such sexually dimorphic brain regions are the anteroventral periventricular nucleus (AVPV) and the hippocampus. These regions express both androgen and estrogen receptors, and ligands of these receptors, dihydrotestosterone (DHT) and E2, regulate expression of numerous genes that may play a role in sexual differentiation. We previously showed that the genes differing most dramatically between males and females in the postnatal day 2 (PND2) AVPV are actin-binding proteins previously thought to be muscle-specific. Males express higher levels of mRNAs encoding titin (Ttn), myosin heavy chain 2 (Myh2), troponin C1 (Tnnc1), nebulin (Neb) and advilin (Adv) among others. To determine whether expression of these genes is regulated by sex hormones, PND1 female rats were injected with vehicle or 10 ng of DHT, E2 or combined DHT and E2 (n=8-11/group). On PND2, we microdissected AVPV and hippocampal tissue from the brains of these animals and used qPCR to measure mRNA levels of the genes of interest. Of the 5 genes examined, DHT upregulated Ttn, Myh2, Tnnc1 and Neb, but not advilin. E2 also increased expression of the same genes, except Myh2. However when DHT and E2 were

combined, there was no additive effect. In the hippocampus, DHT upregulated the expression of Tnnc1, Myh2, Ttn, but not Neb. E2 had no effect on expression of these genes in hippocampus but diminished the effect of DHT when both hormones were administered together. While the neural function of these "muscle" genes are currently unknown, their regulation by hormones indicate they may play a role in the development of sexual dimorphisms in the brain. Our results also support the idea that androgens and the androgen receptor may be important for sexual differentiation of neural structures.

Abstract: Opioid peptides comprise a family of active neuropeptides and neurohormones that are processed from large precursor proteins. An immunoscreening, using affinity-purified rabbit antisera against synthetic μ-opioid agonists−.endomorphins (EM1, EM2) on a whole mouse brain cDNA library, led to the identification a novel protein precursor named as proMexneurin. This latter encodes three different peptide sequences referred as to Mexneurin-1 (Mx-1) (an endomorphin-like peptide), Mexneurin-2 (Mx-2), and Mexneurin-3 (Mx-3). Mx-1 peptide motif shares similar conserved regions with EM1 and EM2, respectively. We explored the hypothesis that Mx-1 might display electrophysiological activity in hypothalamic regions known to respond to μ-opioid agonists. 12 cells recorded from the SCN (shown to be largely unresponsive to μ-agonists) did not respond to Mx-1 by reducing the spontaneous firing rate (SFR). Conversely, 32 out of 99 cells in the rostral subdivision of the SON responded to Mx-1. SFR was strongly

inhibited in response to focal application of Mx-1, similar to EM1. A Mx-1 dose-related response was found after 85 neurons were recorded in a whole cell mode, of which 28 responded with an evoked (outward) current in a dose-dependent fashion (10 nM to 100 µM; EC_{50} = 76.6 nM) (holding a depolarized membrane potential at -50 mV). To examine whether Mx-1 acts through the µ receptor, we tested whether CTOP (100 nM) could inhibit the response to Mx-1(100 nM). Six neurons from SON were allowed to maximally respond to bath application of Mx-1 (42.2 ± 7.2 pA) and CTOP (100 nM) reduced the current amplitude gradually to 3.8 ± 2.0 pA. After antagonist washout, Mx-1 mediated currents returned to 31.0 ± 8.3 pA. To assess the agonist efficacy of Mx-1 on µ-opioid receptors, we measured GPCR activation by direct activation of Gα subunits using [^{35}S]GTPγS binding. Mx-1 stimulated the incorporation of [^{35}S]GTPγS in rat hippocampus membranes, displaying a range of potency and intrinsic activity in a concentration-dependent manner, with a maximal stimulation of 86% over baseline values at 0.6 µM. Naloxone (10 µM) inhibited the Mx-1-inducing the incorporation of γ-GTP. Mx-1 K-conductances evoked electrophysiological responses as a result of µ receptor activation in specific brain regions (i.e., SON) which were sensitivity to µ-opioid antagonists (CTOP) as well to µ-opioid agonists (EM1) among others. [^{35}S]GTPγS stimulation by Mx-1 proposed a binding activity on hippocampal µ-opioid receptors, an effect inhibited by naloxone. Taken together, these results argues in favor of a putative role of this novel peptide as an endogenous µ-opioid receptor agonist in the brain.

Title: Type-2 corticotropin releasing factor receptor modulates the synapse between basolateral amygdala and prefrontal cortex

Authors: *H. E. YARUR, I. M. VEGA-QUIROGA, K. GYSLING
Pontificia Univ. Catolica De Chile, Santiago, Chile

Abstract: Basolateral amygdala (BLA) and prefrontal cortex (PFC) are involved in the modulation of the stress response. Neuronal activity in PFC is reduced when stressful events occur (García et al, 1999). In addition, exposure to stressful events blocks the induction of LTP in the BLA-PFC synapse (Maroun & Richter-Levin, 2003). Drugs of abuse use similar structures and neurotransmitters to those involved in the stress response, such as PFC, ventral tegmental area (VTA) and amygdala, and neurotransmitters such as corticotropin-releasing factor (CRF) and dopamine. There is evidence that type-2 CRF receptor (CRF2) (Guan et al, 2014) and the dopamine D1 receptor (DAD1) (Sanchez et al, 2003) in PFC are involved in relapse to the compulsive search for drugs of abuse. Considering the available evidence, we decided to study whether CRF2 and DAD1 are involved in the neurochemical regulation of the BLA-PFC synapses. The experiments were performed in anesthetized rats in which the BLA was stimulated by a depolarizing solution and extracellular levels of glutamate in the PFC were analyzed by in vivo microdialysis in the presence or absence of pharmacological antagonists for CRF2 and DAD1 receptors. The results showed that the stimulation of BLA increases glutamate extracellular levels in PFC. The intra PFC infusion of antisauvagine-30, a CRF2 antagonist, significantly increased PFC glutamate extracellular levels induced by BLA stimulation. In contrast, the intra PFC infusion of SCH23390, DAD1 antagonist did not cause significant changes in PFC glutamate levels after BLA stimulation. The results suggest that the activation of CRF2 but not DAD1 in PFC reduces the release of glutamate induced by BLA stimulation.

Title: The role of GPR139 in dopamine D2 receptor signaling

Authors: *L. WANG, G. LEE, P. BONAVENTURE, T. LOVENBERG, C. LIU
Janssen Res. & Development, LLC, San Diego, CA

Abstract: Previously, we reported that GPR139, an orphan G-protein coupled receptor (GPCR), is activated by the essential amino acids L-tryptophan (L-Trp) and L-phenylalanine (L-Phe) via Gαq- coupling. GPR139 is highly expressed in the pituitary and central nervous system including habenula, septum, striatum and zona incerta, which are known regions involved in mood regulations. Trp and Phe have been used for the treatment of mood disorders. It was believed that administration of Trp or Phe (which are substrates for synthesis of neurotransmitters such as serotonin, dopamine, and adrenaline) may elevate the levels of these neurotransmitters in the brain and then improve the mood. The finding of GPR139 as the receptor for Trp and Phe

strongly suggests that the therapeutic effects of Trp and Phe may be due to the activation of GPR139. However, the exact physiological roles of GPR139 remain to be studied. RNA-seq studies showed that GPR139 mRNA expression has the very similar pattern to that of dopamine D2 receptor, which is the target for many antipsychotics. We wonder whether GPR139 participates in the functions of D2 receptor. The aim of this study is to investigate the role of GPR139 in the signaling modulation of D2 receptor in vivo and in vitro.

Title: Structural characterization of the heteromer between D1 dopamine and type 2-alpha corticotropin releasing hormone receptors

Authors: *C. A. LOPEZ, H. YARUR, B. COLOMA, K. GYSLING
Fac. of Biol. Sciences, Dept. of Cell. and Mol. Biol., Pontificia Univ. Catolica De Chile, Santiago, Chile

Abstract: A recent study showed that D1 dopamine (D1R) and type 2-alpha corticotrophin releasing hormone (CRHR2α) receptors are capable of heterodimerizing in living cells, interacting physically and functionally (Fuenzalida et al, 2014). It was shown that this interaction produces a change in signaling of D1R and sub-cellular localization of both receptors. CRHR2α is mainly located intracellularly, however when is co-expressed with D1R increases its presence on the plasma membrane. On the other hand, D1R that is mainly at the plasma membrane but it increases its intracellular location when co-expressed with CRHR2α. The aim of the present work is to determine the structural basis of the D1R/CRHR2α heteromer formation. To this end, we generated a D1R mutant, and chimeras between CRHR2α and the type b2 γ-aminobutyric acid metabotropic receptor (GABAb2). First, we mutated a di-leucine motif of the D1R C-terminal domain (D1R-mut). It has been reported that this mutation retains D1R intracellularly (Guo et al, 2011). The results show that the co-expression of D1R-mut with CRHR2α does not modify the localization of CRHR2α. These results suggest that the D1R / CRHR2α heteromer is formed intracellularly. Next, in order to reveal the domains involved in the formation of the D1R/CRFR2 α heteromer, we generated receptor chimeras exchanging the transmembrane domains 4, 5 or 6 (TM4, TM5 or TM6) of CRHR2α by the corresponding domains of GABAb2.

The exchange of TM4 or TM5 of CRHR2α reduces the amount of D1R/CRHR2 complex. Thus, our preliminary data suggest that TM4 and TM5 of CRHR2α are necessary for the interaction between both receptors. Altogether, our results confirm that D1R/CRHR2α heteromerize and add novel evidence regarding the possible domains involved in their physical interaction. The existence of the heteromer could constitute a new therapeutic target for the treatment of addiction to drugs of abuse and the knowledge the structural basis of their interaction should help to develop new ligands.

Title: Identification of two nocistatin-binding proteins by using a novel photoaffinity probe

Authors: *M. HARADA[1], T. MINAMI[2], S. ITO[3], E. OKUDA-ASHITAKA[1]
[1]Dept. of Biomed. Engin., Osaka Inst. of Technol., Osaka-Shi, Japan; [2]Dept. of Anesthesiol., Osaka Med. Univ., Takatsuki-Shi, Japan; [3]Dept. of Med. Chem., Kansai Med. Univ., Hirakata-Shi, Japan

Abstract: Nocistatin (NST) is a neuropeptide produced from the same precursor protein of nociceptin/orphanin FQ (N/OFQ). N/OFQ is involved in a broad range of central functions including pain, learning, memory, anxiety, and feeding via selective binding to its receptor. On the other hand, NST has opposite effects on various central functions evoked by N/OFQ. Although the receptor for N/OFQ has been shown to be highly homologous to opioid receptors, the composition and structure of the receptor(s) for NST remain unclear. In the present study, we identified two NST-binding proteins by using a novel NST photoaffinity probe (Pb-NST). The Pb-NST, kindly provided by Nippon Shinyaku Co. Ltd., contains an azide moiety for the tagging of NST binding protein as well as biotin for protein detection and visualization. Intrathecal administration of the Pb-NST inhibited the N/OFQ-evoked tactile pain allodynia with a half-maximal inhibitory dose (ID_{50}) of 500 fg in a manner similar to that of free bovine NST (ID_{50}=700 fg). Following incubation with mouse spinal cord slices, the Pb-NST-binding proteins were visualized with Alexa488-conjugated streptavidin. Fluorescence analysis indicated that the Pb-NST-binding proteins were primarily localized in the gray matter of the spinal cord. Furthermore, the fluorescence intensity consistently increased over time by Pb-NST in a concentration-dependent manner ranging from 0.1 nM to 1 μM. After photo-crosslinking of the

Pb-NST-protein complex, the protein lysate was separated by gel electrophoresis. Subsequent western blot analysis using a horseradish peroxidase-conjugated streptavidin revealed two dominant Pb-NST-binding protein bands at 58 and 64 kDa. Furthermore, the binding of these proteins to Pb-NST was displaced with an excess amount of unmodified NST. Taken together, these results suggest that there are two proteins (58 and 64 kDa) expressed in the gray matter of the spinal cord that can bind to NST.

Title: A receptor-specific crosstalk between the prostanoid 3 and the Bombesin sub-type 3 receptors

Authors: *Y. ZHANG[1], Y. LIU[2], Z. WANG[3], X. ZHANG[2], A. ALACHKAR[4], X. LIANG[2], O. CIVELLI[5]
[1]Shanghai Jiao Tong Univ., Shanghai City, China; [2]Dalian Inst. of Physics & Chem., Dalian, China; [3]Univ. of California, Irvine, Irvine, CA; [4]Pharmacol., [5]Univ. of California Irvine, Irvine, CA

Abstract: Bombesin receptor subtype-3 (BRS-3) is an orphan G protein-coupled receptor that does not exhibit high affinity for bombesin or the endogenous peptides of the other receptors part of the same subfamily. It is present in the central nervous system, peripheral tissues and in tumors; our understanding of its role in normal physiology/pathophysiology is limited because we lack the identity of its natural ligand. In an attempt to identify this ligand, we screened toad skin extracts and identified prostaglandins as putative ligands. In BRS-3 transfected HEK293 cells we show that prostaglandins, PGE2 being the most potent, fulfill the pharmacological criteria of affinity, selectivity and specificity to be considered as agonists to the BRS-3 receptor. However, we also found that PGE2 was unable to activate BRS-3 in different cellular environments (CHO and Hela cells). We suspected that endogenous prostanoid receptors (EPs) in these environments may be the cause of this cellular selectivity. In particular we found that EP_3 are expressed in HEK293 but not CHO cells. Consequently we set up to reconstitute the

HEK293 environment in CHO cells and found that BRS-3 and EP_3 interact to potentiate PGE2 signaling. This potentiating effect is receptor specific and occurs only when BRS-3 is paired to EP_3 and not other receptor. This represents an example of functional cross-talk between two distantly related GPCRs and may be of clinical importance for BRS-3 targeted therapies.

Title: Hypothalamic miR-132-3p changes in response to intracerebroventricular oxytocin: Relevance for anxiety- and fear-related behaviour

Authors: *A. BLUDAU[1], R. MENON[1], G. MEISTER[2], I. D. NEUMANN[1]
[1]Dept. for Behavioural and Mol. Neurobio., [2]Dept. for Biochem., Univ. of Regensburg, Regensburg, Germany

Abstract: miR-134 and the miR-132/212 family are highly abundant in the brain and known to be crucial regulators of neural plasticity and function. Their dysregulation is implicated in various neurodegenerative and affective diseases. The neuropeptide oxytocin (OXT) reduces anxiety and stress responses when administered to the rat paraventricular nucleus (PVN) of the hypothalamus. However, the underlying molecular mechanisms of OXT receptor (OXTR) signalling in the context of anxiety- and fear-alleviating properties are not well understood. Therefore, we studied the effects of synthetic and endogenous OXT on miRNA level within the PVN of Wistar rats in the context of anxiety-related behaviour.
Deep Sequencing of the rat PVN revealed numerous miRNAs that are changed in their expression in response to acute intracerebroventricular (icv) OXT. Further validation of Deep Sequencing showed an up-regulation of miR-132-3p levels within the PVN of male and female rats 3h after icv OXT, whereas miR-212-3p and miR-134-5p remained unchanged. In males, this effect was seen in a region- and time-specific manner, since no expression changes of miR-132/212 family members were observed in the prefrontal cortex or amygdala 3h after icv OXT and no changes were seen in all studied brain regions 90min after icv OXT.
To further evaluate the effect of endogenous OXT on miRNA expression within the PVN, lactating dams, which are characterized by high availability of OXT in the brain, were compared with virgins and dams without pups for time periods of either 4h or 24h. However, all aforementioned miRNAs were found to be unchanged in the PVN of lactating rats compared to virgins. In support, blockade of endogenous OXTR signalling during lactation by a selective

OXTR antagonist did not change miR-132-3p, or miR-212-3p level. However, separation of the dams from their pups for 4h increased miR-132-3p levels in the PVN in comparison to virgins. Moreover, a 4h separation period tended to increase the expression of this particular microRNA compared to dams with a 24h separation period, possibly indicating an effect of acute maternal stress on intra-PVN miRNA levels. This data reveals a possible gender-independent regulation of miR-132-3p by acute synthetic OXT.
Moreover, chronic availability of endogenous OXT may involve miR-132-3p regulation within the PVN. Generally, OXT also acts within the lateral septum (LS), where it was found to reverse social fear induced by the social fear conditioning paradigm in mice. Therefore, we are currently evaluating miRNA levels within the LS in socially fear-conditioned mice and specifically the role of miR-132-3p in social fear-related behavioural regulation.

Title: Involvement of neuropeptide S, orexin and endocannabinoid in stress-induced cocaine relapse in mice

Authors: *L.-C. CHIOU[1,2], Y.-H. CHOU[3]
[1]Natl. Taiwan University, Med. Col., Taipei, Taiwan; [2]Grad. Inst. of Brain and Mind Sci., [3]Grad. Inst. of Pharmacol., Col. of Medicine, Natl. Taiwan Univ., Taipei, Taiwan

Abstract: The high prevalence of drug relapse severely limits the success of drug rehabilitation programs. Among the relapse initiators, stress in an inevitable inducer in the daily life of extinguished addicts. Recently, we have disclosed a novel mechanism for stress-induced cocaine relapse, i.e. stress can activate the orexin 1 receptor (OX1R) in the ventral tegmental area (VTA) and, via the phospholipase C (PLC) and diacylglycerol lipase (DAGL) enzymatic cascade, generate 2-arachidonolyglycerol (2-AG), an endocannabinoid that inhibits GABAergic transmission in VTA dopamine neurons, resulting in cocaine relapse[1]. Here, we revealed a novel player, neuropeptide S (NPS), a 20 amino acid-containing neuropeptide named by its evolutionally conserved N-terminal serine residue, in this sequential cascade. It was initiated

based on previous findings that 1) stress activated the NPS-containing neurons in the peri-locus cereous (LC) and the parabrachial nucleus (PBN); 2) stress also activated orexin neurons in the lateral hypothalamic (LH); 3) intra-LH microinjection of NPS activated hypothalamic orexin neurons. We used a three-day bias cocaine-conditioned place preference (CPP) paradigm to induce cocaine seeking. The cocaine CPP scores were measured at pre-conditioning, cocaine-conditioning, extinction and reinstatement stages. As reported previously[1], a 30-min acute restraint stress significantly reinstated extinguished cocaine CPP in mice, i.e. inducing cocaine relapse. This stress-induced cocaine relapse was prevented when SHA 68, an NPS receptor antagonist, was *i.p.* administered in mice before restraint stress. Besides, *i.c.v.* injection of NPS significantly reinstated extinguished cocaine CPP in mice. NPS (*i.c.v.*)-induced cocaine relapse was prevented by *i.p.* pretreatment with SHA 68, SB334867 (an OX1R antagonist) or AM 251 (a CB1R antagonist). Furthermore, NPS (*i.c.v.*) increased the orexin A level in the mouse VTA in a manner prevented by SHA 68. These results suggest that during stress, NPS neurons in the PBN and/or peri-LC in mice are activated, releasing NPS that activates orexin neurons via NPS receptors in the LH, releasing orexins that, via OX1Rs, activate dopamine neurons indirectly through the OX1R-PLC-DAGL-2-AG-CB1R cascade in the VTA, leading to cocaine relapse.
[1]Tung et al. (2016) Orexins contribute to restraint stress-induced cocaine relapse by endocannabinoid-mediated disinhibition of dopaminergic neurons. *Nature Communications* 7:12199.

Title: Functionally significant oligomers of ghrelin and dopamine D1-like receptors control dopaminergic cell activity in the VTA

Authors: *W. P. REA[1], C. QUIROZ[1], M. HEARING[2], G. NAVARRO[3], E. MORENO[3], A. CORTES[3], E. I. CANELA[3], V. CASADO[3], S. FERRE[1]

[1]Integrative Neurobio., NIDA/IRP/NIH, Baltimore, MD; [2]Marquette Univ., Milwaukee, WI; [3]Univ. of Barcelona, Barcelona, Spain

Abstract: The orexigenic hormone ghrelin acts on a G protein-coupled receptor known as growth hormone secretagogue (GHS) receptor or GHS-R1a. Cells expressing GHS-R1a also express GHS-R1b, a truncated isoform variant of GHS-R1a lacking the transmembrane domains 6 and 7. Ghrelin does not bind to and therefore does not signal through GHS-R1b. We recently showed that GHS-R1b determines the efficacy of ghrelin-induced GHS-R1a-mediated signaling and the ability of GHS-R1a to form oligomeric complexes with other receptors, including the dopamine D_1 receptor (D1R), promoting profound qualitative changes in ghrelin-induced signaling. Both in mammalian transfected cells and striatal neurons, the D_1-like receptor antagonist SCH-23390 counteracted GHS-R1a-mediated signaling by acting on GHS-R1a-GHS-R1b-D1R oligomers (cross-antagonism). The orexigenic effects of ghrelin are related to its ability to indirectly and directly activate dopamine cells of the VTA, through activation of GSH-R1a localized in neurons of the hypothalamic arcuate nucleus (hypothalamic-VTA connection) and in the somatodendritic region of the dopamine cells in the VTA. Since somatodendritic dopamine release in the VTA is a correlate of dopaminergic cell firing, its analysis can be used to study the local modulation of dopamine cell function. Our recently introduced "infusion-microdialysis probe" allows the slow and constant delivery of large peptides into the same brain region that is being sampled for extracellular concentrations of dopamine. Using this method, we obtained preliminary results showing a substantial increase in somatodendritic dopamine release with direct infusion of ghrelin in the VTA, which was completely blocked by co-perfusion (reverse dialysis) of SCH-23390, strongly suggesting that we identified a significant functional population of GHS-R1a-GHS-R1b-D1R oligomers in the VTA. Since the D_5 receptor (D5R) has been suggested to be the predominant D_1-like receptor in the VTA, we performed experiments in mammalian transfected cells to confirm that GHS-R1a, GHS-R1b and D5R can also from oligomers with the same biochemical properties than GHS-R1a-GHS-R1b-D1 oligomers, including the cross-antagonism. Finally, preliminary data using patch-clamp electrophysiological analysis of dopamine cell activity in the VTA shows that ghrelin does increase spontaneous firing. We intend to show that this effect is counteracted by SCH-23390 and that this cross-antagonism is disrupted by synthetic peptides that disrupt heteromerization, demonstrating the presence of functionally significant GHS-R1a-GHS-R1b-D_1-like receptor oligomers in the dopaminergic cells of the VTA.

Title: Regulation of type 1 glucose transporter (glut-1) levels by histamine h1 and h3 receptors in rats astrocytes in primary cultures

Authors: *J. PARRA
Cinvestav, Ciudad DE Mexico, Mexico

Abstract: Histamine acts as neurotransmitter and neuromodulator in the Central Nervous System and is involved in various functions such as sleep/wakefulness, hormonal secretion, thermoregulation, food intake, memory and glucose metabolism in neurons and glial cells. These effects are mediated by the activation of four G protein-coupled receptors (H_1R, H_2R, H_3R, and H_4R). Astrocytes take up and metabolize large amounts of glucose, and express the 45 kDa isoform of the type 1 glucose transporter (GLUT-1), involved in the bidirectional, facilitated transport of glucose. Astrocytes express H_1Rs and H_3Rs, which through $G\alpha_{q/11}$ and $G\alpha_{i/o}$ proteins, respectively, trigger several signaling pathways. In this work, we therefore set to study whether the activation of H_1Rs and H_3Rs regulates GLUT-1 protein expression in rat astrocytes in primary culture.
Cultures were prepared from the cerebral cortex of neonatal (2 to 7-day old) Wistar rats. Receptor levels were determined by the specific binding to cell membranes of [^{3}H]-mepyramine (H_1R) or [^{3}H]-N-α-methylhistamine (H_3R). H_1R signaling was evaluated by measuring changes in the intracellular concentration of Ca^{2+} ($[Ca^{2+}]_i$), and H_3R function by the inhibition of forskolin-induced cAMP accumulation. GLUT-1 protein expression was evaluated by immunodetection.
Cultured astrocytes expressed both H_1Rs (230 ± 22 fmol/mg of protein) and H_3Rs (77 ± 15 fmol/mg of protein) in their membranes. H_1R activation resulted in Ca^{2+} mobilization from intracellular stores, and H_3R activation inhibited cAMP accumulation. Immunoblot assays showed that incubation for 3 h with 30 μM 2-pyridylethylamine (PEA) or 1 μM immepip (selective H_1R and H_3R agonists, respectively) significantly increased GLUT-1 levels to 164.3% ± 9.9 and 143.2% ± 9.8 of control values, respectively.
These results suggest that H_1Rs and H_2Rs regulate GLUT-1 protein levels and thus glucose uptake by astrocytes.

Title: Mu opioid agonists differentially affect VTA neurons that project to either prelimbic or infralimbic cortices

Authors: *J. M. BRETON[1], H. L. FIELDS[2], E. B. MARGOLIS[2]
[1]Neurosci., Univ. of California Berkeley, Berkeley, CA; [2]Neurol., UCSF, San Francisco, CA

Abstract: The ventral tegmental area (VTA) is a central brain region that is necessary for the hedonic actions of mu opioid receptor agonists. The dopaminergic projection from the VTA to the medial prefrontal cortex (mPFC) has been implicated in both positive and negative hedonic states. Critically, two subregions of the mPFC appear to play different and often opposing roles in behavior: the infralimbic (IL) and the prelimbic (PL) cortices. The PL appears to promote learned fear and drug seeking behaviors, while the IL inhibits these behaviors. Such diversity in the behavioral action raises the possibility that the connectivity, physiological and/or pharmacological properties of the VTA neurons composing these two projections may differ. While it is well established that individual VTA neurons generally project to just one target region, whether PL and IL receive inputs from separate populations of VTA neurons is unknown. To test the hypothesis that different VTA neurons project to the IL and PL, we injected different retrograde tracers ipsilaterally into the PL and IL of rats, and examined the VTA for tracer colocalization. We also performed immunocytochemistry, staining for tyrosine hydroxylase (TH), a marker of dopaminergic neurons. Our findings show there are largely non-overlapping projections from the VTA to the PL and IL and that these projections differ in the percentage of dopaminergic neurons (50% to IL and 23% to PL). These projections also differ in their location; there is a greater percentage of PL projecting neurons in the ventral VTA and IL projecting neurons in the dorsal VTA. Furthermore, we found distinct opioid effects in VTA neurons projecting to PL and IL; the mu opioid receptor agonist [D-Ala^2, NMe-Phe^4, Gly-ol^5]-enkephalin (DAMGO) on average inhibited dopaminergic projections to PL (4/8 TH(+) neurons inhibited, 0/8 excited), but on average *excited* dopaminergic projection to IL (5/16 TH(+) neurons excited, 6/16 inhibited, mean change in V_m = +1.56 mV). On the other hand, many nondopaminergic (TH(-)) neurons in both projections were inhibited by DAMGO (PL: 8/8 inhibited, IL: 5/11 inhibited 1/11 excited).
Our findings demonstrate that projections from the VTA to the PL and IL are anatomically distinct, differ in the proportion that are dopaminergic and are differentially controlled by mu opioid receptor activation. These findings indicate that future studies of mPFC need to carefully differentiate between these two cortical subregions. Future studies will aim to determine whether these two VTA projections contribute differentially to opioid seeking and opioid reinforced behaviors.

Title: G protein-coupled receptors for gastrin releasing peptide regulate EGFR and HER2 transactivation

Authors: *T. W. MOODY
Office the Director, CCR, NCI, Bethesda, MD

Abstract: The bombesin (BB) family of peptides includes gastrin releasing peptide (GRP), which regulates pruritus, and neuromedin B (NMB) which causes satiety and thyrotropin secretion (Jensen et al., Pharmacol Rev 2008; 60: 1). GRP as well as dopamine decarboxylase and neuron specific enolase are present in high concentrations in the neuroendocrine tumor small cell lung cancer (SCLC, Carney et al., Cancer Res 1985; 45: 2913). GRP stimulates SCLC proliferation, whereas the GRP receptor antagonist PD176252 inhibits proliferation (Moody et al., Peptides 2015; 72: 106). Because peptide GPCR regulate RTK transactivation, the effects of GRP were investigated on EGFR and HER2 tyrosine phosphorylation. Addition of GRP to human SCLC cell line NCI-H345 increased EGFR, HER2 and ERK tyrosine phosphorylation 4-, 3- and 2-fold, respectively. The increase in EGFR and HER2 transactivation caused by GRP was inhibited by PD176252, gefitinib (EGFR tyrosine kinase inhibitor), PP2 (Src inhibitor), GM6001 (matrix metalloprotease inhibitor) and TGF alpha monoclonal antibody. GRP addition to SCLC cells increased the secretion of TGFalpha (EGFR agonist) into the media, which was inhibited by GM6001. The results suggest that the GRP receptor regulates MMP activity and that the released TGFalpha binds to the EGFR causing the formation of EGFR homodimers and EGFR/HER2 heterodimers. Gefitinib or PD176252 inhibited whereas GRP increased SCLC colony formation. PD176252 and gefitinib strongly inhibited SCLC growth and EGFR transactivation. The results indicate that the GRPR regulates SCLC proliferation in an EGFR- and HER2-dependent manner.

Title: Multiple receptors for allatostatin-C peptides in the lobster: Nervous system: A possible substrate for differential responses to a neuropeptide?

Authors: *P. S. DICKINSON[1], P. WALSH[1], J. J. HULL[2], S. PONG[1], A. W. PUPO[1], A. E. CHRISTIE[3]
[1]Bowdoin Coll, Brunswick, ME; [2]USDA-ARS ALARC, Maricopa, AZ; [3]Univ. of Hawaii at Manoa, Honolulu, HI

Abstract: Peptides and their receptors represent the largest and most diverse signaling systems in the nervous system. We have identified three allatostatin-C peptide isoforms in the nervous system of the American lobster, *Homarus americanus*. Interestingly, while perfusion of the lobster heart with each of the peptides usually results in a decrease in contraction frequency, each can elicit either a decrease or an increase in contraction amplitude. One hypothesis to explain these differential responses is the differential distribution of multiple AST-C receptors among individuals. Using transcriptomes from the lobster brain and eyestalks, we have identified four putative AST-C receptors, and have confirmed and/or determined the full-length sequences of these receptors using PCR. Using these sequences, we have C-terminally tagged receptors I, II, and IV with EGFP, and have expressed them in insect cell lines; the expression of receptor III is in progress. Receptors I and II are expressed at the cell surface, where they co-localize with TAMRA-labelled AST-C1, suggesting that both receptors bind the AST-C isoform. No evidence of binding was observed in non-transfected cells, indicating that binding is specific to the expressed receptor. Receptor IV, however, appears to remain within vesicles in the cytoplasm; this may result from issues with receptor trafficking due to the presence of the EGFP tag. We are currently using two techniques to determine the relative binding and activation efficiencies of these receptors to the three AST-C isoforms. First, we are using competitive inhibition assays to determine the ability of AST-C2 and AST-C3 to compete with the labeled AST-C1. Second, we have loaded the cells expressing the receptors with a calcium-sensitive dye, and are following the fluorescence triggered by calcium release when the cells are challenged with each of the three peptides. These experiments have confirmed that AST-C receptors I and II are activated by all three peptides; experiments are ongoing to determine the relative binding efficacy of each peptide. Preliminary PCR data suggest that receptors II and III are expressed in the cardiac ganglion; experiments are ongoing to confirm this distribution and to determine whether receptors I and IV are likewise present in the cardiac ganglion. Differential receptor expression and activation by the three peptides may provide an explanation for the differential responses of individuals to allatostatin-C.

Title: Investigation of the role of SynDIG1 in synaptic transmission in the cerebellum

Authors: Y. IDEGUCHI[1], C. QUARSHIE[1], S. VADDADI[1], S. JUNG[1], E. PEREZ[1], E. DIAZ[2], E. G. ANTZOULATOS[1], *D. FIORAVANTE[1]
[1]Ctr. For Neuroscience, Univ. of California Davis, Davis, CA; [2]Dept. of Pharmacol., Univ. of California Davis, Davis, CA

Abstract: SynDIG1 (synapse differentiation induced gene 1) is a highly conserved membrane protein that regulates excitatory synapse number and synaptic strength by associating with AMPA receptors. Specifically, knockdown of SynDIG1 in dissociated hippocampal neurons decreases AMPA receptor content at synapses by approx. 50% (Kalashnikova et al. 2010). Disruption of SynDIG1 results in decreased number of mature synapses and average postsynaptic density (PSD) length in the CA1 region of the hippocampus (Chenaux et al. 2016). Increased short-term structural plasticity is also observed in SynDIG1-deficient mice upon glutamate stimulation of individual dendritic spines (Chenaux et al. 2016). Because SynDIG1 mRNA is upregulated during postnatal development in the cerebellum (Diaz et al. 2002), and in the cerebellum SynDIG1 protein is selectively expressed in Purkinje neurons (Chenaux et al. 2016), we sought to characterize the effects of SynDIG1 disruption on synaptic transmission and plasticity of cerebellar synapses, starting with the parallel fiber to Purkinje cell synapse. Acute cerebellar slices from postnatal day P8-P21 mice were prepared and whole cell voltage-clamp recordings were obtained from Purkinje cells in the presence of the sodium channel blocker TTX and the $GABA_A$ receptor antagonist bicuculline. Preliminary results suggest a decrease in mEPSC amplitude, but not frequency, in SynDIG1-deficient mice compared to wild type littermate controls. This effect, which was seen in slices from P8-P12 but not P18-P21 animals, agrees with the previously observed postsynaptic role of SynDIG1 in AMPA receptor regulation

in the hippocampus. We are currently investigating evoked glutamatergic transmission as well as climbing fiber territory and plasticity.

Title: Neuronal pentraxin 2 binds to the perineuronal nets via hyaluronan

Authors: *H. M. VAN 'T SPIJKER[1], J. C. KWOK[2], J. W. FAWCETT[1]
[1]Clin. Neurosci., Univ. of Cambridge, Cambridge, United Kingdom; [2]Univ. of Leeds, Leeds, United Kingdom

Abstract: Introduction
Perineuronal nets (PNNs) are mesh-like structures which form at the end of the critical period for plasticity, in the extracellular matrix of sub-populations of neurons in the CNS. The PNNs consist of a backbone of hyaluronan (HA) which is linked to a variety of chondroitin sulfate glycosaminoglycans by link proteins. However, the mechanisms by which PNNs interact with synapses are poorly understood.
Materials & Methods
In this project, I aim to investigate a newly identified binding partner of PNNs, Neuronal Pentraxin 2 (NPTX2) and to determine the mechanism by which NPTX2 regulates interactions between PNNs and synapses using both molecular biology and microscopy methods. I applied both modified glycan ELISA and Quartz Crystal Microbalance with Disspation (QCM-D) to investigate the binding properties and I investigated the localization of NPTX2 with primary cortical neuronal cultures and fluorescence microscopy.
Results
With the use of modified glycan ELISA, we observed a strong binding of NPTX2 to HA and chondroitin sulphate E, but not to other PNN glycans. QCM-D investigation of the binding of NPTX2 and HA displayed the binding is reversible. In cultured neurons NPTX2 co-localizes with the PNN.
Discussion
Because NPTX2 has previously been reported as a binding partner for AMPA receptors and removal of PNNs also increase AMPA receptor mobility, our results indicate that PNNs may

control synaptic plasticity through the binding of NPTX2 which regulates the activity and signalling cascade of AMPA receptors. Further experiments are necessary to investigate the potential of NPTX2 as a mediator of the effects of the PNNs.

Title: The synaptome map of the whole mouse brain: A molecular template for the architecture of circuits and behavior

Authors: Z. QIU[1], F. ZHU[1], M. CIZERON[1], R. BENAVIDES-PICCIONE[2], M. KOPANITSA[3], N. SKENE[1], J. DEFELIPE[2], E. A. FRANSEN[4], N. KOMIYAMA[1], *S. G. GRANT[1]

Abstract: The “synaptome” refers to the complement of all synapses in the brain, or part thereof, and to date no studies have mapped the molecular expression in single synapses across the whole brain of any vertebrate. To map the synaptome at the whole brain scale, we have developed a technology pipeline called “Genes to Cognition Synaptome Mapping Pipeline” (G2CSynMaP), which is a standardized image capture and analysis suite built for use with genetically engineered mice expressing tagged postsynaptic proteins. We systematically characterized and classified billions of individual synapses into 37 subtypes in mice based on synaptic molecular composition and physical parameters, and generated the first whole brain scale synaptome maps at the single synapse resolution. Synaptome maps revealed remarkable complexity with many hitherto unknown anatomical features including layers, patches and gradients of different subtypes of synapses. From single synapses on individual dendrites to the whole brain, striking and novel architecture were observed in the spatial diversity of synapse subtypes. The hippocampus showed highest synaptic diversity with gradients that localize neural activity patterns and encode behavioral representations. Long-range connections and mesoscale connectome architecture were also defined by synaptome maps. Mutations causing mental disorders reprogramed global synaptome architecture and reconfigured representations. The

complexity of synaptome maps expanded with vertebrate genome evolution. We propose that synaptome maps act as templates for the representation of behaviors in the brain. We predict that the brain's function may depends on a vast number of synaptome maps and that they will reveal many architectural and functional features at all scales. The whole brain synaptome mapping resources reported here can be expanded to include other synapse proteins, define new anatomical features and be integrated with other large-scale brain map resources. Synaptome technology can be used in a wide range of basic science and medical studies. It can also be used in conjunction with connectomic and optogenetic methods to address how the remarkable molecular and spatial diversity of synapses control the neural networks of the brain.

Title: Synaptic nanostructure is a novel regulator of NMDA receptor activation

Authors: *S. RANSOM METZBOWER[1], S. RAGHAVACHARI[2], T. A. BLANPIED[3]
[1]Physiol., Univ. of Maryland Baltimore, Baltimore, MD; [2]Biol., Univ. of Maryland, College Park, MD; [3]Dept. of Physiol., Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract: Within a single synapse, there are several factors that may regulate NMDA-type glutamate receptor (NMDAR) response amplitude, including receptor number, subunit composition, and posttranslational modification. However, with the development of super-resolution imaging techniques we can now examine the question of how distribution of proteins within the synapse on a nanoscale level controls NMDAR activation. In order to measure NMDAR activation in individual synapses, we imaged the Ca^{2+} indicator GCaMP6f in cultured hippocampal neurons in the presence of TTX, 0 $Mg^{2+,}$ ryanodine, nifedipine and thapsigargin. This revealed miniature spontaneous NMDAR activation in individual dendritic spines, where the GCaMP6f response was sensitive to the total amount of NMDAR channel opening, because event amplitude could be modulated in either direction by altering the extracellular Mg^{2+} or Ca^{2+}

concentration.
Immunocytochemistry and focal glutamate delivery have suggested that tens of NMDARs are present at a single synapse. However, in our experiments, a low concentration of the high affinity antagonist CPP strongly decreased event frequency with a much smaller reduction in mean amplitude. This suggests that very few NMDARs open following spontaneous glutamate release. The low open probability of NMDARs after agonist binding likely contributes to this phenomenon, but, in addition, subsynaptic positioning of NMDARs away from release sites may minimize their activation. To examine the functional impact of subsynaptic NMDAR position, we used Monte Carlo simulations of model synapses created from measured super-resolution maps of NMDAR distribution. Simulating glutamate release at different positions within the active zone revealed that the open probability of NMDARs containing GluN2B but not GluN2A sharply decreased as a function of distance from the site of release (~50% in 80 nm). Surprisingly, in imaging experiments, the GluN2B antagonist eliminated the vast majority of spontaneous events. Thus, few NMDARs are activated during mEPSCs, but they are largely GluN2B-containing. To test the effect of synaptic nanostructure on NMDAR activation, we are combining super-resolution imaging of synaptic proteins with single-spine Ca^{2+} imaging. This revealed a positive correlation between NMDAR activation at single spines and the fractional area of the PSD that was incorporated into a nanodomain. Additionally, spines with prominent nanodomains showed a wider range of average peak amplitudes than spines that lacked nanodomains. Together, these data suggest PSD nanostructure is a novel mechanism for regulation of NMDAR activation.

Title: Spatial action range of glutamate

Authors: *D. DIETRICH, W. SUN, S. MCMAHON, E. A. MATTHEWS, A. J. MÜLLER, S. SCHOCH
Univ. Clin. Bonn, Bonn, Germany

Abstract: Synaptic wiring of neurons is considered to be almost as specific as hard-wiring of electronic devices as potent uptake mechanisms are assumed to remove glutamate before it can activate AMPA receptors at neighboring spines. However, the neuropil ultrastructurally is very crowded such that the nearest neighbor synapse is found at ~300-500 nm but it has not yet been determined which distance glutamate molecules can travel in the extracellular space and activate AMPA receptors before being removed. Here we report that the action range of glutamate at AMPA receptors exceeds the distance to the nearest neighbor synapse in hippocampus predicting that quantal glutamate release regularly co-activate neighboring spines. We used two-photon glutamate uncaging and showed that the amplitude of spine-mediated AMPA receptor currents decline with a length constant of 440 nm (lambda). When blocking glutamate transporters, lambda increased to ~900 nm which also described the extracellular spread of two-photon activated dyes in hippocampus. Using neuronally expressed iGluSnfr we verified that our estimates of lambda based on glutamate uncaging closely match the spatial action range of single action potential-driven glutamate release from mossy fiber boutons. Monte Carlo simulations with a synaptic density of 2 μm^{-3} show that even at small fractions of activated synapses, cross-talk to AMPA receptors at neighboring spines contributes to ~20-30% of total synaptic currents in the input receiving network. The functional impact of this synaptic cross-talk is even enhanced because simultaneous spatially distributed glutamate uncaging events add in a supra-linear fashion at individual spines. Taken together, our data challenge the concept of point-to-point glutamatergic transmission and show that also the micron-scale spatial segregation of postsynaptic structures is a relevant parameter for network computation and excitability.

Title: Differences between synaptically activated sodium concentration changes through AMPA and NMDA receptors in rat hippocampal pyramidal neuron dendritic spines

Authors: K. MIYAZAKI, *W. N. ROSS
New York Med. Col., Valhalla, NY

Abstract: Excitatory synaptic stimulation generates an epsp by activating AMPA and NMDA receptors on spines of pyramidal neurons. Factors that influence the relative contribution of these two receptors include (a) their relative affinity for glutamate, (b) the kinetics of their conductances, and (c) the effectiveness of the voltage-dependent Mg block of the NMDA receptors. We explored these factors and the role of sodium diffusion using simultaneous sodium and calcium imaging (Miyazaki and Ross, 2015) from dendritic spines.
Pyramidal neurons in hippocampal slices were patched and filled with bis-fura-2 (calcium) and ANG-2 (sodium). We selected dendrites near the surface where spines were often visible and positioned a stimulating electrode within 20 µm of a dendrite. Single or paired shocks at 10 ms separation often evoked localized (< 5 µm extent) fluorescence increases corresponding to sodium and calcium concentration changes. In most cases the sodium signal had a fast rise time of ~10 ms, which corresponds well with the rise time of the AMPA conductance. The rise time of the calcium signal was slower than the rise of the sodium signal, and well matched to the NMDA receptor-dependent calcium signal recorded by other investigators. CNQX blocked almost all of the sodium signal and most of the calcium signal. CPP blocked about 15% of the sodium signal and 90% of the calcium signal.
In seven cells we detected signals that clearly originated in single spines. The sodium signal rose sharply in the spine and then appeared later in the nearby dendrite. The calcium signal rose more slowly and was confined to the spine. These responses are consistent with strong buffering of calcium and free diffusion of sodium. The half removal time of the spine sodium signal was ~16 ms. A computer model assuming removal from the spine only by diffusion reproduced the sodium signals in the different compartments assuming spine and dendrite dimensions from the literature and measured value for the sodium diffusion constant. These time courses are consistent with a low spine neck resistance.
The rapid diffusion of sodium out the spine neck and the fast kinetics of the AMPA conductance helps to explain the apparent small contribution of NMDA receptor activation to the synaptic sodium signal. Removal by diffusion prevents the buildup of sodium during the slow activation of the NMDA receptor. In addition, the Mg block of the receptor is only relieved during the short (~7 ms) epsp in the spine, limiting the duration of sodium influx.

Title: Postsynaptic RIM1 modulates synaptic function by facilitating membrane delivery of recycling NMDARs in hippocampal neurons

Authors: *X. LV[1], J. WANG[1], J. LUO[2], S. QIU[3]
[1]Dept. of Neurobio., Zhejiang Univ. Sch. of Med., ZheJiang, China; [2]Zhejiang Univ. Sch. of Med., Zhejiang, China; [3]Zhejiang Univ. Sch. of Med., ZheJiang, China

Abstract: NMDA receptors (NMDARs) are crucial for excitatory synaptic transmission and synaptic plasticity. The number and subunit composition of synaptic NMDARs are tightly controlled by neuronal activity and sensory experience, whereas the molecular mechanism mediating NMDAR trafficking remains poorly understood. Here we report that RIM1α, with a well-established role in presynaptic vesicle release, also localizes postsynaptically in the mouse hippocampus. Postsynaptic RIM1α in hippocampal CA1 region is required for basal NMDAR-, but not AMPA receptor (AMPAR)-, mediated synaptic responses, along with contributions to hippocampus-dependent memory. Moreover, RIM1α levels in hippocampal neurons determine both the constitutive and regulated NMDAR trafficking, with no role in constitutive AMPAR trafficking. We further demonstrate that RIM1α binds to Rab11 and disruption of their interaction or knockdown of RIM1α impairs membrane insertion of Rab11-positive recycling endosomes containing NMDARs. Together, these results identify a novel RIM1α-dependent mechanism critical for modulating synaptic function by facilitating membrane delivery of recycling NMDARs.

Title: Essential role for Parkin in AMPA and NMDA receptor trafficking and signaling

Authors: M. ZHU[1], G. P. CORTESE[2], *C. WAITES[3]
[1]Pathology and Cell Biol., Columbia Univ., New York, NY; [2]Dept. of Neurol., Univ. of Wisconsin-Madison, Madison, WI; [3]Pathology and Cell Biol., Columbia Univ. Med. Ctr., New York, NY

Abstract: The PARK2 gene, encoding the E3 ubiquitin ligase Parkin, was originally discovered as a cause of early-onset Parkinson's disease and has been extensively studied in the context of dopaminergic neuron survival. However, Parkin is highly expressed throughout the brain and is a known component of the postsynaptic density at glutamatergic neurons. Recent genome-wide association studies have identified copy number variations in PARK2 that are linked to autism, developmental delay, ADHD, and intellectual disability, suggesting an essential role for Parkin in synaptic transmission and plasticity. Here, we investigate Parkin's role at glutamatergic synapses of the hippocampus, and find that Parkin deficiency leads to significantly decreased AMPA and NMDA receptor-mediated currents and cell-surface expression. Remarkably, our studies indicate that Parkin regulates the trafficking of each receptor type via a distinct mechanism: AMPA receptors through a structural role at the postsynaptic density, and NMDA receptors through direct ubiquitination. Moreover, we find that the trafficking defects induced by Parkin loss-of-function lead to impaired synaptic plasticity. Our findings demonstrate novel roles for Parkin in regulating synaptic glutamate receptor trafficking, and suggest a mechanism through which PARK2 copy number variations cause dysfunction of excitatory synaptic transmission and plasticity, leading to cognitive deficits associated with autism and intellectual disability.

Title: Synaptotagmin 1 and SNARE proteins in postsynaptic spines: Regulation of AMPA receptor exocytosis

Authors: *S. DAVANGER[1], S. HUSSAIN[2], D. L. EGBENYA[2], H. RINGSEVJEN[2]
[1]Univ. Oslo, Oslo, Norway; [2]Univ. of Oslo, Oslo, Norway

Abstract: The last 25 years we have known that the core SNARE complex of VAMP2 (synaptobrevin 2), syntaxin 1 and SNAP-25 are crucial in facilitating and regulating presynaptic vesicular release. However, indirect evidence has also supported a postsynaptic role for SNARE proteins. The necessary postsynaptic vesicles were for a long time only implicated. Using postembedding immunogold electron microscopy in combination with biochemical techniques, we have demonstrated the presence of small vesicles in postsynaptic spines in the rat hippocampus. SNARE proteins and the Ca^{2+}-sensor synaptotagmin 1 are present on vesicular and plasma membranes in these spines. We find evidence that they are involved with exocytosis of glutamate receptor subunits.
In the current project, we show that **synaptotagmin 1** is present both on cytoplasmic vesicles, and at the postsynaptic density (PSD) and lateral membranes. In cytoplasmic compartments, the highest concentrations of synaptotagmin 1 are found in presynaptic terminals, almost 40 % higher than in postsynaptic spines. However, these spines show about 65 % higher concentrations than the corresponding dendritic shafts, and astrocytic processes showing only background levels of synaptotagmin 1. Less difference is found on cytoplasmic membranes, though also here presynaptic membrane (active zone) is clearly higher than the PSD, which is higher than dentritic membranes. We further investigated whether postsynaptic synaptotagmin 1 is regulated during synaptic plasticity. In a rat model of chronic temporal lobe epilepsy, we found that pre- and postsynaptic concentrations of the protein are reduced compared to control animals. This down regulation may be an adaptive measure to decrease both pre- and postsynaptic calcium sensitivity in excitotoxic conditions. Thus, postsynaptic AMPA receptor

concentrations are reduced correspondingly in the epilepsy model.
Similar to synaptotagmin 1, the SNARE proteins **syntaxin-1, SNAP-25** and **VAMP2** (synaptobrevin 2) are present in the highest concentrations at presynaptic compartments, including the active zone, supporting their role in neurotransmitter release. However, also these SNARE proteins are expressed at significant levels in postsynaptic spines. As we have reported previously, VAMP2 colocalizes with the AMPA receptor subunit GluA1 on the same postsynaptic vesicles. Disrupting VAMP2 by tetanus toxin treatment reduces the concentration of GluA1 in the postsynaptic plasma membrane, indicating that small postsynaptic vesicles containing GluA1 are inserted directly into the spine plasma membrane through a VAMP2-dependent mechanism.

Abstract: Despite the central role PSD-95 plays in anchoring postsynaptic AMPARs, how PSD-95 itself is tethered to postsynaptic sites remained unknown. Here we show that the F-actin binding protein α-actinin binds to the very N-terminus of PSD-95. Knock-down (kd) of α-actinin phenocopies kd of PSD-95. Mutating lysine at position 10 or lysine at position 11 of PSD-95 to glutamate impairs in parallel PSD-95 binding to α-actinin and postsynaptic localization of PSD-95 and AMPARs. Also, expression of mutant α-actinin which cannot interact with PSD-95 showed similar phenotype. These experiments unequivocally identify α-actinin as a critical PSD-95 anchor tethering the AMPAR - PSD-95 complex to postsynaptic sites.

Title: PSD lattice structure and scaffold-adaptor protein model for PSD structure

Authors: *T. SUZUKI[1,2,3], K. KAMETANI[4], W. GUO[2], W. LI[5]
[1]Mol. &Cellular Physiol., Shinshu Univ. Inst. of Med., Matsumoto, Japan; [2]Neuroplasticity, Shinshu University, Grad. Sch. Med., Matsumoto, Japan; [3]Biol. Sci. Intractable Neurol. Dis., Shinshu Univ., Inst. Biomed. Sci., Matsumoto, Japan; [4]Instrumental Analysis, Shinshu Univ., Matsumoto, Japan; [5]Shanghai Jiao Tong Univ., Shanghai City, China

Abstract: Postsynaptic density (PSD) is a dynamic structure, which is localized immediately underneath the postsynaptic membrane and works an essential devise for synaptic transmission and synaptic plasticity. A well-known model for architecture of PSD of type I excitatory synapse comprises of several scaffolding proteins including shank, PSD-95, GKAP and homer, to which various molecules involved in postsynaptic signaling are associated (scaffold/adaptor protein

model). On the contrary, "PSD lattice" has been identified in the preparation obtained after treatment of synaptosome, SPM or Triton X-100-PSD with deoxycholate, a relatively strong detergent, and has been considered to be a basic backbone of type I PSDs before the proposal of scaffold/adaptor protein model. However, major constituents of the PSD lattice and the relationship between the PSD lattice and the scaffold/adaptor protein model have not been known. It is essential to know the details of molecular architecture of PSD for full understanding the mechanisms, at the molecular level, of dynamic nature of PSD, one of basis of synaptic plasticity. We purified a fraction enriched with PSD lattice-like structures. The structure was recovered in the fraction slightly lighter than the pellet that contained PSDs. The lattice-like structure was planar, of which diameter was similar to PSD, sparser than PSD, and contained mesh-like woven fibers when observed in thin-section electron micrograph. Components of the structure were examined by Western blotting, immuno-dot blotting and immuno-gold negative staining electron microscopy. This study will give a new insight on the molecular architecture of type I excitatory PSD and new architecture model will be discussed.

Title: Direct interaction between postsynaptic proteins Shank3 and CaMKII

Authors: *T. L. PERFITT[1], X. WANG[2], T. NAKAGAWA[1], R. J. COLBRAN[1]
[1]Mol. Physiol. & Biophysics, [2]Vanderbilt Brain Inst., Vanderbilt Univ., Nashville, TN

Abstract: Shank3 is a postsynaptic scaffolding protein that is important for organizing neurotransmitter receptor signaling complexes at excitatory synapses. Mutations or deletions in the *SHANK3* gene are associated with neuropsychiatric disorders, such as autism spectrum disorder (ASD) and schizophrenia. Shank3 contains several protein-protein interaction domains that link postsynaptic receptors to downstream signaling proteins and the actin cytoskeleton. Calcium/calmodulin-dependent protein kinase II (CaMKII) is a signaling protein that is activated by calcium influx through these postsynaptic receptors. Recent proteomics data from our lab found that Shank3 is overly abundant in CaMKII complexes in the postsynaptic density. Therefore, we hypothesized that CaMKII can directly bind to Shank3.

Here, we confirm that complexes containing Shank3 and CaMKII can be co-immunoprecipitated from mouse forebrain and co-transfected HEK293 cells. Using GST-pulldown and purified CaMKII, we have identified a minimal CaMKII-binding domain on Shank3. This direct interaction *in vitro* requires pre-activation of CaMKII by Thr286 autophosphorylation. We used site-directed mutagenesis to identify residues in Shank3 that are critical for the direct Shank3-CaMKII interaction *in vitro*, as well as the co-immunoprecipitation from transfected HEK293 cells, but not for Shank3 binding to other proteins, such as $Ca_V1.3$. Moreover, co-immunoprecipitation from transfected HEK293 cells is essentially abrogated by mutation of the Thr286 autophosphorylation site to phospho-null Alanine. Ongoing studies are testing the effects of disrupting the Shank3-CaMKII interaction on Shank3/CaMKII localization and neuronal morphology. Together, our data demonstrate that the synaptic scaffolding protein Shank3 contains a novel binding domain for activated CaMKII.

Title: Severe impaired synaptic transmission in the Shank1/Shank3 double knock out mouse

Authors: *C. SALA[1], A. MOSSA[1], L. PONZONI[2], A. TOZZI[3], M. SALA[1], P. CALABRESI[3], T. M. BOECKERS[4], *C. SALA[1], C. VERPELLI[1]
[1]CNR Neurosci. Inst., Milano, Italy; [2]Fondazione Umberto Veronesi, Milano, Italy; [3]Dept. of Exptl. Medicine, Univ. of Perugia, Perugia, Italy; [4]Inst. for Anat. and Cell Biology, Ulm Univ., Ulm, Germany

Abstract: Shank family proteins (Shank1, Shank2 and Shank3) are large scaffold proteins located at the excitatory glutamatergic synapses. They are essential for building the structure of dendritic spines as their expression is sufficient to drive spine formation and enlargement. Importantly Shank proteins are differentially expressed in brain areas critical for learning and cognition. In particular, Shank1 and Shank3 are both highly expressed in hippocampus and cortex. Since Shank proteins play a crucial role in synaptic formation and function, it is not surprising that deletions and mutations in *SHANK* family genes are strongly associated with neurodevelopmental and neuropsychiatric disorders such as autism spectrum disorders (ASD)

and intellectual disability (ID). To dissect the role of these proteins in synapse function, we generated the Shank1/Shank3 double knock out (DKO) mouse. We found that Shank1/Shank3 deletion strongly reduce mice survival with a pick of mortality at P22-25. We then started to analyze young (P23) Shank1/3 DKO mice. PSD enriched fractions obtained from cortex show that the absence of Shank1 and Shank3 proteins cause a significant reduction of mGlu5 and Homer expression as well as reduced phosphorylation of eEF2, Akt, S6, Erk1/2 and Arc, suggesting that absence of Shank1 and Shank3 causes a functional reduction of the pathway that control protein translation. Moreover, we found that in both cortex and hippocampus of Shank1/3 DKO mice neurons exhibit reduced dendritic arborization and a reduced size of PSD. To clarify how these alterations affect brain functions we performed a battery of behavioral tests revealing that the Shank1/3 DKO mice have strong impairments in cognitive properties, social approach, repetitive behaviors and motor functions. These behavioral alterations are associated with an increase of cortical spikes measured by EEG recording and alterations in hippocampal LTP specifically in CA3. In summary, our results demonstrate the essential role of Shank1 and Shank3 in regulating hippocampal and cortical synapse maturation and function.

Title: Kalirin interacts with neuroligin family members as revealed by unbiased screens from brain and *In situ* analyses

Authors: *J. PASKUS[1], M. BEMBEN[2], Y. LI[1], K. W. ROCHE[1]
[1]Natl. Inst. of Hlth., Bethesda, MD; [2]Univ. of California, San Franscico, San Franscico, CA

Abstract: Alterations in dendritic spine morphology and function are critical for the synaptic plasticity underlying learning and memory. The Rho guanine nucleotide exchange factor Kalirin has been implicated as an important mediator of many processes including synaptic transmission and plasticity. The single Kalirin gene is alternatively spliced, resulting in multiple isoforms; however, Kalirin-7 is the only brain specific protein variant. Kalirin has multiple binding partners that have been reported, though the mechanism by which Kalirin-7 regulates synaptic transmission, particularly which protein-protein interactions are significant, remains largely unclear. To study Kalirin-7 protein interactions we first generated a Kalirin-7 specific antibody. Immunoprecipitating endogenous Kalirin-7 from mouse brain, we used liquid chromatography-tandem mass spectrometry to screen for potential Kalirin-7 interactors. Of potential hits,

members of the Neuroligin (NLGN) family of cell adhesion proteins were of particular interest given their overlapping phenotype with Kalirin-7, namely their ability to regulate spinogenesis. To test whether Kalirin-7 and NLGNs could interact, we performed co-immunoprecipitation experiments both *in vitro* and *in vivo*. Our results demonstrated that Kalirin-7 can interact with NLGN1, 2 and 3. Given high sequence conservation between Kalirin isoforms, we then tested whether other major Kalirin isoforms (5, 9, and 12) could interact with NLGN1 as well. Surprisingly, Kalirin-5 was not able to interact with NLGN1 *in vitro*, suggesting NLGNs interact with the N-terminal domains of Kalirin-7, 9, and 12, which are lacking in 5. Interestingly, Kalirin-7 and 5 both contain a PDZ-interacting motif, that appears not to mediate the interaction with NLGNs. Taken together, we demonstrate that NLGNs can interact with Kalirin-7, but not with all Kalirin isoforms. These data establish a novel isoform-specific interaction between two major proteins of the postsynaptic density.

Title: Identification of a novel PKA regulatory site in neuroligin-1

Authors: *J. JEONG[1], M. A. BEMBEN[1,2], Y. LI[1], K. W. ROCHE[1]
[1]NINDS, BUILDING 35, Bethesda, MD; [2]Univ. of California, San Francisco, San Francisco, CA

Abstract: Neuroligin-1 is a member of the neuroligin gene family encoding a single-pass transmembrane postsynaptic cell adhesion molecule that is critical for excitatory synaptic assembly and function. The large extracellular domain of neuroligin-1 is responsible for transsynaptic binding with neurexin, a presynaptic cell adhesion molecule, and the short cytoplasmic tail of neuroligin-1 is exposed to a variety of intracellular regulation. Importantly, neuroligin-1 binds to PSD-95, a scaffolding protein at excitatory synapses, through the PDZ ligand in the cytoplasmic tail, which is important for neuroligin-1 clustering at excitatory synapses.
In this study, we found protein kinase A (PKA) phosphorylates neuroligin-1, near the PDZ ligand, *in vitro* and in heterologous cells. Interestingly, a phospho-mimetic mutation at the PKA site significantly reduced the interaction between neuroligin-1 and PSD-95 *in vitro* and *in situ*. The phospho-mimetic mutant also showed reduced surface expression levels in cultured neurons, which implies an effect of the phosphorylation in neuroligin-1 trafficking and further functional consequences in neurons. Our results establish a novel molecular mechanism that regulates

neuroligin-1 and PSD-95 binding in a PKA activity-dependent manner, which can provide insights into excitatory synaptic development and function.

Title: AMPA receptor stabilization mediated by non-canonical Wnt signaling protects synapses against $A\beta_{42}$ oligomers synaptotoxicity

Authors: *C. MONTECINOS OLIVA[1,2,3], D. CHOQUET[2,3], N. INESTROSA[4]
[1]Pontificia Univ. Católica De Chile, Santiago, Chile; [2]Univ. de Bordeaux, Interdisciplinary Inst. for Neuroscience, UMR 5297, F-33000, Bordeaux, France; [3]CNRS, IINS UMR 5297, Bordeaux, France; [4]Ctr. for Aging and Regeneration (CARE UC), Pontificia Univ. Católica De Chile, Santiago, Chile

Abstract: AMPA receptors are responsible for most of fast excitatory transmission in hippocampal neurons. They are among the most dynamic glutamate receptors. The mechanisms surrounding the organization of AMPA receptors are being elucidated. Wnt5a, a non-canonical Wnt ligand, is a morphogen acting in the maintenance of dendritic arborization on hippocampal neurons. Wnt5a has been linked to several roles in mature hippocampal neurons; dendritic spine density, number of PSD95 clusters and glutamatergic currents that are tuned by Wnt5a in hippocampal neurons in culture. This leads to suggest a key role of Wnt5a in the architecture of excitatory synapses. Glutamatergic synapses are affected by $A\beta_{42}$ oligomers causing AMPA receptor endocytosis, diminished dendritic spine density and causing overall failures in synaptic excitatory transmission; effects being englobed in the term "Aβ oligomers synaptotoxicity". On the contrary, it has been shown that Wnt5a protects neurons against $A\beta_{42}$ oligomers synaptotoxicity. Given the fact that Wnt5a seems to counteract the distresses caused by $A\beta_{42}$

oligomers. We studied the mechanism through which Wnt5a protects from $A\beta_{42}$ oligomers. This led us to evaluate the effect of Wnt5a on AMPA receptor dynamic. By using super-resolution microscopy in live and fixed hippocampal neurons (14-16 DIV), we found that Wnt5a modulates the dynamic and localization of AMPA receptors. Specifically, Wnt5a immobilizes AMPA receptors in synaptic and extrasynaptic sites. This correlates with an increase in co-localization and interaction between GluA2 and PSD95 in dendritic spines, as measured by immunofluorescence and co-immunoprecipitation. These effects are exerted only by non-canonical activation, through Wnt5a ligand and not by the canonical effects of Wnt7a. Interestingly, pre-incubation of Wnt5a prevents toxicity of $A\beta_{42}$ oligomers and maintains basal AMPA receptors dynamics.
Our data suggests that Wnt5a prevents $A\beta_{42}$ oligomers effects by immobilizing AMPA receptors in synaptic and extrasynaptic sites.

Title: Removal of a genomic mutation in an actin motor protein by DN-CRISPRs reverts hyper-excitability and anxiety behavior in Flailer mice

Authors: *F. J. BUSTOS[1], S. PANDIAN[1], J.-P. ZHAO[1], M. HEIDENREICH[1], H. STROUF[1], F. ZHANG[1,2], M. CONSTANTINE-PATON[1]
[1]McGovern Inst. for Brain Res., MIT, Cambridge, MA; [2]Broad Inst. of MIT and Harvard, Cambridge, MA

Abstract: Myosin Va (MyoVa) is a dimer and + end actin motor. Flailer *(*Flr*)* mice express 2 copies of a mutant *myo5a* driven by the brain-specific promoter for *gnb5* fused in frame with a *myo5a* sequence lacking DNA encoding the distal lever arm and the ATP hydrolyzing end-feet of the motor. Mutant MyoVa thus binds cargo, but cannot perform its CNS function of moving post-synaptic molecules to the PSD on excitatory neuron spines. Both WT GnB5 and WT

MyoVa are intact in these mice. However, when Flr is homozygous for the *flr* gene the transport of WT smooth ER into spines is disrupted (Jones et al., 2000), synaptic molecules are largely restricted to dendritic shafts, and NMDAR LTD is missing (Yoshi et al., 2013). Whole body mutations of *myo5a* cause early death in rodents (Mercer et al., 1991) and humans, (Griscelli et al., 1978 and Elejalde et al., 1979) but mice homozygous for the *flr* gene, despite abnormal behaviors, live and breed normally. Removing the *flr* gene from specific brain regions would allow analyses of the pathways involved in the abnormal behaviors of *Flailer* mice. Double-nicking CRISPRs were targeted to the *flr* genomic sequence to remove a fragment of the *flr* gene without altering the endogenous DNA sequences of either *myo5a* or *gnb5*. This deletion produced a significant decrease in both *flr* mRNA and protein levels in *Flailer* neurons without altering expression levels of WT Gnb5 or MyoVa. Immunofluorescence experiments using antibodies against PSD95 and Synaptophysin demonstrate that clustering of synaptic proteins is recovered in neurons. Whole cell patch clamp recordings showed that hyper-excitability displayed by Flailer neurons was reverted to WT levels after infection with CRISPRs. Finally, viral stereotaxic introduction of these CRISPRs into ventral hippocampus reverted one of the anxiety phenotypes displayed by the Flailer.

Title: Spectroscopy approaches for the study of inhibitory post-synaptic proteins during plasticity

Authors: *F. COLACI[1], L. SCIPIONI[2], A. DIASPRO[2], P. BIANCHINI[2], L. LANZANÒ[2], A. BARBERIS[1]

Abstract: The fast diffusion of synaptic proteins has been shown to play an important role in the activity-dependent shaping of the synaptic strength. Our previous work demonstrated that during inhibitory long term potentiation (iLTP) gephyrin and GABAA receptors are accumulated at post-synaptic inhibitory sites. However, the events modulate the interactions between scaffold proteins and neurotransmitter receptors are poorly understood. To investigate the coordinated diffusion dynamics of the main GABAergic post synaptic proteins gephyrin and GABAA receptors we used Fluorescence Correlation Spectroscopy (FCS) and Raster Image Correlation Spectroscopy (RICS) to study the mobility of fluorescent proteins in both the plasma membrane and the cytoplasmic space. Our data suggest that, similarly to GABAA receptors, gephyrin molecules freely diffuse in the extrasynaptic space and are immobilized at both synaptic and extrasynaptic clusters in mice hippocampal cultured neurons. This spectroscopy approach allowed characterizing the mechanisms of synaptic clustering in basal conditions and during synaptic plasticity at inhibitory synapses.

Title: Free radical scavenger edaravone attenuates oxidative stress-induced gephyrin cleavage in developing neurons and neonatal hypoxia

Authors: *C.-C. HUNG[1], C.-Y. LEE[1], W.-H. CHIEN[1], C.-H. LIN[4], Y.-L. GAN[1], C.-J. JENG[2,3], C.-Y. WANG[1], Y.-H. LEE[1,3]
[1]Physiol., [2]Anat. and Cell Biol., [3]Brain Res. Ctr., Natl. Yang-Ming Univ., Taipei, Taiwan; [4]Nursing, Kang-Ning Univ., Taipei, Taiwan

Abstract: Gephyrin is the postsynaptic scaffolding protein for clustering $GABA_A$ receptors ($GABA_AR$) at inhibitory synapses. Our previous report indicated that gephyrin aggregation is regulated by growth-associated protein 43 (GAP43), an activity-dependent neuroplasticity protein, in developing cortical neurons. The growth-promoting activity of GAP43 depends on the PKC-dependent phosphorylation at serine 41 (S41) to stabilize actin filaments. We have shown that both in vitro and in vivo models of neonatal hypoxic-ischemic (HI) brain injury can increase GAP43-gephyrin association and decrease cell surface $GABA_AR$ via dephosphorylation of GAP43 at Ser41. The production of oxidative stress was found in neonatal HI brain injury. Here

we examined the effect of oxidative stress on the gephyrin clustering by using H_2O_2 and buthioninesulfoximine (BSO), a glutathione (GSH) synthase inhibitor to reduce the endogenous antioxidant glutathione. We found that both oxidative stress inducers moderately dephosphorylated GAP43 and yet markedly promoted gephyrin cleavage, but not misfolding, in developing rat cortical neurons. The BSO-induced gephyrin cleavage was calpain-dependent as it was blocked by calpain inhibitors calpeptin, MDL28170 and ALLN in both cultured neurons and mCherry-gephyrin-transfected HEK293T cells. However, co-immunoprecipitation result showed that BSO did not increase the association of GAP43 with either full-length or cleaved gephyrin. Treatment with edaravone, a clinically used free radical scavenger, to primary cortical neurons attenuated BSO-induced GAP43 dephosphorylation and gephyrin cleavage. In a transient HI-induced neonatal rat brain injury, both GAP43 dephosphorylation and gephyrin cleavage were increased at the ipsilateral cortex, and these detrimental effects were attenuated by intraperitoneal injection of edaravone. Immunofluorescent staining further revealed that tHI increased both gephyrin clusters as well as non-gephyrin misfolded protein signals in CA3 pyramidal neurons. Edaravone treatment profoundly reduced tHI-induced misfolded protein signals without reducing the tHI-increased gephyrin clusters, which represent GABAergic synapses. In summary, our data suggest that oxidative stress induces GAP43 dephosphorylation and calpain-dependent gephyrin cleavage in developing cortical neurons. Edaravone treatment may provide beneficial effect by attenuating these detrimental effects in neonatal brain injury.

Title: A rare variant in ANK3 in a patient with bipolar disorder leads to altered GABAergic inhibitory circuits

Authors: *A. D. NELSON[1,2], R. N. CABALLERO-FLORÁN[2], K. K. WALDER[4], V. BENNETT[5], P. M. JENKINS[3]
[1]Pharmacol., [2]Dept. of Pharmacol., [3]Dept. of Pharmacology, Dept. of Psychiatry, Univ. of Michigan, Ann Arbor, MI; [4]Dept. of Cell Biol., [5]Dept. of Cell Biol. and Departments of Biochemistry, Neurobio., Duke Univ., Durham, NC

Abstract: Bipolar disorder is a common mental illness characterized by pathological swings in mood ranging from mania to depression. Available therapeutics are insufficient for effectively treating the underlying cause of bipolar disorder, thus there is an unmet need to identify the cellular mechanisms that contribute to bipolar disorder to identify new therapeutic targets. Several large genome-wide association studies have identified *ANK3* as one of the most consistent and significant genes associated with bipolar disorder. The giant, 480kDa splice variant ankyrin-G (product of the *ANK3* gene) is a critical adaptor protein essential for the proper formation of axon initial segments and nodes of Ranvier. Recently, giant ankyrin-G was discovered to be critical for stabilizing GABAergic inhibitory synapses, which underlie the proper synchronization and function of neuronal networks, and abnormalities in GABAergic interneuron circuitry have been linked to bipolar disorder. Using cultured neurons, we have shown that giant ankyrin-G interacts directly with GABA receptor associated protein (GABARAP) to inhibit $GABA_A$ receptor endocytosis and stabilize GABAergic synapses. To test this mechanism *in vivo*, we generated a mouse model with a W1989R mutation in *Ank3*, which completely abolishes ankyrin-G association with GABARAP, as well as $GABA_A$ receptor clustering *in vitro.* Coronal brain sections from *Ank3* W1989R mice showed the loss of GABAergic basket cell synapses on cortical pyramidal neurons in layer II/III of the somatosensory cortex. In addition, whole-cell patch clamp recordings of miniature inhibitory postsynaptic currents (mIPSCs) revealed a reduction in both the frequency and amplitude of inhibitory $GABA_A$ receptor-dependent currents. The axon initial segments and nodes of Ranvier are spared in the W1989R mouse, making this a useful model to study the specific role of ankyrin-G and GABAergic circuitry to understand how dysfunction in these circuits may contribute to neuropsychiatric disease. Interestingly, we identified a lithium-responsive individual with bipolar disorder type I who is heterozygous for the W1989R mutation within the giant exon of *ANK3*. Future studies will examine neurons derived from induced pluripotent stem cells (iPCSs) from the W1989R *ANK3* patient and neurotypical controls to evaluate GABAergic signaling and the ability of potential therapeutics, particularly lithium, to rescue abnormal electrophysiology. Ultimately, establishing the mechanisms by which giant ankyrin-G regulates GABAergic circuitry may reveal novel therapeutic targets for the treatment of neuropsychiatric disorders.

Title: A novel role for corticotropin releasing factor signaling in the lateral habenula and its modulation by early life stress

Authors: *M. E. AUTHEMENT[1], R. D. SHEPARD[2], L. D. LANGLOIS[3], F. S. NUGENT[1]
[1]Pharmacol., [2]Uniformed Services Univ., Bethesda, MD; [3]Pharmacol., Uniformed Services Univ. of the Hlth. Scienc, Bethesda, MD

Abstract: Centrally released corticotropin releasing factor (i.e., extrahypothalamic CRF) acting within various brain regions is involved in behavioral and emotional responses to stress. Here, we demonstrate for the first time that extrahypothalamic CRF neurotransmission exists in the lateral habenula (LHb), an epithalamic brain region involved in stress evasion. Dysfunction of the CRF system and LHb is critical for development of stress-related disorders and addiction, however no study has investigated whether CRF signaling plays a role in activity of the LHb. In fact, the LHb shows immunoreactivity for both CRF and its receptor, CRFR1, and receives inputs from the structures that comprise the extrahypothalamic CRF system, but its involvement in this central CRF system is unexplored. Using whole cell patch clamp recording from rat LHb neurons, we found that CRF-CRF receptor 1(CRFR1) signaling increases the intrinsic excitability of LHb neurons through modulation of small- and large-conductance SK- and BK-type K^+ channels. In addition CRF reduced GABAergic synaptic transmission onto LHb neuron promoting LHb hyperactivity. Maternal deprivation (MD), a severe early life stress known to predict later-life psychiatric disorders, increases LHb neuronal excitability and blunts the excitatory actions of CRF on LHb neurons due to down-regulation of SK2 channel expression. Increasing the function of SK channels by positive allosteric modulation not only prevents CRF excitatory action on LHb intrinsic excitability but also reverses the effects of MD on LHb intrinsic excitability suggesting that SK channels may serve as novel pharmacological target in reversal of dysregulated stress-responsivity within the LHb during severe early life stress.

Abstract: Neuropeptides have been targets of therapy in the past, but to no avail, possibly due to our lack of understanding of their physiological role in the brain. In a previous study, we found that locally synthesized and released neurotensin is a significant contributor to chronic stress-induced inhibitory transmission changes in the oval Bed Nucleus of the Stria Terminalis (BNST) and promote anxiety-like behaviours in rats. Here, we combined, optogenetic neurophysiology and fluorescent *in situ* hybridization imaging to better understand the neurocircuitry affected by local neuropeptides release in this brain region. We show that neurotensin and dynorphin bi-directionally regulated central amygdala inhibitory inputs onto ovBNST neurons in the mouse. In sum, our data expands our understanding of neuropeptidergic neuromodulation within extended amygdala circuits.

Title: IGF-1 receptor differentially regulates spontaneous and evoked transmission via mitochondria at hippocampal synapses

Authors: *N. GAZIT[1], I. VERTKIN[1], I. SHAPIRA[1], M. HELM[2], E. SLOMOWITZ[1], M. SHEIBA[1], Y. MOR[1], S. RIZZOLI[2], I. SLUTSKY[1]
[1]Physiol. and Pharmacol., Tel Aviv Univ., Tel Aviv-Yafo, Israel; [2]Univ. of Goettingen Sch. of Med., Goettingen, Germany

Abstract: The insulin-like growth factor-1 receptor (IGF-1R) signaling is a key regulator of lifespan, growth, and development. While reduced IGF-1R signaling delays aging and Alzheimer's disease (AD) progression, whether and how it regulates information processing at central synapses remains elusive. In this study we aimed to identify the role of IGF-1Rs in normal synaptic function, characterize cellular and molecular mechanisms underlying IGF-1R-mediated synaptic modifications and determine whether IGF-1R signaling impacts early synaptic dysfunctions in AD model mice. To answer these questions, we combined fluorescence resonance energy transfer (FRET) spectroscopy, FM-based optical imaging of synaptic vesicles, cytosolic and mitochondrial Ca^{2+} imaging, electrophysiology and biochemistry. We show that the majority of IGF-1Rs are localized at the presynaptic site and that presynaptic IGF-1Rs are normally activated under resting conditions, elevating evoked release probability (*P*r), while suppressing spontaneous vesicle release at excitatory hippocampal synapses. Acute IGF-1R blockade or transient knockdown suppresses spike-evoked synaptic transmission and presynaptic cytosolic Ca^{2+} transients, while promoting spontaneous transmission and elevating cytosolic resting Ca^{2+} level. This dual effect on transmitter release is mediated by the mitochondria which attenuate Ca^{2+} buffering in the absence of spikes and decrease ATP production during spiking activity. Furthermore, our study reveals that IGF-1R expression / activation level inversely correlates to short-term synaptic plasticity and demonstrates that diminished IGF-1R tone rescues hippocampal hyperactivity and impaired synaptic plasticity observed in young APP/PS1 model mice. We conclude that the mitochondria, activated by IGF-1R signaling, constitute a critical regulator of information processing in hippocampal neurons by maintaining evoked-to spontaneous transmission ratio, while constraining synaptic facilitation at high frequencies. Moreover, excessive IGF-1R tone may contribute to hippocampal hyperactivity associated with Alzheimer’s disease.

Title: Modulation of hippocampal synaptic transmission by the tryptophan metabolites 3-hydroxy-kynurenine (3HK) and xanthurenic acid (XA)

Authors: S. A. NEALE[1], *T. E. SALT[2,1]
[1]Neurexpert, London, United Kingdom; [2]UCL Inst. Ophthalmology, London, United Kingdom

Abstract: The kynurenine pathway is a major route of tryptophan metabolism, and this pathway may be disturbed in several psychiatric and neurodegenerative disorders (Schwarcz *et al* 2012). 3-Hydroxy-kynurenine (3HK), a molecule arising from tryptophan, is a precursor for several kynurenines, including xanthurenic acid (XA). As we have previously shown that XA can reduce hippocampal synaptic transmission (Neale *et al* 2013), we sought to determine whether 3HK could have similar actions. Furthermore we tested the effects of the KAT inhibitor AOAA in order to investigate whether effects of 3HK could be due its conversion to XA (Salt *et al* 2016).
Parasaggital *in vitro* slice preparations were made from the brains of adult male Sprague-Dawley rats. Extracellular field recordings were made from the dentate gyrus (DG) area of the hippocampus in an interface bath at ~30°C. Field excitatory postsynaptic potential (fEPSP) responses were evoked (0.1ms pulses applied every 20s) by a bipolar stimulating electrode positioned in the lower to middle portion of the molecular layer of the DG.
Addition of XA (3mM) resulted in a reversible reduction in the fEPSP slope (8.4 ± 1.4 % reduction, n=5). These results are qualitatively similar to those we have previously obtained with XA in this experimental preparation in the mouse (Neale et.al., 2013). Addition of 0.3 mM 3HK to the perfusion medium had little effect on the fEPSP slope, whereas higher concentrations caused significant reductions in fEPSP slopes at 1mM (14.1 ± 2.0 % reduction, n=7) and 3mM (41.2 ± 4.2 % reduction, n=7). Pre-application of the non-specific KAT inhibitor amino-oxyacetic acid (AOAA; 1 mM) to the slices resulted in a significantly ($P<0.001$) lesser reduction (84.9 ± 3.7 % of control, n=5) of the fEPSP slope caused by 3mM 3HK.
In summary, we have shown that 3HK, the direct metabolic precursor of XA, has similar effects to XA in reducing synaptic transmission in the hippocampus. Furthermore, the action of 3HK could be reduced by the inhibitor AOAA. These findings are consistent with the idea that changes in 3HK levels could drive XA levels and thus produce effects on neuronal circuit function, although it does not exclude the possibility that 3HK has direct effects. Thus, malfunction of the kynurenine pathway, known to occur in diseases of the brain, could cause changes in synaptic function.

Title: CB1 receptor mediated neurotransmission in female adolesence

Authors: *C. G. REICH, A. FERRARO, P. WIG, N. AMADA, S. O'SULLIVAN, J. BOSCARINO
SSHS/Psychology, Ramapo Col. of New Jersey, Mahwah, NJ

Abstract: A previous study demonstrated that hippocampal CB1 receptor (CB1R) levels are lower in female adolescent animals compared to males (Reich et al., 2009). Following 21 day exposure to chronic mild stress, CB1 increased in females while decreasing in males; thus suggesting that hippocampal CB1 responds differentially to stress depending on sex. Several other lines of converging evidence clearly indicate a functional sex difference in the endocannabinoid system and behavioral reactions to exogenous cannabinoids in both human and animals (Rubino and Paralaro, 2011). However, there remains a paucity of data how these sex differences are manifested physiologically. We, therefore, begun a series of neurophysiological investigations on the endocannabinoid system in female adolescent rats. Preliminary studies show that exogenous activation of CB1 (WIN 55-212-2) enhances excitatory neurotransmission in the CA1 of female animals, while it classically decreases excitatory transmission in males. The latter is due to a CB1-mediated suppression of glutamate release. In females, we now provide evidence that CB1-modulation of excitatory neurotransmission results from enhancement of CB1-mediated suppression of GABAergic neurotransmission (inhibitory). Preliminary observations suggest that tonic CB1 activity at GABAergic synapses provides the mechanism for augmented suppression of inhibition in females.

Title: Conditional deletion of gbeta5 in sensory ganglia leads to changes in nociceptive but not pruriceptive responses in mice

Authors: *M. PANDEY[1], P. ADIKARAM[1], J.-H. ZHANG[1], A. AWE[1], A. GENIS[1], C. KITTOCK[1], C.-K. CHEN[2], W. F. SIMONDS[1]
[1]Metabolic Dis. Br., NIH, NIDDK, Bethesda, MD; [2]Ophthalmology, Baylor Col. of Med., Houston, TX

Abstract: Gβ5, an atypical member of Gβ family of proteins is an obligate binding partner of R7-RGS regulator of G protein signaling proteins. The role of Gβ5 and its interacting partners has been largely elucidated in sensory phototransduction but little is known about its role in somatosensation. R7 binding protein (R7BP) is a protein partner of R7-RGS/Gβ5 protein complex which helps in anchoring the complex to the neuronal plasma membrane and augmenting its signal regulatory activity. While testing the role of Gβ5 protein complex in somatosensation we recently discovered that R7BP plays a key role in pruriception. To further understand the function of Gβ5 in somatosensation we used a transgenic mouse with a floxed *Gnb5* allele to make a conditional knock out (KO) of Gβ5, since mice with a germline KO of Gβ5 have multiple abnormalities, making it hard to study its function. Mating the floxed *Gnb5* mice with specific Cre lines with known restricted expression patterns gave us the advantage of identifying the role of Gβ5 at the cellular level. We used two different Mice Cre lines, *Advilin Cre* and *Wnt-1 Cre* with floxed *Gnb5* to create conditional KO of Gβ5 in (a) sensory neurons, and (b) sensory and CNS neurons known to lie in the somatosensory circuit, respectively. *Advilin Cre* mice mated with a reporter mice expressing lox-STOP-lox-tdTomato revealed Cre activity specifically in dorsal root ganglia but not in spinal cord or brain tissue. However, *Wnt-1 Cre* activity in reporter mice revealed a wider expression in dorsal root ganglia, dorsal horn of spinal cord and several regions in mid brain and hind brain. Immunoblotting in *Advilin Cre*- Gβ5 floxed/floxed mice revealed a specific decrease in Gβ5 levels in dorsal root ganglia but not in spinal cord and brain. *Advilin Cre*- Gβ5 floxed mice showed no significant changes in response to pruritogenic chloroquine, 48/80 and gastrin releasing polypetide (GRP) as compared to cage matched littermates. These mice showed significant behavioral changes to pain stimulation, however, when exposed to capsaicin and mustard oil in eye wipe assays and hot plate analgesia,

but not for mechanical pain. In contrast, *Wnt-1 Cre*- Gβ5 KO mice showed significant behavioral changes to chloroquine and GRP but not 48/80 when compared to controls. These mice also showed a nociceptive phenotype similar to that of *Advilin Cre*- Gβ5 KO mice. These findings suggest that Gβ5 in sensory neurons may have a significant role to play in nociceptive signaling but not pruriceptive signaling in mice. Discovery of the functional role of Gβ5 in somatosensory signaling is important to understand its physiologic function and may allow its use as a drug target for treatment in pathologic pain or itch.

Title: GluN2-specific NMDA receptor regulation of synaptic transmission and excitability in the thalamus

Authors: *S. A. SWANGER, S. F. TRAYNELIS
Dept. of Pharmacol., Emory Univ., Atlanta, GA

Abstract: Communication between the cortex and thalamus is necessary for integrating cognitive, emotional, sensory, and motor information, and disrupted corticothalamic connectivity is evident in neurological disorders such as epilepsy, mood and anxiety disorders, and schizophrenia. Although corticothalamic circuits are critical for numerous brain functions and behaviors, the mechanisms controlling synaptic transmission and excitability in corticothalamic circuits remain unclear. The cortex and thalamus are reciprocally connected by glutamatergic corticothalamic and thalamocortical projections, which send collaterals to gabaergic neurons in the reticular thalamus. Reticular neurons negatively regulate thalamic circuits via feed-forward and feedback inhibition of thalamocortical neurons. In this study, we examined how synaptic and tonic N-methyl-D-aspartate receptor (NMDAR) activity regulates thalamic neurons. NMDARs are non-selective cation channels activated by co-agonists glutamate and glycine, and subject to voltage-dependent block by extracellular Mg^{+2}. NMDARs are tetrameric assemblies of two GluN1 and two GluN2 subunits, and the GluN2 subtypes (GluN2A-D) have distinct functional

properties such as deactivation rate and sensitivity to Mg^{+2} block. In reticular neurons, excitatory postsynaptic currents (EPSCs) recorded from mouse brain slices can be separated into two populations based on deactivation time course and relative size of the NMDAR component; these two EPSC populations have been proposed to be mediated by corticoreticular and thalamoreticular inputs (Deleuze and Huguenard, 2016). We found that GluN2 subunit-selective modulators affected the NMDAR component of these two EPSC populations differently, suggesting that the EPSCs may be mediated by distinct NMDAR subtypes. In addition, inhibition of GluN2C/D-containing NMDARs reduced the frequency of spontaneous inhibitory postsynaptic currents recorded from thalamocortical neurons, which we interpret to reflect decreased feed-forward inhibition from reticular neurons. NMDARs have been shown to mediate a tonic depolarizing current in reticular neurons due to activation by ambient glutamate, and our data may suggest that this tonic current is mediated GluN2C/D-containing NMDARs, which have reduced Mg^{+2} block at resting membrane potential compared to GluN2A/B. This work suggests that NMDARs have diverse functional roles in regulating synaptic transmission and excitability in the reticular thalamus, and these distinct functions may be mediated by receptors containing different GluN2 subunits.

Title: Syringaresinol selectively depresses excitatory synaptic transmission in hippocampal slices through the presynaptic inhibition

Authors: *Y. CHO, W. SONG, S. YOON, K.-Y. PARK, M.-H. KIM
Seoul Natl. Univ. Col. of Med., Seoul, Jongno-Gu, Korea, Republic of

Abstract: Many conventional drugs acting on the nervous system are originated from botanical sources. Psychoactive substances of plants affect the nervous system by mimicking actions of endogenous neuromodulators or neurotransmitters. Here we show that syringaresinol (SYR), a plant lignan found in Castela emoryi or Prunus mume, induces short-term depression of excitatory synaptic transmission via presynaptic modulations. Bath application of SYR transiently reduces the slopes of the field excitatory postsynaptic potentials (fEPSPs) at the hippocampal Schaffer collateral (SC)-CA1 synapse in a dose-dependent manner. This SYR-induced synaptic depression was insensitive to the blockers of NMDARs, the group I mGluRs,

and mAChRs. SYR mainly reduced excitatory synaptic transmission, while inhibitory synaptic transmission remained unchanged. However, SYR had no effect on the both conductance and desensitization of AMPARs but increased paired-pulse ratios of synaptic responses at short (20 and 50 ms) inter-stimulus intervals. These presynaptic changes were associated with the reduction of the readily releasable pool size. SYR also increased K^+-conductance in neurons, whereas Ca^{2+} currents were decreased by SYR. Collectively, our study identifies SYR as a new psychoactive compound and suggests that SYR reduces excitatory neurotransmitter release.

Title: Unique role of J domain of synapsin III in regulation of neurotransmitter release: Control by MAP kinase phosphorylation

Authors: *S.-H. SONG[1,2], G. J. AUGUSTINE[3]
[1]Lee Kong Chian Sch. of Medicine, NTU, Singapore, Singapore; [2]Marine Biol. Lab., Woods Hole, MA; [3]Lee Kong Chian Sch. of Med., Singapore, Singapore

Abstract: Among the 3 mammalian synapsin genes, synapsin III is unique in its regulation of release of dopamine (J. Neurosci. 30:9762), glutamate (J. Neurosci. 28:10835), and GABA (J. Neurosci. 36:6742). Presumably these functional attributes are conferred by the J domain, a structure found only in synapsin III. To examine the function of the J domain, we first injected a peptide from the J domain of rat synapsin III into squid giant presynaptic terminals. This peptide reversibly inhibited synaptic transmission, while a scrambled version did not; thus, the inhibitory effect is sequence-specific. Analysis of the kinetics of synaptic depression during high-frequency stimulus trains (50 Hz) revealed that J domain peptide inhibits synaptic transmission both by reducing the size of the readily-releasable pool (RRP) and by slowing mobilization of vesicles from the reserve pool (RP) to the RRP. A J domain peptide pseudophosphorylated (JD) at a MAPK phosphorylation site (S470) inhibited synaptic transmission, while a non-phosphorylatable version (JN) did not. Thus, regulation of transmitter release by J domain is under the control of the MAPK signaling pathway. Inhibition of synaptic transmission occurred more rapidly and at lower concentrations for JD compared to J peptide, suggesting that J peptide is phosphorylated before it blocks synaptic transmission. We also examined J domain function in microisland cultured mouse hippocampal neurons. Expressing recombinant J domain did not

affect the amplitude of autaptic EPSCs. During repetitive stimulation (10 Hz), wild-type J domain slowed the time constant of synaptic depression (24.3 ± 1.2 s) compared to control neurons (13.5 ± 0.4 s). However, pseudophosphorylated J domain (S470D) accelerated the rate of synaptic depression (8.5 ± 1.2 s), while a phospho-null mutant J domain (S470A) did not (23.0 ± 1.5 s). Thus, in both squid and mouse neurons, phosphorylation of J domain controls the ability of synapsin III to regulate mobilization of RP vesicles. However, J domain is not phosphorylated by MAPK under basal conditions in mouse neurons, while it is phosphorylated within minutes in squid neurons. Immunoprecipitation indicates that recombinant J domain inhibits multimerization of synapsin IIIa, suggesting a possible molecular mechanism for J domain control of RP mobilization. In summary, our results indicate that interactions mediated by the J domain of synapsin IIIa determine the dynamics of both RRP and RP vesicles, thereby regulating neurotransmitter release. Further, this regulation is controlled by MAPK phosphorylation.

Title: Glutamate release potentiation by NMDAR-inhibiting neurosteroid pregnanolone sulfate: Implications for neuroprotection

Authors: *T. SMEJKALOVA, Z. NAIMOVA, L. VYKLICKY
Inst. of Physiology, CAS, Praha, Czech Republic

Abstract: NMDAR activation by synaptically released glutamate is key to synaptic plasticity and can be neuroprotective. However, excessive NMDAR activation by tonically elevated extracellular glutamate mediates excitotoxicity. Recently, we have shown that endogenous neurosteroid pregnanolone sulfate (PA-S) selectively inhibits tonically over synaptically activated NMDARs, while potentiating presynaptic glutamate release. The mechanism of the PA-S-induced increase in synaptic glutamate release, and the implications of this effect for PA-S neuroprotection are unknown.
To address the mechanism of presynaptic potentiation by PA-S, we compared PA-S and a structurally similar neurosteroid pregnenolone sulfate (PE-S), which increases mEPSC frequency in primary hippocampal cultures by elevating presynaptic [Ca^{2+}]. We confirmed that pre-treatment of cells with 10μM extracellular BAPTA-AM blocked mEPSC frequency increase caused by 2μM Ca^{2+} ionophore ionomycin (+267±132% in control; +17±6% after BAPTA-AM;

p=0.06), and by 30μM PE-S (+330±193% in control; -1±13% after BAPTA-AM, p=0.04). Surprisingly, we found that presynaptic Ca^{2+} chelation with BAPTA-AM did not block the mEPSC frequency potentiation by 100μM PA-S (+164±42% in control; +122±10% after BAPTA-AM; p=0.45), suggesting that PA-S potentiates glutamate release downstream of Ca^{2+} influx.
We used oxygen-glucose deprivation (OGD) in primary hippocampal cultures to test neuroprotective properties of PA-S in two experiments. First, we tested the effect of PA-S present during acute OGD. While NMDAR inhibition by PA-S would be expected to be neuroprotective, increased synaptic glutamate release by PA-S could exacerbate toxic glutamate buildup during OGD. We found that that the balance of PA-S actions during acute OGD results in neuroprotection (36±4% neuronal death after 1h OGD; 14±3% after OGD with 50μM D-AP5, p=0.01; 21±3% after OGD with 100μM PA-S, p=0.06). Second, stimulation of excitatory synaptic activity prior to OGD, a form of ischemic preconditioning, reduces subsequent OGD damage. Given the ability of PA-S to potentiate glutamate release, we asked whether PA-S may be an effective preconditioning stimulus. Remarkably, we found that PA-S applied for 48h prior to (but not during) 1h OGD was indeed significantly neuroprotective (neuronal death was 38±2% in control; 20±6% after preconditioning with 50μM bicuculline+500μM 4-AP, p=0.04; 24±3% after preconditioning with 100μM PA-S, p=0.03). Together, our results show that PA-S, with its unique combination of synaptic effects, is exceptionally well suited to promote neuronal survival in the face of excitotoxic challenge.

Abstract: Modulation of neurotransmitter exocytosis by activated Gi/o-type G-protein coupled receptors (GPCRs) is a universal regulatory mechanism used both to avoid overstimulation and to influence circuitry. One of the known modulation mechanisms is Gβγ and soluble N-ethylmaleimide-sensitive factor attachment protein receptor (SNARE) complex interaction. There are 5 Gβ and 12 Gγ subunits, but specific Gβγs activated by a given GPCR *in vivo* are not known. Presynaptic α_{2a}-adrenergic receptors (α_{2a}-ARs) in both adrenergic (auto α_{2a}-ARs) and non-adrenergic neurons (hetero α_{2a}-ARs) inhibit neurotransmitter release and affect various physiological functions such as anesthetic sparing and working memory enhancement. Here, we investigate whether auto α_{2a}-ARs in sympathetic neurons use the same Gβγ subunits as hetero α_{2a}-ARs in other neuronal types to inhibit exocytosis by interacting with SNARE. Using several mice models including transgenic Flag-α_{2a}-ARs, knock-in HA-α_{2a}-ARs, co-immunoprecipitation and mass spectrometric analysis, we have determined the Gβ and Gγ subunits that interact with auto and hetero α_{2a}-ARs and SNARE complexes. So far, we find that $G\beta_2$, $G\gamma_2$, and $G\gamma_3$ preferentially interact with activated auto α_{2a}-ARs. We also see a basal Gβγ-SNARE interaction and a 2 fold enhancement of this interaction upon the auto α_{2a}-ARs activation. Further understanding Gβγ specificity and Gβγ-SNARE interaction may offer new insights into the normal functioning of the brain, as well as better understanding of disease progression.

Title: Cannabinoid receptor expressing interneurons of layer 2/3 exhibit specific morphological and functional properties in primary and secondary visual cortical areas

Authors: *M. MONTMERLE[1], A. AGUIRRE[1], O. SCHLUETER[2], J. LOURENÇO[1], A. BACCI[1]
[1]Inst. du Cerveau et de la Moelle Epiniere (ICM), Paris, France; [2]Univ. of Pittsburgh, Pittsburgh, PA

Abstract: During sensory processing, the correct subjective representation and interpretation of the external world is accomplished by a constant bi-directional communication between primary and secondary sensory cortices. Yet, the synaptic rules governing the processing of sensory information in these distinct cortical areas, and the specific microcircuit players involved, are still poorly characterized. After finding that the cannabinoid receptor (CB1) is more widely expressed in secondary than in primary areas, we asked whether the neurons expressing CB1 had different properties in the two areas. CB1 is mainly expressed in large inhibitory basket cells that target the soma of other neurons, thereby modulating their output. Using whole-cell patch clamping, we found that in layer 2/3 of the primary visual area of mice (V1), CB1+ interneurons exerted strong and reliable inhibition onto pyramidal cells. Interestingly, in the secondary visual area (V2) CB1+ interneurons exerted small and unreliable inhibition onto excitatory cells. Interestingly, pharmacological blocking of CB1Rs in V2 led to a potentiation of inhibition, while in V1 this effect was not observed, suggesting that CB1 interneurons in V2 are ‘doped’ by tonically or constitutively activated receptors. Differences in the kinetics of recovery from depolarization-induced suppression of inhibition (DSI) also support this hypothesis. In addition, we found a different innervation pattern of CB1+ interneurons in the two visual areas: in V2, CB1+ interneurons projected their axons both within their cortical layer and to deeper layers, while in V1 these projections were principally intralaminar. This study suggests that different visual areas exhibit differential CB1-mediated modulation of perisomatic inhibition onto layer 2/3 pyramidal neurons. Moreover, our results show differences in microcircuit connectivity patterns, suggesting area-specific differences in the integration of visual information.

Title: Nociceptive input imbalance mediated by ablation of C-fibers causes plastic change of GABAergic neuronal circuits in the insular cortex

Authors: *K. YAMAMOTO[1], S. MURAYAMA, 1018310[2], M. KOBAYASHI[3]
[1]Dept. of Pharmacology, Nihon Univ. Sch. of Dent., Chiyoda Kanda Surugadai, Japan; [2]Endodontics, Nihon university, Tokyo, Japan; [3]Nihon Univ. Sch. Dent., Chiyoda-Ku, Japan

Abstract: Sensory experience plays critical roles in the refinement of cortical connections. The cortical plastic changes have been enthusiastically studied in the visual cortex that monocular deprivation during a juvenile period yields a strong shift of ocular dominance column toward the non-deprived eye (ocular dominance plasticity). The unbalance of signal inputs causes plasticity in visual cortex. Therefore, we hypothesized that the addition of the primary afferent fibers (Aδ and C-fiber) induces plastic changes in insular cortex (IC), which receives orofatial nociceptive inputs. To test the hypothesis, we made the model whose C-fibers were ablated by capsaicin injection and examined plastic changes of inhibitory neuronal circuits in this model. At postnatal days 1-2, neonatal rats received subcutaneous injection of capsaicin (100 mg/kg) to the base of the neck. Miniature inhibitory postsynaptic currents (mIPSCs) were recorded from excitatory pyramidal neuron (Pyr) in IC layers II/III on 18 to 28 days after injection. Unitary IPSCs (uIPSCs) were recorded from the connection between inhibitory fast-spiking interneuron (FS) and Pyr. To evaluate the precise synaptic profiles including the number of release sites, release probability, and quantal size, we employed variance-mean (V-M) analysis. To estimate the quantal size of IPSCs in FS→Pyr connections, we replaced 2 mM $[Ca^{2+}]_o$ with 4 mM Sr^{2+}, which induces asynchronous release of GABA (aIPSC). Pyr of the capsaicin-treated rats (CAP) showed the smaller amplitude of mIPSCs than Sham without changing the frequency of mIPSC. The amplitude of uIPSCs obtained from CAP was also smaller than that from Sham. V-M analysis demonstrated the smaller quantal size in CAP compared to that in Sham. On the other hand, the release probability and the number of release sites were not statistically different between them.

In agreement with the results of the mIPSCs and the quantal size of V-M analysis, the amplitude of aIPSCs in CAP was smaller than that in Sham. We demonstrated that inhibitory synaptic transmission in IC was significantly reduced by ablation of C-fibers. The suppression of postsynaptic mechanisms of $GABA_A$ receptors is likely to be an underlying mechanism of the smaller amplitude of m, u, and aIPSCs.

Title: Examining the effect of systemic oxytocin on mesolimbic dopamine transmission

Authors: *M. K. ESTES, T. G. FREELS, W. T. PRATER, M. SWAMY, D. B. LESTER
Psychology, Univ. of Memphis, Memphis, TN

Abstract: Oxytocin is receiving much attention for its role in maternal bonding, stress, memory and learning, and social bonding. Growing research, both preclinically and clinically, indicates oxytocin may also relieve anxiety and attenuate addictive behaviors, particularly related to psychostimulant use. Mesolimbic dopamine transmission is known to be involved in both anxiety and addiction, but the interaction between oxytocin and dopamine is not clear. The present study investigated the effects of chronic oxytocin administration on dopamine release in the nucleus accumbens (NAc). Using in vivo fixed potential amperometry with carbon fiber recording electrodes, ventral tegmental area (VTA) stimulation-evoked dopamine release was recorded in the NAc of anesthetized C57BL/6J mice following either chronic oxytocin or saline administration. The chronic pretreatment paradigm, which has shown to alter related behaviors in mice (Sobota et al., 2015), included 4 ip injections of oxytocin (1mg/kg) or saline with 48 hours between injections. During dopamine recordings, mice received an ip injection of either the dopamine reuptake blocker nomifensine (10 mg/kg) or saline. Compared to saline pretreatment, chronic oxytocin pretreatment decreased baseline dopamine release by 42.9% ($p=0.001$). Baseline dopamine half-life was also decreased following chronic oxytocin pretreatment compared to saline pretreated controls (0.19 and 0.25 sec, respectively; $p=0.039$), which indicates increased dopamine transporter (DAT) efficiency in the oxytocin pretreated mice. Nomifensine had a reduced effect following chronic oxytocin in that the percent change in dopamine half-life was significantly less than that of saline pretreated mice 20 min post injection (344.1% and 586.6%, respectively; $p=0.015$). Overall, the present study provides direct evidence

that systemic oxytocin administration can alter mesolimbic dopamine transmission. Chronic oxytocin pretreatments reduced mesolimbic dopamine transmission and attenuated the effect of a psychostimulant (nomifensine) on this well-established reward pathway. An understanding of the neural effects of oxytocin are particularly important given the potential multitudes of therapeutic uses for this drug.

Title: Gene-based synaptic inhibition using adenovirus mediated botulinum toxin A fragments

Authors: *Y. CHEN, O. P. KEIFER, JR, L. DI, N. M. BOULIS
Dept. of Neurosurg., Emory Univ. Sch. of Med., Atlanta, GA

Abstract: Spasticity is a debilitating disorder of motor neuron hyperexcitation characterized by involuntary muscle contractions that can be extremely painful and incapacitating. It affects more than 12 million people worldwide, and is associated with a wide spectrum of diseases, including stroke, multiple sclerosis, and cerebrospinal trauma. One of the prevailing treatments for spasticity is botulinum neurotoxin (BoNT) injection, which ameliorates excessive muscle contractions by preventing presynaptic acetylcholine (Ach) release at the neuromuscular junctions (NMJ). However, the need for repeated injections and the high cost of such treatment render this option suboptimal. In this study, we present a novel application of gene-based neuromodulation for control of spasticity by delivering transgenes containing different gene fragments of BoNT serotype A (BoNT/A) to spinal cords of rats. BoNT/A consists of a light chain (LC), which contains the catalytic domain, and a heavy chain (HC), which contains the translocation domain (TD) and the receptor-binding domain (RBD). The efficacy of different combinations of gene fragments is compared in behavioral tests, histology, and Western blotting. As a translational laboratory, our ultimate goal is to develop a gene-based neuromodulatory therapy for spasticity that can be utilized for human clinical trials.

Title: Functional analysis of TRIM55 gene in human induced pluripotent stem cells from individuals with idiopathic autism

Authors: *J. NESTOR[1], P. D. STEIN[2], M. W. NESTOR[2]
[1]Hussman Inst. For Autism, Baltimore, MD; [2]Hussman Inst. for Autism, Baltimore, MD

Abstract: Background: GWAS studies of Patients with Autism have elucidated genetic candidates that are involved in synaptic vesicle transmission and overall electrophysiological network organization. Tripartite Motif Containing 55 (TRIM55 also known as MURF2) is a *de novo* mutation with high penetrance that has been identified in a subset of our hiPSC lines from individuals with idiopathic autism via whole genome sequencing (Cukier et a., 2014).
Objective: We have designed a Lenti-GFP-TRIM55 knock-down vector to investigate a possible role for TRIM55 synaptic transmission and overall network activity in two individuals with idiopathic autism who harbor this suspected variant.
Methods: Human induced pluripotent stem cell (hiPSC) lines from two individuals with idiopathic autism and two controls were differentiated into mixed cortical cultures using dual-SMAD inhibition protocols. After terminal differentiation and aging *in vitro* for 30 or 60 days, synaptic transmission was investigated using a chemical LTP (cLTP)-inducing protocol. Cultures were assayed using high-content imaging provided by the ThermoFisher ArrayScan XTI. The intensity of phospho-CREB staining was used to analyze the robustness of cLTP across the hiPSC - derived neuronal cultures. Multi-electrode arrays (MEAs) were then used to study the overall network activity in control and autism lines within treatment and non-treatment cLTP groups. Finally, the genetically encoded calcium indicator Gcamp6 was used to assay calcium transients in the lines.
Results: We observed a significant decrease in the network spiking activity as measured by MEA as well as the number of spontaneous somatic calcium transients in one of the lines that harbor the TRIM55 mutation but not the other. Additionally, use of the scratch assay revealed a significant decrease in the migration of both lines as compared to controls.
Conclusions: This study suggests a possible role for TRIM55 interactions with other *de novo* variants in individuals with idiopathic autism, with effects on synaptic function and cell migration.

Title: Effect of histamine H_3 receptor activation on rat prefrontal cortex dopaminergic transmission and in a model of schizophrenia

Authors: *G. AQUINO-MIRANDA[1], J. ESCAMILLA-SÁNCHEZ[2], R. GONZÁLEZ-PANTOJA[2], L. E. RAMOS-LANGUREN[3], A. BUENO-NAVA[4], C. RIOS[3], J.-A. ARIAS-MONTANO[2]

Nacional de Rehabilitación Luis Guillermo Ibarra Ibarra, Secretaría de Salud, Mexico City, Mexico

Abstract: Alterations in the function of the prefrontal cortex (PFCx) have been related to schizophrenia. The PFCx expresses high levels of histamine H_3 receptors (H_3Rs) and it is innervated by dopaminergic neurons located in the ventral tegmental area (VTA). In this work, we set out to determine the effect of H_3R activation on dopaminergic transmission in the rat PFCx by analyzing [^{3}H]-dopamine uptake by synaptosomes and depolarization-evoked release of [^{3}H]-dopamine in slices, as well as the effect of the local administration (prelimbic cortex) of H_3R ligands in a rat model of schizophrenia. The presence of H_3Rs was confirmed by the specific binding of N-α-[methyl-^{3}H]-histamine ([^{3}H]-NMHA) to CPFx synaptosomal membranes (maximum binding, B_{max}, 274 ± 26 fmol/mg protein, K_d, 2.27 nM). [^{3}H]-NMHA binding was inhibited by the H_3R agonists histamine (inhibition constant, Ki, 21.9 nM), immepip (Ki 3.2 nM) and RAMH (Ki 6.3 nM), and by the antagonists/inverse agonists clobenpropit (Ki 24.1 nM), ciproxifan (Ki 26.6 nM) and iodophenpropit (Ki 43.4 nM). The uptake of [^{3}H]-dopamine by PFCx synaptosomes was inhibited by GBR-12909 (IC_{50} 112.2 nM), desipramine (IC_{50} 3.4 nM) and fluoxetine (IC_{50} 1,737 nM), indicating that [^{3}H]-dopamine is taken up by dopaminergic and noradrenergic nerve terminals. The uptake of [^{3}H]-dopamine was not affected by the H_3R agonist RAMH (10^{-10}-10^{-6} M). Furthermore, H_3R activation with RAMH (1 µM) or immepip (1 µM) had no effect on the depolarization-evoked release of [^{3}H]-dopamine from PFCx slices, in the presence of sulpiride (1 µM) to block D_2 autoreceptors. In the rat model of schizophrenia, the administration in the prelimbic cortex of RAMH (19.8 ng/1 µl, 1 mM) increased, but not significantly, the locomotor activity induced by the systemic administration of MK-801 (0.3 mg/kg, ip), a noncompetitive antagonist at the NMDA glutamate receptors. In contrast, RAMH inhibited significantly (-46%) the spontaneous activity of control rats. Negative symptoms in the schizophrenia model were evaluated by prepulse-inhibition (PPI) of the startle response. The

local administration of RAMH (19.8 ng/1 µl) in the prelimbic cortex prevented the inhibition of PPI induced by MK-801 (0.15 mg/kg, ip), and the effect of the H_3R agonist was blocked by the previous injection of ciproxifan (30.6 ng /1 µl), supporting a H_3R-mediated action. In perfused PFCx slices, MK-801 (10 µM) significantly inhibited depolarization-evoked [^{3}H]-dopamine release (-32.8 ± 2.62% of control values), but this effect was not modified by RAMH or ciproxifan. Our results suggest that through the activation of postsynaptic H_3Rs histamine modulates dopaminergic transmission in the prefrontal cortex

Title: A study on the behavioral and neuronal phenotype of syntaxin 1B gene-ablated mice: Involvment of syntaxin 1B in the fever-associated epilepsy syndromes

Authors: *T. MISHIMA[1], T. FUJIWARA[1], T. KOFUJI[2], Y. TERAO[1], K. AKAGAWA[1]
[1]Cell Physiol., [2]Radioisotope Lab., Kyorin Univ. Sch. of Med., Tokyo, Japan

Abstract: Two syntaxin 1 (STX1) isoforms, HPC-1/STX1A and STX1B, are coexpressed in neurons and function as neuronal target membrane (t)-SNAREs. However, little is known about their functional differences in synaptic transmission. STX1A null mutant mice develop normally and do not show abnormalities in fast synaptic transmission, but monoaminergic transmissions are impaired (Mishima *et al*. J Neurosci, 2012). We previously reported that STX1B is primarily involved in the regulation of different types of fast synaptic vesicle exocytosis, including spontaneous and evoked release of glutamatergic and GABAergic synaptic transmission (Mishima *et al.* PloS one, 2014). Recently, mutations in the STX1B gene have been shown to cause a broad spectrum of fever-associated epilepsy syndromes. In the present study, in order to examine involvement of STX1B in pathogenesis of fever-associated epilepsy syndromes, we assessed for susceptibility to seizures induced by systemic administration of PTZ or kainic acid in STX1B gene-ablated mice. We found that STX1B heterozygote mice showed increased susceptibility to the drugs. PTZ-induced seizures were blocked by anti-convulsant drug VPA and Phenytoin. We also examined the effect of acute high temperature to burst activity of cultured neuronal networks which resembling epileptiform seizures. High temperature decreased burst

frequency in wild-type neurons but not in STX1B heterozygote neurons. To clarify the influence of temperature on synaptic functions of STX1B, we examined presynaptic properties of neurotransmitter release and transporter kinetics in glutamatergic and GABAergic synapses of cultured hippocampal neurons. Implication of STX1B in fever-associated epilepsy syndromes will be discussed.

Title: Spinal potentiation after hindpaw ischemia mediated by group II mGluRs and nitric oxide in mice

Authors: *T. ONISHI[1], T. WATANABE[1], M. SASAKI[1], Y. KAMIYA[1], T. KOHNO[2], M. HORIE[3], H. TAKEBAYASHI[4], H. TSUKANO[5], R. HISHIDA[5], H. BABA[1], K. SHIBUKI[5]

Institute, Niigata Univ., Niigata-Shi, Japan

Abstract: Transient ischemia of the extremities produces nerve conduction block and tingling sensation, suggesting that nerve conduction block may modulate spinal neural circuits. Previously, we have reported that spinal potentiation together with reduced mechanical thresholds for hindpaw-withdrawal reflex were produced after transient ischemia applied to the hindpaw in mice. These changes were likely mediated by group II metabotropic glutamate receptors (group II mGluRs), since they were inhibited by application of an agonist for group II mGluRs. We also reported that spinal potentiation was induced bilaterally after ischemic treatment applied only to the left hindpaw, suggesting that some diffusible messengers may be involved in these changes. In the present study, we investigated a possible role of nitric oxide (NO), one of diffusible mediators that may induce neuropathic pain in a wide area of the spinal cord. We confirmed that NO donor applied to the intrathecal space alone potentiated the cortical responses. To investigate the effects of NO application at the spinal cord, we used von Frey test. Mechanical allodynia was induced after spinal application of NO donor. The potentiation observed at the spinal cord and the cortex induced by hindpaw ischemia was clearly suppressed by spinal application of L-NG-nitroarginine methyl ester (L-NAME), an inhibitor of NO

synthase (nNOS). Furthermore, no potentiation was observed in nNOS knockout mice. To visualize NO formation in the spinal cord during hindpaw ischemia, we used diaminofluorescein-FM (DAF-FM), a fluorescent NO indicator. We found that an increase of fluorescence derived from the DAF-FM and NO complex was found at the ischemic side. A similar but slightly smaller increase was also observed at the contralateral side. These results clearly indicated the roles of NO production in the spinal and cortical potentiation. We investigated the relationship between nNOS and group II mGluRs in spinal cord. In immunohistochemical staining, we found that nNOS and group II mGluRs were present in the superficial layers of the dorsal horn. Furthermore, we confirmed some cell bodies at dorsal horn had nNOS and group II mGluRs using in situ hybridization. These results suggest that the failure of group II mGluR activation, which may be produced by nerve conduction block during hindpaw ischemia, might produce NO that triggers potentiation in spinal neural circuits. These changes might be involved in the induction of neuropathic pain.

Abstract: Dysbindin, a subunit of the octomeric BLOC-1 complex, is necessary for proper synaptic function and GABAerigic interneuron development. In post-mortem tissue of patients with schizophrenia, there is a significant reduction of dysbindin in the hippocampus. Dysbindin null mice and mouse models of neurodevelopmental disorders are characterized with defective GABAerigic transmission, potentially due to an observable loss of parvalbumin-positive

interneurons. This could describe a common molecular pathway is several diverse neurodevelopmental disorders. For this study, we define the transcriptome of the wild type and dysbindin null mouse. We report changes in parvalbumin in agreement with previously reported data. We further examined the number of paravlbumin-positive neurons within the subregions of the hippocampus. We also demonstrate changes in chloride co-transporters NKCC1, KCC2, and NCKX2. Additionally, we observed changes in potassium channel subunits Kcne2 and Kcnj13. This study suggests that loss of dysbindin results in altered expression of molecules that regulate the excitatory/inhibitory balance in the hippocampus.

Title: GV-58, a novel calcium channel gating modifier, reverses aging-induced weakness in transmitter release from mouse neuromuscular synapses

Authors: M. WU[1], J. KING[2], *S. D. MERINEY[2]
[1]neuroscience, Univ. of Pittsburgh, Pittsburgh, PA; [2]Univ. Pittsburgh, Pittsburgh, PA

Abstract: We have studied the changes in neuromuscular junction (NMJ) structure and function as these synapses mature and undergo age-related changes. Our goal was to test the hypothesis that our newly developed calcium channel agonist gating modifier (GV-58) could provide symptomatic relief for normal aging-related NMJ weakness. First, we documented changes in NMJ organization and function with aging. Neuromuscular synapses matured to their adult form and function over the first few months after birth, and then remained relatively stable at a quantal content of about 80 for about 14-16 months. The first aging-related changes appeared to be postsynaptic as receptor staining broke apart (documented by small patches of α-bungarotoxin staining) and acetylcholine sensitivity appeared to be reduced (as evidenced by reductions in miniature endplate potential amplitude). These postsynaptic changes began at about 17-18 months of age, and progressed gradually until death (between 24-32 months of age). The hypothesized reduction in postsynaptic acetylcholine receptor sensitivity was supported by what appeared to be a presynaptic homeostatic increase in transmitter release between 18-24 months of age (quantal content averaged 131.6 + 10.4 at 20 months of age). This transient increase in

quantal content reversed, and transmitter release was reduced such that by 25-30 months of age, quantal content was significantly lower than normal adult values. This age-related biphasic time-course of changes in presynaptic quantal content gradually led to NMJs with reduced immunohistochemical staining for presynaptic markers of active zone organization (bassoon and Cav2.1 calcium channels). Interestingly, after NMJs became weaker than normal adults (quantal content averaged 23.0 ± 3.6), and before they degenerated to the point that transmitter release was nearly eliminated (endplate potentials less than 2 mV), our novel calcium channel agonist gating modifier (that prolongs mean open time) could reverse synaptic weakness (increasing quantal content to an average of 45.7 ± 6.5; or a paired analysis increase of 2.35 ± 0.3 fold). These data provide evidence that GV-58 could be developed as a symptomatic treatment for neuromuscular weakness associated with aging.

Title: Memory-enhancing and neuroprotective drug noopept modulates synaptic activity and $[Ca^{2+}]_i$ dynamics in CA1 hippocampal neurons

Authors: *V. G. SKREBITSKY, S. N. KOLBAEV, R. V. KONDRATENKO, I. S. POVAROV
Res. Ctr. of Neurology., Moskva, Russian Federation

Abstract: Proline-containig dipeptide Noopept (NP) is a structural analog of piracetam, one of the first generation nootropics. Like piracetam, NP demonstrates wide spectrum of cognition improvment as well as neuroprotective properties in vivo and in vitro although at much lower doses. Its positive effect was also confirmed in patients with mild cognitive impairment of cerebrovascular and traumatic origin, in animal models of brain ischemia, Alzheimer and Parkinson diseases (Ostrovskaya et al., 2008; Jia et al., 2011). Although the effectiveness of NP was shown in a number of studies, the mechanism of its action, cellular targets as well as affected signaling pathways are still poorly understood. Our previous results demonstrated that NP significantly increased action potential (AP) frequency in stratum radiatum (SR) interneurons and the frequency of AP-dependent IPSC in pyramidal cells. In this study, we continued this line performing direct measurements of neuronal intracellular calcium in hippocampal organotypic slices from postnatal (p6) rats. We showed for the first time that NP activated neuronal calcium dynamics in regional specific manner. It selectively increased the frequency of Ca transients in

hippocampal neurons located in SR without significant changes in pyramidal layer (SP) and basal level of Ca in all investigated neurons. The amplitude and duration of transients as well as the background level of intracellular calcium was not subject to significant changes during the NP application. Taking into account layer specificity of neuronal distribution in hippocampus we conclude that NP selectively changes intracellular calcium activity in SR interneurons without significant changes in SP neurons - preferentially pyramidal neurons. The most straightforward assumption is that NP affects glutamate or cholinergic transmission. Besides the fact that both types of synapses are abundant in CA1, they also have Ca-permeable postsynaptic targets selectively expressed in SR interneuron: Ca-permeable AMPAR (Buldakova et al.,2007) and alpha 7-containing nicotinic AChR (Khiroug et al., 2003). Selective stimulation of cholinergic transmission may explain compensatory effect of NP in experimental models of memory loss (Belnik et al.,2007) and augmentation of response to exogenous ACh (Ostrovskaya et al., 2001). Involvement of cholinergic transmission is supported by our preliminary electrophysiological results demonstrating the block of NP effect on IPSCs in pyramidal neurons by methyllycaconitine -selective antagonists of alpha 7-containing nicotinic AChR. Additional experiments are required to elucidate the target of NP effect.

Title: CASY-1, an ortholog of mammalian Calsyntenins regulates GABA release at *C. elegans* neuromuscular junction in an isoform-specific manner

Authors: *S. THAPLIYAL[1], Y. DONG[2,3], A. VASUDEVAN[4], J. BAI[2,3], S. P. KOUSHIKA[4], K. BABU[1]
[1]Dept. of Biol. Sci., Indian Inst. of Sci. Educ. and Res., Mohali, India; [2]Basic Sci. Division, Fred Hutchinson Cancer Res. Ctr., Seattle, WA; [3]Dept. of Biochem., Univ. of Washington, Seattle, WA; [4]Dept. of Biol. Sci., Tata Inst. of Fundamental Res., Mumbai, India

Abstract: Abstract:
A remarkable feature of nervous system is the specific connections between the neurons that are

responsible for the orchestrated neural networks and circuitry of our brain. Considering the complexity of the nervous system, a tightly controlled spatial and temporal regulation of several different classes of cell adhesion molecules (CAMs) is essential. Existing literature highlighting the role of neural CAMs suggests that CAMs are not only specific to adhesion but are also required for various aspects of synapse development and function.
GABA is a neurotransmitter that is functional in both vertebrate and invertebrate nervous systems. In vertebrates, 30-40% of the CNS synapses are thought to be GABAergic and alterations in GABAergic neurotransmission have been associated with several different neurological disorders. Despite, such an important role in the nervous system, our knowledge about the regulation of GABAergic neurotransmission has just started to evolve. In this study, we are proposing a novel role of CASY-1, a *C. elegans* ortholog of the mammalian Calsyntenins, in regulating GABAergic neurotransmission at the *C. elegans* NMJ in an isoform-specific manner. Despite considerable reports of involvement of Calsyntenins in GABAergic synapse development and function, it has been very difficult to deduce the cellular and molecular mechanisms and implications of these proteins on animal behavior and function.
The *C. elegans* homolog of mammalian Calsyntenins, *casy-1,* is an evolutionarily conserved type I transmembrane protein that is highly enriched in the nervous system. We report here a crucial role of *casy-1* in regulating GABAergic synaptic transmission at the *C. elegans* neuromuscular junction (NMJ) in an isoform-specific manner. The shorter isoforms of *casy-1,* CASY-1B and CASY-1C, express and function in GABAergic motor neurons to regulate GABA neurotransmission. Using pharmacological, behavioral, electrophysiological and optogenetic approaches we have established that GABA release is compromised at the NMJ in *casy-1* mutants. Further, we demonstrate that CASY-1B and CASY-1C functions in GABAergic motor neurons to modulate the release kinetics of GABA by direct interaction with the synaptic vesicle (SV) precursor motor, UNC-104/KIF1A, which is indispensable for the trafficking of synaptic proteins at the synapse. In this study, we propose a mechanism for how *casy-1*, a non-classical Cadherin can shape the functioning of the synapse and suggest a possible model for the regulation of GABAergic synaptic functioning in the mammalian brain by Calsyntenins.

Title: Augmentation of purinergic modulation of GABA-ergic transmission in the supraoptic nucleus during intense hormone secretion

Authors: *M. IVETIC[1], A. BHATTACHARYYA[2], H. ZEMKOVA[3]
[1]Dept. of cellular and molecular neuroendocrinology, Inst. of Physiol. of Acad. of Sci. CR, Praha, Czech Republic; [2]Cell. and Mol. Neuroendocrinology, Inst. of Physiology, Acad. of Sci. of the Czech republic, Prague, Czech Republic; [3]Inst. of Physiol. ASCR, Prague, Czech Republic

Abstract: The supraoptic nuclei (SON) of the hypothalamus produce hormones vasopressin and oxytocin that play important roles in the water balance, blood pressure, parturition and lactation. The release of hormones is dependent on the rate and pattern of neuronal electrical activity that is regulated by glutamatergic, excitatory, and gamma-aminobutyric acid (GABA)ergic, inhibitory, synaptic inputs. ATP has been shown previously to be the major neuromodulator of SON neurons that potentiates glutamate and GABA release by activating presynaptic and extrasynaptic P2X receptors. Although presynaptic P2X responses have been described in many parts of the brain, the precise physiological function of this form of presynaptic facilitation is unknown. Therefore, in the current study we investigated purinergic facilitation under conditions of physiologically-induced increases in the activity of magnocellular neurons. Secretion of vasopressin and oxytocin is potentiated after short term fasting and subsequent refeeding. We examined changes in the P2X receptor-mediated modulation of GABAergic transmission in the SON during food state-related changes in hormone secretion. Experiments were performed on hypothalamic slices prepared from 30-day-old rats under provision of food ad libidum and rats after 48h of fasting and subsequent refeeding with standard chow. In normally fed rats, application of ATP evoked somatic current and increased the frequency of spontaneous GABAergic postsynaptic currents (sIPSCs) in about 50 % of SON and similar effect was observed in rats refed after fasting. However, the amplitude of ATP-induced inward current was higher in refed animals (118 ± 22 pA) as compared with normally fed rats (70 ±15 pA). The averaged basal frequency of sIPSC was also similar in control and refed rats, 2.71 ± 0.23 Hz and 2.11 ± 0.22 Hz, respectively. Application of ATP induced increase in the frequency of sIPSCs in 63 % of neurons from control rats (by 1264±202%) and in 83% of neurons from refed rats (by 1833±641 %), without changing their amplitude. In neurons without somatic ATP-induced current (accumulating evidence indicate that these cells are oxytocin neurons), ATP increased the frequency of sIPSC by 207±22% and 231±96 % in control and refed rats, respectively. In conclusion, we observed a significant increase in the effect of ATP within the SON of refed vs normal rats, suggesting that rapid alteration of purinergic signaling may occur in association with potentiated hormone release.

Title: Divergent effects of loss of diazepam binding inhibitor signaling on synaptic inhibition in hippocampal CA1 and dentate gyrus

Authors: *C. D. COURTNEY[1], C. A. CHRISTIAN[2]
[1]Neurosci., Univ. of Illinois At Urbana-Champaign, Champaign, IL; [2]Mol. and Integrative Physiol., Univ. of Illinois at Urbana-Champaign, Urbana, IL

Abstract: The diazepam binding inhibitor (DBI) peptide family is ubiquitously expressed in cells and highly conserved in all eukaryotic species. Though primarily studied as an intracellular signaling molecule critical in lipid metabolism, evidence is growing that DBI can be secreted extracellularly in the brain and modulate gamma-aminobutyric acid (GABA) type-A receptors ($GABA_ARs$). However, the precise roles DBI plays in GABAergic neurotransmission are largely undefined, as DBI-dependent modulation of $GABA_ARs$ appears to be specifically localized in certain areas of the brain, and DBI and/or DBI fragments may exert both agonist and inverse agonist actions. DBI may also indirectly impact $GABA_ARs$ by modulation of neurosteroidogenesis. Whether DBI signaling modulates GABAergic transmission in the hippocampus has not yet been demonstrated. To assess the impact of genetic loss of DBI on synaptic inhibition in the hippocampus, we made whole-cell voltage-clamp recordings in CA1 pyramidal cells and dentate gyrus (DG) granule cells in acute brain slices from DBI wild-type (WT) and knockout (KO) mice. Miniature inhibitory postsynaptic currents (mIPSCs) were recorded at room temperature in the presence of tetrodotoxin and ionotropic glutamate receptor antagonists kynurenic acid or APV and DNQX. In CA1, we observed an increase in mIPSC amplitude in cells from DBI KO mice (n=14 cells, 39.67 ± 1.37 pA) compared to WT mice (n=10 cells, 34.34 ± 1.68 pA) ($p=1.53^{-4}$, Kolmogorov-Smirnov [KS] test). By contrast, in DG granule cells mIPSC amplitude was reduced in cells from DBI KO mice (n=11 cells, 32.74 ± 1.29 pA) compared to WT mice (n=9 cells, 43.62 ± 2.05 pA) ($p=2.14^{-21}$, KS test). In DG, mIPSC frequency was also reduced in the KO mice (1.45 ± .08 Hz) (p=.0013, Student's t-test), but decay time was increased (35.04 ± 1.73 ms) ($p=4.03^{-8}$, KS test) compared to cells from WT mice (frequency 2.71 ± .35 Hz; decay time 29.93 ± 1.37 ms). In CA1, neither frequency nor decay time were different between WT and KO. At this time, we cannot yet rule out that at least some of these changes reflect altered neuronal and synaptic development, which may be influenced by DBI actions of $GABA_ARs$, or compensatory changes in $GABA_AR$ subunit composition. The

present results, however, indicate that genetic loss of DBI impacts synaptic inhibition in the adult hippocampus, and that the directions of DBI-mediated modulation of inhibition can vary discretely between specific subregions of the same larger brain structure.

Title: Combining pharmacogenetic neuromodulation by DREADDs with imaging brain-wide functional connectivity in wildtype mice

Authors: *M. MARKICEVIC[1], M. PRIVITERA[2], J. BOHACEK[2], M. RUDIN[3], N. WENDEROTH[1], V. ZERBI[1]
[1]Dept. of Hlth. Sci. and Technology, Neural Control of Movement lab, ETH Zurich, Zuerich, Switzerland; [2]Brain Res. Inst., Univ. of Zurich, Zuerich, Switzerland; [3]Inst. for Biomed. Engin., UZH and ETH Zurich, Zuerich, Switzerland

Abstract: Motivation: Complex behavior is a result of numerous interactions of anatomically connected brain regions, forming specialized circuits. Current research suggests that variety of neurodevelopmental and psychiatric disorders, such as Autism Spectrum Disorder, schizophrenia and depression may be associated with altered connectivity within specific brain circuits. One popular method for estimating brain-wide functional connectivity patterns is resting-state functional magnetic resonance imaging (rs-fMRI), however, it is unclear whether this macroscopic measure is sensitive enough to capture small alterations of neural activity. To answer this question we combine rs-fMRI with circuit specific neuromodulation of Designer Receptors Exclusively Activated by Designer Drugs (DREADDs) (Urban and Roth, 2015). As a first step we asked whether modulating neural activity within the somatosensory-striatal network, a structurally and functionally well-known circuit, translates into macroscale functional connectomic changes as measured by a DREADD-fMRI approach.
Methodology: Primary somatosensory cortex of wildtype mice is targeted with DREADDs causing either neuronal inhibition or excitation (AAV-hSyn-hM4Di/hM3Dq-mCherry). Three to four weeks upon surgery, anaesthetized mice are scanned using a 7T scanner, equipped with a cryogenic coil. Rs-fMRI gradient echo EPIs are acquired for 60 minutes (3600 repetitions, TR=1s), while CNO is intravenously injected after 15 minutes from the scan start to activate the DREADDs. Rs-fMRI data are cleaned from artifacts and analyzed via seed-based approaches and dynamic connectivity analyses (Zerbi et al., 2015). CNO-induced changes in brain connectivity within the somatosensory network are compared between DREADDs- and SHAM-

operated mice. Standard immunohistochemistry protocols are used to validate the DREADDs expression.
Expected outcome and impact: First results indicate that functional connectivity of somatosensory cortex is significantly modulated by CNO such that inhibitory DREADDs cause a relative decrease and excitatory DREADDs a slight, relative increase of connectivity. Our results form the first step towards establishing a DREADD-fMRI approach to investigate the causal link between neural activity at the cell population level and markers of brain-wide, macroscopic functional connectivity as measured with rs-fMRI. Using mice as a model system is advantageous because the structural connectome is well-known and the DREADD-fMRI approach could be readily extended to disease models.

Abstract: Synapses in the mammalian brain are exposed to two biologically active pools of glutamate: 1) transient synaptic glutamate resulting from neuronal vesicular release and 2) ambient nonsynaptic glutamate released from both neurons and glia through a variety of molecular mechanisms. While the role of synaptic glutamate has been extensively studied, much of the function of nonsynaptic glutamate remains unknown. Several lines of evidence have shown that changes in nonsynaptic glutamate are linked to developmental, physiological, and behavioral defects in mammals. Approximately 60% of extracellular glutamate in the mouse hippocampus is released by the xCT transporter, a cystine-glutamate antiporter which is highly expressed and active on astrocytes surrounding CA1 pyramidal neurons. Mice lacking a functional xCT transporter ($xCT^{-/-}$) show both enhanced synaptic strength and increased AMPA receptor abundance at hippocampal CA3-CA1 synapses. Additionally, mutant $xCT^{-/-}$ miniature excitatory post-synaptic potentials (mEPSCs) are phenocopied by incubating control slices in glutamate-free solution. Here we show the effect of incubation in Group I metabotropic glutamate receptor (mGluR) antagonists and agonists on both control and $xCT^{-/-}$ slices and

propose a possible mechanism by which extracellular glutamate acts through mGluR5 to modulate synaptic strength at hippocampal CA3-CA1 synapses.

Title: TrkB receptors facilitate striatonigral transmission

Authors: *P. E. REYNA, A. ÁVALOS-FUENTES, T. GARCÍA-MORENO, S. ALBARRÁN-BRAVO, F. PAZ-BERMÚDEZ, J. ACEVES-RUIZ, B. FLORÁN-GARDUÑO

Abstract: The role of BDNF on striatonigral transmission has remained so far unknown although it is released together with dopamine from dopaminergic dendrites in substantia nigra *pars reticulata.* This study examined the pre-synaptic presence of TrkB receptors on the striato-nigral terminal and the influence of its activation on K+ depolarization-induced [3H] GABA release, as well as the signaling pathway, in nigral slices of rat. Kainic acid injected into the striatum reduced by 60% the presence of TrkB receptor protein in synaptosomes of striatonigral terminals indicating the expression of the receptors by striatonigral neurons and their transport to the terminals in *pars reticulata.* The TrkB receptor agonist, 7,8-dihydroxyflavone (7,8-DHF) dose-dependently increased the high K^+-induced GABA release. The increase was blocked by ANA-12, a selective TrkB receptor antagonist. Because D1 dopamine receptors are also present in striatonigral terminals, we examined a possible interaction between both types of receptors, since a synergistic effect on synaptic plasticity and long-term potentiation has been observed in the hippocampus. We found that the D1 receptor antagonist SCH 23390 did not completely prevent the [^{3}H] GABA release increase induced by 7,8-DHF, suggesting that both D1 and TrkB receptors act independently on [^{3}H]GABA release. Furthermore, 7,8-DHF maintained its stimulatory effect even in reserpinized rats. These results suggest an independent pathway for each receptor to bring about the increase in GABA release. U73122, a PLC inhibitor, abolished the stimulatory effect of 7,8-DHF on GABA release, suggesting that the increased release is in part, due to the increase in intracellular Ca^{2+} via IP3 receptors. Since intracellular Ca^{2+} mobilization leads to calcium-channels opening, we determined the type of channel involved. Nifedipine (10 μM) did not completely prevent GABA release facilitation by 7,8-DHF, while ω-agatoxin (1 μM) totally blocked it. These results altogether suggest that the activation of TrkB receptors present on striato-nigral terminals facilitate GABA release through a dopamine

independent mechanism that requires P/Q calcium channels. These results open a novel target for BDNF in the control of motor alterations in Parkinson's disease.

Title: Interfering insulin/IGF-1 signaling in habenula reduces alcohol intake in rats

Authors: *W. ZUO[1], H. ZHANG[2], R. FU[3], J. YE[4]
[1]Anesthesiol., Rutgers New Jersey Med. Sch., Newark, NJ; [2]Rutgers, New Jersey Med. SCh, Newark, NJ; [3]Anesthesiol., Rutgers, The State Univ. of New Jersey, Newark, NJ; [4]Rutgers, New Jersey Med. Sch., Newark, NJ

Abstract: Alcohol abuse is a severe socioeconomic and health problem in our society. Evidence suggests that acute and chronic ethanol exposure could induce changes in gene transcription, protein translation and post-translational modification in the nervous system. Our recent work has shown that neurons in the lateral habenula (LHb), an epithalamic structure, are very sensitive to ethanol and plays a crucial role in alcohol intake and other related behaviors. However, the underlying molecular mechanisms remain largely unknown. Chronic alcohol intake could cause major abnormalities in the central nervous system, which may be correlated with sustained impairments of insulin and insulin-like growth factor (IGF) signaling. Indeed, a recent clinical study showed a reduced reliance on glucose as the main energy substrate for resting brain metabolism in heavy drinkers (Volkow ND et al., 2015), implying that ethanol may decrease the neuronal sensitivity or response to insulin. In this study, using the phosphorylate antibodies microarray, we found that a single intraperitoneal (IP) injection of alcohol caused a robust change in insulin/IGF-1 signaling and related proteins in the habenula of rats. Conversely, acute bath application of ethanol robustly increased the frequency of spontaneous excitatory postsynaptic currents (sEPSCs), and this increase was substantially potentiated by AG1024 or picropodophyllotoxin (PPP), inhibitors of insulin and IGF-1 receptors; but was significantly attenuated by phosphatidylinositol 3-kinase (PI3-K) inhibitor, wortmannin. PI3-K is one of

major players in the insulin signaling transduction cascade. Also, a significant increase in insulin and IGF-1 receptor expression in the habenula was observed in rats treated with alcohol (2 g/kg body weight, IP) for 5, 10 or 15 days, suggesting insulin/IGF-1 resistance has occurred. Finally, intra-LHb microinjection of AG1024 (1.5 pmol, 300 nl/ side) or insulin (2 μUnit, 200 nl/side) significantly reduced alcohol intake and preference in rats in the intermittent access to 20% ethanol two-bottle free choice procedure. Together these data suggest that interfering with insulin/IGF-1 resistance by decreasing the highly-expressed receptors or elevating hormone level could reduce alcohol intake, probably a result of an increase in excitatory drive onto LHb neurons.

Abstract: Even after memories fade over long time, the lost memories may persist latently in the brain and sometimes reappear spontaneously. Reinforcement of positive modulators for retrieval of remote memory may recover the ostensibly forgotten items. However, how the retrieval of remote memory is modulated is less understood than recent memory. Thus, a method that promotes the retrieval of forgotten remote memories has not been well established. Histamine in the central nervous system is implicated in learning and memory. Histamine H_3 receptors inhibit the presynaptic release of histamine and other neurotransmitters and negatively regulate histamine synthesis. Because histamine H_3 receptors are constitutively active, their inverse agonists upregulate histamine release. Therefore, histamine H_3 receptor inverse agonists may enhance learning and memory. In this study, we examined whether histamine H_3 receptor inverse agonists enhance retrieval of remote memory and recover the forgotten remote memory in mice and humans. A single treatment of histamine H_3 receptor inverse agonists (thioperamide and betahistine) followed by memory retrieval tests restored apparently forgotten object recognition memories in mice. The treatment induced the recall of forgotten memories even 1 week and 1 month after training. Activation of histamine receptor signaling in the perirhinal cortex (PRh) was critical for thioperamide-induced memory recovery because intraperitoneal thioperamide treatment increased PRh histamine release, and intra-PRh injection of ranitidine (H_2 receptor antagonist) and ESI-09 (exchange protein directly activated by cAMP (Epac) inhibitor) blocked the thioperamide-induced memory recovery. In neuronal and neuronal circuit levels, histamine depolarized PRh neurons, enhanced their spontaneous activity, and facilitated the reactivation of behaviorally activated neurons. Chemogenetically increased spontaneous activity in the PRh was sufficient for the memory recovery. Moreover, in a human clinical trial, betahistine treatment enhanced retrieval of object recognition memory. The enhancement of memory retrieval was more evident for items that are more difficult to remember and subjects with poorer performance. These findings indicate that activation of histamine receptor signaling in the PRh boosts reactivation of weak memory engrams and restores the apparently forgotten memories.

Title: Emergence of oscillatory activity via spike timing dependent plasticity

Authors: *M. SHAMIR[1], S. NAGAR[2]
[1]Ben-Gurion Univ., Be'er-Sheva, Israel; [2]Physics, Ben-Gurion Univ. of the Negev, Be'er-Sheva, Israel

Abstract: Neuronal oscillatory activity has been reported in relation to a wide range of cognitive processes. In certain cases changes in the oscillatory activity have been related to pathological states. Although the specific role of these oscillations has yet to be determined, it is clear that neuronal oscillations are abundant in the central nervous system. These observations raise the question of the origin of these oscillations: are the mechanisms responsible for generation and stabilization of these oscillations genetically hard-wired or can they be acquired via a learning process? Here we focus on spike timing dependent plasticity (STDP) and ask: Can oscillatory activity emerge in a neuronal network via an unsupervised learning process of STDP dynamics? If so, how and what features of the STDP learning rule govern and stabilize the resultant oscillatory activity? To this end we studied the STDP dynamics of the effective coupling between two competing neuronal populations with reciprocal inhibitory connections. To analyze the system it is convenient to study the phase-diagram that depicts the possible dynamical states of the network as a function of the effective inhibitory couplings. This phase diagram displays a rich repertoire of possible dynamical behaviors including regions of different fixed point solutions, bi-stability and a region in which the system exhibits oscillatory activity. STDP introduces dynamics for the inhibitory couplings themselves; hence, induces a flow on the phase-diagram. We studied the STDP-induced flow on the phase diagram and investigated the conditions for the flow to converge to an oscillatory state of the neuronal network. We characterized how the features of the STDP rule govern and stabilize these oscillations.

Title: Maternal deprivation modulates glutamatergic spike-timing dependent plasticity in the lateral habenula

Authors: *L. D. LANGLOIS[1], M. E. AUTHEMENT[2], F. S. NUGENT[2]
[1]Pharmacol., Uniformed Services Univ. of the Hlth. Scienc, Bethesda, MD; [2]Pharmacol., Uniformed Services Univ., Bethesda, MD

Abstract: The lateral habenula (LHb) is involved in reward and aversion by sending negative reward signals to monoaminergic systems. Our previous work has linked epigenetic modifications and metaplasticity of GABAergic synapses onto ventral tegmental area (VTA) dopamine neurons with a single episode of maternal deprivation (MD) as an early life stressor. Given the negative control of VTA dopamine neurons by the LHb, we extended our MD studies to the LHb and found that LHb neurons of MD rats (P21-P30) are also hyperexcitable and exhibit postsynaptic glutamatergic synaptic potentiation. Up to date no study has shown that glutamatergic synapses onto LHb neurons are capable of expressing spike-timing dependent plasticity (STDP) whose modulation could underlie MD-induced changes in LHb neuronal excitability and DA signaling from the VTA. Our study here demonstrates that glutamatergic STDP can be triggered in LHb neurons in response to near-coincident pre- and post-synaptic activities. We completely defined the STDP window using different pre post spiking order and time intervals (ranging from -50 to +50 ms). Coincident pre and postsynaptic firing is required for glutamatergic STDP of LHb neurons as pre or postsynaptic activity alone is insufficient to induce plasticity. Neither neurons displaying silent, tonic nor irregular firing pattern expressed bidirectional STDP in response to STDP induction protocols. Tonic firing neurons showed presynaptic long-term potentiation (LTP) regardless of spiking order. Instead, quiet and irregularly firing neurons expressed no plasticity or long-term depression (LTD) in response to similar protocols. This suggests that LHb neurons display activity-dependent symmetrical Hebbian STDP. LTP was abolished by bath application of an NMDA receptor antagonist (D-AP5) or inclusion of a fast calcium chelator (BAPTA) in the patch pipette, suggesting that NMDA receptors are the coincident detectors for this calcium-dependent STDP. MD impaired LTP in response to pre-post protocol (+5ms interval) and even shifted LTP toward LTD in response to post-pre protocol (-5ms interval) in tonic firing neurons suggesting an induction of metaplastcity by MD at glutamatergic synapses onto LHb neurons. The induction of STDP was

unaltered for silent and irregularly firing neurons suggesting that MD-induced metaplasticity was specific to neurons with tonic activity. We will identify the nature of the retrograde signaling molecule mediating presynaptic LTP in LHb neurons and determine whether MD-induced changes in neuromodulation of LHb neuronal activity contribute to metaplasticity of STDP.

Title: Disruption and repair of cortical excitatory-inhibitory balance

Authors: *R. E. FIELD[1], J. A. D'AMOUR[2], R. C. FROEMKE[3]
[1]Skirball Institute, Neurosci. Institute, Departments of Otolaryngology and Ne, New York Univ. Sch. of Med., New York, NY; [2]Eunice Kennedy Shriver Natl. Inst. of Child Hlth. and Human Develop., Natl. Inst. of Hlth., Bethesda, MD; [3]Otolaryngology, NYU Med., New York, NY

Abstract: The fine tuning of inhibition to excitation is critical for spike generation, network activity, synaptic plasticity, and seizure generation (Froemke, 2015). During development, cortical excitatory-inhibitory (E:I) balance is refined in an experience-dependent manner (Dornn et al. 2010). Chronic imbalances of cortical excitation and inhibition have been found in epilepsy, autism spectrum disorders, and other neurological and psychiatric conditions (Rubenstein & Merzenich 2003; Yizhar et al. 2011). In the mature cortex, E:I balance is altered by plasticity at excitatory synapses as well as by various neuromodulatory systems (Froemke et al. 2007; Letzkus et al. 2011). As E:I balance is disrupted in some forms of epilepsy, synaptic plasticity may help repair epileptic circuits (Mathern et al. 1999). Here we examine how spike-timing-dependent plasticity (STDP) calibrates E:I balance across multiple inputs onto layer V pyramidal neurons in developing mouse auditory cortex and human temporal lobe tissue from epileptic patients. We simultaneously monitored multiple synaptic inputs onto neurons and then induced synaptic modifications by repetitively pairing single E/IPSPs with postsynaptic action potentials. Pre-before-post pairing elicited excitatory and inhibitory long-term potentiation

(LTP), while post-before-pre pairing elicited excitatory long-term depression (LTD) and inhibitory LTP (D'Amour and Froemke, 2015). In mouse auditory cortex (n=23) and human temporal lobe (n=13), manipulations at paired inputs induced heterosynaptic modifications that increased overall E:I balance. The original best excitatory input and the original best inhibitory input underwent LTD, and the overall correlation between excitation and inhibition across all channels increased (mouse auditory cortex, LTD at original best excitatory input: -22±4%, $p<0.01$, LTD at original best inhibitory input: -15±6%, $p<0.05$; human temporal lobe, LTD at original best E: -12±5%, $p<0.05$, LTD at original best I: -9±4%, $p<0.05$). In mouse auditory cortex, heterosynaptic modifications were abolished by inhibiting calcium release from internal calcium stores (n=13), providing a mechanism for regulating heterosynaptic plasticity. We are now asking if similar mechanisms are spared in the human temporal lobe. Our results show that heterosynaptic plasticity can rapidly normalize excitation and inhibition in neurotypical and epileptic circuits. Furthermore, manipulation of the excitatory-inhibitory relationship at a network level may allow for recovery of E:I balance within epileptic circuits and offer a promising approach to treating temporal lobe
epilepsy.

Title: Altered neuronal response modulation in developing cerebellar white matter following chronic perinatal hypoxia

Authors: *S. KUNDU, V. GALLO
Neurosceince Res., Childrens Natl. Med. Ctr., Washington, DC

Abstract: White matter injury is a major feature of prematurity-related pathology in infants. Multiple lines of evidence indicate that perinatal hypoxia leads to myelination deficits and white matter (WM) abnormalities in premature neonates. At the cellular level, emerging evidence indicates that the physiology and cellular differentiation of glial precursors in the developing WM changes in response to neurotransmitter release. Previously, we have shown that in a chronic sub lethal perinatal hypoxia (Hx) mouse model GABAergic signaling between migrating interneurons and oligodendrocyte precursor cells in the cerebellar WM is significantly attenuated, leading to OPCs maturation deficits and dysmyelination. The same study also suggested that cerebellar Purkinje cells (PCs) morphologically recovered from Hx induced injury in their dendritic arborization defects at three weeks of postnatal development. Recently, we

have shown that the PCs still displayed abnormal spike activity at that age compared to their normoxic (Nx) counterpart. The impact of Hx induced injury on PCs axonal input on developing WM cells, and subsequent Hx mediated dysmyelination in WM has not been yet been determined. In the present study, we used *in vivo* extracellular multiunit recording combined with optogenetic techniques to investigate the response modulation of cells in cerebellar WM from P13 mice and define how response modulation is altered due to injury. We optogenetically stimulated PCs *in vivo*, and recorded response modulation from WM cells simultaneously. We found that responsive cells in the WM of Nx evoke 78.2% excitatory (n = 78) and 21.8% inhibitory responses upon optogenetic PCs stimulation. Strikingly, Hx completely abolished PCs evoked excitation responses in WM cells, as all 18.78% responsive cells (n=126), only displayed evoked inhibitory responses at P13. At P21, although the % of responsive cells in WM of Hx animals increased to 37.84% (n=114) all cells still evoked inhibitory response, suggesting changes in cell plasticity in WM due to Hx induced modulation of PCs axonal inputs. Finally, we also categorized responsive cells based on spike frequency and found that a larger percentage of responsive cells - perhaps OPCs displayed slow spike frequencies in Hx, as compared with responsive cells with fast spike frequencies, identified as WM interneurons. We are currently identifying these putative WM OPCs and interneurons by using different approaches. Our study uses a novel approach to shed light on neuronal modulation affecting myelination in the cerebellar WM, and how this may potentially disrupted by perinatal Hx, leading to a range of neurodevelopmental disabilities.

Title: Movement-dependent electrochemical stimulation for promoting cortico-cortical plasticity

Authors: *S. MOORJANI, S. I. PERLMUTTER, E. E. FETZ
Physiol. & Biophysics, Univ. of Washington, Seattle, WA

Abstract: Hebbian conditioning paradigms seek to modulate synaptic connectivity through precisely timed activation of pre- and post-synaptic neurons. One such paradigm, developed in

our laboratory, uses action potentials recorded from one neuron to trigger delivery of electrical stimuli to neighboring cells in the motor cortex of intact monkeys.[1] Since this protocol relies on single-neuron recordings, which can be unstable over time, we are investigating movement-triggered stimulation (MTS) to induce cortico-cortical plasticity between neurons at co- and reciprocally-activated sites. Changes in cortical connectivity are directly assessed with stimulus-evoked potentials. To enhance and prolong electrical-conditioning effects, we will deliver plasticity-enhancing neuromodulators, such as brain-derived neurotrophic factor (BDNF), in conjunction with MTS.

A monkey is implanted with metal microwires and mictotubes, placed bilaterally in the sensorimotor cortex. The microtubes, interfaced with battery-operated microinfusion pumps, can administer chemicals in addition to recording neural signals and delivering electrical stimulation. The monkey is trained to perform a wrist flexion-extension target-tracking task. Movement-related activity at two cortical sites (Nrec and Nstim) is inferred from the motor output elicited by stimulation at those sites. MTS is delivered to Nstim during movements that activate neurons at Nrec. MTS is preceded and followed by delivery of test stimuli at Nrec to assess the strength of the connection to Nstim. We have found that MTS strengthens cortical connections for Nrec and Nstim sites with similar motor outputs, as seen by an increase in the size of cortical potentials evoked at Nstim, which in some cases were 150% larger after conditioning compared to preconditioning levels. Early analyses suggest that MTS increases the excitability of Nrec, creating a plastic landscape in which the monkey's wrist activity drives conditioning-induced gains even after the stimulation has ended. Importantly, the resultant plasticity persisted for up to 3 weeks after brief conditioning for 90 minutes.

We are currently characterizing the time course and activity dependence of conditioning. This will be followed by conditioning site pairs that elicit reciprocal motor outputs and, finally, delivery of BDNF at Nrec, Nstim, or both sites to test its effect on the resultant plasticity. Plastic changes arising from such electrochemical systems could provide a means to augment damaged pathways, a research direction we are currently pursuing in spinal-cord injured rats.

Abstract: Spike-timing dependent plasticity (STDP) is a form of synaptic plasticity controlled by the relative timing of pre- and post-synaptic activity. Positive timing between pre- and post-synaptic activity (EPSP before spike) lead to Long-Term Potentiation (LTP) whereas negative timing (spike before EPSP) induce Long-Term Depression (LTD). This plasticity involves signaling by intracellular calcium (Ca2+), suggesting that extracellular Ca2+ concentration is likely to play a critical role. Yet, most if not all in vitro STDP studies used non-physiological Ca2+ concentrations: 2-3mM, compared to the physiological range 1.3-1.8mM. Calcium-based models of STDP where Ca2+ transients result from back-propagating action potentials and EPSPs predict that the sign and magnitude of STDP depends on Ca2+ concentration. In this context, high Ca2+ concentrations could lead to an overestimate of the in vivo levels of plasticity. To investigate STDP in physiological Ca2+, CA1 pyramidal neurons in acute hippocampal slices of juvenile rats (P14-20) were recorded in whole-cell configuration. Plasticity was examined at the Schaffer collateral to CA1 synapse. With a standard pre- and post-synaptic spike pair protocol, no plasticity could be induced at 1.3mM external Ca2+, and only LTD could be induced by positive or negative time delays in 1.8mM external Ca2+. LTP is restored if the number of post-synaptic spikes was increased from 1 to 4; and with a single post-synaptic spike when the pairing frequency was increased from 0.3 to 5Hz. We built a Ca2+-based plasticity model, where LTD and LTP depend on transient changes in postsynaptic Ca2+. We found that the nonlinearity of transient calcium changes conferred by NMDA receptor activation, is critical to quantitatively account for the entire experimental dataset. In line with recent experimental work, this contribution depends on coincident firing of pre- and post-synaptic neurons, and the resulting calcium transient is endowed with a long timescale of decay. Taking into account presynaptic short term facilitation is also critical to correctly match the experimental dataset. We conclude that the STDP rule is profoundly altered in physiological Ca2+ but that a classical STDP profile can be restored under specific activity regimes.

Title: GSK3 modulates spike timing-dependent plasticity in layer 2/3 of somatosensory cortex through direct phosphorylation of Kv4.2 channels

Authors: G. ACETO[1], A. RE[2], A. MATTERA[1], A. S. BARBATI[1], M. RINAUDO[1], C. RIPOLI[1], F. SCALA[3], S. FUSCO[1], F. LAEZZA[4], C. GRASSI[1], *M. D'ASCENZO[1]

Abstract: Spike timing-dependent plasticity (STDP) is an activity-dependent remodeling occurring in brain circuits. Despite its key role during development and learning the cellular and molecular mechanisms underlying STDP are still poorly understood. Here, we identified glycogen-synthase kinase 3 (GSK3) and the voltage-gated K^+ channel Kv4.2 as novel molecular targets of STDP in the mouse somatosensory cortex. We performed whole-cell patch-clamp recordings of pyramidal neurons in layer 2/3 of the mouse somatosensory cortex and studied spike timing-dependent long term depression (tLTD) in the presence of selective kinase inhibitors. We found that upon intracellular perfusion of the GSK3 inhibitor CT99021 (1 μM) the amplitude of tLTD was significantly increased compared to control conditions, while perfusion of triciribine (10 μM), an inhibitor expected to increase the level of active GSK3, resulted in an opposite phenotype. Previous studies have provided significant evidence for A-type K^+ current as a modulator of tLTD by shaping the spatio-temporal profile of dendritic back-propagating action potentials. Given that GSK3 phosphorylates Kv4.2 subunit, consequently leading to decreased A-type K^+ currents, we posited that the CT99021 would increase tLTD by inhibiting A-type K^+ current. In support of this hypothesis, bath application of 4-amynopyridine (4-AP), an A-type K^+ current inhibitor, prior to tLTD induction occluded the effect of CT99021. Furthermore, in the same neurons A-type K^+ currents were found to be bi-directionally modulated by CT99021 and triciribine. To provide a mechanistic link to these studies, HEK293 cells expressing Kv4.2 subunit were utilized for confirmatory pharmacological studies and biochemical analysis of phosphorylation of Kv4.2 at Ser-616 by GSK3. Collectively, these results identify a novel functional interaction of GSK3 with the Kv4.2 channel as a novel mechanism for STDP modulation providing novel insight into the understanding of GSK3 regulation of synaptic plasticity.

Title: The balance, the morphology, and the dendritic mosaic

Authors: *N. IANNELLA[1], T. LAUNEY[2]
[1]Sch. of Mathematical Sci., The Univ. of Nottingham, Nottingham, United Kingdom; [2]RIKEN, Brain Sci. Inst., Wako-shi, Japan

Abstract: Neurons are continuously altering the way they process information in response to changes in dynamic stimuli. Their ability for such changes ultimately relies on understanding how the interplay between synapse location, the nonlinear properties of the dendrite, and synaptic plasticity shapes the strengths and spatial arrangements of converging afferent inputs to neuronal dendrites. Both experimental and theoretical investigations support the formation of memory traces or engrams promotes the formation of clusters or hotspots of functional synapses resulting from synaptic plasticity. Our previous studies have illustrated that spike timing-dependent plasticity (STDP) can lead to synaptic efficacies arranged into spatially segregated clusters across the dendrite, which we have called a dendritic mosaic. We have recently found that the dendritic mosaic is influenced by the balance between the amount of depression and potentiation admitted by the temporal learning window describing STDP, and recently dendritic morphology also has a role to play.
Here, using a biophysically detailed neuron model of a layer 2/3 cortical cell, we find that both dendritic morphology and STDP balance has an important role to play for this spatial organization to emerge, where altering the degree of balance or the shape of the dendrite leads to changes in the occurrence and patterning of efficacy clusters. Over a broad range of STDP parameters, our model suggests that synaptic plasticity shapes the spatial arrangement of synapses in a fashion favouring the formation of efficacy clusters, however the emergence of this spatial organization is also influenced by changes in dendritic morphology. These findings suggest that under favourable conditions the branching patterns of dendrites, along synaptic plasticity leads to a subdivision of dendritic space, but such subdivision of dendritic space is

subjective in nature, appearing to be conditionally dependent function of the shape of the dendrite.

Title: GABAergic input modulates Hebbian plasticity and the free energy minimization *In vitro*

Authors: *T. ISOMURA[1,2], T. TOYOIZUMI[1], K. KOTANI[2], Y. JIMBO[2]
[1]RIKEN Brain Sci. Inst., Saitama, Japan; [2]The Univ. of Tokyo, Tokyo, Japan

Abstract: The free-energy principle predicts that neurons, synapses, and neuromodulators act to minimize unpredictability of the current sensory inputs. This free-energy principle can be implemented by the Hebbian-like synaptic plasticity rule, where changes of synaptic weights depend on the product of pre- and post-synaptic neural activities. However, the pure Hebbian plasticity is not sufficient and some extra dependency on the third factor (i.e., not pre- or postsynaptic) is required for the free energy minimization, while it is not clear if real neurons have access to this third factor.
Recent studies have reported that GABAergic input modulates synaptic plasticity of excitatory synapses. Such modulation may act as the third factor that is required for the free energy minimization. Here, we investigate whether the change in the GABAergic input affects the free energy minimization in cultured neural networks.
Rat cortical cells were dissociated and cultured on microelectrode arrays (MEAs) which have 8×8 microelectrodes embedded in the bottom of the dishes. Electrical stimulations and recordings were performed using a custom MEA system. We prepared two lines of hidden sources and induced their mixture into neural networks. The training trial was repeated 100 times. Based on recorded evoked responses, free energy was calculated in each trial.
We previously showed that response specificities of neural responses to two different source states increased. The change, which was NMDA dependent, indicates that cultured neurons learned to tune in to one source while ignoring the other (the so-called blind source separation). Moreover, free energy decreased during the training. To see the role of GABAergic input, we trained cultured neural networks in the presence of an antagonist of GABAA receptor

(bicuculline) or an agonist of benzodiazepine receptor (diazepam), and found that both bicuculline and diazepam blocked the reduction of the free energy, while retaining the Hebbian plasticity. These results suggest that GABAergic input modulates Hebbian plasticity and the free energy minimization in cultured neural networks.

Title: Extracellular calcium influences on long-term plasticity

Authors: *R. PERIN[1], G. CHINDEMI[2], E. MÜLLER[2], H. MARKRAM[1]
[1]Brain Mind Institute, EPFL, Lausanne, Switzerland; [2]Blue Brain Project, Geneva, Switzerland

Abstract: Calcium is an essential ion involved in determining how neuronal activity impacts long-term synaptic plasticity. Here we studied the effects of varying extracellular calcium concentration on long-term potentiation in thick-tufted layer 5 pyramidal neurons of the somatosensory cortex of young rats (postnatal days 14 to 18). Patch-clamped neurons in acute brain slices *in vitro* maintained in extracellular calcium concentrations ranging from 1.2 mM to 2 mM were stimulated with long-term potentiation inducing protocols. We stimulated the presynaptic cells with trains of pulses, fitted the measured responses to the Tsodyks-Markram model of short-term plasticity and calculated the changes occurring under the different conditions to parameters such as release probability, absolute synaptic efficacy and vesicle pool recovery time constant. Our results suggest that synaptic plasticity *in vivo* should also be affected by network states which influence calcium availability at synapses.

Title: Optogenetic induction of spike-timing-dependent plasticity at Schaffer collateral synapses in rat organotypic hippocampal slices

Authors: *M. ANISIMOVA, B. VAN BOMMEL, T. G. OERTNER, C. E. GEE
Inst. for Synaptic Physiol., Ctr. For Mol. Neurobio. Hamburg (ZMNH), Hamburg, Germany

Abstract: Modification of synaptic strength is believed to be key for the formation of memories. Whether the strength of connections is maintained as analog or digital changes remains an open question. To examine long-term changes in neuronal circuits, we are developing a method to induce synaptic plasticity without impaling or patch-clamping the pre- or postsynaptic neurons. We induce timing-dependent plasticity at Schaffer collateral synapses in rat organotypic hippocampal slices by an all-optical method, stimulating pre- and postsynaptic neurons that express channelrhodopsins that are activated by different wavelengths of light. Action potentials were evoked in CheRiff-expressing CA1 neurons with 400 nm light. ChrimsonR was expressed in CA3 cells by AAV_{Rh10} and action potentials were evoked with 635 nm light. Using this combination of opsins and wavelengths we can reliably and independently stimulate the two populations of neurons. Single action potentials were evoked in presynaptic neurons and were paired with bursts of 3 light flashes at 50 Hz to cause action potentials in the postsynaptic neurons, either after arrival of the presynaptically-evoked postsynaptic potential (EPSP, causal pairing) or prior to the EPSP (anti-causal pairing). To assess whether the strength of synaptic connections was altered by the pairing protocol, excitatory postsynaptic currents (EPSCs) were recorded from CA1 neurons while the CA3 neurons were stimulated. EPSCs from at least 2 non-transfected (i.e. non-paired) CA1 neurons were averaged and used to normalize the EPSCs recorded from transfected (i.e. paired) CA1 neurons. Three days after pairing, normalized EPSCs were significantly larger in slices that underwent causal pairing (300x at 5 Hz, ~10 ms EPSC-spike interval) than in control slices that were not stimulated with light, or slices where only the postsynaptic bursting was induced. When causal pairing was evoked at 0.1 Hz (360x), however, EPSCs of the paired neurons were not larger than in the control slices 3 days later, suggesting that all-optical STDP is frequency-dependent. Interestingly, when paired at 5 Hz, anti-causal pairing also increased EPSCs, suggesting that the LTP window is broad at this frequency. The immediate early gene c-Fos was induced in paired CA1 neurons and CA1 neurons that received only the postsynaptic stimulation. In slices where only presynaptic neurons were stimulated, c-Fos expression was not increased in CA1, confirming that CA1 neurons were not driven to burst by the CA3 input. In conclusion, our all-optical method allows us to induce plasticity at defined hippocampal synapses and to assess changes in synaptic strength days after induction.

Title: Dopamine-endocannabinoid interactions mediate spike-timing dependent potentiation in the striatum

Authors: *L. VENANCE[1], H. XU[1], S. PEREZ[1], B. DETRAUX[2], A. CORNIL[2], I. S. PROKIN[3], Y. CUI[1], B. DEGOS[1], A. DE KERCHOVE D'EXAERDE[2], H. BERRY[4]
[1]CIRB INSERM, Paris, France; [2]Univ. Libre de Bruxelles, Brussels, Belgium; [3]INRIA Rhône-Alpes, Villeurbanne, France; [4]INRIA, Villeurbanne, France

Abstract: Striatal synaptic plasticity is a key substrate for action selection and procedural learning and is tightly modulated by dopamine. Thus, characterizing the repertoire of activity-dependent plasticity in striatum and its dependence on dopamine is of crucial importance. While plasticity under prolonged activation is well elucidated, its expression in response to few spikes remains less documented. Using spike-timing dependent plasticity (STDP) as a synaptic Hebbian learning paradigm, we recently unraveled a new form of plasticity in the dorsolateral striatum: a spike-timing dependent potentiation (tLTP) induced by few coincident pre- and post-synaptic spikes (~5-15), mediated by endocannabinoids (eCB-tLTP) through a signaling pathway that relies on the activation of type-1 cannabinoid receptor (CB_1R) and transient receptor potential vanilloid type-1 (TRPV1) and on eCB dynamics (Cui et al., 2015 J Physiol; Cui et al., 2016 eLife). Thus eCBs not only promote depression but also potentiation, i.e. they act as a bidirectional system, depending on the regime of activity pattern on either side of the synapse. Whether this eCB-tLTP interacts with the dopaminergic system and consequently be affected in Parkinson's disease remains to be investigated.
Here, we report that eCB-tLTP is controlled by dopamine, impaired in Parkinson's disease and rescued by L-DOPA. We found that opto-inhibition of dopaminergic neurons prevents eCB-tLTP induction and that eCB-tLTP involves specifically dopamine type-2 receptors (D_2Rs) located presynaptically in corticostriatal glutamatergic afferents, but not D_2Rs expressed by in striatal projecting neurons (belonging to indirect pathway), cholinergic interneurons or dopaminergic

cells. Therefore, dopamine-endocannabinoid interactions via D_2Rs are required for the emergence of a tLTP in response to few coincident pre- and post-synaptic spikes and control eCB-plasticity polarity (tLTP *vs* tLTD) by modulating the eCB thresholds. We also provide a realistic mathematical model for the dynamics of the implicated signaling pathways. While usually considered as depressing synaptic function, our results show that eCBs in presence of dopamine constitute a versatile system underlying bidirectional plasticity implicated in basal ganglia pathophysiology.

Title: Remembering how to breathe: Enhanced excitatory synaptic strength preserves motor output from the respiratory network after months of motor inactivity in bullfrogs

Authors: *J. SANTIN, M. M. VALLEJO, L. K. HARTZLER
Wright State Univ., Dayton, OH

Abstract: Compensatory plasticity of neurons stabilizes neural networks and stores memories during increases or decreases in neural activity. Most studies testing this idea use pharmacological or pathological means to alter neural activity without connecting mechanisms for network stabilization to ecologically relevant perturbations. American bullfrogs, *Lithobates catesbeianus*, undergo respiratory motor inactivity during the cold winter months (Santin & Hartzler, 2017, *J. Exp. Biol.*) because adequate skin gas exchange allows them to reside in ice-covered ponds without lung breathing at low metabolic rates. After winter, however, they produce normal respiratory motor output (Santin & Hartzler, 2016, *J. Physiol.*). We hypothesized that respiratory motoneurons undergo increases in excitatory synaptic strength and/or intrinsic excitability to preserve respiratory network output following 2-3 months of respiratory inactivity. To test this hypothesis we measured miniature excitatory postsynaptic currents (mEPSCs) and intrinsic neuronal properties using whole-cell patch clamp in labeled vagal motoneurons of the laryngeal branch from adult bullfrogs. We found that amplitude and charge transfer, but not

frequency, of mEPSCs mediated by AMPA receptors increased after winter inactivity (WI) (Amplitude: 17.4±1.3 pA *vs*.24.3±2.0, p=0.007; Charge transfer: 128.0±13.6 fC *vs.* 216.9±25.5 fC, p=0.001; Frequency: 10.1±2.2 Hz *vs.* 10.65±1.2 Hz, p=0.822). Rank ordering mEPSC amplitudes from control and WI distributions generated a scaling factor of 1.51. Dividing the cumulative distribution of mESPC amplitudes from WI motoneurons by the scaling factor produced a scaled distribution that overlaid the control distribution (Kolmogorov-Smirnov test; p=0.08). WI did not alter membrane potential, input resistance, and firing frequency-current relationship (p>0.5 for all). To determine if increases in excitatory synaptic strength on motoneurons preserve output from the respiratory network after months of inactivity, we recorded vagal nerve discharge from an *in vitro* brainstem preparation that produces respiratory burst activity resembling breathing *in vivo*. We demonstrate that a sub-saturating concentration of AMPA receptor antagonist (4 μM DNQX) does not influence the amplitude respiratory motor bursts in control bullfrogs; however, after WI DNQX reduced amplitude by 36.7±9.7% (p=0.005). This indicates that increased excitatory synaptic strength on respiratory motoneurons preserves motor output after months of natural inactivity linking mechanisms of compensatory neural plasticity to a critical adaptation for survival in an animal.

Title: Visualizing homeostatic normalization in the output of long-range auditory subcortical projection neurons following a sudden drop in peripheral afferent drive

Authors: *M. ASOKAN[1,2], R. S. WILLIAMSON[2], K. E. HANCOCK[2], D. B. POLLEY[3,2]
[1]Speech and Hearing Biosci. and Technol., Harvard University, Div. of Med. Sci., Cambridge, MA; [2]Massachusetts Eye and Ear Infirmary, Boston, MA; [3]Otolaryngology, Harvard Med. Sch., Boston, MA

Abstract: Following a sudden loss of peripheral input, cortical inhibition plummets and never fully recovers. Presumably, cortical disinhibition helps to compensate for the drop in afferent drive and restores the net output from the cortical column to its homeostatic set point. To test this

directly, we tracked daily changes in layer 5 (L5) projection neurons in the auditory cortex before and after a selective loss of auditory nerve afferent synapses. The excitability of L5 subcortical projection neurons was measured directly by expressing a genetically encoded calcium indicator, GCaMP6s, and directly visualizing sound-evoked signals from L5 cortical axons on the dorsal cap of the inferior colliculus in awake, head-fixed adult mice. After several days of imaging stable sound-evoked L5 corticocollicular (CCol) activity in a baseline state, mice were exposed to moderate noise that caused only a temporary shift in cochlear and brainstem thresholds but a permanent loss of auditory nerve afferent synapses. We found that the auditory gain of CCol responses dropped the day after noise exposure but then spiked, exceeding baseline levels for several days before returning to baseline. These findings reveal short-term dynamics in the auditory corticofugal pathway following cochlear synaptopathy and suggest that local circuit changes in the auditory cortex might allow corticofugal projection neurons to stabilize their output in the face of large swings in afferent drive. Our ongoing work examines the local circuit mechanisms that support this homeostatic plasticity.

Title: Synergistic shifts in AMPA and $GABA_A$ receptor transcripts underlying recovered auditory processing in the adult auditory cortex following peripheral denervation

Authors: *P. BALARAM[1,2], D. B. POLLEY[1,2]
[1]Otolaryngology, Harvard Med. Sch., Boston, MA; [2]Massachusetts Eye and Ear Infirmary, Boston, MA

Abstract: A selective, near-complete loss of cochlear afferent nerve fibers depresses sound-evoked activity at early stages of the auditory pathway but causes a paradoxical increase in activity at the level of auditory cortex (ACtx). Increased “central gain” is associated with variable levels of recovered cortical processing; some mice regain normal auditory thresholds while other mice show no recovery of auditory processing, despite an equivalent loss of cochlear

afferent synapses and auditory brainstem responses.
How do auditory cortical neurons recover responses to sound following peripheral denervation? We hypothesized that homeostatic regulation of AMPA and $GABA_A$ postsynaptic receptors would contribute to central gain after neuropathy, and might explain functional outcomes for sensory processing between individuals. Further, homeostatic regulation of postsynaptic receptors could differ between excitatory and inhibitory cortical neurons, and the opposing directions of receptor shifts between these two populations could work synergistically to maximally increase central gain.
To address these questions, we measured sound-evoked responses in awake, adult head-fixed mice using widefield and two-photon imaging of cortical neurons expressing GCaMP6s under control of the CAMKIIa promoter. We tracked daily changes in sound-evoked responses for five days following near-complete denervation of cochlear afferent nerve fibers and documented variable levels of damage and functional recovery between mice. We quantified transcriptional levels in genes that encode AMPA and $GABA_A$ receptor subunits in individual auditory cortical neurons. Changes in the transcription of these subunits reflect subsequent changes in the translation of AMPA and $GABA_A$ receptors, thus providing a correlative measure of synaptic scaling in ACtx.
Cortical neurons were chemotyped by documenting the expression of *VGLUT1* or *VGLUT2* mRNA (excitatory neurons), or *VGAT* mRNA (inhibitory neurons). Expression levels of *Gria2* mRNA, which encodes the GluA2 subunit of AMPA receptors, and *Gabra1* mRNA, which encodes the α1 subunit of $GABA_A$ receptors, were separately quantified in *VGLUT*-positive and *VGAT*-positive neurons across ACtx layers (L)2/3, L4 and L5/6 . Following neuropathy, *Gria2* and *Gabra1* transcripts were significantly shifted relative to sham-operated controls, with complementary transcriptional shifts between *VGLUT*-positive and *VGAT*-positive neurons. These synergistic transcriptional shifts across local cortical networks may provide the means to increase the gain on reduced afferent inputs and recover normal activity levels in the ACtx.

Title: Neurotransmitter switching in the adult mouse hippocampus and changes in episodic memory

Authors: *S. ZAMBETTI, J. O. CONNORS, N. C. SPITZER
Biol. Sci., UC San Diego, LA Jolla, CA

Abstract: Neurotransmitter (NT) switching is a newly recognized form of plasticity in which neurons acquire a novel function by changing the NT that is expressed and released, allowing the brain to adapt to internal and external stimuli. Extensively investigated in the developing Xenopus nervous system (Spitzer, 2017), it has recently been discovered in adult rodents (Dulcis et al., 2013).
We previously showed that one week of running induces disappearance of a thousand neuropeptide Y (NPY)- expressing neurons and appearance of an additional thousand VGluT1-expressing neurons in the hilus of the dentate gyrus (DG) of adult mice. The loss of NPY neurons was associated with a decrease in the NPY fiber density in the molecular layer (ML) of the DG, to which the NPY neurons project (Deller & Leranth 1990). No cell death or neurogenesis was associated with these changes in the hilus although increased neurogenesis was observed in the subgranular zone.
We now report that animals that have been running for four weeks still exhibit the changes in the number of NPY and glutamatergic neurons observed after just one week of running. However, mice that have been running for one week and then deprived of the running wheel for another week present no change in number of NPY and glutamatergic neurons compared to controls, demonstrating the reversibility of the change.
In addition, we have investigated the involvement of NPY-Glu switching in the behavioral outcome of running. Three weeks of running increase episodic memory evaluated with the object recognition test (Bolz et al., 2015). We found that mice spend more time interacting with the novel object than the familiar one after one week of running, compared to controls. Furthermore, animals that have been resting for one or two weeks after running for one week still performed better than controls, suggesting that NPY-Glu switching may contribute to a long lasting effect on the DG circuit. We hypothesize that the loss of NPY neurons affects the response of mature and new born granule cells (GC) to entorhinal cortical (EC) input. NPY fibers are enriched in the projection zone of the lateral EC (Amaral et al., 2007) and NPY can regulate the release of Glu (Silva et al., 2003). Thus, the decrease in NPY neurons may trigger a long lasting potentiation of the EC-GC connections.
To dissect the involvement of NT switching in the regulation of neurogenesis and the increase memory performance we will prevent the loss of NPY and the gain of Glu expression using Cre-dependent viruses expressing NPY and a small interference (si) VGlut1 stereotaxically injected into the DG of NPY-Cre mice (Shi et al., 2013) before the onset of the running period.

Title: Regulation of motor coordination by neurotransmitter switching in the brainstem

Authors: *H. LI, N. C. SPITZER
Neurobio. Section, Div. of Biol. Sciences, Kavli Inst. for Brain, UC San Diego, La Jolla, CA

Abstract: Motor control is required for accurate movement and can be disrupted in natural aging or motor disorders, e.g. ataxia. Exercise is a therapy that improves motor coordination but the mechanism is obscure. Neurotransmitter (NT) switching is a newly appreciated form of plasticity in the adult brain (Spitzer, 2017). Here we report exercise-induced NT switching in motor circuits and its role in motor control.

Adult mice given free access to running wheels for 1 week had enhanced motor coordination compared to non-runner controls, exemplified by a higher speed at fall from an accelerating rotarod and a shorter time to cross a balance beam. We then examined whether running induced NT switching in motor circuits and discovered the disappearance of ~600 ChAT (choline acetyltransferase) neurons and the appearance of an additional ~600 GAD1 (glutamate decarboxylase 1) neurons in the caudal pedunculopontine nucleus (cPPN) of runners compared to controls. No neuronal death or neurogenesis was detected.

The loss of ChAT and gain of GAD1 both occur in the same neuronal population. Neuronal nitric oxide synthase (nNOS), which is co-localized with ChAT in the cPPN and did not change with running, was used as a cell marker to label ChAT neurons. Triple-staining ChAT mRNA, GAD1 mRNA and nNOS protein revealed a decrease in ChAT and an increase in GAD1 transcripts in nNOS cells in runners compared with controls.

To test for causality between NT switching and behavioral change, we overexpressed ChAT in the cPPN by injection of ChAT-Cre mice with AAV-DIO-ChAT-mRuby2 and found it prevented the improvement in motor coordination gained by running. Expression of a control virus (AAV-DIO-mRuby2) did not affect the improvement. These findings suggest that NT switching is necessary for the enhancement of motor coordination. We are now testing the behavioral consequence of suppressing the increase in expression of GAD1 with AAV-DIO-GAD1shRNA.

To learn how NT switching regulates coordination, we will co-label retrograde tracers, ChAT mRNA, and nNOS protein to determine the target nuclei of the neurons that switch their NT.

The reversibility of behavioral changes and NT switching was tested when running wheels were

removed after 1 week of running. Strikingly, runners sustained better performance than controls in the re-test after 1 week of rest although the numbers of ChAT and GAD1 neurons were not different from controls. The results suggest that NT switching was reversed but improvement in learned skills was sustained for at least 1 week. We are currently investigating how long the enhancement of coordination is sustained.

Title: Environmental models of Autism engage neurotransmitter switching in prefrontal cortex

Authors: *S. K. GODAVARTHI, N. C. SPITZER
Neurosci., Univ. of California San Diego, San Diego, CA

Abstract: Neurotransmitter switching (NTS) is a form of homeostatic plasticity characterized by loss of one NT and gain of another in the same neuron (Spitzer, 2017). NTS is essential for normal CNS development (Misgeld et al., 2002; Root et al., 2008) and generally involves a change in the sign of the synapse from excitatory to inhibitory or vice versa. This raises the possibility that NTS could contribute to neurodevelopmental disorders, often characterized by excitation-inhibition imbalances. We are investigating the role of inadvertent and unwanted NTS in emergence of autism spectrum disorders (ASDs), focusing on prefrontal cortex (PFC), a key region implicated in ASDs.

Using environmental models of autism (EMA), developed by injecting valproate or poly Inosine:Cytosine in pregnant dams at E12.5, we previously reported loss of ~6000 GAD67+ neurons and gain of ~6000 vGluT1+ neurons in the medial PFC (mPFC) in postnatal day 10 (P10) EMA mice with respect to control mice. Absence of changes in cell death and total neuronal number indicate that there is respecification of GAD67+ in mPFC of EMA mice with vGluT1 as the switching partner. Parvalbumin (PV)+ (~4000) and Cholecystokinin (CCK)+ (~2000) inhibitory neurons account for the GAD67+ reduction.

In order to assess how early the switch occurs and how long it persists, we examined EMA mice for NT changes in an age-dependent manner. At embryonic day 18.5 (E18.5), there is no difference in the number of Dlx2+ neurons and Tbr1+ neurons (inhibitory and excitatory progenitor neuron markers respectively) between EMA and control animals, suggesting that the switch is a postnatal phenomenon. Similar to P10, there is a reduction of ~7000 GAD67+

neurons, and gain of ~7000 vGluT1+ neurons at P25. At P30, although the difference is smaller, there is still a loss of ~2000 GAD67+ neurons and gain of ~2000 vGluT1+ neurons. mPFC cells positive for both GAD67 and vGluT1 further support the switching partnership.
By P90 there is no difference in the GAD67+ and vGluT1+ neuron numbers between control and EMA mice. Thus, the switch does not persist into adulthood. As expected, P90 EMA mice show symptoms associated with autistic behavior- stereotypical and repetitive behavior and reduced social-interaction.
Early-postnatal NTS in EMA mice may affect the trajectory of PFC development, although NT balance is recovered in adulthood. The altered circuits in turn may lead to altered behavior. We will test this hypothesis by preventing NTS by overexpressing GAD67 and knocking down vGluT1 specifically in PV neurons of early-postnatal PV-Cre mice, to learn if it rescues the behavioral deficits.

Title: Plasticity of identified, functionally heterogeneous synapses shapes cell-wide plasticity of V1 neurons *In vivo*

Authors: *S. EL BOUSTANI[1,2], J. IP[2], V. BRETON-PROVENCHER[2], H. OKUNO[3], H. BITO[4], M. SUR[2]

Abstract: Neuronal circuits in the developing and mature brain are subject to dramatic changes driven by sensory inputs or motor learning, causing individual cells to modify their responses to individual inputs while maintaining a relatively stable level of overall activity. Cell-wide homeostatic plasticity was initially reported as a global mechanism for stabilizing the output

firing rate of a cell by uniformly scaling up or down the effective strength of all its synapses. More recent experimental evidence in vitro has suggested the existence of local homeostatic mechanisms acting at the level of dendritic stretches or even at single synapses that would potentially confer rich functional compartmentalization within the dendritic tree. However, the existence and nature of local homeostatic plasticity in vivo and its implications for the coherent reorganization of single cell responses remains unexplored. Here we have used visual-optogenetic pairing to demonstrate that induction of receptive field plasticity in single visual cortex neurons of awake mice alters identified synapses on neuronal dendrites. Such plasticity potentiates specific synapses and depresses others within short stretches of the same dendrite, consistent with functionally heterogeneous local sets of synapses that convey diverse receptive field inputs to a neuron. Crucially, depressed spines lie in close proximity to potentiated spines, indicating coordinated Hebbian and homeostatic plasticity in vivo that involves neighboring synapses. AMPA receptors are trafficked into potentiated spines and removed from depressed spines via targeted expression of the immediate early gene product Arc in the latter spines. The spatially local distribution of depressed spines around potentiated spines, in conjunction with functionally intermixed synaptic inputs to dendrites, highlight a possible mechanism that organizes cell-wide plasticity with local dendritic interactions.

Title: Redistribution of synaptic proteins between identified synapses of V1 neurons during experience-dependent plasticity *In vivo*

Authors: *P. IP[1], S. EL-BOUSTANI[1], V. BRETON-PROVENCHER[1], H. OKUNO[2], H. BITO[3], M. SUR[1]

Abstract: Cortical circuits are remodeled in response to changes driven by sensory inputs. Regulation of AMPA receptor (AMPAR) membrane expression and targeting of immediate early genes such as Arc is critical for synaptic plasticity. However, our understanding of the mechanisms of AMPAR and Arc targeting *in vivo* is limited, in part by a lack of time-lapse imaging strategies at the synaptic level. Furthermore, because conventional transfection methods such as viral vectors require weeks to express, they are less suitable for the expression of molecular probes to study synaptic dynamics during development. To overcome these issues, we delivered plasmids into individual neurons of mouse primary visual cortex (V1) by two-photon guided electroporation. Expression of fluorescently tagged probes in spines and dendrites enabled us to visualize surface AMPAR subunits and Arc in awake mice and to study their synaptic targeting in single, identified layer II-III neurons. We observed prominent redistribution of AMPAR and Arc in spines and along dendritic branches under different conditions *in vivo*. Ocular dominance (OD) plasticity in V1 during a critical period is a well-established model for studying experience-dependent cortical changes. V1 neurons show reduced responses from a deprived eye following monocular deprivation (MD), followed by recovery of responses when the deprived eye is re-opened. We imaged V1 neurons following MD, before and a few hours after eye re-opening during the critical period for OD plasticity, to assess how an increase in synaptic drive from the re-opened eye remodeled spines. By measuring eye-specific drive in neurons and spines in which we expressed GCaMP6s, we found that spines with input from the re-opened eye rapidly enlarged and showed reduced Arc expression, whereas nearby spines were reduced in size and showed increased Arc expression. These studies suggest that active redistribution of synaptic proteins underlies functional experience-dependent plasticity of V1 neurons.

Title: The role of external tufted cells in activity-dependent plasticity of the olfactory bulb

Authors: *C. HAHN, M. S. GRUBB
Ctr. for developmental neurobiology, King's Col. London, London, United Kingdom

Abstract: Neuronal plasticity allows networks to learn and adapt to the environment and change behaviour accordingly. The highly plastic olfactory bulb network serves as a good model to study plasticity. Olfactory bulb plasticity is viewed as primarily an interneuron phenomenon as these cells replenish throughout life and undergo activity-dependent plasticity. External tufted cells (ETC) are excitatory interneurons found in the glomerular layer of the olfactory bulb that are major modulators of olfactory sensory processing. However, surprisingly little is known about activity-dependent alterations in these neurons, though their location and monosynaptic connection to olfactory sensory neurons (OSNs) would suggest a role in adapting the network to environmental changes.
To understand whether these cells are important for adapting the olfactory network, ETC functional and structural characteristics were compared in control and 24 hour naris occluded mice. Whole-cell patch clamp recordings in acute olfactory bulb slices reveal that intrinsic excitability, assessed by multiple spiking properties, does not change with this manipulation. Additionally, ETC-characteristic spontaneous burst firing does not change in terms of number of spikes fired, or burst properties. Furthermore, neither single spike properties nor sag potential amplitude show significant differences after occlusion. However, when assessing synaptic properties, ETCs in occluded conditions have larger long lasting excitatory currents, with no change in the frequency of their occurrence. We further investigated whether occlusion results in a change in the release probability at OSN synapses by recording from ETCs while stimulating OSN axons. We found that after occlusion the paired-pulse ratio (PPR) of these inputs decreases, suggestive of an increase in release probability at OSN synapses.
These alterations are indicative of adaptive plasticity in excitatory signalling in the olfactory bulb glomerular network. They may act to control the gain of information flow through the circuit, maintaining sensory performance in the face of external perturbations.

Title: Characterising dopaminergic plasticity in the mouse olfactory bulb

Authors: *D. J. BYRNE, M. S. GRUBB
Ctr. for Developmental Neurobio., King's Col. London, London, United Kingdom

Abstract: Olfactory bulb dopaminergic neurons are inhibitory interneurons involved in the early processing of odour information in the glomerular layer. These neurons can be readily identified by the expression of tyrosine hydroxylase (TH) and comprise of two main distinct populations that can be classified based on soma size. We use a Cre-driver mouse line under the control of the dopamine transporter (DAT) to label dopaminergic neurons. Initial experiments have been to characterise this population using immunohistochemistry and induce activity-dependent changes by unilateral naris occlusion. Co-localisation of DAT-tdTomato expression with TH in the mouse glomerular layer is restricted to dopaminergic neurons with a small soma size. A proportion of DAT-tdTomato neurons were found to not express TH. Co-staining with another dopaminergic marker dopa decarboxylase (DDC) reveals co-localisation with TH-positive neurons and absence from DAT-tdTomato neurons that are TH-negative. Investigating markers of other known glomerular layer neurons demonstrated that this subpopulation is part of the calretinin population of neurons. Olfactory dopaminergic neurons are known to be particularly plastic, altering their structure, function and gene expression in an activity-dependent manner. We use slice electrophysiology and immunohistochemistry to examine experience-dependent changes in DAT-tdTomato neurons after one and three days of unilateral naris occlusion. Using manual sorting, we can isolate DAT-tdTomato neurons from manipulated mice and perform targeted gene expression analysis. We have a mouse model that predominately labels a distinct subpopulation of olfactory bulb dopaminergic neurons. We can readily manipulate the activity of these neurons and to investigate how functional plasticity is regulated by activity-dependent changes in gene expression and epigenetic modifications.

Title: Input specific plasticity with visual experience by Homer1a mediated Metabotropic glutamate receptor 5 signaling in mouse primary visual cortex

Authors: *V. B. CHOKSHI[1], M. GAO[2], P. F. WORLEY[3], H.-K. LEE[4]
[1]Biol., Johns Hopkins Univ., Baltimore, MD; [2]Dept. of Neurobio., Barrow Neurolog. Institute, St. Joseph's Hosp. and Med. Ctr., Phoenix, AZ; [3]Dept Neurosci/Neurol, [4]Dept. of Neuros/ The Mind Brain Inst., Johns Hopkins Sch. Med., Baltimore, MD

Abstract: Sensory systems inform us about the surrounding environment. It is well accepted that sensory experience during development shapes proper functional connectivity of cortical neurons. Brain deprived of sensory inputs in early development is not able to recover its normal functionality when sensory input is restored at a later age. Hence it is important to understand the mechanisms by which cortical synapses recover function with sensory experience during an early critical period . It has been shown that depriving vision of mice (P21-P120) for two days strengthens excitatory synapses on principal neurons in layer 2/3 of primary visual cortex (V1) in an input specific manner (Petrus et al. 2015). Intracortical inputs measured as α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid receptor (AMPAR) mediated synaptic currents are strengthened, while the strength of feed-forward excitatory inputs from layer 4 is unchanged. We found that the strength of intracortical synapses is reversed rapidly upon restoring visual experience for two hours, which requires an activity-dependent immediate early gene Homer1a (H1a). Using knockin mice that specifically lack H1a signaling through metabotropic glumatate receptor 5 (mGluR5FR KI), here we demonstrate that mGluR5-H1a signaling is critical for rapid experience-dependent homeostatic depression of intracortical synapses. Furthermore, mGluR5FR KI mice show defective ocular dominance plasticity (ODP) measured using intrinsic optical signal imaging method. Our reults suggest a key role of mGluR5 mediated H1a signaling in experience-dependent plasticity in mouse V1.

Title: Homeostatic plasticity of excitatory synapses in *Ex vivo* cortical circuits

Authors: *B. D. GRIER[1,2], V. CHOKSHI[3,2], A. DYKMAN[4], E. NIEBUR[1,2], H.-K. LEE[1,2]
[1]Neurosci., [2]Mind Brain Inst., Johns Hopkins Univ. Sch. of Med., Baltimore, MD; [3]Biol., [4]Robotics, Johns Hopkins Univ., Baltimore, MD

Abstract: Synapses within the central nervous system show a remarkable ability to undergo functional change in order to store information, as in the hippocampus, or in response to changes in sensory input, as in sensory cortex. Hebbian plasticity, such as long-term potentiation and long-term depression, underlies much of the functional plasticity seen at excitatory synapses. This form of plasticity is inherently unstable however, and left unchecked, would lead to runaway potentiation and depression, resulting in neuronal firing outside of a physiologically

relevant range. Homeostatic plasticity works to preserve efficient information transfer at central nervous system synapses in the face of changing information processing needs of a system. Prolonged changes in visual experience trigger homeostatic plasticity of excitatory synapses, which has been measured *ex vivo* in primary visual cortex (V1) layer 2/3 (L2/3) pyramidal neurons (Goel et al., 2006; Goel & Lee, 2007). However, the relevant pattern of neural activity that drives such plasticity *in vivo* is currently unknown. To determine this, we aimed to develop an *ex vivo* stimulation paradigm, using acute cortical slices, that may allow parametric analysis of different components of *in vivo* activity patterns that drive homeostatic synaptic plasticity. An advantage of using this system compared to conventional neuronal cultures is that it mostly preserves *in vivo* circuitry. Recent studies using cortical slices demonstrated that homeostatic synaptic changes can be restricted to a certain set of inputs onto cortical neurons (Petrus et al., 2015), which highlights the critical need to study homeostatic synaptic plasticity in the context of a neural circuit. By stimulating V1 layer 4 to fire with biologically relevant patterns of activity, we have observed homeostatic synaptic plasticity in L2/3 pyramidal neurons. Further, by employing computational algorithms we have begun to dissect the components of neuronal firing patterns that are necessary for driving homeostatic change. Development of an *ex vivo* preparation will allow parametric analysis of the neural activity necessary for homeostatic plasticity *in vivo*, as well as provide an efficient platform to test molecular mechanisms of *in vivo* homeostatic synaptic plasticity in a reduced preparation.

Title: Extinction of aversive taste memory homeostatically prevents the maintenance of *In vivo* insular cortex LTP: Calcineurin requirement

Authors: *A. RIVERA-OLVERA[1], ***A. RIVERA-OLVERA**[2], J. NELSON-MORA[3], M. GONSEBATT[3], M. ESCOBAR[1]
[1]Facultad De Psicologia, UNAM, Ciudad DE Mexico, Mexico; [2]Facultad de Psicologia, UNAM, Mexico City, Mexico; [3]Inst. de Investigaciones Biomédicas, UNAM, Ciudad DE Mexico, Mexico

Abstract: Accumulating evidence indicates that homeostatic plasticity mechanisms dynamically adjust synaptic strengths to promote stability that is crucial for memory storage. Our previous studies have shown that prior training in conditioned taste aversion (CTA) prevents the subsequent induction of long-term potentiation (LTP) in the projection from the basolateral nucleus of the amygdala (BLA) to the insular cortex (IC) in vivo. We have also reported that induction of LTP in the BLA-IC pathway modifies the CTA extinction. Memory extinction involves the formation of a new associative memory that inhibits a previously conditioned association. A body of evidence suggests that protein phosphatase calcineurin (CaN) is involved in the extinction of some behavioral tasks. The aim of the present study was to analyze the effect of CTA extinction on the ability to induce subsequent LTP in the BLA-IC projection in vivo, as well as, the role of CaN in this process. Thus, 48h after CTA extinction animals received high frequency stimulation in order to induce IC-LTP. Our results show that extinction training allows the induction but not the maintenance of IC-LTP and increases the CaN expression. These findings reveal that CTA extinction promotes a homeostatic regulation of subsequent IC synaptic plasticity maintenance through increases in CaN levels. Supported by: PAPIIT IN215816 and CONACYT 417634.

Title: Linking homeostasis of neurons and networks in freely behaving rats

Authors: Z. MA[1], R. WESSEL[1], G. TURRIGIANO[2], *K. B. HENGEN[3]
[1]Physics, Washington Univ. in St. Louis, Saint Louis, MO; [2]Dept of Biol., Brandeis Univ., Waltham, MA; [3]Biol., Washington Univ. In St. Louis, Saint Louis, MO

Abstract: The rapid modifiability of neural networks, such as those in the cerebral cortex, underlies learning and cognition. However, such modifiability makes neuronal networks prone to severe destabilizing forces. Homeostatic plasticity is assumed to compensate for these effects and thus underlie the capacity of networks to be simultaneously stable and rapidly modifiable. While cell-autonomous homeostatic mechanisms have been well described in vitro and ex vivo, the assumed connection to network activity, the basis of brain function, has never been evaluated. Does the stabilization of neuronal firing rates underlie stable network dynamics?
To address this question, we investigated the dynamics of regular spiking (RS) and fast spiking (FS) neurons in the context of cortical circuit dynamics in freely behaving rats during a direct homeostatic challenge. Specifically, we obtained continuous, 16-channel extracellular (wire electrode) array recordings from visual cortex of freely behaving rats for 9 days and concurrently monitored behavioral conditions. The experimental protocol consisted of (i) three days of baseline activity and (ii) six days of monocular deprivation. We extracted single-unit spiking from the extracellular recordings using spike-sorting algorithms and distinguished between regular spiking (RS) and fast spiking (FS) units.
Based on the RS spike trains, we evaluated cortical circuit dynamics with respect to “criticality” using the measure of neuronal avalanches, which are cascades of contiguous spikes. This network analysis revealed three important features. First, during baseline cortical activity, neuronal avalanches had power law size and duration distributions. Furthermore, avalanche sizes and durations followed a scaling relation, thus providing an important evidence of a dynamical critical system. Second, following monocular deprivation, network dynamics shifted away from criticality and then recovered towards criticality within several days. Third, change of RS network dynamics (and FS firing rate) preceded RS firing rate changes.
In conclusion, these results link homeostasis of neurons and networks in freely behaving rats and raise the question to what extent FS firing rate homeostasis determines network dynamics and RS firing rate homeostasis.

Sch. of Med., Palo Alto, CA; [6]Neurosci., Rosalind Franklin Univ. of Med. and Sci., North Chicago, IL

Abstract: Functional output of the nucleus accumbens (NAc) relies on how the membrane excitability of its principle medium spiny neurons (MSNs) translates excitatory synaptic inputs into action potential firing, while deviated NAc function contributes to drug addiction. Here, we report a synapse-membrane homeostatic crosstalk (SMHC), through which an increase/decrease in excitatory synaptic strength induced a homeostatic decrease/increase in the membrane excitability, and vice versa, resulting in overall functional stability of NAc MSNs. After short-term withdrawal from cocaine self-administration, despite no actual change in excitatory synaptic strength in NAc MSNs, GluN2B NMDA receptors, the SMHC sensors of synaptic strength, were upregulated, creating false signals that induced an SMHC-mediated decrease in membrane excitability. This decreased membrane excitability is partially mediated by increased expression of SK2 type calcium-activated potassium channels. The decreased membrane excitability subsequently induced another SMHC cascade to increase excitatory synaptic strength over long-term cocaine withdrawal through synaptic accumulation of calcium-permeable AMPA receptors. Disrupting the cascading of SMHC-based dysregulation in NAc neurons prevented the progressive intensification of cocaine seeking after drug withdrawal. Thus, cocaine exposure triggers cascades of homeostatic dysregulation to promote progressive intensification of drug seeking after withdrawal.

Title: Integrative morphological analyzes to enhance NMJs diagnostic power

Authors: *S. BARBAT, R. ROBITAILLE
Univ. De Montréal, Montreal, QC, Canada

Abstract: The neuromuscular junction (NMJ) is increasingly pointed out in various models where losses of muscle mass and function are noted. The desire to determine the involvement of NMJs in those phenomena has greatly motivated the development of methods to analyze them. Yet, these morphological analyzes remain superficial and often limited to the organization of the postsynaptic endplate and the level of fragmentation. Yet, NMJs are composed of three main components; AChRs, but also the axon terminal and Perisynaptic Schwann Cells (PSCs; Glial cells covering pre- and post-synaptic elements). Here, we propose a systematic and extensive methodology using all 3 components to study the morphology of NMJs. To test the sensitivity of the method, we compared active and sedentary adult mice (12 months) where changes should be subtle owing to their young age. In each group, 15 soleus were stained for AChRs (α-BTX), axonal terminal (NFM/SV2), and PSCs (S100β). Five soleus were also used to determine the motor unit type by staining for MHCI, MHCIIa and AChRs. At least 20 surface NMJs for each muscle were imaged by confocal microscopy. As expected, NMJs of sedentary mice were more fragmented (4.0±0.1 vs. 2.3±0.1 fragments, $p<0.0001$). However, the innervation status was similar between active and sedentary mice (≈95% innervated, 4% partially denervated and 1% denervated in both groups). Similarly, the coverage of pre and post-synaptic elements by PSCs was similar between active and sedentary mice (≈97% covered, 2% partially covered and 1% not covered in both groups). Yet, more detailed analyzes revealed that sedentary mice had higher proportions of NMJs with ectopic fragments (0.1±0.1% vs. 1.6±0.5%, $p=0.0038$). Interestingly, this was not MHC-type dependent. Furthermore, more terminal (13.5±0.7% vs. 8.8±1.1%, $p=0.0017$) and axonal (6.0±0.8% vs. 3.3±0.8%, $p=0.0190$) sprouting were observed in sedentary compared to active mice. Similarly, more terminal (8.4±1.0% vs. 4.3±0.7%, $p=0.0012$) and axonal (5.7±0.8% vs. 3.3±0.7%, $p=0.036$) glial extension were observed in sedentary compared to active mice. Furthermore, by using *relative risk analyzes* we observed that the interaction between events was influenced by sedentarity. In conclusion, where superficial analyzes failed to reveal differences, more detailed analyzes revealed high level of instability underlying the presence of dynamic mechanisms. Given that changes at the NMJ precede and trigger changes at the muscle (that is, losses of muscle mass and strength), using this method and being able to observe such subtle changes may confer a powerful predictive advantage compared to traditional methods.

Title: Vital imaging of myonuclei

Authors: *R. HASTINGS, W. J. THOMPSON
Biol., Texas A&M Univ., College Station, TX

Abstract: Skeletal muscle fibers are multinucleate cells generated in early development by the fusion of individual myoblasts. The nuclei initially lie in the center of elongating myotubes but move to the sarcolemma at the periphery of each maturing fiber. When a muscle fiber is damaged, necrosis of the damaged segment is followed by regeneration from satellite cells that migrate to the injury site, differentiate, fuse, and grow to regenerate the muscle fiber. After this regeneration event, the nuclei of the former satellite cells remain, at least temporarily, in the center of the fiber. Therefore, the presence of “central myonuclei” has long been accepted as a marker for a degeneration/regeneration event having occurred in the muscle fiber. It is unclear, however, whether these central myonuclei ever migrate outwards to become peripheral myonuclei. To determine whether central myonuclei migrate to the periphery, I have bred mice possessing a vital transgenic fluorescent label of myonuclei that allows for repeated *in vivo* imaging. I am using these mice to observe damage events in which central myonuclei appear in the muscle fiber, and to observe when and whether those myonuclei subsequently migrate to the periphery of the muscle fiber.

Title: Myofiber development and regeneration in a mouse model of muscular dystrophy

Authors: *R. MASSOPUST, W. THOMPSON
Texas A&M Univ., College Station, TX

Abstract: Duchenne muscular dystrophy (DMD) is an X-linked degenerative muscle disease that affects roughly 1:3,500 males. Caused by frame-shift mutations in the dystrophin gene, dystrophic individuals lack functional dystrophin protein. This dysfunction leads to membrane instability, progressive muscle degeneration, fibrosis, loss of ambulation, and ultimately, premature death. Because diagnosis typically does not occur until 4 years old there is little known about muscle development at early stages of the disease. Muscular dystrophy x-linked (*mdx*) mice are models of DMD and are caused by a homologous mutation. The onset of obvious disease pathology in *mdx* mice occurs between 3 and 8 weeks, depending on the muscle. Over the course of subsequent weeks, the muscle undergoes significant necrosis and repair. During development, myoblasts fuse to form multiple and centrally nucleated myotubes. Nuclei then move from the center to the periphery of the fiber coincident with the formation of myofibrils. After muscle injury such as that occurring in mdx, satellite cells proliferate to form myoblasts. Similar to development, myoblasts line up at the site of damage and fuse to repair the myofiber, leaving behind chains of centrally located nuclei. There is debate regarding whether central nuclei in regenerated myofibers move to the periphery as they do in development. Centrally positioned nuclei after initial development have long been appreciated as a marker of regenerated muscle fibers, but not as a contributor to disease states. In the present work, single myofibers were isolated from 2, 6, 12 and 24 week old *mdx* and wild type (WT) mice. Myofibers were stained with α-bungarotoxin and DAPI, to image acetylcholine receptors (AChRs) and nuclei respectively. Myofibers were reconstructed using confocal microscopy. At 2 weeks of age, before the onset of obvious necrosis, *mdx* myofibers have significantly larger volume and increased myonuclear number relative to age-matched WT fibers. At 12 weeks of age, *mdx* myofibers are hypernucleated and have a significantly higher incidence of central nuclei. By 24 weeks of age, myofibers have significantly larger volume, are hypernucleated and have a higher incidence of central nuclei relative to age-matched controls. These results indicate *mdx* myofibers are developmentally distinct from WT even before the onset of disease pathology.

Title: Neuromuscular acetylcholine receptor dynamics in dystrophic mice mimic those caused by endogenous muscle injury

Authors: *S. HADDIX[1], W. J. THOMPSON[2]
[1]Inst. for Neurosci., [2]Biol., Texas A&M Univ., College Station, TX

Abstract: Duchenne muscular dystrophy (DMD) is a fatal myopathy that has no cure. There are also abnormalities of the neuromuscular junction (NMJ) in animal models of DMD, which include fragmentation and expansion of the acetylcholine receptor (AChR) endplate, changes in axon morphology, and an increased number of terminal Schwann cells. The remodeling is likely initiated by muscle fiber necrosis and regeneration at the junction. To investigate the events underlying the restructuring of dystrophic NMJs, we utilize a technique to visualize the dynamics of AChRs in *mdx* mice, a murine model of DMD. A low concentration of bungarotoxin (BTX) conjugated to a fluorophore is applied to the sternomastoid muscle of an *mdx* mouse to label junctions *in vivo*. Following a 10-day recovery period, which allows for natural myofiber degeneration and regeneration and receptor turnover, the animal is sacrificed and labeled with BTX conjugated to a different fluorophore. We hypothesize that if a necrotic event occurs at the endplate region during the 10-day period the first color BTX will be lost or remodeled. The second color BTX will stain robustly, as receptors must be inserted into the sarcolemma for transmission to resume or as a result of the ongoing AChR turnover. In control animals the first and second BTX applications label the same population of receptors and show no difference in morphology. These we interpret to be fibers that have not undergone a necrotic event at the junction during the 10-day interval. However, in a significant number of the *mdx* synapses the first color BTX has mostly disappeared and the second color of BTX labels a fragmented endplate. We term these dynamic junctions. We show here that receptor turnover is higher in dystrophic muscles, corresponds to synaptic remodeling and suggest that the cause of increased receptor dynamics is necrosis and subsequent regeneration of the muscle fiber at the endplate region. Indeed these endplates are similar to the endplates in two models of muscle injury. The proportion of dynamic junctions is elevated and constant in *mdx* mice from P38 to P450. Our results indicate that muscle fiber degeneration and regeneration is occurring at a consistent rate well beyond the proposed “crisis” period and contributes to synaptic remodeling in dystrophy. Additionally, when tension recordings are made from the sternomastoid muscles of P160 animals, preliminary evidence shows discrepancies in neuromuscular transmission suggesting that this turnover and remodeling has functional repercussions.

Title: Difference in the timing of neuromuscular synapse elimination correlates with properties of target muscle fibers

Authors: *Y. LEE[1], W. J. THOMPSON[2]
[1]Dept. of Biol., [2]Biol., Texas A&M Univ., College Station, TX

Abstract: The emergence of a mature nervous system requires a significant refinement of synaptic connections and neuronal networks initially formed during development. Such refinement includes elimination and remodeling of existing synapses, commonly termed "synapse elimination," and occurs throughout the nervous system. Similar synaptic remodeling also occurs during aging, in disease and throughout life providing cellular basis for learning and memory. The process of developmental synapse elimination is most extensively studied at the rodent neuromuscular junction (NMJ). At a mature NMJ, high-density aggregates of the postsynaptic acetylcholine receptors (AChR) are each apposed by presynaptic terminals of a single motor neuron, and the processes of terminal Schwann cells (tSCs; glia of the NMJ) cap the synaptic apposition. During early postnatal development, each of up to ~10 motor axons that converge onto a postsynaptic muscle fiber; these inputs are removed until each NMJ is innervated by a single motor neuron. Previous studies, including our own, have demonstrated that neuronal activity as well as behaviors of synaptic glia influence the course of synapse elimination. It is, however, unclear whether target muscle fibers are more than naïve substrates for innervation but rather are active participants in removal of redundant axonal inputs. I present evidence that the rate at which synapse elimination proceeds depends, at least partly, on the contractile property (fast vs. slow) of the target muscle fiber on which the synapse is situated. Thus, the results indicate that postsynaptic muscle fibers, whose contractile properties are matched with the activity patterns of the innervating motor neurons, likely also provide instructive cues that affect the outcome of local synapse elimination.

Title: Cortactin expression is driven by wingless and neuronal activity to allow synaptic plasticity at the *Drosophila* neuromuscular junction

Authors: *C. M. DOMINICCI-COTTO[1], M. PEREZ CARAMBOT[2], C. MALDONADO[3], B. MARIE[4]
[1]Inst. of Neurobio., San Juan, PR; [2]Biol., Inst. of Neurobio., San Juan, Puerto Rico; [3]Inst. of Neurobio., Old San Juan, PR; [4]Inst. of Neurobio., Univ. of Puerto Rico - Med. Sch., San Juan, PR

Abstract: Wingless (Wg), a major signaling molecule, is essential for the plasticity of the nervous system. Recently, it was shown that the Drosophila neuromuscular junction (NMJ) serves as a model to understand the molecular mechanisms underlying activity-dependent synaptic plasticity. Upon repeated stimulations, the NMJ undergoes modifications in synaptic structure (apparition of de-novo synaptic boutons) which are dependent on the Wg signaling pathway. Still, little is known about the cytoskeletal changes or molecular components controlled by Wg that allow this plasticity. Here, we focus on how the actin regulator Cortactin (Cttn) is related to this process. Using genetics and confocal microscopy, we assess the role of Cttn in regulating activity-dependent synaptic plasticity. We show that Cttn is present at the NMJ pre- and post-synaptically and that de-novo synaptic structures related to synaptic plasticity are dependent on pre-synaptic Cttn. Indeed, these synaptic structures that appear after high neuronal activity contain Cttn at an early stage of their formation. In addition, we show that Cttn protein levels increase after repeated stimulations and that this increase is required for activity-dependent plasticity. To strengthen these results, we blocked action potentials and neurotransmitter release with the use of paralytic (para) and synaptotagmin (syt) mutants respectively. After repeated stimulations, there is no increase of Cttn and no plasticity in para and syt mutants, thus neuronal activity is required for the increase of Cttn and synaptic plasticity. Lastly, since the Wg pathway is required for activity-dependent synaptic plasticity, we tested wether the increase in Cttn after stimulation is also dependent on this pathway. To do so, we asked whether Cttn intensity was affected in Wg mutant larvae and frizzled (fz2) RNAi transgenic larvae (Fz2 is the Wg pre-synaptic receptor). We found that Cttn is not increased after stimulation in both Wg and fz2 deficient larvae and that plasticity is also impaired. This suggests that the pre-synaptic Wg signaling is required for the increase of Cttn and for plasticity. Overall our results strongly suggest that during repeated stimulation the expression of Cttn is required for the regulation of synaptic plasticity under the control of Wg signaling.

Title: Cortactin controls electrophysiological properties during activity-dependent synaptic plasticity at the *Drosophila* larva neuromuscular junction

Authors: *C. MALDONADO[1], M. PEREZ[1], C. DOMINICCI[1], B. MARIE[2]
[1]Inst. of Neurobio., Old San Juan, PR; [2]Inst. of Neurobio., Univ. of Puerto Rico - Med. Sch., San Juan, PR

Abstract: In the nervous system, changes in activity lead to modifications in synaptic structure and function. This phenomenon is referred to as synaptic plasticity and is thought to be the basis of learning and memory. Such changes can be studied at the *Drosophila* neuromuscular junction (NMJ) where we can address the molecular mechanisms underlying activity-dependent synaptic plasticity. Recent work has shown that, after repeated stimulations, *de novo* synaptic structures form at the NMJ while an increase in the frequency of spontaneous release occurs. The secreted molecule Wingless (Wg)/Wnt is known to underlie the structural and electrophysiological changes during activity-dependent plasticity at the NMJ. However, little is known about how this signal mediates the cellular changes that lead to plasticity. In this work, we investigate the role of the actin regulator Cortactin (Cttn) in activity-dependent synaptic plasticity. With confocal microscopy, we show that the synaptic structures that are formed during synaptic plasticity are dependent on presynaptic Cttn expression. In turn, we focused on the functional modifications to the synapses. Through intracellular electrophysiological recordings of the larva NMJ, we show that Cttn-deficient synapses have a significant reduction in the frequency of spontaneous release. Such reduction can only be rescued by the presynaptic expression of Cttn, which suggests that the neuronal expression of Cttn is necessary for maintaining the rate of spontaneous vesicle fusion at the NMJ. Interestingly, Cttn seems to be important for the potentiation of spontaneous release that occurs after activity-dependent synaptic plasticity. Indeed, there is no potentiation of spontaneous release in Cttn mutants and in NMJs depleted of presynaptic Cttn. However, this potentiation is achieved if Cttn is expressed presynaptically in Cttn mutants, or if Cttn is

removed only postsynaptically. It is likely then, that Cttn is responsible for presynaptic functional changes after activity-dependent synaptic plasticity. Overall, our findings suggest that Cttn is an important regulator of structural and physiological properties of the synapse in response to activity.

Title: Genetic interaction of DISC1 and Neurexin in the development of fruit fly glutamatergic synapses

Authors: *K. FURUKUBO-TOKUNAGA[1], H. PANDEY[2], K. BOURAHMOUNE[2], K. KURITA[2], A. SAWA[3]
[1]Biol. Sci., Tsukuba, Japan; [2]Univ. of Tsukuba, Tsukuba, Japan; [3]Dept. of Psychiatry, Johns Hopkins Univ., Baltimore, MD

Abstract: Originally identified at the breakpoint of a chromosome (1;11)(q42.1; q14.3) translocation in a Scottish family, DISC1 is a highly potent susceptibility gene for various mental disorders. To study neurodevelopmental functions of DISC1 in a genetically tractable model, we have examined functional interactions of *DISC1* and other risk factor genes using the fruit fly (*Drosophila melanogaster*). Here, we show that DISC1 interacts with *dnrx1*, the *Drosophila* homolog of the human neurexin (NRXN1) gene, in the development of glutamatergic synapses. We show that reduction of *dnrx1* activity abolished DISC1-mediated suppression of synaptic bouton areas while DISC1 caused suppression of axonal terminal branching in both *dnrx1* mutant and RNAi background. Reduction of *dnrx1* also suppressed DISC1-mediated stimulation of active zone density and upregulation of the expression of Bruchpilot, a *Drosophila* ELKS/CAST protein, in presynaptic motoneurons. Reduction of *dnrx1* activity also modified DISC1 overexpression phenotypes in postsynaptic cells. Thus overexpression of DISC1 in wild-type background stimulated the expression of DGluRIIA but failed to do so in the *dnrx1* heterozygous background. Moreover, overexpression of DISC1 in the *dnrx1* heterozygous background caused mislocalization of Disc-large, the *Drosophila* PSD-95 homolog. We further show that overexpression of DISC1 in pre- but not postsynaptic cells suppressed the DNRX1 expression in the synaptic boutons. Analyses with a series of DISC1 domain deletion constructs have revealed that axodendritic localization of DISC1 is crucial for efficient suppression of

DNRX1. These results thus suggest an intriguing converging mechanism controlled by the interaction of neurexin and DISC1 in the developing glutamatergic synapses.

Title: The alterations of neurite outgrowth and synapse development in tdp-43^{A315T} primary cortical neurons

Authors: *T. JIANG, M. BRIZUELA, E. HANDLEY, E. DAWKINS, T. DICKSON, C. BLIZZARD
Menzies Inst. for Med. Res., Hobart, Australia

Abstract: Neurite outgrowth alterations and synapse dysfunction have been implicated in models of Amyotrophic lateral sclerosis (ALS). The mislocalisation and/or the mutation of the RNA binding protein TDP-43 are a frequent occurrence in ALS pathogenesis. Recent research indicates that RNA binding protein may play an important role at the neuronal synapse, however the early pathophysiological dysfunctions causing impairment in synapse are still unknown. Here we utilized the prpTDP-43^{A315T} : YFP mouse model expressing human mutant TDP-43 (TDP-43^{A315T}) in cortical motor neurons to investigate the influence of TDP-43^{A315T} on neurite structure and synapse formation. Primary cortical neurons, derived from individual E15.5 embryos were grown to 3, 5, 10 and 15 days in vitro (DIV). In primary cortical neurons TDP-43^{A315T} expression was localized to both the nucleus and cytoplasms. Our data implicated that there was a significant difference between wild type (WT) and TDP-43^{A315T} primary cortical neurons in total dendrite length, mean length at 15 DIV, with no effect on dendrite complexity. Using YFP positive WT and TDP-43^{A315T} cortical neurons we demonstrated a significant decrease in dendritic spines density in the TDP-43^{A315T} cortical neurons in comparison to WT controls at both 10 and 15 DIV. Furthermore, we discovered that axonal growth cone dynamics and growth cone pausing and extension was significantly altered by overexpression of TDP-43^{A315T} and whilst there was no change in axonal outgrowth and growth cone areas. This work indicates TDP-43^{A315T} mutation may play a role in the formation of synaptic structures and

function in cortical neurons. Unravelling the mechanisms that render neurons in the cortico-motor system vulnerable to TDP-43 misprocessing and pathology will be imperative in the pursuit of identifying novel therapeutic interventions.

Title: Excessive lysosomal degradation induced by the Christianson Syndrome mutation NHE6 ΔES impairs AMPA receptor trafficking and structural plasticity in hippocampal neurons

Authors: *A. Y. GAO[1], A. ILIE[2], J. ORLOWSKI[2], R. A. MCKINNEY[3]
[1]Integrated Program in Neurosci., [2]Physiol., [3]Pharmacol. & Therapeut., McGill Univ., Montreal, QC, Canada

Abstract: Proper endosomal trafficking is important for neuronal morphology and plasticity, and deficits in this process have recently been implicated in a number of neurological disorders. This includes Christianson Syndrome (CS), an X-linked neurodevelopmental disorder characterized by intellectual disability, epilepsy, ataxia, and autistic features. Although CS is believed to be one of the most common forms of X-linked intellectual disability worldwide, little is known of its underlying etiology, and intervention for affected individuals is thus lacking. CS is due to mutations in the *Slc9a6* gene encoding intracellular sodium/proton exchanger NHE6, which localizes to early and recycling endosomes and regulates their luminal pH. We were the first to show that in hippocampal neurons, NHE6 colocalizes with a subset of AMPA receptors (AMPARs) and is recruited to excitatory synapses following chemical long-term potentiation (LTP). However, the impact of clinical mutations in NHE6 upon neuronal structure and function have not yet been studied. To this end, we are investigating a prevalent NHE6 loss-of-function mutation with deletions of amino acids Glu287 and Ser288 (NHE6 ΔES). Sparse transfection of NHE6 ΔES into primary hippocampal neurons decreased dendritic branching and mature dendritic spine density. Moreover, NHE6 ΔES showed reduced colocalization with early and recycling endosomal markers, yet greater colocalization with markers for late endosomes and lysosomes, which implied an excessive degree of lysosomal degradation. To investigate how this could impact receptor trafficking, we then assessed the localization of tropomysin receptor kinase B (TrkB), the high-affinity receptor for brain-derived neurotrophic factor (TrkB). While

overall levels of TrkB were comparable, there was a significant attenuation in active phosphorylated TrkB in NHE6 ΔES-transfected cells. This suggested an impairment in BDNF/TrkB signaling, which is crucial for proper spine formation and maturation. Furthermore, NHE6 ΔES expression prevented spine enlargement and AMPAR insertion into synaptic sites following LTP, indicating an impairment in cellular learning mechanisms. However, applying inhibitors of lysosomal degradation to NHE6 ΔES-expressing neurons partially rescued their deficits in dendritic spine density, AMPAR trafficking, and the structural response to LTP. Overall, we find that NHE6 ΔES disrupts the structure and remodeling of hippocampal pyramidal neurons, which may be the cause of learning and memory impairments in CS patients.

Title: Autism-associated mutation of syntaxin binding protein 5 disrupts dendritic morphology

Authors: *W. SHEN, Y.-C. LIN
Hussman Inst. For Autism, Baltimore, MD

Abstract: Autism is a neurological condition that features marked qualitative differences in communication and social interaction. Genetic studies have implicated numerous risk genes, many of which encode proteins important for synaptic development and function and may contribute to autism phenotypic diversity. Deletions and mutations of syntaxin binding protein 5 (STXBP5, also known as tomosyn) are identified in some individuals with autism. STXBP5/tomosyn is a syntaxin binding protein that contains a WD40 domain at the N-terminus and a SNARE motif at the C- terminus. STXBP5/tomosyn has a presynaptic role that negatively regulates neurotransmitter release by forming syntaxin-1-SNAP25-tomosyn complex. STXBP5/tomosyn has also been shown to regulate neurite outgrowth in immature neurons. The WD40 domain has a scaffolding function harboring molecules necessary for signal transduction and vesicle trafficking. Interestingly, two autism-associated variants of STXBP5 exhibit missense mutations at the WD40 domain. Whereas the crucial role of STXBP5/tomosyn in presynaptic terminals has been defined in detail, little is known about its postsynaptic role in dendritic integrity and synaptic strength. Here, we test the hypothesis that the autism-associated STXBP5/tomosyn mutant disrupts dendritic morphology by altering the regulation of dendritic

exocytosis.
To test this hypothesis, the subcellular localization of wildtype (WT) and mutant STXBP5/tomosyn in cultured hippocampal neurons was determined. WT- and mutant tomosyn was found to all localize to axons, dendrites and dendritic spines. Knockdown of STXBP5/tomosyn in cultured neurons reduced dendrite arborization, soma size, and dendritic spine density, but the expression of the mutant tomosyn protein failed to rescue the reduced spine density in tomosyn knockdown neurons. Moreover, the mutant tomosyn altered its binding to syntaxin-4, a postsynaptic t-SNARE protein involved in glutamatergic receptor trafficking, potentially leading to disruption of dendritic integrity and synaptic strength.
In conclusion, STXBP5/tomosyn plays an important role in regulating dendritic morphology. Mutations of *STXBP5* found in individuals with autism may alter structural and functional plasticity of dendritic spines, and potentially disrupt normal developmental processes in brain formation.

Abstract: The unmet clinical need of those suffering from mental illness is staggering, with Schizophrenia alone accounting for 16.8 million Disability Adjusted Life Years (DALYs) globally. There is urgent need, consequently, to better understand the molecular mechanisms important in the pathogenesis of schizophrenia. Aberrant developmental pruning of synapses may be one important mechanism contributing to schizophrenia risk; we showed that increasing gene-dosage of Complement Component 4 (C4) increased schizophrenia risk and that loss of C4 in a mouse abrogated normal synaptic refinement in the developing visual system. From this previous work, we hypothesized that there might also be an endogenous negative-regulator of this pruning machinery hypofunction of which might also lead to over-pruning in a way that would contribute to schizophrenia risk. We conducted an in depth inquiry into whether such a negative regulator of pruning could be encoded by the giant gene, CSMD1 (CUB and Sushi Multiple Domains 1), which is robustly associated with schizophrenia risk through recent genome-wide association studies (GWAS). CSMD1 is a ~ 2Mb gene on chromosome 8 that encodes a brain-enriched, large type-I transmembrane protein. Both of the protein interaction domains, CUB and Sushi domains, are present in known regulators of complement and a previously published in vitro study has shown that small fragments of CSMD1 can bind and act as a cofactor for degradation of multiple members of the complement cascade, including C4. Despite these intriguing findings, very little is known about the normal functions of CSMD1 in the brain and how variation in the gene contributes to schizophrenia risk. Using a csmd1 KO mouse and a human embryonic stem cell line with biallelic frame-shifting deletions in CSMD1, we present here the first evidence that CSMD1 has a role in vivo and in human neural cells in regulating complement activation, synapse number, and functional biomarkers of pruning. Our preliminary data show that loss of Csmd1 leads to enhanced complement fixation over-refinement of the developing mouse retinogeniculate system, and that pruning-relevant dysfunction extends beyond the visual system in mice. Our preliminary findings show that disruptions to complement biology extend as well to human embryonic stem cell derived NGN2-positive neurons lacking CSMD1. Though many questions remain, this poster presents the first evidence for a role of CSMD1 in regulating synapse number and complement in the murine brain and human neural tissues, and suggests

Title: CCL5 regulating synaptogenesis promotes memory formation

Authors: *S.-Y. CHOU[1], R. AJOY[1], B. J. HOFFER[2], Y.-H. CHEN[3]
[1]Grad. Inst. of Neural Regenerative Med., Taipei Med. Univ., Taipei, Taiwan; [2]Scientist Emeritus, NIDA/NIH, Lyndhurst, OH; [3]Tri-Service Gen. Hospital/National Def. Medi, Taipei City, Taiwan

Abstract: Introduction - CCL5 belongs to CC chemokine family and locates in chromosome 17 in humans. Previous studies have identified that CCL5 releasing from astrocyte promotes neurite outgrowth and neuronal activity. CCL5 responses for Hepatocyte Growth Factor (HGF) mediated axon outgrowth and branching which linking CCL5 to axon morphogenesis. Also, lower serum level of CCL5 was found in Alzheimer's disease (AD) patients. Some studies suggest that CCL5 protects the neurons from the damaging effects of Aβ deposits and could be an reitical factor in AD stem cell therapy. However, the mechanism of CCL5 in memory and neuronal function remains unclear. In the current study, we investigate the contribution and mechanism of CCL5 in mouse memory performance with a CCL5 knockout mouse (CCL5-/-). Methods - Novel Object Recognition Test, Object Location Test, stereotactic surgery, Western Blot for protein analysis, Synapsosome purification (for the isolation of synaptic proteins), cell culture, Immunostaining, and EPSP test. Results - The results showed that mice lacking of CCL5 performed impaired memory in both object recognition/location tests and hippocampal neuron electroactivity as EPSP. The performance on behavioral tasks and hippocampal neuron EPSP was improved when re-introducing CCL5/RANTES into the hippocampal region of the CCL5-/- mice. Protein analysis found increased synaptic-related proteins - PSD 95, Synaptophysin and GAP43 in hippocampus regions by CCL5/RANTES administration. Further cellular studies we identified CCL5 activates PI3K and increases mitochondria synaptic movement which promotes synaptogenesis. Conclusions - CCL5 plays a vital role in memory formation through its ability to enhance the Mitochondrial responded synaptogenesis.

Title: Activity-dependent structural changes in subsurface cisterns of hippocampal neurons

Authors: *J.-H. TAO-CHENG
NINDS, NIH, Bethesda, MD

Abstract: Subsurface cistern (SSC) is a specialized compartment of the endoplasmic reticulum (ER) in neuronal soma and primary dendrites that is in close apposition (~10 nm) to the plasma membrane (PM). Such ER-PM close appositions (called “ER-PM contact sites”) are involved in intracellular calcium regulation. Here, structural changes of SSC in hippocampal neurons were examined by electron microscopy upon depolarization with high K^+ or treatment with NMDA. In both experimental systems (10-14 day old organotypic hippocampal slice cultures and 3 week old dissociated hippocampal cultures), the number of SSC-PM contact sites in neuronal somas significantly decreased under these excitatory conditions. In hippocampal slice cultures, the number of SSC in pyramidal cells of the CA1 region decreased to ~40% of control levels after 1 min of high K^+ (90 mM, 2 exp), and to ~ 50% after 1 min of NMDA (50 µM, 2 exp) treatment. In dissociated hippocampal cultures, the number of SSC decreased to ~55% of control levels after 2 min of high K^+ (3 exp), and to ~ 65% after 2-3 min of NMDA (2 exp) treatment. Furthermore, in dissociated neuronal cultures, the average length of the SSC-PM contact area significantly decreased to ~ 60% of control values upon depolarization or NMDA treatment. This decrease in SSC-PM apposition was reversible 30 min after the cessation of treatment in both experimental systems. These results demonstrate a structural decoupling between the SSC and the PM upon stimulation, suggesting that there may be a functional decoupling of the calcium regulation. Because SSC-PM contact sites mediate calcium influx, the decrease in contact area may protect neurons from calcium overload upon intense stimulation.

Title: TMEM24, a lipid transporter at ER-plasma membrane contacts enriched in neurons and regulated by calcium

Authors: *M. MESSA[1], E. W. SUN[2], P. V. DE CAMILLI[3,4]
[1]Cell Biol., [2]Neurosci., Yale Univ. Sch. of Med., New Haven, CT; [3]HHMI/Yale Univ., New Haven, CT; [4]Kavli Inst. for Neuroscience, Yale Univ. Sch. of Med., New Haven, CT

Abstract: The endoplasmic reticulum (ER) is a sub-cellular compartment with a multiplicity of functions, including synthesis of most membrane lipids. The ER is functionally interconnected to most other cellular membranes via vesicular transport. In addition, it forms juxtapositions (10-30nm distance) with other membranes, including the plasma membrane (PM), via protein tethers. Some of these tethers contain lipid transport modules and mediate lipid exchange between the two adjacent bilayers, independently of fusion and fission reactions. Several such tethers have been identified and characterized, but the full picture is far from complete. TMEM24, an integral membrane protein of the ER predominantly expressed in neurons and neuroendocrine cells, functions as a tether between the ER and the PM. It comprises in sequence an N-terminal transmembrane region, an SMP domain (a module that transports glycerolipids), a C2 domain and a polybasic, unstructured C-terminal region that binds the PM in trans. We have previously shown that in pancreatic ß-cells the membrane tethering properties of TMEM24, which are required for its lipid transport function, are regulated by cytosolic Ca^{2+} via the interplay of protein kinase C and calcineurin (1). We have additionally provided evidence for a role of TMEM24 in insulinoma cells in the control of pulsatile Ca^{2+} elevations, suggesting feed-back loops between lipid transport and the dynamics of Ca^{2+} required for secretion (1). Here we have begun to explore the function of TMEM24 in the nervous system. TMEM24 is preferentially enriched in neurons versus glial cells and its expression in neuronal cells correlates with neuronal differentiation and maturation. Transfected TMEM24-EGFP localizes at neuronal ER-PM contacts at rest, but is shed from these contacts and rapidly redistributes throughout the entire ER upon experimental manipulations that result in elevation of cytosolic Ca^{2+}. These include trains of electric stimulation, K^+ depolarization, NMDA stimulation and Ca^{2+} uncaging. A similar concentration at ER-PM contract sites at rest is observed in gene edited neuroblastoma cells expressing EGFP-tagged TMEM24 at endogenous levels. We are currently further investigating the dynamics of TMEM24 and its role in neuronal function.

Title: *In vivo* imaging of mitochondrial localisation during structural synaptic plasticity

Authors: *R. M. LEES[1], J. D. JOHNSON[1], L. M. COLLINSON[3], P. VERKADE[2], M. C. ASHBY[1]
[1]Ctr. for Synaptic Plasticity, Sch. of Physiology, Pharmacol. and Neuroscie, [2]Univ. of Bristol, Bristol, United Kingdom; [3]The Francis Crick Inst., London, United Kingdom

Abstract: Most synapses in the adult mammalian cortex are assumed to persist for the entire lifetime of the animal. However, a small but significant population are transient, continually being formed and eliminated. This process of structural synaptic plasticity is thought to modify connectivity within cortical circuits during learning and memory formation. Mitochondria are found at a subset of presynaptic terminals where they can modulate neurotransmission through calcium sequestration and adenosine triphosphate (ATP) provision. While it is thought that mitochondria are essential for synaptic function, it is not known whether they are required for the persistence of presynaptic terminals. In particular, whether the recruitment of resident mitochondria relates to the long-term stability of a presynaptic terminal.
To answer these questions, in vivo two-photon imaging was used to track mitochondrial and synaptic localisation over short (<4 days) and long (>30 days) time periods. A bicistronic AAV1/2 was used to express cytosolic enhanced green fluorescent protein (EGFP) and mitochondrially-targeted red fluorescent protein (mito-tagRFP) in pyramidal neurons of the primary motor cortex. A cranial window was implanted over the somatosensory cortex to allow repeated imaging of the structure and mitochondrial content of projecting axons and their presynaptic boutons over time.

Mitochondria were found to be more stably localised to synaptic sites than non-synaptic sites. The initial recruitment of mitochondria to newly formed presynaptic terminals was related to the stabilisation of those synapses. The profile of mitochondrial localisation at pre-existing stable synaptic sites was also analysed to reveal the influence of mitochondrial recruitment on their longevity.
Mitochondrial function and localisation has been linked to synaptic function, and dysregulation of mitochondrial dynamics is linked to many neurodegenerative and neurological diseases. Therefore, the relationship between mitochondrial recruitment and reconfiguration of synaptic connectivity could provide understanding of the dynamics of neuronal and circuit plasticity, leading to a basis for mechanistic intervention.

Title: Neurolastin, a brain-specific dynamin-family gtpase, modulates mitochondrial dynamics

Authors: *R. M. LOMASH[1], R. S. PETRALIA[2], M. C. TSUDA[3], Y.-X. WANG[4], R. YOULE[1], H. A. CAMERON[5], K. ROCHE[1]

Abstract: Neurolastin is a recently discovered member of the dynamin-family of GTPases. It is a brain-specific protein with both GTPase and E3 ligase activities and shows a cytosolic and endosomal localization. Neurolastin plays an important role in synaptic transmission as its absence *in vivo* leads to fewer dendritic spines, lesser functional synapses, reduced paired pulse facilitation and smaller sized endosomes. We have now found that neurolastin in steady state is partially localized to the mitochondria as well. We have determined that the N-terminus of neurolastin contains a mitochondrial targeting sequence and the protein is being imported into the mitochondrial intermembrane space. By expressing multiple truncations and mutations of neurolastin in HeLa cells and neurons, we observe that inactivation or deletion of the RING domain alters the localization of the protein and leads to a near complete mitochondrial localization, whereas inactivation of the GTPase domain has no effect on localization.

Subsequently, we compared the mitochondrial morphology between wild-type and neurolastin knockout animals in cerebellar Purkinje cells by electron microscopy. We find that the mitochondria in the knockout are more abundant with smaller area and feret diameter, consistent with more fragmented mitochondria. Additionally, we observe that expression of inactive mutants of the GTPase domain leads to more fragmented mitochondria in HeLa cells. We also find that the neurolastin knockout has fewer PCNA positive and DCX positive cells in the adult dentate gyrus suggesting involvement of neurolastin in neurogenesis. Thus, we find that neurolastin is imported into the mitochondrial intermembrane space and regulates mitochondrial membrane dynamics and adult neurogenesis.

Title: Activity-dependent excitatory synapse stabilization in mouse visual cortex

Authors: *K. MICHEL, J. SUBRAMANIAN, M. R. BENOIT, E. NEDIVI
Picower Inst. for learning and Memory, MIT, Cambridge, MA

Abstract: Experience-dependent plasticity drives cortical networks to adapt to environmental changes, allowing appropriate reaction to sensory stimulation throughout life. In mature neuronal networks, plasticity occurs mainly at the synaptic level by forming new synapses and eliminating pre-existing ones. Multiple steps are required for excitatory synapse initiation, stabilization and maturation; however, it has been difficult to delineate the sequence of these events *in vivo* and identify which ones are influenced by activity due to the difficulty of independently labeling and simultaneously tracking dendritic spines and synaptic proteins at high temporal resolution.
To gain insight into the molecular mechanisms that connect sensory stimulation with the selective stabilization of new dendritic spines, we analyzed the role of the activity regulated gene *cpg15* during excitatory synapse stabilization in the visual cortex. By using *in vivo* multi-color two-photon microscopy, we resolved the daily and weekly dynamics of dendritic spines and the postsynaptic scaffolding molecule PSD95 in *cpg15* knockout (KO) mice. CPG15 is a small extracellular molecule whose expression in the cortex is spatially and temporally correlated with

periods of synapse formation and activity dependent plasticity, and can be induced in response to sensory experience. In CPG15 KO mice we found a similar rate of spine initiation compared to wild type mice, however fewer of these new spines were able to recruit PSD95 and stabilize. This difference in spine stabilization was only apparent with normal visual experience, suggesting CPG15's function in synapse stabilization is indeed coupled to sensory stimulation. CPG15 is a component of the AMPA receptor proteome and its expression can promote synapse maturation through the incorporation of AMPA receptors into the postsynaptic membrane. By investigating CPG15's interaction with AMPA receptors and its functional relevance to cortical plasticity, we propose a novel mechanism for the selective stabilization of excitatory synapses in response to sensory stimulation.

Title: Modulation of Neurofilament kinetics and axonal morphology near excavation of mouse optic nerve

Authors: *Y. LI[1], A. BROWN[2], P. JUNG[3]
[1]Sch. of Systems Sci., Beijing, China; [2]Dept Neurosci., Ohio State Univ., Columbus, OH; [3]Dept. of Physics and Astronomy, Ohio Univ., Athens, OH

Abstract: Neurons send signals out to target neurons via action potentials propagating along axons, and the rate of which is proportional to the diameter of axonal caliber. Axon is comprised of three typical cytoskeletal proteins, neurofilaments (NFs) are the most abundant filaments, which mainly determine the axonal morphology. After synthesized in the cell body, NFs are continuously shipped out by molecular motors along microtubule tracks by a 'stop and go' manner, which is called "Slow Axonal Transport" by the slow average velocity of 0.1-3 mm/day. The "Slow Axonal Transport" of NFs has been mathematically described by the '6-state' model. In the model, NFs can alternate between on-track running, on-track short term pausing (with seconds to minutes) and off-track long term pausing (with hours) states in both anterograde and retrograde directions. The probability of NFs transit from one state to another is determined by

specific transition rates, which can be observed from experiments. Near the excavation region of mouse optic nerve, the number of NFs has doubled around 100 and 150 micron meter, and further increased to a total of threefold at 1200 micron meter, as observed by experiments. We hypothesize that the Conservation Law in physics provides a fundamental principle to dissect the relationship between NF kinetics and morphology of axons. The modification of on-track rate can successfully reproduce the population distribution of NFs, and it gives a prediction on the changes of NFs kinetic properties through this excavation region. Biophysically, the on-track rate is correlated closely with the cytoskeletal composition, especially the variation of ratios of microtubules to neurofilaments along this excavation area.

Title: Neural cell adhesion molecule NCAM regulates perisomatic synapse remodeling and inhibition of pyramidal cells in the developing mouse frontal cortex

Authors: *C. S. SULLIVAN[1], X. ZHANG[1], M. KRATZ[2], P. MANIS[2], P. MANESS[2]
[1]Biochem. and Biophysics, [2]Univ. of North Carolina Chapel Hill, Chapel Hill, NC

Abstract: Establishment of a proper balance of excitatory and inhibitory (E/I) connectivity is achieved during development of cortical networks by mechanisms that are not clearly defined. Neural cell adhesion molecule NCAM and receptor tyrosine kinase EphA3 regulate perisomatic synapse density of inhibitory GABAergic interneurons onto pyramidal cells in the mouse frontal cortex through ephrin-A5-induced axonal growth cone collapse. Here we show that NCAM binds EphA3 through an interface between the extracellular NCAM immunoglobulin-2 (Ig2) domain and EphA3 cysteine-rich domain (CRD). The binding interface was further refined through molecular modeling and mutagenesis, and it was shown to be comprised of complementary charged residues in the NCAM Ig2 domain (Arg156, Lys162) and EphA3 CRD (Glu248, Glu264). Ephrin-A5 co-clustering induced activation of surface-bound EphA3 and

NCAM in GABAergic cortical interneurons in culture. NCAM enhanced ephrin-A5-induced EphA3 autophosphorylation and activation of RhoA GTPase, indicating a potentiating role for NCAM in EphA3 signaling by promoting receptor clustering.
To determine whether NCAM acts presynaptically, a novel NCAM conditional knockout mouse was generated (Parvalbumin-Cre; $NCAM^{F/F}$; Ai9 Lox-Stop-Lox tdTomato) to selectively delete NCAM from inhibitory basket and chandelier interneurons. Presynaptic deletion of NCAM led to increased numbers of perisomatic synapses of GABAergic interneurons onto cortical pyramidal cell soma. Using two-photon live-imaging of perisomatic synapse remodeling in acute brain slices, the rates of formation and elimination of perisomatic synapses were assessed in control and NCAM conditional null mice. Parvalbumin-Cre;$NCAM^{F/F}$;Ai9 mice were found to have a decreased rate of synapse elimination compared to control $NCAM^{F/+}$ mice. This phenotype is currently being correlated with behavioral studies and electrophysiology. To further assess the functional consequences of NCAM deletion on the organization of inhibitory cirtcuits in the frontal cortex, laser scanning photostimulation in brain slices of vesicular GABA transporter (VGAT)-channelrhodopsin2 (ChR2)- EYFP transgenic mice crossed to WT or $NCAM^{-/-}$ mice was performed. Results indicated that NCAM deletion increased the strength of close-in inhibitory connections to pyramidal cells of the frontal cortex, consistent with increased numbers of perisomatic synapses. The increase of inhibitory tone onto pyramidal cells likely alters E/I balance and may contribute to circuit dysfunction in neurodevelopmental diseases such as schizophrenia and bipolar disorder.

Title: Cell-cell communication may underlie radiation-induced synaptic dysfunction of mature neurons

Authors: *A. PUSPITASARI[1], N. KOGANEZAWA[3], T. SHIRAO[3], K. D. HELD[1,4], T. NAKANO[2]
[1]Gunma Univ. Initiative for Advanced Res. (GIAR) Intl. Open Labo, [2]Radiation Oncology, Gunma Univ. Grad. Sch. of Med., Maebashi, Japan; [3]Gunma Univ. Grad Sch. Med., Maebashi, Gunma, Japan; [4]Radiation Oncology, Massachusetts Gen. Hospital/Harvard Med. Sch., Boston, MA

Abstract: Radiation-induced synaptic dysfunction is of considerable interest with regards to the consequences of irradiation. In the brain, neurons are surrounded by glial cells. Neurons and astrocytes have a unique way to communicate with each other, and the healthy functional mature neurons and astrocytes must be in balance to have appropriate synaptic function. Radiation could alter this balance and affect synaptic function. Previously, we showed that a single dose of 10 Gy of X-irradiation could cause synaptic dysfunction 8 h after irradiation *in vivo*. In this study, we analyze the mechanisms of radiation-induced synaptic dysfunction which may underlie cell-cell communication such as between astrocytes and mature neurons. We investigate the synaptic function 8 h after irradiation *in vitro* using 21st days in vitro (DIV) primary hippocampal cultured neurons. We performed the irradiation in three conditions. The first condition is a single 10 Gy of X irradiation given to the astrocytes and mature neurons.The second condition is irradiating astrocytes alone, then co-culturing the irradiated astrocytes with the non-irradiated mature neurons, and the third condition is irradiating neurons alone, then co-culturing the irradiated neurons with the non-irradiated astrocytes. Cultures were then incubated for 8 h for all conditions, after which the neurons were fixed for analyzing the synaptic function. We examine the synaptic proteins using synapsin I as a presynaptic marker and drebrin as a postsynaptic marker. Radiation given to both neurons and astrocytes has effects on the resulting in a decrease of both synaptic proteins synapsin I and drebrin. Interestingly, radiation to the astrocytes and neurons alone also causes reduction of both synapsin I and drebrin of mature neurons. The decrease of drebrin in irradiated neurons alone was found to be more remarkable. This suggests that the cell to cell communication thought to be important for the radiation-induced synaptic dysfunction.

Title: Exploring the molecular mechanisms underlying rapid estrogenic modulation of neuronal connectivity

Authors: *P. RAVAL[1], J. MUKHERJEE[2], K. J. SELLERS[1], S. J. MOSS[2], N. J. BRANDON[2,3], D. P. SRIVASTAVA[1]

[1]Basic and Clin. Neurosci., King's Col. London, London, United Kingdom; [2]AstraZeneca-Tuft's Lab. for Translational Neurosci., Boston, MA; [3]AstraZeneca Neurosci. IMED, Waltham, MA

Abstract: There is increasing evidence that the regulation of structure and function of neuronal circuits is an essential component of normal cognitive function and behaviour. Several studies have demonstrated concurrent changes in connectivity between neurons during and following the acquisition of learned behaviours. Estrogens, particularly its biologically active form 17β-estradiol (E2), have repeatedly been illustrated to have long-lasting influences over cognitive function and behaviour, which is believed to be, in part, driven by estrogenic regulation of neuronal plasticity. Specifically, estrogens have been shown to rapidly regulate dendritic spine dynamics and shape synapse structure and function through non-genomic actions. These rapid effects can result in the initiation of signalling pathways leading to several cellular events, many of which are independent of gene transcription such as: dendritic spine turnover/remodelling; protein/receptor trafficking; and local protein translation. However, the molecular and cellular mechanisms that underlie this rapid regulation of synaptic plasticity, and enhanced cognition, have yet to be fully elucidated.

As the remodelling of neuronal connectivity is believed to be an essential component of cognitive function, we have focused on understanding the intracellular signalling pathways that are initiated by acute estrogenic treatment. Specifically, to understand how these pathways drive target protein and receptor trafficking/expression and local protein translation in response to E2 in both primary neurons and acute slices. We have previously found that there is a transient increase in dendritic spine turnover in response to acute E2 treatment, which is dependent on the P13K/Akt and ERK1/2 pathways, but independent of the mTOR pathway. What is more, by employing a combination of super-resolution imaging and biochemical assays such as Surface Sensing of Translation (SUnSET) we have found that acute E2 treatment leads to an increase in protein translation interestingly, mirroring an increase in key synaptic proteins within the cortex and hippocampus in both males and females. These data provide an insight into the signalling pathways and cellular events that potentially contribute to the effects of estrogens on dendritic spine plasticity. Thus, by further elucidating the molecular underpinnings of rapid estrogenic-modulation of hippocampal and cortical connectivity, we hope to add to the growing understanding of how estrogens influence long-lasting changes in neural circuitry and cognitive function.

Title: Cholinergic interneurons enhance thalamostriatal excitation of indirect pathway spiny projection neurons in a Parkinson's disease model

Authors: *A. TANIMURA[1], Y. DU[2], J. KONDAPALLI[2], D. SURMEIER[3]
[1]Physiol., [2]Northwestern Univ., Chicago, IL; [3]Prof. Dept. Physiology/ NUIN, Northwestern Univ. Dept. of Physiol., Chicago, IL

Abstract: Both the centrolateral (CL) and parafascicular (PF) nuclei of the thalamus innervate the striatum and are implicated in the control of movement and in the network pathophysiology in Parkinson's disease (PD). However, these projection systems differ both in the information they convey and in their striatal connectivity, making a rigorous dissection of how each system changes in PD models important. To this end, a BAC transgenic mouse expressing Cre recombinase selectively in the CL was used with viral delivery of Cre-off expression constructs to optogenetically interrogate the PF projection to the striatum in *ex vivo* brain slices. Following 6-hydroxydopamine lesioning of medial forebrain bundle, PF-evoked, glutamatergic responses in indirect pathway SPNs (iSPNs) were enhanced, but those of direct pathway SPNs (dSPNs) were unchanged. In parallel, PF-evoked responses in cholinergic interneurons (ChIs) were increased in this PD model. The PF-evoked responses in iSPNs were normalized by antagonism of nicotinic acetylcholine receptors (nAChRs) or by chemogenetic silencing of ChIs. Consistent with a presynaptic locus for nAChRs mediating the enhancement, the release probability of glutamate at iSPN-PF synapses was increased in the PD model and normalized by nAChRs antagonism. To determine the behavioral consequences of this feed-forward circuit, ChIs were chemogenetically silenced. This manipulations significantly improved locomotor activity and rotarod performance in the PD model, suggesting that enhanced feed-forward, presynaptic control of PF-iSPN synapses by ChIs substantively contributes to the hypokinetic symptoms of PD.

Title: Calcium-dependent mechanisms underlying long-term depression of electrical synapses in the thalamic reticular nucleus

Authors: *J. S. HAAS[1], S. FITTRO[1], E. L. HECKMAN[2], J. SEVETSON[3]
[1]Dept. of Biol. Sci., [2]Biol. Sci., Lehigh Univ., Bethlehem, PA; [3]Neurosci., Brown Univ., Providence, RI

Abstract: Long-term depression (LTD) of connexin36-based electrical synapses in the rat thalamic reticular nucleus (TRN) has been demonstrated following paired burst-spiking activity and following activation of metabotropic glutamate receptors by tetanic stimulation of corticothalamic afferents, but the interactions between and downstream mechanisms of these two paradigms for LTD induction remain unclear. Using dual whole-cell recordings in brain slices containing TRN, we demonstrate that these two stimuli induce LTD by separable pathways. We show that LTD following application of the mGluR agonist ACPD occludes LTD from paired bursting in pairs of coupled TRN neurons, and LTD following paired bursting occludes ACPD-dependent LTD. We further show that burst-induced LTD depends on calcium influx via T-type channels, that calcium influx into the intracellular environment recruits calcium release from internal stores, and that the calcium-activated neuronal phosphatase calcineurin is required for activity-dependent LTD. In contrast, ACPD-induced LTD can be induced independently of those sources of calcium. Together, these results provide support for a mechanistic model whereby paired activity-induced depression is mediated by calcium entry and dynamics, while afferent activity-induced depression is not. We hypothesize that the two induction mechanisms converge at a shared downstream pathway. We discuss the implications for these two different activity inductors of LTD on thalamocortical processing.

Title: Regulation of synaptic plasticity by the dark/light cycle

Authors: *K.-W. HE[1], A. KIRKWOOD[2]
[1]IRCBC, Chinese Acad. of Sci., Shanghai, China; [2]Mind Brain Inst., Johns Hopkins Univ., Baltimore, MD

Abstract: Normal sleep is crucial for learning and memory formation. Moreover, a wealth of evidence indicates that the learning-related changes in synaptic connectivity initiated in the waking states are further consolidated and enhanced during the sleep stages. Most likely these synaptic changes require activity dependent forms of plasticity: long-term potentiation (LTP) and depression (LTD). Indeed, manipulations that disrupt the induction of LTP and LTD also disrupt sleep consolidation of learning. In this context, it is well established that sleep-deprivation severely impairs the induction and expression of LTP. However, whether LTP and LTD are regulated by the natural sleep/wake cycle is still unclear. As a step into that direction we compared LTP/LTD in acute hippocampal slices harvested from mice that were sacrificed at the end of either the 12 h DARK cycle (mostly awake) of the 12 h LIGHT cycle (mostly sleep). We found that magnitude of LTP and LTD changes in opposite ways and the end of each cycle, and in a manner consistent with the BCM model of metaplasticity.

Title: Sonic hedgehog (Shh) control the balance between long-term potentiation and long-term depression in hippocampal neurons

Authors: *S. C. SUNDBERG, G. M. SANCHEZ, F. ANDERSSON, M. ALENIUS, B. GRANSETH
Dept. of Clin. and Exptl. Med., Linköping Univ., Linköping, Sweden

Abstract: The morphogen Sonic hedgehog (Shh) has a well-defined role in organism development. In recent years a more regulatory role of Shh-signaling in adult organisms has been realized. Shh stimulate proliferation and differentiation of neural progenitor cells in adult hippocampus. High frequency stimulation, such as during an epileptic seizure, release Shh. It can be speculated that Shh acts to balance network activity. However, the specific role of Shh-signaling in adult brain is poorly understood. We demonstrate that blocking Shh-signaling induces dramatic changes in synaptic strength in rat hippocampal cultures. We investigated the role of Shh using patch clamp electrophysiology and confocal microscopy. Shh bind the negatively regulating receptor Patched (Ptc) resulting in an activation of the signal transducer

Smoothened (Smo). Blocking Smo during 2-3 days using the specific antagonist Vismodegib generates a massive amplitude increase in miniature excitatory post-synaptic currents (mEPSCs) compared to controls. Vismodegib block of Smo only generated increased mEPSC amplitudes in mature neurons, not in neurons during network establishment. Shh signals simultaneously via a canonical and a non-canonical signaling pathway. Interestingly, blocking the canonical pathway using GANT61 we saw an increase in mEPSC frequency but no effect on amplitude. Suggesting differing effects of the canonical and the non-canonical Shh-signaling pathway on network activity. Mechanistically we show that Vismodegib block of Smo induce an up-regulation of surface AMPA-receptors, specifically GluA1 and GluA2 subunits but not GluA3. The effect of Vismodegib on hippocampal neurons is dependent on activation of the NMDA- receptor, linking Shh to NMDA-receptor signaling. The NMDA-receptor antagonist APV blocked the effect from Vismodegib while the NMDA-receptor pore blocker MK801 reversed the effect (reduced mEPSC amplitude). Taken together, our findings show a specific role of Shh-signaling in mature networks and suggest that Shh can act to control the balance between long-term potentiation and long- term depression.

Title: Synaptic plasticity through activation of GluA3-containing AMPA-receptors

Authors: *E. ALBERS, M. C. RENNER, N. GUTIERREZ-CASTELLANOS, N. R. REINDERS, A. N. VAN HUIJSTEE, H. W. KESSELS

Abstract: Excitatory synaptic transmission is mediated by AMPA-type glutamate receptors (AMPARs). In CA1 pyramidal neurons of the hippocampus two types of AMPARs predominate: those that contain subunits GluA1 and GluA2, and those that contain GluA2 and GluA3. Whereas subunits GluA1 and GluA2 have been extensively studied, the contribution of GluA3 to synapse physiology has remained unclear. Here we show that GluA3-containing AMPARs are in a low-conductance state under basal conditions, and although present at synapses they contribute little to synaptic currents. When intracellular cyclic AMP (cAMP) levels rise, GluA3 channels

shift to a high-conductance state, leading to synaptic potentiation. This cAMP-driven synaptic potentiation is mediated by the small GTPase Ras. Together, these experiments reveal a novel type of plasticity at CA1 hippocampal synapses that is expressed by the activation of AMPAR subunit GluA3.

Title: Epigenetic reprogramming during late memory reconsolidation is critical for the incubation of cocaine craving

Authors: *K. YUAN[1], Y. HAN[2], C. CHEN[3], L. LU[4]
[1]Natl. Inst. of Drug Dependence, Beijing, China; [2]Natl. Inst. on Drug Dependence and Beijing Key laboratory of Drug Dependence, Peking Univ., Beijing, China; [3]Peking Univ. Sixth Hosp., Beijing City, China; [4]Inst. Mental Health,Peking Univ. Sixth Hosp., Beijing City, China

Abstract: Introduction: One of the challenges of addiction treatment is the incubation of drug craving, which contributes to relapse to drug use after prolonged withdrawal. The nature of drug craving is a kind of pathological memory based on modification of synaptic plasticity. Previous studies revealed a late protein synthesis-dependent phase, termed as late consolidation, for the maintenance and persistence of long-term memory traces. However, the relationship between memory late consolidation and drug incubation and the underlying mechanisms are still unknown. **Methods:** Here, using western blot, we detected the time course of changes in c-fos and DNMT3a expression following cocaine self-administration in several brain regions, including prelimbic cortex (PrL), infralimbic cortex (IL), basolateral amygdala (BLA) and central amygdala (CeA). Next, protein synthesis inhibitor anisomycin or DNA methyltransferase inhibitor RG-108 was microinjected into the PrL at different time point after last self-administration training to explore the time window of the involvement of PrL in drug memory late consolidation and its role in cocaine incubation. **Results:** We found both an early wave (0.5 h) and a late wave (18 h) of c-fos and DNMT3a expression in the PrL after cocaine self-administration training. Only an early phase of c-fos expression increased in the BLA, and there

were no significant changes in c-fos expression in the CeA. Inhibition of protein synthesis or DNA methylation 0.5 h after the last cocaine self-administration training section decreased active nosepokes during extinction test after early or prolonged withdrawal. Inhibition of protein synthesis or DNA methylation 18 h after the last cocaine self-administration training section decreased active nosepokes during extinction test after prolonged withdrawal but not early withdrawal, indicating that a delayed protein synthesis- and DNA methylation-dependent phase is required for the incubation of cocaine craving. **Conclusion:** Our results indicate that protein synthesis at definite post-training time points in the PrL is involved in cocaine incubation, and epigenetic modulation during late memory consolidation plays a critical role in this process.

Title: Cocaine conditioned place preference alters the firing properties of perineuronal net surrounded neurons in the prelimbic prefrontal cortex

Authors: *E. T. JORGENSEN[1], C. M. CASSIDY[1], B. A. SORG[2], T. E. BROWN[1]
[1]Neurosci., Univ. of Wyoming, Laramie, WY; [2]Integrative Physiol. and Neurosci., Washington State Univ., Vancouver, WA

Abstract: Repeated drug use creates persistent drug-related memories, which contribute to chronic relapse in drug addicts. Our laboratory is interested in studying how the extracellular matrix and associated proteins contribute to the development and persistence of drug memories. Perineuronal nets (PNNs) are specialized extracellular matrix structures that primarily surround the soma and proximal neurites of inhibitory parvalbumin-containing interneurons. PNNs provide protection from oxidative stress, help regulate the ionic microenvironment, and play a significant role in synaptic stabilization. Previous work by our collaborator, Dr. Sorg, has shown that degradation of PNNs within the medial prefrontal cortex disrupts cocaine-induced reinstatement. In addition, work by us and others have shown that PNNs influence the firing properties of cells. This work looks to expand upon our previous findings and systematically define the dynamic changes in intrinsic excitability and synaptic transmission from neurons with

and without PNNs within the prelimbic PFC (PL-PFC) following acute and repeated cocaine exposure. To characterize the electrophysiological properties of cells within the PL-PFC, brain slices from male Sprague Dawley rats were prepared following cocaine conditioned place preference (cocaine-CPP) and whole-cell recordings were performed. PNN positive cells were identified by Wisteria floribunda agglutinin (WFA)-induced fluorescence. Cocaine-CPP decreased the firing patterns of WFA(+) and WFA(-) interneurons relative to naive controls. However, for acute exposure to cocaine we only observed an attenuation in spike number in the WFA- neurons. This suggests that WFA(+) neurons may only be sensitive to intrinsic adaptations following repeated exposure to cocaine. Through this work, we hope to identify the functional consequences of cocaine-induced PNN changes, which may lead to novel therapeutics for the treatment of drug addiction.

Title: Age-dependent alteration of oxidative stress and expression level of glutamate receptors in senescence-accelerated mouse prone 8

Authors: *S. TANIGUCHI[1], M. HANAFUSA[2], H. TSUBONE[2], D. YAMANAKA[1], K. ITO[1]
[1]Univ. of Tokyo, Kasama, Ibaraki, Japan; [2]Univ. of Tokyo, Tokyo, Japan

Abstract: Senescence-accelerated mouse (SAM) developed through selective inbreeding of the AKR/J strain shows short lifespan and rapid advancement of senescence. Many behavioral tests revealed that SAM prone 8 (SAMP8) exhibits age-related deficits on learning and memory. However, the basic mechanism of loss of cognitive function remains still unclear. Progression of aging is thought to be induced by systemic oxidative stress. Recently, new approaches to evaluate reactive oxygen species using an indicator termed Diacron-Reactive Oxygen Metabolites (d-ROM) and reduction capacity using Biological Antioxidant Potential (BAP) measurement have been developed. Besides, aging impairs the cognitive performance in association with degradation of the synaptic plasticity in which N-methyl-d-aspartate receptor (NMDAR) plays a crucial role. To test if the alteration of oxidative stress and/or expression of glutamate receptors underlies the decline of cognitive function with aging, we quantitatively investigated the d-ROM and BAP values and expression levels of glutamate receptors with age

using SAMP8 in this study. After we confirmed if SAMP8 has a short life-span in our experimental environment compared with SAM resistant 1 (SAMR1), which is the control strain of SAMP8, we measured the d-ROMs and BAPs from the blood serum of SAMR1 and SAMP8. The d-ROM level of 1-year-old SAMP8 was significantly higher than not only that of age-matched SAMR1 but also that of 6-month-old SAMP8, although 2-year-old SAMR1 showed higher d-ROM level compared to 6-month and 1-year-old SAMR1. BAP level was the highest in 6-month-old SAMP8, whereas SAMR1 presented the sustained BAP values for its entire life. These results indicate that the d-ROM level of SAMP8 elevated earlier than SAMR1 and that antioxidant capacity decreases with age in SAMP8 but not in SAMR1. Next, we studied the protein expression of NMDAR subunits, that is, GluN1, GluN2A and GluN2B. All NMDAR subunits decreased with age in both SAMR1 and SAMP8 although no significant differences were observed between these strains. The inconsistency of oxidative stress level and NMDAR expression remains to be solved currently in progress.

Abstract: MicroRNAs (miRNAs) are small non-coding RNA molecules that fine-tune gene expression at post-transcriptional level. Recent studies have shown that deregulation of specific miRNAs could be involved in the development and progression of Alzheimer's disease (AD).

However, few studies have explored the relationship between miRNAs deregulation in AD and synaptic plasticity despite the involvement of some miRNAs in synaptic plasticity. Moreover, a comprehensive analysis of the miRNome during AD progression is lacking. In this study, we performed a microarray analysis (Affymetrix® miRNA 4.1) in the entorhinal cortex, hippocampus, prefrontal cortex and cerebellum of AD patients at different Braak stages. We found that 47 miRNAs were deregulated in the entorhinal cortex (17 down-regulated and 30 up-regulated) and 23 in the hippocampus (17 down-regulated and 6 up-regulated) at Braak stage I/II compared to age-matched non-demented controls. miRNAs targeting synaptic-related mRNAs were identified using the miRWalk database and validated by RTqPCR. qPCR analysis confirms a reduction of several miRNAs including miR-92a-3p (log2 relative expression = -0,7 ± 0,33), miR-181c-5p (log2 relative expression = -0,46 ± 0,33) and miR-210-3p (log2 relative expression = -1,16 ± 0,42) levels during early stages of AD (Braak I/II) in the entorhinal cortex, but not in the hippocampus. Our results show altered levels of specific miRNAs related to synaptic plasticity processes, which may play important roles during early AD pathology.

Title: Astrocytic activation generates de-novo neuronal potentiation and memory enhancement

Authors: ***A. KOL**, A. ADAMSKY, T. KREISEL, T. MELCER, R. REFAELI, L. REGEV, M. LONDON, I. GOSHEN
Neurobio., The Hebrew Univ., Jerusalem, Israel

Abstract: Astrocytes are capable of sensing synaptic activity and responding to it with complex internal calcium signaling. Evidence obtained in the last two decades suggests that astrocytes not only respond to neuronal activity but may also directly affect synaptic function and create dynamic bidirectional communication with neurons. In this work we examined whether synaptic plasticity and behavior can be modulated purely by activating astrocytes. We specifically modulated astrocytic calcium activity by expressing the Gq-coupled designer receptor hM3Dq in hippocampal CA1 astrocytes to test the effect of astrocytic calcium signaling on synaptic transmission.We found that astrocytic Gq pathway activation increased both frequency and amplitude of neuronal spontaneous release events. Furthermore, we discovered that astrocytic activation is not only necessary for synaptic plasticity, but sufficient to induce *de-novo* potentiation of CA3 to CA1 synapses. These plastic changes manifested in behaving mice as marked memory enhancement in mice with already intact memory. A similar recall enhancement was not achieved by randomly increasing neuronal activity directly, which in fact dramatically impaired memory. Our findings show for the first time that astrocytic manipulation can induce de-novo synaptic potentiation which result in enhanced memory acquisition.

Title: Activation of neuroplasticity pathways in the rat spinal cord through treadmill exercise

Authors: *Y. OKA[1], ***Y. OKA**[1], Y. SHIROSE[2], N. KUWABARA[1], K. NAKAMOTO[3], T. KOKUBUN[4], K. MURATA[1], N. KANEMURA[4]
[1]Dept. of Hlth. and Social Services, Grad. Sch. of Saitama Prefectural Univ., Koshigaya/Saitama, Japan; [2]Yokohama Rosai Hosp., Yokohama, Japan; [3]Shiraoka Orthopedics, Shiraoka/Saitama, Japan; [4]Saitama Prefectural Univ., Koshigaya/Saitama, Japan

Abstract: Exercise is recommended to prevent disease and improve physical function. Previous studies have reported that treadmill running greatly affects the expression of neurotrophic factor in rats. However, intracellular signaling involving the phosphatidylinositol 3-kinase (PI3K)/Akt pathway needs to be assessed to confirm activation of the cell. Therefore, we assessed rats of different ages, which performed running exercise, to determine the influence of age and exercise on the PI3K/Akt pathway. Thirty-eight rats were randomly assigned to two groups: treadmill-

exercised (ages: 10 weeks, 6 and 12 months [n=5 for each], and 24 months [n=3]) and nonexercised (ages: 10 weeks, 6, 12, and 24 months [n=5 for each]). The exercise consisted of 3.6 m/min (10 min) → 5.8 m/min (50 min) for 4 weeks (5 days a week). After the exercise, we collected their lumbar spinal cords. Primary antibodies against PI3K, Akt, and cAMP response element binding (CREB) were used for the immunohistochemical staining. Cross-sectional staining intensity > 50 was considered positive. The cells were counted (cell counts) with image analysis software and classified by cross-sectional area (100-499 or 500-799 μm^2). The groups were compared with a two-way factorial analysis of variance and Bonferroni correction for multiple comparisons. The numbers of PI3K-positive cells were significantly increased in the 100-499-μm^2 (glial cells) and 500-799-μm^2 (motor neurons) areas in the 12-month-old exercised group compared with the nonexercised group ($p < 0.05$). In the 12-month-old exercised group, the levels of expression of PI3K in the glial cells and motor neurons were significantly increased compared with the 24-month-old exercised rats ($p < 0.01$). No significant differences in the levels of Akt or CREB were found among the groups, but the levels of expression tended to be increased in the exercised groups compared to the nonexercised groups. The PI3K results showed that, in the 12-month-old rats, exercise increased the expression of neurotrophic factor, which is produced by muscle and nerve cells, and activated part of the activation pathway in motor neurons. These results suggested that running exercise only slightly activated neurons at 24 months of age because of age-related deterioration of the metabolic function of cells and the shedding of motor neurons. The trend for the increased expression of Akt and CREB may influence the activation of neurons. A previous study reported that running at 10 m/min increased the expression of trophic factors at 6 months of age. However, the result of this study, wherein the rats ran at about half the speed, indicated that cells were not activated at 10 weeks or 6 months of age.

Title: FoxO3a/Zdhhc3/AMPA receptor GluR1 cascade at the crossroad between insulin resistance and impairment of synaptic plasticity and memory

Authors: *S. FUSCO[1], M. SPINELLI[1], M. MAINARDI[1], F. SCALA[1], F. NATALE[1], R. LAPENTA[2], A. MATTERA[1], M. RINAUDO[1], D. D. LI PUMA[1], C. RIPOLI[1], A. GRASSI[2], M. D'ASCENZO[1], C. GRASSI[1]
[1]Inst. of Human Physiol., Universita' Cattolica Med. Sch., Rome, Italy; [2]Dept. of Chem. and Biol., Univ. of Salerno, Salerno, Italy

Abstract: High-fat diet (HFD) and metabolic diseases cause detrimental effects on hippocampal synaptic plasticity, learning and memory through molecular mechanisms still poorly understood. Mice fed a HFD for 6 weeks showed reduced long-term potentiation (LTP) at CA3-CA1 synapses (standard diet [SD] = 186.2 ± 19.9%, HFD = 123.6 ± 8.1%; n=9 for each group; $p<0.05$) and memory deficits evaluated by novel object recognition test (preference index: SD = 67.9 ± 1.8%, HFD = 59.2 ± 1.6%; n=10 for each group; $p<0.001$) and Morris water maze task (time spent in the target quadrant during the probe test: SD = 34.6 ± 1.3 s, HFD= 21.4 ± 1.3 s; n=8 for each group; $p<0.001$). HFD mice also exhibited increased palmitic acid deposition in the hippocampus and brain insulin resistance leading to FoxO3a-mediated overexpression of the palmitoyl-transferase Zdhhc3. The excess of palmitic acid along with higher Zdhhc3 levels induced hyper-palmitoylation of AMPA glutamate receptor subunit GluR1 (+30 ± 1%; n=5; $p<0.05$) and reduced its phosphorylation at serine 845 (-35 ± 1%; n=4; $p<0.05$). To deeply investigate the molecular mechanism underlying the diet-dependent change of GluR1 palmitoylation we set up an *in vitro* model resembling the *in vivo* metabolic stress. Mouse hippocampal neurons treated for 24h with 20 nM insulin and 200 µM palmitic acid (IPA) showed: i) increased GluR1 palmitoylation/S845 phosphorylation ratio; ii) reduced GluR1 trafficking to the plasma membrane and lower binding with PSD-95 (-70 ± 2% of controls; n=4; $p<0.01$); iii) loss of GluR1 activation upon a chemical LTP protocol. Accordingly, AMPAR current amplitudes and, more importantly, their potentiation underlying synaptic plasticity, were inhibited upon IPA treatment. Strikingly, both hippocampus-specific silencing of ZDHHC3 and intranasal injection of a palmitoyl-transferase inhibitor counteracted GluR1 hyper-palmitoylation and restored synaptic plasticity and memory in HFD mice. Our data reveal a key role of FoxO3a/Zdhhc3/GluR1 axis in the HFD-dependent impairment of cognitive function and identify a novel mechanism underlying the crosstalk between metabolic and cognitive disorders.

Abstract: Understanding the cellular and synaptic mechanisms underlying brain aging provides insight into potential therapeutic targets for interventions. The only nongenetic intervention that reliably increases life- and healthspan is caloric restriction (CR), a dietary regimen based on lowering daily caloric intake. Life-long calorically-restricted animals have delayed age-related physiological changes and prevention of some cellular and synaptic alterations in the brain. CR and its potential mimetic, rapamycin, have been found to exert their effects through the mammalian target of rapamycin complex in the nutrient signaling pathway. Currently there is a paucity of information on the short-term effects of CR and its potential mimetics, as well as similarities in their cellular mechanisms. In the present study, we investigated whether different short-term durations of CR and rapamycin treatment had beneficial effects on key synaptic proteins known to deteriorate with age, and whether rapamycin similarly mimics CR's beneficial effects. Wild type AB strain young (9-11 months) and old (27-33 months) zebrafish, maintained in standard conditions, were used to determine whether the brain responds to CR and rapamycin. To date only a few studies have performed true CR regimens on zebrafish, which has become a popular model to study brain aging. Six groups were included for a total of 115 animals. There were *ad libitum* (AL)-fed fish receiving no drug treatment, AL-fed animals with rapamycin treatment, and animals calorically-restricted with an every-other-day feeding approach. Four, six and eight weeks of CR and rapamycin treatment were examined to identify differential effects on body weight and length, key synaptic protein levels, and cortisol levels. Aquaria parameters such as water pH, nitrate levels, and temperature were monitored closely to minimize stress, and also maintain optimal housing conditions. Following euthanization, body weight and length were measured, brains were dissected for Western blot analysis, and bodies were analyzed for

measurements of cortisol levels. As expected our results demonstrated significant changes in body weight (30% reduction in CR groups, increases in AL and Rapamycin groups, 30% and 35% respectively). These data suggest that zebrafish respond to CR and rapamycin treatment in an expected manner, and are an appropriate model to investigate the potential effects of CR and rapamycin on brain aging. Moreover, our findings indicated that the longer treatment (8 weeks) was more effective than shorter ones (4 and 6 weeks). Studies are continuing to determine specific treatment effects on synaptic protein and body cortisol levels.

Title: Experience dependent spatio-temporal changes in the early and late evoked patterns of cortical activity in anesthetized mice using wide-field voltage-sensitive dye imaging

Authors: *E. J. BERMUDEZ CONTRERAS[1], A. LUCZAK[1], M. MOHAJERANI[1], B. MCNAUGHTON[1,2]
[1]CCBN / Univ. of Lethbridge, Lethbridge, AB, Canada; [2]Univ. of California, Irvine, CA

Abstract: The evoked response in the primary sensory areas of the brain is divided into two components, an early response and a late response. The early component usually lasts for less than 100 ms after stimulus onset, is associated with direct thalamo-cortical connections and encodes the stimulus features. Conversely, the late response starts around 200 ms after stimulus onset, lasts a couple of hundred ms and is associated with sensory perception.
One characteristic of perception is that it is not fixed but it can be modified by experience. Therefore, one can ask whether the perceptual signal observed during the late evoked response could be modified by experience and if so, in what way? In addition, the cortical dynamics of the evoked response is not limited to the corresponding sensory area but propagates extensively across the cortical mantle. Moreover, perception involves complex processes in multiple and distributed cortical areas. Therefore, it is important to study the spatiotemporal dynamics of the late sensory evoked response at the mesoscale level.
We use wide-field Voltage-sensitive dye imaging over most of the right hemisphere to compare sensory evoked activity before and after tetanic stimulation in urethane anesthetized mice injected with amphetamine. We observed that the spatiotemporal evoked pattern changes

significantly during the late response after tetanic stimulation. In particular, the amplitude of the late evoked response increases after tetanic stimulation. To evaluate whether the observed changes are stimulation dependent, we give tetanic auditory stimulation first and compare the evoked responses of the auditory (AC) and somatosensory cortices (SS) before and after the tetanic stimulation. Subsequently, we give tetanic hindlimb stimulation and compared again the auditory and somatosensory evoked responses. When we give tetanic auditory stimulation we observe an increase of the late evoked response in AC but not in the SS. Subsequently, when we give tetanic hindlimb stimulation we observe an increase in the late response in SS and a decrease of the late response in AC. Moreover, we show that after tetanic stimulation, the spatiotemporal evoked pattern during the late response resembles more closely the pattern of the early response. These experience dependent spatiotemporal changes observed during the late evoked response could be a top-down cortical mechanism to enhance early sensory processing. Our results provide evidence of experience dependent spatiotemporal changes in the late evoked response that can help to clarify the relationship between sensory perception and cortical plasticity at the mesoscale level.

Title: Deep brain stimulation induced synaptic depletion is a robust phenomenon independent of synapse type

Authors: A. FAROKHNIAEE[1], R. W. ANDERSON[2], *C. C. MCINTYRE[3]
[2]Sch. of Medicine, Biomed. Engin., [3]Dept. of Biomed. Engin., [1]Case Western Reserve Univ., Cleveland, OH

Abstract: Deep brain stimulation (DBS) is a successful clinical therapy for a wide range of neurological disorders; however, the physiological mechanisms of DBS remain unresolved. Computational models of DBS commonly suggest robust generation of DBS-induced action potentials (APs) in neural pathways that course by the electrode and that those APs propagate to their axon terminals. From a network activity perspective, the fundamental effect of AP invasion into a synaptic terminal is transmitter release. However, little attention is typically paid to quantifying the actual synaptic effect of the DBS-activated pathways on their post-synaptic

targets. We propose that one hypothesis that can help explain the mechanisms of DBS is the exhaustion of synaptic transmitter release in directly stimulated pathways. Synapses typically have a readily releasable pool of neurotransmitters packaged in vesicles and machinery to replenish that pool once they are released. However, high frequency (~130 Hz) driving of a synapse quickly exhausts the readily releasable pool and overwhelms the recycling machinery. In turn, postsynaptic currents (PSC) during DBS can be dramatically reduced, effectively eliminating the ability of the synapse to modulate the post-synaptic neuron or transmit any information. This basic phenomenon can be most easily studied at glutamatergic synapses where a wealth of experimental data is available to parameterize the model. However, multiple glutamatergic synapse types are known to exist, including Depressing (D), Facilitating (F), and Pseudo-Linear (PL). Therefore, we set out to quantify how these different synapse types would respond to DBS. We used a leaky integrate and fire (LIF) neuron model to evaluate the post-synaptic response to DBS-driven synaptic inputs. Our theoretical results suggest that the synaptic depletion is a robust effect in DBS activated glutamatergic pathways, independent of the synapse type. In turn, DBS effectively creates a "synaptic lesion" in directly stimulated pathways and this mechanism is especially relevant to DBS of the hyperdirect pathway for the treatment of Parkinson's disease.

Title: Transcranial direct current stimulation enhances SSVEP response over multiple days: A role for consolidation

Authors: *J. AU[1], S. JAEGGI[1], S.-M. MOON[1], B. GIBSON[1], R. SRINIVASAN[2]
[1]UC Irvine, Irvine, CA; [2]Univ. California Irvine, Irvine, CA

Abstract: Transcranial direct current stimulation (tDCS) is a form of noninvasive brain stimulation that has been increasing in popularity over the past decade, both within and without the scientific community. Among its many touted effects include cognitive enhancement, motor rehabilitation, and depression management, to name a few. Nevertheless, despite its rise in popularity, there has not been a proportionate increase in mechanistic understanding. The putative mechanism of action most widely described by researchers is a polarity-dependent shift in the resting membrane potential of target neurons lying in the path of the current, resulting in a

polarity-dependent change in cortical excitability. This mechanism is derived from *in vitro* work, and supported by *in vivo* human studies in which motor-evoked potentials (MEP) have been demonstrated to respectively increase or decrease in strength after anodal or cathodal stimulation to the motor cortex. Results from these *in vitro* and motor studies have been extrapolated to guide translational tDCS research in other cortical areas. However, few studies have actually sought to investigate basic tDCS effects on neural activity outside the motor cortex. The present study uses EEG to measure steady-state visual evoked potentials (SSVEP) as an extra-motor analogue of MEPs to investigate short- and long-term excitability effects of tDCS over the parietal cortex. In a within-subjects design, participants came in over three consecutive days and were randomly assigned to receive two sessions of active tDCS and one session of sham tDCS in a counterbalanced manner. SSVEPs were measured with EEG before and after tDCS, and a visual working memory task was also performed. Results showed that SSVEP power increased after active, but not sham tDCS, but only when measured the next day. We conclude that tDCS can promote consolidation of sensory networks in the parietal cortex, and that these consolidation effects are more robust than any immediate excitability changes brought upon by putative shifts in resting membrane potential. Furthermore, we confirm SSVEP as a tool to study basic tDCS effects over the parietal cortex, and provide a critical avenue for the field to advance its mechanistic understanding of tDCS in brain regions outside the motor cortex.

Abstract: Long-term potentiation (LTP) has been investigated extensively in animal studies as an important mechanism of experience-dependent plasticity in the brain, including learning and memory. The recent introduction of transcranial magnetic stimulation (TMS) has provided the

opportunity to investigate similar mechanisms in the intact human brain with protocols of repetitive TMS (rTMS) that resemble those used in experimental preparations. The therapeutic effects of rTMS are encouraging, however, little is known about the underlying neurophysiological mechanisms in the intact brain.We performed invasive recordings from epilepsy patients with electrodes implanted in the motor cortex. Intermittent theta burst stimulation, a type of excitatory rTMS which has recently shown strong effects, was applied to the motor cortex. Motor thresholds, cortico-cortical evoked potentials (CCEPs) were conducted before and after iTBS interleaved with baseline resting ECoG periods for ~ 1hour. We found that motor thresholds were reduced after ITBs, and that they gradually recovered over the course of 1 hour. Time-frequency analysis of the CCEPs revealed a strong beta burst ~200ms after stimulation which was reduced after iTBS and gradually recovered over the course of ~1 hour. Analysis of CCEPs N1 and N2 responses showed increased peak amplitude after iTBS but the effect fail to completely wash out. These effects may contribute to the understanding of the therapeutic potential of these methods in treating patients with neuropsychiatric disorders.

Title: Test-retest reliability of the effects of continuous theta-burst stimulation (cTBS) in healthy adults

Authors: *A. JANNATI[1], P. J. FRIED[1], G. BLOCK[1], L. M. OBERMAN[2], A. ROTENBERG[3], A. PASCUAL-LEONE[1]

[1]BIDMC, Harvard Med. Sch., Boston, MA; [2]Bradley Hosp., Riverside, RI; [3]Boston Children's Hosp., Boston, MA

Abstract: Objective: To evaluate the reliability of cTBS aftereffects as indices of the efficacy of the mechanisms of cortical plasticity, and to test whether cTBS reliability is modulated by brain-derived neurotrophic factor (*BDNF*) and apolipoprotein E (*APOE*) polymorphisms.
Methods: 28 healthy adults (25 males, age 36.8 ± 14.5) underwent cTBS of the left primary motor cortex (M1) at 80% active motor threshold (AMT). Cortico-motor reactivity was measured before and after cTBS by sets of 30 biphasic, single pulses of neuronavigated transcranial magnetic stimulation (TMS) applied to M1 at 120% resting motor threshold (RMT). TMS was performed with a MagPro X100 stimulator, MC-B70 Butterfly Coil, and Brainsight neuronavigation. Two identical visits (7-33 days apart; median interval = 9.5 days) were conducted per participant. Saliva samples from 22 participants were used to assess *BDNF* and *APOE* polymorphisms.
Motor evoked potentials (MEPs) were recorded from the right first dorsal interosseous muscle. Log-transformed, baseline-corrected MEP amplitudes (LnMEPs) were calculated at 5-, 10-, or 15-minute intervals post-cTBS (*T5*-*T120*). Intraclass correlation coefficients (ICCs) were calculated to assess reliability.
Results: LnMEP measures were most reliable at T50 (ICC = 0.53), followed by T30 (ICC = 0.37). This order was reversed for *absolute* LnMEP values (|LnMEPs|) which were most reliable at T30 (ICC = 0.50), followed by T50 (ICC = 0.34). Reliability of maximum MEP depression (ICC = 0.38) and maximum absolute modulation (ICC = 0.31) were in range of other measures.
LnMEP area-under-the-curve (AUC) was the most reliable if derived from T0-T60 values (ICC = 0.40), followed by T0-T120 and T0-T50 (ICCs = 0.37 and 0.36). All |LnMEPs| AUCs over T0-T50 and beyond had ICCs >= 0.42.
LnMEPs at T20, T30, T40, T90, and T105 were significantly more reliable in 14 participants with the Val66Val *BDNF* single-nucleotide polymorphism (ICCs = 0.64, 0.50, 0.60, 0.46, and 0.52) than in 8 participants with the Val66Met variant (ICCs = -0.47, -0.42, -0.09, -0.09, and -0.01), p's < 0.016.
LnMEPs at T5, T20, T30, T40 were significantly more reliable in 12 *APOE* ε4- participants (ICCs = 0.49, 0.52, 0.81, 0.64) than in 10 *APOE* ε4+ participants (ICCs = -0.12, -0.31, -0.12, 0.07), p's < 0.024.
Conclusions: As reflected in altered MEP amplitude, cTBS aftereffects are most reliable when obtained 30 or 50 minutes after cTBS, or when the AUC is calculated over at least 50 minutes post-cTBS. The reliability of cTBS aftereffect is significantly lower in *BDNF* Val66Met and *APOE* ε4+ participants.

Title: Continuous theta-burst stimulation as a neurophysiologic biomarker for children with autism spectrum disorders

Authors: *G. BLOCK[1], A. JANNATI[1], H. L. KAYE[2], L. M. OBERMAN[3], A. PASCUAL-LEONE[1], A. ROTENBERG[2]
[1]Neurol., Beth Israel Deaconess Med. Ctr., Boston, MA; [2]Dept. of Neurology, Div. of Epilepsy and Clin. Neurophysiol., Boston Children's Hosp., Boston, MA; [3]Bradley Hosp., Riverside, RI

Abstract: Objectives: To evaluate the measures of cortical plasticity by continuous theta-burst stimulation (cTBS) as a potential physiologic biomarker for children with autism spectrum disorders (ASD). Previous studies have found TBS-induced hyperplasticity in adults with ASD (IQ > 70) compared to controls.
Methods: 10 children with non-syndromic ASD (9 males, age mean ± *SD*, 13.2 ± 2.0, IQ > 70), and 7 neurotypical children (NT; 2 males, age 10.0 ± 3.7, IQ > 70) underwent cTBS consisting of bursts of three pulses of 50 Hz stimulation at 80% individual active motor threshold, repeated at 200 ms intervals for 40 seconds (for a total of 600 pulses). Cortico-motor reactivity was assessed before and after cTBS by single pulses of transcranial magnetic stimulation (TMS) with a figure-of-eight coil to the left primary motor cortex (M1) at 120% of individual resting motor threshold. Peak-to-peak amplitudes of motor evoked potentials (MEPs) were recorded from the right first dorsal interosseous muscle. Log-transformed, baseline-corrected, average MEP

amplitude (LnMEP) was calculated at 5-, 10-, or 15-minute intervals between 5 and 120 minutes post-cTBS (*T5–T120*). Saliva samples were collected from children with ASD to assess the effect of *BDNF* Val66Met polymorphism on cTBS-induced cortical plasticity.
Results: Although cTBS in healthy adult volunteers most commonly induces depression of the MEPs, the hand MEPs were potentiated in 50% of pediatric subjects with ASD. The extent of maximum MEP modulation in response to cTBS was greater in the ASD group than in the NT group ($p = .026$). Within the ASD group, *BDNF* Val/Met children showed greater suppression of LnMEPs than *BDNF* Val/Val children at all post-cTBS time points (T5–T120). This difference was statistically significant at T50 ($p = .028$).
Within the ASD group, age was positively correlated with larger maximum suppression of LnMEPs ($p = .02$). This relationship was not significant in the overall group ($p = .61$) or in the NT group ($p = .46$).
Conclusions: Our results support the value of exploring cortical plasticity measures by cTBS as a physiologic biomarker in children with ASD further. The contribution of *BDNF* isoform and age to cTBS-induced plasticity in the ASD group provide further insight into interindividual differences in cTBS measures of cortical plasticity. This may also indicate impaired *BDNF*-mediated cortical plasticity in children with ASD.

Title: α_{1A}-adrenergic receptor activation decreases epileptiform activity in the murine hippocampal CA3 region

Authors: *J. P. BIGGANE[1], Z. O. DENT[1], D. M. PEREZ[2], V. A. DOZE[1]
[1]Biomed. Sci., Univ. of North Dakota, Grand Forks, ND; [2]Mol. Cardiol., Lerner Res. Inst., Cleveland, OH

Abstract: Norepinephrine (NE) is a well-known modulatory neurotransmitter, signaling via the adrenergic receptors (ARs), that mediates a potent antiepileptic effect *in vivo*. Previous studies suggest that α_1-ARs may underlie part of this antiepileptic effect, possibly by effecting inhibitory GABAergic interneuron activity. The α_{1A}-AR is of particular interest because we found that α_{1A}-AR knockout mice experience frequent spontaneous seizures while α_{1B}-AR knockout mice were somewhat resistant to seizures. Importantly, we also found that α_{1A}-AR activation improves memory, mood, and synaptic plasticity; which directly opposes most other antiepileptic mechanisms. In this study, we have further elucidated the pharmacology and physiology of α_{1A}-AR activation on epileptiform activity generated using low magnesium in acute hippocampal slices. Spontaneous epileptiform activity was measured using electrophysiological field potential recordings in the *stratum pyramidale* of the CA3 hippocampus. Slices were treated with α_1-AR-selective agonists (phenylephrine, epinephrine, A61603, or cirazoline), alone or in the presence of an α_{1A}-AR-selective antagonist (5-methyl urapidil) or $GABA_A$ receptor blocker (picrotoxin). Our results suggest that α_1-AR activation leads to a significant decrease in epileptiform activity (30-50% depending on the agonist), while α_{1A}-AR blockade abolishes agonist-induced reductions in frequency, in the absence of influence from α_2-ARs and β-ARs. Furthermore, $GABA_A$ receptor blockade also eliminated the α_1-AR-mediated reduction in epileptiform activity. Overall, α_{1A}-AR activation was shown to be the predominant subtype responsible for α_1-AR-mediated antiepileptic effects, likely via modulation of inhibitory GABAergic interneuron activity.

Title: Interictal and ictal events are different cortical response to same global thalamic input

Authors: *H. MA[1], E. BAIRD-DANIEL[1], J.-Y. LIOU[2], M. ZHAO[1], D. LI[3], C. A. SCHEVON[2], T. H. SCHWARTZ[1]

[1]Dept Neurolog. Surgery, Weill Cornell Med. Col., New York, NY; [2]Columbia Univ., New York, NY; [3]Dept. of Radiology, First Hosp. of Jilin Univ., Changchun, China

Abstract: Rationale: Interictal spikes (IISs) are the hallmarks of the presence of an active epileptic focus. However, the relationship between IIS and ictal events has been widely debated. While some studies indicate that IIS may trigger an interictal-to-ictal transition, it is also reported that interictal events may play a role in the control of seizures. The main reason for this debate relies on the lack of knowledge on the initiation dynamics of both IIS and ictal events. Here, we observe the initiation processes of both IIS and ictal events in a focal neocortex epilepsy model. Methods: The focal epilepsy model was created by local injection of 4-Aminopyridine (15mM, 0.5 μl) (4-AP) and the local field potential was recorded from the 4-AP injection electrode. Wide field calcium imaging was employed for wide-field recording of neuronal activity. Multielectrode arrays (10 by 10 grid, 40 μm spacing) were used to recorded local field potential and multiunit activity. In some experiments, local field potentials were recorded from both the neocortex and the thalamus. A bipolar electrode with an interelectrod distance of 150 μm was employed to deliver single or train squire wave stimulation to the ventrolbasal thalamus. Results: The 4-AP induced ictal events were focally distributed near the 4-AP injection site, the ictal focus. On the other hand, the ictal first spike and IISs propagated to the whole field of view. Both IIS and the first spike initiated from cortical areas far removed from the ictal focus and propagated back into the focus. During both the first spike and IIS, thalamic involvement reliably lead the cortical activity. These results indicate that both ictal events and the IIS were triggered by thalamocortical connections. This was further supported by the observation that TTx injection into the thalamus suspended both IIS and ictal events. We then delivered electrical stimulation to the ventrolbasal thalamus. Single or a train of square-wave stimulation was found to trigger the onset of both the first spike of ictal event and the IIS. Conclusion: We demonstrate that IIS and the first spike of ictal events have similar spatiotemporal dynamics and are both triggered by thalamocortical input. Our data indicates that IIS and ictal events may be arise as different cortical response to a global thalamic input.

Title: A heterogeneous thalamic network model that recapitulates oscillations modulated by GABA transporter blockade

Authors: *A. LU[1], C. K. LEE[4], B. TRUONG[2], J. R. HUGUENARD[5], M. P. BEENHAKKER[3]
[1]Med. Scientist Training Program, [3]Pharmacol., [2]Univ. of Virginia, Charlottesville, VA; [4]Dept. of Neurol. and Neurolog. Sci., Stanford Univ. Sch. of Med., Palo Alto, CA; [5]Dept Neurol & Neurolog. Sci., Stanford Univ. Sch. Med., Palo Alto, CA

Abstract: Absence seizures are thought to result from 3~5 Hz generalized thalamocortical oscillations. Understanding how such oscillations persist could lead to novel treatments for the most common form of pediatric epilepsy. Previous work has shown that electrically-induced oscillations in acute thalamic slices were prolonged upon pharmacological blockade of GABA transporters GAT1 or GAT3 individually, but were suppressed upon dual blockade of GAT1 and GAT3. We sought to understand this paradox by developing a biophysical thalamic network model that can recapitulate these findings. To this end, we first used pharmacological manipulations to isolate 4 distinct temporal profiles of inhibitory post-synaptic currents from GABAB receptors of thalamocortical (TC) relay neurons. Each profile corresponded to a particular pharmacological condition: (1) control, (2) GAT1 blockade, (3) GAT3 blockade, (4) dual blockade. Then, using dynamic clamp, we recorded voltage responses of 36 TC neurons to each of these 4 GABAB IPSC profiles. By simulating IPSC responses in a 3-compartment single neuron model and fitting them to all experimental data, we sought to determine those neural parameters that account for inter-cell variability and those parameters that account for inter-trial variability. Finally, we combined the distinct single neuron models into a heterogeneous thalamic network model to simulate intrinsic oscillations modulated by distinct GABAB IPSC profiles. In summary, we have developed a biophysically-based computational model that recapitulates most effects of GABA transporter antagonists on thalamic oscillations. These results will suggest that modulation of GABA transporters is a potential novel treatment for absence epilepsy.

Title: Chemogenetic silencing of projections from the basolateral amygdala to the mediodorsal thalamus attenuates limbic seizures

Authors: *E. WICKER[1], P. A. FORCELLI[1,2]
[1]Pharmacol. and Physiol., [2]Interdisciplinary Program in Neurosci., Georgetown Univ., Washington, DC

Abstract: The mediodorsal thalamus (MD) has been theorized to play a key role in seizure propagation (Bertram et al., 2008), in part due to its direct connections with key ictogenic structures including the hippocampus, piriform cortex and basolateral amygdala (BLA). Indeed, upon stimulation of the BLA, the MD displays almost immediate electrographic discharges (Sloan et al., 2011). Consistent with these anatomical and neurophysiological findings, microinjection of the GABA-A receptor agonist muscimol into the MD attenuates seizures evoked from each of these areas. However, the functional role of specific efferent and afferent pathways linking the MD to these ictogenic regions have not been directly manipulated in the context of seizures. This level of circuit resolution, while unattainable with focal pharmacological manipulations, is now possible using new-generation techniques. We have recently reported that chemogenetic silencing of a large region of the midline and intralaminar thalamus was sufficient to block amygdala kindled seizures. Here, we employed chemogenetics to examine investigate the specific role of the MD and its direct input from the BLA in seizures originating from the BLA. Male, Sprague-Dawley rats were injected with virus (AAV-hSyn-hM4Di) into the MD, and implanted with a stimulating electrode in the BLA; a subset of animals also received a cannula placed bilaterally into the MD to allow for focal delivery of the DREADD agonist, clozapine-N-oxide (CNO). Following systemic administration of CNO (5 mg/kg), amygdala kindled seizures were significantly decreased in severity ($p=0.03$) and duration ($p<0.001$). To directly target and manipulate the projection from the BLA to the MD, we microinjected 500 pmol of CNO in 0.2 µl. In this manner, projections from BLA to MD, but not from BLA to other brain regions were silenced. We found a significant decrease in seizure score ($p=.02$) and duration ($p=0.005$) following bilateral focal silencing of BLA to MD projections. We also found an attenuation of seizure score ($p=0.03$) and duration ($p=0.03$) after silencing of the MD ipsilateral to the stimulating electrode. These data show that silencing of the MD or silencing of the direct projection from the BLA to the MD, is sufficient to attenuate amygdala kindled seizures. This suggests that direct, rather than indirect, propagation of activity from BLA to MD is critical in limbic ictogenesis. The specificity of projection-level targeting may have a translational utility and provides further opportunity to dissect the role of the MD in seizure propagation.

Title: Hypoxic activation of midline thalamus

Authors: *K. A. SALVATI, M. P. BEENHAKKER
Dept. of Pharmacol., Univ. of Virginia, Charlottesville, VA

Abstract: Childhood Absence Epilepsy (CAE) is the most common pediatric epilepsy. A striking feature of CAE is the unassailable ability to trigger seizures by hyperventilation. The mechanism(s) underlying hyperventilation-induced seizures is unknown. However, insight into hyperventilation-induced absence seizures will lead to more efficacious treatments than the current, ill-favored anti-epilepsy drugs. Our lab demonstrates that hyperventilation-induced seizures are inducible in the WAG/Rij rat, a rodent model of CAE. Moreover, immunohistochemistry and *in situ* hybridization data reveal *c-fos* expression in the midline thalamus after exposure to 30min of hypoxia to induce hyperventilation. Indeed, thalamocortical circuits are intimately associated with CAE. Identification of *c-fos* positive cells in the midline thalamus is a novel finding and provides us a first glance into understanding how hyperventilation modulates thalamocortical activity to produce absence seizures. Long-standing evidence demonstrates that the midline thalamus has diffuse projections throughout the cortex, as well as reciprocal connectivity with the reticular thalamic nucleus (RT). Additionally, our *c-fos* data highlights an active population of midline cells during hypoxia-induced seizures. We hypothesize that the midline exerts a strong modulatory tone within intrathalamic and thalamocortical circuits, making the midline a likely critical node for the generation of spike-and-wave discharges (SWDs), the electrical signature of absence seizures. To determine how the midline modulates SWD activity, we performed *in vivo* optogentic and EEG experiments to assess SWD expression upon light-induced activation and silencing of midline neurons. In investigating how midline projections alter RT neuron activity, we performed combined patch-clamp and optogentic experiments in acute brain slices. All experiments were conducted using the rodent model of absence epilepsy, the WAG/Rij rat.

Title: Large scale 4 Hz oscillations control the expression of neocortical fast-ripples in hippocampal sclerosis

Authors: *L. SHEYBANI[1], P. VANMIERLO[1], M. BAUD[2], S. VULLIEMOZ[2], M. SEECK[2], C. MICHEL[1,3,2], C. QUAIRIAUX[1]

Abstract: A conceptual shift in our understanding of focal epilepsy has led to the recognition that epileptic networks (EN), and not solely the localized brain region named “epileptic focus” (EF), are major pathogenic factors of the disease. However, how large-scale EN recruit distant pathological nodes, and whether this promotes the emergence of pathological activities remote from the focus remain largely unknown. Here, we show that neocortical fast-ripples (FRs) are generated in hippocampal sclerosis and are triggered by large-scale synchronizing 4-Hz waves that start in both hippocampi and then spread to frontal regions. These slow oscillations constrain bursts of paroxystic 20-30 Hz activity to which neocortical FRs are time-locked. We further show that the mechanism through which slow oscillations favor the generation of FRs might be through a modulation of neuronal firing, as we observed a strong phase-coupling of action potentials over the 4-Hz phase during these events. These low- and high-frequency coupling mechanisms demonstrate an intriguing parallel with cross-frequency coupling observed in certain physiological brain functions. Thus, similar mechanisms might underlie normal and pathological brain functions that rely on large-scale physiological or pathological networks.

Title: Laminar distribution of ultra high frequency oscillations in the epileptic brain induced by focal cortical dysplasia in mice

Authors: *Q.-Q. SUN[1], A. WILLIAMS[2]
[1]Dept Zoo/Physiol, Neurosci Programe, Univ. Wyoming, Laramie, WY; [2]Zoology and Physiol., Univ. of Wyoming, Laramie, WY

Abstract: Abstract The epileptic brain is often associated with the presence of high frequency oscillations (HFOs, >25 Hz) that have recently gained attention as potential biomarkers to help define the cortical seizure zone. Here we evaluate the aberrant spectral architecture and spatial distribution of HFOs associated with spontaneous spike-wave discharge (SWD) patterns in an experimental model of focal cortical dysplasia (FCD) induced by neonatal freeze lesions (FLs) to the right S1 cortex. Chronic bipolar recordings from awake, behaving animals indicated a high prevalence of spontaneous SWDs in 83% (10/12) of animals exposed to the FL injury as evaluated at 5-11 months of age. SWDs were associated with a strong increase in HFOs locked to the spike/wave seizure pattern and largely confined to the ipsilateral cortex near the site of the FL injury. Additional acute recordings with linear micro-electrode arrays were obtained to evaluate laminar differences in HFOs during spontaneous periods of hyper-excitable burst-suppression activity under general anesthesia. FL animals exhibited significant increases in spontaneous HFOs that were confined to granular and supragranular layers with a concomitant increase in unit activity while control animals exhibited minimal changes in 'ultra-high' frequency responses above 100 Hz (i.e. ripple waves). Spike sorting of well-isolated single-units from FL cortex indicated a differential expression pattern of putative excitatory (EXC) versus inhibitory (INH) cells. EXC cells were predominately observed in the outer cortical layers and showed only weak association with HFOs while the deeper INH units were strongly phase-locked to ripple oscillations (100-500 Hz). The spontaneous cyclic spiking of cortical inhibitory cells appears to be the driving substrate behind HFOs and may prove useful in identifying regions of hyperexcitable tissue in the epileptic brain. In summary, the current studies indicate a strong prevalence of HFO activity in a model of FCD that are 1) mainly confined to the injured cortex, 2) originate in the upper cortical layers, 3) are most prominent during high-amplitude 'spike' deflections of the local field potential, and 4) indicate strong phase-locking to putative INH cells predominately within the supragranular layers of the malformed cortex. As demonstrated in the current study, the utilization of commercially available electrode arrays offers a powerful high-resolution tool for mapping the cortical circuitry of seizurogenic tissue and identification of key cellular markers underlying brain hyperexcitability and may help guide clinical diagnosis and treatment of the epileptic brain.

Title: The superior colliculus is a site for anticonvulsant action for cannabinoid agonists

Authors: *R. HAMMACK[1], V. R. SANTOS[2], E. WICKER[1], P. N'GOUEMO[4], P. A. FORCELLI[3]
[1]Pharmacol. and Physiol., [2]Dept. of Pharmacol. and Physiol., [3]Dept of Pharmacol., Georgetown Univ., Washington, DC; [4]PEDIATRICS, GEORGETOWN UNIVERSITY MEDICAL CENTER, Washington, DC

Abstract: Despite growing evidence for anticonvulsant properties of drugs targeting the cannabinoid system (e.g., CB_1 receptor agonists), the site of anticonvulsant action of these drugs remains unknown. CB_1 receptors are expressed in high density in limbic structures such as the hippocampus, as well as in components and targets of the basal ganglia. One area of the brain with a large number of these receptors is the deep and intermediate layers of the superior colliculus (DLSC). The DLSC receives inhibitory input from the substantia nigra pars reticulata, another region with high density of CB_1 receptors. These latter structures are of particular interest because activation of the DLSC or inhibition of the SNpr display broad-spectrum anticonvulsant effects. Since CB_1 receptors have been shown to preferentially target both presynaptic and inhibitory synapses, activation of these G_i coupled receptors would hypothetically cause disinhibition of DLSC and thus an anticonvulsant effect. To test this hypothesis, we employed two rat models of seizures: (1) focally evoked limbic seizures triggered by microinjection of bicuculline into the “Area Tempestas” (AT) and (2) audiogenic seizures evoked in genetically epilepsy prone rats (GEPR-3). Using a within-subject design, we microinjected the CB_1 agonist CP 55,490 (26.5 nmol in 0.5 µl) or vehicle in into the DLSC prior to evoking seizures. In the AT model, we found that microinjection of CP 55,490 significantly decreased the severity of seizures compared to vehicle injection ($P=0.016$). Moreover, the number of limbic motor seizures that occurred during the one hour observation was significantly decreased by CP 55,490 ($P=0.0007$). In the GEPR model, CP 55,490 microinjection likewise decreased the severity of evoked seizures ($P=0.031$). These data suggest that activation of CB_1 receptors within the DLSC is sufficient to produce anticonvulsant effects. Studies are currently underway to determine if activation of these receptors is necessary for the anticonvulsant effects of systemically administered CB agonists, and to determine the effect of CB agonists on synaptic transmission within the DLSC.

Title: Cortical macrostructure influences the spread of epileptiform activity

Authors: *R. R. PARRISH, A. OFFER, C. RACCA, A. J. TREVELYAN
Newcastle Univ., Newcastle Upon Tyne, United Kingdom

Abstract: Seizures are the defining feature of epilepsy. They typically arise in a discrete focus in the brain and then propagate to surrounding regions; exactly how seizures propagate, however, and what endogenous mechanisms exist to resist this spread, are poorly understood. Previous work, from multiple groups, has demonstrated the presence of a powerful initial inhibition ahead of the ictal wave front. Nevertheless, it remains unclear how cortical areal boundaries and layers may influence the propagation. We therefore examined this issue, using low magnification Ca^{2+} network imaging (GCaMP6f, 2.5x objective) of spreading epileptiform activity. We performed Ca^{2+} network imaging while simultaneously recording extracellular local field potentials at two locations, flanking the area 17/18 cortical boundaries. Epileptiform activity was induced by bathing brain slices in 0 Mg^{2+} artificial cerebro-spinal fluid (ACSF).
As described by many researchers, the 0 Mg^{2+} model displays a variety of pathological discharge patterns, but in this study, we focused on propagation of full ictal events (IEs), which are characterised by a wavefront of intense neuronal firing, probably incorporating all neurons locally, and followed typically by rhythmic discharges, very similar to that seen in vivo during tonic-clonic seizures. Early IEs propagate slower than later ones. These early events preferentially spread in the deep laminar layers, with a higher number of initial IEs in each slice appearing in the deep laminar layer over the superficial. Consequently, the propagation speed during IEs in the deep layer is also generally faster. No medio-lateral directionality preference was seen in propagating IEs and on occasions, we observed successive events propagating in opposite directions, suggesting that the same circuits are responsible for propagation regulation in both directions. In all cases, propagation was not steady, but rather proceeded in episodic steps across the network. Our imaging was centred on primary visual cortex, because the borders of this area are reasonably well defined in adult mice using immunohistochemical markers. We observed instances where the seizure spread paused in the middle of area 17, and also close to the areal boundaries. Slices were fixed, and prepared for histological examination of these boundaries. We will present these analyses at the meeting. These studies will shed light into how

seizures spread through cortical tissue and allow for us to then study how neocortical anatomy contributes to propagation, delay, and restraint of seizure activity.

Title: Graph theoretic analysis of limbic subnetwork in left vs right temporal lobe epilepsy

Authors: *S. SUBRAMANIAN[1], N. PELED[1], R. L. GOLLUB[3,1], M. HIBERT[1], L. DOUW[1], S. M. STUFFLEBEAM[2]

Abstract: Purpose: To investigate differences in limbic network functional connectivity between left and right temporal lobe epilepsy (TLE) on a large data set of patients using graph theory.
Methods: Interictal resting state fMRI was performed in 81 left and 33 right TLE patients. Functional connectivity networks were constructed based on the Lausanne 2008 parcellation (from Connectome mapper) of 219 cortical surface regions using Pearson correlation. These networks were thresholded at a range of biologically plausible connection densities (25-50%) and graph theoretic properties were computed, including betweenness centrality, clustering coefficient, local and global efficiency, and eigenvector centrality (EVC). A subset of 52 bilateral limbic network regions (anterior cingulate, posterior cingulate, fusiform, entorhinal, orbitofrontal, insula, parahippocampus, superior temporal) was selected based on a priori knowledge, and the distributions of graph theoretic properties for these regions was computed for left and right TLE with 95% confidence intervals (CI). The mean values of all graph properties for the overall limbic subnetwork were also computed for left and right TLE with 95% confidence intervals. Regional and global limbic subnetwork distributions were examined for differences between left and right TLE, as evidenced by non-overlapping 95% CI for at least 20% of the densities analyzed.
Results: Global properties show that patients with left TLE have higher clustering coefficient and EVC across the limbic subnetwork than those with right TLE. Upon examination of individual sub-regions, the right superior temporal gyrus (rSTG) shows significant differences between right and left TLE across multiple metrics and densities. Overall, patients with right TLE have

lower EVC, clustering coefficient, local efficiency, and betweenness centrality in the rSTG than those with left TLE.
Conclusions: Graph theoretic analysis reveals limbic subnetwork differences between left and right TLE at resting state that may have important diagnostic and prognostic implications.

Title: Network origins of epileptic activity

Authors: *S. GHIASVAND[1], Y. BERDICHEVSKY[2]
[1]Lehigh university, Bethlehem, PA; [2]Lehigh Univ., Bethlehem, PA

Abstract: Introduction: Epilepsy is a neurological disorder characterized by recurrent abnormal neuronal activity or seizures. Epilepsy is a multi-scale disease that can be brought about by

changes at the cellular or network level. Currently, the precise network parameters necessary for epileptic behavior are not well defined. We wish to examine particularly the effects of network size (number and density of neurons) and connectivity as a characterization of epileptic network topology. We employ both *in vitro* and computational approaches to vary the network topology and examine the effects on network firing patterns. This investigation will elucidate more effective mechanisms for antiepileptic drugs.
Materials and Methods: The *in vitro* aspect of our study was conducted using organotypic hippocampal slice cultures (OHCs). OHCs have been shown to be an effective model of posttraumatic epilepsy as they become spontaneously epileptic after one to two weeks *in vitro.* We created and cultured OHCs and hippocampal sub-regions (i.e. CA3 and CA1-DG) in order to vary the network size and circuitry. We quantified firing patterns using chronic electrical recordings. Immunohistochemistry was used to quantify neuronal number and density. The computational modeling employed Integrate-and-Fire neurons connected via synapses with short-term depression mechanism in order to examine the effects of network size and synaptic strength on synchronous bursting or seizure propagation.
Results and Discussion: We successfully modeled neuronal networks of different dimensions. We have also begun culturing organotypic slices of hippocampal sub-regions. Electrical recordings from these sub-regions reveal different firing patterns and different rates of development of epileptic behavior. The CA3 sub-region cultures demonstrated a more rapid development of incidence of seizures.
Conclusion: We have developed both computational and *in vitro* models to study the effects of network topology on epileptogenesis. Our results from electrical recordings from OHCs and sub-regions reveal that epileptogenesis is affected by network size and circuitry. These results are also compatible with the results obtained from our network simulation. Combined computational and experimental results may give insights into the network origins of epileptic activity.

Title: Quantification of seizurogenic activity with multiwell microelectrode array technology for proconvulsant risk assessment

Authors: *D. C. MILLARD, H. B. HAYES, C. A. ARROWOOD, A. M. NICOLINI
Axion Biosystems, Atlanta, GA

Abstract: The lack of advancement in anti-epileptic drugs (AEDs) over the last 30 years, along with the continued need for improved proconvulsant screening in drug safety, motivates the need for new assays of seizurogenic neural activity. Previous work has established an in vitro approach for detecting and quantifying seizurogenic activity using multiwell microelectrode array (MEA) technology, providing a predictive and high-throughput avenue for the evaluation of the efficacy of AEDs and the proconvulsant risk of other drug candidates. Here, we present an updated assay of seizurogenic activity based upon guidelines developed in the HESI NeuTox consortium, which is a collection of academic, commercial, and pharmaceutical representatives working towards the development of in vitro assessment of proconvulsant risk. We used previously published metrics for the detection of burst spiking events and the quantification of synchronization across a neural population, in spontaneous and evoked conditions. Data are included from cryopreserved rat cortical neurons evaluated with the 10 compounds selected by the NeuTox consortium, which include reference compounds with known proconvulsant risk via multiple mechanisms and negative control compounds. Our results support the combined use of evoked and spontaneous neural activity, collected using multi-well MEA technology, for the high throughput evaluation of complex neuronal networks in vitro to quantify the proconvulsant risk of candidate pharmaceuticals in a pre-clinical setting.

Title: Gluconate inhibition of CLC-3 chloride channels as a novel treatment for neonatal seizure

Authors: *Z. WU
Huck Life Sci., University Park, PA

Abstract: Neonatal seizure is different from adult seizure, and many antiepileptic drugs that are effective in adults often fail to treat neonatal seizure. Here, we report that gluconate inhibits neonatal seizure by blocking CLC-3 chloride channels. We discover a voltage-gated outward rectifying Cl^- current mediated by CLC-3 Cl^- channels in early developing brains but not in the adult brains. Blocking CLC-3 Cl^- channels by gluconate inhibits seizure activity both in neonatal brain slices and in neonatal animals. Consistently, neonatal neurons in the CLC-3 knockout mice lack the outward rectifying Cl^- current and show reduced epileptiform activity upon stimulation. Mechanistically, we demonstrate that activation of CLC-3 Cl^- channels may alter intracellular Cl^- homeostasis and enhances GABA excitation. Our study identifies gluconate as a novel antiepileptic drug to treat neonatal seizures through inhibiting CLC-3 Cl^- channels.

Title: Effect of levetiracetam treatment on neurotransmission in the dentate gyrus of rats with temporal lobe epilepsy

Authors: *L. PICHARDO-MACIAS[1,2], B. A. RAMÍREZ[3], K. B. SÁNCHEZ- HUERTA[2], I. J. CONTRERAS[2], M. S. NAVARRETE[2], E. M. GARCÍA[2], S. R. ZAMUDIO[4], J. L. CHAVEZ[3], J. G. MENDOZA-TORREBLANCA[2]
[1]Inst. Politecnico Nacional, México, Mexico; [2]Neurociencias, [3]Farmacología, Inst. Nacional de Pediatría, México D.F., Mexico; [4]Lab. de Neurociencia conductual I, Inst. Politécnico Nacional, México D.F., Mexico

Abstract: Temporal lobe epilepsy (TLE) is characterized by the appearance of epileptic foci in limbic structures, particularly in the hippocampal formation. Three fundamental pathophysiological features have been described in this condition: an imbalance between inhibition-excitation, hyper-excitability and neuronal hyper-synchrony. Levetiracetam (LEV) is an anticonvulsant drug with a unique profile of activity that results in a decrease of spontaneous recurrent seizures (SRZ). The exact mechanism by which LEV reduces SRZ is still unknown, but its mechanism of action may involve effects on neurotransmitter release. It is not clear whether

these effects include excitatory or inhibitory neurotransmission or both, since LEV´s primary target, the synaptic vesicle protein 2A, is ubiquitously expressed in nearly all types of synaptic vesicles. Therefore, the objective of the present study was to evaluate the effects of LEV on inhibitory and excitatory neurotransmission of the dentate gyrus (a region with major synaptic changes during TLE). For this purpose, male Wistar rats were divided into the following groups: a) control, b) control + LEV, c) epileptic and d) epileptic + LEV. TLE was generated by the systemic administration of lithium and pilocarpine, seizure scores were determined by behavioral analysis of videotapes. LEV treatment lasted one week (300 mg / kg / d) and was done by osmotic minipumps. The animals were implanted with a cannula in the dentate gyrus, then 14 dialysate samples were collected using microdialysis. The amino acids contained in the dialysates were quantified by high performance liquid chromatography (HPLC) coupled to fluorometric detection. The extracellular concentration of each amino acid (GABA, glutamate, aspartate, glutamine, taurine and glycine) was measured under basal conditions as well as in the presence of a depolarizing stimulus that consisted of the application of a high potassium solution (100 mM). TLE caused an imbalance between excitatory and inhibitory neurotransmitter systems in the dentate gyrus. Treatment with LEV increased the concentration of GABA, tending to restore the lost balance; a mechanism by which it could also reduce epileptic seizures.

Title: Epileptic circuits revealed using EpiPro, a novel synthetic activity-modulated promoter

Authors: *C. T. BURKE[1], I. VITKO[1], A. GAWDA[1], J. KIM[1], K. BRODIE[1], K. SULLIVAN[1], B. WALKER[1], M. OTTOLINI[2], D. PEREZ-REYES[1], J. KAPUR[3], M. PATEL[2], E. PEREZ-REYES[1]
[1]Pharmacol., [2]Anesthesiol., [3]Neurol., Univ. of Virginia, Charlottesville, VA

Abstract: Temporal lobe epilepsy (TLE) is a disease in which seizures originate in the hippocampus (or parahippocampal structures) and can spread throughout the brain. We have developed an activity modulated synthetic promoter (“EpiPro”) that contains the response elements of transcription factors known to be upregulated in patients with epilepsy. To map the

epileptic circuit in a rat model of TLE, an adeno-associated virus (AAV) with EpiPro driving GFP was injected into the temporal lobes of epileptic and naïve rats. Expression in naïve animals was low, with the exception of Mossy cells inside the dentate hilus and subsets of subicular neurons. In animals induced to have spontaneous recurring seizures with lithium-pilocarpine, there was large activation of dentate granule cells, and modest activation of subicular neurons. These subicular neurons projected throughout the brain, and likely explain how seizures spread from the hippocampal focus. These findings provide in vivo evidence to support the "dentate gate breakdown" hypothesis. Our data also validates the use of EpiPro to selectively drive gene therapies in epileptic neurons.

Title: Closed-loop gene therapy for intractable focal epilepsy

Authors: *A. LIEB, Y. QIU, C. DIXON, D. M. KULLMAN
Clin. and Exptl. Epilepsy, UCL / Inst. of Neurol., London, United Kingdom

Abstract: Around 50 Million people worldwide are affected by epilepsy, of whom 20% do not respond to commonly available drugs. New drug development is limited by difficulties in differentiating between neurons involved in seizure generation and normal brain function. Many antiepileptic drugs show a relatively narrow therapeutic window and elicit a variety of serious side-effects, mainly because they affect the whole brain. The only effective treatment option for focal-onset refractory epilepsy to date is surgical resection, which is often restricted by the proximity to eloquent cortex. Recent research has focused on controlling epileptic seizure activity on demand by i) optogenetics, ii) chemogenetics, iii) electrical stimulation, iv) focal cooling, or v) targeted drug-delivery. However, all these approaches are limited in their translational applicability. In contrast to these approaches, we propose a closed-loop method for biochemical detection and ion-channel based suppression of epileptic seizures.

We created a viral construct which was initially biophysically characterized by heterologous overexpression in Neuro-2A-cells and whole-cell patch-clamp recordings. Subsequently, it was evaluated in the acute chemoconvulsant induced model of epilepsy, where it showed particular effectiveness in reducing spike-wave complexes occurring at 4-14Hz (associated with motor convulsions), the absolute number of spikes, and the cumulative coastline. In addition we demonstrated the efficiency of the viral construct in reducing the total number of spontaneously generated epileptic seizures in the chronic Tetanus Toxin induced model of focal refractory epilepsy.
In this work we propose a novel closed-loop gene therapeutic approach, able to biochemically detect and inhibit seizure generation in generalization. This novel approach presents the first autoregulatory gene-therapeutic strategy targeting intractable focal epilepsy.

Title: Transcranial near-infrared laser treatment suppresses pentylenetetrazol-induced severe seizure behaviors and status epilepticus in developing rats

Authors: *C.-M. TSAI[1], S.-F. CHANG[1], H. CHANG[3,2]
[1]Grad. Inst. of Med. Sciences, Col. of Med., [2]Pediatrics, Sch. Of Med., Taipei Med. Univ., Taipei, Taiwan; [3]Dept. of Pediatrics, Taipei Med. Univ. Hosp., Taipei, Taiwan

Abstract: OBJECTIVE To evaluate effects of transcranial near-infrared laser treatment (NILT) on subcutaneous pentylenetetrazole (scPTZ)-induced seizure behaviors and SE in developing rats. **METHODS** Sprague-Dawley rats aged postnatal day 30-36 were divided into NILT group and sham group. We injected PTZ (90 mg/kg) subcutaneously to rats in each group and applied gallium-aluminum-arsenide diode laser to rats in the NILT group transcranially prior to PTZ injections. We staged the intensities of seizures to mild, moderate, and severe seizures based on “revised Racine’s scale” with minor modifications. The seizures were evaluated with parameters including total duration of seizures (TDs), percentage time in seizures (PTs), maximum seizure stages per five minutes (Max), “weighted seizure score” (W), in which stage and duration were weighted, and latency to seizures (Ls). The SE, modified from Sato SM and Woolley CS’s definition, was evaluated with percentage of rats developed SE (PRSE), total duration of SE (TDSE), percentage time in SE (PTSE), and latency to SE (LSE). We analyzed the results of PTs, Max, W, PRSE, and PTSE with repeated measures two-way ANOVA, and unpaired t test for data of TDs, Ls, TDSE, and LSE. **RESULTS** The total duration of severe seizures was

significantly shorter and percentage time in severe seizures was significantly lower in the NILT group ($p<0.05$) compared to those in the sham group. As for mild and moderate seizures, there was no significant difference either evaluated with TDs or PTs. The data of PTs, Max, and W were lower in the NILT group ($p<0.05$). PRSE was significantly lower in the NILT group ($p<0.01$), also significantly shorter TDSE and significantly lower PTSE were detected in the NILT group ($p<0.05$). There was no significant difference in terms of LSE or Ls.
CONCLUSION Our findings show that transcranial NILT reduces durations and severities of scPTZ-induced severe rather than mild or moderate seizure behaviors and the incidence and durations of SE in developing rats. This is the first report demonstrating the effectiveness of transcranial NILT on PTZ-induced seizure behaviors and especially on suppressing SE, and this might shed light on the application of transcranial NILT for children with convulsive status epilepticus.

Title: Selective inhibition of $Na_V1.6$ drives anticonvulsant efficacy in mouse models of epileptic encephalopathy ($SCN8A^{N1768D+/-}$) and adult partial onset seizures (maximal electroshock)

Authors: C. M. DUBE[1], P. KARIMI TARI[1], M. WALDBROOK[1], K. NELKENBRECHER[1], J. MARK[1], T. FOCKEN[2], N. SHUART[3], K. KHAKH[3], R. WINQUIST[4], J. EMPFIELD[2], C. J. COHEN[3], *J. JOHNSON, JR[5]

Abstract: Voltage-gated sodium channel inhibitors are commonly used as anti-epileptic drugs for treating patients with partial and tonic-clonic seizures. While effective for some patients, these drugs are non-selective among Na_V's and are dose limited by their adverse effects. Decreased expression of $Na_V1.1$ in inhibitory interneurons can cause seizures, as in Dravet syndrome, so the off-target activity of non-selective antagonists may work at cross-purpose to the intended effect. Excitatory pathways in the CNS are preferentially mediated by $Na_V1.6$, and missense mutations of SCN8A cause gain-of-function $Na_V1.6$ channels leading to a rare form of severe childhood epilepsy (Early Infantile Epileptic Encephalopathy 13, EIEE13). We have developed highly selective $Na_V1.6$ inhibitors that spare all other Na_V isoforms and others that

selectively inhibit both $Na_V1.6$ and $Na_V1.2$ but spare $Na_V1.1$. We tested these selective compounds in two mouse models of seizures, a 6Hz psychomotor seizure assay in $Na_V1.6$ transgenic mice ($N1768^{D/+}$) and the maximal electroshock (MES) assay in wild type mice. Selective $Na_V1.6$ inhibitors prevented induced seizures in EIEE13 mice. Anticonvulsant activity was well correlated with inhibition of $Na_V1.6$ and independent of inhibit of $Na_V1.1$ or $Na_V1.2$. The same was true in the MES assay with mice that lack mutant sodium channels ($p<0.05$). These data suggest that the primary driver of efficacy for selective and non-selective Na_V inhibitors in both $SCN8A^{N1768D/+}$ and wild type mice is inhibition of $Na_V1.6$. This implies that selectively targeting $Na_V1.6$ could confer anti-seizure efficacy while sparing off-target activities. We anticipate that eliminating inhibition of the sodium channel isoforms not necessary for efficacy, particularly $Na_V1.1$ and $Na_V1.5$, will lead to better tolerated and more efficacious treatments for patients with epilepsy.

Abstract: Dravet syndrome is a catastrophic childhood epilepsy often caused by genetic mutations in the voltage-gated sodium channel *SCN1A*. Currently available antiepileptic drugs do not offer adequate seizure control for these patients; therefore there is a significant need for the discovery and development of new therapies. Zebrafish larvae with a mutation in homologous sodium channel gene, *scn1lab,* recapitulate the spontaneous seizure activity and mimic the convulsive behavioral movements observed in Dravet syndrome. Importantly, *scn1lab* mutant zebrafish also show pharmacoresistance to several antiepileptic drugs, emulating the persistent drug resistant seizures observed in human patients (Baraban et al. 2013; Dinday and Baraban, 2016). Using *scn1lab* mutant zebrafish larvae, we developed an in vivo drug screening platform to identify potential antiepileptic compounds. In a blind screen of more than 3000 drugs, the 1st generation antihistamine clemizole was identified as having potent antiepileptic properties. Further characterization of clemizole revealed novel binding to the serotonin receptors HTR2A and HTR2B in addition to its known binding to the histamine H1 receptor. Structure-activity relationship studies were performed using clemizole as our hit compound. Using medicinal chemistry we synthesized a library of 28 clemizole analogs with favorable drug-like properties. These 'clemalogs' aimed to improve the antiepileptic activity of clemizole by enhancing the HTR2 receptor activity. Three novel clemalogs were identified as capable of suppressing the convulsive seizure behaviors in our zebrafish drug screening platform. Furthermore, pharmacological analysis using radioligand binding assays confirmed strong binding affinities to human HTR2 receptors. In addition to developing clemalogs, a targeted screen of 65 of FDA approved serotonin modulating compounds was performed. Two 5HTR2 agonists, lorcaserin and trazodone, were identified as mimicking the antiepileptic activity of clemizole in *scn1lab* larvae. Under a compassionate use off-label program we treated five Dravet syndrome patients with lorcaserin (Belviq). All patients reported an initial reduction in seizure activity confirming our preclinical zebrafish data (Griffin et al. 2017). We conclude zebrafish-based drug discovery and development confirms a role for the modulation of serotonin signaling as an effective antiepileptic treatment for Dravet syndrome.

Title: Assessment of midazolam and diazepam to treat nerve agent-induced seizures in pediatric and adult rats

Authors: K. HAINES[1], E. N. DUNN[2], L. M. MATSON[2], C. ARDINGER[2], H. S. MCCARREN[2], S. M. MILLER-SMITH[2], *J. H. MCDONOUGH, Jr.[1]
[1]Nerve Agent Countermeasures, Neurosci. Program, US Army Med. Res. Inst. Chem Def, Gunpowder, MD; [2]Nerve Agent Countermeasures/Neuroscience Br., US Army Med. Res. Inst. of Chem. Def., Gunpowder, MD

Abstract: Chemical warfare nerve agents like sarin (GB) and VX cause severe central nervous system effects, the most devastating of which is a state of prolonged seizures known as status epilepticus. In a civilian nerve agent exposure situation, children would likely be among the worst casualties as they are more susceptible than adults to seizures (Haut et al., 2004; Rakhade & Jensen, 2009; Sidell et al., 2008). The current study compared the anticonvulsant efficacy of midazolam and diazepam in male and female pediatric and adult rats. We determined the median effective dose (ED_{50}) and the incidence of seizure at one and four hours post-treatment to inform future clinical treatment of nerve agent-induced seizures across age groups. Female and male postnatal day (PND) 21, 28, and 70 rats were implanted with electroencephalographic (EEG) electrodes to monitor seizure activity. Animals were exposed to the nerve agents GB or VX and then treated five minutes after seizure onset with either midazolam or diazepam. The up-down method (Dixon & Massey, 1983) was used to determine the anticonvulsant ED_{50} for each sex, agent, and age group. Based on the ED_{50} confidence intervals, PND21s exposed to VX had lower midazolam and diazepam ED_{50} values than adults. There were no clear age differences in animals exposed to GB, but the results suggest that PND21 males had a lower ED_{50} value for diazepam compared to other age groups. We also observed a significant change in incidence of seizure for animals treated with midazolam between one hour (42.3%) and four hours (46.8%), $\chi^2_{(1)} = 5.00$, $p = .041$, $OR = 3.0$ [95% CI: 1.09, 8.25]. This was seen most frequently in PND21s, although no significant differences between the age groups were found. In conclusion, ED50 values for midazolam were similar across age groups, suggesting that a similar treatment dose may be effective across all age groups. Because there was a greater variability in the doses of diazepam across age groups, midazolam may be the better treatment option for nerve agent-induced seizures to be used in a mass casualty situation involving both pediatric and adult populations. However, its effects are only temporary because some animals had seizure activity

at four hours. Experiments are currently ongoing to determine if either treatment protects susceptible brain regions from neuronal loss.

Title: Investigating the antiepileptic potential of mycophenolate mofetil in a rat model of temporal lobe epilepsy

Authors: *A. G. MAZUMDER, V. PATIAL, D. SINGH
CSIR-Institute of Himalayan Bioresource Technol., Palampur, India

Abstract: Traumatic brain injuries in case of temporal lobe epilepsy gives rise to the emergence of several neuroinflammatory mediators which cause excitotoxicity and severe neuronal impairment. Mycophenolate mofetil, commonly used as an immunosuppressant, has been widely used in various organ transplantations across the globe. However, its neuroprotective effects have been reported in several preclinical and clinical studies. The present work was envisioned to explore the effects of mycophenolate mofetil on seizure severity and aggressive behavior in a rat model of lithium-pilocarpine-induced spontaneous recurrent seizures. Male wistar rats were randomly divided into different groups, and were subjected to lithium pilocarpine induced status epilepticus method, following the drug treatment. The rats were treated for 28 days with mycophenolate mofetil at different doses, 28 days after induction of seizures. The behavior of the rats were video recorded for 72 h prior to the end of treatment for seizure severity score and the aggressive behavior was evaluated using various behavior paradigms such as, approach response test, touch response test and pick up test. These results showed that treatment with the drug distinctively reduced lithium-pilocarpine instigated spontaneous recurrent seizures severity score with reduced aggression like behavior. These findings concluded that mycophenolate mofetil has antiepileptic effect and it reduces seizure linked aggressive behavior.

Title: Traumatic brain injury alters Huperzine-A cerebral pharmacodynamics

Authors: *U. DAMAR[1], R. GERSNER[1], J. JOHNSTONE[2], K. KAPUR[1], S. COLLINS[2], S. C. SCHACHTER[3], A. ROTENBERG[1]
[1]Neurol., Boston Children's Hosp., Boston, MA; [2]Biscayne Neurotherapeutics, Miami, FL; [3]Neurol., Beth Israel Deaconess Med. Ctr., Boston, MA

Abstract: Introduction: Traumatic brain injury (TBI) may affect the pharmacodynamics of centrally acting drugs. Paired-pulse transcranial magnetic stimulation (ppTMS) a safe and noninvasive measure of cortical GABA-mediated cortical inhibition. Huperzine A (HupA) is a naturally-occurring acetylcholinesterase inhibitor with newly discovered potent GABA-mediated antiepileptic capacity, which is reliably detected by ppTMS. To test whether TBI alters cerebral HupA pharmacodynamics, we exposed rats to fluid percussion injury (FPI), and tested whether ppTMS metrics of cortical inhibition differ in magnitude and temporal pattern in injured rats.
Methods: Anesthetized adult rats were exposed to FPI or sham injury, and treated with either saline or HupA. 90 minutes following the injury, rats were injected with HupA or saline (0.6 mg/kg, i.p.). Cortical inhibition was measured by 15 paired pulses immediately before the injections at baseline, and then every 15 minutes for 90 minutes post-injection. Log transform of the test:conditioning ratio of the motor evoked potential (MEP) amplitudes were compared across treatment conditions. Repeated Measures ANOVA was used to compare saline and HupA in both sham and TBI groups. Mann Whitney U test was used to compare TBI and sham groups regarding baseline cortical inhibition and the time to maximum HupA effect. To compare time to maximal HupA effect, we also adopted a longitudinal model using linear mixed-effects regression model, and included linear and quadratic effects of time and their interaction with group to differentiate the trajectories of sham and TBI groups.
Results: TBI resulted in reduced cortical inhibition 90 minutes after the injury compared to sham controls ($p=0.03$). HupA enhanced cortical inhibition after both sham injury ($p=0.002$) and TBI ($p=0.02$). There was a trend in lower magnitude of HupA-induced cortical inhibition in TBI animals than in sham-TBI animals. However, time to maximal HupA effect was delayed in the TBI group. The median time to maximum HupA inhibition in sham and TBI groups were 46.4 and 76.5 minutes, respectively ($p=0.03$). This is consistent with a quadratic trend comparison

that projects HupA-mediated cortical inhibition to last longer in injured rats (p=0.007). **Conclusions:** We show that (1) cortical GABA-mediated inhibition, as measured by ppTMS, decreases acutely after TBI, and (2) HupA restores lost post-TBI GABA-mediated inhibition, and (3) HupA-mediated enhancement of cortical inhibition is delayed after TBI. We anticipate that these and analogous experiments will enable improved dosing of neuropsychiatric medications after brain injury.

Title: Investigation of the effect of licofelon on absence epilepsy

Authors: *T. SAHIN, F. DEDE, N. ATES
Physiol. Dept., Kocaeli Univ. Med. Fac., Kocaeli, Turkey

Abstract: Usually beginning in childhood, absence epilepsy is one type of non-convulsive epilepsies. Recent studies have suggested that some specific inflammatory pathways may be related with the pathogenesis of epilepsy. Cyclooxygenase (COX) and lipoxygenase (LOX) are key enzymes involved in the arachidonic acid cascade, lead to the release of pro-inflammatory mediators. Licofelone is an anti inflammatory agent, reduces inflammation by blocking the COX and LOX pathway. The aim of this study is to demonstrate the possible anti-epileptic effects of licofelone on spike-wave discharges (SWDs) occurance in the absence epileptic Wistar Albino Glaxo/Rijswijk (WAG/Rij) rats strain. Twelve male six months old WAG/Rij rats, born and raised in the laboratory of Kocaeli University, served as subjects in our study. Three groups were created as, 10 mg/ kg/ ip licofelone (n=4) , DMSO control (n=4) and salin control (n=4). All rats were implanted with tripolar electrode sets which were placed on the frontal cortex, parietal cortex and cerebellum. The short and long term effects of licofelone administration were investigated on electroencephalography (EEG) recordings in basal conditions (one hour before the injections were done) and at 1. , 2. and 24. hours. DMSO administration did not cause any

differentiation in the number and total duration of SWD at 24.hour compared to the baseline and first hour. On the other hand licofelone administration reduced the number and total duration of SWD at 24. hour, compared to the both. According to our results; the long term effect of licofelon is reduction in the number and total duration of SWD in absence epilepsy. Licofelone may have anti-epileptic effects in absence epileptic WAG/Rij rats. Experiments of this study are currently in progress.

Title: Resampling technique effects for lasso in seizure prediction

Authors: *P.-N. YU[1], *P.-N. YU[2], C. N. HECK[1], C. LIU[1], D. SONG[2], T. W. BERGER[2]
[2]Biomed. Engin., [1]USC, Los Angeles, CA

Abstract: Patients with epilepsy suffer from unexpected and uncontrolled seizures and may be vulnerable in dangerous situations, such as standing on a staircase or swimming. To avoid such situations and enable patients to move to a safer place, it would be clinically useful to have a device to warn a patient an upcoming seizure. Seizure prediction using power spectrum, cross-correlation coefficients and autoregressive model coefficients as features along with lasso classifier scored around 0.8 areas under the classification curve (AUC), much better than random guessing having an AUC around 0.5. That score, however, cannot be an informative index to warn patients the upcoming seizures. A practical way for patients is a binary index which simply lets a patient know whether a seizure is coming or not. For binary classification, a common problem need to be resolved is that a predictor would give a predictive probability toward to the majority class as opposed to the minority class when the majority class (i.e. interictal data) outnumbers the minority class (i.e. preictal data). To counteract the problem of imbalanced data, this study proposes using resampling techniques to change the class distribution and make the data balanced. Random undersampling, random oversampling and SMOTE (synthetic minority oversampling technique) were used to resample features generated from the power spectrum, cross-correlation coefficients and autoregressive model coefficients and then lasso predictor was used to classify those features into interictal samples and preictal samples. The higher area under classification curve and Matthews correlation coefficients in 4 subjects with 53 sets of seizures suggest that SMOTE is the most appropriate resampling technique.

Title: Benzenamides as anticonvulsants

Authors: *S. E. MEZA TOLEDO, C. MARTÍNEZ APARICIO, E. FUENTES CAPISTRÁN, E. ROMERO MARTÍNEZ
Dept. de Bioquímica, Escuela Nacional De Ciencias Biológicas, IPN, Ciudad de Mexico, Mexico

Abstract: In an effort to discover novel anticonvulsants, we prepared and characterized several benzenamides and studied their anticonvulsant activity against seizures induced by convulsants drugs acting at the gamma-aminobutyric acid (GABA) neurotransmission, in CD-1 mice. Compounds 2-hydroxy-2-ethyl-2-phenyl butyramide (1), 2-hydroxy-2-(3'-trifluoromethylphenyl)butyramide (2), 2-hydroxy-2-(3',5'-bis(trifluoro methylphenyl) butyramide (3), 3-hydroxy-3-ethyl-3-phenyl pentanamide (4), 3-hydroxy-3-(3'-trifluoromethylphenyl) pentanamide (5) and 2-hydroxy-2-(3',5'-bis(trifluoromethylphenyl) pentanamide (6) were prepared using condensation reactions and characterized through infrared spectrophotometry and nuclear magnetic resonance spectroscopy. Each of the six compounds exhibited a significant anticonvulsant activity in mice against seizures induced by bicuculline, a competitive $GABA_A$ receptor antagonist, or thiosemicarbazide, a glutamate decarboxylase inhibitor, the enzyme which produces GABA. Incorporation of trifluoromethyl groups in the phenyl ring of compounds 2, 3, 5 and 6 increased their anticonvulsant activity respect non-halogenated compounds 1 and 4. The protection by benzenamides against seizures induced by convulsant drugs which block GABA neurotransmission suggests that they may be acting through GABAergic mechanisms. This study shows that benzenamides represent a new class of anticonvulsant compounds worthy of further development for potential antiepileptic therapy.

Title: Suppression of epileptic activity by lactate in subicular pyramidal neurons

Authors: *P. JORWAL, S. K. SIKDAR
Mol. Biophysics Unit, Indian Institue of Sci., Bangalore, India

Abstract: Epilepsy is a group of neurological disorders characterized by unprovoked recurrent seizures. Many evidences suggest that the subiculum in hippocampus plays an important role in initiation and maintenance of epileptic discharges. Lactate is neuroprotective against various types of brain damage including ischemic, excitotoxic, and mechanical insults. Increased cerebral metabolic activity during epileptic discharges is accompanied by excess brain lactate formation which reaches upto 5-6 mM during seizures. We investigated the effect of lactate on subicular pyramidal neurons after induction of epileptogenesis using 4AP-0Mg^{2+} in an in vitro epilepsy model in rats. We found that application of 6 mM lactate after epileptic induction reduced spike frequency and hyperpolarised the resting membrane potential of subicular pyramidal neurons in whole cell patch clamp experiments in acute hippocampal slices. G Protien-coupled receptor 81 (GPR81) is present in many regions of brain and it gets activated with 6 mM lactate, so we hypothesized that the effect of lactate might be through GPR81 receptors. Therefore the expression of GPR81 was checked using immunohistochemistry and it was found to be present in subicular pyramidal neurons. To study the signaling mechanism involved behind the effect of lactate, a specific GPR81 agonist- 3,5-dihydroxybenzoate and antagonist- 3-hydroxy-butyrate was used. Electrophysiological recordings showed reduction in spike frequency and hyperpolarization in the presence of agonist but not in presence of GPR81 antagonist. Our findings suggest a new role of lactate as a neuroprotectant acting via GPR81 receptor in subicular pyramidal neurons.

Title: Evaluating the anti-inflammatory effects of curcumin in Scn1a mouse models of epilepsy

Authors: *A. B. VAN DERVEER[1], S. B. DUTTON[2]
[1]Neurosci., Agnes Scott Col., Colorado Springs, CO; [2]Biology/ Neurosci. Program, Agnes Scott Col., Decatur, GA

Abstract: Epilepsy is characterized by recurrent seizures that are not provoked. There are various forms of epilepsy, varying in seizure severity and age of occurrence. Of particular interest are the epilepsy syndromes Genetic Epilepsy with Febrile Seizures Plus (GEFS+) and Dravet Syndrome (DS). Both syndromes are caused by mutations in the voltage gated sodium channel $Nav_{1.1}$ (gene *SCN1A*). Patients with these epilepsy syndromes experience severe febrile and afebrile seizures and are often refractory to current available pharmacological treatments. Therefore, there exist a need for the development of alternative treatment options to alleviate the frequency and/or occurrence of seizures in this patient population. Curcumin, the primary constituent of turmeric, has been shown to reduce cell death and decrease inflammation in experimental models of epilepsy. To determine if curcumin would be an effect treatment for patients with *SCN1A* mutations, we first determined the neuroprotective properties of curcumin in Pc12 cells using the glutamate toxicity paradigm. We then evaluated the ability of curcumin to alter the expression of the proinflammatory cytokines IL-6, IL-Iβ, and TNF-α in a mouse model of *Scn1a* epilepsy. Our results indicate alterations in expression and suggest the potential usages of curcumin in this patient population.

Title: Ferulic acid supplementation for management of depression in epilepsy

Authors: *T. SINGH, R. K. GOEL
Dept. Of Pharmaceut. Sci. and Drug Res., Punjabi University, Patiala, Patiala, India

Abstract: Neuroinflammation driven altered neurochemical milieu have been reported to play a significant role in pathogenesis of comorbid depression in epilepsy. Most of the antiseizure drugs (ASDs) such as levetiracetam, taigabine, topiramate have not been reported any significant effect in alleviating neuroinflammation, which may explain their ineffectiveness in ameliorating depression associated with epilepsy. The supplementation of antidepressants (ADs) attracts various pharmacokinetic and pharmacodynamic interactions with ASDs and was considered unsafe in epilepsy. This scenario pushes us to search therapies beyond ADs by critically exploring the disease mechanism. Thus, as suggested by our previous findings, anti-inflammatory phytotherapy (Ferulic acid) appears a promising adjuvant therapy with levetiracetam for effective and safe management of depression associated with epilepsy. Pentylenetetrazole kindling induced epileptic animals were treated with vehicle, levetiracetam (40mg/kg/day i.p.) and levetiracetam in combination with two doses of ferulic acid (40mg/kg; 80mg/kg)/day/p.o. for 15 days. Every 5^{th} day during the treatment, depression was evaluated and animals were administered pentylenetetrazole to evaluate the effect of different pharmacological interventions on seizure severity. The epileptic animals were reported decreased seizure threshold associated with comorbid depression. The treatment with levetiracetam was found ineffective in ameliorating the associated depression, however ferulic acid supplementation with levetiracetam ameliorated comorbid depression supported by restoration of elevated circulating corticosterone levels as well as proinflammatory cytokines (IL-1β, TNF-α) and indoleamine 2,3-dioxygenase activity in mice brain. Thus, suggesting supplementation of anti-inflammatory phytomolecules such as ferulic acid as safe and effective adjuvant therapy for the management of comorbid depression in epilepsy.

Title: Analysis of the anticonvulsant properties of thalidomide in mice

Authors: *A. M. ISLAS, C. CAMPOS-RODRÍGUEZ, A. ALVAREZ-GUERRA, E. RAMÍREZ-SAN JUAN
Physiol., Escuela Nacional De Ciencias Biológicas, Inst., Ciudad de México, Mexico

Abstract: Thalidomide was introduced in the 1950s as an antiepileptic drug. In 1957, it was commercialized as a safe sedative and it was widely used as an antiemetic. However, in 1961, it was withdrawn from the market because of its teratogenic effects. After thalidomide's output of the market, other outstanding pharmacological properties were discovered. Despite all of its therapeutic applications, none of them was used for the treatment of primary neurologic or psychiatric diseases, main reason why it was synthesized. Although there is history of the anticonvulsant effects of thalidomide in rats and antiepileptic effects in patients, there is no evidence of a systematic study of its anticonvulsant properties in mice, so in this protocol, we analyzed the possible protective effects of thalidomide against pentylenetetrazol (PTZ) and 4-aminopyridine (4-AP)-induced seizures, essential models in the studies of potential antiepileptic agents. Male CD1 mice were distributed randomly in 5 groups of 12 animals each one. The treatments for the groups were: carboxymethylcellulose 0.5% in phosphate buffer solution, sodium valproate dose of 300 mg/kg for PTZ model and dose of 400 mg/kg for 4-AP model, and thalidomide in three different doses (100, 200 and 400 mg/kg), all of the treatments were injected intraperitoneally. After 1 hour of the treatment with thalidomide (30 minutes for groups treated with sodium valproate), we administered subcutaneously the convulsant agents PTZ (90 mg/kg) or 4-AP (10 mg/kg) respectively and we evaluated variables such as latency and number of seizures, duration of seizures, percentage of animals convulsed and dead, and the latency of the death. In addition, a locomotor activity test was performed to prove the sedative effect of thalidomide, we used 4 groups of 12 mice each one, with a control group and 3 groups treated with the thalidomide's proved doses. The results show that thalidomide reduces significantly the locomotor activity starting from 100 mg/kg, due to significant decreases found on the ambulation and stereotypy time in mice treated with thalidomide, as well as a significant increase in the immobility time. Otherwise, the 4-AP model does not show a significant decrease in the percentage of convulsed and dead animals treated with thalidomide comparing with the control group. While the PTZ model shows favorable significant differences on the variables mentioned above in the groups treated with thalidomide compared with the control group. We found that

thalidomide (1) induces the typical sedative effects, (2) has not anticonvulsant effect in mice treated with 4-AP and (3) has anticonvulsant effect, dose dependent, in mice treated with PTZ.

Title: Gene therapy for epilepsy using non-integrating lentiviral delivery of an engineered potassium channel gene

Authors: *A. SNOWBALL, E. CHABROL, B.-L. CHANG, A. LIEB, M. C. WALKER, D. M. KULLMANN, S. SCHORGE
UCL Inst. of Neurol., London, United Kingdom

Abstract: Gene therapy is a promising treatment strategy for pharmacoresistant epilepsy. While several approaches have demonstrated preclinical efficacy, their suitability for clinical translation can be brought into question by poor vector or study design. Here we present a novel gene therapy vector designed and tested to maximize its translational potential. The vector encodes a Kv1.1 voltage-gated potassium channel gene, *KCNA1*, engineered to increase channel expression and reduce inactivation. To improve safety, the engineered *KCNA1* sequence is placed under a CAMK2A promoter to restrict transgene expression to excitatory neurons, and packaged into an integration-deficient lentivirus to reduce the risk of insertional mutagenesis. When injected into the rat visual cortex, our lentivector was well tolerated and drove transgene expression specifically within the target excitatory neuron population. In a randomized, blinded, preclinical trial, our treatment rapidly and persistently suppressed seizures in a rodent model of focal

neocortical epilepsy. This demonstration of therapeutic efficacy in a clinically-relevant setting, combined with the improved safety conferred by cell type specific expression and integration-deficient delivery, suggest our optimized gene therapy is well placed for clinical translation in the treatment of refractory focal epilepsy.

Title: Intramuscular midazolam, allopregnanolone and perampanel combination therapy terminates seizures in a rat model of DFP-induced status epilepticus

Authors: *A. DHIR, M. A. ROGAWSKI
Neurol., Univ. of California, Davis, SACRAMENTO, CA

Abstract: Status epilepticus (SE), a common neurological complication of organophosphate (OP) poisoning, is associated with brain damage and ultimately death. The first line therapies of choice are benzodiazepines, especially diazepam or midazolam. These drugs have reduced efficacy or are ineffective when administered following a delay after the onset of seizures. Allopregnanolone, a neurosteroid agent that acts on both synaptic and extrasynaptic GABA-A receptors, potentiates the effect of benzodiazepines on GABA-A receptors. Excessive cholinergic stimulation in OP poisoning leads rapidly to glutamate release, which plays a critical role in the seizure activity through an action on excitatory ionotropic glutamate receptors, including AMPA receptors. The present study evaluated the effect of addition of allopregnanolone and the AMPA receptor antagonist perampanel to standard therapy with midazolam in a DFP (diisopropylfluorophosphate) SE animal model. SE was induced in male Sprague-Dawley rats with a 4 mg/kg, SC injection of DFP, followed 1-min later by intramuscular administration of atropine (2 mg/kg, IM) and pralidoxime (25 mg/kg, IM). The triple therapy was administered 40 min after DFP administration. Animals were continuously monitored for a minimum of 5 h using video-EEG from cortically implanted electrodes. Behavioral seizures were scored using a modified Racine scale. DFP induced robust continuous behavioral and EEG seizures within minutes of its administration and was associated with high mortality. Midazolam (1.8 mg/kg, IM) was ineffective in terminating SE in these rats. Dual therapy with midazolam and allopregnanolone (6 mg/kg, IM) caused a reduction in the seizure score and cessation of

electrographic SE in 83% of the animals; the remaining animals continued to exhibit electrographic seizures and spikes. Triple therapy with midazolam, allopregnanolone and perampanel (2 mg/kg, IM) stopped both behavioral and electrographic SE within a few minutes of administration in 100% of the animals tested. There was no mortality in any of the treatment groups. Both dual and triple therapy resulted in sedation. In conclusion, addition of allopregnanolone or allopregnanolone plus perampanel to standard-of-care benzodiazepine therapy caused rapid seizure termination, and may represent promising approaches to manage OP nerve agent-induced SE.

Title: GIRK activator ML297 depresses epileptiform afterdischarges and seizure propagation in mouse brain slices using conventional and MEA extracellular recordings

Authors: *B. ZOU[1], W. CAO[1], C. PASCUAL[1], K. XIAO[1], C. LINDSLEY[2], D. WEAVER[2], X. XIE[1]
[1]AfaSci Res. Labs., Redwood City, CA; [2]Dept. of Pharmacol., Vanderbilt Univ., Nashville, TN

Abstract: G protein-gated inwardly-rectifying potassium (GIRK) channels have been implicated in various pathophysiological conditions in the nervous system including epilepsy, addiction, ataxia and Parkinson’s disease. Although this important channel has been intensively studied, a selective and potent activator was not available until the recent discovery of the GIRK biologic probe ML297, a selective direct activator of the GIRK channel. Field potential with a population of spikes were recorded extracellularly using a single glass pipette or multi channels array (MEA) in hippocampal or thalamus brain slices prepared from either young or old mice. In general, brain slices from aged animals were prone to generate epileptiform afterdischarges

following the initial population of spikes. Perfusion of low Ca^{2+} (0.2mM), 0 Mg^{2+} or the voltage-gated potassium channel blocker, 4-Aminopyridine (4-AP, 3 - 50µM), induced afterdischarges in slices from young animals and exacerbated seizure activity in slices from aged animals. All afterdischarges induced by these three conditions were completely blocked by ML297 (10 - 30 µM). A low dose of 4-AP (3 µM) induced multiple afterdischarges resembling those induced by low Ca^{2+} or 0 Mg^{2+}. A high dose of 4-AP (50 µM) induced more afterdischarges and also caused elevation of baseline, suggesting hyperpolarization. ML297 (10 - 30 µM) completely blocked low-dose 4-AP induced-afterdischarges without affecting the elevated baseline. Low Ca^{2+} (0.2mM) or 0 Mg^{2+} induced seizure activity propagating multiple sites in the slices containing the hippocampus and thalamus revealed by MEA recording. The seizure propagation was blocked with ML297 (10 - 30 µM). These results indicate that direct activation of GIRK powerfully depresses neuronal excitability and prevents synchronized firing in multiple recording sites. Direct GIRK activation is a potential new approach to treat partial and generalized seizures involved in the whole brain. **Key words:** 4-Aminopyridine, Epilepsy, GIRK, hippocampus, MEA, seizure

Title: Alterations of the cholinergic system during epileptogenesis in animal models of temporal lobe epilepsy

Authors: S. MELLER[1], C. BRANDT[1], J. KLEIN[2], *W. LOSCHER[1]
[1]Univ. of Vet. Med. Hannover, Hannover, Germany; [2]Goethe Univ. Frankfurt, Frankfurt, Germany

Abstract: Purpose: Epileptogenesis is often induced by brain insults so that patients at risk for epilepsy can be identified. Therefore, a prophylactic pharmacological intervention after the initial brain insult may be possible, but as yet this is an unmet clinical need. Based on recent data

on a potential role of the cholinergic system in epileptogenesis, pharmacological modulation of this system in the brain might provide a new approach to interfere with epileptogenesis. For instance, high extracellular levels of the excitatory neurotransmitter acetylcholine (ACh) seem to play an important role in initiation and maintenance of status epilepticus (SE) in the pilocarpine rat model of acquired epilepsy. However, its role as a putative pro-epileptogenic factor is not well understood and, therefore, is investigated in the present study.
Method: Extracellular alterations of hippocampal ACh concentrations were assessed during SE and post-SE epileptogenesis. For this purpose, two post-SE models of temporal lobe epilepsy were used in female Sprague Dawley rats: the pilocarpine model and a model with SE induction by prolonged electrical stimulation of the basolateral amygdala (BLA model). In both models the SE acts as the initial brain insult. We used microdialysis to sample extracellular fluid in the hippocampus before induction of SE (baseline), while SE was developing, and after termination of SE by diazepam and phenobarbital. In addition, we collected samples during epileptogenesis at day 1, 4, 8, and during the chronic phase 10 weeks after SE. Animals were video-EEG monitored for one week during both the latency and the chronic phase. ACh concentration was measured by high-performance liquid chromatography.
Results: First data show that levels of hippocampal ACh in rats increase rapidly during development of SE and decrease immediately below baseline values after termination of SE in both models. Concentrations of ACh during epileptogenesis, however, only show slight alterations in comparison to sham controls.
Conclusions: Our measurements do not reveal alterations in extracellular concentrations of ACh during epileptogenesis neither in the pilocarpine model nor in the BLA model. Latter was used to investigate a non-cholinergic stimulus of SE induction. However, alterations of cholinergic receptors during epileptogenesis cannot be excluded. This issue will be addressed by antiepileptogenesis studies with the muscarinic antagonist scopolamine.

Title: Protracted post-traumatic neuronal death in the developing hippocampus

Authors: *T. BALENA[1], Y. SAPONJIAN[2], K. J. STALEY[3]
[2]Neurol. Dept., [1]Massachusetts Gen. Hosp., Charlestown, MA; [3]Massachusetts Gen. Hosp., Boston, MA

Abstract: New fluorophores and microscopy techniques have made possible more detailed explorations of the process of neuronal death. In the present study we evaluated the death of neurons in a chronically epileptic in vitro preparation in which multiphoton microscopy could be performed over a period of several days. Organotypic hippocampal slice cultures were made from wild-type C57BL/6J mice, and imaged with transgenic fluorophores as well as the Na^+ dye SBFI. Organotypic slice cultures were prepared on P6 and incubated *in vitro* until use, with SBFI added 24 hours prior to imaging. Two-photon imaging was used to excite SBFI at both Na^+-sensitive and -insensitive wavelengths, allowing for the ratiometric determination of the $[Na^+]_i$. Immediately post-trauma, neurons had significantly higher $[Na^+]_i$ than has been reported in undamaged neurons. After a brief recovery period, $[Na^+]_i$ again rose to high levels and remained elevated for days. Elevated $[Na^+]_i$ followed decreased synthesis of virus-induced fluorescent proteins such as TurboRFP and genetically-encoded fluorescent indicators such as Clomeleon, preceded morphological changes such as cell shrinkage and retraction of processes, and coincided with increases in membrane permeability (allowing for the passive influx of dyes and stains such as propidium iodide) and elevated caspase activity (as indicated by FLICA positivity). The high $[Na^+]_i$ was mitigated by the activity of Na^+/K^+ ATPases, cation/Cl^- cotransporters, and Na^+/Ca^{2+} exchangers in order to support high rates of transmembrane Na^+ flux during epileptogenesis. Inhibition of COX-2 and the protein Bax significantly lowered $[Na^+]_i$, and antibody staining demonstrated that the Bax-inhibiting peptide V5 caused a reduction in the number of cells expressing Bax, with a homozygous Bax knockout mouse showing almost no expression. This suggests that an apoptotic pathway leading to an increase in cytoplasmic membrane permeability may be responsible for the rise in $[Na^+]_i$ and related changes. Overall, a stereotypical sequence of events preceded neuronal death by at least several days, and often over a week. This began with quenched emission of fluorescent proteins, and continued with dendritic retraction, elevation in $[Na^+]_i$, and terminal cell shrinkage. ATPase activity and secondary ion transport remained robust throughout this process. We are currently investigating the role of mitochondria in producing ATP in these neurons, as well as testing whether the mitigation of elevated $[Na^+]_i$ reflects a translationally useful neuroprotective effect or a specific effect on $[Na^+]_i$.

Title: Effects of inhibition of the mammalian target of rapamycin (mTOR) pathway in an organotypic slice culture model for temporal lobe epilepsy: Anti-epileptogenic properties of curcumin

Authors: *C. M. DRION[1], L. KOOIJMAN[1], E. ARONICA[2,1,3], E. A. VAN VLIET[2], W. J. WADMAN[1], P. CHAMEAU[1], J. A. GORTER[1]
[1]Swammerdam Inst. for Life Sciences, Ctr. for Neurosci., Univ. of Amsterdam, Amsterdam, Netherlands; [2]Dept (Neuro)Pathology, Academic Med. Ctr., Amsterdam, Netherlands; [3]Stichting Epilepsie Instellingen Nederland (SEIN), Heemstede, Netherlands

Abstract: Inhibition of the mammalian target of rapamycin (mTOR) pathway could be anti-epileptogenic in temporal lobe epilepsy (TLE), possibly via anti-inflammatory actions. We studied effects of rapamycin and curcumin, both mTOR inhibitors with anti-inflammatory properties, on epileptogenesis and inflammation in an in vitro rodent model of TLE: the organotypic slice culture. Slice cultures containing hippocampus and parahippocampal cortex were made from 6-day-old rat pups and maintained in culture for up to 3 weeks. Rapamycin (20 nM), curcumin (10 µM) or vehicle (0.05% DMSO) was added to the culture medium from day 2 in vitro onwards. Western blot analysis indicated that mTOR activation (shown as the phosphorylated-S6/S6 ratio) was suppressed after 1, 2 and 3 weeks by both rapamycin and curcumin. Whole cell patch-clamp recordings and field potential recordings were performed in the *cornu ammonis* (CA) 1 of cultures at 1, 2 and 3 weeks in vitro, without the drugs present in the recording medium (artificial cerebrospinal fluid). Immunohistochemistry was used to study the development of slice architecture and qPCR was used to study expression of inflammatory markers. Electrophysiological recordings revealed epileptic-like activity that developed over 3 weeks in vitro. In week 3, seizure-like events (SLE) could be detected in whole cell recordings from CA1 principal neurons. Field potential recordings revealed that these SLE were also present at the network level. The percentage of recorded CA1 neurons displaying SLE was 72.5% (29/40) in vehicle-treated slices, 52% (13/25) in rapamycin-treated slices ($p = 0.11$ compared to vehicle), and 25.8% (8/31) in curcumin-treated slices ($p < 0.01$ compared to vehicle). Preliminary qPCR results show lower values of inflammatory markers interleukin 1β (IL-1β), interleukin 6 (IL-6) and transforming growth factor β (TGF-β) after 3 weeks of treatment with both rapamycin and curcumin compared to vehicle, although the data did not reach significance. Our results show that curcumin can suppress SLEs in an organotypic slice culture model for TLE, suggesting anti-epileptogenic properties of curcumin in vitro that may be related to anti-inflammatory actions.

Title: Abeta oligomers: Biophysical properties predict cellular pathogenesis

Authors: *M. A. MOSS[1,2], K. M. PATE[1], D. N. DEAN[3], V. RANGACHARI[3]
[1]Dept. of Chem. Engin., [2]Biomed. Engin. Program, Univ. of South Carolina, Columbia, SC;
[3]Chem. and Biochem., Univ. of Southern Missisippi, Hattiesburg, MS

Abstract: Alzheimer's disease (AD), the leading cause of dementia in the elderly, is characterized by the presence of amyloid plaques in the brain parenchyma and cerebrovasculature. These deposits are comprised primarily of aggregated amyloid-β protein (Aβ). In particular, Aβ oligomers have emerged as the primary toxic agents responsible for early synaptic dysfunction and neuronal death. Despite observations that Aβ oligomers elicit a number of physiological responses, ranging from alterations in protein expression to cell death, the identity of the oligomer specie(s) accountable for these responses remains uncertain. Thus, it is important to characterize the physiological activity elicited by different Aβ oligomer species. To explore this relationship, we have paired biophysical characterization techniques for Aβ oligomers with a cell culture system that probes oligomer physiological acidity.
SH-SY5Y human neuroblastoma cells were used evaluate the manner in which large fatty acid derived oligomers (LFAOs) can influence Aβ-induced neuronal death, and results revealed an unexpected inverse dose-response. In contrast, activation of a broad spectrum of caspases correlated directly with concentration, suggesting distinct mechanisms for these two cellular responses. These observed differences in physiological activity were found to correspond to changes in oligomer biophysical properties associated with their self-propagative nature. Specifically, a concentration-dependent shift in LFAO size from a 12-mer to a 24-mer and the associated changes in surface hydrophobicity may alter the manner in which oligomers to interact with neuronal cells. This work reveals an important interplay between the biophysical characteristics of Aβ oligomers and their physiological activity. Further knowledge of these relationships has the potential to direct therapeutic strategies aimed at modulating Aβ oligomer formation.

Title: Generation and characterization of neurotoxic tau oligomers

Authors: *G. GHAG, D. V. CANTU, M. J. GUERRERO-MUNOZ, U. SENGUPTA, R. KAYED
Neurol., Univ. of Texas Med. Br., Galveston, TX

Abstract: Various studies have proposed that fibrillary aggregates of tau and other amyloidogenic proteins are neurotoxic and result in numerous neurodegenerative diseases. However, these studies usually involve sonication or extrusion through needles prior to the experimentation. As a consequence, these methods may fragment large aggregates in the sample, producing a mixture of aggregated species rather than intact fibrils; therefore, the results of these experiments may be reflective of other amyloidogenic species, such as oligomers and/or protofibrils. In order to investigate the effects of sonication on the aggregation of tau and other amyloidogenic proteins, fibrils were prepared and well-characterized, then sonicated and evaluated by various biochemical and biophysical methods to identify the aggregated species present. We found that indeed a mixture of aggregated species was present along with the fibrils indicating that sonication leads to impure fibril samples and should be analyzed with caution. Our results corroborate the previous studies showing that sonication of prion and Aβ fibrils leads to the formation of toxic, soluble aggregates. We also show that the oligomeric forms are the most toxic species, though it is unclear precisely how sonication causes oligomer formation. Results from our lab suggest that these small toxic oligomers produced by sonication, rather than the stable fibrillar structures, are prion-like in nature, acting as seeds to induce the misfolding of tau and other amyloidogenic proteins.

Title: Molecular insights into Aβ oligomer strains and phenotypic variations in AD

Authors: *V. RANGACHARI[1], D. N. DEAN[2]
[1]Chem. and Biochem., Univ. of Southern Missisippi, Hattiesburg, MS; [2]Chem. and Biochem., Univ. of Southern Mississippi, Hattiesburg, MS

Abstract: Widespread phenotypic differences observed among Alzheimer disease (AD) patients are one of the diverse clinical manifestations in all neurodegenerative diseases. Deciphering the molecular mechanisms that underpin such differences especially for an idiopathic disease is rather challenging. Aggregation of amyloid-β (Aβ) peptides has long been known as the key trigger in AD pathology. Polymorphism observed within the aggregation end products of Aβ fibrils seem to correlate with clinically observed pathologic variations, which has in part, corroborated the hypothesis that ‘conformeric strains’ of Aβ aggregates could manifest in distinct phenotypic outcomes. In our lab, we propose to understand this phenomenon in the context of whether and how the strains of low molecular weight oligomers could propagate their structure faithfully towards morphologically distinct fibrils with conspicuous pathological phenotypes. By biophysical investigations, we recently demonstrated that an Aβ42 dodecamer called Large Fatty Acid derived Oligomers (LFAOs) is able to quantitatively replicate at low concentrations, and at elevated concentrations, propagate their mesoscopic structure faithfully towards morphologically unique fibrils containing the discrete LFAO units. Furthermore, LFAO-seeded aggregates were able to selectively induce massive amounts of cerebral amyloid angiopathy (CAA) to transgenic CRND8 mice as opposed to unseeded or fibril seeded aggregates, which induced more parenchymal deposits. Results based on our model oligomer demonstrate that certain oligomeric strains could faithfully propagate their structure towards distinct fibrils and induce selective pathological phenotypes in the brain. Overall, these results bring forth important mechanistic insights into strain specific propagation of oligomers that have remained elusive thus far.

Title: HDAC6 inhibitor tubastatin A reduces pathological tau burden in the brain of transgenic AD mice model

Authors: *H. KIM[1], J. YANG[2], H. CHOI[3], W. LEE[4], I. MOOK-JUNG[5]
[1]Seoul Natl. Univ. (college of Medicine), Seoul-City, Korea, Republic of; [2]Seoul Natl. Univ. Col. of Med., Seoul, Korea, Republic of; [3]Seoul Natl. Abstract: A large portion of dementia patients are suffering from Alzheimer’s disease (AD). AD has two typical pathological phenotypes, neurofibrillar tangle (NFT) and amyloid beta (Aβ) plaques. NFTs are composed of tau protein aggregates. Tau undergoes diverse post translational modifications (PTMs) such as phosphorylation, ubiquitination, glycosylation and acetylation. PTMs are considered as important features of abnormal pathological tau. This study focused on acetylation by inhibiting HDAC6 (histone deacetylase 6) in AD pathology because acetylated tau contributed for AD pathogenesis. Axonal transport deficit caused by Aβ was recovered by up-regulating acetylation level by tubastatin A (TBA), HDAC6 inhibitor, in primary hippocampal neuron culture. Acetylation level was increased by intraperitoneal injection of TBA on AD mice model, resulting in significant recovery of memory deficits. TBA also reduced phosphorylated tau in sarkosyl-insoluble fraction and AT 180 immuno-reactive tau, but did not altered Aβ pathology and gliosis in these mice. With these data, we suggest targeting HDAC6 inhibition is a good therapeutic target by reduction of tau burden in AD.

Abstract: Plasma β-Amyloid (Aβ) is a potential candidate for an Alzheimer's disease (AD) biomarker because blood is an easily accessible bio-fluid, which can be routinely collected, and Aβ is one of the major hallmarks of AD pathogenesis in the brain. However, the association between plasma Aβ levels and AD diagnosis is still unclear due to the instability and inaccurate measurements of plasma Aβ levels in the blood of patients with AD. If a consistent value of plasma Aβ from the blood can be obtained, it might provide a clue whether plasma Aβ is a potential biomarker for AD diagnosis. We predicted the brain amyloid deposit by measuring the plasma Aβ levels. This cross-sectional study included 353 participants (215 cognitively normal, 79 with mild cognitive impairment, and 59 with AD dementia) who underwent Pittsburgh-compound B Positron Emission Tomography (PiB-PET) scans. We treated a mixture of protease inhibitors and phosphatase inhibitors (MPP) and detected plasma Aβ42 and Aβ40 (MPP-Aβ42 and MPP-Aβ40) in a stable manner using xMAP technology. MPP-Aβ40 and MPP-Aβ42/40 (MPP-Aβs) were significantly different between subjects with positive amyloid deposition (PiB+) and those with negative amyloid deposition (PiB-) (***$P < 0.0001$). Furthermore, MPP-Aβ40 (***$P < 0.0001$, $r = 0.23$) and MPP-Aβ42/40 (***$P < 0.0001$, $r = -0.23$) showed significant correlation with global PiB deposition (SUVR) respectively. In addition, our integrated multi-variable (MPP-Aβ42/40, gender, age, and Apolipoprotein E genotypes) logistic regression model proposes a new standard for the prediction of cerebral amyloid deposition. MPP-Aβ might be one of the potential blood biomarkers for the prediction of PiB-PET positivity in the brain.

Abstract: To elucidate the underlying mechanisms through which amyloid beta (Aβ) and tau contribute to Alzheimer's disease (AD) pathogenesis, we herein generated a novel animal model of AD. The ADLP^{APT} mice (AD-Like Pathology) carry mutated versions of human amyloid precursor protein, human presenilin-1, and human tau; at an early age, they exhibit accelerated neurofibrillary tangles together with senile plaques, neuronal loss in the hippocampal CA1 area, and memory deficits. To characterize the generated mice, we analyzed hippocampal proteome of the ADLP^{APT} mice using state-of-the-art quantitative proteomics strategy including 10-plex tandem mass tag (TMT). In addition, bioinformatics analysis of differentially expressed proteins (DEPs) revealed that ADLP^{APT} mice experienced age-dependent active immune responses and synaptic dysfunctions. Since the ADLP^{APT} mouse is the proper model to recapitulate the main features of AD pathogenesis, these proteome data based on hippocampus serve as a novel resource for researches of Aβ-tau axis and pathophysiological changes in vivo.

Abstract: Cerebral amyloidosis and severe tauopathy in the brain are key pathological features of Alzheimer's disease(AD), resulting in reactive gliosis and behavioral abnormalities of learning and memory. Despite a strong influence of the intestinal microbiota on neurodevelopment, neurological disorder and neurodegenerative diseases, a functional link between gut microbiota and AD remains unknown. Using mice that overexpress human mutant APP/PS1 and mutant tau, we examined the impact of the host microbiome on AD pathogenesis in this study. Fecal microbiota transplantation from a healthy wild type mouse into the diseased mouse caused the microbial re-colonization and ameliorated Aβ plaque and neurofibrillary tangle formation. In addition, we also observed attenuated glial reactivity and improvement of learning behavior in these recipient animals. These findings implicated that the gut microbial community of AD model mouse is involved in the disease development. It suggests that gut microbial dysbiosis and gut microbiota-derived factors might contribute to the pathogenesis of AD.

Title: Oligomer-to-oligomer propagation between wild-type and mutant amyloid-beta

Authors: *D. N. DEAN[1], S. Z. VANCE[2], R. P. CAMPBELL[1], M. A. MOSS[2], V. RANGACHARI[1]
[1]The Univ. of Southern Mississippi, Hattiesburg, MS; [2]The Univ. of South Carolina, Columbia, SC

Abstract: Soluble oligomers of amyloid-β (Aβ) are the primary toxic agents responsible for neuronal dysfunction in Alzheimer disease (AD) brains. While parenchymal deposits of Aβ characterize AD, deposition in the cerebral vasculature defines a condition called cerebral amyloid angiopathy (CAA). A high incidence of CAA exits among AD patients. Mutant forms of Aβ40 and Aβ42 (Arctic, Italian, and Dutch) are known to lead to severe CAA. The co-existence of AD and CAA could suggest an interplay between WT and mutant forms of Aβ. We have previously revealed that an oligomeric strain of synthetic WT Aβ42, called LFAOs, selectively induces CAA in transgenic mice. Furthermore, we have reported a novel self-propagating oligomer that forms distinct fibrils containing the repeating oligomer unit. Here, we report a detailed kinetic mechanism for LFAO self-propagation and also show oligomer-to-oligomer cross-propagation of WT LFAOs with Arctic (E22G) Aβ42. We also show the reverse-cross-propagation of E22G Aβ oligomers with WT Aβ42 monomers. Such a mechanism of propagation produces unique hybrid aggregates containing both WT and E22G Aβ. We have investigated the ability of such a hybrid aggregate species to induce apoptosis in human neuroblastoma cells. These results will be reported and discussed.

Title: Using Nilotinib to improve mitochondrial function in Alzheimer’s disease

Authors: *B. C. ALBENSI[1], R. S. TURNER[2], A. ADLIMOGHADDAM[1]
[1]Pharmacol. & Therapeut., Univ. of Manitoba, Winnipeg, MB, Canada; [2]Neurol., Georgetown Univ., Washington, DC

Abstract: Objective: Alzheimer's disease (AD) is a progressive age-related neurodegenerative disorder. AD is also associated with the build-up of amyloid beta (AB) plaques and tau neurofibrillary tangles (NFTs) in brain tissue; however, AD is considered a multifactorial condition. The earliest deficits in the pathological progression of AD actually seem to be caused by impaired mitochondrial function - before the robust appearance of AB and NFTs. In fact, current evidence suggests there are several mechanisms that can affect mitochondrial function that are associated with normal aging and/or linked with AD and other mitochondrial disorders. In this study, we investigated the effect of the FDA-approved anti-cancer drug, Nilotinib, on mitochondrial function and evaluated mitochondrial protein subunit expression. **Methods**: Astroglia cells (microglia and astrocytes) were isolated from the brain cortices of 7 day old C57BL/6 mice (control background strain) and 3xTg mice, a transgenic model of AD. After 2-3 weeks, cells were cultured on Seahorse XF24 analyzer (Seahorse BioSciences) plates at a density of 80,000 cells/well. After 24 hrs., the oxygen consumption rate (OCR) was measured in control vs. 3xTg cells in real time using the XF24 analyzer after dose-dependent treatment with Nilotinib (10 nm-1 uM). Additionally, Western blots were used to detect expression levels of key proteins involved in mitochondrial function: nuclear factor kappa B (NF-κB) p50/p105/p65/C-rel subunits, and manganese superoxide dismutase (MnSOD), cAMP response element-binding protein (pCREB), and select oxidative phosphorylation (OXPHOS) complex protein subunits in astroglia cells in the presence and absence of Nilotinib treatment. **Results**: Our data show Nilotinib enhances mitochondrial function putatively through the up-regulation of transcription factor NF-κB, and via changes associated with antioxidant MnSOD, pCREB, and OXPHOS signaling. Both basal and maximal respiration levels were significantly increased ($p<0.05$) after a 24 hr. treatment with 100 nM Nilotinib in astroglial cells from AD mice, but not in control cells. Additionally, we found Nilotinib increased expression of NF-κB p50/p105 subunits, and pCREB, and MnSOD in AD cells and NF-κB p50/p105 subunits and pCREB in control cells. Moreover, Nilotinib increased expression of mitochondrial complex (I-V) protein subunits in 3xTg cells, but not in control cells. **Conclusions**: These results highlight a potential role for Nilotinib in regulating astroglial bioenergetics in early-stage AD and suggest that energy metabolism may be an effective therapeutic target for preventing or treating AD.

Title: The action of nobiletin on brain mitochondria and yeast cells

Authors: *N. SHARIKADZE[1,2,3], N. JOJUA[1], E. ZHURAVLIOVA[1,4], N. HAMMAD[2,3], N. AVERET[2,3], M. RIGOULET[2,3], A. DEVIN[2,3], D. G. MIKELADZE[1,4]
[1]Inst. of Chem. Biol., Ilia State Univ., Tbilisi, Georgia; [2]Univ. Bordeaux, IBGC, UMR 5095, Bordeaux, France; [3]Inst. de Biochimie et Génétique Cellulaires, CNRS UMR 5095, Bordeaux, France; [4]I. Beritashvili Ctr. of Exptl. Biomedicine, Tbilisi, Georgia

Abstract: Citrus flavonoid nobiletin has anticancer, antiviral, neuroprotective, anti-inflammatory activities and depending on the cell types exhibits both pro- or anti-apoptotic properties that suggest the effect of this compound on the central metabolic systems, such as mitochondrial bioenergetics. **The aim** of our study was to investigate the possible target of nobiletin on the components of the mitochondrial respiratory chain. Our preliminary results have shown that one of possible target of nobiletin may be is complex I. Thus in this study we used isolated bovine brain mitochondria and two strains of yeast, whereas yeast foam strain exhibits two external NADH dehydrogenases and one internal NADH dehydrogenases that have no proton pumping activity, the yeast Candida utilis mitochondria exhibit a complex I that is proposed to pump protons and an external NADH dehydrogenase that does not pump protons. **Methods:** Analysis of mitochondrial enzymes' activities, estimation of respiration rate in bovine brain isolated mitochondria, mitochondrial membrane potential, ROS production were performed in bovine brain mitochondria to evaluate the direct effect of nobiletin on the mitochondrial bioenergetics, yeast strains culture medium and growth conditions, oxygen consumption assay. **Results:** We have found that nobiletin decreases oxygen consumption in the presence of glutamate and malate and increases in the presence of succinate. In parallel, nobiletin increases NADH oxidation, alpha-ketoglutarate dehydrogenase activities and alpha-ketoglutarate-dependent production of ATP. Additionally, nobiletin reduces the production of peroxides in the presence of complex I substrates and does not change succinate-driven peroxide formation. Besides, nobiletin induces transient elevation of membrane potential followed by mild depolarization. Nobiletin inhibits mitochondrial respiratory chain on whole cells in a similar fashion for Yeast foam and Candida utilis. This inhibition is partially alleviated after one hour of cells incubation in the presence of nobiletin. **Conclusion :** Nobiletin may act as a mild "uncoupler", which through activation of a-KGDH-complex and acceleration of matrix substrate-level phosphorylation maintain membrane potential at a normal level. This switch in mitochondrial metabolism could elevate succinate-driven oxygen consumption. We propose that nobiletin changes oxidative metabolism that results in respiration inhibition and could "adapt" cell to low-oxygen conditions.

Title: Perturbed sphingolipid metabolism in mouse models of type-2 diabetes and AD

Authors: *N. R. BHAT, V. PALADUGU, S. MOHANTY
Neurosciences, Med. Univ. South Carolina, Charleston, SC

Abstract: While metabolic disorders including Type 2 diabetes (T2DM) are considered risk factors for Alzheimer’s disease (AD), increasing evidence further supports insulin resistance (IR) and mitochondrial dysfunction as key pathogenic mechanisms underlying AD in common with T2DM. Since perturbed sphingolipid (SPL) metabolism leading to increased ceramide (Cer) is known to induce such metabolic defects in peripheral tissues, it was of interest to determine brain SPL profiles in a mouse model of T2DM (-induced with a high-fat diet plus low-dose streptozotocin regimen) and a transgenic (Tg) AD model. Sphingolipidomic analysis of hippocampi from T2DM mice using HPLC-MS/MS showed that although the increase in total Cers did not reach significance, there was a significant increase in the levels of C14-Cer (1.61pmol/mg tissue protein vs. 0.825pmol/mg non-diabetic control; *p=0.005*) and C16-Cer (17.33pmol/mg vs. 9.30pmol/mg; *p=0.012*) with a parallel increase in the expression of CerS6, the enzyme that produces these Cer species. There was a reciprocal decrease in sphingosine (Sph)-1 phosphate (S1P) levels implying imbalanced 'SPL rheostat'. SPL profiles of 10mo-old PDAPP Tg showed increased hippocampal levels of C16 (13.29pmol/mg vs. 9.30pmol/mg; *p=0.032*) and C18 Cer (700.41pmol/mg vs. 389.86pmol/mg; *p=0.036*) relative to wild-type mice. Interestingly, comparative analysis of SPL profiles of younger/adult (10mo) vs. aged (18mo) Tg mice revealed an age-related shift in Cer/S1P with a drastic reduction in total Cers (from 2136pmol/mg total Cers at 10mo to 742pmol/mg at 18mo) reflecting significant decreases in individual species, vs. a striking increase in S1P (23.86pmol/mg at 18mo vs. 1.42pmol/mg at 10mo). Immunoblot analysis indicated age-dependent increased expression of acid sphingomyelinase, a Cer-generating enzyme and acid ceramidase, which converts Cer to Sph, as well as Sph kinase (type-2), which phosphorylates Sph to produce S1P. The results will be discussed in terms of the potential role of Cer in IR and/or mitochondrial dysfunction in response to hyperglycemia/hyperinsulinemia (T2DM) and to Abeta (PDAPP Tg at disease onset) as well as, age-related shift in Cer/S1P potentially contributing to amyloid accumulation and disrupted autophagic flux associated with pathological progression.

Title: Ascorbate deficiency and altered glutamate clearance increase seizure susceptibility and cognitive decline in a mouse model of Alzheimer's disease

Authors: ***F. E. HARRISON**[1], S. DIXIT[4], D. J. MI[2], T. A. WARNER[3], J.-Q. KANG[3]
[2]Med., [3]Neurol., [1]Vanderbilt Univ. Med. Ctr., Nashville, TN; [4]Neurosci., Vanderbilt Univ., Nashville, TN

Abstract: Alzheimer’s disease is considered a disease of accelerated aging, and it is likely that pathogenic processes begin decades prior to changes in brain atrophy and cognitive decline are detected in clinic. Seizures are an important shared pathological feature of several neurodegenerative diseases that can dramatically increase cognitive decline by triggering apoptosis and cell death in hippocampus and cortical regions critical for learning and memory. Ascorbic acid (ascorbate, vitamin C) deficiency plays a critical role in pathogenic and metabolic changes that accompany seizures susceptibilty. Following glutamate uptake via the astrocyte glutamate transporter GLT-1, ascorbate is released into the synapse through volume regulated anion channels, and as such may be critical for neuronal protection against glutamate toxicity during seizures. Mice carrying familial Alzheimer’s disease mutations (APP_{SWE}/$PSEN1^{dE9}$) and ascorbate deficient mice, either through an inability to synthesize ascorbate (gulolactone oxidase knock-out mice; $gulo^{-/-}$), or through decreased ascorbate transport via heterozygous expression of the sodium vitamin C transporter, type 2 (SVCT2), are more sensitive to the seizure-inducing effects of kainic acid (10 mg/kg, i.p.) than wild-type mice, or mice with adequate ascorbate. Accelerated and prolonged response patterns were observed in both EEG and behavioral studies. Even a single mild seizure negatively impacted learning and memory in the water-maze in APP_{SWE}/$PSEN1^{dE9}$mice compared to wild-type controls, and retention of a new platform location was correlated with seizure onset latency in SVCT2-heterozygous and APP_{SWE}/$PSEN1^{dE9}$mice. Low brain ascorbate altered expression of genes involved in glutamate transport in the hippocampus, including GLT-1, GLAST and EAAC1. Chronic treatment with the beta-lactam antibiotic ceftriaxone (200 mg/kg, i.p.), which upregulates GLT-1, was protective against acute kainic acid-induced immobility. Glutamate toxicity may be particularly harmful in low ascorbate

conditions due to increased oxidative stress from mitochondrial dysfunction associated with Alzheimer's disease. Mitochondria isolated from $APP_{SWE}/PSEN1^{dE9}$mice consumed greater levels of oxygen and generated more reactive oxygen species. Furthermore, mitochondria isolated from the brains of SVCT2-heterozygous mice also generated greater levels of reactive oxidative species. Together these studies support the role of ascorbate deficiency in increased seizure susceptibility, which may be particularly relevant in Alzheimer's disease.

Title: Late-onset Alzheimer's disease is associated with inherent changes in bioenergetics profiles

Authors: *K. C. SONNTAG, W.-I. RYU, K. M. AMIRAULT, R. A. HEALY, A. J. SIEGEL, D. L. MCPHIE, B. FORESTER, B. M. COHEN
McLean Hospital, Harvard Med. Sch., Belmont, MA

Abstract: Body-wide changes in bioenergetics, i.e., energy metabolism, occur in normal aging and disturbed bioenergetics may be an important contributing mechanism underlying late-onset Alzheimer's disease (LOAD). We investigated the bioenergetic profiles of fibroblasts from LOAD patients (n = 10) and healthy controls (n = 20, 7 age-matched to LOAD and 13 younger subjects), as a function of age and disease. LOAD cells showed impaired respiratory consumption, and an abnormal redox potential, associated with reduced expression of the complex I subunit NADH:Ubiquinone Oxidoreductase Core Subunit 4 (MTND4), but not with mitochondrial mass, transmembrane instability, the production of reactive oxygen species, or DNA deletions. LOAD fibroblasts demonstrated a shift in energy production to glycolysis, despite an impairment in increasing glucose uptake in response to IGF-1. The increase of glycolysis and abnormal redox potential in LOAD appeared to be inherent, as they were disease- and not age-specific. Our findings support the hypothesis that impairment in multiple interacting components of bioenergetic metabolism may be a key mechanism contributing to the risk and pathophysiology of LOAD.

Abstract: Alzheimer’s diseases (AD) is the most common age-related neurodegenerative disorder affecting millions of people worldwide. Therefore, finding effective interventions and therapies is extremely important. AD is one of over 18 different diseases known as tauopathies, characterized by the pathological aggregation and accumulation of tau. During the disease, tau detaches from the microtubules and undergoes conformational changes leading to the formation of different types of aggregates and inclusions such as the well-characterized neurofibrillary tangles (NFTs). Recent evidences suggest that NFTs are the least toxic form of tau aggregates as compared to the smaller, soluble and dynamic tau oligomers. However, the structural and biological features of tau oligomers are still poorly understood due to their dynamic nature and conformational heterogeneity. Therefore, they can manifest in many conformations known as tau oligomeric strains. Studies focusing on the mechanisms underlying tau oligomeric strain formation and characteristics are challenging and could explain how the aggregation and accumulation of tau causes many disorders and diverse phenotypes in different individuals within the same disease. In preclinical studies, tau aggregates have been effectively targeted by immunotherapeutic approaches, aptamers and anti-sense oligonucleotides (ASO). We hypothesize that small molecules, able to target and modulate tau aggregation pathways, can be used to neutralize the formation and toxicity of the predicted large number of tau oligomeric strains, thus preventing the spread of pathology. Here, we used newly synthetized curcumin-like compounds to modulate tau oligomeric strains toxicity. We performed *in vitro* techniques including direct ELISA and Western Blot analyses as well as biophysical assays to characterize

tau oligomeric strains and their reactivity with tau oligomer specific polyclonal and monoclonal antibodies, T22 and TOMAs respectively, in the absence and presence of curcumin analogs. Our data suggest that novel curcumin derivatives are able to bind and alter tau aggregation pathways, resulting in the formation of tau structures with decreased toxicity. Based on these preliminary results, we propose that screening small molecule libraries against different oligomeric strains may lead to the discovery of new compounds which are effective against one or more tau strain and move the tau field forward. Finally, curcumin analogs could contribute both in the development of novel therapeutic approaches for AD and other tauopathies as well as imaging agents able to detect toxic tau oligomeric strains in the early stages of the disease.

Abstract: For a long time Tau pathology has been implicated in a number of neurodegenerative tauopathies such as Alzheimer’s disease (AD), progressive supranuclear palsy (PSP), and recently Parkinson’s disease (PD), dementia with Lewy bodies (DLB) and Huntington disease. However, each disorder is characterized by a unique combination of symptoms and other pathological hallmarks which regularly overlap. Large body of research suggest that oligomeric tau is the most toxic form of the protein and represent potent seeds causing spread of disease pathology, the focus has been on the meta-stable tau fibrillar strains. These oligomers have prion-like properties may play a disease specific role in the pathogenesis of neurodegenerative disorders. Therefore, it is of great importance to understand the ability of tau to form disease specific oligomeric strains, characterize them and investigate potentials mechanisms for their formation in different diseases and their potential role in disease phenotypes and pathophysiology. We isolated and characterized novel disease associated tau oligomeric strains

form PD, DLB, AD and PSP tissues and performed thorough biochemically, biophysically and immunological characterization. Moreover we studied the seeding potential in vitro and propagation in vivo. We found that disease associated tau oligomeric strains are capable of seeding propagating in vivo in a prion-like fashion and induced distinct speeding patterns and phenotypes in Htau mouse model. Amyloid-β, α-synuclein and other amyloidogenic proteins may affect tau strain characteristics and toxicity. The formation of different tau oligomeric strains may be responsible for different phenotypes that are disease-specific and/or overlapping. Tau and α-synuclein oligomers may have a toxic synergistic relationship. Tau and α-synuclein oligomeric structures represent main targets for therapeutic agents. Tau oligomeric strains may provide new insights into mechanisms of disease onset and diversity.

Title: The role of alpha-synuclein oligomeric conformations on tau aggregation and the formation of oligomeric strains

Authors: *U. SENGUPTA[1], J. GERSON[3], D. CASTILLO-CARRANZA[2], R. KAYED[1]
[1]Neurol., [2]Univ. of Texas Med. Br., Galveston, TX; [3]Neurosci. and Cell Biol., UTMB, Galveston, TX

Abstract: Each neurodegenerative disorder is characterized by a unique combination of symptoms and pathological hallmarks of proteinaceous aggregates. However, these aggregates and symptoms often overlap between different diseases. Tau pathology has been implicated in a number of neurodegenerative tauopathies such as Alzheimer’s disease (AD), progressive supranuclear palsy (PSP), and recently Parkinson’s disease (PD), dementia with Lewy bodies (DLB). I hypothesized that tau oligomers with prion-like properties may play a disease specific role in the pathogenesis of synucleinopathies .Therefore, I am investigating the role different synuclein oligomeric strains inducing the formation of different strains of tau oligomers in synucleinopathies and compare these different populations of tau oligomers with the classical AD and PSP brain-derived tau oligomers.

Despite the large body of research that shown oligomeric tau is the most potent and toxic form of the protein causing spread of disease pathology, the focus has been on the meta-stable tau fibrillar strains. Therefore, it is of great importance to understand the ability of tau to form disease specific oligomeric strains, characterize them and investigate potentials mechanisms for their formation in different diseases and their potential role in disease phenotypes and pathophysiology.
We isolated alpha-synuclein oligomers and tau oligomers form PD, DLB brain tissues. We also isolated tau oligomers from AD and PSP tissues and performed thorough biochemical, biophysical and immunological characterization of these brain-derived oligomers. Moreover we studied the seeding potential in vitro and propagation in vivo.
Different tau oligomeric strains induced by different synuclein oligomeric strains may be responsible for diverse and or overlapping phenotypes that are disease-specific. Tau and a-syn oligomers may have a toxic synergistic relationship. Thus oligomeric structures of these two pathogenic proteins and their interplay represent main targets for therapeutic agents.

Title: Development of sensitive, robust and quantitative assays for tau aggregation, phosphorylation and fragmentation, and their use for the characterization of tau pathology in transgenic mouse models

Authors: *C. THEUNIS, K. VAN KOLEN, B. VAN BROECK, G. DANEELS, M. VANDERMEEREN, M. MERCKEN

Abstract: Protein Tau, and its related pathology in Alzheimer’s disease (AD) and other tauopathies, is currently under investigation in clinical and preclinical studies as a target for immunotherapeutic interventions. In this regard it is becoming increasingly important to have validated and sensitive assays to measure the development of tau aggregation, phosphorylation and fragmentation in preclinical mouse models, but also as clinical biomarker tools for measuring therapeutic efficacy in humans.
We developed and compared immunoassays to measure tau aggregation, phosphorylation and fragmentation on different platforms; meso scale discovery (MSD), AlphaLISA and ELISA. We concluded that the MSD platform, using electrochemiluminescence detection, was the most

sensitive method, displaying the largest dynamic range and very low inter- and intraplate variation. Additionally a standard was developed for the aggregation assays to allow quantification of tau aggregation.
The MSD assays that were developed, were used to characterize the progression of tau pathology in the brains of different preclinical mouse models for tauopathy. In these transgenic models, mutated human tau is overexpressed in neurons leading to increased tau phosphorylation and to aggregation of tau into tangles. The models are used to evaluate efficacy of different tau-targeting treatments but caution has to be taken when interpreting the results. The tau transgene in the mouse models is continuously expressed in abnormally high amounts in the cells and results in pathology that does not fully mimic the gradual spatial progression of tauopathy in human disease. A detailed characterization of the development of tauopathy in the transgenic models is therefore needed to determine the optimal treatment window with the best estimated translatability to the human situation.
We characterized the onset and progression of tau phosphorylation and aggregation in 3 different tau transgenic mouse models, Tau.P301L, PS19 and P301S/Bl6. The assays that were developed can play a major role for the measurement of different Tau species, not only in brain homogenates, but also in body fluids with lower tau concentrations such as interstitial fluid, blood and CSF.

Title: Effect of oral and intrahippocampal administration of tideglusib on the regulation of tau phosphorylation, amyloid beta peptide and memory in diabetic rats

Authors: *T. PONCE-LOPEZ[1,2], M. ABASCAL-DIAZ[2], S. GARCÍA-ANDRADE[2], A. FLORES-VIZCAYA[2], D. MURILLO-REYES[2], A. VARGAS[2]

Abstract: Several studies have shown that patients with diabetes mellitus type 2 (DM2) are at increased risk of developing Alzheimer's disease (AD). Due to the profound socioeconomic

impact of diabetes and AD, understanding the mechanisms that could link both diseases is essential. Oxidative stress, dysfunction of glucose and cholesterol metabolism, and mitochondrial activity, among others, have been shown to be associated with diabetes and AD. In fact, patients with diabetes have cognitive impairment, beta amyloid peptide deposits and hyperphosphorylated tau protein, neuropathological features of AD. It has been associated with disorders of signal transduction of the insulin receptor (IR), termed "cerebral insulin resistance". This is analogous to peripheral insulin resistance, represented by impaired neuronal insulin functions; such as glucose regulation, growth, neuronal survival and remodeling, and assembly of microtubules. Insulin is known to regulate tau phosphorylation through the PI3K-Akt-GSK3 pathway of insulin receptor (IR), disruption of this balance leads to abnormal phosphorylation of tau and amyloid deposits. As a consequence, GSK3 inhibitors have emerged as potential therapeutic tools for neural diseases dealing the tiadiazolidindione-derivative tideglusib ATP-noncompetitive GSK3 inhibitor has been shown to induce beneficial effects in some clinical trials for AD treatment with cognitive decline. This study aims to evaluate and compare the effect (systemic and intrahippocamcal) of chronic treatment of tideglusib a memory impairments, disruption insulin receptor (IR), phosphatidylinositol-3-kinase/protein kinase B/GSK3 (PI3K-Akt/PKB-GSK3) signaling cascade, and abnormal phosphorylation of tau and Beta amyloid peptide in a DM2 model. Wistar rats were given streptozotocin (STZ; 45 mg/kg) and a high-fat diet. The oral administration of tideglusib will be for 14 days and stereotactic surgery will be performed for the intrahippocampal administration of tideglusib (50 mg/kg). The spatial memory were assessed by Morris water maze. We are quantifying peripheral insulin and lipids by the ELISA test, the insulin receptor, the Akt, GSK3 and tau protein will be through western blot in hippocampus. Results showed that tideglusib improved spatial learning and memory. This evidence will provide insight about the role PI3K-Akt/PKB-GSK3) signaling cascade of IR and the therapeutic benefits of tideglusib on abnormal phosphorylation tau and memory dysfunction to prevent the development of the AD in patients with DM2.

Title: SUVN-D4010, a potent and selective 5-HT_4 receptor partial agonist - effect of food, gender and age on human pharmacokinetics

Authors: *G. BHYRAPUNENI, K. MUDIGONDA, R. PALACHARLA, P. JAYARAJAN, R. ABRAHAM, R. SUBRAMANIAN, V. GOYAL, S. PANDEY, D. AJJALA, A. MOHAMMED, S. JETTA, R. NIROGI

Abstract: SUVN-D4010 is a potent, selective and orally bioavailable 5-HT_4 receptor partial agonist being developed for the treatment of Alzheimer's disease. SUVN-D4010 has shown to improve the episodic, working and emotional memory in preclinical animal models. At pharmacologically effective doses, SUVN-D4010 also produced significant increase in the brain acetylcholine and cortical sAPPα levels with simultaneous decrease in amyloid-β protein levels. SUVN-D4010 was studied in a single-center, multi-faceted, Phase 1 clinical trial (US IND) to evaluate its safety, tolerability, and pharmacokinetics after single and multiple ascending doses in healthy male subjects. For single dose evaluation, subjects were dosed with 5 mg, 15 mg, 30 mg or 45 mg of SUVN-D4010 tablets, once. For multiple ascending dose evaluation, the once daily doses of 10, 25 and 40 mg SUVN-D4010 were administered for 14 days. Additional Phase 1 clinical study (US IND) was carried out to evaluate the effects of food, gender and age on pharmacokinetics in healthy human volunteers. SUVN-D4010 was administered at a dose of 25 mg for evaluation of food, gender and age effect. Effect of food on SUVN-D4010 pharmacokinetics was evaluated under fed and fasted conditions in healthy adult male subjects. Effect of gender was evaluated in healthy adult male and female subjects under fasted conditions. For evaluation of age effect, SUVN-D4010 was administered under fasted conditions in healthy adult and elderly subjects. SUVN-D4010 was quantified in plasma using a validated LC-MS/MS method. Safety and tolerability was assessed throughout the study by the incidence and severity of AEs, abnormalities in vital signs, ECG and clinical laboratory assessments. SUVN-D4010 was well tolerated up to the highest tested dose of 45 mg single dose or 40 mg/day multiple doses in healthy male subjects. There were no clinically relevant or serious adverse events reported. During single ascending dose studies, the absorption of SUVN-D4010 was rapid and exposures (C_{max} and AUC) were dose proportional at the tested doses between 5 mg to 45 mg. During multiple ascending dose studies, Food, gender and age had no effect on human pharmacokinetics of SUVN-D4010. SUVN-D4010 has excellent safety and pharmacokinetic profile following single or multiple dose administration for 14 days in healthy male subjects. Projected efficacy concentrations of SUVN-D4010 achieved during multiple ascending dose studies and attained steady state on day 3 in healthy male subjects. Phase 2 enabling long term non-clinical safety studies for SUVN-D4010 are currently ongoing.

Title: Effects of glucocorticoid and adenosine agonist addition on glucocorticoid receptor translocation in SH-SY5Y cells

Authors: *D. E. OSEID[1], S. LEAR[2], A. S. ROBINSON[2]
[1]Neurosci., [2]Tulane Univ., New Orleans, LA

Abstract: Multiple lines of evidence suggest a chronic upregulation of circulating glucocorticoids may be correlated with cognitive deficits and Alzheimer’s disease (AD). Since glucocorticoids may have an impact on the lipid bilayer (Oliveira, T.G. 2016; Dindia, L., 2012), we hypothesized that the effect of glucocorticoids related to AD are an effect of fluidization of the lipid bilayer that then stimulates unliganded glucocorticoid receptor (GR) translocation to the nucleus. Here, we have monitored nuclear translocation of the cytosolic GR in SH-SY5Y human neuroblastoma cells using live-cell imaging of a GR-GFP fusion protein, reported in previous studies (Muglia L.J., 2002). In contrast to our expectation, fluidizing the membrane with 25 mM benzyl alcohol and depleting membrane cholesterol with 5 mM methyl-β-cyclodextrin did not induce nuclear translocation of GR-GFP. Interestingly, a BSA-conjugated dexamethasone (Dex-BSA) stimulated nuclear translocation of GR-GFP, but at a significantly slower rate than free cortisol. This result suggests that there is steroid action at the level of the membrane that induces unbound cytosolic GR to traffic to the nucleus, and this mechanism likely does not involve bulk changes to membrane bilayer rigidity. In follow-up studies, we investigated a possible interaction between the adenosine $A_{2A}R$ receptor and GR, which has been recently supported through evidence of transcriptional activation of GR with $A_{2A}R$ agonists (Batahala, V.L., 2016). In our studies, adenosine $A_{2A}R$ activation with the agonist CGS21680 was not sufficient to induce rapid translocation of GR-GFP after fifty minutes. Taken together, these results suggest there is an undetermined mechanism at the membrane for rapid, unliganded GR nuclear translocation that likely does not directly involve changes to membrane fluidity or $A_{2A}R$ signaling.

Title: The relationship between insulin resistance and amyloid pathology in diabetic AD model mice

Authors: *K. MATSUI[1], K. YAMAGUCHI[1], A. MANO[1], T. SANO[1], T. HASHIMOTO[1], T. KUBOTA[2], N. KUBOTA[2], T. KADOWAKI[2], T. WAKABAYASHI[1], T. IWATSUBO[1]
[1]Dept. of Neuropathology, Grad. Sch. of Med., [2]Dept. of Diabetes and Metabolic Diseases, Grad. Sch. of Med., The Univ. of Tokyo, Tokyo, Japan

Abstract: Alzheimer's disease (AD) is a progressive neurodegenerative disorder pathologically characterized by the deposition of amyloid β (Aβ) in the brain. Recent large-scale epidemiological studies revealed that type 2 diabetes mellitus (T2DM) increases the risk of dementia including AD. Although glucose intolerance and insulin resistance have been associated with augmentation of amyloid pathology, the molecular mechanism that links T2DM and AD in brain remains unclear. To elucidate the mechanism of AD progression by T2DM, we generated APP transgenic mice (A7 line) fed with high-fat diet (HFD) for 2, 6 and 12 months. HFD-fed A7 mice recapitulated diabetic phenotypes including elevated body weight, blood glucose and insulin levels, as well as insulin resistance. HFD feeding also induced increased expression of TNFα in the periphery. In addition, both 5 and 9-months-old HFD-fed A7 mice displayed reduced insulin response in the brains. Histopathological and biochemical analyses revealed that Aβ levels and amyloid deposition were significantly increased in the brains of 15-months-old HFD-fed mice compared to those fed with normal diet. To gain insights into the mechanism of increase in Aβ levels by metabolic overloading, we examined de novo Aβ secretion in acute slice cultures of the brains. Slices of 9-months-old HFD-fed A7 mice, at an age prior to the start of Aβ deposition, did not display changes in Aβ secretion. We next examined the effect of diabetic phenotypes on AD pathology in A7 mice genetically lacking insulin receptor substrate 2 (IRS-2), which displayed DM phenotypes in the periphery, i.e. hyperinsulinemia, hyperglycemia and insulin resistance. Although the Aβ levels did not change in IRS-2 deficient A7 mice at 5 months of age, Aβ deposition was significantly decreased in the brains of those at 15 months of age. IRS-2 deficient A7 mice also did not display changes in Aβ secretion level from brain slices at 5 months of age before Aβ deposition starts. In contrast to the HFD-fed A7 mice, A7 mice did not show elevated expression of TNFα in the adipose tissue by IRS-2 deficiency. We therefore examined whether metabolic loading would increase Aβ

deposition in IRS-2 deficient A7 mice. As a result, long-term HFD-feeding in IRS-2 deficient A7 mice led to a significant increase in Aβ deposition compared to those fed with normal diet. These results suggest that causal factors in the development of insulin resistance, e.g., chronic inflammation or stress responses, rather than hyperinsulinemia, hyperglycemia and reduced insulin responsiveness, might be associated with accelerated Aβ pathology in the brains of HFD-fed AD model mice.

Title: Insulin resistance mediates neuronal cell cycle re-entry, dysfunction and degeneration

Authors: *H. CHOW[1,2], A. CHENG[1], K. HERRUP[1]
[1]Div. of Life Sci., The Hong Kong Univ. of Sci. and Technol., Hong Kong, Hong Kong; [2]Inst. for Advanced Study., The Hong Kong Univ. of Sci. and Technol., Hong Kong, Hong Kong

Abstract: Several longitudinal studies have suggested that the risk of developing Alzheimer's disease (AD) is almost double in patients with insulin resistance. There are many paths to develop insulin resistance, and prolonged hyperinsulinemia is a major one. Although insulin import from the periphery to the brain is reduced in AD, this may yet be a consequence rather than the cause as hyperinsulinemia is most often observed before the disease onset. We wished to understand the chronic effect of high to saturated levels of insulin such as that seen during the early pre-clinical stages of AD when the blood brain barrier remains fully functional for insulin import. We find that wild type, non-diabetic mice with higher plasma insulin levels show elevated levels of insulin in cerebrospinal fluid, markers of neuronal insulin resistance and impaired immediate early gene responses upon novelty exposure. In culture, prolonged insulin exposure induces cell cycle re-entry, loss of neurite branching and reduced synaptic density. Our data suggest a direct pathogenic link between peripheral hyperinsulinemia, elevated cerebrospinal fluid insulin levels and neuronal dysfunction. The early appearance of hyperinsulinemia in the progression of AD leads us to hypothesize that the shutdown of the

blood brain barrier might be a homeostatic mechanism to avoid further insulin-induced neuronal damage.

Title: Folate metabolism disturbances in aging mice: A mouse model for sporadic Alzheimer's disease?

Authors: *R. BAHOUS[1], M. COSÍN-TOMÁS[3], L. DENG[1], M. PALLÀS[3], P. KALIMAN[4,5], R. ROZEN[1,2]
[1]Human Genet., [2]Dept. of Pediatrics, McGill Univ., Montreal, QC, Canada; [3]Pharmacol. Unit, Fac. of Pharmacy, Inst. de Neurociència Univ. de Barcelona (IBUB), Nucli Universitari de Pedralbes, Barcelona, Spain; [4]Inst. of Biomed. Investigation of Barcelona, Spanish Natl. Res. Council, Barcelona, Spain; [5]Ctr. for Mind and Brain, Univ. of California Davis,, Davis, CA

Abstract: Folate is an important B vitamin required for methylation reactions, nucleotide synthesis and maintenance of homocysteine at nontoxic levels. It is also essential for neuronal survival and neurotransmitter synthesis. Disturbances in folate metabolism can be genetic or dietary. They result in hyperhomocysteinemia (HHcy) and methylation disturbances, which may impact risk for Alzheimer’s disease (AD). There is a common polymorphism in an important gene in the folate pathway, methylenetetrahydrofolate reductase *(MTHFR),* which is required for homocysteine lowering and generation of the methyltetrahydrofolate used in methylation. Individuals homozygous for the *MTHFR* 677C>T polymorphism represent approximately 10-15% of many populations in North America and Europe, and have mild HHcy. Low folate intake can also result in HHcy. Many studies have used transgenic mouse models of AD in combination with low folate diets to elucidate the mechanisms by which HHcy can contribute to AD pathology. However, these models do not recapitulate the sporadic cases of AD. In our study, we fed our *Mthfr*-deficient mouse model with control or folate-deficient diets, to assess the impact of genetic and nutritional causes of HHcy, and their potential interaction, on features of AD. Memory was assessed in these mice at 8 and 10 months of age using the novel object recognition test (NOR) and the Y-maze, and anxiety was measured using the open field test. In the 10-

month-old mice, short-term memory impairment and decreased cortical expression of the neurotrophic factor *Brain derived neurotrophic factor* (*Bdnf*) was observed due to the *Mthfr*$^{+/-}$ genotype. We also observed increased expression of *Presenillin-1* (*Psen1*), in cortex of folate-deficient 10-month-old mice. Importantly, increased *Psen1* can result in amyloid plaque deposition, which is a hallmark of AD. Moreover, DNA methylation of the aforementioned genes was examined by pyrosequencing, and we observed a negative correlation between methylation levels at the promoter and gene expression. Additional experiments are in progress to further assess the specific contributions of disturbances in folate metabolism to AD pathology.

Title: SUVN-502 + donepezil + memantine (triple combination) for the symptomatic treatment of Alzheimer’s disease

Authors: *R. V. NIROGI, K. MUDIGONDA, J. RAVULA, G. BHYRAPUNENI, V. BENADE, N. MUDDANA, V. PALACHARLA, D. AJJALA, V. GOYAL, S. PANDEY, J. FERNANDES, R. ABRAHAM, P. JAYARAJAN, R. KAMBHAMPATI, K. KANDUKURI, A. SHINDE
Suven Life Sci., Hyderabad, India

Abstract: SUVN-502 is a pure 5-HT_6 receptor antagonist. SUVN-502 is being evaluated in a phase 2a multicenter, randomized, double-blind, parallel group, 26-week, placebo-controlled study. This study is regulated by US FDA. A total of 537 subjects with moderate Alzheimer's disease receiving stable doses of donepezil HCl and memantine HCl are being recruited. Subjects will receive placebo or SUVN-502 (50 or 100 mg) on top of stable doses of donepezil and memantine for 26 weeks. Rationale for phase 2 study: The effect of SUVN-502 + donepezil + memantine combination was evaluated in animal models for procognitive property (Morris water maze task), acetylcholine modulation (microdialysis) and theta modulation (electrophysiology). Co-treatment of SUVN-502 with donepezil and memantine significantly potentiated the procognitive effects when compared with memantine and donepezil treatment in the Morris water maze task. SUVN-502 potentiated the effects of donepezil and memantine combination in hippocampal acetylcholine levels and brain oscillatory activity. There were no significant changes in the exposures of SUVN-502 or donepezil or memantine. SUVN-502 + Donepezil +

Memantine represent a promising new approach for symptomatic treatment of Alzheimer's disease.

Title: SUVN-G3031: A potent and selective histamine H_3 receptor inverse agonist -effect of food, gender and age on human pharmacokinetics

Authors: *N. MUDDANA, G. BHYRAPUNENI, K. MUDIGONDA, P. JAYARAJAN, R. ABRAHAM, R. SUBRAMANIAN, V. GOYAL, S. PANDEY, D. AJJALA, A. SHINDE, J. RAVULA, R. NIROGI
Suven Life Sci. Ltd., Hyderabad, India

Abstract: SUVN-G3031, a potent and selective histamine H_3 receptor inverse agonist is being developed for the treatment of cognitive deficits associated with Alzheimer's disease. SUVN-G3031 demonstrated cognitive enhancement and relevant neurochemical changes without affecting the sleep in rodent models. SUVN-G3031 was studied in a single-center, multi-faceted, Phase 1 clinical study (US IND) to evaluate the effects of food, gender and age on pharmacokinetics in healthy human volunteers. SUVN-G3031 was administered at a dose of 6 mg for evaluation of food, gender and age effect. Effect of food on SUVN-G3031

pharmacokinetics was evaluated under fed and fasted conditions in healthy adult male subjects. Effect of gender was evaluated in healthy adult male and female subjects under fasted conditions. For evaluation of age effect, SUVN-G3031 was administered under fasted conditions in healthy adult and elderly subjects. SUVN-G3031 was quantified in plasma using a validated LC-MS/MS method. Safety and tolerability was assessed throughout the study by the incidence and severity of AEs, abnormalities in vital signs assessments. SUVN-G3031 was well tolerated up to the highest tested dose of 20 mg/day single dose or 12 mg repeated dose in healthy adult subjects. There were no clinically relevant or serious adverse events reported by any subject during the Phase 1 study. During single ascending dose studies, exposures (C_{max} and AUC) of SUVN-G3031 were observed to be dose-proportional at the tested doses between 0.1 mg to 20 mg. SUVN-G3031 was tolerated up to the highest tested dose of 20 mg/day following single oral administration in healthy adult subjects. During multiple ascending dose studies, SUVN-G3031 has shown an excellent pharmacokinetic profile. SUVN-G3031 achieved the projected efficacy concentrations and attained steady state on day 6 in the tested population. Food, Gender and Age had no effect on human pharmacokinetics of SUVN-G3031. There were no clinically relevant or serious adverse events observed at any of the doses tested. SUVN-G3031 has excellent safety and pharmacokinetic profile after single and multiple dose administration for 14 days in healthy human volunteers. Projected efficacy concentrations of SUVN-G3031 were achieved during multiple ascending dose studies and attained steady state from day 6 in healthy male subjects. Food, Gender and Age had no effect on human pharmacokinetics of SUVN-G3031. Phase 2 enabling long term non-clinical safety studies for SUVN-G3031 are currently ongoing.

Abstract: Frontotemporal dementia (FTD) is the second most frequent type of presenile dementia. Loss-of-function mutations in the progranulin gene (GRN) reduces levels of the secreted glycoprotein Progranulin (PGRN) and causes FTD. Our goal is to discover small molecules that normalize PGRN protein levels in the brain, protecting GRN haplo-insufficient individuals from FTD. We screened 200,000 novel small molecules for the ability to increase PGRN in vitro utilizing a luciferase reporter. Of the 200,000 compounds, 2144 compounds showed at least a two-fold increase in luciferase activity. We chose 1280 of the most active compounds for a confirmation of activity and investigation of toxicity. In a second screen the top 130 compounds with the highest activity were tested in Neuro2A cells. We found a total of nine hits which increased PGRN levels by at least two-fold. We then used osmotic pumps to deliver our top compounds directly into the brain using intracerebroventricular cannulation. GRN Heterozygous mice were treated with vehicle (artificial cerebrospinal fluid+10% DMSO) or compound for seven days. Tissue samples were probed for changes in PGRN protein levels. Four of the nine compounds showed significant increases in PGRN levels compared to vehicle. We next investigated the pharmacokinetic properties of our lead compounds. The initial findings revealed that all three compounds penetrated the blood brain barrier and accumulated at pharmacologically effective levels. Medicinal chemistry refinement is ongoing.

Title: P. cattleianum extract prevents neurochemical alterations observed in metabolic syndrome

Authors: *A. G. BARSCHAK[1], P. S. OLIVEIRA[2], M. S. P. SOARES[2], N. P. BONA[2], P. G. DA SILVA[2], J. S. CARDOSO[2], C. L. LENCINA[2], R. M. SPANEVELLO[2], F. M. STEFANELLO[2]
[1]DCBS, UFCSPA, Porto Alegre, Brazil; [2]Univ. Federal de Pelotas, Pelotas, Brazil

Abstract: Metabolic syndrome (MetS) is characterized by a combination of cardiovascular risk factors including hyperglycemia, insulin resistance, dyslipidemia and visceral obesity. Data in the literature suggests that increased energy intake can enhance the production of reactive oxygen species, which has been directly related to MetS complications and to development of neurological and neuropsychiatric disorders such as depression. Besides, acetylcholine-mediated neurotransmission is crucial to central nervous system function. Its inhibition is associated to progressive deterioration of cognitive, autonomic and neuromuscular functions. Bioactive compounds of *P. cattleianum* have demonstrated beneficial effects on alterations observed in the MetS. In the present study we investigated the effect of *P. cattleianum* fruit extract in neurochemical and behavioral parameters in rats fed with highly palatable diet (HPD). Rats were divided into 4 experimental groups and treated for 150 days: (1) received standard chow and water orally, (2) standard chow and *P. cattleianum* extract (200 mg/kg, p.o), (3) HPD and water orally, (4) HPD and *P. cattleianum* extract (200 mg/kg, p.o). Our results showed that HPD consumption increased the immobility time in forced swim test (FST) indicating depressive-like behavior. However, treatment with *P. Cattleianum* extract prevented this behavior alteration. We also observed that HPD did not modify the locomotion demonstrating that the increase in immobility time in FST is not related to the locomotor activity. In addition, *P. cattleianum* treatment prevented increased acetylcholinesterase (AChE) activity in prefrontal cortex caused by HPD consumption. In summary, our results demonstrate that *P. cattleianum* extract showed antidepressant-like and neuroprotective effects in an animal model of MetS, suggesting that *P. cattleianum* extract can be a potential therapeutic agent for individuals with this syndrome.

Title: Anticonvulsant and neuroprotective effects of cannabidiol in immature rats

Authors: *L. K. FRIEDMAN[1], J. P. WONGVGRAVIT[2]
[2]Cell Biol. & Anantomy, [1]New York Med. Col., Valhalla, NY

Abstract: Appropriate antiepileptic drugs (AEDs) for specific age groups with epilepsy are presently unavailable due to poor understanding of how early-life seizures affect the brain at critical stages in development. Cannabidiol (CBD), the major non-psychoactive constituent of marijuana which has low affinity for cannabinoid receptors, reduces seizure frequency in adult experimental epilepsy models by unknown action. Less is known about the anticonvulsant effects of CBD in the immature brain. Two models were examined on postnatal (P) day 20. Kainic (KA) acid was either injected unilaterally into the hippocampus (KAih) or systemically (KAip) to induce status epilepticus (SE). Intrahippocampal CBD was co-administered (KA+CBDih) or followed KAih after onset to SE (KA/CBDih). Sytemic CBD followed KAip 30 min after onset to SE (KA/CBDip). KA+CBDih was most efficacious to lessen seizure severity but seizures were also attenuated by KA/CBDih or KA/CBDip. The electroencephalogram (EEG) revealed reduced spike amplitude and frequency without high burst ossicillations. Hyper-locomotion of open field activity was reversed by KA+CBDih and systemic post-seizure delivery. Nissl stains and NeuN immunohistochemistry revealed neurons throughout the hippocampus of KA+CBDih treated animals had regular morphology and most resembled the controls. Similarly, after KA+CBDih, a significant percentage of reactive astroglia were less intense and fewer in number within the vulnerable CA1 and deep proliferative dentate hilar regions compared with the other treatment groups. Somatic labeling of interneurons with PV was hardly affected after KAip. In contrast, dendrtic staining was reduced or absent after KAih or KA/CBDih and increases in ipsilateral dendritic/ neuropil density were observed. Cannabinoid receptor 1 (CB1) immunodensity was minimally affected after KAih or KA/CBDih and even more steady after KA+CBDih, which contrasts elevations observed after KAip. Intrahippocampal seizure data suggest that CBD is more effective in certain types of epilepsies with hippocampal origin and/or focus rather than when extra-hippocampal amygdala/cortical structures are triggered by systemic treatments. Higher and more frequent dosing may increase peripheral efficacy. The developmental stability of CB1 expression in both seizure models implies that they play important neuroprotective roles in regulating the hippocampal seizure threshold at young ages before neurotoxicity becomes progressive and irreversible.

Abstract: Background: Niemann-Pick disease type A (NPD-A) is a lysosomal storage disorder characterized by neurodegeneration and death in early childhood. It is caused by loss of function mutations in the gene encoding acid sphingomyelinase (ASM), which hydrolyzes sphingomyelin. Enzyme replacement therapy has proven successful to treat NPD-A peripheral symptoms but not brain pathology. To date, gene therapy using direct brain injection of different serotypes of adeno associated viral vectors (AAV) carrying a functional copy of the human ASM cDNA has showed limited success in the knockout ASM mouse model (ASMko). As well, few experiments using the same strategy have been performed in non-human primates (NHP), but levels of transfections were only limited to the injection site and inflammation was found.
Objective: We evaluated the safety of cerebellomedullary cistern (CM) injection of AAV serotype 9 encoding human ASM (AAV9-hASM) in NHP and its therapeutic benefit in the ASMko mouse model.
Methods: AAV9-hASM vector was delivered into the CSF throughout the CM into NHP and ASMko mouse model. After 21, 30 and 90 days, monkey brains were collected and levels of transduction were evaluated by histological immunostaining. Standard immune markers as vascular infiltration, microglia reaction or astrocytic activation were also evaluated as part of the safety assessment. Similar vector dose (adjusted by weight) was injected into ASMko CM also

by stereotactic-guided injection. Behavioral, biochemical and enzymatic analyses were performed to assess efficacy.
Results: AAV9-hASM CM injection in NHP resulted in transgene expression in brain cells along the anteroposterior axes, including cerebellum, without significant inflammatory response in all survival times evaluated. ASMko mouse experiments revealed that vector dose tested was efficacious, showing motor and memory skills improvement, with no sphingomyelin accumulation and neuronal death.
Conclusion: Our results support CM injection for future AAV9-based clinical trials in NPD-A as well as other monogenic lysosomal storage brain disorders.

Title: Effects of a specific Histone Deacetylase (HDAC) inhibitor, on neuronal health and rescue of transcription in a primary neuronal culture model of Huntington’s disease

Authors: *A. N. ABDO[1], M. LOPES[1], F. PARASKEVOPOULOU[2], C. ROSENMUND[2], F. YILDIRIM[1]
[1]Psychiatry and Psychotherapy, [2]Neurosci. Res. Ctr., Charité – Universitätsmedizin Berlin, Berlin, Germany

Abstract: Huntington’s disease (HD) is a progressive, fatal, autosomal dominant hereditary, neurodegenerative disorder which affects the central nervous system. Previous studies showed massive downregulation of many key genes in HD models. Here we investigated the molecular and the morphological effects of a histone deacetylase inhibitor (HDACi) targeting HDAC class I subtype 1 and 3. We investigated its potential beneficial effects in HD cell culture model and evaluated its effects on downregulated key genes and neuronal morphological parameters (Soma size, dendritic length and synapse number). We used Lentivirus-expressing mutant- (Mut-Htt) and wild-type-Huntingtin (WT-Htt) exon 1 in neuronal cultures as an *in vitro* model of HD. After 24 hour incubation with the HDAC inhibitor, several cell cytotoxicity/viability tests were performed and reverse transcriptase quantitative real-time PCR was carried out to assess levels

of expression of five key genes (BDNF, Egr1, Arc, C-fos and synaptophysin) in cortical cells and (Darpp32, DrD1, DrD2, synaptophysin, Egr1) in striatal cells. We also checked the differences in morphology and synaptic density in the cultures upon HDACi treatment via staining the cultures with neuron-specific marker MAP2 and vesicular GABA transporter VGAT. We detected a significant difference in the expression levels of the tested genes known to play a crucial role in growth and differentiation of both cortical and striatal neurons. We detected beneficial effects of HDAC inhibition where the cell viability was enhanced in HDACi-treated mutant Htt cultures compared with untreated mutant Htt cultures. We also detected significant beneficial effects on the morphology of the neurons and the expression of VGAT, comparing the mutant cultures versus mutant treated cultures, suggesting promotion of synaptic connectivity by HDACi treatment. We are currently conducting further assays to fully assess the neuroprotective potentials of this specific HDAC inhibitor in the R6/1 model via a battery of behavioural assessments, mouse brain imaging tools and RNA sequencing to elucidate the extent of the transcriptional rescue by this agent.

Title: The Impact of running wheel exercise on ceramide-induced cognitive decline

Authors: *C. WANG[1,3,5], J. HOFMEISTER[1,3], C. J. BILLINGTON[2,6,5], C. M. KOTZ[7,4,5,1]
[2]Endocrinol., [1]Minneapolis VA Hlth. Care Syst., Minneapolis, MN; [3]Food Sci. & Nutr., Univ. of Minnesota, St. Paul, MN; [4]Neuroscience, Food Sci. & Nutrition, Integr Physiol., Univ. of Minnesota, Minneapolis, MN; [5]Minnesota Obesity Ctr., Minneapolis, MN; [6]Med., Univ. of Minnesota, Minneapolis, MN; [7]GRECC (11G), Mpls VAHCS and Univ. of Minnesota, Minneapolis, MN

Abstract: Background: Consumption of diets high in saturated fats is an important risk factor for cognitive impairment. Ceramides, synthesized de novo from saturated fatty acids, are elevated in brain along with aging and Alzheimer's disease, and an increased ceramide level has been

suggested as a biomarker for mild cognitive impairment and AD. Previously we found that: 1) a high fat diet impaired rodents' learning ability; 2) reducing ceramide production (with myriocin) attenuated palmitate-induced apoptosis in hippocampal cells *in vitro*; 3) ceramide directly reduced viability in hippocampal cells *in vitro*; 4) *in vivo* peripheral injection of C6-ceramide led to cognitive decline; and 5) exercise could reverse high fat diet impaired cognitive decline . These data suggest mediation of ceramide in high saturated fat induced cognitive decline, and potential protection of exercise. In this experiment, we determine the impact of exercise on peripheral ceramide induced cognitive decline and immunohistochemistry change in the hippocampus.
Methods: SD male rats were divided into vehicle (Veh) and C6-ceramide (C6, 2 μg/kg) treatment groups, based on even distribution of body weight, fat mass, and baseline of cognitive evaluation (task for two-way active avoidance, TWAA). The treatment was given (IP) every other day for 14 injections. Then based on even distribution of cognition scores and body mass, both Veh and C6 groups were further divided into sedentary (Sed) and running wheel exercise (RW) subgroups: Sed_Veh, RW_Veh, Sed_C6, and RW_C6. TWAA was tested once per week. Following 4-week of exercise the animals were perfused, and hippocampal immunohistochemistry is processed for ceramide-induced hippocampal injury and cellular signaling for exercise-induced cognitive improvements.
Results & Conclusion: learning impairment occurred at three-week of IP ceramide injections, indicated by increased escape latency and failures (no escape response) vs. Veh treatment. Compared to Sed_C6 rats, RW_C6 rats showed significant reduction in escape latency and failures since week two of exercise. RW_C6 rats also showed significant reduction in escape latency and failures, compared to their pre-intervention baseline. Thus exercise exerts a neuroprotective effect against cognitive decline induced by ceramide. Currently the analysis for hippocampal immunohistochemistry is in processing.

Abstract: Impaired BDNF - TrkB signaling has been implicated in the pathology of neurodegeneration, and in particular Huntington's Disease (HD), a monogenetic neurodegenerative disorder caused by a CAG expansion in the HTT gene. Therefore, therapeutic strategies aimed at identifying TrkB agonists are actively being pursued. Whereas assays measuring downstream effects of TrkB activation (such as the CellSensor platform) are available to support such efforts, assays measuring TrkB activation more proximally thus far are not. We therefore aimed to develop immunoassays for quantitatively measuring TrkB phosphorylation in cell and tissue lysates using the Mesoscale Discovery (MSD) platform, and to apply these in cell-based assays for low-throughput characterization of TrkB agonism of potential therapeutics. A range of antibodies was first characterized by western blot, using lysates of CellSensor Trk reporter cell lines and rodent brain samples stimulated with BDNF or vehicle. Selected antibodies were then tested in MSD assays in different combinations and orientations for capture and detection, resulting in selection of one combination for detection of phosphorylated TrkB (p-TrkB) and two combinations for total TrkB. Applying these TrkB MSD assays we found a time and concentration-dependent increase of TrkB phosphorylation in CellSensor TrkB cells and rat primary neurons upon treatment with BDNF. Similar TrkB activation kinetics were found with an agonist TrkB antibody (38B8). To assess downstream signaling induced by BDNF and 38B8 antibody we also configured commercially available AlphaLISA bead-based immunoassays for measurement of total and phosphorylated ERK1/2 and Akt. Compared to TrkB phosphorylation, kinetics were similar for Akt phosphorylation but delayed for ERK phosphorylation. In conclusion, we successfully developed sensitive immunoassays for quantification of TrkB phosphorylation that can be used to show target engagement of TrkB agonists in cell lysates and preclinical samples.

Title: Age related changes in cognition in a rodent model of hydrocephalus

Authors: *D. L. POETA[1], H. A. BOUNDS[1], P. M. KLINGE[3], R. D. BURWELL[1,2]
[1]Cognitive, Linguistic and Psychological Sci., [2]Dept. of Neurosci., Brown Univ., Providence, RI; [3]Dept. of Neurosurg., Rhode Island Hosp., Providence, RI

Abstract: Normal pressure hydrocephalus (NPH) is a cerebrospinal fluid (CSF) disorder resulting from abnormal CSF absorption and its accumulation in the ventricles of the brain. The accumulation of CSF results in enlarged ventricles (ventriculomegaly) and damages surrounding brain tissue. NPH patients exhibit cognitive impairments in memory and executive functioning as well as gait abnormalities such as short, shuffling steps and wide stance (reviewed in Peterson et al. 2016). Because NPH is highly correlated with age and the aging brain is vulnerable to disease and dementia (Li et al, 2013; Martinelli et al, 2013), age may play an important role in the severity of NPH symptoms. The nature and causes of these symptoms, particularly the cognitive dysfunction, is still unknown, and there are limited studies using animal models of NPH that address this open question. Previously, the rat kaolin model of hydrocephalus was shown to cause ventriculomegaly and anatomical changes involving hippocampal structures (Klinge et al, 2003) that are similar to those found in NPH patients. In the present study, we employed this model to examine the cognitive and gait impairments associated with NPH and whether such deficits are more severe with age of onset.
Adult male Long Evans rats were separated into two age groups, young and middle-aged. The young cohort of animals was 3 months old (n=13), while the middle-aged cohort was 10 months old (n=13) at the time of surgery. Rats received either a sham surgery or kaolin injection via the cisterna magna to induce hydrocephalus. After recovery, cognitive and motor impairments were assessed with a battery of tasks: 3-Dimensional Spontaneous Object Recognition (3D SOR), gait analysis, open field, and contextual fear conditioning. All rats underwent an MRI scan to verify ventricle size. In both cohorts, NPH rats showed gait deficits such as shortened stride length and increased number of falls. Interestingly, in the 3D SOR task, recognition memory was significantly impaired in middle-aged NPH animals, but not in the young NPH animals. Because there was no significant difference in locomotor activity, this decline in performance can be attributed to age. Our interpretation is that younger subjects are more resilient to cognitive impairments. We will continue to investigate this effect of age by using other cognitive tasks involving regions known to be affected by NPH, such as the hippocampus, parahippocampal, and prefrontal cortices.

Title: Diurnal variations of glutamateric system in brain motor cortex in rat

Authors: *F. E. ROJO[1], V. ARRIAGA[2], R. GUEVARA-GUZMÁN[2], M. MARTÍNEZ-VARGAS[2], L. NAVARRO[2], E. COBALLASE-URRUTIA[3], L. CARMONA-APARICIO[3]

Abstract: Introduction: The glutamatergic system is the principal excitatory factor in the brain, is involved in process like excitotoxicity after a Traumatic brain injury (TBI)or a ischemic process is a major public health problem. Previous data from our laboratory suggests that recovery from a TBI depends on the time that TBI is induced. The study shows how the glutamic system varies both in the expression of the NMDA receptor (NMDAR) and in the release of glutamate, along to the time of the day, which may have implications for the processes of damage and neuroprotection that occur after trauma or ischemia process.
Method: Wistar rats were subjected to TBI at different times of day and their recovery was analyzed 24 hours later. We also analyzed NMDAR expression in the cerebral cortex via western blotting in control rats killed at different hours of the day and in rats subjected to TBI and killed 24 hours after. We also analyzed de glutamate release along to the day by microdialisis technic.
Results: Our results show that both; NMDAR expression and release of glutamate in the cerebral cortex rats shows a trend toward maintaining a diurnal rhythm. NMDAR expression in the cerebral cortex shows a diurnal rhythm in rats subjected to TBI at different hours of the day, with minimum expression in the hours of darkness. In the other hand the glutamate released in control rats show a diurnal variation.
Conclusions: Both NMDAR expression and released of glutamate appears to follow a diurnal rhythm in the cerebral cortex, which in turn modulates excitotoxicity; this may explain why TBI recovery is dependent on the time when the damage occurs.

Title: The anticholinesterase paraoxon elicits presynaptic decline in the dendritic field of hippocampal slices in correspondence with enhanced levels of astrocytic processes and β1 integrin response

Authors: *K. G. FARIZATTO, M. F. ALMEIDA, H. W. ROMINE, K. RENTSCHLER, B. A. BAHR
Biotech. Res. and Training Ctr., Biotech Ctr. / William C. Friday Lab., Pembroke, NC

Abstract: Anticholinesterase toxins include dangerous nerve agents (e.g. soman) that produce seizures, convulsions, memory deficits, and neuronal loss. The hippocampus is particularly vulnerable, with hippocampal slices also exhibiting synaptic and cytoskeletal vulnerability after low-level soman exposure (Munirathinam & Bahr 2004 J Neurosci Res 77:739). How anticholinesterases affect synaptic integrity is important since evidence indicates post-insult repair responses are mediated through synaptic signaling (Bahr et al. 2002 Exp Neurol 174:37). Here, the toxic anticholinesterase paraoxon (Pxn) was applied to rat hippocampal slice cultures to determine if changes in synaptic composition occur and whether such changes are associated with reactive astrocytes. An acute, high-dose Pxn insult (200 μM) resulted in distinct presynaptic vulnerability after 24 h, evident by a 64% reduction in synapsin IIb immunoblot levels ($p<0.001$) and a similar reduction in synaptophysin. In contrast, the postsynaptic protein GluR1 appeared unaffected by Pxn. Synapsin II tissue staining also exhibited Pxn-mediated decline, a 73% loss of punctate labeling area in the dendritic field of the dentate's molecular layer ($p=0.025$). In the same dendritic view-fields, staining for the specific astrocyte marker GFAP increased significantly. The staining area for astrocytic processes increased 87% in the molecular layer, and the extent of this increase correlated with the extent of reduced dendritic staining of synapsin II in double-labeled confocal images ($R=0.746$, $p=0.033$). Astrogliosis often leads to the generation of harmful free-radicals. Relatedly, the Pxn-treated slice samples were found to exhibit i) more GFAP isoforms than control samples, ii) increased levels of lipocalin-2, a marker of reactive astrocytes, and iii) labeling of the oxidative stress-related 4-HNE marker. The latter was in the form of stable 4-HNE-protein adducts, and they were also found to be released into the culture medium of Pxn-treated slices. Lastly, Pxn caused a nearly two-fold increase in the β1 integrin level, and integrins are known to regulate synapses and the dynamics of the synaptic

environment (see Park & Goda 2016 Nat Rev Neurosci 17:745). These data indicate that Pxn induces distinct synaptotoxicity in combination with a pathogenic cascade involving disruption of cellular homeostasis. They also may shed light on astrocyte-neuron interactions at play during toxin responses in the brain. This work was supported by the U.S. Army Research Office under grant W911NF-15-1-0432, and partly by NIH grant 5R25GM077634-04.

Title: Vascular risks in older adults are correlated with brainwave patterns of learning and memory

Authors: E. BEDINGAR[1], L. S. BROSTER[1], E. L. ABNER[2], X. ZHAO[3], J. LI[4], G. A. JICHA[2], R. KRYSCIO[2], F. A. SCHMITT[2], C. D. SMITH[2], D. M. WILCOCK[2], *Y. JIANG[1]

Abstract: BACKGROUND. Vascular cognitive impairment (VCI) is considered the second most common cause of dementia after Alzheimer’s disease. Currently there is limited understanding on Cerebrovascular disease (CVD) risk and neural correlates of cognitive functions. Using Electroencephalography (EEG) and Cognitive Event-related potentials (ERP), we tested the hypothesis that vascular risk factors are associated with alteration of neural mechanisms underlying short-term memory (explicit working memory & implicit repetition learning).
METHODS. 19 older adults (mean age 75.3) from the community-based aging cohort, Univ. of Kentucky Alzheimer’s Disease Center were included in the study. The Framingham 10-Year Risk Percentage and Hachinski Ischemic Score (HIS) for stroke were used to estimate CVD risk of an individual. Systolic Blood Pressure (BPSYS) was used as a proxy to the extent of small vessel disease. Scalp EEG during resting and cognitive ERP during working memory retrieval and repetition at 14 electrode sites were tested. We further conducted a robust regression which accounted for potential effect of an outlier.
RESULTS. We found that Framingham 10-year risk scores were negatively correlated with ERP patterns indexing better working memory [1] at the left frontal sites ($p=0.02 \sim 0.04$). Other sites

did not show significant correlations. Also, HIS and BPSYS did not correlate with the Left frontal ERP, nor machine learning based EEG markers during resting state. In contrast, BPSYS was positively correlated with the right frontal (F4) neural repetition during retrieval of targets (p=0.02) and non-targets (p=0.03). The 10-year Framingham risk and the repeated match and non-match (p=0.04). Also, BPSYS was positively correlated with the neural repetition (i.e. enhanced repetition learning as BPSYS increased). HIS did not show any correlation. CONCLUSIONS. The present results revealed that the left-frontal cognitive ERP (working memory related brainwave patterns) were correlated with the 10-year risk percentage, but not HIS. Additionally, BPSYS was correlated with neural repetition at the bilateral frontal during implicit learning. Our results suggest that various vascular risk factors reflecting stroke or small vessel disease in older adults are associated with different types of short-term memory.

Title: *In vitro* effects of Epidiferphane on adult human neural progenitor cells

Authors: *T. ZHENG[1], D. F. BIELINSKI[1], D. R. FISHER[1], B. SHUKITT-HALE[1], B. A. REYNOLDS[2], D. A. STEINDLER[1]

Abstract: Neural stem cells have the capacity to respond to their environment, migrate to the injury site and generate functional cell types, and thus they hold great promise for cell therapies. In addition to representing a source for central nervous system (CNS) repair, neural stem and progenitor cells also show great promise for drug screening and toxicity testing. We propose that human neural stem/progenitor cells can also be utilized as a reliable *in vitro* bioassay model for testing, in addition to standard of care and emerging therapies, diet and nutrient components that have potential beneficial bioactions on both the developing and aging human CNS. Adult human neural progenitor cells (AHNPs) isolated and characterized previously in our lab, demonstrate impressive ability to generate diverse neuronal populations. They are used here as an *in vitro* model for testing the effects of Epidiferphane™ (EDP) on progenitor cell's viability,

proliferation and differentiation. EDP is a combination of phytochemicals incorporating green tea catechin epigallocatechin gallate, “EGCG”, the polyphenol curcumin from turmeric, and the isothiocyanate sulforaphane from broccoli sprouts. These nutrient components, together constituting a polymolecular botanical drug, are non-toxic and have demonstrated anti-cancer, anti-inflammatory as well as anti-oxidant properties.
AHNPs were cultured in uncoated plastic dishes in N2 medium supplemented with 5% fetal bovine serum, bovine pituitary extract and growth factors. They were then treated with various doses of EGCG, curcumin and broccoli sprouts, either separately or in combination for 4 days. The viability of the treated cells was examined using the Trypan Blue exclusion method, and proliferation of these cells was evaluated using the ethynyl-deoxyuridine (EdU) assay. A subset of treated cells was labeled with a battery of neuronal markers to examine the differentiation of these cells. To determine whether EDP or its individual compounds could protect AHNPs from stress induced by dopamine (DA) present in the media, some pre-treated cells were exposed to DA for 2 hours and their viability, proliferation as well as calcium buffering were then examined.
While EDP as well as its individual components did not show significant effects on the viability, proliferation and differentiation of AHNPs, they did demonstrate neuroprotection for the AHNPs following cellular stress induced by DA. The data also supports the notion that synergetic effects from the whole compound appear to be more protective when compared to each of the individual components in this human neural progenitor cell bioassay. Supported by the USDA ARS.

Title: Blueberry and Epidiferphane (EDP) enhance calcium buffering in rat hippocampal cells and reduce stress signalling in microglial cells

Authors: D. R. FISHER, T. ZHENG, D. F. BIELINSKI, D. A. STEINDLER, *B. SHUKITT-HALE
USDA, ARS, USDA-ARS Human Nutr. Res. Ctr. on Aging, Boston, MA

Abstract: Age-related decrements are thought to result from increased susceptibility to and accumulating effects of oxidative stress and inflammation. Some foods and food compounds contain bioactive phytochemicals that exhibit potent antioxidant and anti-inflammatory activities, and these foods have been shown to mitigate cognitive decline in aged animals and humans, perhaps by increasing neurogenesis. At least part of the loss of cognitive function in aging may be dependent upon a dysregulation in Ca^{2+} homeostasis, and this loss affects numerous signaling pathways. This study examined whether the polyphenolics from blueberries or Epidiferphane™ (EDP), a combination of phytochemicals incorporating green tea catechin (epigallocatechin gallate, EGCG), curcumin from turmeric, and broccoli sprouts which contain the isothiocyanate sulforaphane, could enhance calcium buffering in neurons and/or reduce stress signalling in microglial cells. Therefore, rat hippocampal neurons or HAPI microglial cells were pre-treated for a week with various concentrations of either freeze-dried blueberry (BB) extract, EDP, or its individual components before inducing deficits in Ca^{2+} buffering with dopamine (DA, 0.1uM for 2 hours) or inflammation using lipopolysaccharide (LPS, 100 ng/ml overnight), respectively. Results showed that BB and EDP were able to protect against deficits in Ca^{2+} buffering (both % of cells that recovered and time to recovery, $p < 0.05$) induced by DA, showing that pre-treatment with these compounds can reduce both stress- and inflammatory- induced neuronal dysfunction. Additionally, BB and EDP reduced ($p < 0.05$) stress-mediated signalling in HAPI rat microglial cells by attenuating LPS-induced nitrite release, iNOS expression, TNF-alpha release, and COX-2 expression. The individual components of EDP were not as effective as the whole compound, showing that the individual polyphenols in the different components may be acting synergistically or exerting their effects through different and/or independent mechanisms. Therefore, dietary intervention with compounds such as those found in blueberry, green tea, turmeric, or broccoli sprouts can play a role in reducing the age-related central nervous system inflammation, microglial activation, and stimulation of immune pathways that reduce neurogenesis and impair cognitive function.

Title: Berry phenolics are associated with cognitive enhancement in blueberry- and strawberry-supplemented healthy older adults

Authors: *M. G. MILLER[1], A. K. SANDHU[2], N. THANGTHAENG[1], T. M. SCOTT[1], B. B. BURTON-FREEMAN[2], B. SHUKITT-HALE[1]
[1]Neurosci. and Aging Lab., USDA-HNRCA, Boston, MA; [2]Ctr. for Nutr. Res., Inst. for Food Safety and Health, Illinois Inst. of Technol., Chicago, IL

Abstract: The aging process often involves functional declines in cognition, leading to lower quality of life and increased need for care among older adults. Epidemiological evidence suggests that a diet rich in fruits and vegetables can reduce the risk of age-related cognitive impairment, in part due to the presence of antioxidant and anti-inflammatory phytochemicals in these foods, e.g., polyphenols. In recent double-blind, placebo-controlled clinical trials conducted by our laboratory, healthy older adults (ages 60-75) consumed 12 g of freeze-dried blueberry (equivalent to 1/2 cup blueberries) or strawberry (equivalent to 1 cup strawberries) twice daily for 90 days. In both studies, participants in the control groups consumed an equal amount of a seemingly identical, isocaloric placebo powder twice daily. Participants completed a battery of 8 cognitive tests and provided blood samples at baseline, and again following 45 and 90 days of intervention. Participants in the blueberry group showed enhanced executive function as evidenced by significantly fewer repetition errors in the California Verbal Learning test (CVLT-II; $p = 0.031$) and a reduced switch cost on a task-switching test ($p = 0.033$) across study visits, relative to placebo controls. Participants in the strawberry group showed enhanced learning and memory as evidenced by significantly improved probe trial performance in a virtual water maze during the midpoint visit ($p = 0.020$) and improved word recognition in the CVLT ($p = 0.014$). No significant effects were observed on the other tests. Plasma phenol concentrations, including both parent compounds and metabolites, were measured after an overnight fast and 2 hours postprandial at each time point (the standardized meal included supplement or placebo at 45- and 90-day visits). Levels of circulating polyphenolics, including anthocyanins, ellagitannins, and phenolic acids were significantly altered as a result of berry consumption. Results showed that blueberry and strawberry polyphenols were absorbed and extensively metabolized, resulting in the production of various phenolic acid derivatives and their conjugates. Regression analysis showed that changes in circulating levels of specific phenolic compounds were correlated with the observed changes in cognition. Therefore, the addition of easily achievable quantities of berry fruit to the diets of older adults can improve some aspects of cognition, likely due to increased levels of circulating berry phenolics and their metabolites.

Park, Champaign, IL

Abstract: Cocoa-derived flavanols, and in particular (-)-epicatechin, have been extensively shown to exert beneficial effects on vascular function in humans. More recently, there has been a growing interest in understanding to what extent such beneficial vascular effects in the periphery might benefit the central nervous system and further impact cognitive function, particularly in aging. In the present study, we examined the long-term impact (6 months) of oral supplementation with either i) cocoa-flavanols (containing (+)-catechin, (-)-epicatechin and procyanidins) or ii) pure (-)-epicatechin (both delivering a total of 948 ug of flav/g food) on cerebral blood perfusion as assessed by 99m-Tc-HMPAO Single Photon Emission Computed Tomography (SPECT), in an aged mice model (16 to 22 months old). Preliminary data suggests that long-term chronic supplementation (6 months) with cocoa is more effective at maintaining cerebral blood perfusion in aging (parallel design, n=8; age x treatment effect: p=0.019), than pure (-) -epicatechin when delivered at equivalent doses. We are currently examining the effects of the dietary interventions on specific regions across the brain to identify the areas which were significantly affected by flavanol supplementation. Furthermore, we have observed that changes in blood perfusion are unlikely to be mediated by increases in density of blood vessels, as shown by our preliminary data depicting no differences in density of blood vessels across the hippocampal formation. Collectively, these data support a positive modulation of cerebral blood perfusion by cocoa flavanols and may have the potential to counteract age-associated decreases in brain health and cognition.

Title: Comprehensive longitudinal evaluation of aging-related phenotypes of frailty, neurosensory, motor, and cognitive measures in C57BL/6J mice

Authors: T. L. GREEN, T. MCGARR, S. S. WINTER, *L. ANDERSON, S. J. SUKOFF RIZZO
Mouse Neurobehavioral Phenotyping Facility, The Jackson Lab., Bar Harbor, ME

Abstract: The relationship of biological age and chronological age as measures of health span and lifespan vary amongst individuals. Several studies in mice have aimed to identify the most translational measures that best reflect healthy aging and have mainly been limited to physiological assessments that do not include behavioral measures relevant to neurodegeneration. The present studies aimed to evaluate aging mice through a comprehensive, non-invasive behavioral testing battery which included assessments of motor and fine motor function, vision, hearing, short term and working memory, strength, motor coordination and frailty which could be employed longitudinally over the course of an individuals' life span. As expected, male and female C57BL/6J mice (n=8-13 per sex per age) demonstrated aging-dependent increases in a composite frailty index score in line with previous reports for healthy aging mice (Whitehead et al., 2014 J Gerontol A Biol Sci Med Sci) which was inversely correlated with an aging-dependent reduction in core body temperature. In the open field test, male and female C57BL/6J mice demonstrated aging-dependent reductions in distance traveled and rearing activity as well as aging-dependent reductions in spontaneous homecage wheel running consistent with aging related motor impairments. Aging-dependent changes were also observed for visual acuity and acoustic startle responses indicative of aging-related deficits in vision and hearing, respectively. Cognitive assessments of hippocampal spatial working memory in the spontaneous alternation task and short term memory in a novel spatial recognition task also revealed aging-dependent reductions, while interestingly anxiety-like behaviors were decreased with age. Taken together the present studies demonstrate the sensitivity of these behavioral measures to detect aging-related changes in healthy aging C57BL/6J mice and demonstrate the utility of this non-invasive, comprehensive behavioral testing battery for longitudinal assessments across the lifespan of individual mice that could further be employed to study the potential of therapeutic interventions to attenuate the progression of aging related impairments.

Title: Thrombospondin repeat-derived peptide (NX210): Antioxidative and neuroprotective properties

Authors: *N. DELÉTAGE[1], M. CHALUS[2], A. BOILEAU[2], S. GOBRON[1], L. SAKKA[2]
[1]NEURONAX, Saint-Beauzire, France; [2]Lab. d'Anatomie, Neurodol - Faculté de Médecine, Clermont-Ferrand, France

Abstract: Oxidative stress is a major, contributing factor to the pathogenesis of traumatic and degenerative affections of the central nervous system (CNS). Oxidative stress arises from a disturbed redox system homeostasis that generates free radicals, activates kinase cascade and finally leads to apoptotic cell death. Neural cells are particularly sensitive to oxidative damages in relation to a relative scarcity in antioxidant compounds and a high level of poly-unsaturated fatty acid that gives them a high susceptibility to lipoperoxidation. Thus, stimulating antioxidant capacities of the neural cells appears as important strategy in the prevention of secondary damage after traumatic injury of the CNS. NX210 is a peptide derived from a thrombospondin type 1 repeat sequence of SCO-spondin, a protein of the extracellular matrix naturally secreted by the CNS during embryogenesis. NX210 was previously shown to increase neurite outgrowth and fasciculation and to inhibit apoptotic cell death. Here we demonstrate the neuroprotective effect of NX210 in several stress conditions on 2 rat cellular models: a B104 neuroblastoma cell line and primary cortical neurons. Treatment with NX210 at 80, 190 and 380 µM in presence of H_2O_2 significantly enhanced B104 cell viability in a dose dependent manner (respectively 39 %, 71% and 94% of viable cells) as compared to B104 cells exposed to H_2O_2 alone (13% of viable cells). We demonstrate NX210 neuroprotective effect was not mediated by β1 integrin, a receptor involved in NX210 neuroregenerative properties. We demonstrate NX210 might reverse the H_2O_2-induced oxidative through an activation of PI3K/Akt and MAPK/ERK signaling pathways. NX210 might modulate the action of various enzymes involved in the redox regulatory system. The protection against oxidative stress was confirmed on primary cortical

neurons exposed to H_2O_2 with a 4-fold increase of cell viability at 380 µM. NX210 did not exert protection against glutamate-induced cytotoxicity on this model. In conclusion, NX210 combines neuroregenerative properties with antioxidative and antiapoptotic properties that suggest NX210 as a promising candidate to be investigated in traumatic and degenerative affections of the CNS.

Abstract: Traditional Chinese medicine is usually formulated as a complex of herbs which may have synergistic effects for a disease. Sometimes, the overwhelming effect from a particular herb can be alleviated by antagonistic herbs. Therefore, mixtures of herbal ingredients may have advantages of multiple target regulation. *Caulis Spatholobi*, a commonly used herbal medicine for blood-activating and stasis-dispelling, has been reported to promote angiogenesis. Leaf and root extracts of *Salvia officinalis* (Common name: Sage) have been shown to have antiproliferative effects on hepatocellular carcinoma cells. *Mentha citrate* has been found to have antioxidative effects. In the present study, the individual and multiple effects of *Caulis Spatholobi* extract, seed extract of *Salvia officinalis* and leaf extract of *Mentha citrate* against hydrogen peroxide-induced neuronal cell death were studied. The extracts were prepared by dissolving the powder of ground *Caulis Spatholobi*, fresh sage seed and fresh Mentha's leaves in ethanol and insolubles were filtered out by 0.22 micro-meter membrane filter. Non-differentiated SH-SY5Y cells were pre-treated with a single or multiple extracts for 24 hours in DMEM supplemented with 2% fetal bovine serum. Following the removal of the extracts, SH-SY5Y cells were treated with 400 micro-molar of hydrogen peroxide for 24 hours in DMEM with 2%

fetal bovine serum. Results indicated that there were differential effects of the extracts against hydrogen-peroxide induced cytotoxicity. This implies that some of the extracts may offer neuroprotection.

Title: G-protein coupled receptor 110 in synaptamide-induced optic nerve regeneration and improvement of visual function after optic nerve damage

Authors: *H. KWON, T. PARK, H.-Y. KIM
NIAAA/National Instiutes of Hlth., Rockville, MD

Abstract: The adult mammalian central nervous system (CNS) has a very limited ability to regenerate axons, and therefore, axonal damage often leads to irreversible functional deficits. Synaptamide (*N*-docosahexaenoylethanolamine), a structural analog of the endocannabinoid anandamide, is produced endogenously from an omega-3 fatty acid docosahexaenoic acid (DHA). We have previously demonstrated that synaptamide promotes neurite outgrowth and synaptogenesis in developing neurons *in vitro* as well as *in vivo* by binding to G-protein coupled receptor 110 (GPR110, ADGRF1) the expression of which becomes negligible in the brain after development except for the hippocampus. We have also observed using an *in vitro* axonal injury model that synaptamide at10 nM significantly promotes axon regrowth in developing cortical neurons. In this study, we demonstrate that synaptamide induces axon regeneration in adult mice after optic nerve injury in a GPR110-dependent manner, resulting in improved visual activity. To test the axon regeneration by synaptamide *in vivo*, we performed optic nerve crush (ONC) followed by an intravitreal injection of synaptamide (25 mg/kg) and the optic nerve tissues were collected after 4 weeks after injury. Optic nerve visualization performed by the intravitreal injection of a fluorescent anterograde tracer cholera toxin B subunit (CTB) at 3 days before the tissue collection indicated that synaptamide but not oleoylethanolamide strongly promoted axon regeneration; however, such synaptamide effect was not observed in *gpr110 KO* mice. Moreover, the visual function evaluated at 12 weeks after injury by the electroretinogram (ERG) and visual evoked potential (VEP) was restored by the single injection of synaptamide following ONC in wild type but not *gpr110 KO* mice. When the CTB-stained retinal ganglion cell

projection to the brain was examined at 12 weeks after injury, the retinal fiber innervation was detected in mice treated with synaptamide while no such innervation was apparent in vehicle treated animals. Significant and persistent induction of *gpr110* in retina was observed by *in situ* hybridization and qRT-PCR in as little as 30 min post injury, indicating that *gpr110* is not only a developmental gene but also an injury-responding gene that facilitates the repair. Taken together, these findings suggest that the synaptamide/GPR110 signaling is a potential therapeutic target for functional recovery after CNS injury such as optic nerve or spinal cord injury.

Title: Therapeutic targets in vascular cognitive impairment and dementia: Neuroinflammation and endothelial dysfunction

Authors: *D. J. BRAUN, A. BACHSTETTER, D. GOULDING, D. WILCOCK, L. VAN ELDIK
Univ. of Kentucky, Lexington, KY

Abstract: Vascular cognitive impairment and dementia (VCID) is recognized as the second leading cause of dementia behind Alzheimer’s disease (AD). Although a distinct clinical entity from AD, VCID has many similar pathological dysfunctions and risk factors. Pathogenic mechanisms responsible for VCID are diverse and overlapping, however two major contributors can be broadly identified: dysregulated inflammatory processes, and endothelial dysfunction. Hyperhomocysteinemia (HHcy) is defined by elevated plasma homocysteine levels, and it is an established risk factor for cardiovascular disease, VCID, and AD. Mice fed a diet deficient in folate, vitamin B6, and vitamin B12, and supplemented with excess methionine, develop HHcy. This corresponds with microhemorrhages, neuroinflammation, and cognitive deficits, and is therefore a useful animal model of VCID. Using this HHcy model, we have explored several potential approaches to ameliorate pathological damage: pharmacological attenuation of glial pro-inflammatory cytokine expression with a highly brain-penetrant small molecule, genetic knockout (KO) of p38α mitogen activated protein kinase (MAPK) from myeloid cells, and reducing permeability of the blood brain barrier by KO of myosin light chain kinase (MLCK) from endothelial cells. Pharmacological inhibition of glial cytokine release did not attenuate pathology. Loss of p38α MAPK, however, reduced neuroinflammatory changes and

microhemorrhage, as did KO of MLCK from endothelial cells. Taken together, our data suggest that targeting peripheral or vascular-associated inflammation, and in particular reducing leukocyte infiltration into the brain, may be a useful approach in ameliorating VCID-associated neuropathology.

Title: Daidzein induces cytoprotection against binge-like ethanol exposure *In vitro:* Role of high mobility group box 1 protein?

Authors: *M. A. SAUNDERS, J. E. JAGIELO-MILLER, M. A. PRENDERGAST
Psychology, Univ. of Kentucky, Lexington, KY

Abstract: An estimated 18 million Americans currently meet criteria for an alcohol use disorder. While there are currently four medications approved by the US Food and Drug Administration to treat AUD: disulfiram, naltrexone, long-acting injectable naltrexone, and acamprosate, these treatments have not been successful, with 50-80% reporting relapse at 1 year follow-up. The lack of efficacy of the current treatments may be attributed to their focus on the motivational behaviors of abuse, rather than the neurobiological effects of alcohol that may underlie those behaviors. Thus, understanding the neurobiological mechanisms which result in the neurological deficits and cognitive decline from chronic alcohol use and withdrawal remains a major goal in the development of effective pharmacotherapies for alcohol use disorder (AUD). Naturally found isoflavonoids, a sub-class of flavonoids, have been demonstrated to reduce ethanol (EtOH) intake in rats and humans. Notably, these compounds are reported to have a myriad of properties (i.e. estrogen receptor binding, anti-inflammatory, antioxidant, cytoprotective). However, the mechanisms by which isoflavonoids attenuate on EtOH consumption it not yet know. The current studies examined the effects of daidzein (0.0001-0.01 µM), a prototypical isoflavonoid which has been demonstrated to attenuate ethanol consumption *in vivo*, on EtOH (100 mM)-induced cytotoxicity in organotypic hippocampal slice cultures. EtOH (100mM) induced

significant cytotoxicity (as measured by propidium iodide [PI] uptake) at 48h. Daidzein was protective against EtOH (100mM) - induced cytotoxicity at all concentrations tested. Follow-up studies were conducted to examine if daidzein exerts its neuroprotective effects through inhibition of neuroinflammation. *High mobility group box 1* protein (HMGB1) interacts with *toll-like receptor 4* (TLR4) receptors, and is considered a pro-inflammatory signal associated with binge EtOH consumption. EtOH (100mM) significantly increased secreted HMGB1 concentrations in culture medium at 48h. Daidzein significantly attenuated this increase at all concentrations tested. These results suggest potential anti-inflammatory properties of daidzein which may contribute to its cytoprotective effects in the presence of EtOH. These findings further highlight the potential applications of daidzein for use in the treatment of AUD.

Title: Pgrmc1 mediates progesterone-induced protection against oxidative stress glial and neuronal cells

Authors: *S. KIM, T. NGUYEN, J. TOOFAN, N. RYBALCHENKO, M. SINGH
Ctr. for Neurosci. Discovery, Univ. of North Texas Hlth. Sci. Ctr., Fort Worth, TX

Abstract: Our laboratory has previously reported that Brain-derived neurotrophic factor (BDNF) is a critical mediator of progesterone's (PROG) cytoprotective effects on brain cells. And though the effects of PROG on BDNF expression (mRNA and protein) are regulated by the classical progesterone receptor (PR), our lab has identified Pgrmc1 as a novel receptor for PROG that mediates BDNF release from glia. Accordingly, we hypothesized that Pgrmc1 plays an equally important role in mediating the protective effects of PROG in both astrocytes and neurons, given the recognized importance of BDNF on both neurons and glia. Using C6 astrocytes and differentiated SH-SY5Y neuronal cells, we found that PROG protects both cells from the pro-oxidative insult, H_2O_2. Interestingly, this effect was independent of the classical PR. We then used RNA interference (RNAi)-mediated gene depletion to knock down the expression of Pgrmc1 and determined if PROG-induced BDNF release was attenuated. Pgrmc1 depletion completely abolished the BDNF release elicited by PROG. We also used pharmacological strategies to determine whether the effect of PROG on cell viability (both C6 and SH-SY5Y) was mediated by the classical PR, the 5-alpha reduced metabolite of PROG, Allopregnanolone, or Pgrmc1. While neither the pharmacological inhibitors of the PR and 5-alpha reductase altered the protective effects of PROG against H_2O_2, inhibition of Pgrmc1 prevented PROG from

protecting against this pro-oxidative insult. Further, inhibition of trkB also abolished the PROG protective effect, implicating that the release and subsequent binding of BDNF to its cognate receptor was, at least in part, involved in mediating the protective effects of PROG. The data offered here support our model that Pgrmc1 is critical to progesterone's capacity to elicit the release of BDNF and trigger downstream signaling events that are vital for cell viability.

Abstract: Converging evidence suggests that exercise may protect against a number of age-related conditions, including dementia and motor dysfunction. Improved mitochondrial and bioenergetic function, as well as increased neurotrophic factor expression, likely underlie the beneficial effects of exercise. While preclinical aging studies have focused almost exclusively on aerobic exercise, recent studies report the beneficial effects of resistance exercise in maintaining neuronal integrity. Research into the effects of long-term resistance training on neuroprotective mechanisms in the brain is hampered by limitations in implementing resistance training in animals. The resulting knowledge gap is important given the limitations of implementing aerobic exercise regimens in the elderly. The goal of the study was to determine whether long-term resistance training can increase neuroprotective proteins in key brain regions of aged rats. After being trained to perform a unilateral isometric forelimb resistance task, 18-month-old Sprague-Dawley rats performed the task daily for 6 months. Tissue was harvested from striatum, hippocampus, and other brain regions from strength-trained vs sedentary rats at 24 months of

age. Results will be discussed in relation to neuroprotection against age-related cognitive and motor decline.

Title: Discovery of protective small molecules for the treatment of vincristine-induced peripheral neuropathy

Authors: *I. V. UTKINA-SOSUNOVA, H. LI, C. KARAN, S. PRZEDBORSKI, F. LOTTI
Columbia Univ., New York, NY

Abstract: Chemotherapy-induced peripheral neuropathy (CIPN) is a common and dose-limiting side effect in cancer treatment with platinum compounds, taxanes, vinca alkaloids, and proteasome inhibitors. Vincristine, a widely used vinca alkaloid, is unique among cancer chemotherapeutics because in addition to sensory neuropathy, its exposure causes motor deficits that are observed as early as one week after initiation of treatment. However, very little attention is reserved to the mechanisms underlying vincristine-induced motor dysfunction. We are using a pharmacological approach to understand the mechanisms underlying vincristine-induced axonal degeneration in motor neurons and to devise therapeutic strategies to treat or/and prevent vincristine-induced peripheral neuropathy (VIPN). Toward this goal, we developed an automated, an imaging-based assay suitable for 96- and 384- well plate formats to determine motor neuron cell number and neurite length. Using this setup, we tested the effect of several concentrations of vincristine on survival and neurite length of genetically labeled motor neurons derived from mouse embryonic stem cells and found that 24 hours treatment of motor neurons with 2nM of vincristine resulted in a significant and highly reproducible reduction in neurite length without affecting cell survival. To validate the ability of our cell-based assay to identify compounds that protect axons from vincristine-induced degeneration, we screened a library of biologically active small molecules. The reliability of our screening methodology is highlighted by the identification within the hits of compounds whose targets have been previously implicated

in axon degeneration. Thus, we established a consistent and robust cell-based phenotypic assay that accurately measures vincristine-induced effects on neurite length of motor neurons and is amenable to high-throughput chemical and genetic screens.

Title: Intranasal orexin-A (hypocretin-1) activates cholinergic and GABAergic neurons in select brain regions of aged animals

Authors: *C. B. CALVA[1], J. R. FADEL[2]
[1]Univ. of South Carolina, Columbia, SC; [2]Pharmacology, Physiology, Neurosci., Univ. of South Carolina Sch. of Med., Columbia, SC

Abstract: Hypothalamic orexin/hypocretin (OX) neurons have recently been implicated in coordinating homeostatic and cognitive functions. OX neurons send widespread projections to the cortex and provide robust innervation to all subgroups of the basal forebrain cholinergic system (BFCS). Prior work from our lab has demonstrated an age-related reduction of OX neurons in rats, suggesting that orexins play a role in the cognitive and homeostatic dysfunction seen with age. Intranasal orexin-A (OxA) has been suggested as a novel therapeutic for the treatment of age-related cognitive disorders, including Alzheimer's disease. We have previously demonstrated that intranasal OxA activates cortical and basal forebrain regions involved in attention and learning, and increases cortical acetylcholine and glutamate release. Accordingly, we investigated the effects of intranasal OxA administration in aged animals. Here, aged (26-28 months) male Fisher344/Brown Norway rats received intranasal administration of vehicle (0.9% saline) or OxA (25 ul of a 100uM solution) into each nare. At two hours post-treatment, animals were sacrificed and their brains were processed for immunohistochemical detection of the neuronal activity marker, c-Fos, and phenotypic markers of specific neuronal populations. Intranasal OxA significantly increased c-Fos expression in the prelimbic medial prefrontal cortex (mPFC) and agranular insular cortex (AIC) compared to vehicle treatment. The medial prefrontal (mPFC) and agranular insular cortices (AIC) are involved in attentional and interoceptive

functions, respectively. Interestingly, c-Fos expression in parvalbumin positive (PV+) interneurons was decreased in the mPFC. Intranasal OxA also increased c-Fos expression in PV+ GABAergic neurons of the nucleus basalis/ventral pallidum/substantia innominata (VP/SI/NBM), which tend to form inhibitory synapses onto cortical PV+ GABAergic interneurons. Intranasal OxA also significantly increased activation of cholinergic neurons in both limbs of the diagonal band of broca (DBB) and in the NBM/VP/SI continuum. NBM/VP/SI provides cholinergic innervation to the cortex while the DBB supplies cholinergic innervation to hippocampal regions. Intranasal OxA did not alter c-Fos expression in all cortical and basal forebrain regions, suggesting that intranasal OxA effects are not a global phenomenon. In total, these data demonstrate a capacity for intranasal OxA administration to activate brain regions and neurotransmitter systems that degenerate in aged animals and, therefore, may serve as a viable therapeutic option for treating age-related cognitive disorders.

Abstract: Chemical warfare nerve agents (CWNAs) such as sarin and soman are potent inhibitors of acetylcholinesterase. Inhibition of acetylcholinesterase causes accumulation of acetylcholine, resulting in hypersecretions, convulsions, seizures, and death. Recent events in Syria demonstrate the severe effects of these agents and underscore the need for improved medical countermeasures for treatment of exposure. To facilitate identification of candidate countermeasures for CWNA exposure, genomic analysis was performed on piriform cortex samples from wild-type mice (C57BL/6J) exposed to a convulsive dose of soman (1.6 x LD_{50}). Samples were collected at 1, 3, 6, 12, 24, and 48 hours following soman exposure, and flash

frozen in liquid nitrogen. Total RNA was isolated and processed for hybridization to Affymetrix HT MG-430 PM array plates. After robust multiarray averaging (RMA) for normalization, principal component analysis (PCA) was used to identify major sources of variation in the data. ANOVA (analysis of variance) was then conducted to identify soman-induced changes in gene expression over time (p-value $\leq .05$; fold change ≤ -1.5 or ≥ 1.5). Identified genes were imported into Ingenuity Pathways Analysis software, and upstream analysis was used to identify potential therapeutic compounds. Eleven compounds were observed in the upstream analysis across all time points, with an additional 4 compounds observed for 1 through 24 hours. Upstream analysis at 48 hours resulted in the greatest number of potential therapeutic compounds (97), followed by 12 hours (93) and 6 hours (89). Therapeutics previously identified and evaluated based on known physiological and biochemical effects of soman were also identified including pentobarbital, thalidomide, resveratrol, and anakinra. Down selection of the candidate countermeasures for efficacy testing in animals will be conducted based on the therapeutic window for administration of the compound, mechanism of action of the compound, and known physiological effects of CWNA exposure.

Title: Proton irradiation and pomegranate supplementation can both increase proliferation of new cells in the mouse brain

Authors: *N. KALYNOVSKA[1], M. DULCICH[2], N. BAJWA[2], D. XU[3], D. BAYLINK[3], R. HARTMAN[2]
[1]Psychology, Loma Linda Univ., Los Angeles, CA; [2]Psychology, [3]Med., Loma Linda Univ., Loma Linda, CA

Abstract: Previous research has demonstrated substantial health benefits of dietary polyphenols. These compounds, which are present in a variety of foods (including pomegranates), have demonstrated neuroprotective effects against various types of neuropathology, including Alzheimer's disease and stroke. Additionally, maternal diet can impact future mental health of the developing embryo, and prenatal pomegranate supplementation has been shown to increase resilience to neonatal hypoxic-ischemic brain injury in mice. Irradiation with protons (e.g., radiotherapy for cancer) can induce cognitive and other behavioral deficits in mice, and we recently showed that dietary supplementation with pomegranate juice protected against some of those effects, although the mechanisms were undetermined. We therefore hypothesized that dietary supplementation with pomegranate juice either protected the brain or enhanced its repair following proton irradiation. Mice received pomegranate juice via mothers' intake for 10-16 days prior to birth and after birth via their drinking water. At 13-14 weeks of age, mice were irradiated with 2 Gy proton radiation (1-2 gy/min) and sacrificed 1 week later. Intriguingly, histological analyses implementing Ki-67 and DAPI stains revealed increased numbers of new cells in irradiated and pomegranate-exposed mice, with the greatest numbers of new cells observed in those mice exposed to both.

Title: Troxerutin has neuroprotective effect in rodent model of Parkinson's disease

Authors: *G. M. ANDRADE[1], P. C. SOUSA[1], M. R. CARMO[1], J. R. BEZERRA[1], A. A. ALVES[1], I. VIEIRA[2]
[1]Physiol. and Pharmacol., Federal Univ. Ceara, Fortaleza, Brazil; [2]Parque de Desenvolvimento Tecnológico – PADETEC, Federal Univ. of Ceará, Fortaleza, Brazil

Abstract: Parkinson's disease (PD) is the second most common form of neurodegenerative disease in the elderly. It is characterized by a progressive degeneration of dopaminergic neurons in the substantia nigra. The clinical aspects of PD shows an intersection between motor symptoms, cognitive, behavioral and neuropsychiatric changes. The neurotoxin 6-hydroxydopamine (6-OHDA), leads to destruction of dopaminergic nerve terminals, mimicking behavioral, biochemical, and pathological changes that are typical of PD. Several studies have

been showing that natural products, especially flavonoids, have protective effect in the prevention or treatment of neurodegenerative diseases. The troxerutin, naturally occurring substance, has strong anti-inflammatory activity, with potential neuroprotective action. The aim of this study was to investigate the effects of troxerutin on neurotoxicity induced by 6-OHDA. Male Wistar rats were divided (220-250 g) into four groups: sham-operated (SO), SO + T200 (animals treated with troxerutin 200 mg/kg intragastrically for 18 days), 6-OHDA (animals that received stereotaxic injections of 6-OHDA 18 g/3μl in the right striatum for 18 days), and 6-OHDA +T200 (animals that received stereotaxic injections of 6-OHDA and were treated with troxerutin 200 mg/kg intragastrically for 18 days). Treatment with troxerutin decreased the number of contralateral rotations in the test of apomorphine, improved the early memory of the animals in the passive avoidance test and procedure memory in the cued version of the Morris Water maze. The troxerutin also prevented the microgliosis and astrogliosis in the striatum and decreased the neuro-inflammation by reducing expression of TNF-α, NF-κB p65 and p-Akt in the striatum. These findings reveal the neuroprotective action of troxerutin via attenuation of neuroinflammation, and encourage further investigations on using troxerutin, as a possible preventive and/or adjuvant therapeutic intervention against PD.

Title: Planning and execution deficits of anterior lateral motor cortex and licking in hemi-parkinsonian mice

Authors: *K. CHEN, R. VINCIS, A. FONTANINI
Dept. of Neurobio. and Behavior, Stony Brook Univ., Stony Brook, NY

Abstract: Parkinson’s disease (PD) is characterized by a progressive degeneration of dopaminergic neurons that results in problems with movement initiation and execution. Experimental evidence shows that, in physiological conditions, the motor cortex plays an important role in motor planning, initiation and execution. In rodents, the anterior lateral motor (ALM) cortex has been shown to be responsible for planning and execution of licking. Little is known about the potential dysfunction of ALM circuits in PD-like conditions. Here, we combine electrophysiological recordings, two-photon calcium imaging, behavioral training and

pharmacological manipulations to study how the abnormal neural activity in ALM causes abnormal licking in a mouse model of PD.
6-hydroxydopamine was unilaterally injected into the medial forebrain bundle (MFB) to produce a mouse model of PD. A control group received a MFB injection of vehicle. In order to investigate licking preparation and execution, mice were trained to lick a movable spout to receive sucrose 1 s after an anticipatory auditory cue (tone, 2k Hz, 70dB). In one group of mice, 16-electrode arrays were bilaterally implanted into ALM to record spiking activity from neurons in both hemispheres. In a second group, AAV virus expressing GCaMP6s, a genetically encoded calcium indicator, was injected into ipsilateral ALM and a chronic window was implanted above ALM. Neural activity was recorded through 2-photon microscopy.
Hemi-parkinsonian mice displayed two types of licking deficits. First, licking initiated later and terminated earlier in hemi-parkinsonian mice compared to control mice. Second, tongue protrusions were deviated towards the lesion side. The first symptom was fully recapitulated by local infusion of dopamine D1/D2 receptor blockers (SCH23390 and raclopride) in ALM, suggesting a causal role of dopaminergic signaling in this area for preparatory deficits.
Electrophysiological recordings and calcium imaging in the ALM of control hemispheres revealed that most neurons in ALM changed their firing activity in preparation for licking. The ALM of lesioned hemispheres showed a significant reduction in the number of neurons with inhibitory preparatory responses. Ramping of preparatory activity was also slower in the lesioned hemisphere of hemi-parkinsonian mice compared to controls.
In conclusion, our data show that hemi-parkinsonian mice display problems with licking initiation and execution, some of which directly relate to disruption of dopaminergic signaling in ALM. Neural activity in ALM of hemi-parkinsonian mice shows deficits that are consistent with the behavioral observations.

Title: Synaptic transmission onto primary motor cortex neurons in a mouse model of Parkinson's disease

Authors: *O. K. SWANSON[1], A. MAFFEI[2]
[1]Neurobio. and Behavior, SUNY Stony Brook, Stony Brook, NY; [2]Neurobio. and Behavior, SUNY-Stony Brook, Stony Brook, NY

Abstract: Primary motor cortex (M1) is a major output center in the circuit for voluntary movement. M1 receives motor signals from the basal ganglia via a glutamatergic projection from the motor thalamus (VA/VL), integrates these signals with inputs from other motor-related areas, and sends its output to descending motor tracts to drive movement. Despite its crucial role in the motor circuit, little is known about the synaptic physiology of neurons in M1. Furthermore, the loss of dopamine signaling that occurs in Parkinson's Disease (PD) has been shown to alter synaptic transmission in other nodes of the motor circuit, but the role that M1 plays in the pathophysiology of this disease remains unclear. To investigate how diminished dopamine signaling impacts overall synaptic transmission in M1, we performed whole-cell recordings of excitatory M1 neurons in acute slice preparations from mice with unilateral nigral 6-hydroxydopamine (6-OHDA) lesions or vehicle injections. We measured spontaneous excitatory and inhibitory postsynaptic currents by blocking action potentials and recording at the reversal potentials for inhibitory or excitatory events, respectively. Analysis of synaptic currents onto layer 2/3 excitatory neurons in M1 revealed that the balance between excitation and inhibition was shifted toward greater inhibition in 6-OHDA lesioned mice (6-OHDA = 0.377±0.035, Control = 0.530±0.0556; $p < 0.04$). Previous studies have shown that in mouse models of PD, pyramidal neurons in M1 undergo changes in spine dynamics, suggesting that PD affects glutamatergic signaling in this region. In view of these data, we hypothesized that the observed shift in E/I balance may be due to altered glutamatergic transmission onto M1 neurons. We focused on the thalamocortical projection from VA/VL to M1 as this constitutes a major glutamatergic input to this area, and published work suggests that in PD the excitability of neurons in the motor thalamus may be suppressed by increased inhibition from the basal ganglia. We combined nigral 6-OHDA or vehicle injections with optogenetic tools to selectively stimulate VA/VL terminal fields, and measured the magnitude and short-term dynamics of the evoked responses in excitatory M1 neurons. Preliminary data show a trend toward reduced VA/VL-M1 input onto layer 2/3 neurons of lesioned animals (EPSC amplitude (pA), 6-OHDA = 120.509±57.259, Control = 341.897±114.653). Overall, this study will further our understanding of the effects of PD on the circuit in M1, possibly helping to identify more targeted treatment options for this disease.

Title: Movement-related activity in the basal ganglia-recipient motor thalamus (VLa) of the parkinsonian macaque

Authors: *D. KASE[1,2], A. J. ZIMNIK[4], T. M. PEARCE[3,2], R. S. TURNER[2]
[1]Dept. of Neurobio., Systems Neurosci. Inst., Pittsburgh, PA; [2]Dept. of Neurobio., [3]Dept. of Pathology, Univ. of Pittsburgh, Pittsburgh, PA; [4]Dept. of Neurosci., Columbia Univ., New York City, NY

Abstract: Disordered function of the VLa thalamus is thought to be a critical step in the pathophysiology of motor impairments in Parkinson's disease (PD). For example, the traditional "rate model" hypothesizes that elevated discharge rates in efferents from the parkinsonian basal ganglia cause excessive inhibition of VLa neurons, which may be evidenced by reduced baseline discharge rates and/or reduced magnitude of movement-related increases in activity. Little information is available, however, on how the activity of VLa neurons is altered in the parkinsonian state. To address this gap in knowledge, we sampled single unit extracellular activities from the VLa before and after (n=99 and 96 units, respectively) the induction of hemiparkinsonism by intracarotid MPTP administration in one macaque monkey. The animal performed a simple choice reaction time reaching task for food reward. The animal was able to perform the task throughout the months-long recording period following MPTP, but with markedly prolonged and more variable reaction times and movement durations (reaction time: 248±35 ms vs. 457±215 ms, movement durations: 244±35 ms vs. 845±333 ms, means±SEM pre- vs. post-MPTP respectively; $p<0.01$ for both K-S test). The baseline firing rates of VLa neurons, sampled during attentive rest while the animal waited for the task's "go" stimulus, were not altered by MPTP (14.0±1.2 Hz pre- vs. 12.0±1.1 Hz post-MPTP respectively; $p>0.05$, K-S test). Large fractions of neurons changed firing rates around the time of reach onset (92% and 83% of neurons pre- and post-MPTP; $p=0.07$ χ^2-test), with increased firing as the earliest change in 79% (pre-MPTP) and 61% (post-MPTP) of these cells, and decreased firing as the earliest change in the remainder. This shift following MPTP toward early movement-related decreases in firing was significant ($p=0.01$; χ^2-test). In addition, the magnitudes of movement-related increases in firing were reduced markedly following MPTP (20.9±2.2 Hz pre- vs. 5.0±0.7 Hz post-MPTP; $p<0.01$ K-S test) whereas the magnitude of decreases did not differ (6.2±0.8 Hz pre- vs. 6.1±1.0 Hz post-MPTP). Finally, peri-movement activity began earlier relative to movement onset following MPTP (96.5±14.2 ms pre- vs. 176.8±19.9 ms post-MPTP respectively; $p<0.01$, K-S test). The shift in timing was similar for increases and decreases in firing. The observed MPTP-induced reductions in the prevalence and magnitude of movement-related increases in activity lend partial support for the traditional rate model of PD pathophysiology.

Title: Unified neural field theory of brain dynamics underlying oscillations in Parkinson's disease and generalized epilepsies

Authors: *E. J. MULLER[1], S. J. VAN ALBADA[2], J.-W. KIM[1], P. ROBINSON[1]
[1]Sch. of Physics, Univ. of Sydney, Sydney, Australia; [2]Res. Ctr. Juelich, Juelich, Germany

Abstract: The mechanisms underlying pathologically synchronized neural oscillations in Parkinson’s disease (PD) and generalized epilepsies are explored in parallel via a physiologically-based neural field model of the corticothalamic-basal ganglia (CTBG) system. The basal ganglia (BG) are approximated as a single effective population and their roles in the modulation of oscillatory dynamics of the corticothalamic (CT) system and vice versa are analyzed. In addition to normal EEG rhythms, enhanced activity around 4 Hz and 20 Hz exists in the model, consistent with the characteristic frequencies observed in PD. These rhythms result from resonances in loops formed between the BG and CT populations, analogous to those that underlie epileptic oscillations in a previous CT model, and which are still present in the combined CTBG system. Dopamine depletion is argued to weaken the dampening of these loop resonances in PD, and network connections then explain the significant coherence observed between BG, thalamic, and cortical population activity around $4-8$ Hz and 20 Hz. Parallels between the afferent and efferent connection sites of the thalamic reticular nucleus (TRN) and BG predicts low dopamine to correspond to a reduced likelihood of tonic-clonic (grand mal) seizures, which agrees with experimental findings. Furthermore, the model predicts an increased likelihood of absence (petit mal) seizure resulting from pathologically low dopamine levels; this agrees with experiments that show an increased likelihood of absence seizures following dopamine depletion. Suppression of absence seizure activity is demonstrated when afferent and efferent BG connections to the CT system are strengthened, which is consistent with other CTBG modeling studies. The BG are demonstrated as having a suppressive effect on activity of the CTBG system near tonic-clonic seizure states and support the reported efficacy of treatments targeting BG circuits. Sleep states of the TRN are also found to suppress pathological PD activity. Overall, the findings demonstrate strong parallels between coherent oscillations in generalized epilepsies and PD, and provide insights into possible comorbidities.

Title: Deletion of the striatal matrix and striosome signaling molecules, CalDAG-GEFI and CalDAG-GEFII, mitigates the onset of abnormal motor responses to L-DOPA in a Parkinson's disease model mouse

Authors: *J. R. CRITTENDEN[1], T. KITSUKAWA[3], H. BOWDEN[2], D. E. HOUSMAN[2], A. M. GRAYBIEL[2]
[1]McGovern Inst. for Brain Research, Brain & Cognitive Sci., [2]MIT, Cambridge, MA; [3]Osaka Univ., Suita, Japan

Abstract: In Parkinson's disease, difficulty in initiating voluntary movement is relieved by dopamine replacement therapy with oral L-DOPA (L-3,4-dihydroxyphenylalanine), which is thought to make up for the degeneration of dopamine-containing neurons in the substantia nigra pars compacta (SNc). A complication of this therapy is the occurrence of L-DOPA-induced dyskinesia (LID), which consists of involuntary movements driven in part by striatal projection neurons (SPNs) that signal abnormally because of severe dopamine depletion and unregulated dopamine release from various cellular sources that convert L-DOPA to dopamine. We previously found that expression of two SPN-enriched signaling molecules of the Ras/Rap/ERK signaling cascade, CalDAG-GEFI and CalDAG-GEFII, is oppositely dysregulated in a rat model of LID. CalDAG-GEFII, which is enriched in the striosome compartment of the striatum, exhibits increased expression, whereas expression of CalDAG-GEFI, which is normally enriched in the extra-striosomal matrix, is reduced. CalDAG-GEFII-positive striosomal SPNs make specialized connections ('striosome-dendron bouquets') with a subset of ventral dopamine-producing neurons, potentially corresponding to those that die early in Parkinson's disease. By contrast, CalDAG-GEFI-positive matrix SPNs target the surrounding, non-dopaminergic nigral regions.
Single CalDAG-GEF knockout mice showed normal motor learning, indicating that they are potential therapeutic targets. We crossed single CalDAG-GEF knockout mice to *pitx3*$^{ak/ak}$

Parkinson's disease model mice to test for changes in responsiveness to L-DOPA treatment. Young *pitx3*$^{ak/ak}$ mice have bilateral loss of SNc neurons and show severe hyperactivity in response to repeated L-DOPA treatments. Mice that were double mutants for *pitx3*$^{ak/ak}$ and either *CalDAG-GEFI* or *CalDAG-GEFII* deletion showed relatively reduced hyper-responsiveness to L-DOPA early in the course of treatment, suggesting that the CalDAG-GEFs might be important for the establishment of L-DOPA hyper-responsivity. To test for molecular correlates of this partial rescue, we evaluated the striatal transcriptome, by RNAseq, from *pitx3*$^{ak/ak}$ mice in the early phase of L-DOPA treatment with and without *CalDAG-GEFI/II* deletion. A dopamine-regulating neuropeptide was found to be upregulated in the *pitx3*$^{ak/ak}$ mice but not in the double mutants, suggesting a possible molecular mechanism for how CalDAG-GEF deletion mitigates L-DOPA hyper-responsiveness. Our findings suggest that the striatum-enriched CalDAG-GEF genes are important for the genesis of LID symptoms in models of this debilitating disorder.

Title: Aberrant corticostriatal plasticity in Parkinsonian motor inhibition

Authors: *M. J. PATEL[1], D. S. MCGEHEE[2], X. ZHUANG[1]
[1]Neurobio., [2]Anesthesia & Critical Care, Univ. of Chicago, Chicago, IL

Abstract: Parkinson's disease (PD) is a progressive neurodegenerative disease that is characterized by the death of midbrain dopamine neurons and the long-lasting deterioration of motor output. The indirect pathway of the basal ganglia, which is known to suppress movement, is believed to be hyperactive in PD following the loss of dopamine in the striatum. Our laboratory recently reported that motor training in mice with a D2 dopamine receptor blockade results in a long lasting, experience-dependent motor inhibition that persists even after normal dopamine signaling is restored. To examine the mechanisms that underlie this motor inhibition, we measured changes in corticostriatal plasticity in brain slices following the onset of experience-dependent motor inhibition. We found that motor training under D2 receptor blockade results in strengthening of corticostriatal synapses in the indirect pathway. Furthermore, we found that combining optically driven corticostriatal activity with D2 receptor

blockade led to lasting motor impairment in mice. Our data provide support for potential therapeutic approaches that target corticostriatal plasticity for treating PD.

Title: Origin of rest tremor in parkinson's disease: Oscillations in neuronal signals or feedback-induced instability in the sensorimotor loop?

Authors: *T. HOMAYOUNI[1], V. V. SHAH[2], S. GOYAL[3], H. PALANTHANDALAM-MADAPUSI[4]

Abstract: Rest tremor is one of the most common and disabling symptoms of Parkinson's disease (PD). The exact neural origin of rest tremor is still not clearly known. There is a good evidence that tremor may have a pathophysiology different from most other Parkinson's disease symptoms. To date, the pathophysiology of rest tremor is not clearly established. Further, rest tremor does not respond well to dopamine replacement therapy compared to other motor symptoms in PD. Understanding the neural origin of parkinsonian rest tremor is important to optimize the existing treatment strategies such as Deep Brain Stimulation or to develop new alternative treatment strategies for rest tremor reduction.There are broadly two categories of theories that are gaining prominence to explain the origin of parkinsonian rest tremor. The first category is the central oscillator theory, which proposes that the rest tremor is a manifestation of oscillatory signals originating from the brain. These could be produced either by a nucleus with spontaneous rhythmicity or by instability in the local (central) feedback loop consisting of neuronal populations or different nuclei and their axonal connections in the brain. The second category is the feedback-induced instability theory which proposes that the rest tremor is a limit-cycle oscillation that occurs due to feedback-induced instability in the sensorimotor loop caused by increased reaction time (delay in sensorimotor loop). We implemented these two categories of theories in a simulation example of a simple control system, and compared the simulated trends with established clinical observations. We found that majority, but not all of the clinically observed trends support the feedback-induced instability theory. So, in order to arrive at a conclusive answer, we suggest some clinical tests inspired by our simulations.

Title: Striatal cholinergic interneurons integrate the attentional control of complex movements

Authors: ***A. J. KUCINSKI**, D. BALLOUZ, Y. KIM, M. SARTER
Psychology, Univ. of Michigan, Ann Arbor, MI

Abstract: In addition to the disease-characterizing motor symptoms that reflect primarily striatal dopamine loss, Parkinson's disease (PD) is characterized by widespread neurodegenerative processes in non-dopaminergic brain systems, including cholinergic systems projecting to telencephalic and diencephalic regions. Consistent with the functions of forebrain cholinergic systems in attention, PD patients with cholinergic losses have a propensity for falls attributed to impairments in the attentional supervision of balance and movement. Specifically, cholinergic losses are hypothesized to disrupt attentional processing of exteroceptive and interoceptive cues that normally mediate balance and movement, particularly movements across unfamiliar or dynamic surfaces. As a result, such information is not effectively forwarded to striatal circuitry where, in interaction with dopaminergic losses that cause slow and low-vigor movements, movement planning and sequencing are disrupted and lead to falls. We previously developed a rat model of falls caused by partial basal forebrain cholinergic and striatal dopamine losses. Here we tested the hypothesis that silencing of striatal cholinergic interneurons is sufficient to reproduce such fall propensity, suggesting that these neurons integrate interactions between deficient cue import and low-vigor movement. Rats were familiarized with the Michigan Complex Motor Control Task that requires them to traverse increasingly taxing 3-m long beams, including rotating and zig-zag rods in the presence of distractors. Rats then received bilateral infusions of an inhibitory DREADD (AAV-hSyn-DIO-hM4D(Gi) either into the dorsomedial striatal projection field of the prefrontal cortex or the dorsolateral sensorimotor tier of the striatum. Silencing of dorsomedial, but not dorsolateral, striatal interneurons with CNO administration (5 mg/kg; i.p.) fully reproduced the types and frequency of falls caused by dual cholinergic-dopaminergic lesions. To verify the efficacy of the DREADD we demonstrated attenuated striatal acetylcholine release in response to potassium-evoked depolarization (via reverse microdialysis). These findings suggest that striatal cholinergic interneurons integrate the cortical-striatal import of cue information with high-vigor, dopaminergically-mediated

movement. Treatments to attenuate the risk for falls in PD patients therefore may target striatal interneuronal output to benefit movement error detection and enhance the organization and speed of complex movements.

Title: Effects of neurofeedback control of beta band oscillations in motor cortex on finger tapping in parkinsonian patients

Authors: *P. KHANNA[1], N. C. SWANN[2], P. A. STARR[3], J. M. CARMENA[1]
[1]UC Berkeley, Berkeley, CA; [2]Neurolog. Surgery, Univ. of California, San Francisco, San Francisco, CA; [3]Neurosurg., Univ. of California San Francisco Dept. of Neurolog. Surgery, San Francisco, CA

Abstract: Parkinsonian patients have been shown to exhibit exaggerated basal ganglia beta power when they are off-medication or off-stimulation suggesting that exaggerated beta oscillations may contribute to their bradykinesia, rigidity, or tremor symptomology. Previous studies have also demonstrated that motor cortical beta oscillations tend to precede those observed in the basal ganglia suggesting that motor cortex (M1) may be driving downstream basal ganglia beta oscillations. One surprising finding then, is that M1 beta power is not affected by medication or stimulation therapies. Here, we seek to test the role of motor cortical beta power levels on motor actions by using a neurofeedback - movement task structure. Patients learn to control their motor cortical beta oscillations in real time by making a cursor on a screen (which reflects current beta state) increase or decrease to reach a specified level depending on trial. After successfully reaching the instructed beta level, patients immediately after execute a six-second finger tapping sequence. This sequential task structure allows investigation of how high and low motor cortical beta states support subsequent movements.
In previous work we show that patients are able to perform neurofeedback above chance-level,

yet do not exhibit significant improvements within a 1-2 hour session. Thus, in this study, patients get 10 days of training in the comfort of their own home so that they can become proficient at performing neurofeedback control. In one patient with multiple systems atrophy (MSA, parkinsonian subtype), we find that the high and and low beta states reached during neurofeedback precede slower and faster finger tapping onset times respectively. This finding suggests that motor cortical beta power does have a role in movement initiation in the parkinsonian state. We also study the dynamics of finger tapping movements following high and low beta states, dynamics of simultaneously recorded STN beta power signals, and improvement in neurofeedback performance over days. This work contributes to our understanding of M1-STN beta frequency range interactions, M1 beta power dynamics with movement, and develops a potentially therapeutic neurofeedback paradigm for training patients to initiate movement more fluidly.

Title: Causality of beta frequency oscillations in bradykinetic/akinetic parkinsonian symptom generation in rats

Authors: *C. BEHREND[1], D. SCHULTE[1], D. BROCKER[1], W. M. GRILL[1,2]
[1]Biomed. Engin., [2]Neurobio. & Surgery, Duke Univ., Durham, NC

Abstract: Substantial correlative evidence links the synchronized, oscillatory neural firing patterns that emerge in Parkinson’s disease (PD) in the “beta” frequency range (13-30Hz) with bradykinesia in PD. However, conflicting evidence exists, and whether these changes in neural firing pattern are causal of motor symptoms in PD remains unclear. We tested the hypothesis that the synchronized beta oscillations that emerge in PD are causal of symptoms of bradykinesia/akinesia. We designed novel patterns of stimulation that mimicked the temporal characteristics of single unit beta bursting activity seen in PD rats and humans. We applied these beta-patterned paradigms along with continuous low and high frequency controls to the subthalamic nucleus (STN) of healthy and levodopa-treated parkinsonian rats. We quantified the degree of unit entrainment in the substantia nigra reticulata (SNr) as a function of pattern and

amplitude by calculation of the excitatory effective pulse fraction (eEPF) (Agnesi et al 2015). The eEPF (range: 0-1) is a ratio of the number of unit firings evoked by a stimulus pulse to the total number of stimulation pulses referenced to the effects of 'virtual' stimulus pulses during a baseline period. We further quantified the increase in SNr unit spectral beta frequency power due to the applied stimulation paradigms. We found that while patterns entrained units equally, beta-patterned paradigms induced significantly more beta frequency activity than continuous low frequency controls. However, we found no deleterious effects on motor performance across a wide battery of validated behavioral tasks including the bar test, open field test, forelimb akinesia test, adjusting steps test, and skilled forelimb reach test. We applied the same methodology in parkinsonian rats to test whether the neural substrate that emerges in parkinsonism would be more susceptible to the effects of the beta-ergic stimulation patterns. We administered levodopa to 6-OHDA lesioned animals to disrupt endogenous beta activity and allow us to separate the effects of our patterns on motor performance from baseline parkinsonian motor performance. However, although most tests were sensitive to hemiparkinsonism induced by unilateral 6-OHDA lesion, we again found no impact of our patterns on motor performance. Our results uncovered no evidence of a causal relationship between beta frequency oscillations and bradykinesia/akinesia in PD.

Title: Transient beta oscillation dynamics in experimental Parkinsonism

Authors: *H. CAGNAN[1,2], N. MALLETT[3,2], P. J. MAGILL[2], P. BROWN[2], A. SHAROTT[2]
[1]Univ. Col. of London, London, United Kingdom; [2]Univ. of Oxford, Oxford, United Kingdom; [3]CNRS, Bordeaux, France

Abstract: There has been a renewed interest in the transient beta dynamics of cortex and subcortical brain regions involved in motor control. The probability and temporal dynamics of these transient oscillations, referred to as beta burst, have been related to motor performance, and Parkinson's disease treatment state. There have been numerous theories regarding the origin of excessive beta oscillations in the motor circuits of the forebrain, attributing this oscillatory state

to (1) subthalamic and pallidal coupling, (2) internal cortical dynamics, and (3) the interaction between subcortical drive modulating the cortex in a laminar specific fashion. Lesioning any part of the motor circuit however has the capability of quenching neural synchrony in the beta frequency band, highlighting the interdependency between the cortico-basal ganglia circuit and oscillations in the beta band. Previous studies explored time-averaged dynamics of the cortico-basal ganglia circuit during Parkinson's disease with respect to control or medicated Parkinsonian state; however, to accurately determine dynamics underlying the Parkinson's disease pathophysiology, it is vital to characterize the transient changes across the motor circuit at the onset, and the offset of a beta burst. In this study, we set out to address the following questions (1) how is the subcortical neural synchrony and spiking activity modulated at the onset, and offset of a beta burst? and (2) which neural dynamics distinguish physiological short duration beta bursts from pathophysiological long duration beta bursts? In 6-OHDA-lesioned rat model of Parkinsonism, cortical beta bursts consist of short transient oscillations that can last for several beta cycles; maximum beta burst duration being on average 413 ± 67 ms (STD). Basal ganglia nuclei, including the striatum, external globus pallidus and subthalamic nucleus, exhibit enhanced background unit activity (BUA) in the beta band, time locked to the onset of a cortical beta burst. Across different epochs, emergence of rhythmic activity in basal ganglia nuclei is temporally correlated; highlighting that sub-cortical beta can emerge only at a fixed phase relationship with respect to cortical neural activity. Crucially, the phase relationship between the sensorimotor cortex and basal ganglia nuclei changes at the onset and termination of a cortical beta burst. Together, these results provide a framework for characterising the transient oscillations across the motor circuit.

Abstract: Dopamine agonists (DA) that are widely used to treat motor deficits in patients with Parkinson's disease (PD) are frequently associated with the development of abnormal-impulsive behaviors (AIB). The pathophysiology of AIB is poorly understood and there is a need for reliable animal models. We have analyzed the behavior of parkinsonian (injection of adeno-associated viral vectors (AAV) encoding for A53T mutated hα-syn in the substantia nigra compacta) and control (AAV-GFP expression) rats under chronic treatment with the D2/D3 receptor DA pramipexole (PPX) during 4 weeks, in OFF and ON medication states, using the 5-Choice Serial Reaction Time-Task (5-CSRTT). Before PPX treatment, the dopaminergic lesion increased the premature responses rate (waiting impulsivity) that was further increased with PPX during the 4 weeks of treatment in ON medication state and that was significantly higher than in control rats. A similar pattern of changes was observed in the variables related to attention (reduced accuracy in the responses and increased omissions). Premature response rate before and after treatment (both in ON and OFF medication) were correlated. In turn, premature responses before treatment and in OFF correlated with the striatal dopaminergic depletion (Dopamine transporter (DAT) immunochemistry). No significant changes were observed in OFF medication state in premature responses rate respect to the pretreatment state. The striatal expression of FosB/ΔFosB inversely correlated with the DAT expression and was higher in the lateral region of both striata and in the shell and core of the nucleus accumbens in parkinsonian than in control rats. In conclusion, these results indicate that the dopaminergic lesion is a risk factor to develop abnormal impulsive behaviors in PD under DA treatment and that this model could be a valid tool to investigate the pathophysiology of AIB in PD.

Title: Does the Lempel-Ziv algorithm provide an unbiased measure of neuronal complexity in the subthalamic nucleus of 6-OHDA lesioned rats?

Authors: *A. MANOHAR, *A. MANOHAR, M. J. MARINO
Merck & Co, Philadelphia, PA

Abstract: Parkinson's disease (PD) is characterized by a loss of dopaminergic neurons in the substantia nigra pars compacta (SNpc), leading to increased striatal activity, increased inhibition of the globus pallidus externa (Gpe) and subsequent disinhibition of the subthalamic nucleus (STN). Neurons in the STN often exhibit a characteristic burst firing pattern in PD patients. Selective lesions of the nigro-striatal pathway in rodents using a neurotoxin, 6-hydroxy dopamine (6-OHDA),produces changes in basal ganglia physiology including burst firing in the STN which mimic the pathophysiology of Parkinson's. This model has been used extensively to both understand disease mechanisms and develop therapeutic interventions. It has been a challenge to objectively quantify aberrant firing patterns of neurons observed in pathological conditions without making prior assumptions. Here we investigate analytical methods that can potentially overcome this by measuring the complexity of neuronal spike trains without any assumptions about the source. Lempel-Ziv complexity has been broadly used for data compression and loss-less transmission of code for many years. More recently, LZ has been applied to measure the complexity of discrete-time physiological signals. We adapted the LZ complexity for binarized spike trains and normalized the value to the maximum complexity that can be obtained using a spike train of given length. Treating the spike train as string consisting of 0s and 1s we form a vocabulary of distinct words encountered in the string leading to a complexity value. We evaluated the differences in complexity of spike trains obtained from STN neurons in a group of naïve rats (N=41 neurons) and a group of 6-OHDA lesioned rats (N=28 neurons). Our results strongly indicate that the estimation of the LZ complexity is inherently tied to the density of 1s (i.e. the firing rate of the neuron). This finding bears significance, both for understanding our results as well as appropriately interpreting results from previous studies.

Title: Parkinson's disease does not alter knee and ankle joint threshold for detection of passive movement

Authors: *G. G. GENOVES[1], C. F. CRUZ[1,2], J. A. BARELA[1,3]
[1]Cruzeiro Do Sul Univ., Sao Paulo, Brazil; [2]Univ. of São Paulo, São Paulo, Brazil; [3]São Paulo State Univ., Rio Claro, Brazil

Abstract: Proprioception is an important source of sensory information and the integrity of proprioceptive information is crucial for performing daily activities. People with Parkinson's disease show changes in several daily tasks such as postural instability and locomotion difficulties. Some of these changes due to the Parkinson's disease have been attributed, among other causes, to proprioceptive impairment of the lower limbs. However, there is still a need to assess and, consequently, to farther uncover possible changes in proprioceptive cues due to Parkinson's disease. Therefore, the aim of this study was to evaluate the threshold for knee and ankle passive movement detection in patients with Parkinson's disease. Ten patients with Parkinson's disease (Age 64.3 ± 5.9 years, stages 1 and 2 on the Hoehn & Yahr scale) and ten health elderly (age 64.1 ± 5.9 years) participated in this study, the age and gender were matched. Initially, participants performed a simple computer reaction time test. Afterward, participants were seated with eyes closed in a chair with a lever that, driven by a motor, passively moved (speed of 0.5º/s) the participant's knee or ankle joint in both directions. At initial position, knee and ankle joints were positioned at 90º. Participants were asked to press a switch, as soon as they detected the limb movement, interrupting the movement. Each participant performed three attempts for each direction in the sagittal plane, randomly distributed, totalizing six attempts for each joint (right and left knee, right and left ankle). A motion analysis system (OPTOTRACK Certus) captured the displacement of the emitters in the chair lever. Total displacement was obtained using the initial and the final position of the device lever. Single reaction time was similar between patients with Parkinson's disease and their peers. Similarly, threshold for knee and ankle passive movement detection did not differ between groups. These results suggest that proprioceptive cues coming from the lower limbs are intact in patients with Parkinson's disease and indicate passive motion of the lower limbs as in health older adults. Thus, any possible changes in proprioceptive information coming from the lower limbs in patients with Parkinson's disease are questioned at least for passive positioning.

Title: Grey matter changes of vervet monkeys after MPTP administration: Voxel-based morphometry analysis

Authors: *G. RAMÍREZ GARCÍA[1,2], C. CASTILLO-HERNANDEZ[3], J. FERNANDEZ-RUIZ[4], A. CAMPOS-ROMO[5,2]

Nacional Autonoma Mexico, Ciudad de Mexico, Mexico; [5]UNAM, Ciudad de Mexico, Mexico

Abstract: Parkinson´s disease (PD) is a chronic and progressive disorder characterized by a neurodegenerative process resulting in motor and non-motor disturbances. The main histopathological change is dopaminergic neuron death in the substantia nigra pars compacta that results in low dopamine levels in the striatum. However, other brain structures besides the SNc could be affected in PD. Voxel-based morphometry (VBM) is a neuroimaging technique used to analyze the density changes of grey matter (GM) tissue. Using this technique in PD patients it has been shown GM decreases in frontal and parietal cortices, cerebellum, striatum and hippocampus.
In this study, we used 6 vervet monkeys (*Chlorocebus aethiops*). 3 of them were administrated with MPTP at a dosage of 0.5 mg/Kg of weight once per day (im) during 4-5 consecutive days. The others 3 animals conformed the control group. Whole-brain T1-3D images were obtained in a GE Discovery MR750 3T scan. A specific GM population-template was created with T1 images to make a VBM analysis. The images where analyzed using VBM-FSL tool. Images were reoriented and the inhomogeneities were corrected with FAST-FSL. Brain extraction tool was used to remove the skull from an image. The resulting image was registered to the specific GM template with FNIRT, then a specific template was created and each image was non-linearly registered to the new template and concatenated into a GM 4D template. A second non-linear registration was made between each GM image and a specific GM template was created. The resulting image was multiplied by the Jacobian of the warp field to modulate. Each image was concatenate into a 4D image. Finally, randomize for the TFCE-based analysis between groups was carried out and was corrected by permutation test. The threshold applied was a t value of 2.3 corrected a $p = 0.05$.
The results show GM decrease in the cerebellum, caudate, putamen, thalamus and orbitofrontal, prefrontal, cingulate, temporal and visual cortices. It has been suggested that both striatal and cerebellar changes would be related to the motor alteration, while GM changes in prefrontal and temporo-parietal cortex would reflect cognitive damage. It is known, that PD patients present neurodegeneration in different neuronal systems. In our model, these neuronal damages are reproduced by MPTP administration, for that reason, this neurotoxin represents an excellent way to reproduce the mainly characteristics of PD. These results show that MPTP lesion induces a GM decrement in brain regions related with motor and cognitive process as occurs in PD. Thus,

MPTP vervet monkey is a suitable animal model, useful for neuroimaging studies to evaluate the brain changes in PD.

Title: Reduction of SPN firing by NMDAR blockade or DREADDs activation normalizes motor responses to dopamine in animal models of Parkinson's disease

Authors: *G. BECK[1], A. SINGH[2], P. CHANG[2], D. KANG[2], S. M. PAPA[2,3]
[1]Yerkes Natl. Primate Res. Ctr., Atlanta, GA; [2]Yerkes Natl. Primate Res. Center, Emory Univ., Atlanta, GA; [3]Dept. of Neurol., Emory Univ., Atlanta, GA

Abstract: Dopamine replacement is an effective treatment for motor dysfunction of Parkinson's disease (PD). However, long-term dopaminergic therapy is associated with changes in motor responses and the development of involuntary movements known as L-Dopa-induced dyskinesia (LID). Studies in rodent and nonhuman primate (NHP) models, as well as in patients with PD, have shown that striatal projection neurons (SPNs) are hyperactive at the baseline parkinsonian state ("off" state). These neurons respond to dopaminergic stimulation with unstable firing changes at the peak of the response, which are associated with the expression of LID. This study was aimed at examining whether decreasing the baseline SPN firing rates towards the low activity found in normal conditions would reduce LID. The SPN activity was reduced "acutely" using local NMDAR blockade in NHP. A selective NMDAR antagonist (LY235959) was infused into one side of the putamen of advanced parkinsonian NHPs (n=3). In addition, the SPN activity was reduced "chronically" by expressing inhibitory DREADDs (designer receptor exclusively activated by designer drugs), hM4Di, in hemiparkinsonian rats. hM4Di is an engineered version of the M4 muscarinic receptor selectively activated by clozapine-N-oxide (CNO), which leads to hyperpolarization in neurons. We injected rAAV-hSyn-hM4D(Gi)-mCherry or the control virus rAAV-hSyn-GFP into the left striatum of rats with 6-hydroxydopamine lesions of the left medial forebrain bundle (n=9). The whole motor response and LID or AIMs (abnormal involuntary movements) were assessed using standardized rating scales for primates and rodents. Results showed that the striatal injection of NMDAR antagonist in the "off" state of NHP significantly reduced LID scores on the contralateral side without

affecting the antiparkinsonian action of L-Dopa acutely. Also, activation of inhibitory DREADDs in rats significantly reduced AIMs during the chronic testing period of two weeks with daily treatment of L-dopa plus CNO. Virus transduction in the rat striatum was confirmed with histological examination. These results indicate that therapeutic strategies to reduce the hyperactivity of SPNs may help to control dyskinesias and improve motor responses to dopamine in patients with PD.

Title: 3D mapping of circuitry integration of transplanted human embryonic stem cell derived neurons in the adult rat brain

Authors: *B. MATTSSON, T. CARDOSO, D. HOBAN, A. HEUER, S. NOLBRANT, A. KIRKEBY, S. GREALISH, M. PARMAR
Lund Univ., Lund, Sweden

Abstract: We have developed a monosynaptic tracing technique to map circuitry integration of transplanted hESCs (Grealish et al., Stem cell Reports). This technique allows for histology-based analysis of host-to-graft connectivity. With this technique, we have developed quantitative and qualitative methods for whole brain mapping/representation of connectivity in 3D-reconstruction and combined that with assessment of graft innervation. Fiber outgrowth from the transplant is outlined in serial sections based on hNCAM stainings and displayed as a volume in a 3D brain reconstructed from Paxinos brain atlas. With the same technique, the traced cells

detected by mCherry are placed in the 3D brain map and each connecting structure is color coded according to a heat map to show the nuclei containing the highest concentration of host cells connecting to the graft. Using this method we have mapped the circuitry integration of midbrain patterned cells transplanted to the midbrain 6 weeks and 6 months after grafting. Analysis of innervation showed that the grafted cells innervated the forebrain target structures after 6 months. Analysis of connectivity revealed that the transplanted cells are integrated with host neurons already by 6 weeks with only minor changes at the 6 month time point. In summary, rabies based tracing combined with 3D re-construction is a valuable method for better understanding kinetics and patterns of graft innervation and integration.

Title: Synaptic integration of intrastriatal versus intranigral grafts of human embryonic stem cell derived neurons in the adult rat brain

Authors: *T. CARDOSO, D. HOBAN, B. MATTSSON, A. HEUER, S. NOLBRANT, A. KIRKEBY, S. GREALISH, M. PARMAR
Lund Univ., Lund, Sweden

Abstract: Human embryonic stem cell (hESC)-derived neurons survive long-term, release dopamine and extensively innervate correct host structures after transplantation into adult rat brain. Using the monosynaptic tracing technique, we have recently shown that hESC-derived neurons integrate into host circuitry, establishing both host-to-graft and graft-to-host synaptic

connectivity (Grealish et al., 2015, Stem Cell Reports). Here we use the same methodology to investigate connectivity of midbrain (MB) and forebrain (FB) patterned hESCs-derived neurons transplanted either to striatum or substantia nigra of 6-OHDA lesioned rats. To assess for synaptic connectivity, animals were injected with rabies vector 23 weeks after transplantation and perfused one week later. Analysis 24 weeks post-grafting revealed that host neurons established extensive local and distal synaptic connections with both intrastriatal and intranigral grafts. Connectivity varied more depending on the location of transplantation than the phenotype of the cells grafted. For example, intranigral grafts received more inputs from hypothalamus and intrastriatal grafts received more input from thalamus. In summary, we show that intrastriatal and intranigral grafts of hESC-derived neurons can integrate into host circuitry and that pattern of host connectivity is primarily dependent on location of the transplant.

Title: Network correalates of the effects of repetitive transcranial magnetic stimulation on freezing of gait in patients with Parkinson's disease

Authors: *S. SEOL[1], W. CHANG[1], J. LEE[3], J. CHO[2], J. YOUN[2], Y.-H. KIM[1]
[1]Dept. of Physical and Rehabil. Med., [2]Dept. of Neurol., Samsung Med. Ctr., Seoul-City, Korea, Republic of; [3]Dept. of Neurol., Sungkyunkwan Univ., Seoul, Korea, Republic of

Abstract: Introduction: High-frequency repetitive transcranial magnetic stimulation (rTMS) over the lower leg primary motor cortical area can alleviate freezing of gait (FOG) in patients with Parkinson’s disease (PD). However, the response to high-frequency rTMS is highly variable between patients, and the mechanisms of action are also uncertain. The aim of this study was to identify the functional brain connectivity associated with improvement of FOG in response to high-frequency rTMS in patients with PD. **Methods:** Sixteen patients with PD (mean age 63.6 yrs) participated. All patients received high frequency rTMS (90% of resting motor threshold, 10 Hz, 1,000 pulses) over the lower leg primary motor cortical area of the dominant hemisphere (M1-LL) for 5 consecutive days. The FOG Questionnaire (FOG-Q) was performed before and immediately after rTMS. FOG-Q changes greater than or equal to 5 points were considered to the good responder group. Presence or absence of BDNF polymorphism was assessed and Resting-

state functional MRI (rs-fMRI) was acquired in all patients before rTMS and we performed seed to voxel analysis to assess connectivity of parietal opercular cortex and central opercular cortex in each patient. The laterality index was calculated to measure asymmetry in functional connectivity between both hemispheres. Various demographic and clinical characteristics and the laterality index of connectivity of rs-fMRI were compared between good and poor responder groups of rTMS. **Results:** Eight (50.0%) and 8 (50.0%) patients were classified as good and poor responders, respectively. There was no significant difference in age, sex, duration of PD, and Hoehn-Yahr stage between good and poor responder groups. In addition, severity of motor impairment and FOG-Q showed no significant difference between two groups. The number of Met heterozygote was significantly higher in the poor responder group than the good responder group ($p<0.05$). In the analysis of rs-fMRI, the laterality index of the central opercular cortex showed significantly higher asymmetry in the good responder group than the poor responder group ($p<0.05$). **Conclusion:** These results suggest that BDNF genotype the lateralization of connectivity of rs-fMRI can be used for designing individually-tailored rTMS to reduce FOG in patients with PD (Supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (MSIP) (NRF-2017R1A2A1A05000730, NRF-2016R1A2B4012054)).

Abstract: Combination antiretroviral therapy (cART) has allowed individuals infected with Human Immunodeficiency Virus (HIV) to reach typical life expectancy. Now, HIV positive individuals are subject to age-related processes including neurodegenerative diseases similar to that of Parkinson's disease (PD), given that both diseases affect subcortico-cortical pathways. We compared neural networks in 20 older healthy controls (HC), 20 HIV-infected individuals, and 22 individuals with PD using resting-state functional connectivity MRI. Functional connectivity (fc) was determined using the Stanford 90ROI functional atlas (findlab.stanford.edu/functional_ROIs.html) for ROI-to-ROI analysis testing differences in interregional fc among the 3 groups (pFWE<0.05, 2-tailed). Significant group differences were observed for fc between parietal and frontal, thalamic, and cerebellar regions, and between left and right motor cortices. Follow-up analysis revealed a graded pattern from strong fc in PD to weaker fc in HIV and weakest fc in HC between left angular cortex and precuneus, posterior and middle cingulate, and superior frontal regions, and the opposite graded pattern from weak fc in PD, stronger fc in HIV, and strongest fc in HC between parietal-orbitofrontal regions. Older age in HIV was associated with greater angular-precuneus fc (r=.65, p=.002). Specifically, HIV showed weaker bilateral thalamo-precuneus fc than HC, in whom greater thalamo-precuenus fc correlated with faster fine finger movement (FFM; all p's <0.05). PD most notably exhibited weaker fc than HC and HIV between left and right motor cortices and between cerebellar vermis and parietal cortices, with the latter being associated with slower left hand FFM performance in PD (r=.55, p=.007). Together our findings indicate both, a graded pattern of fc alteration with HIV being in-between HC and PD, and diagnosis-specific neurofunctional consequences for intrinsic interregional brain networking that have meaning for motor skills. Title: Changes in free-water along motor tracts in parkinson's disease and atypical parkinsonian syndromes

Authors: *W. T. CHU[1], D. B. ARCHER[1], N. R. MCFARLAND[2], M. S. OKUN[2], S. LAI[3], D. E. VAILLANCOURT[4]
[2]Neurol., [3]Radiation Oncology, [4]Applied Physiol. and Kinesiology, [1]Univ. of Florida, Gainesville, FL

Abstract: Diffusion imaging (dMRI) could provide a unique method for non-invasive in vivo quantification of Parkinson's disease progression. The objective of this work was to explore the changes in free-water along key white matter tracts in the brain that are important in movement in Parkinson's disease (PD), multiple system atrophy (MSA), and progressive supranuclear palsy (PSP). These tracts include the corticostriatal, cerebello-thalamo-cortical, and corticospinal tracts. The study examined a cohort of 38 controls, 46 PD patients, 16 MSA patients, and 19 PSP patients who each received two MRI scans one year apart (baseline and 1-year). A unique probabilistic tractography algorithm was used to derive these motor tracts and average free-water along the tracts in each axial slice was quantified. These values were then compiled to create free-water profiles. An ANOVA, with covariates using age and sex, was conducted at each axial slice for each tract profile to determine group effects. Additionally, a cross-sectional analysis was conducted correlating area under the curve (AUC) of the free-water profiles with clinical scores at baseline and 1-year separately. The large majority of all motor tracts were found to have significantly [$p<0.05$, false discovery rate (FDR) corrected] increased free-water in PSP compared to controls. Additionally, portions of the cerebello-thalamo-cortical tract showed significantly [$p<0.05$, FDR corrected] increased free-water in MSA compared to controls. Free-water AUC was found to significantly correlate with the Purdue Pegboard test performance [baseline: $R^2=56.4\%$, $p<0.001$; 1-year: $R^2=59.9\%$, $p<0.001$] and Unified Parkinson's Disease Rating Scale (UPDRS) scores [baseline: $R^2=43.0\%$, $p=0.003$; 1-year: $R^2=43.0\%$, $p=0.003$] at baseline and 1-year time points. Evidence has been provided for structural alterations within important tracts relevant to movement. These results further show that the structural alterations correlate with clinically relevant measures such as the Purdue Pegboard and UPDRS.

Title: Functional connectivity in the somatosensory network in the akinetic-rigid and tremor Parkinson's disease patients

Authors: *Y. JIANG[1,2], Y. YUE[2], R. YE[2], T. SHEN[2], B. ZHANG[2], H.-Y. LAI[1]
[1]Interdisciplinary Inst. of Neurosci. and Technol., Zhejiang Univ, Zhejiang Province, China; [2]Dept. of neurology, Second Affiliated Hospital, Sch. of Medicine, Zhejiang Univ., Hangzhou, China

Abstract: Parkinson’s disease (PD) is a neurodegenerative disorder characterized by movement disorder. Convergent evidence has indicated that PD patients also experience an array of somatosensory problems. The underlying mechanism of somatosensory deficits in PD is still poorly understood. In addition, the symptoms are also assumed to contribute to the deficits in sensorimotor integration which is considered to degrade motor performance in PD. The goal of this study was to characterize the functional connectivity (FC) in the cortical somatosensory network and the correlation between the activation pattern of somatosensory network and the motor symptoms in different PD types. To this end, we used the resting-state functional magnetic resonance imaging (fMRI) to explore the FC change in the cortical somatosensory network,

including BA1, 2, 3A, 3B, 5 and 7, which were extracted from the Julich Cytoarchitectonic Mapping. We analyzed the mean FC of somatosensory network in 35 patients, 21 akinetic-rigid Parkinson's disease (PD AR) and 14 tremor Parkinson's disease (PDT), along with 20 age-matched healthy controls (HC). All Parkinson's patients were evaluated by Unified Parkinson's Disease Rating Scale (UPDRS). Our data demonstrated that the widespread deficits in FC within the somatosensory network in the PDAR subjects, as compared to HC ($P<0.01$, Bonferroni correction) and PDT subjects ($P<0.001$, Bonferroni correction). There is no significant difference between HC and PDT in mean Fisher's r-to-Z score for all connections within the somatosensory network. In addition, the rigidity score of PDAR is significantly negative linear related to the mean FC of somatosensory network ($P<0.005$). Taken together,the results indicated that the somatosensory network may play an important role in PDAR subtype and the FC strength of somatosensory network may be related to the motor performance in PD.

Abstract: The death of dopaminergic neurons in the substantia nigra (SN) pars compacta is the pathological hallmark of Parkinson disease (PD). Although numerous imaging techniques have been used to evaluate PD, most of them are based in qualitative MR images rather than quantitative MR images. Qualitative MR are very sensitive of acquisition parameters and the way of the analysis is performed. We propose to study this anatomical region using quantitative T1 maps that estimate the spin relaxation time for each pixels which could be related with the integrity of the tissue. We proposed that the T1 value (measured in ms) would be related with the degree of nigral degeneration in PD as compared with healthy controls (HC). Also we compared

the asymmetry in SN T1 values in PD subjects. Patients and Methods: PD patients diagnosed according to the London brain Bank criteria were included. Patients were scanned in a 1.5T Achieva Philips scan and a T1 mapping was performed using a sequence that employs two non-selective inversion pulses with inversion times ranging from 20ms to 2000ms, followed by 8 segmented readouts for 8 individual images. T1 values were computed on a pixel-by-pixel basis using an in-house software (Matlab, Natick, MA). Healthy volunteers were scanned as controls. Results: Ten PD patients and 10 HC were included. T1 maps showed a different pattern between PD and HC. The average T1 relaxation time of the whole SN between HC and PD was significant different (Figure). No differences were found in the SN in PD between more and less affected sides. Segmental analysis in the T1 values demonstrated significant differences in the middle and posterior section of the SN between HC and PD groups. Conclusions: T1 map is a quantitative technique that could provide new information for the diagnosis and follow-up of PD patients. Additionally its quantitative properties allow to compare the results between different patients and to evaluate progression in a quantitative and objective way. Larger and prospective studies are needed to confirm these findings.CJ is supported by FONDECYT 11130534 and MA by Anillo ACT1416.

Title: Changes in motor subtype designation of Parkinson's disease patients from two cohorts

Authors: *R. S. EISINGER[1], D. MARTINEZ-RAMIREZ, 32605[2], C. W. HESS[2], M. S. OKUN[2], A. GUNDUZ[3]
[1]Neurosci., [2]Ctr. for Movement Disorders and Neurorestoration, [3]Biomed. Engin., Univ. of Florida, Gainesville, FL

Abstract: Background: Distinct motor subtypes of PD have been identified through both clinical observation and data-driven approaches. However, the extent to which motor subtypes are mutable during disease progression is not fully known.
Methods: We used the Parkinson's Progression Markers Initiative (PPMI) database of 423 newly diagnosed PD patients and the National Institute of Neurology and Neurosurgery database from Mexico (UNAM) of 197 PD patients. Using hierarchical correlational clustering, in both cohorts we found distinct Tremor Dominant (TD), Axial Dominant (AxD), Appendicular Dominant (ApD), Rigidity Dominant (RD), and Postural Instability and Gait Disorder/Dominant (PIGD) groups. For each motor assessment time point, we mathematically assigned patients to one of these five subtypes. We then converted these categories to an ordinal scale by assigning each subtype a numerical value from 1 to 5. For patients with inconsistent subtypes over time, we computed relative subtype frequencies over time using a bin width of 3 months to produce population-level averages. We analyzed subtype drift over time using univariate analysis, ANOVA, and regression.
Results: Subtypes for 52% and 72% of patients within the PPMI and UNAM cohorts respectively fit criteria for at least two different subtypes across time points. For the PPMI cohort, 59.3% of patients were categorized as TD and 21.4% as PIGD. By 4.5 years after diagnosis, these values shifted to 40.6% and 35.9% respectively. Similarly, for the UNAM cohort, 60% of patients were categorized as TD and 21% as PIGD soon after diagnosis. By 6 years, these numbers shifted to 37% and 42% respectively. By ANOVA, there was a significant increase in subtype values over time within the PPMI cohort, $p < 0.001$, and within the UNAM cohort, $p < 0.001$. In other words, on the spectrum from TD to PIGD, the cohort as a whole progressed away from a TD phenotype with disease progression. A linear regression model of motor subtype dependent on time suggests that subtype increased by about 0.22 units per year after diagnosis within the PPMI group ($p < 0.001$) and by 0.14 units per year after diagnosis within the UNAM cohort ($p < 0.001$). These results demonstrate that PD motor subtypes may change or progress over time.
Conclusions: PD subtypes are stable for some patients and unstable for others. By frequency, more patients are classified as TD soon after diagnosis. There is an overall shift away from TD and towards PIGD with disease progression.

Title: Altered cortico-striatal functional connectivity in REM sleep behavior disorder with subtle motor dysfunction

Authors: G. YAMADA[1], *Y. UEKI[2], N. OISHI[4], T. OGURI[1,5], A. FUKUI[3], M. NAKAYAMA[3], N. MATSUKAWA[1]

Abstract: Subtle motor dysfunction is reported to be a high-risk factor of neurodegenerative disorders in REM sleep behavior disorder (RBD), however, there are few studies as to evaluate the motor function. We investigate whether finger tapping movement is already impaired in some patients with RBD and if so, it is attributed to the nigrostriatal degeneration and/or sensorimotor network abnormality. Twenty patients with RBD and twenty age-matched healthy controls (HC) were included. Sixteen patients were diagnosed as RBD by polysomnography and four patients were determined as probable RBD by the Mayo Sleep Questionnaire. In finger tapping, participants were instructed to tap their index finger and thumb as rapidly and as widely as possible during 15 seconds. Mean amplitude, peak open velocity and peak close velocity were recorded using a magnetic sensing device. When either of these parameters in RBD is less than two standard deviations of that in HC, these RBD patients were classified as “poor performer”. DAT SPECT and Resting-state fMRI were performed and compared between HC and poor performer of RBD. Six RBD patients were classified as poor performer. The laterality index |Right-Left|/((Right+Left)/2)) of SBR in posterior putamen was significantly higher in poor performer of RBD compared with HC. Moreover, they exhibited decreased functional connectivity between striatum and cortical areas compared to HC. These results revealed the nigrostriatal degeneration and altered cortico-striatal network in RBD patients with poor finger tapping performance. Stratification of RBD patients with finger tapping might be useful for early diagnosis of pre-clinical neurodegenerative disorders.

Title: Individualized tractography-based parcellation of the globus pallidus pars interna using 7-Tesla magnetic resonance imaging in movement disorder patients prior to deep brain stimulation surgery

Authors: *R. PATRIAT[1], Y. DUCHIN[2], J. NIEDERER[2], C. LENGLET[2], J. AMAN[3], S. COOPER[3], J. VITEK[3], N. HAREL[2]

Abstract: The success of deep brain stimulation (DBS) surgeries for Parkinson’s disease relies on the accurate placement of an electrode within the motor portion of subcortical brain targets with the goal of maximizing the patient’s benefits while minimizing side effects. Today’s targeting methods do not ensure such accuracy and it is estimated that 15-34% of DBS procedures require revisions. Common targeting methods typically consist in fitting template information onto the patient’s anatomy, which results in errors in the determination of the location, shape, size and orientation of the actual DBS targets. These inaccuracies may engender the DBS electrode to be placed either outside of the target or within the target but not in the motor territory, thus, causing debilitating side effects. We have previously demonstrated that 7-Tesla magnetic resonance imaging (MRI) can be used to produce high-resolution images enabling accurate visibility of the basal ganglia structures. In this study, we show that 7-Telsa diffusion MRI can be used to uncover the functional territories of the globus pallidus pars interna (GPi) in Parkinsonian patients prior to their DBS surgery. We show a consistent organizational pattern of functional territories across patients with the motor region in the posterior region of the GPi immediately followed anteriorly by the associative and limbic territories (Figure 1). We validate our results using micro-electrode recording obtained during the surgery. Additionally, we use post-surgery images to identify the final location of the DBS electrode and stimulation contacts for each patient and include information about the DBS programming to further validate

our results (Figure 1). This method has the potential to greatly improve targeting for DBS surgeries, not only for Parkinson's disease but also other movement disorders.

Title: Abnormal BOLD fMRI resting state lag structure in idiopathic Parkinson disease

Authors: *A. Z. SNYDER[1], A. MITRA[3], A. TANENBAUM[3], M. C. CAMPBELL[4], J. S. PERLMUTTER[2]

Abstract: Degeneration of nigrostriatal dopaminergic neurons with consequent dysfunction of neural circuits involving basal ganglia, thalamus, and cerebral cortex contribute to the motor and cognitive manifestations of Parkinson disease (PD). Striatal function affects motor and cognitive domains with putamen more directly affecting movement and caudate influencing cognition. In conventional resting-state fMRI, functional connectivity (FC) is defined in terms of blood oxygen level dependent (BOLD) signal temporal correlations at zero-lag. Altered cortical-striatal FC has been reported in PD, albeit with substantial variability across laboratories. A recently described, alternative approach (LAGS), based on evaluating BOLD signal temporal delays, has revealed highly reproducible propagation patterns of infraslow (less than 0.1 Hz) activity in normal individuals. We applied this LAGS strategy to determine whether putamen and caudate exhibit different temporal relationships with respect to cortical regions. We studied 62 adults with idiopathic PD (age 64±6.8 yrs) off meds overnight and 22 demographically matched, healthy controls (age 65± 9.6 yrs). Statistical significance was assessed clusterwise in seed-based lag maps using threshold-extent criteria computed by extensive permutation resampling. LAGS analysis revealed that, in controls, anterior cingulate, anterior insula and visual cortex are early but motor cortex is late with respect to caudate. In PD, anterior cingulate and visual cortex lead caudate by a smaller temporal lag whereas motor cortex now leads the caudate and anterior insula follows rather than leads caudate. In controls, dorsal anterior cingulate (dAcc) leads visual, pre-motor, putamen and motor cortex. In PD, dAcc leads visual, pre-motor and motor cortices but less so than in controls. Putamen, however, now leads dAcc instead of following. Thus, signal propagation between selected cortical regions and striatum is markedly altered in PD and, in several instances, reversed in direction. Moreover, these effects are distinct in putamen vs. caudate. Conventional (i.e., zero-lag) FC analysis of the same data showed only comparatively modest effects (moderately reduced FC in PD). These results demonstrate that dysfunction in PD manifests in the lag structure of intrinsic brain activity much more than in correlation-based FC analyses, and may provide insight into potential different functional consequences of dopaminergic drugs on caudate and putamen.

Title: Frequency dependent brain signal oscillations in HIV infection and Parkinson's disease modulated by age

Authors: J. Y. HONG[1], E. M. MÜLLER-OEHRING[2], H. M. BRONTË-STEWART[3], T. MARTIN[3], K. L. POSTON[3], E. V. SULLIVAN[2], *A. PFEFFERBAUM[1], T. SCHULTE[1,4]

Abstract: Over 30 years after the epidemic of HIV infection, and with the advances of antiretroviral therapy, patients with human immunodeficiency virus (HIV) infection are now aging and may be at risk for age-related neurofunctional decline similar to that of Parkinson's disease (PD), given that both diseases affect subcortico-cortical pathways. We examined resting-state functional MRI multiband frequency power in 20 older healthy controls (HC), 20 HIV-infected individuals, and 22 individuals with PD. To test the effect of aging on intrinsic neurofunctional properties of HIV and PD relative to HC, we measured fMRI activity across different frequency bandwidths by quantifying the amplitude of low frequency fluctuation (ALFF) for the frequency power spectrum for each voxel across three bandwidths: Low (LF: 0.01-0.027Hz), middle (MF: 0.027-0.073Hz) and high frequency (HF: 0.073-0.17Hz). Frequency oscillation power has been linked to neuronal physiological properties. Overall, subcortical regions exhibited higher ALFF values in the HF band, whereas cortical regions had higher ALFF

values in the MF and LF bands. Regardless of diagnosis, older age was associated with greater HF oscillation power in the pallidum and greater LF power in temporal cortices. In HC, older age was associated with greater HF and LF power in the basal ganglia, hippocampal and brainstem areas. Older age in HC was negatively correlated with HF power in the precuneus, medial and dorsolateral prefrontal cortices. HIV showed greater HF power in the basal ganglia with older age. In PD, however, older age was mainly related to less HF power in the cuneus. In sum, both HC and HIV showed positive age-HF power relations in the basal ganglia, which were not seen in PD. Lower precuneus and medial prefrontal HF power with healthy aging was associated with lower scores in memory span. In HIV and PD, greater LF power in the basal ganglia correlated with lower scores in the dementia rating scale. Our findings suggest that normal aging changes subcortical and cortical neural properties that can partially account for working memory limits experienced in older age. Aging with HIV was associated with enhanced alteration of basal ganglia neural properties that had ramifications for global cognitive functioning similar to PD (where basal ganglia properties were independent of age). This study is novel in identifying age-related characteristics in BOLD oscillation power in aging HIV and PD patients. Age-related oscillation power changes may serve as a landmark for understanding the brain functioning in healthy aging and with neurodegeneration. Title: Functional neuroimaging of prefrontal cortex in Parkinson's disease using fNIRS: Effects of cognitive task during seated and standing postures

Authors: *G. KERR[1], M. MUTHALIB[2], R. PEGORARO[2], L. ROEDER[2], I. STEWART[2], S. SMITH[2], N. WHITE[2]
[2]Inst. of Hlth. & Biomed. Innovation, [1]Queensland Univ. Technol., Brisbane Q4059, Australia

Abstract: Objective: To determine how prefrontal cortex activation is affected during concurrent cognitive and balance tasks in people with Parkinson’s disease (PD).
Background: In PD, reduced executive function has been associated with poorer quality of life,

decreased activities of daily living and increased balance and gait disturbance. Neural circuits involving activation of prefrontal cortex and involved in executive function are thought to be critical for control of balance and gait.
Methods: Functional near-infrared spectroscopy (fNIRS) imaging was used to determine how prefrontal cortex activation was affected during concurrent cognitive and balance tasks. Pre-frontal cortex alterations in concentration of oxy- (O2Hb) and deoxy-haemoglobin (HHb) in cerebral microcirculation blood vessels were recorded using fNIRS during performance of an executive function task (verbal fluency). During this task, participants were either seated or standing quietly on a force plate. Early stage PD, healthy age matched control, and young participants were assessed according to the following protocol repeated 5 times during sitting and standing: Baseline (30s), Verbal Fluency (30s), Week Days Recital (30s).
Results: Both the young, control and the PD groups had similar performance in the verbal fluency and the week day recital tasks. In the young group, neuronal activation during the verbal fluency task (relative to baseline) caused a change in regional blood flow, which was characterized by an increase in O2Hb and a decrease in HHb in the right dorsolateral prefrontal cortical (DLPFC) region during the seated condition. These changes were observed in the DLPFC bilaterally during the standing condition. Similar, but reduced changes were observed for the age-matched control group. For the PD group during the verbal fluency task there was a bilateral increase in DLPFC O2Hb during the seated condition but this was greatly reduced in amplitude. During the standing condition there was negligible change in DLPFC O2Hb in both hemispheres for PD participants. There was negligible change in O2Hb during the week day recital task for all groups.
Conclusions: These changes in O2Hb indicate that activation of the DLPFC is reduced in PD during executive function tasks. During standing activation of the DLPFC is further reduced, in contrast to young and control participants who have increased bilateral activation.

Title: Connectivity correlates of cognitive deficits in deep brain stimulation therapy for Parkinson disease

Authors: *S. C. NANIVADEKAR[1], Q. YANG[1], P. TAYLOR[2], C. LUNGU[1], S. HOROVITZ[1]
[1]NINDS, [2]NIMH, NIH, Bethesda, MD

Abstract: Subthalamic Nucleus Deep brain stimulation (STN-DBS) treats motor symptoms in Parkinson disease (PD) patients by stimulating the STN. PD patients show cognitive decline in executive functions after STN-DBS surgery [Demeter, 2017]. Using diffusion-weighted-imaging (DWI) and clinical data, we investigated the potential neural correlates of cognitive side effects. We hypothesize that the perturbation of task-specific functional networks might lead to cognitive deficits. We recorded the Stroop Color Word Task and Verbal Fluency Task scores from 23 patients with DBS pre-operatively and at 3 months post-operatively as measures of executive function and language. The Stroop scores significantly decreased from pre-Op (50.68±9.32) to post-Op (42.45±7.52) and the Fluency scores decreased significantly from pre-Op (51.57±10.54) to post-Op (44.76±10.37). T1, T2, and DWI were collected pre-Op and T2 images and CT scans were collected post-Op. We modeled patient-specific DBS contacts using DBSproc [Lauro, 2015]. Volumes of tissue activated (VTA) were calculated based on stimulating voltage and impedance at 3 months after DBS. Diffusion data was preprocessed in TORTOISE [Pierpaoli, 2010]. We performed probabilistic tractography between the VTA to the functional networks for the Stroop and Fluency task defined by fMRI studies [Leung,2000; Schlosser,1998], and tested them in a 1-sample t-test with changes in behavioral scores as covariates. For significantly correlated clusters (p-value <0.05), we computed the correlation between the average number of voxels within each ROI and the change in scores. For this analysis, an $R^2 > 0.6$ and an even distribution was considered to be a strong correlation. Voxelwise correlation showed that an increase in connectivity to the Caudate, Putamen and Globus Pallidus led to worsening of Stroop scores with R^2 of 0.70, 0.62, 0.646 respectively. Increased connectivity to the Stroop network showed greater performance deficits (R^2= 0.694). Overall effect in the Fluency network was not strong (R^2=0.22), however the Insula connectivity showed a strong negative correlation (R^2= 0.699) with the deficits in Fluency scores. Stimulating the insula in the Fluency Task network improved performance, suggesting a beneficial compensation by the DBS stimulation. However, stimulating areas of the Stroop network resulted in a decline in performance suggesting that avoiding these clusters could prevent cognitive decline of executive functions. Our findings suggest changes in connectivity to functionally relevant regions in the brain as neural correlates of cognitive deficits.

Title: White matter integrity changes in stroop color words interference tasks in Parkinson's Disease

Authors: *Q. YANG[1,3], S. NANIVADEKAR[1], P. TAYLOR[2], C. LUNGU[1], S. HOROVITZ[1]
[1]NINDS, [2]NIMH, NIH, Bethesda, MD; [3]The Third affiliated Hosp. of Sun Yet-sen Univ., Guangzhou, China

Abstract: Parkinson's Disease (PD) is a common movement disorder thought to be caused, in part, by dopaminergic neurons degeneration in substantia nigra pars compacta. PD is recognized by its motor symptoms, however, nonmotor symptoms, including cognitive deficits, are reported in PD patients and significantly reduce quality of life. Stroop Color Words interference task (SCW) is commonly used to test executive function deficits in PD patients. How white matter ingegrity affects SCW is not fully known. In our studies, SCW task scores were collected, by a neuropsychologist, from 20 non-demented on-medication PD subjects (age range 44-75,11 females). Diffusion Tensor Images (DTI) were collected at 3T scanner. Images preprocessing was completed in TORTOISE. The tractographic Connectivity Analysis Toolbox(FATCAT) was used for tractography analysis among regions of the Stroop Network, defined from functional MRI studies (Leung HC, et al, 2000). We performed a 1-sample t-test of the FA for the tracts connecting the Stroop Network ROIs ($p<0.005$, cluster size >100) using the SCW scores as covariates. The results showed that connectivity to clusters in left superior temporal gyrus(r=.72), right transverse temporal gyrus(r=.76), had a strong positive correlation with the SCW scores. The tracts affected include left superior longitudinal fasciculus, inferior fronto-occipital fasciculus. The left superior frontal gyrus(r=-0.89) and right middle frontal gyrus(r=-.90) show negative correlations with SCW scores. The tracts affected include the anterior thalamic radiation and right superior longitudinal fasciculus. As previous reported, (Catherine G, et al, 2013, Rebecaa J. T, et al, 2013) we showed that FA values of white matter were positively correlated with Stroop performance. We also showed, in our PD patients, that increased connectivity to some regions could reflect cognitive deficits.

Title: Use of functional MRI to assess effects of deep brain stimulation frequency on brain activation in Parkinson Disease

Authors: *M. DIMARZIO[1], I. HANCU[4], E. FIVELAND[4], J. PRUSIK[2], S. JOEL[4], R. MADHAVAN[4], J. DURPHY[5], E. HANSPAL[5], D. SHIN[3], J. G. PILITSIS[2]

Abstract: Introduction: Deep brain stimulation (DBS) is a well-validated treatment of motor symptoms in Parkinson’s disease (PD). While DBS has been used for many years, its mechanism of action remains unclear. With a recent change in labeling that allows MRI to be performed with DBS in the ON state, we present the first experience with functional MRI (fMRI) with subjects with DBS for PD. Specifically; we examine how frequency changes affect blood oxygen level dependent (BOLD) activation on fMRI. **Methods:** PD subjects with optimized DBS programming underwent fMRI with BOLD activation. Frequency was altered and fMRI obtained at various settings. To ensure that fMRI cycling and subject programmer cycling were synced, an electronics box coupled to electrocardiogram leads were integrated into workflow. Model-based voxel-wise General Linear Model (GLM) using the DBS-off data was used to determine which regions were more activated during the DBS-on periods with respect to the DBS-off periods. **Results:** Six of seven enrolled subjects had data able to be analyzed while the seventh had significant artifact preventing its use. Subjects differed in site implanted, subthalamic nucleus (STN)) for 5 and Globus pallidus interna (Gpi) for 1. In four patients, we showed motor deactivation at one frequency. Subject symptoms were primarily tremor in 2 subjects and hypokinetic in 4 subjects. The two subjects with hypokinetic symptomatology with bilateral STN DBS demonstrated dorsomedial prefrontal cortex activation at their optimal settings. **Discussion:** Our findings show that we are able to use fMRI to visualize BOLD activation that was caused by alterations in frequency. These findings will allow us to visualize the activation patterns that should be present when a subject’s frequency is in an optimal setting. Understanding these patterns, will allow us to improve the standard of care post DBS implantation by decreasing the amount of time it takes to choose the correct settings that would provide beneficial effects and eliminate side effects.

Title: Frontostriatal functional connectivity is associated with both cognitive and motor symptoms in parkinson's disease

Authors: ***S. KANN**[1], P. MANZA[2], H.-C. LEUNG[3]
[1]Psychology, Stony Brook Univ., Stony Brook, NY; [2]NIH, Bethesda, MD; [3]SUNY Stony Brook, Stony Brook, NY

Abstract: Parkinson's Disease (PD) is a neurodegenerative disorder associated with depletion of dopamine neurons in the midbrain. While dopamine loss plays a role in both motor and cognitive deficits in PD, disease progression is heterogeneous, leading to strong individual differences in these symptoms. Specifically, motor symptoms may present as either akinetic/rigid or tremor dominant subtypes, and critically, cognitive symptoms are more often associated with the akinetic/rigid subtype. Impaired performance on executive function tasks are associated with altered basal ganglia-cortical functioning in PD patients. However, whether similarly altered connectivity plays a role in akinetic/rigid symptoms, independent of executive function scores, remains unknown. The present study therefore examined basal ganglia-cortical connectivity in relation to executive function and akinetic/rigid scores within PD patients. Using the Parkinson's Progressive Marker Initiative (PPMI) database, 93 participants with early stage PD (Hoehn and Yahr $\leq$ 2) were assessed for functional connectivity between the basal ganglia and the frontal regions in relation to executive function scores (M=-.36, SD=.79) as well as akinetic/rigid scores (M=10.18, SD=5.59). All regression analyses conducted controlled for patients' medication status (drug naïve=35) gender (f=35), study site, rest tremor (M=1.51, SD=1.55) and age (M=61.31, SD=10.31). Motor and cognitive measures were also related to measures of dopamine transporter (DAT) in the caudate and putamen. Replicating previous research, we found that rigidity scores negatively correlated to executive control scores, while DAT values from the caudate differentiated these two behavioral measures in that greater DAT were associated with better cognitive scores, while lower DAT were associated with greater rigidity symptoms.

Importantly, this differentiation was also evident in basal ganglia-cortical connectivity. Greater connectivity between the caudate and ventromedial prefrontal cortex was associated with lower scores on executive function, controlling for rigidity, while greater connectivity between the putamen/pallidum and ventromedial prefrontal cortex was associated with higher rigidity scores, controlling for executive function. These findings suggest that both rigidity and executive functioning symptoms are independently related to altered basal ganglia-cortical connectivity as well as depletion of striatal dopamine within PD. These shared neural correlates may offer insight into the disease progression associated with impaired cognition and akinetic/rigid symptoms within PD.

Title: Alternations in striato-pallidal intrinsic functional connectivity as a prodrome of Parkinson’s disease

Authors: *E. DAYAN, N. BROWNER
Univ. of North Carolina at Chapel Hill, Chapel Hill, NC

Abstract: Although the diagnosis of Parkinson’s disease (PD) remains anchored around the cardinal motor symptoms of bradykinesia, rest tremor, rigidity and postural instability, it is becoming increasingly clear that the clinical phase of the disease is preceded by a long period of neurodegeneration, which is not readily evident in terms of motor dysfunction. The neurobiological mechanisms that underpin this prodromal phase of PD remain poorly understood. Based on converging evidence of basal ganglia (BG) dysfunction in early PD, we set out to establish whether the prodromal phase of the disease is characterized by alternations in functional communication within the input and output structures of the BG. We analyzed resting-state functional MRI data collected from patients with REM sleep behavior disorder (RBD) and/or hyposmia, two of the strongest markers of prodromal PD, in comparison to age-matched controls. Relative to controls, subjects in the prodromal group showed reduced interhemispheric functional connectivity in each of the tested BG nuclei (putamen, caudate, pallidum) as well as reduced striato-pallidal inter- and intrahemshpric connectivity. The data suggest that local interactions between input and output BG structures may be disrupted already in the prodromal phase of PD.

Title: Functional connectivity deficits in Parkinson Disease

Authors: *C. GRATTON[1], J. KOLLER[2], B. SHANNON[4], D. J. GREENE[3], S. E. PETERSEN[1], J. S. PERLMUTTER[1], M. C. CAMPBELL[1]
[1]Neurol., [2]Radiology, [3]Psychiatry, Washington Univ. in St. Louis, Saint Louis, MO; [4]BioRankings, Saint Louis, MO

Abstract: Introduction: Parkinson Disease (PD) neuropathology includes proteinopathy and multiple neurotransmitter deficits impacting widespread brain regions, which clinically manifests as a heterogeneous pattern of motor, cognitive, and psychiatric features. Thus, a whole-brain network-level (*connectome*) description provides a window into the distributed deficits present in PD. This approach allows us to determine (1) the relative magnitude and specificity of functional deficits across brain systems, (2) whether differences extend to cross-system interactions, and (3) how systems-level differences are related to behavior.
Methods: We measured resting-state functional connectivity (FC) in a large, well-characterized dataset of participants with PD (N=107) and healthy older controls (HC, N=46). Connectomes were defined across a comprehensive sampling of cortical and subcortical systems, including striatal, thalamic, and cerebellar regions. We applied rigorous motion correction and quality assurance measures to reduce artifacts. Novel graph-based statistical methods were used to quantify differences between the PD and HC connectome and validated with split-half analyses.
Results: Connectomes differed significantly in PD relative to HC, and were characterized by selective system-to-system reductions in the magnitude of positive or negative FC. Cortical somatomotor (SM) systems exhibited the most robust differences in FC, both within the SM system itself and between SM and specific sensory, association, and subcortical systems.

Cerebellar and thalamic systems also differed strongly between PD and HC, primarily showing decreased magnitude of FC within each system and between these systems and cortical SM and sensory systems. Striatal FC displayed a similar pattern of differences as the thalamus, but was less strongly affected. A subset of system-to-system FC differences was related to motor and cognitive performance.
Conclusion: These findings indicate that PD is associated with modulations within and between selective cortical and subcortical systems. PD primarily diminished the magnitude of FC, suggesting a weakening of systems-level organization in SM, thalamic, and cerebellar systems. Notably, striatal FC deficits were less prominent than FC of downstream brain regions, which highlights the widespread, potentially emergent, functional effects of distributed neuropathology in PD. Furthermore, select FC deficits were related to specific behavioral deficits, potentially helping to explain the variability of clinical features exhibited in PD.

Title: Abnormal dynamic functional networks in Parkinson’s disease: A resting-state fMRI study

Authors: *J. KIM[1,2], M. CRIAUD[1,2], S. S. CHO[1,2], M. D. CIRARDA[1,2], A. MIHAESCU[1,2], S. COAKELEY[1,2], C. GHADERY[1,2], M. VALLI[1,2], M. F. JACOBS[1,2], S. HOULE[1], A. P. STRAFELLA[1,2,3]
[1]Res. Imaging Ctr., Campbell Family Mental Hlth. Res. Institute, CAMH, Toronto, ON, Canada; [2]Div. of Brain, Imaging and Behaviour – Systems Neurosci., Krembil Res. Institute, UHN, Toronto, ON, Canada; [3]Morton and Gloria Shulman Movement Disorder Unit & E.J., Safra Parkinson Dis. Program, UHN, Toronto, ON, Canada

Abstract: Parkinson's disease (PD) is a neurodegenerative disorder characterized by nigrostriatal dopamine depletion leading to whole-brain neural circuit changes (Khoo et al., 2013, Neurology, 80, 276-281; Weingarten et al., 2015, Neurosci Biobehav Rev, 59, 16-52). There have been previous studies showing altered functional connectivity in PD patients using static resting-state functional MRI(rs-fMRI) (Göttlich et al., 2013, PLoS One, 8, e77336; Sharman et al., 2013, Mov Disord, 28, 447-454). However, dynamic resting-state functional connectivity network (d-FNC) in PD remains largely unknown. In this study, we aimed to examine time-varying aspects of

functional network connectivity and topological properties in PD. Thirty-one PD patients ON medication (65.7±7.2 years) and twenty-four healthy controls (64.5±8.3 years) were included in the analyses. Resting-state fMRI data were collected in a GE 3T scanner (TR = 2s, 8 min 24 sec duration, eyes closed). Pre-processing was performed using SPM 12: motion correction, normalization to the MNI template, and spatial smoothing with a 6 mm Gaussian kernel. Using group spatial independent component analysis in GIFT toolbox, the preprocessed rs-fMRI data were decomposed into functionally relevant brain networks, resulting in 44 independent components (ICs). In dynamic functional connectivity (FC) analysis based on previous studies (Allen et al., 2014, Cereb Cortex, 24, 663-676), time-varying covariance matrices were computed using a sliding windows approach (TRs = 44, 1 TR steps) and were clustered two discrete FC states using K-mean clustering methods. We, then, compared the temporal properties: dwell time of state and number of state transitions. Dynamic FC analysis revealed that compared to HC, PD patients spend significantly shorter time in state I (a state which occurs frequently and has weak FC between components) and longer time in state II (a rarer state but with stronger FC pattern). The UPDRS motor symptom score was positively correlated with the number of the state transitions and negatively correlated with the dwell time of state I in PD patients. Our findings provide new insight into understanding the role of the dynamic FC network in PD which is not as well characterized. This research will provide a better understanding of the pathological mechanisms of PD.

Title: Functional connectivity abnormalities in Parkinson and Alzheimer disease are more similar than different

Authors: *J. S. PERLMUTTER[1], A. TANENBAUM[3], M. CAMPBELL[4], A. MITRA[6], J. KOLLER[5], A. Z. SNYDER[2], B. M. ANCES[7]

Sch. of Med., Saint Louis, MO; [7]Neurol., Washington University, St. Louis, Saint Louis, MO

Abstract: Resting state fMRI (RS-fMRI) permits investigation of the physiological integrity of specific functional systems. This approach has been increasingly applied since the initial demonstration of reduced functional connectivity (FC) within the default mode network (DMN) in Alzheimer disease (AD), a compelling finding as the DMN is integral to episodic memory, which characteristically is impaired early in the course of AD. Similarly, RS-fMRI frequently demonstrates altered striatal FC in Parkinson disease (PD). However, the specificity of these FC effects with respect to degenerative condition has not been systematically investigated. We evaluated FC in 78 people with PD vs. 31 age-matched controls ($Control_{PD}$) and 88 symptomatic AD participants vs. 57 age-matched controls ($Control_{AD}$). FC was assessed using seed-based correlation in 6526 regions of interest defined by dividing all gray matter into 6 mm cubes. Denoising was accomplished by a CompCor-like procedure with the signal averaged over the whole brain included as a nuisance regressor. Scan protocol differences between the PD and AD studies precluded direct comparison of the functional data acquired in each affected cohort. Accordingly, the specific effects of degenerative condition (PD vs. AD) were evaluated by comparison of affected - control FC differences in both conditions. Affected - control FC differences in both conditions were remarkably similar. The most prominent effect in both PD and AD was comparably reduced FC of the somatomotor (SMN) network. Loss of FC was also observed in subcortical structures. Loss of FC in the default mode network (DMN) was not prominent in either AD or PD. Topographic similarity of FC change was computed by evaluating the $(PD - Control_{PD}) \cdot (AD - Control_{AD})$ vector dot product along each column of the difference matrices. Inspection of these results revealed a striking topographic similarity of FC changes highlighting the SMN, visual and infero-temporal cortex, and anterior thalamus, but not the DMN. In neither PD nor AD did FC differences localize to the most pathophysiologically abnormal parts of the brain (i.e., putamen and brainstem in PD, medial temporal lobe and DMN in AD). Rather, the common topography of affected - control differences resembles the effects of sleep in healthy, young individuals. Although sleep disturbances are well documented in both PD and AD, the sign of the presently observed effects (loss of FC in primary cortices) is opposite to that which would be expected on the basis of excessive daytime sleepiness in affected individuals. The pathophysiological significance of these observations presently is uncertain.

Title: Beta oscillatory activity of single neurons in the subthalamic nucleus in patients with Parkinson’s disease

Authors: *K. KOBAYASHI[1], M. WATANABE[1], T. OBUCHI[1,2], T. KANO[1], H. OSHIMA[1], C. FUKAYA[1], A. YOSHINO[1]
[1]Nihon Univ. Sch. of Med., Tokyo, Japan; [2]Div. of Neurosurg., Saitamaken Sogo Rehabil. Ctr. Dept. of Rehabil. Medicine,, Saitama, Japan

Abstract: Introduction: The subthalamic nucleus (STN) is a common target for deep brain stimulation (DBS) for treatment of Parkinson’s disease (PD). Recording of local field potentials in the STN in PD patients has shown increased beta-band activity, which is related to akinesia. On the other hand, analysis of neural activity of a single neuron in PD patients has shown increased neuronal firing in the STN; increased neuronal firing in the STN activity is associated with increased inhibitory drive to the motor thalamus via output nuclei of the basal ganglia, which could cause akinesia. These findings suggest that both beta-band activity and increased neuron firing in the STN are involved in akinesia. However, the relationship between beta-band activity and firing rate in the STN is unclear. Because the dorsal part of the STN is a motor area, we hypothesized that there would be a relationship between the STN motor area and the distribution of beta-band activity, which is related to motor symptoms (akinesia). In this study, we investigated the beta-band activities of single neurons and analyzed their relationships with the neuronal firing rate. In addition, we investigated the relationship between the STN motor area and the distribution of beta-band activity. **Methods:** We analyzed the frequencies of 119 single neurons in 10 patients with advanced PD who underwent implantation of deep brain stimulation electrodes in the STN. The neurons were classified as beta-band neurons (neurons with significant oscillatory activity at the beta-band) and nonoscillatory neurons (neurons without significant oscillatory activity at any band). Firing rates, distributions within the STN, and the proportions of neurons responding to passive joint movement (kinesthetic neurons) were compared between the 2 groups. **Results:** Of the 119 neurons, 16 (14%) and 83 (70.0%) were beta-band neurons and nonoscillatory neurons, respectively. The firing rate of beta-band neurons was significantly higher than that of nonoscillatory neurons (median firing rates, 48 Hz vs. 25 Hz, $p < 0.05$). Beta-band neurons were widely distributed within the STN, and there was no significant intergroup difference in neuron distribution between the dorsal STN and the ventral

STN. We did not note any significant intergroup difference in the proportion of kinesthetic neurons. **Conclusion:** The higher firing rate of beta-band neurons was consistent with the firing rate model of akinesia. The dorsal STN is a motor area, but the beta-band activity of a single neuron may not specifically reflect the motor symptoms of PD because of the wide distribution of beta-band neurons.

Universitario Donostia, San Sebastián, Spain; [6]Univ. de Málaga, UMA, Málaga, Spain; [7]Univ. del País Vasco-Euskal Herriko Unibertsitatea, Bilbao, Spain

Abstract: Background: Impulse Control Disorders (ICD) is a frequent and severe psychiatric complication in Parkinson's disease (PD) whose physiopathology is poorly understood. **Objectives:** To investigate the functional neural basis of decision-making in PD-ICD subjects

using a modified version of the Iowa Gambling Task (IGT) paradigm.
Material and methods: 18 PD-ICD patients, 17 PD non-ICD patients and 18 healthy controls (HC) matched for age, gender and education, underwent functional MRI (fMRI) scanning while performing a modified version of the IGT using a block experimental design. The task was divided in 3 sections: response to positive, negative and mixed feedback. Whole-brain, Region-of-Interest (ROI) and multivariate functional connectivity analyses were performed.
Results: The PD-ICD group showed increased activation across the 3 conditions compared to HC in prefrontal cortex (PFC) (bilateral frontal superior medial gyrus, left middle frontal gyrus and left mid-orbitofrontal cortex), motor regions (bilateral pre-supplementary area), left middle temporal gyrus, parietal cortex (left inferior and superior giri) and bilateral putamen. Compared to PD non-ICD, PD-ICD patients showed enhanced activation in left inferior parietal cortex, right precuneus and bilateral putamen. Time course analyses revealed a Group by Condition interaction in the left and right insula, and right inferior frontal gyrus, where PD-ICD patients had lower activation in the mixed feedback condition than the other groups. Group differences in functional connectivity with the striatum were observed. Relative to HC, PD-ICD patients had stronger coupling with the bilateral dorsolateral PFC, and PD non-ICD patients had stronger connectivity with the orbitofrontal cortex/ventromedial PFC.
Conclusions. PD-ICD patients show altered activation of the cortex (insula and inferior frontal gyrus) and abnormal functional connectivity (striatum-PFC regions) in structures involved in risk and uncertainty during reward-based decision-making. Differences in the response to mixed feedback decision could be associated with a difficulty of acquisition of probabilistic contingencies in the learning phase in comparison to a non ICD population.

Title: Firing rate and proportion of subthalamic oscillatory neurons increase associatd with Parkinson's disease progression

Authors: *P. ZHUANG[1], Y. WEN[2], M. HALLETT[3], Y. ZHANG[2], Y. LI[2]
[2]Beijing Inst. of Functional Neurosurg., [1]Xuanwu Hosp, Capital Med. Uni, Beijing, China;
[3]Human Motor Control Sec, Natl. Inst. of Neurolog. Disorders and Stroke, Bethesda, MD

Abstract: Objective To explore whether neuronal firing rate and proportion of oscillatory neuronal activity in the subthalamic nucleus (STN) is associated with severity in patients with Parkinson's disease (PD). **Methods** Twenty-two patients (M:9, F:13) with Parkinson's disease who received subthalamic deep brain stimulation treatment were included. Microelectrode recording was performed in the STN. Single unit analysis including interspike interval (ISI) was used to study neuronal firing rate and patterns. Power spectral analysis was used to evaluate neuronal oscillation. Clinical outcome was assessed using Unified Parkinson's Disease Rating Scales (UPDRS III) pre-and post-surgery. The groups of the early-stage and the advanced-stage were defined based on the UPDRS III scores, disease duration and the side of initial symptoms. **Results** Of total 163 neurons identified from 32 STN, there were 66 neurons with mean firing rate of 46.2±13.6 Hz obtained from the patients in the early-stage group whereas 97 neurons with mean firing rate of 59.9±17.1 Hz were obtained from patients in the advanced-stage group. Power spectral analysis showed that there were 27 (40.9%) oscillatory neurons identified from the STN neurons in the early-stage patient group (n=66) whereas 55 (56.7%) oscillatory neurons were identified from the STN neurons in the advanced-stage patient group (n=95). Further analysis found that 29.7% (8/27) ß oscillatory neurons were observed in the early-stage group whereas 52.7% (29/55) ß oscillatory neurons were observed in the advanced-stage group. When comparing the mean firing rate and proportion of oscillatory neurons in the STN of early-stage group with that of neurons in the STN of advanced-stage group, it was found that there was a 29. 6% increase STN mean firing rate of neurons (46.2±13.6 Hz vs. 59.9±17.1 Hz, $P<0.05$) and a 36.8% increase proportion of oscillatory neurons (40.9% vs. 56.7%) between the two groups. In particular, a 77.7% increase proportion of ß oscillatory neurons was obtained between the early-stage and advanced-stage groups (29.7% vs.52.8%, $P<0.01$). **Conclusions** The results strongly suggest that both subthalamic nucleus neuronal firing rate and proportion of ß oscillatory neurons increase with PD progression.

Title: Visual tracking abnormalities in hemisphere-asymmetric Parkinson's disease

Authors: *J. CHEN[1,2], L. ZHOU[3], D. B. LISTON[4], J. LIU[5], L. LI[1,2]
[1]Dept. of Psychology, The Univ. of Hong Kong, Hong Kong, Hong Kong; [2]NYU-ECNU Inst. of Brain and Cognitive Science, New York Univ. Shanghai, Shanghai, China; [3]Sch. of Medicine, Shanghai Jiao Tong Univ., Shanghai, China; [4]neuroFit Inc., Mountain View, CA; [5]Ruijin Hospital, Shanghai Jiao Tong Univ., Shanghai, China

Abstract: Parkinson's disease (PD) usually has a hemispheric asymmetry of neurodegeneration, clinically manifested as one side of the body being more affected than the other. It has been proposed that the right hemisphere is superior to the left in oculomotor control and thus PD patients with right hemisphere neurodegeneration should theoretically have more severe oculomotor abnormalities than patients with left hemisphere neurodegeneration. However, little research has studied this question and the reported limited results are inconsistent. In current study, we used a visual tracking task (Liston & Stone, 2014) to examine whether and how hemispheric asymmetry in PD affects general visual tracking ability. Specifically, participants visually tracked step-ramp target motion that varied unpredictably from trial to trial (speed: 16°/s-24°/s; direction: 0°-360°) to minimize the expectation effect. The task took a reasonably short time to finish (less than 15 minutes) but can evaluate many independent aspects of eye tracking ability (e.g., initial pursuit latency, initial pursuit acceleration, steady-state pursuit gain, & proportion of smooth pursuit vs. saccadic tracking). We tested 27 idiopathic patients with hemisphere-asymmetric PD ON medication and 21 demographically-matched healthy controls. In 13 patients, the motor symptoms were predominant on the left side of the body reflecting right-hemispheric neurodegeneration (LPD); in 14 patients, the motor symptoms were predominant on the right side of the body reflecting left-hemispheric neurodegeneration (RPD). LPD and RPD patients were demographically matched and had similar cognitive abilities and degree of motor-symptom asymmetry. The two patient groups also contained a matched number of akinetic-rigid and tremor-dominant patients. We found that RPD patients did not differ from healthy controls in their visual tracking performance. However, LPD patients displayed larger initial pursuit latency, smaller initial pursuit acceleration, lower steady-state pursuit gain and smaller proportion of smooth pursuit tracking than did healthy controls, indicating that visual tracking abnormality is specific to LPD patients with right-hemispheric neurodegeneration. Our study is the first study that systematically examined how hemispheric asymmetry of neurodegeneration influences visual tracking ability in PD. Our results are in line with previous findings that unilateral hemispheric lesions can cause asymmetrical oculomotor abnormalities for both smooth pursuit and saccadic eye movements, and that neurodegenerative symptoms can be tracked with oculomotor methods.

Title: Neural correlates of impaired motor timing processing during speech production and hand movement in Parkinson’s disease

Authors: *R. BEHROOZMAND[1], K. JOHARI[2], P. HERATH[2], J. D. GREENLEE, M.D.[3]
[1]Communication Sci. and Disorders, Univ. of South Carolina, Irmo, SC; [2]Univ. of South Carolina, Columbia, SC; [3]Dept Neurosurg, Univ. Iowa, Iowa City, IA

Abstract: Patients with Parkinson’s disease (PD) demonstrate impairments in temporal processing aspects of motor function, which can affect their speech and hand movement reaction time. However, the underlying neural bases of such motor timing impairment in PD has remained unclear. Previous studies in neurotypical healthy adults have demonstrated that temporal predictability of sensory cues were associated with attenuated neural activities during the preparatory phase of movement initiation and inhibition for speech production and hand movement, leading to improved motor reaction time. This effect was explored by examining the suppression of premotor event-related potentials (ERPs) elicited prior to the onset of speech and hand movement initiation and inhibition in response to temporally predictable vs. unpredictable sensory stimuli. This evidence supports the notion that the timing aspects of sensory stimuli can modulate neural processing of motor responses in speech and hand modalities. In this study, we investigated neural activities prior to the onset of speech and hand movement in response to temporally-predictable and unpredictable sensory stimuli in patients with PD and a healthy age-matched control group. Event-related potentials (ERPs) were recorded in 15 PD patients and 15 control subjects while they were visually-cued to prepare to produce a steady vocalization of a vowel sound (speech task) or press a button (hand movement task) in a randomized order, and to initiate the cued movement following the onset of a circle on the screen (go signal) and inhibit ongoing movement after the circle disappeared (stop signal). We found that the motor reaction times for speech and hand movement initiation and inhibition were significantly slower in PD patients compared with control subjects. In addition, analysis of ERP responses for control subjects revealed that the premotor neural activities (time window: -100 to 0 ms) over the frontal and parietal areas were significantly suppressed in response to temporally-predictable sensory cues before speech and hand movement initiation and inhibition. However, the suppression of premotor ERPs were not observed in PD Patients in response to temporally-predictable stimuli, suggesting the impairment of motor timing processing in PD patients. These findings implicate

the role of basal ganglia in temporal information processing during movement. Based on these results, we argue that the PD patients suffer from motor timing deficits that impair their ability to extract temporal information from external sensory cues for driving motor responses for speech and hand movement initiation and inhibition.

Title: Low-frequency oscillations in postural sway vary with sensory weighting and scale with fall-risk in Parkinson's disease

Authors: *M. HEARN[1], P. E. GILBERT[2], J. V. FILOTEO[3], I. LITVAN[5], M. SARKAR[3], D. J. GOBLE[1], H. S. BAWEJA[4]

Abstract: Studies have demonstrated that aging, visuomotor processing and neurological disease (e.g. stroke and cerebellar ataxia) influence oscillations from 0-1 Hz in isometric force contractions. However, these effects have not been studied in postural control, which is necessary for maintaining balance and preventing falls. Therefore, the purpose of this study was to investigate the effects of sensory weighting on low-frequency oscillations in postural sway, and their implications for fall-risk in people with Parkinson’s disease. 70 Parkinson’s disease patients (69.5 ± 8.1 yrs, 22 females), 38 older adults (68.8 ± 8.5 yrs; 16 females) and 21 young adults (19.1 ± 0.9 yrs; 9 females) volunteered to participate in this study. All subjects performed a static balance assessment using a portable force plate. Sensory weighting was examined by having subjects maintain quiet unperturbed standing with both eyes closed and eyes open over six 20-s trials. Parkinson’s disease patients were further sub-grouped based on average COP excursions during the eyes closed trials into high- (>38 cm) and low (<38 cm) fall-risk groups. Changes in low-frequency oscillations were quantified by examining the absolute wavelet power in nine frequency bins from 0-1.08Hz at every 0.12 Hz. We find that low frequency oscillation in postural sway increase with removal of visual feedback and increase with increasing fall-risk. Furthermore, Parkinson’s disease patients at high fall-risk are highly dependent on vision for postural control when compared with healthy controls and PD patients at low risk for falls.

Title: Correlation between electroencephalogram and electromyogram in parkinson's disease: A review

Authors: *A. SAIKIA, V. K. PANDEY, S. PAUL
Biomed. Engin., North Eastern Hill Univ., Shillong, India

Abstract: The main of this study is to correlate the Electroencephalogram (EEG) and Electromyogram (EMG) in Parkinson's disease patients. It will be a true scientific validation tool to justify the clinical and mathematical correlation between two of the biophysical parameters. Parkinson's disease (PD) is a chronic, progressive, neurodegenerative disorder with a multi-factorial etiology. The pathological hallmarks of Parkinson's disease (PD) are marked loss of dopaminergic neurons in the substantianigra pars compacta (SNc), which causes dopamine depletion in the striatum, and the presence of intracytoplasmic inclusions known as Lewy bodies in the remaining cells. It remains unclear why dopaminergic neuronal cell death and Lewy body formation occur in PD. The pathological changes in PD are seen not only in the SNc but also in the locus coeruleus, pedunculo pontine nucleus, raphe nucleus, dorsal motor nucleus of the vagal nerve, olfactory bulb, parasympathetic as well as sympathetic post-ganglionic neurons, Mynert nucleus, and the cerebral cortex. It will be a novel scientific validation to correlate between EMG and EEG in Parkinson' Disease patients. EMG is the electrical potential that is caused by the function of muscles. EMG signal can be measured from muscles by using needle electrodes or surface electrodes attached to the skin surface which is known as surface EMG measurement. The traditional methods to analyze surface EMG signals are mainly based on amplitude and spectral analysis which are mainly used to measure level of muscle activation and fatigue. The advantage of using EMG in the assessment of PD is its objectivity and quantitativeness to evaluate the motor function. Neurophysiological measurements may help in the near future in advancing the diagnosis and in the differential diagnosis of PD. EEG is one of the oldest methods for studying brain function. It has been proposed as a promising mathematical tool for the detection of cognitive decline in neurodegenerative disorders including PD.

Title: The effect of Parkinson's disease on multisensory temporal integration

Authors: Y. OH[1], C. S. SHAYMAN[1], *T. HULLAR[2]
[2]Otolaryngology, [1]Oregon Hlth. and Sci. Univ., Portland, OR

Abstract: Multisensory integration is crucial to perceptual understanding, but cues from multiple sensory modalities do not necessarily arrive at the brain simultaneously. The window of time over which sensory inputs can be separated in time but still interpreted as simultaneous is termed the "temporal binding window" (TBW). Extended TBW of auditory and visual stimulus combinations can be associated with dyslexia, schizophrenia, and even obesity, raising the possibility it may a contributing pathologic factor in these conditions. Parkinson's disease (PD) is known to affect unimodal temporal discrimination, but its relationship to the perceptual timing of multisensory events is not known. To examine the relationship between PD and temporal binding, 8 individuals with PD for a minimum of 2 years and 25 healthy controls without cognitive, auditory, or visual impairments were presented with video + audio stimuli of a hammer striking a board, or a speaker saying "Ba." Audiovisual asynchrony varied in 10 msec increments. Two-down, one-up interleaved staircase procedures (71% correct psychometric response) were used for stimuli going from perfectly in-sync (0 msec offset) to out-of sync and vice-versa. Temporal binding window was defined as the average of the 71% correct values on the staircases in each direction. An extended temporal binding window was apparent in the PD cohort for both stimulus types (mean±std: 573±71 msec for speech and 539±154 msec for hammer) as compared to healthy controls (mean±std: 467±146, 411±137 msec for speech and hammer, respectively). The control cohort did not exhibit an age effect (r=0.145), however, PD temporal binding was strongly related to the duration of PD (r=0.734). These results demonstrate that PD disrupts temporal regulation and that this effect correlates with disease duration. Widening of the TBW may make it difficult for patients to perform tasks, such as walking, that involve multimodal perception and are commonly disturbed in PD. Given that TBW can be narrowed through perceptual training, these data may offer a therapeutic intervention to help ameliorate symptoms in PD.

Title: Abnormal characteristics of physiological network in patients with idiopathic REM sleep disorder during REM sleep

Authors: *S. HEO[1], D. YEO[1], P. SEO[1], H. KIM[1], K. CHA[1], J. CHOI[1], K.-Y. JUNG[2], K. KIM[1]

Abstract: Rapid-eye movement (REM) sleep behavior disorder (RBD) is a sleep disorder characterized by dream enactment behavior (DEB) and the loss of muscle atonia during REM sleep (RSWA). In this study, we performed multiple physiological signal analysis using time delay stability (TDS) methods in patients with idiopathic RBD (iRBD) and healthy controls during sleep, in order to investigate the abnormal characteristics of physiological network associated with iRBD.
11 drug-naïve idiopathic RBD patients (age: 66.36±6.73 years, F: 2, M: 9) and 10 healthy controls (age: 62.30±7.45 years, F: 3, M: 7) participated in the experiment. 21-channel EEG, electrooculography (EOG), electromyography (EMG), electrocardiography (ECG) and respiration signal were recorded during one overnight sleep. Artifact-free 30-second epochs of the signals were extracted at each sleep stage. The physiological signals were converted to characteristic value time-series that represent the physiological activities of the brain (alpha, beta, sigma, theta, and delta subbands), eye, arm, leg, heart, and respiration. The TDS was calculated to quantify the coupling between physiological time-series. Statistical comparisons between iRBD patients and controls were performed using independent t-test and FDR correction for multiple comparisons. The correlation between the TDS and clinical measures was investigated by Pearson’s correlation coefficient.
The TDSs were significantly increased in the RBD patients compared to the controls during REM sleep for delta-alpha, delta-sigma, delta-beta, theta-alpha, theta-sigma, theta-beta, delta-HR and beta-eye couplings ($t<-3.3$, $FDR<0.02$). The delta-alpha coupling was significantly anti-correlated with Korean version of the sniffin’ sticks test (KVSS) score, which is known as a

good index of the severity of neurodegenerative disease, in only RBD patients (r=-0.837, p=0.001). Also, significant anti-correlation was observed between TDS of delta-HR coupling and the KVSS (r=-0.816, p=0.002).
The increments of delta-HR coupling, which is anticipated to be related to sleep control mechanisms, can be reflects a cardiac autonomic dysfunction in RBD patients. The abnormally increased TDSs during only REM sleep could be may be related to abnormal characteristics of RBD such as DEB and RSWA. We found abnormal characteristics of physiological network associated with RBD.

Title: Global and local oscillatory changes associated with pallidal deep brain stimulation in Parkinson disease

Authors: *Y. SHAHRIARI[1,2], M. MALEKMOHAMMADI[3], A. O'KEEFFE[3], X. HU[2], N. POURATIAN[3]

Abstract: Parkinson disease (PD) is a neurodegenerative disorder of central nervous system that affects motor function. Abnormal neural beta oscillatory activity has been observed in the subthalamus nucleus (STN) and Globus Pallidus internus (GPi) of patients with PD. Deep brain stimulation (DBS) of GPi has been shown in randomized clinical trials to manage PD symptoms. Despite its documented clinical efficacy, the underlying mechanisms of GPi-DBS, within regions and across regions, is still not well understood. In this study, we hypothesize that GPi-DBS may

reduce the hyper-synchrony oscillatory pattern in patients with PD. To do so, we explore the effect of DBS on both local and global oscillatory activity. Seven patients with PD underwent GPi-DBS implantation. Intraoperative recordings of GPi local field potentials (LFPs) and ipsilateral motor cortex electrocorticography (ECoG) were obtained in two modes of on and off GPi stimulation. To investigate the subcortical-cortical phase synchrony relationships, before and during DBS, phase lag index (PLI) was used. Power spectrum analysis was done at both subcortical and cortical levels to explore the effect of DBS on the local oscillatory activity. The sub-beta analysis was performed in low beta (13-20 Hz) and high beta (21-35 Hz) frequency bands separately. All the cortical analysis was mainly limited to three major areas of premotor, primary motor, and sensorimotor cortex. Spearman correlation coefficient was calculated to obtain the relationships between the DBS related symptom improvement, during DBS, and the neural phase synchrony changes. The phase analysis showed significant subcortical-cortical synchrony reduction (Wilcoxon signed rank test, p-value<0.016) particular to the primary motor cortex during DBS in the high beta band. No statistical subcortical-cortical phase synchrony difference was observed at the premotor and sensorimotor sites between two conditions. The local spectral analysis did not show any significant changes in the beta (and the sub-bands) at GPi and cortical level. We observed a positive correlation (R=0.35) between pallidal-M1 phase synchrony changes and the clinical score improvement during DBS. These findings suggest suppression of pallidocortical high beta coupling may be a critical therapeutic mechanism of GPi DBS. An exaggerated pallidocortical high beta coupling may, therefore, be a critical pathophysiological underpinning of PD. A better understanding of the DBS mechanisms on the alleviation of PD symptoms can contribute to the development of closed-loop DBS in which the patients' neurophysiological parameters will be considered in optimizing the DBS parameters.

Title: Multimodal fMRI investigation of reward-driven behaviors in Parkinson's disease

Authors: *K. PETERSEN[1], A. STARK[2], R. KESSLER[3], N. VAN WOUWE[2], M. DONAHUE[2], D. O. CLAASSEN[2]
[1]Chem. and Physical Biol., [2]Vanderbilt Univ., Nashville, TN; [3]Univ. of Alabama Sch. of Med., Birmingham, AL

Abstract: Impulse-control disorders (ICDs) in Parkinson's disease (PD) are associated with the use of non-ergot dopamine agonist (DAA) drugs, which preferentially target D2/D3-type dopamine receptors. ICDs vary in manifestation, but center around compulsive participation in reward-driven activities. We aim to identify regional changes in brain activity related to both short-term response to DAA and network activity patterns distinguishing ICD-sensitive and ICD-resistant individuals.
PD patients (n=37; gender=12F/25M; age=61.8±8.4 years) were recruited from the clinic, and classified as ICD+ or ICD- based on a semi-structured clinical interview. Pseudo-continuous arterial spin labeling (TR/TE=4000/11ms, post-labeling delay=1500ms) was used to quantify cerebral blood flow as a measure of regional metabolic activity, while blood oxygenation level-dependent fMRI (TR/TE=2000/35ms) was employed to examine resting state functional connectivity effects. This scan protocol was applied both On-DAA (but not levodopa) and Off-dopamine therapy. Acute metabolic DAA response was defined as percent change in blood flow from Off-dopamine to On-DAA state. We hypothesized that (1) PD patients with ICDs would exhibit greater responses to DAA administration than patients without ICDs in mesocortical and mesolimbic circuit components, especially the ventral striatum; and (2) that these networks would exhibit increased temporal synchrony in ICD+ patients when On-DAA, but not in ICD- patients.
Blood flow response to acute DAA in the ventral striatum was significantly greater in ICD+ than ICD- patients ($p=0.03$). No other tested subcortical regions exhibited significant differences between groups. Functional connectivity between the ventral striatum and anterior cingulate gyrus ($p=0.03$), globus pallidus ($p=0.02$), thalamus ($p=0.02$), and putamen ($p=0.01$) was significantly greater in the ICD+ group. No direct effect of DAA administration on connectivity was identified, although DAA and ICD group status interacted to increase connectivity between amygdala and midbrain ($p<0.01$).
We found that, in the ventral striatum, PD patients with ICDs exhibit both an elevated acute metabolic response to DAAs, and greater connectivity with mesocorticolimbic circuits. We conclude that enhanced DAA activation of ventral striatal dopamine receptors, especially D3-type receptors, is likely important in sensitizing a subset of PD patients to reward-driven behaviors.

Title: Use of iPSC-derived human motor neurons in high-throughput phenotypic screening

Authors: *M. L. HENDRICKSON[1], J. KOUZNETSOVA[2], W. ZHENG[2], Z.-W. DU[1]
[1]BrainXell, Inc., Madison, WI; [2]NCATS/NIH, Rockville, MD

Abstract: There exists a dire need for more effective drugs to treat disorders of the central nervous system (CNS), and new cell culture models that are more relevant to psychiatric and neurological diseases are needed to improve the success rate of drug development programs. One such approach is the use of neurons differentiated from patient induced pluripotent stem cells (iPSCs), which present new opportunities for modeling disease processes and screening drug libraries. We have developed technology to produce very large quantities of highly enriched human neurons from patient iPSCs and to greatly accelerate their maturation. We subsequently developed two high-throughput screening (HTS) systems using human motor neurons derived from individuals with amyotrophic lateral sclerosis (ALS) and spinal muscular atrophy (SMA). Using genome editing techniques on the iPSC lines, the reporter nanoluciferase (NLuc) was fused to endogenous neurofilament light chain (NF-L) for ALS and full-length SMN2 for SMA. Nanoluciferase is more sensitive than the traditional luciferase and allows for a simple and quantitative readout of NF-L and SMN2 protein levels. The assays were adapted to meet HTS requirements, including: large batch sizes, 1536-well format, minimal well-to-well variation, short-term culture, plating by automated dispenser, and low reagent volumes. Applying a quantitative HTS approach, we screened the LOPAC, NPC, and MIPE libraries (>6,000 compounds) in a dose dependent manner on both motor neuron lines with a hit rate of ~0.5%. This work demonstrates the feasibility of running HTS campaigns using human neurons, which present a more physiologically relevant drug discovery platform.

Title: Genetic and functional comparison of hESCs- and iPSC-derived Schwann cells

Authors: *R. MI, J. EHMSEN, Q. SHI, B. MUKHERJEE-CLAVIN, G. LEE, A. HOKE
Johns Hopkins Univ. Sch. Med., Baltimore, MD

Abstract: Injury to the peripheral nervous system (PNS) results in significant morbidity and affects quality of life. Although the PNS can regenerate in adult mammals, functional recovery is relatively poor in humans especially after proximal nerve lesions. This is primarily due to atrophic changes in chronically denervated Schwann cells in the distal nerves. Transplanted primary Schwann cells can replace/supplant atrophic host Schwann cells in the distal nerves, but human embryonic stem cell- (hESC) or human induced pluripotent stem cell- (hiPSC) derived Schwann cells offer greater potential for future therapeutic interventions. However, differentiation potential and impact on functional recovery of hESC- versus hiPSC-derived Schwann cells is unknown.

In order to explore whether Schwann cells derived from hESCs and hiPSCs are comparable to each other in terms of gene expression after differentiation under identical protocols, we performed RNA-seq profiling of CD49d positive cells (Schwann cells) derived from three HESCs (H1, H7 and H9) and three hiPSCs (GM08398, GM02623 and GM01582). For Schwann cell differentiation, hESCs or hiPSCs were maintained and differentiated according to the protocol developed in the Lee lab, and purified by FACS using an antibody against CD49d. We validated Schwann cell identity by immunocytochemistry using known Schwann cell markers. CD49d-positive differentiated cells were positive for GFAP, s100B and p75. RNA-seq analysis identified only 105 differentially expressed genes between hESC-derived and hiPSC-derived Schwann cell lines, out of nearly 40,000 transcripts (~0.27%). For those genes that appeared to be differentially expressed, ~40% and ~20% showed very low expression in the hESC-derived and hiPSC-derived Schwann cell lines, respectively. Similarly, only 290 out of nearly 60,000 isoforms were differentially expressed between the cell lines (~0.49%).

These results indicate substantial genetic similarity between the hESC- and hiPSC-derived Schwann cell lines. Ongoing experiments to assess the myelination potential of these hESC- and hiPSC-derived Schwann cells *in vitro* and *in vivo* include co-culture experiments using GFP labeled hESC- and hiPSC-derived Schwann cells with rat primary dorsal root ganglion (DRG) neurons, and transplantation into two peripheral nerve injury models focusing on chronic nerve

injury to mimic human disease. If myelination potential is confirmed in *vivo*, these hESC- or hiPSC-derived Schwann cells may prove useful for future human clinical trials.

Title: V-Smart™ Nanomedicine for the Treatment of ALS (LAUR-301): Non-Invasive Targeted Delivery of GDNF to Degenerating Motoneurons in ALS

Authors: *I. HOLLANDER[1], M. POPOV[1], E. SHAUBI[1,2], A. ARMOZA[1], J. MILAM[1], E. HARLEV[1], V. KAS'YANOV[1], C. LINDER[1,2], E. HELDMAN[1,2]
[1]Lauren Sci. LLC, New York, NY; [2]Ben-Gurion Univ. of the Negev, Beer Sheva, Israel

Abstract: Lauren Sciences has developed the novel V-Smart™ nanovesicle platform (comprised of its novel proprietary bolaamphiphiles) for targeted drug delivery. V-Smart™ can encapsulate non-brain penetrant therapeutic agents, cross the blood-brain barrier (BBB) following systemic administration, target specific sites in the central nervous system (CNS) and selectively release the encapsulated therapeutic agents at target sites.
Based on its V-Smart™ technology, Lauren Sciences successfully designed a V-Smart™ Nanomedicine for the treatment of ALS -- LAUR-301. LAUR-301 is customized to encapsulate glial cell line-derived neurotrophic factor (GDNF), and engineered to deliver the encapsulated GDNF to the CNS, target the encapsulated GDNF to regions in the CNS where motoneuron degeneration occurs in ALS patients and selectively release the GDNF at its site of action. GDNF has shown beneficial effects, by preventing motoneuron degeneration, in preclinical studies of ALS mouse models. However, GDNF does not penetrate the BBB, is susceptible to proteases, does not diffuse well from direct application sites in the CNS (due to tight binding to components of the extracellular matrix) and causes adverse effects at high local concentrations. LAUR-301 solves these problems, as LAUR-301 is administered systemically, delivers GDNF to the CNS while encapsulated, and distributes GDNF to its targeted action sites without producing high local concentrations (unlike direct application to the CNS), thus, enabling the GDNF to potentially provide an effective therapy for ALS.

Here, the data presented shows that LAUR-301: (1) selectively targets cultured cells known to accumulate at CNS regions where ALS motoneuron degeneration occurs; (2) efficiently encapsulates GDNF while maintaining its activity; and (3) delivers, in a dose dependent manner, significant amounts of GDNF into brain and spinal cord of wild type mice, after i.v. administration, without toxicity.
Next, Lauren Sciences plans to prove that, after systemic administration, LAUR-301: (1) delivers GDNF into brain and spinal cord of ALS mice and distributes it to regions of motoneuron degeneration; (2) is effective in treating ALS mice, by disease modification (slowing or reversing neurodegeneration) and extension of life span. Therapeutic efficacy in ALS mice will facilitate IND enabling studies and provide strong rationale for clinical trials.
The goal is for LAUR-301 to be a transformative V-Smart™ Nanomedicine that protects against neurodegeneration, and induces neurorestoration, in ALS patients. LAUR-301 success can also pave the way for development of other V-Smart™ Nanomedicines for ALS.

Title: Occipital nerve stimulation for the treatment of refractory occipital neuralgia: a case series

Authors: *A. DIAZ, O. P. KEIFER, Jr, M. C. CAMPBELL, Y. B. BEZCHLIBNYK, N. M. BOULIS
Neurosurg., Emory Univ. Sch. of Med., Atlanta, GA

Abstract: Occipital neuralgia (ON) is a debilitating cranial neuropathy that is associated with lancinating pain within the distribution of the greater (~90%), lesser (~10), and/or third occipital nerves (rare). It is a relatively understudied entity, and, thus, there is limited epidemiological data on incidence, prevalence, or predisposing risk factors. As of yet, there is no clear standard of care

and many of the treatment options for occipital neuralgia are under active investigation. Occipital nerve stimulation (ONS) has been reported in limited studies (mean of 9-10 patients) for the treatment of medically refractory cases of occipital neuralgia. The appeal of ONS lies in its reversible nature and ability to provide a trial stimulation period to assess efficacy. In a partial readdress, we present a retrospective case series analysis on the use of ONS for ON in 20 patients. A total of 29 patients were evaluated at the Emory Neurosurgery Clinic. Of those 20 (69%) were naïve to ONS treatment, underwent a trial and then permanent implantation of the system. The analysis of patient outcomes was based on pre- and post-operative pain score comparisons using a paired t-test. The majority of patients had unilateral ON, with both a constant and lancinating pain component. The average reported pain scores were quite elevated at 7.4, with the average maximum reported pain-score at 8. These patients failed an average of 7 drugs of various classes and the average follow-up time was 410 days. Of the patients selected for ONS trial stimulation 75% (20 of 25) went onto full implantation of the system. Of these patients, 85% self-reported an improvement of greater than 50% pain reduction. This is corroborated by a significant reduction in the average reported pain score of 7.4 pre-operatively to 2.9 during post-operative follow-up (paired t-test, $P<0.005$). The results of the study suggest that ONS is a feasible treatment option for long term control of the symptoms of ONS. With an increasing interest in occipital neuralgia in neurology and neurosurgery, it is hoped that future work will focus on long-term prospective studies.

Title: Chronic intermittent mild whole-body hypothermia is therapeutic in a mouse model of ALS

Authors: *L. J. MARTIN, M. WONG
Pathology, Div. of Neuropathology, Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: Therapeutic hypothermia (targeted temperature management) is the standard of care for neonatal hypoxic-ischemia encephalopathy and adult cardiac arrest and is being tested for the treatment of CNS trauma. The possibility that therapeutic hypothermia has applications in chronic neurodegeneration has not been examined, despite the likelihood that mechanisms of

acute and chronic neurologic injury may have some commonalities. We tested the hypothesis that chronic, intermittent, whole-body, mild hypothermia has therapeutic efficacy in a mouse model of amyotrophic lateral sclerosis (ALS). Transgenic mice expressing high levels of human mutant superoxide dismutase-1 (hSOD1-G93A variant) were used. Male and female mice culled from several litters were randomly assigned to groups receiving euthermia/normothermia (NT, n=25) or therapeutic hypothermia (HT, n=25) initiated at early symptomatic stages of disease. The HT protocol was whole-body mild cooling (1-3 ^{0}C) of freely moving mice in a cooling chamber for 12 hours on alternate days. Body temperature was monitored rectally, orally, and axillary. Mice underwent spontaneous rewarming when removed from the cooling chamber. NT mice were maintained at room temperature (37 ^{0}C). HT significantly ($p < 0.05$) reversed and attenuated functional decline on a motor test (running wheel) and significantly ($p < 0.05$) extended lifespan of hSOD1-G93A mice. Effects appeared greater in female mice. HT was associated with significantly ($p < 0.05$) elevated levels of tissue mitochondrial uncoupling protein 3, heat-shock protein, and protein sumoylation, motor neuron protection, and decreased mitochondrial pathology and inflammatory reaction during the disease process. This work demonstrates that targeted temperature management and rewarming may have application in chronic neurodegenerative disorders as well as in acute neurological injury. We show in a preclinical mouse model of ALS that longitudinal intermittent HT has therapeutic effects on neurologic and pathologic outcomes that may be relevant clinically for human chronic neurodegenerative disorders.

Title: Drp1 hyperactivation in ALS

Authors: A. U. JOSHI[1], A. D. CUNNINGHAM[1], N. L. SAW[2], M. SHAMLOO[2], *D. MOCHLY-ROSEN[1]
[1]Chem. & Systems Biol., Stanford Univ., Stanford, CA; [2]Behavioral and Functional Neurosci. Lab., Stanford Univ. Sch. of Med., Stanford, CA

Abstract: Mitochondrial dysfunction, bioenergetic failure, and oxidative stress are common pathological hallmarks of amyotrophic lateral sclerosis (ALS). However, there is a limited understanding of the exact mechanisms underlying the molecular events leading to the disease progression. One of the reported contributors to ALS pathology is mitochondrial dysfunction associated with excessive mitochondrial fission and fragmentation. Excessive mitochondrial fragmentation is a process mediated, at least in part, by Drp1 hyperactivation. Here we examined the hypothesis that mitochondrial dysfunction is due to Drp1 hyperactivity and mitochondrial excessive fission and fragmentation in ALS. To that end, we determined whether pharmacological inhibition of Drp1/Fis1 interaction with P110 affects disease progression. We observed mitochondrial excessive fragmentation and dysfunction in several familial forms of ALS patient-derived fibroblasts as well as in cultured motor neurons expressing SOD1 mutant. In both patient-derived cells and in the rodent cell model, inhibition of Drp1/Fis1 interaction by a selective peptide inhibitor, P110, led to a significant reduction in mitochondrial reactive oxygen species levels, and to improvement in mitochondrial structure and functions. We then treated mice expressing G93A SOD1 mutation (a mouse model of ALS) with P110. Sustained treatment, beginning at the symptomatic phase of the disease starting at the age of 90 days, correlated with decreased Drp1 association with the mitochondria in the spinal cord and produced an improvement in motor performance and survival. Together, these data suggest that inhibitors of Drp1 hyperactivation, such as P110, may be an attractive therapeutic approach for ALS patients.

Title: Splicing repression is a major function of TDP-43 in motor neurons: Identification of a novel therapeutic strategy for ALS/FTD

Authors: *A. N. DONDE[1], J. P. LING[2], K. E. BRAUNSTEIN[3], M. SUN[5], L. CHEN[2], P. C. WONG[4]
[1]Neurosci., [2]Johns Hopkins Univ., Baltimore, MD; [3]Div. Neuropathology, Dept. of Pathology, [4]Dept Pathol, Johns Hopkins Sch. of Med., Baltimore, MD; [5]Dept. of Pathology, Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: In sporadic amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD), Tar DNA-binding protein 43 (TDP-43), a conserved RNA-binding protein (RBP), clears from the nucleus and forms cytoplasmic inclusions, a pathological hallmark thought to be central to disease pathogenesis. While evidence supports the notion that nuclear depletion of TDP-43 underlies cytotoxicity, the precise mechanism is unknown.
We discovered that TDP-43, a founding member of a new class of RBPs, represses the splicing of non-conserved cryptic exons by binding to simple microsatellite repeats, a function compromised in ALS patients. Depletion of TDP-43 leads to incorporation of cryptic exons that usually alters the proteome of affected cells. Because several putative roles have been attributed to TDP-43, it will be critical to establish first that this splicing repression is a major role of TDP-43 in motor neurons. We initially showed that cryptic exons can be repressed in TDP-43 deficient cells using a chimeric protein consisting of the N-terminal RNA-recognition domain of TDP-43 fused with an unrelated but well-known splicing repressor (RAVER1), indicating that TDP-43 splicing repression is its major role in replicating cells. To establish this in post-mitotic mammalian motor neurons *in vivo*, we used a mouse model lacking Tdp-43 in lower motor neurons that exhibits age-dependent motor neuron disease. As predicted, incorporation of cryptic exons occurred in the spinal cords of these knockout mice.
We then delivered our chimeric construct in neonatal mice using an AAV9 viral vector, maintaining long-term expression in 55-70% of lower motor neurons without overt toxicity. Treated conditional Tdp-43 knockout mice showed a delayed onset, attenuated progression of motor symptoms as measured by hanging wire rotarod tests, and extended lifespan. Transcriptome analysis of FACS-isolated Tdp-43 deficient motor neurons from mice treated with our chimeric construct showed the extent of splicing re-suppression. Our findings establish that splicing repression is a major role of TDP-43 in mammalian motor neurons and support the idea that the inability to repress TDP-43 splicing is a major pathogenic mechanism underlying TDP-43 pathology, pointing to a promising AAV9 therapeutic strategy for ALS/FTD.

Title: Small molecules targeting catalytic multiprotein complexes that misassemble TDP43 in ALS

Authors: S. TROSSBACH[1], S. SELVARAJAH[2], S. SAHU[2], I. SOLVIEV[2], N. DEYARMAN[2], V. BADER[1], S. JACOBSEN[3], N. BRANDON[3], K. PAULVANNAN[2], V. ASUNDI[2], D. DEY[2], *C. KORTH[1], V. R. LINGAPPA[2]
[1]Heinrich Heine Univ. Dusseldorf, Dusseldorf, Germany; [2]Prosetta, San Francisco, CA; [3]AstraZeneca, Cambridge, MA

Abstract: Background: Our working hypothesis is that multiprotein complexes (MPCs) are not formed spontaneously, but rather are catalytically assembled by other transient and highly dynamic MPCs, which we term assembly machines. We hypothesize that pathological protein aggregation is the result of aberrant assembly machine function occurring upstream in the relevant biochemical pathway. If small molecules binding to allosteric sites that normalize assembly machine composition and function could be found, they should be efficacious against particular protein aggregation diseases We have identified 300 small molecule chemotypes, termed the Hit-finder Collection, that are active against a diverse array of assembly machines commandeered by viruses for their capsid formation. These have served as an effective starting point for specific assembly machine-modulating drug development.
Objective: Identify hit-finder compounds active against TDP-43 aggregation in ALS.
Methods: Induction of stress granule formation and cytosolic TDP-43 accumulation were performed by treating SH-SY5Y cells with sodium arsenite, a cellular model for ALS. We developed a novel biochemical assay allowing us to directly assess drug action on cytoplasmic TDP-43 mislocalization, aggregation and association to stress granules. This assay involved a combination of *in vitro* crosslinking, low salt protein extraction and gradient ultracentrifugation. The potency of the Hit-finder Collection to correct TDP-43 pathology was screened by an immunocytochemistry (ICC) approach and the best chemotypes were more intensely investigated by the biochemical assay, drug resin affinity chromatography, and a C.*elegans* swimming-induced paralysis animal model.
Results: Three lead series correcting cellular TDP-43 pathology were identified. Analogs were shown to have a robust structure-activity-relationship. Drug resin affinity chromatography (DRAC) was used to identify distinctive MPCs for each chemotype each containing different protein previously implicated in ALS.
Conclusion: Three ALS lead series suitable for preclinical drug development have been identified each targeting a different aberrant assembly machine involved in ALS.

Title: Systemic Angiogenin delivery reverses defects in spinal cord capillary density and delays motor dysfunction in $SOD1^{G93A}$ mice

Authors: *J. H. PREHN[1], M. CRIVELLO[2], S. O'RIORDAN[2], I. WOODS[2]
[1]Royal Col. of Surgeons in Ireland, Dublin, Ireland; [2]RCSI, Dublin, Ireland

Abstract: Loss-of-function mutations in the Angiogenin (*ANG*) gene have been identified in patients with familial and apparently 'sporadic' forms of ALS. Previous work from our group identified Angiogenin as a protective factor for cultured primary motor neurons under stress conditions, and provided *in vivo* proof-of-concept that daily intraperitoneal (i.p.) injections of Angiogenin protein *post* symptom onset increased lifespan and delayed disease progression in $SOD1^{G93A}$ mice. Angiogenin's mechanism of action after systemic administration *in vivo* however remains less well understood. In the present study, we implemented a preclinical *in vivo* study design using sex- and litter-matched $SOD1^{G93A}$ mice to validate our previous *in vivo* report, provide pharmacokinetic data on serum levels and protein distribution after i.p. administration *in vivo*, and to explore Angiogenin *in vivo* acted on cells other than motor neurons. $SOD1^{G93A}$ mice (n=43) and non-transgenic controls (n=30) were sex- and litter-matched according to the Ludolph *et al.* guidelines, and treated with Angiogenin (1 µg, i.p., 3 times/week) or vehicle from symptom onset (90 days). Increased Angiogenin serum levels were detectable 2 and 24 h after i.p. injection in both transgenic and non-transgenic mice. Angiogenin was taken up by Podocalyxin-positive cells, suggesting a vascular mechanism of action. Treatment with Angiogenin increased survival ($p<0.05$) and delayed the onset of motor dysfunction assessed by Rotarad analysis ($p < 0.05$). To determine changes in vascularization and motor neuron degeneration, Angiogenin or vehicle were administered from 90 days until 115 days after which spinal cords were assessed histologically. Stereological measurements of vessel number, density and volume indicated that vehicle-treated $SOD1^{G93A}$ mice showed decreased vascular coverage, and that Angiogenin treatment resulted in improved maintenance of vascular integrity and increased motor neuron survival. Our data suggest that Angiogenin represents a new class of ALS therapeutics that also acts on the spinal cord vasculature to delay disease progression.

Abstract: Amyotrophic lateral sclerosis (ALS) is an incurable fatal paralytic disease that affects adults. ALS is characterized by the degeneration of both upper and lower motor neurons (MNs). This study investigated the therapeutic value of the translocator protein 18KDa (TSPO) ligand PK11195 (PK), which we found to be highly protective for MNs and their processes against ALS astrocyte toxicity in both the superoxide dismutase 1 (SOD1) rodent and human co-culture models of ALS that we previously developed (Nagai et al., 2007; Re et al., 2014). Our two goals were: 1) to define the cellular target of PK and its mechanism of neuroprotection in MNs co-cultured with ALS astrocytes; 2) to assess the efficacy of PK in mutant SOD1G93A (mSOD1) mice. *In vitro*, we found that PK acts directly on MNs to prevent their death, not via ALS astrocytes, although TSPO is expressed and up-regulated in both. Immunoelectron microscopy

shows a differential distribution of TSPO among MNs and astrocytes, suggesting cell-specific roles. Knockdown of MN TSPO did not mimic PK protective effect, indicating that is not acting as an antagonist. Also, TSPO is likely part of a neuroprotective pathway as its expression is highest in astrocyte-resistant MNs. For our preclinical study, we determined by high pressure liquid chromatography that PK is quickly eliminated from the CNS after single injection, but is very stable at 37^0C, allowing for its continuous delivery via subcutaneous osmotic mini-pump. 3 groups of mSOD1 mice were formed: vehicle (PEG400), 10 µM, and 100 µM of PK in the pump; both doses lead to significant CNS levels, but only PK10 maintained nM range TSPO-specific levels. mSOD1 mice show a significant deficit at the loaded grid test (grip strength) compared to non-transgenic littermates, as early as 6 weeks (wks) of age, while rotarod score (general motor performance) declines only after 10 wks. Pumps were implanted in 5 wk-old mice and then replaced every 5 wks. Overall, we found that both doses of PK significantly improve grip strength and motor performance, earlier for PK10 (7 vs. 9 wks) but more sustainably for PK100, while both effects lessen with paralysis progression (gone by 16 wks). In agreement, histopathological analyses show a striking dose-dependent protection of neuromuscular junctions (NMJs) in 8-9 wk-old mice. At 14 wks, NMJ preservation has vanished and MN numbers in the lumbar spinal cord are not different among groups. Also, PK does not delay the onset of paralysis (P90-100) and does not extend mouse lifespan. This supports the view that only the combination of therapies targeting neuroprotection and the lessening of glial cell neurotoxicity will hold some promise for clinical efficacy in ALS.

Title: Silencing of the mutant huntingtin gene via CRISPR-Cas9 in an *In vitro* model of Huntington's disease

Authors: *N. KOLLI[1,6], M. LU[2,6], P. MAITI[3,7], J. ROSSIGNOL[6,3], G. L. DUNBAR[4,6,5]
[1]Neurosci., Central Michigan Univ., Nellore, India; [2]Neurosci., Central Michigan Univ., Mount pleasant, MI; [3]Central Michigan Univ., Mount Pleasant, MI; [4]Dept Psychol, Central Michigan Univ., Mt Pleasant, MI; [5]Neurosci., Central Michigan Univ., Mount Pleasant, MI; [6]Field Neurosciences Inst. Lab., Mount Pleasant, MI; [7]Saginaw Valley State Univ., Saginaw, MI

Abstract: Huntington's disease (HD) is a fatal neurodegenerative genetic disease characterized by a loss of neurons in the striatum. It is caused by a mutation in the Huntingtin gene (*HTT*) that codes for the protein huntingtin (HTT). The mutant Huntingtin gene (m*HTT*) contains extra poly-glutamine (CAG) repeats from which the translated mutant huntingtin proteins (mHTT) undergo inappropriate post-translational modifications, conferring a toxic gain of function, in addition to its non-functional property. In order to curb the production of the mHTT, we have constructed two CRISPR (clustered regularly interspaced short palindromic repeat)-Cas9 (CRISPR associate protein) plasmids, among which one nicks the DNA at untranslated region upstream to the open reading frame (uORF), and the other nicks the DNA at exon1-intron boundary. The primary goal of this study was to apply this plasmid into mesenchymal stem cells (MSCs) extracted from the bone-marrow of YAC128 mice, which carries the transgene for HD. Our results suggest that the disruption of uORF through CRISPR-Cas9 influences the translation of mHTT negatively and, to a lesser extent, disrupts the exon1-intron boundary, which affects the translation of the mHTT. These findings also revealed the pattern of the nucleotide addition or deletion at the site of the DNA-nick in this model.

Title: Riluzole but not Melatonin ameliorates acute motor neuron degeneration and inhibits disrupted mitochondrial ca2+ signaling in amyotrophic lateral sclerosis

Authors: *M. K. JAISWAL
Germany, Göttingen, Germany

Abstract: Selective motoneurons (MNs) degeneration in the brain stem, hypoglossal motoneurons (HMNs), and the spinal cord resulting in patients paralysis and eventual death are prominent features of amyotrophic lateral sclerosis (ALS). Previous studies have suggested that mitochondrial respiratory impairment, low Ca^{2+} buffering and homeostasis and excitotoxicity are

the pathological phenotypes found in mice, and cell culture models of familial ALS (fALS) linked with Cu/Zn-superoxide dismutase 1 (SOD1) mutation. In our study, we aimed to understand the impact of riluzole and melatonin on excitotoxicity, neuronal protection and Ca^{2+} signaling in individual HMNs ex-vivo in symptomatic adult ALS mouse brain stem slice preparations and in WT and SOD1-G93A transfected SH-SY5Y neuroblastoma cell line using fluorescence microscopy, calcium imaging with high speed charged coupled device camera, together with immunohistochemistry, cell survival assay and histology. In our experiments, riluzole but not melatonin ameliorates MNs degeneration and moderately inhibit excitotoxicity and cell death in SH-SY5Y^{WT} or SH-SY5Y^{G93A} cell lines induced by complex IV blocker sodium azide.

In brain stem slice preparations, riluzole significantly inhibit HMNs cell death induced by inhibiting the mitochondrial electron transport chain by Na-azide. In the HMNs of brainstem slice prepared from adult (14-15 weeks) WT, and corresponding symptomatic SOD1^{G93A} mice, we measured the effect of riluzole and melatonin on $[Ca^{2+}]i$ using fura-2 AM ratiometric calcium imaging in individual MNs. Riluzole caused a significant decrease in $[Ca^{2+}]i$ transients and reversibly inhibited $[Ca^{2+}]i$ transients in Fura-2 AM loaded HMNs exposed to Na-azide in adult symptomatic SOD1^{G93A} mice. On the contrary, melatonin failed to show similar effects in the HMNs of WT and SOD1^{G93A} mice. Intrinsic NADH fluorescence, an indicator of mitochondrial metabolism and health in MNs, showed enhanced intrinsic NADH fluorescence in HMNs in presence of riluzole when respiratory chain activity was inhibited by Na-azide. Riluzole's inhibition of excitability and Ca^{2+} signaling may be due to its multiple effects on cellular function of mitochondria. Therefore formulating a drug therapy to stabilize mitochondria-related signaling pathways using riluzole might be a valuable approach for cell death protection in ALS. Taken together, the pharmacological profiles of the riluzole and melatonin strengthen the case that riluzole indeed can be used as a therapeutic agent in ALS whereas claims of the efficacy of melatonin alone need further investigation as it fail to show significant neuroprotection efficacy.

Title: Increased frequency of pudendal nerve stimulation improved recovery from a dual nerve and muscle injury

Authors: *B. M. BALOG[1,3,4], D. LIN[4], B. HANZLICEK[4], M. S. DAMASER[2,5]
[2]Biomed. Engin., [1]Cleveland Clin. Lerner Res. Inst., Cleveland, OH; [3]Biol., Univ. of Akron, Akron, OH; [4]Advanced Plateform Technol. Ctr., Louis Stokes Cleveland VA hospital, Cleveland, OH; [5]Advanced Platform Technol. Ctr., Louis Stokes Cleveland VA Hosp., Cleveland, OH

Abstract: Stress Urinary Incontinence is the involuntary leakage of urine. The primary risk factor in women is childbirth, which injures the pudendal nerve and the external urethral sphincter, creating a dual muscle & nerve injury and pudendal nerve dysfunction up to 5 years after delivery. Electrical stimulation (ES) of injured nerves can accelerate nerve regeneration and functional recovery. Twice weekly stimulation has been shown to decrease functional recovery time after simulated childbirth injury in rats consisting of pudendal nerve crush (PNC) and vaginal distension (VD). We hypothesize that daily electrical stimulation will result in greater improvement in recovery after PNC+VD than less frequent stimulation.
Sprague-Dawley rats either received PNC+VD or sham injury; half of sham injured rats and all PNC+VD rats had wire electrodes implanted. Sham injured rats with electrodes receive sham stimulation (SI + SS). One third of PNC+VD rats received sham stimulation (PNC+VD + SS), an additional 1/3 received electrical stimulation 4 times a week (PNC+VD + 4ES) and the remaining animals received daily stimulation (PNC+VD + DES). Stimulation lasted 1 hour at 20 Hz, 0.1ms, 0.3mA under isoflurane anesthesia; sham stimulation consisted of 1 hour of isoflurane anesthesia. Animals were stimulated for 2 weeks after the injury and survived another 2 weeks when leak point pressure (LPP) with simultaneous external urethral sphincter electromyography (EUS EMG) and pudendal nerve sensory branch potential (PNSBP) were recorded. Data is shown as mean ± sem. An ANOVA followed by a Student-Newman-Keulsposthoctest was used to determine significant differences between groups ($p<0.05$).
LPP was not significantly decreased after PNC+VD + 4ES (39.9 ± 3.0 cm H_20) compared to sham injury no implant (SI +NI; 40.6 ± 3.45 cm H_20) or SI + SS groups (39.9 ± 2.31 cm H_20), although LPP of PNC+VD + SS (19.0 ± 2.43 cm H_20) and PNC+VD + DES (26.5 ± 1.96 cm H_20) rats were significantly decreased. EUS EMG amplitude was significantly decreased after PNC+VD + SS (1.5 ± 2.33μV) and PNC+VD + DES (1.2 ± 0.52μV) compared to SI + NI (13.5 ± 3.79μV) and SI + SS (13.7 ± 3.97μV), but not in PNC+VD + 4ES (5.8 ± 1.92μV). All electrode implanted groups: SI + SS (0.2 ± 0.09 μV), PNC+VD + SS (0.1 ± 0.02 μV), PNC+VD + 4ES (0.2 ± 0.10 μV), and PNC+VD + DES (0.1 ± 0.04 μV) had a significant reduction in PNSBP amplitude compared to IS + NI (0.6 ± 0.06 μV).
While 4 stimulations per week improved LPP and EUS EMG beyond daily stimulation, it did not influence PNSBP recovery. The implanted electrodes likely had a negative effect on the pudendal nerve, since the SI + SS group had a reduction in PNSBP amplitude.

Title: Brain-derived neurotrophic factor treatment leads to partial recovery after a dual nerve and muscle injury

Authors: B. M. BALOG[1], X. YUAN[3], M. KUANG[2], D. LIN[4], B. HANZLICEK[4], H. YAN[5], *M. S. DAMASER[6]

Abstract: Stress urinary incontinence (SUI) is a prevalent disorder affecting 30% of women over the age of 40. The primary risk factor for SUI is childbirth which injures both the pudendal nerve and the muscle it innervates: the external urethral sphincter, creating a dual muscle & nerve injury. Upregulation of brain-derived neurotrophic factor (BDNF) is needed for neuroregeneration but can inhibit myogenesis. Treatment with the secretions of mesenchymal stem cells (MSCs), which contain BDNF, accelerates functional recovery in a rat model of SUI consisting of pudendal nerve crush (PNC) and vaginal distension (VD). We hypothesize that the accelerated functional recovery via CCM treatment is caused by the BDNF accelerating the recovery of the pudendal nerve and functional recovery.
Bone marrow-derived MSCs were collected from Sprague-Dawley donor rats and cultures. BDNF knockdown (KD) MSCs were created using an anti-BDNF shRNA lentivirus vector. A scrambled sequence was used as a transfection control (scrambled). Cells were cultured for 24 hours in serum and antibiotic free media before the Media was concentrated 50x to create concentrated conditioned media (CCM) containing the secretions of MSCs. Unmanipulated cells were used to create control CCM. Concentrated control media (CM) was created with media that was not conditioned by cells. Rats underwent a PNC+VD or Sham injury (SI). One hour and 1 week after injury animals received 300µl treatment intraperitoneally. SI rats received CM; PNC+VD rats received CM, CCM, KD CCM or scrambled CCM. Three weeks later, rats underwent leak point pressure (LPP) and pudendal nerve sensory branch potential (PNSBP) recordings. The urethra and pudendal nerve were harvested for histological assessment. An ANOVA followed by a Student-Newman-Keuls posthoc test was used to determine significant

differences between groups ($p<0.05$).
LPP was significantly decreased in PNC+VD + CM (28.3 ± 2.1 cm H_2O) or KD CCM (31.1 ± 2.5 cm H_2O) compared to SI (40.9 ± 3.3 cm H_2O), but not with scrambled (36.0 ± 3.1 cm H_2O) or CCM (51.1 ± 3.1 cm H_2O). PNSBP firing rate showed a significant decrease in CM treatment (399 ± 100 Hz) compared to SI (977 ± 93 Hz). Immunofluorescence showed healthier neuromuscular junction in the sphincter in KD CCM, scrambled CCM, and CCM but not CM compared to SI.
While the immunofluorescence and PNSBP shows regeneration of the pudendal nerve and recovery of its function with any CCM treatment, the LPP results for KD CCM animals would suggest it may take longer to recover continence without BDNF. This study shows while BDNF is important, it is not the only factor needed for the recovery from a dual nerve and muscle injury.

Abstract: Amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD) belong to a group of complex neurodegenerative disorders. Patients with ALS show loss of motor neurons, resulting in progressive muscle weakness, whereas FTD is characterized by the degeneration of the frontal and temporal lobes, resulting in early dementia. Clinical overlap between both diseases is described, suggesting them to be the borders of a disease spectrum. A subgroup within this spectrum, the FUSopathy, is characterized by FUS inclusions in neurons and glial

cells. To gain insight into the pathogenetic mechanism of FUS pathology, we set up an unbiased screen in a drosophila model. In this model, mutant and WT FUS overexpression in the motor neurons results in a pharate adult eclosion defect. We identified 75 candidate genes, able to modify this phenotype. It became apparent that many proteins in this list were present in intracellular RNA granules. Combining this with the fact that FUS inclusions in ALS and FTD patients are positive for stress granule markers, further validation experiments will be performed to investigate the functional importance of these candidate proteins for FUS positive granules.

Title: Effects of interleukin-37 in amyotrophic lateral sclerosis

Authors: *A. MARTINEZ-MURIANA[1], C. A. DINARELLO[2,3], R. LÓPEZ-VALES[1]
[1]Cell biology, physiology and immunology, Univ. Autonoma De Barcelona, Bellaterra, Spain; [2]Div. of Infectious Diseases, Univ. of Colorado Denver, Aurora, CO; [3]Dept. of Med., Radboud Univ. Med. Ctr., Nijmegen, Netherlands

Abstract: Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disorder that affects upper and lower motor neurons (MNs). MNs loss results in skeletal muscle weakness, spasticity and paralysis, leading to the death of patients by respiratory failure 3 to 5 years after diagnosis. As occurs in several neurological disorders including ALS, inflammation is a pathological hallmark. Several reports have provided evidence that glial cells and leukocytes accelerate the course of the disease in animal models of ALS, suggesting that therapies aimed at targeting inflammation may be a valuable approach for this neurodegenerative disease. IL-37 is the only member of the IL-1 family that exerts broad anti-inflammatory effects over innate and acquired immunity. We have previously demonstrated that IL-37 mediates marked anti-inflammatory actions in the injured central nervous system, and confers protections against secondary tissue damage and functional deficits after spinal cord contusion injury in mice. However, whether IL-37 exerts similar beneficial effects in neurodegenerative conditions is not known yet. In the

present study, we investigated whether IL-37 suppresses inflammation and slows the clinical course of the disease in a mouse model of ALS ($SOD1^{G93A}$ mouse). Since no mouse genomic sequence corresponding to human IL-37 has been found yet, we crossed transgenic mice expressing the human form of IL-37 with $SOD1^{G93A}$ mice to assess the effects of IL-37 in ALS. Our data reveals that transgenic expression of IL-37 slowed ALS disease progression, extended lifespan of $SOD1^{G93A}$ mice, and increased the preservation of spinal cord motoneurons. We also observed that IL-37 attenuated microgliosis and astrogliosis in the lumbar spinal cord of $SOD1^{G93A}$ mice. Since microgliosis and astrogliosis are regulated, in part, by cytokines, we assessed whether IL-37 modulated the protein levels of several cytokines in the sciatic nerve and spinal cord of ALS mice. Luminex experiments revealed that IL-37 attenuated the expression of IL-4 and IL-6 in the sciatic nerve of $SOD1^{G93A}$ mice and reduced the levels of MCP1 in both, sciatic nerve and spinal cord. Interestingly, IL-37 increased in ~4 fold the protein levels of the anti-inflammatory cytokine IL-10 in the spinal cord. This data demonstrates the anti-inflammatory and beneficial actions of IL-37 in a mouse model of ALS. Since previous studies reveal that IL-37 can act extracellularly by forming a complex with the IL-18Rα and IL-1R8, as well as, by translocating to the nucleus, we will dissect out, in future experiments, to what degree the beneficial actions of IL-37 in ALS are mediated via extracellular or intracellular function.

Title: *In vivo* safety and efficacy evaluation of a novel 3rd generation antisense oligonucleotide against TGFßRII to treat amyotrophic lateralsclerosis

Authors: *S. PETERS[1], E. ZITZELSPERGER[1], S. KUESPERT[1], R. HEYDN[1], L. J. AIGNER[2], S. KORTE[3], T.-H. BRUUN[1], U. BOGDAHN[1]
[1]Dept. for Neurol., Univ. Hosp., Regensburg, Germany; [2]Paracelsus Med. Univ., Salzburg, Austria; [3]Covance Preclinical Service GmbH, Münster, Germany

Abstract: Amyotrophic Lateralsclerosis (ALS) is a fatal neurodegenerative disease in adults with a progressive loss of upper and lower motorneurons. ALS patients exhibit an enhanced TGFß system activity critically mediating the imbalance of neurodegeneration and neuroregeneration. Neurodegeneration is accompanied by a profound pro-inflammatory and neurotoxic immune profile, an inhibited/arrested adult neurogenic niche activity, and an

increased pro-fibrotic status. A novel 3rd generation antisense oligonucleotide (ASO) targeting the TGFßRII, significantly reaches target and modulates all three pathophysiological aspects of neurodegeneration in human neuronal progenitor cells (ReNcell CX). We first investigated ASO tolerability by using a dose escalation paradigm with increasing dose levels every single week for 4 weeks. One male and female Cynomolgus monkey received an intrathecal ASO injection and physical/neurological parameters were investigated directly and following 4h after administration. For clinical chemistry, bioanalytics, biomarker determination, and target regulation, blood and CSF samples were taken before each dosing and tissue samples (liver, kidney, spinal cord, brain) were collected at the end of the study. In a second study ASO pharmacokinetics was evaluated by bioanalytical determination of ASO tissue concentrations following 2 or 4 wks post intrathecal drug administration of two different ASO doses. CSF was taken before necropsy to determine ASO half-life. Further, CNS tissue samples (spinal cord, brain) were collected to evaluate tissue distribution. Finally, in a third paradigm the ASO was injected repeatedly over a 13-week approach at two different doses to simulate a long-time administration period and to investigate possible ASO saturation levels. For analysis, blood, CSF and tissue samples were taken as described for the tolerability study. Target regulation as well as TGFß system activity with the expression levels of the ligands and the most important downstream target molecules was determined within the spinal cord, motor cortex, dentate gyrus, and the subventricular zone. Consequently, effects of an altered TGFß system activity on the adult neurogenic niche was investigated by measuring neuronal stem cell and neurogenesis markers. All parameters of interest were determined via qRT-PCR, Western Blot analysis, and immunofluorescence staining. Taken together, the results of the current study indicate that the novel 3rd generation ASO is a well tolerated, stable and efficient molecule to alter TGFß system and adult neurogenic niche activity. Therefore, it might represent a potential candidate to treat ALS.

Title: Widespread spinal cord transduction with a modified AAV vector: Implications for spinal cord diseases

Authors: J. NAIDOO[1], *L. M. STANEK[2], P. HADACZEK[1], L. SAMARANCH[1], C. O'RIORDAN[2], J. BRINGAS[1], C. SNIECKUS[1], J. SULLIVAN[2], S. NASS[2], M. MATTINGY[2], D. WOODCOCK[2], K. S. BANKIEWICZ[1], L. SHIHABUDDIN[2]
[1]Univ. of California San Francisco, San Francisco, CA; [2]Sanofi, Framingham, MA

Abstract: Background: A key limiting factor for the clinical application of gene therapy in spinal cord disorders is the low levels of transduction that current vectors can achieve in the motor neurons (MN) of spinal cord. We have addressed this issue with a modified adeno-associated viral vector capsid (AAV*). **Objective:** The goal of this study was to evaluate the efficiency of MN transduction of AAV*-GFP in non-human primate (NHP) after either lateral ventricle or thalamus delivery. **Methods:** Six adult male NHP (*Macaca mulatta*), negative for neutralizing antibodies against the AAV capsid, were randomized assigned to two treatment groups. Group I (n=3) received a single dose of AAV*-CBA-eGFP into lateral ventricle (1.5 mL/hemisphere) and animals from group II (n=3) received an injection into thalamus (130 - 280µL/hemisphere). All injections were performed under magnetic resonance imaging (MRI) guidance. Three weeks later, spinal cords were harvested, and 15 µm sections were analysed by immunohistochemistry against GFP and NeuN. Percentage of MN transduction was determined on consecutive sections from cervical, thoracic, lumbar and sacral regions. **Results:** Robust GFP expression was observed in both cell bodies and fibres in all regions of the spinal cord after lateral ventricle injection. 92.8% of MN were transduced in the cervical region, 83.6% in thoracic, 85.1% in lumbar and 92.6% in sacral region. On the other hand, animals with a thalamic infusion showed levels of transduction of 64.8% in cervical, 33.5% in thoracic, 38.3% in lumbar and 33.0% in sacral regions. Further analysis for immune reaction reveled no perivascular infiltration, microglia hyper-reactive or astrocytic activation in any of the treated groups. **Conclusion:** Lateral ventricle injection of a modified AAV vector can globally transduce MN of the spinal cord with no significant immune response.

Title: GM604 as a novel therapeutic strategy for treatment of ALS and other neurodegenerative diseases: Pre-clinical and bioinformatic data and findings from a phase 2A randomized placebo-controlled clinical trial

Authors: M. S. KINDY[1], K. BOJANOWSKI[2], P. LUPINACCI[3], T. K. SHUM[4], *D. KO[4]
[1]Pharmaceut. Sci., Univ. of South Florida, Tampa, FL; [2]Sunny BioDiscovery, Inc., Santa Paula, CA; [3]Dept. of Mathematics and Statistics, Villanova Univ., Villanova, PA; [4]Genervon Biopharmaceuticals LLC, Pasadena, CA

Abstract: Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disease that lacks effective treatment options. As a novel treatment strategy, Genervon Biopharmaceuticals has discovered and developed GM604 (GM6), a 6-amino acid peptide drug modeled upon an endogenous embryonic protein isolated from the developing nervous system (human motoneuronotrophic factor, MNTF). We have hypothesized that GM6 has multi-target effects replicating the MNTF activity spectrum, leading to improved survival of neurons in neurodegenerative patients. Through *in vivo* pre-clinical studies, we have shown that GM6 prevents functional decline and promotes neuron lesion recovery in rodent models of neurodegenerative disease. These models have included the SOD1-G93A transgenic model (ALS), mice treated with 6-hydroxydopamine or 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (Parkinson's disease, PD), and mice injected with myelin proteolipid protein (Multiple sclerosis, MS). *In vitro* assays using rat cortical neurons additionally demonstrated that GM6 protected against toxic factors in CSF isolated from patients diagnosed with these diseases. Using DNA microarrays, we identified 1259 genes altered at least 2-fold in SH-5YSY cells, including 89, 48, 46 and 9 genes associated with ALS, AD, PD and MS, respectively. Functional enrichment analyses of these GM6-sensitive genes suggested cellular changes related to repression of the intrinsic apoptotic pathway and stimulation of mitotic/proliferation pathways. To demonstrate the clinical significance of these findings, we recently reported results from a multi-site phase 2A randomized, double-blind, placebo-controlled pilot trial of GM6 for treatment of ALS. Our phase 2A findings demonstrate clinical safety of GM6 and observed favorable shifts in ALS biomarkers and improved functional measures. In this study, GM6 decreased plasma levels of key ALS biomarkers (TDP-43, $P = 0.008$; Tau, $P = 0.037$; SOD1, $P = 0.009$). Compared to a historical control cohort in definite ALS patients, GM6 slowed functional decline based upon the

ALS Functional Rating Scale (P = 0.005), and we observed site-specific improvement in forced vital capacity (P = 0.027). These findings support the hypothesis that GM6 triggers developmental-stage cascades to ultimately encourage neuron survival to attenuate progression of neurodegenerative diseases. We are now conducting a new generation of studies to better delineate mechanisms by which GM6 may promote neuron survival (e.g., using high-throughput complementary DNA sequencing, RNA-seq). We have designed a phase 3 ALS randomized placebo-controlled trial planning to start in 2017.

Title: Identification of novel CNS-active inducers of SMN2 expression

Authors: ***M. E. BUTCHBACH**[1,2,3], R. W. KIRK[1], A. W. HARRIS[1], K. M. HINKLE[2], A. J. CONNELL[1], A. PESYAN[4]
[1]Ctr. for Applied Clin. Genomics, Nemours Biomed. Research/A. I. duPont Hosp. For Children, Wilmington, DE; [2]Biol. Sci., Univ. of Delaware, Newark, DE; [3]Pediatrics, Thomas Jefferson Univ., Philadelphia, PA; [4]AurimMed Pharma, Inc., Park City, UT

Abstract: Spinal muscular atrophy (SMA), a leading genetic cause of infant death worldwide, is an autosomal recessive motor neuron disease caused by the loss of *SMN1* but retention of *SMN2*. The number of copies of *SMN2* inversely correlates with disease severity in SMA patients making *SMN2* a target for therapeutics development. AurimMed Pharma, Inc. has developed a focused library of potent CNS active compounds. In this study, we screened this library for modulators of *SMN2* expression using reporter cell lines as well as fibroblasts derived from SMA

patients. The compound library was screened using NSC34 motor neuron-like cell lines expressing either a reporter gene under the control of the 3.4 kb *SMN2* promoter or a mini-gene construct containing exons 6 through 8 of *SMN2* as well as their intervening introns. The effects of hit compounds on *SMN2* expression were measured in type II SMA fibroblasts (GM03813) by quantitative real-time PCR, immunoblot and immunofluorescence. Of the 64 compounds in this library, 26 showed enhanced *SMN2* promoter activity relative to vehicle (DMSO)-treated cells and 5 showed increased inclusion of exon 7. Some of these hits were validated in GM03813 type II SMA fibroblasts. 5 compounds—AMP-X-0079, AMP-X-0080, AMP-X-0026, AMP-X-0009 and AMP-X-0024—increased *SMN2* mRNA and protein levels in these cells. We have identified new compounds that increase *SMN2* expression in NSC34 cells and in SMA fibroblasts. Future work will determine the mechanisms by which these compounds are increasing *SMN2* expression. Furthermore, these compounds will be moved forward into preclinical studies using mouse models of SMA.

Title: Promotion of the M2 microglial state and enhanced neuronal trophic support extend survival in the murine model of ALS

Authors: *A. M. SNYDER[1], E. B. NEELY[1], O. MROWCZYNSKI[1], R. PAYNE[1], A. GERONIMO[3], Z. SIMMONS[2], J. R. CONNOR[1]
[1]Neurosurgery, MC H110, [2]Neurol., Penn State Univ. Coll Med., Hershey, PA; [3]Dept. of Neurosurg., Pennsylvania State Univ. Dept. of Neurosurg., Hershey, PA

Abstract: Amyotrophic Lateral Sclerosis is a multi-faceted disease with microglial activity impacting the environment for motor neuron viability. Biomarker analyses indicate that ALS

patients with a longer survival time have increased levels of trophic factors that support M2 microglia polarity, suggesting that this may be a point for therapeutic intervention. Our objective is to determine if providing metabolic support *in vivo* to neurons and promoting the M2 microglial phenotype extends survival in the well-characterized $SOD1^{G93A}$ murine model of ALS. At 80 days of age, ozmotic mini-pumps were loaded with our formulation of an artificial CSF (SCSF) solution with interleukin 9 (IL-9), granulocyte colony stimulating factor (G-CSF), chemokine (C-C motif) ligand 2 (MCP-1), and macrophage inflammatory protein-1-β (MIP-1β). A group of animals with received PBS infusion as an infusion control. Disease onset was assessed by performance on the rotarod apparatus, and endpoint was determined by the inability of the animal to right itself after 30 seconds. In a sub-set of animals, behavioral analyses extended beyond onset to determine the fall rate as disease progressed towards endpoint. Our results suggest that infusion with SCSF with factors that promote M2 microglial polarity extend survival rates in the murine model. There was a 3 day extension in survival as compared to the No surgery group and a 5 day extension as compared to the PBS-infused group, suggesting that infusion of a buffer solution that clears the CSF, such as PBS, is inadequate to positively impact disease progression. The rate of falls after disease onset was more severe in the PBS group, suggesting that this data may be informative in correlating murine behavioral data to for quality of life in the human population.

Title: Involvement of the LPA-LPA_2 axis in the physiopathology of ALS

Authors: *M. PUIGDOMENECH POCH, A. MARTINEZ-MURIANA, R. LÓPEZ-VALES
Cell Biology, Immunol. and Physiology., Univ. Autonoma De Barcelona, Bellaterra, Spain

Abstract: Lysophosphatidic acid (LPA) is a pleiotropic extracellular lipid mediator with many physiological functions that signals through 6 known G protein-coupled receptors (LPA_{1-6}). LPA_{1-3} share high homology in amino acid sequence and belong to the endothelial differentiation gene (edg) family LPA receptors, whereas LPA_{4-6} are genetically more distant and belong to the non-edg family LPA receptors. LPA mediates a wide range of LPA effects in the central nervous system, including neural progenitor cell physiology, glial activation, neuronal cell death, and

axonal retraction. We have previously shown that microglial cells become cytotoxic upon LPA-LPA_1 activation and lead to myelin loss after spinal cord injury. We have also unpublished data indicating that activation of microglia LPA_2 also leads to demyelination, as well as, to neuronal loss, especially motor neurons, after spinal cord injury. Similar detrimental actions of LPA have been also shown after brain injury by using an LPA antibody. Since microgliosis is a common hallmark of most neurological conditions, we hypothesized that LPA could be involved in the pathophysiology of neurodegenerative diseases, such amyotrophic lateral sclerosis (ALS). This is a fatal neurodegenerative disease characterized by the loss of upper and lower motor neurons. The underlying mechanisms leading to the degeneration of motor neurons in ALS are diverse and not fully known, however, there is evidence supporting the detrimental action of inflammation in the course of this disease. However, whether LPA is involved in the physiopathology of ALS has not been studied yet. Since our unpublished data shows that LPA-LPA_2 axis is involved in motor neuron death after spinal cord injury, we assessed whether activation of LPA_2 contributes to ALS. With this purpose, we crossed LPA_2 null with $SOD1^{G93A}$ mice and characterized the course of the disease by means of functional and electrophysiological tests. Our results revealed that the decline of the amplitude of the compound muscle action potential of the tibialis anterior muscle was slower in ALS mice lacking LPA_2 as compared to WT littermates, suggesting that the neuro-muscular integrity was better preserved in the absence of LPA_2 activity. Similarly, rotarod testing showed that the lack of LPA_2 also resulted in delayed onset and slowed progression of the disease. To our knowledge, these data suggests for the first time the detrimental actions of the LPA-LPA_2 axis in the physiopathology of ALS.

Abstract: Amyotrophic Lateral Sclerosis (ALS) is an adult-onset neurodegenerative disease, characterized by loss of motor neurons, progressive paralysis and death. Dominant mutations in the superoxide dismutase 1 (SOD1) gene are among the most frequent causes of inherited ALS. In our previous studies, we utilized Adeno-Associated Virus Serotype 9 (AAV9) carrying a GFP reporter to deliver a short hairpin RNA (shRNA) downregulating SOD1. This vector significantly improved disease outcome in mouse models. The treatment was safe and well-tolerated, but the presence of a foreign transgene and regulatory elements excluded a direct application of this vector in clinical trials. Hence, the main objective of the current study was to design and test the efficacy of an AAV9-SOD1-shRNA vector devoid of any foreign transgenes, enabling its direct use in clinical trials. We determined the *in vitro* efficiency of SOD1 downregulation and *in vivo* efficacy to delay the disease onset and progression with the modified AAV9 vector carrying SOD1 shRNA expression cassette and a non-coding stuffer sequence instead of GFP. In mice, we tested 2 different delivery routes for vector administration: intravenous (IV) and intracerebroventricular (ICV). Male and female SOD1G93A mice, overexpressing human mutant SOD1, were administered with modified AAV9-SOD1-shRNA vector via IV or ICV at postnatal day 1 and monitored throughout their lifespan. Both treatments resulted in significant improvement in rotarod performance and hindlimb grip strength. Moreover, removal of the GFP cassette markedly improved the therapeutic effect of the vector by significantly extending the median survival of ALS mice by 70 days which is almost twice the effect achieved with pervious construct. Importantly, similar therapeutic effect was achieved by ICV delivery of the vector at a 10-fold lower dose as compared to IV. To translate this approach to clinic, we also administered AAV9-SOD1-shRNA vector in adult (10 year old) non-human primates (Rhesus monkeys). A single intra-lumbar infusion of the vector resulted in significant SOD1 reduction throughout the monkey brain and spinal cord, thus corroborating our dosing rationale and route of delivery. In summary, we have successfully designed and tested the modified AAV9-SOD1-shRNA vector that would meet FDA requirements. We report one of the longest survival extensions achieved in the most severe ALS mouse model, using just a single CSF administration of AAV9-SOD1-shRNA. Finally, successful translation of this therapy in non-human primates paves the way for future clinical trials for ALS patients.

Abstract: Amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD) are devastating and incurable neurodegenerative diseases characterized by a progressive loss of neurons. An intronic GGGGCC repeat expansion in the gene C9ORF72 is the most common cause of both ALS and FTD, accounting for over 10% of each disease. The precise disease mechanisms by which this repeat expansion causes disease is not fully understood, yet both gain- and loss- of function of the mutant allele are expected to contribute to disease. Here, we aim to circumvent addressing disease mechanisms by targeting the repeat expansion directly. We employ the gene-editing strategy of CRISPR-Cas9 and delivery by AAV9. By intrathecal injection in mouse neonates we obtain a high transduction efficiency with AAV9-GFP in the spinal cords, predominantly transducing large motor neurons, as well as transduce neurons in different areas of the brain, including cerebellum and hippocampus. For optimal AAV9 packaging, we use a split Cas9 enzyme. Our designed CRISPR-Cas9 guide RNAs are compatible with this enzyme and cut close to the repeat expansion without disruption of the C9ORF72 coding sequence. These guide RNAs are tested in human HEK293T cells for excision efficiency. We utilize commercially available C9ORF72-BAC transgenic mice and assess cellular readouts, such as dipeptide repeat proteins and RNA foci, to confirm excision in transduced cells. This research is the first step in ALS and FTD towards assessing the potential of CRISPR-Cas9 gene-therapy in vivo.

Abstract: Skeletal muscle is a highly adaptive tissue capable of changes in size, contractility, and metabolism according to functional demands. Atrophy is a decline in mass and strength caused by pathologic loss of myofibrillar proteins, and is associated with numerous conditions including disuse, immobilization, malignancy, aging (sarcopenia), and denervation caused by injury or motor neuron diseases such as amyotrophic lateral sclerosis (ALS) and spinal muscular atrophy (SMA).
Regardless of the underlying condition, several key signaling pathways have been identified as important mediators of atrophy, including NF-KB and MAPK cascades that lead to induction of key E3 ubiquitin ligases and effectors of proteasomal degradation. Genetic disruption of NF-KB signaling in mouse models is partially protective against muscle atrophy induced by denervation and other physiologic models of atrophy, pointing to its centrality in mediating atrophy. However, denervation-induced triggers and regulators of these cascades within skeletal muscle remain unclear.
In addition to the functional limitations of muscle weakness caused by chronic denervation, chronically denervated muscle shows severely diminished capacity for functional re-innervation. The molecular changes that underlie this resistance to re-innervation are also unclarified.
To begin to add detail to these important features of the atrophic process, we used RNA-Seq to characterize transcriptional changes occurring in mouse gastrocnemius following tibial nerve transection. We performed a longitudinal analysis capturing transcriptional changes occurring acutely after denervation (1 day post-denervation), early changes during the window of most rapid atrophy (3, 7, and 14 days post-denervation), and changes associated with chronic denervation (30 and 90 days post-denervation).
Our data suggest innate immune system signaling and immunoreceptor-like signaling as potential mediators and/or modifiers of denervation atrophy. Inflammatory signatures are still apparent in chronically denervated and severely atrophied muscle, along with gene expression changes suggestive of increased integrin-mediated focal adhesion and altered chromatin structure. We anticipate that further clarifying the origin and consequences of these transcriptional changes will afford new opportunities to modify the course of atrophic disease.

Title: A personalized gene therapy approach for charcot-marie-tooth disease type 2d

Authors: *K. H. MORELLI[1], K. L. SEBURN[1], N. PYNE[2], A. FOWLER[2], S. Q. HARPER[2], R. W. BURGESS[1]
[1]The Jackson Lab., Bar Harbor, ME; [2]The Res. Inst. at Nationwide Children's Hosp., Columbus, OH

Abstract: Charcot-Marie-Tooth Disease (CMT) is a heterogeneous group of inherited peripheral neuropathies affecting 1:2500 individuals worldwide. To date, fifteen different mutations in *GARS (*glycyl-tRNA synthetase*)* have been identified in patients with autosomal dominant CMT Type 2D (CMT2D). Although the mechanisms through which mutant forms of GARS cause axon degeneration remain controversial, preliminary data from CMT2D patients and mouse models of the disease (*Gars*$^{C201R/+}$ and *Gars*$^{P278KY/+}$) suggest that the expression of mutant GARS may cause toxic gain-of-function effects in peripheral nerves. As such, the selective silencing of mutant *GARS* expression should benefit patients with this disorder. In response, we have developed a gene therapy strategy that reduces the expression of mutant *Gars* transcripts through allele-specific RNAi. To test the proof-of-principle of this approach, we developed self-complementary adeno-associated viral vectors (scAAV9) expressing therapeutic microRNAs engineered to specifically silence the mutant mouse *Gars* allele P278KY (referred to as mi.P278KY). Untreated *Gars*$^{P278KY/+}$ mice show a CMT2D-like neuropathy, including motor dysfunction and axon atrophy. We found that scAAV9-mi.P278KY delivered at birth (pre-disease onset) largely prevented these CMT2D-like phenotypes. We are now testing the ability of scAAV9-mi.P278KY delivered after disease onset to arrest or reverse the CMT2D-like neuropathy. To this end, we have shown that scAAV9-mi.P278KY treatment of adult *Gars*$^{P278KY/+}$ mice increases body weight and improves grip strength. We are now evaluating the ability of our gene therapy to rescue axon and muscle degeneration in adult *Gars*$^{P278KY/+}$ mice. In future, we will test efficacy of patient-specific vectors in “humanized” mouse models carrying

CMT2D-patient-associated mutations in the mouse *Gars* gene. Success with this allele-specific approach would provide a promising avenue for treatment of CMT2D and other dominantly inherited neuromuscular diseases.

Title: The role of D_2 Dopamine receptor in modulating the protective effect of A_{2A} Adenosine receptor in Amyotrophic lateral sclerosis

Authors: *J. LAI[1,2], Y. CHERN[2], Y.-J. LIU[2], H.-L. LAI[2], Y. CHERN[1]
[1]life sciences, Natl. Def. Med. Ctr., Taipei, Taiwan; [2]Academia Sinica/ Inst. of Biomed. Sci., Taipei, Taiwan

Abstract: $A_{2A}R$ is a seven transmembrane protein and couple to Gαs protein that activates cAMP -dependent and -independent pathways upon the stimulation. Dopamine D_2 receptor (D_2R) is also a seven transmembrane protein but couple to Gαi protein that inhibits cAMP dependent signaling and regulates cAMP- independent pathways. It was demonstrated that $A_{2A}R$ forms dimmer and interacts with D_2R in the human and mouse striatum region and several cells lines, such as SHSY5Y and CHO cells. $A_{2A}R$-D_2R complex formation would affect to $A_{2A}R$ or D_2R functions. TAR DNA-binding protein (TDP-43) was detected in the nuclear and regulates transcription and RNA splicing, in normal physiology. In pathological, TDP-43 was found that located in the cytoplasm in several neurodegeneration diseases, such as amyotrophic lateral sclerosis (ALS) and frontotemporal lobar degeneration (FTLD). So far, there is no effective treatment to prevent TDP-43 mislocalization. In our published data indicated that a novel agonist (T1-11 analog) of adenosine $_{2A}$ receptor ($A_{2A}R$) prevented reactive oxygen species (ROS) induced TDP-43 redistribution in a mouse motor neuron cell line (NSC34) and played a neuroprotective role in a TDP-43 transgenic mice. In the following study showed that $A_{2A}R$-D_2R co-expressed on motor neurons of ALS patient's spinal cord tissues and NSC34. $A_{2A}R$-D_2R complex did not modified T1-11binding affinity but diminished downstream signaling cAMP. Activation of D_2R modulated the beneficial effect of $A_{2A}R$, including ROS-induced AMPK-overactivation and TDP-43 distribution in NSC34. Taking together, our study demonstrated that co-activation of $A_{2A}R$-D_2R interrupted the neuroprotection of the $A_{2A}R$ in ALS.

Title: Parkin regulates mitophagic cell death in adult hippocampal neural stem cells following insulin withdrawal

Authors: *H. PARK, K. CHUNG, H.-K. AN, S. JUNG, S.-W. YU
DGIST, Daegu, Korea, Republic of

Abstract: Insulin is a key factor in the hippocampal function, and proliferation of hippocampal neural stem (HCN) cells is dependent on insulin signaling. We have previously demonstrated that adult rat HCN cells undergo autophagic cell death (ACD) following insulin withdrawal despite their intact apoptotic capability. Here, we show that insulin-deprived HCN cells undergo ACD through Parkin-dependent mitophagy. Mitophagy is one of the selective forms of autophagy to maintain healthy mitochondria by degradation of defective or damaged mitochondria in various stress condition. However, excessive mitophagy may also lead to mitophagic cell death. Insulin withdrawal increased the amount of depolarized mitochondria and induced LC3-II translocation from the cytosol to depolarized mitochondria in HCN cells. Interestingly, insulin withdrawal up-regulated both mRNA and protein levels of Parkin in c-Jun-dependent manner. CRISPR/Cas9-mediated knockout of the Parkin gene reduced mitophagy level and ACD. Taken together, these results indicated that Parkin is required for the induction of mitophagic cell death in HCN cells following insulin withdrawal.

Abstract: Reactive oxygen species (ROS) attack several living organs and induce cell death. We revealed that treatment with a low concentration of hydrogen peroxide in cultured cells induced neurite degeneration prior to the cell death. At the regions of degeneration, we found mitochondrial accumulation and mitochondrial-dependent super oxide production. From these results, we think that ROS-derived mitochondrial dysfunction is one reason of the neurite degeneration. However, the detailed mechanism of it has not been elucidated. On the other hand, several kinds of evidence have been demonstrated the relationship between ROS-dependent mitochondrial dysfunction and cell death in neurodegenerative disorders. Furthermore, it is well known that mitochondrial disruption is occuerred in Alzheimer's disease (AD) brain. So, here we compared to the antioxidative protein expressions in isolated mitochondria in mice brains, and used as a sample in this study. Nicotinamide adenine dinucleotide quinone oxideredactase 1 (NQO1) expressions were significantly increased in aged AD mice compared to the age-matched control. Conversely, nicotinamide mononucleotide adenylyltransferase 3 (NMNAT-3) and superoxide dismutase 2 (SOD2) expressions in aged AD mice were significantly decreased compared to the age-matched control. NQO1, 3-nitrotyrosine (3-NT) expressions of control group were significantly increased in normal aged mice. Expressions of nNOS were unchanged of all groups. On the other hand, phosphorylated nNOS expression significantly increased in normal aged-group. These results indicate that changes in antioxidative protein expressions may be involved in neurite degeneration and progression of AD.

Title: Optic nerve metabolic vulnerability in DBA/2J model of glaucoma and potential intervention by ketogenic diet

Authors: *M. HARUN-OR-RASHID, D. M. INMAN
Pharmaceut. Sci., Northeast Ohio Med. Univ., Rootstown, OH

Abstract: Recent evidence supports energy disruption is an early indication of pathology in a wide range of neurodegenerative disease. Reduced ATP production and compound action potentials have been observed in glaucomatous optic nerve (ON), suggesting metabolic dysfunction. These experiments investigated the source of ON metabolic vulnerability and tested whether ketogenic diet can intervene in that vulnerability. We examined energy storage, energy exchange and metabolic control in the ON. DBA/2J (D2) mice that develop glaucoma-related optic neuropathy and age-matched DBA/2J$^{wt\text{-}gpnmb}$ (D2G) control eyes were injected with cholera toxin B (CTB) to assess axon transport status. Mice were grouped by age (3, 6, and 10m); biochemical assays were performed with ON; protein levels were analyzed by WES (Simple western) and immunostaining was performed on ON sections and flat-mount retinas. For the intervention study, 9m old D2 mice were fed with ketogenic and control diets for 8 weeks and analyzed as above. Biochemical analyses showed decreased glycogen, l-lactate, NAD^+ levels and creatine kinase activity in 10m D2 ON compared to 10m D2G, indicating insufficient energy storage and availability in D2 ON. MCT1 and MCT4 transport energy metabolites from glial cells and MCT2 takes up those metabolites into axons. GLUT1 is a glucose transporter specific to glial cells. Significant decreases in MCT1, MCT2, MCT4 and GLUT1 protein levels were observed in 10m D2, which indicate energy transport deficit in ON. We observed robust AMPK activation (phosphorylated-AMPK) in 6m and 10m D2 compared to D2G age groups, indicating high energy demand in the ON. The PGC-1α levels were significantly decreased in 10m D2 compared to 10m D2G, suggesting impaired mitochondrial biogenesis in ON. Feeding of the ketogenic diet enhanced the energy storage in ON by increasing l-lactate, NAD^+ levels and creatine kinase activity. The ketogenic diet significantly improved the energy transport in ON by increasing MCT1 and MCT2 levels, and normalized energy demand as shown by significantly decreased AMPK activation. PGC-1α levels were also significantly increased in the ON of ketogenic mice, suggesting increased mitochondrial biogenesis. CTB transport and RGC numbers were significantly increased in ketogenic mice, demonstrating that the ketogenic diet

prevents axonopathy and retinal ganglion cell loss in glaucoma. Thus, these data conclude that the ON metabolic vulnerability that occurs in glaucoma can be alleviated by the ketogenic diet.

Title: Mitochondria-mediated structural and functional adaptations of neuronal circuits to intermittent bioenergetic challenges

Authors: *M. P. MATTSON, A. CHENG, Y. LIU, K. MAROSI, N. GHENA, R. WAN
Lab. of Neurosciences, NIA Biomedial Res. Ctr., Baltimore, MD

Abstract: Evolution favors individuals whose brains and bodies function optimally when in a food deprived/fasted state (imagine a cougar that has not eaten for a week chasing a rabbit, or our human ancestors hunting with bows and arrows). We have been interrogating the cellular and molecular responses of neuronal circuits in the brain to intermittent fasting (IF) and running, and have elucidated structural and functional adaptations involving reciprocal interactions between neurotrophic factor and neurotransmitter signaling pathways, and mitochondrial biogenic and stress adaptations. The ketone 3-hydroxybutyrate, which is generated from fatty acids during fasting and extended exercise, up-regulates BDNF expression in neurons and, in turn, BDNF induces mitochondrial biogenesis via CREB- and PGC-1alpha pathways. Moreover, mitochondrial biogenesis is necessary for BDNF-induced synaptogenesis, suggesting pivotal roles for mitochondria in exercise- and IF-induced synaptic plasticity. IF and running induce the expression of the mitochondrial protein deacetylase SIRT3, and this enzyme protects neurons against metabolic and excitatory stress. SIRT3-mediated neuronal network adaptations to IF involve upregulation of GABAergic tone which constrains neuronal network activity in the hippocampus and amygdala, and is associated with reduced levels of anxiety and sustained cognitive performance. Interestingly, similar to the sleep quality-enhancing effects of regular exercise in humans, we find that mice adapted to IF exhibit a doubling of the time they spend in slow wave sleep, despite a moderate reduction in overall sleep time. Additional implications for human performance come from our recent data demonstrating that endurance is enhanced in mice when they are maintained on IF during treadmill training (see Moehl K et al., poster).

Finally, our findings suggest that bolstering of mitochondrial stress resistance may be an important mechanism by which IF and running increase resistance of neurons to dysfunction and degeneration in neurological disorders ranging from epilepsy and stroke, to Alzheimer's, Parkinson's and Huntington's diseases (see Ghena N et al. poster). Title: Calcium ionophore induces neurite degeneration in neuroblastoma cells via mitochondrial membrane oxidations

Authors: *K. FUKUI, S. NAKAMURA
Shibaura Inst. Technol., Saitama, Japan

Abstract: Treatment with a low concentration of hydrogen peroxide induced neurite and axonal degeneration prior to the cell death. We also observed cell membrane oxidations, microtubules alterations and inactivation of autophagy. If cell membranes are oxidized by ROS, a large parts of receptors and ion channels may be also damaged. Here, we show the elucidation of the relationship between calcium influx and neurite degeneration in cultured neurons. Before start of study, we optimized calcium ionophore concentration. Treatment with an ionomycin induced neuronal cell death in a concentration- and a time-dependent manner. Treatment with a low concentration of ionomycin induced neurite degeneration, such as induction of beading and shrinkage formation. Co-treatment with Fluo-4AM, we recorded calcium influx after ionomycin treatment using a time-lapse live imaging system. The relative intensities of Fluo-4AM significantly increased in ionomycin-treated cells compared to the controls, rapidly. The relative intensities of MitoSOX also significantly increased in ionomycin-treated cells compared to the controls. However, the time point was different compared to Fluo-4AM assay. Finally, we checked mitochondrial membrane oxidations. Treatment with an ionomycin significantly increased fluorescent emissions of mitochondrial membrane oxidations compared to the controls. These results show that treatment with a low concentration of ionomycin induced neurite degeneration via mitochondrial oxidation, and one reason of its phenomena may be depend on the influx of calcium ion into the intracellular region. Neurite degeneration is well known in a development and a progression of severe neurodegenerative disorders. These phenomena via calcium-related pathway impact on the onset of neurodegenerative disorders.

Title: Mitochondrial functions of 4-nitrophenylphophatase domain and non-neuronal SNAP25-like protein homolog 1 in mouse dorsal root ganglion neurons

Authors: *E. OKUDA-ASHITAKA, E. MATSUOKA, I. OHTSU, Y. YANO
Osaka Inst. of Technol., Osaka, Japan

Abstract: 4-Nitrophenylphosphatase domain and non-neuronal SNAP25-like protein homolog (NIPSNAP) 1 is expressed in the synaptic membrane and the mitochondria. Synaptic NIPSNAP1, which interacts with the neuropeptide nocistatin, has been implicated in the inhibition of tactile pain allodynia. On the other hand, in the mitochondria, NIPSNAP1 presents in the matrix and the inner membrane, and it binds several protein, including amyloid precursor protein, mitochondrial matrix chaperone heat shock protein 60, and the E2 component of mitochondrial branched-chain α-keto acid dehydrogenase enzyme complex. However, the effects of NIPSNAP1 on mitochondrial functions remain unclear. Here, we investigated the involvement of NIPSNAP1 in the mitochondrial functions in the dorsal root ganglion (DRG) neurons prepared from NIPSNAP1-deficient mice.
The cellular ATP content was only slightly increased in the NIPSNAP1-deficient DRG cells, as determined using a luciferase-based luminescence assay. The level of reactive oxygen species (ROS) production, which was determined by dihydroethidium staining, was found to increase approximately 4-fold in NIPSNAP1-deficient cells, which was equivalent to the increase in the wild-type cells treated with a mitochondrial uncoupler, carbonyl cyanide m-chlorophenyl hydrazine (CCCP). The level of LC3-II, an autophagosome-associated form of the protein, was increased in the NIPSNAP1-deficent cells. Furthermore, NIPSNAP1 deficiency induced a significant increase and punctate arrangement of p62, an autophagosome substrate, which localized with the mitochondria. CCCP increased the intensity of this punctate arrangement of p62 and the subsequent colocalization of the mitochondria with lysosomal-associated membrane protein-1, in the wild-type cells, whereas the colocalization with the lysosome disappeared in the NIPSNAP1-deficent cells. These results suggest that NIPSNAP1 is involved in the regulation of ROS production and the autophagy of the mitochondria in DRG neurons.

Autònoma de Barcelona, Bellaterra, Barcelona, Spain; [6]ICREA, Barcelona, Spain

Abstract: Background: Apolipoproteins (ApoE) are cholesterol carriers that in humans exist in three alleles: E2, E3 and E4. ApoE4 is the most important genetic risk factor in late onset Alzheimer´s disease (LOAD)— particularly affecting women—but its pathogenic mechanism remains unclear. The novelty of our approach is: 1) we focus on the pathological actions of *endogenous* ApoE4 in astrocytes, the cells that produce most of ApoE in the brain; and 2) we aim to link mitochondrial dysfunction, a hallmark and biomarker of LOAD, with ApoE4-elicited astrocyte dysfunction. Specifically, a decrease in mitochondrial DNA (mitDNA) contents has been detected in cerebrospinal fluid (CSF) of patients at early stages of LOAD, particularly in ApoE4 carriers (*Podlesniy et al. Annals of Neurology 74:655668, 2013*). The decreased CSF mitDNA suggests alteration of mitochondrial fusion, fission and mitophagy, which are essential to keep mitochondria healthy. We seek to determine whether impaired mitochondrial dynamics in ApoE4 carriers originate in astrocytes. Methods: For proof of concept, we used immortalized astrocytes expressing human ApoE isoforms. Mitochondrion dynamics were assessed by computerized morphometry (Image J), and by measurements of squared displacement (D^2 , Imaris) of mitochondria stained with MitoTracker. Molecules that regulate mitochondrial fusion/fission, kinesis and mitophagy were examined by qPCR and Western blots. ATP and lactate were assessed as bioenergetics markers. Results: As compared to ApoE3 astrocytes, ApoE4 astrocytes showed: 1) defective fission, as evidenced by increased network contents in cells challenged by stimuli that fragment mitochondria such as oligomycin; 2) greater D^2 , suggesting increased motility; 3) reduced ATP and increased lactate production, suggesting

impairment of mitochondrial respiration and activation of compensatory glycolysis, and 4) decreased PARKIN, a protein key to mitophagy; and 5) increased expression of *Miro* mRNA—which encodes for a protein that regulates mitochondrial motility. Conclusions: ApoE4-harboring astrocytes may present hyperfusion and hypermotility associated with impaired energetics and altered mitophagy. Ongoing work is aimed to: 1) understand why ApoE4 impairs mitochondrion dynamics in astrocytes; 2) confirm *in vitro* observations in ApoE4 mouse and human brains, and 3) assess whether the decrease in mitDNA concentration in CSF of LOAD patients correlates with altered contents of proteins related to mitophagy and motility; the overarching goal is to generate an astrocyte-based mitochondrion signature of early LOAD.

Title: Deletion of the mitochondrial protein prohibitin in neurons leads to mitochondrial dysfunction and impaired autophagy

Authors: L. QIAN[1], C. J. ANDERSON[1], G. MANFREDI[1], C. IADECOLA[1], *P. ZHOU[2]
[1]Feil Family Brain and Mind Res. Inst., Weill Cornell Med., New York, NY; [2]Brain and Mind Res. Inst., Weill Med. Coll Cornell Univ., New York, NY

Abstract: Prohibitin (PHB) has recently emerged as a key modulator of mitochondrial function. We have demonstrated that PHB upregulation provides strong neuroprotection in several injury modalities including cerebral ischemia (J. Neurosci., 32:583, 2012, Stroke 45:1131, 2014). However, it remains unclear whether PHB deletion specifically in neurons affects their survival and, if so, through which mechanisms. To address this question we used the cre/-lox system to delete PHB in neuronal cultures. PHB flox/flox neurons were cultured from E16 mouse embryos. At 1 day in vitro (DIV), a cre lentivirus (cre) under a CMV promoter or vector (control) was added to initiate PHB deletion. Cell viability was assessed by morphological criteria and the MTT assay. Mitochondrial membrane potential (TMRM fluorescence imaging), mitochondrial

morphology (MitoDsRed imaging), OPA1 processing (Western blotting), and autophagy (LC3-II and p62) were also analyzed. Cre mediated PHB deletion was complete 3 days after recombination, and PHB protein started decline at 3DIV and was maximal at 7DIV. No changes in cell morphology, MTT and ATP levels were noticed in cre-treated neurons until 9DIV, but at 14DIV all cells were dead. Next, we analyzed mitochondrial function and autophagy in cre cultures at 7 days, when PHB protein is low but cells are still viable. At this time, there was a small but significant mitochondrial membrane potential drop in cre treated cells (836±27 RFI units) compared to controls (971±32, $p<0.05$, n=3). Many of these cells had fragmented mitochondria (cre: 49±8%; controls: 19±5%, $p<0.05$), associated with processing of the long isoform of OPA1, a mitochondrial inner membrane protein involved in fusion and maintaining cristae structure. We then assessed the role of PHB deletion in autophagy. We found that LC3II and p62, well-characterized autophagy markers, are significantly lower in cre-treated cells (normalized protein band intensity LC3II: 4.8±0.3, p62: 1.6±0.1) than in controls (LC3II: 6.3±6, p62: 1.8±0.06, n=6, $p<0.05$), suggesting impaired autophagy. We conclude that PHB is involved in maintaining normal mitochondrial function and neuronal autophagy. Disruption of PHB expression will lead to mitochondrial dysfunction and autophagy impairment, contributing to neurodegeneration.

Abstract: Recruitment and retention of early Alzheimer's patients in clinical trials provide both challenges and opportunities for improvement (Watson, 2012). To expedite recruitment of 24 participants at a single clinical site for NCT02221622 we sought to move past traditional recruitment approaches of physician referrals. We discuss innovative methods to recruit, retain, and budget for an early phase trial in a university setting. Recruitment materials included paper and web-based flyers, social media, health fairs, and radio advertisements (3 local radio stations). All recruitment materials were approved by IRB. Qualified staff with current protected health information compliance certificates conducted phone pre-screens and entered caller information into a secure REDCap database. The Clinical Study Coordinator called potential volunteers for follow-up phone interviews, scheduled screening visits, and maintained communication throughout the trial. Many participants (55%) opted to use taxi transportation that allowed real-time smartphone GPS tracking for both the caregivers and clinicians, improving appointment efficiency and reducing uncertainty. Only reimbursements for transportation and parking costs were afforded in the recruitment process. The trial was conducted at USC and funded by NIH-NIA and ADDF. Of the recruitment materials used, radio advertisements proved most effective in Greater Los Angeles. Radio Station: KUSC (11.8%), KNX (86.3%), KOST (0.0%), Other (2.0%). Self-referral: Yes (45.7%), No (54.3%). Age range: 56-91, mean 71.47 +/-10.19. Previous diagnosis of dementia: Yes (48.8%), No (51.2%). Study Partner available: Yes (92.3%), No (7.7%). Previous MRI: Yes (42.1%), No (42.1%), Maybe (15.8%). Pre-screen results: Pass (31.6%), Fail (17.1%), Declined to participate (17.1%), Called for information only (34.2%). Of those that passed pre-screen inclusion/exclusion criteria, 47% of those screened at clinic were enrolled with acceptable MRI results and MMSE >20. Of those enrolled there was one dropout. We developed an effective recruitment framework to enroll 24 volunteers with early Alzheimer's disease into a double-blind placebo controlled phase-1b study to test the safety of once-per-week intravenous Allopregnanolone, a candidate regenerative therapeutic. The recruitment funnel was most effective through brief radio advertisements followed by prescreening interviews and medical record review to recruit and retain willing volunteers. Our recruitment strategy utilized local radio announcements and convenient ride-share transportation and serves as an innovative model for efficient clinical trial recruitment.

Title: Evaluating sex- and apoe genotype dependent response to allopregnanolone treatment

Authors: *M. K. DESAI[1], R. W. IRWIN[2], M. PRAJAPATI[3], R. D. BRINTON[5,4]
[1]Clin. Pharm. and Pharmaceut. Econ. & Policy, [2]Pharmacol. and Pharmaceut. Sci., [4]Sch. of Pharm., [3]USC, Los Angeles, CA; [5]Ctr. for Innovation in Brain Sci. and Dept. of Pharmacol., Univ. of Arizona, Tucson, AZ

Abstract: Currently there is no therapeutic intervention to prevent, cure or delay the progression of Alzheimer's disease (AD). The ApoE4 allele, present in ~20% of the population, increases the risk for AD but affects women and men differently. While males heterozygous for ApoE4 have hardly any increased risk of AD compared with males that are ApoE4 negative, ApoE4 substantially increases AD risk in females. In the present study, we aimed to compare the efficacy of allopregnanolone (Allo), an neuroregenerative therapeutic, in male and female mice with different ApoE status. ApoE3, ApoE4 and ApoE3/4 mice were subjected to a weekly intramuscular injection of Allo (1.5 mg/mL) at 2 mg/kg dose or saline for 26 weeks starting from 10 months of age. The dose, formulation and duration of treatment were chosen to reflect the Phase 1b/2a clinical trial of Allo, currently in progress (ClinicalTrials.gov ID: NCT02221622). We have completed novel object recognition (NOR) testing on these mice and intend to carry out further analyses using biochemical, metabolomic and next-generation sequencing techniques. Results of the behavior study demonstrate that while Allo benefits both ApoE3 and ApoE4 males and females, Allo-treated ApoE4 mice have much higher discrimination index (DI) scores compared to their ApoE3 counterparts. There were no significant differences in the body weight or food intake between the Allo-treated and control animals. We are currently conducting transcriptomic analyses of the hippocampi from these mice to reveal the underlying mechanisms of Allo-induced neuroregeneration, and their interaction with sex and ApoE background. Plasma-based metabolomics data from mice will be compared to human metabolomics data from participants of the ongoing clinical trial. Characterization of the lipidomic profile in the plasma of these mice will elucidate Allo's role as a modulator of lipid metabolism and AD pathogenesis, considering ApoE4 being responsible for abnormal lipid profile and dysregulated cholesterol metabolism in AD. While its neuroregenerative therapeutic potential has been repeatedly demonstrated, this is the first time Allo is being tested in a targeted genotype, as an ongoing effort to promote precision medicine in AD patients and at-risk populations with different sexes and genetic background. This work was supported by NIA P01AG026572, Alzheimer's Association SAGA-17-419459 and Paul Slavic Trust to RDB.

Title: Development of an iPSC based biomarker strategy to identify neuro-regenerative and mitochondrial responders to Allopregnanolone

Authors: *C. M. SOLINSKY[1], J. A. PARK[4], H. C. CHUI[2], M. BLURTON-JONES[5], J. ICHIDA[2], R. D. BRINTON[6,3]
[1]Clin. Pharm. and Pharmaceut. Econ. & Policy, [3]Sch. of Pharm., [2]USC, Los Angeles, CA; [4]Univ. of California Irvine, Irvine, CA; [5]Neurobio. & Behavior, Univ. of California, Irvine, Irvine, CA; [6]Ctr. for Innovation in Brain Sci. and Departments of Pharmacol. and Neurol., Univ. of Arizona, Tucson, AZ

Abstract: Alzheimer’s disease (AD) is a national and global epidemic with complex pathoetiology including compromised brain metabolic activity and decreased regenerative capacity. Allopregnanolone (Allo) is an investigational neuroregenerative therapeutic, currently in Phase 1b clinical trial for AD (NCT02221622, https://clinicaltrials.gov/ct2/show/NCT02221622?term=NCT02221622&rank=1). In rodent preclinical models, Allo promotes neural stem cell (NSC) proliferation and neural differentiation and improves mitochondrial function. To develop biomarkers to predict regenerative response to Allo, we have initiated proof of concept analyses to determine the impact of Allo on human induced pluripotent stem cells (iPSCs) and iPSC-derived neural cells. T-cells from Allo clinical trial participants were reprogrammed via a non-integrating, non-viral method, to iPSCs. Additional iPSCs were provided by the University of California Irvine Alzheimer’s Disease Research Center (UCI-ADRC) and the Institute for Memory Impairments and Neurological

Disorders. Using dual inhibition of SMAD signaling, iPSCs were differentiated to NSCs. Analyses were conducted to determine the regenerative and bioenergetic effect of Allo on clinical trial participant iPS-derived NSCs. Mitochondrial respiration and regenerative capacity were determined by metabolic analyzer and flow cytometry evaluation of EdU incorporation respectively. Within the cell lines of the first dose cohort of clinical trial participants, after in vitro Allo treatment, 40% had increased NSC proliferation (mean increase 14% versus vehicle) and bioenergetic capacity (mean increase 13% versus vehicle). These participant cell lines have been labeled 'responders', while those that did not have increased NSC proliferation or metabolic capacity are 'non-responders'. These data demonstrate that Allo promotes regeneration and mitochondrial function of iPSC-derived NSCs in a subset of clinical trial participants. In order to translate these in vitro data to clinical relevance, the next step is to analyze the cell data for correlations with the clinical trial cognitive and imaging data as well as single nucleotide polymorphism analysis to identify potential genetic markers of responders versus non-responders. These data form the foundation for developing the first biomarker of regenerative potential in brain to determine and monitor response to allopregnanolone as a regenerative therapeutic.

Title: Pharmacokinetics and safety profile of a single-dose administration of an estrogen receptor β-selective phytoestrogenic formulation (PhytoSERM) in peri and postmenopausal women

Authors: *G. D. HERNANDEZ[1], ***G. D. HERNANDEZ**[1], L. ZHAO[5], Y.-L. CHEN[2], A. FRANKE[6], W. J. MACK[2], L. S. SCHNEIDER[3], R. D. BRINTON[4]
[1]Pharm., [2]Preventive Med., [3]Psychiatry and the Behavioral Sci., [4]Sch. of Pharm., USC, Los Angeles, CA; [5]Sch. of Pharm., Univ. of Kansas, Lawrence, KS; [6]Univ. of Hawaii, Honolulu, HI

Abstract: Background: Of all victims of Alzheimer's disease (AD) 68% are postmenopausal women. Estrogen and hormone replacement therapies (HRT) begun at the time of menopause transition have been associated with reduced risk and delayed onset of AD. However, adverse outcomes of HRT have led to an increasing number of women declining its use but seeking non-pharmaceutical alternatives. The search for a safe approach to promote estrogenic signaling in

the brain, without eliciting adverse effects, has focused on the development of tissue-selective estrogen receptor modulators (SERMs). Selective estrogen receptor-β (ER-β) targeting has been attempted in the development of therapies for a range of conditions including cognitive impairment and menopausal symptoms. PhytoSERM, a preparation of genistein, daidzein, and S-equol, has an 83-fold selective affinity for (ER-β) and may promote neuronal survival and estrogenic mechanisms in the brain without having feminizing activity in the periphery.
Objective: To assess the safety, tolerability and single-dose pharmacokinetics of the phytoSERM formulation in peri- and postmenopausal women.
Methods: Eighteen women aged 45-60 years from a 12-week clinical trial evaluating cognitive performance and vasomotor symptoms were randomly assigned to placebo, 50mg, or 100mg phytoSERM treatment groups. Plasma levels of the 3 parent phytoestrogens and their metabolites were measured before and at 2, 4, 6, 8 and 24 hours after ingestion by isotope dilution HPLC electrospray ionization tandem mass spectrometry.
Results: Plasma concentrations of genistein, daidzein and S-equol peaked at 9, 6 and 4 h, respectively for the 50mg dose, and at 6, 6 and 5 h, respectively for the 100 mg dose. The maximum concentration (C_{max}) and area under the curve (AUC) for the 3 parent compounds were greater in the 100 mg dose group indicating a dose-dependent change in concentration with the phytoSERM treatment. No adverse events were elicited.
Conclusion: The phytoSERM combination was well tolerated, appeared without adverse effects, and exhibited a favorable pharmacokinetic profile. After single oral administration of 50 and 100mg tablets of the phytoSERM formulation, the phytoestrogens genistein, daidzein and S-equol were rapidly absorbed, reached high plasma concentrations, and showed a dose proportional increase in concentration exposures in its pharmacokinetics. The formulation may prove to be advantageous in future clinical trials for several peri- and postmenopausal conditions.

Title: Impact of allopregnanolone on the differentiation of neural stem cell

Authors: *S. CHEN[1,2], J. YAO[2], K. WONG[2], R. D. BRINTON[1,2]
[1]Ctr. for Innovation in Brain Sci. and Dept. of Pharmacol., Univ. of Arizona, Tucson, AZ; [2]Sch. of Pharm., USC, Los Angeles, CA

Abstract: Previous studies demonstrated that the endogenous steroid allopregnanolone promotes proliferation of both human and rodent neural stem cells (NSCs) *in vitro* and *in vivo* in the triple transgenic mouse model of Alzheimer's disease (3xTgAD). In this study, we aimed to investigate the impact of allopregnanolone on neural differentiation. We first assessed the effect of aging and Alzheimer's-associated genotype on the differentiative capacity of adult NSCs from 3xTgAD mice. NSCs from 3-, 6- and 15-month 3xTgAD and non-transgenic mice were cultured and their differentiation capacity was determined. We demonstrated that there is an age- and Alzheimer's gene-dependent decrease in overall NSCs differentiation accompanied by a shift from neuronal to glial differentiation. Allopregnanolone treatment significantly increased the ratio of MAP2-positive-neurons to GFAP-positive-astrocytes in adult mouse NSCs, in consistency with our findings in allopregnanolone-treated embryonic rat NSCs. The *in vivo* efficacy of allopregnanolone to prevent or reverse the loss of neuronal differentiative capacity was investigated in 5-month-old male 3xTgAD mice. Flow cytometry-based analysis indicated that allopregnanolone increased the number of newly generated neurons as indicated by the increase in the number of BrdU positive, and BrdU/NeuN double positive cells. Allopregnanolone also upregulated the expression of neural proliferation marker, PCNA, and the immature neuronal marker, doublecortin, which was further confirmed by immunohistochemistry labeling. In addition, the expression of Olig2, an oligodendrocyte precursor cell marker, was also increased by allopregnanolone treatment, supported by immunohistochemistry analyses where increased distribution of Olig2 positive cells were found in the corpus callosum area in the brain. Interestingly, the increased differentiation in neuronal cell and oligodendrocyte precursor is in parallel with an increase of expression in insulin-like growth factor-1 (IGF-1) and IGF-1 receptor (IGF-1R). To explore the underlying mechanisms of allopregnanolone-induced neural differentiation and the involvement of the insulin/IGF-1 pathway, we are currently investigating the activation and expression of AKT, a key node in IGF-1/IGF-1R signaling cascade. Collectively, these findings suggest that allopregnanolone is a regenerative therapeutic candidate that could be capable to prevent or delay neurogenic deficits associated with Alzheimer's disease.

Title: Zn^{2+}-induced mitochondrial dysfunction: Dependence upon disruption of buffering, synergism with Ca^{2+} and contributions to neuronal injury *In vitro* and *In vivo*

Authors: *S. G. JI[1], Y. V. MEDVEDEVA[2], H. Z. YIN[2], J. H. WEISS[2]
[1]Anat. & Neurobio., [2]Neurol., Univ. of California, Irvine, Irvine, CA

Abstract: Ca^{2+} and Zn^{2+} contribute critically to the induction of acute ischemic neurodegeneration. Zn^{2+} is released at synapses, where it can enter postsynaptic neurons. There are also intracellular Zn^{2+} pools bound to buffering proteins, which can be released during ischemia. Prior studies found Zn^{2+} to potently disrupt mitochondrial function, suggesting that these organelles may be important targets of its effects. Yet key pertinent questions remain.
(1) Quantitative relationship between mitochondrial Zn^{2+} loading and its effects. Most prior studies have used exogenous Zn^{2+} exposures to study the effects of mitochondrial Zn^{2+} accumulation, but the quantitative relationship between cytosolic buffering, mitochondrial Zn^{2+} uptake and dysfunction has been little examined. Using a combination of exogenous Zn^{2+} exposure and graded disruption of intracellular buffering on cultured neurons, we found that while brief 300 µM Zn^{2+}/90 mM K^+ exposures (to trigger entry through voltage gated Ca^{2+} channels [VGCC]), caused modest mitochondrial dysfunction, with disrupted buffering, substantial effects occurred with far lower Zn^{2+} exposures.
(2) Synergy of Zn^{2+} effects with Ca^{2+}. As most studies of Zn^{2+} have been done in Ca^{2+}-free conditions, it is critical to examine how Ca^{2+} impacts the effects of Zn^{2+} on mitochondria to better model its roles in pathophysiologic conditions. We found that while mitochondrial Zn^{2+} uptake through VGCC was attenuated in the presence of Ca^{2+}, its impact on mitochondrial function was significantly increased, suggesting strong synergy between Ca^{2+} and Zn^{2+} despite reduced accumulation.
(3) Mitochondrial calcium uniporter (MCU) and interventions. Zn^{2+} entry through the MCU contributes to its effects. We are presently examining the dependence of these effects upon the MCU, and the ability of interventions delivered after the Zn^{2+} exposure to reverse mitochondrial dysfunction and improve cell survival.
(4) Mitochondrial Zn^{2+} in ischemic neurodegeneration. Using hippocampal slices and *in vivo* rat cardiac arrest models, we have begun examining how mitochondrial accumulation of endogenous Zn^{2+} may contribute to *in vivo* ischemic injury. We found that differential vulnerabilities of CA1 and CA3 hippocampal pyramidal neurons may in part reflect differences in their handling of mitochondrial Zn^{2+}. Furthermore, preliminary *in vivo* studies provide evidence for early mitochondrial Zn^{2+} accumulation in many injured neurons after transient ischemia.
Present studies lend further support to a role of mitochondrial Zn^{2+} accumulation in neurodegeneration; we hope ongoing work will suggest new approaches for therapeutic interventions.

Title: Targeting mitochondrial fission for neuroprotection in peripheral diabetic neuropathy

Authors: *Y. LIU[1], K. FLIPPO[1], R. A. MERRILL[1], M. YOREK[2], G. PERKINS[3], Y. USACHEV[1], S. STRACK[1]
[1]Pharmacol., [2]Intrnl. Med., Univ. of Iowa Carver Col. of Med., Iowa City, IA; [3]Ctr. for Res. in Biol. Systems, UCSD, San Diego, CA

Abstract: Diabetes has become a fully-blown epidemic requiring global attention. WHO reported that 422 million people currently living with the disease and it is estimated to become the 7th leading cause of death in 2045. Presenting with loss of sensation and chronic pain, peripheral diabetic neuropathy (PDN) is a debilitating comorbidity affecting at least 50% of the diabetic patient population. With palliative care being the only option now, there is an urgent need of innovative therapies for PDN. Emerging evidence recently indicated compromised mitochondria structure and function in diabetes without a clear understanding of underlying mechanism. Mitochondria forms highly dynamic networks that constantly undergoing the process of fission and fusion, governed by the dynamin family of large GTPases. Balanced fission and fusion are required for proper function of mitochondria. Interestingly, excessive mitochondrial fission was implicated in many neurodegenerative disorders including Alzheimer's and Huntington's diseases. Therefore, we investigated whether targeting mitochondrial fission can be a potential therapeutic strategy for PDN. Dynamin-related protein 1 (Drp1) is an essential mitochondrial fission enzyme activated by dephosphorylation via two phosphatases including calcineurin and a neuron-specific, mitochondria localized isoform of protein phosphatase 2A containing the Bβ2 regulatory subunit (PP2A/Bβ2). We generated the Bβ2 knock-out (KO) mouse in which we observed elongated mitochondria in neurons as well as reduced high-glucose induced superoxide production in their DRG neurons. Bβ2 deletion increased mitochondrial length and axonal localization, while preventing axonal mitochondrial fission and depletion in sciatic nerve in the STZ model of type-1 diabetes. These animals were shown to be protected from thermal hypoalgesia. Moreover, KO of Bβ2 also provided protection from both thermal and mechanical hypoalgesia as well as impaired nerve conductivity in the db/db mouse model of type-2 diabetes. Taken together, our preliminary data showed that Bβ2 KO animals are resistant to PDN in both type-1 and type-2 diabetes models. Hence, targeting

mitochondrial fission through PP2A/Bβ2 may provide new strategies for the treatment of diabetic neuropathies.

Title: Mediterranean diet and physical activity improve the age dependent decrease in mRNA expression of genes of mitochondrial function in NMRI mice

Authors: *C. V. SILAIDOS, H. ASSEBURG, S. HAGL, G. ECKERT
Nutr. in Prevention and Therapy, Justus-Liebig-University, Giessen, Germany

Abstract: Mitochondrial dysfunction (MD) represents a key factor in brain aging and neurodegenerative diseases (ND) including decreased mitochondrial respiration and ATP levels. Therefore MD is a promising target for nutritional prevention strategies. Recent studies confirm that physical and cognitive activity combined with the Mediterranean diet is associated with a decreased risk for dementia. Therefore this study aimed to investigate effects of a grape seed extract and a natural *Extract* of Olive Mill Waste Water (Group RO) combined with physical activity (group ROEn) on mitochondrial function of aged NMRI mice. Male mice were fed for 6 month comparing mitochondrial function with 3-month old mice (group YC) and to old matched (19-month) control-fed mice (group OC). mRNA expression analysis was conducted using brain tissue focusing on genes playing a role for mitochondrial function and for hormesis. The expression rates were calculated in relation to the young control group (100%). Gene expression analysis of complex I and IV of the respiratory chain revealed a non significant decrease in complex I expression in the aged group and a significant increase in the RO and ROEn group (104,6%;106,9%). The complex IV expression of the OC group was significant lower than in the YC group (69,2%). Through the intervention the expression increased significantly for the RO (90,9%) and for the ROEn (96%) group. Significantly decreased of gene expression of PGC1α, CREB, and Synaptophysin 1 was detected in OC in comparison to the YC group whereas BNDF levels were unchanged. The decreased mRNA expression was reversed in the RO and ROEn intervention groups. An aged-dependent decrease in gene expression was also found for AMPK and for the sirtuines Sirt1 and Sirt3. The RO and the ROEn intervention increased the Sirt3 expression (103% and 98,8%, respectively). The ROEn intervention showed a higher Sirt1 and

AMPK expression compared to the OC group. In conclusion, components of the Mediterranean diet in combination with physical activity appears to be a successful approach to improve or prevent the age dependent decrease in gene expression of genes which are associated with mitochondrial function and hormesis. Title: Purified olive polyphenols improve mitochondrial dysfunction in a cell model of early Alzheimer´s disease

Authors: *R. GREWAL[1], J. VOLK[2], A. SARAFEDDINOV[3], J. ZOTZEL[3], S. MARX[3], J. TRETZEL[3], H. WARZECHA[2], G. ECKERT[1]

Abstract: As components of the Mediterranean diet olive polyphenols may play a crucial rule for the prevention of Alzheimer`s disease (AD). Since, mitochondrial dysfunction plays a major role in both, brain aging and early AD, effects of different highly purified phenolic secoiridoids were tested on mitochondrial function in SH-SY5Y-APP cells - a cellular model of early AD. SH-SY5Y-APP cells were incubated with Hydroxytyrosol, Tyrosol, Oleacein, Oleurosid, Oleuropein and Oleocanthal which were obtained in a novel biotechnological and preparative approach, for 24h, or pre-incubated for 1h and insulted with the complex I - inhibitor Rotenon, for 24h. All tested secoiridoids significantly increased basal ATP levels. For advanced testing the best compounds were selected for high-resolution respirometry using an Oxygraph-2k (Innsbruck, Austria). Oleacein and Oleocanthal (0.05 µM each) showed a significant elevated endogenous mitochondrial respiration. In addition, Oleocanthal lead to an increase in complex l activity, as well as in OXPHOS and ETS respiratory states. To investigate the underlying molecular mechanisms the expression of genes associated with mitochondrial biogenesis, respiration, dynamics, and synaptic plasticity (PGC1α, SIRT, AMPK, CREB, Nrf1, Tfam, complex l, lV and V, Drp1, Mfn1, Opa1) are currently under investigation. So far, the findings have especially identified Oleocanthal as promising olive compound to prevent Alzheimer´s

disease in an early state. (Supported by the German Ministry of Education and Research; BMBF #031A590C)

Title: Effects of long-term treatment with purified olive secoiridoids improve cognition and mitochondrial dysfunction in aged NMRI mice

Authors: *M. REUTZEL[1], R. GREWAL[1], C. SCHAEFER[1], J. VOLK[2], A. SARAFEDDINOV[3], J. ZOTZEL[3], S. MARX[3], J. TRETZEL[3], H. WARZECHA[2,3], G. ECKERT[1]
[1]Inst. Für Ernährung In Prävention Und Therapie, Giessen, Germany; [2]Technische Univ. Darmstadt, Darmstadt, Germany; [3]N-Zyme BioTech GmbH, Darmstadt, Germany

Abstract: As components of the Mediterranean diet olive polyphenols may play a crucial role for the prevention of Alzheimer`s disease (AD). Since, mitochondrial dysfunction plays a major role in both, brain aging and early AD the effects of mixture of highly purified olive secoiridoids (24.7 % hydroxytyrosol, elenolic acid derivates 10.5 %, oleacein 14.6 %, oleuropein 7.2 %, oleuropein aglycone 36.7 %, and oleurosid 6.2 %) were tested on mitochondrial function and behavioral performance in a mouse model of brain aging. Over 6 months female NMRI mice (12 months of age) were fed with the polyphenol-rich extract (13.75 mg/kg b.w.; manufactured by N-Zyme BioTec GmbH, Darmstadt, Germany) or a modified, study diet (C1000; Altromin, Lage, Germany). C1000 fed 3 month old mice served as young control.
Mice were behaviorally tested at the beginning and at the end of the feeding study. After 6 months, ATP-levels were measured in dissociated brain cells (DBC's). In contrast to young mice, aged control mice showed significant reduced willingness to explore new environment in the Y-Maze-test. The dietary supplementation with secoiridoids strongly improved the short-term memory and locomotor activity of aged mice. Even the long-term memory was slightly increased after 6 months of supplementation as elaborated in the Passive Avoidance-test. Secoiridoid-fed mice showed significant increased ATP-level which almost compensated for age related mitochondrial dysfunction. Our results so far show that a high purified polyphenol-rich diet has positive long-term effects on cognition and energy metabolism in the brain. To investigate the underlying molecular mechanisms, the expression of genes associated with

mitochondrial biogenesis, respiration, dynamics, and synaptic plasticity (PGC1α, SIRT, AMPK, CREB, Nrf1, Tfam, complex l, lV and V, Drp1, Mfn1, Opa1) are currently under investigation. (Supported by the German Ministry of Education and Research; BMBF #031A590C)

Title: Molecular composition and regulation of mitochondrial permeability transition pore

Authors: *N. MNATSAKANYAN, H.-A. PARK, J. WU, L. R. CLIFFORD, P. MIRANDA, E. A. JONAS
Dept. of Intrnl. Med., Yale Univ., New Haven, CT

Abstract: The mitochondrial permeability transition (mPT) is the main cell death pathway during neurodegenerative diseases, traumatic brain injury and stroke. The opening of the mitochondrial permeability transition pore (mPTP) occurs during mitochondrial Ca^{+2} overload accompanied by oxidative stress and adenine nucleotide depletion. While the molecular nature and composition of mPTP remain controversial, its regulation and pharmacology have been well studied. We have recently characterized a novel large conductance ion channel located in the membrane-embedded c-ring of F_1F_o ATP synthase, which we suggest, based on its biophysical and pharmacological properties, to form the pore of mPT. We have over-expressed and purified recombinant human c-subunit from different host cells and demonstrated that it forms a voltage-gated channel with ~100 pS average conductance as a subconductance state and up to ~1.5-2 nS peak conductance. The c-subunit is a part of the membrane-embedded F_o subcomplex, which tightly interacts with the soluble F_1 portion of ATP synthase. We have now shown that the stoichiometric ratio between the c-subunit ring and the F_1 subunits is crucial for closing the c-subunit leak channel and for increasing the bioenergetic efficiency of mitochondria. We are currently studying the ATP synthase structure and the conformational re-arrangements necessary for c-subunit gating. We are also investigating the role of the c-subunit leak channel in neuronal death and survival and its regulation by different pharmacological agents. These findings will provide us with increased understanding of the role of mPTP in aging and neurodegeneration.

Title: Exploration of mitochondrial bioenergetics using human iPSC-derived neurons

Authors: K. KIM, N. AOYAMA, K. MANGAN, M. HANCOCK, *C. B. CARLSON
Cell. Dynamics Intl., Madison, WI

Abstract: The advent of induced pluripotent stem cell (iPSC) technology now grants the scientific community access to previously unattainable human cell types, specifically those from the brain. Moreover, iPSC technology enables us to compare cells from apparently healthy normal individuals to those cell types from disease-specific and patient-derived samples. Neurological and neurodegenerative disorders are a global health concern. Many of these disease pathologies are thought to be driven by dysfunctional mitochondria creating an imbalance in cellular bioenergetics. The ability to measure discrete changes in cellular energy and metabolism in a real-time, label-free approach is possible with Seahorse XF technology. We have used this instrument to assess the impact of numerous conditions (ranging from neuronal culture medium, time in culture, cell density, mitochondrial stress agents, and genetic mutations) on the bioenergetics profile human iPSC-derived cell types. Here we focus on development of the methods and protocols to evaluate mitochondrial stress in GABAergic, glutamatergic, dopaminergic, and motor neurons. Additionally, we have tested iPSC-derived astrocytes, macrophages, and skeletal muscle as each of these cell types are possibilities for co-culture to generate more complex and biologically relevant cell models. Finally, establishing baseline assay signals for these various cell types derived from apparently healthy normal donors paves the way for disease modeling. Examples of neurons and astrocytes with the SOD1 G93A mutation will be presented.

Title: Quantifying brain susceptibility to metabolic stress using autofluoresence in mouse brain slices

Authors: *K. STEBBINGS, K. MURPHY, K. ZWONITZER, D. LLANO
Univ. of Illinois At Urbana Champaign, Urbana, IL

Abstract: Taking advantage of the natural auto-fluorescence of the cell's main energy carrying molecules, FAD^{2+} and NADH, we have created methods which can quantitatively assess the sensitivity of brain tissue metabolism to low oxygen (hypoxic) and oxidative stress. The ratio of the imaged fluorescence of oxidized FAD^{2+} to reduced NADH is known as the redox ratio or redox potential and changes characteristically with both types of stress. Slice imaging allows us to test deeper structures than is possible even with advanced in-vivo imaging techniques and can more accurately quantitate the relative sensitivity of different areas of the brain simultaneously. We show here that certain areas seem to be more susceptible to hypoxic stress than others, including the hippocampus and substantia nigra. Areas more sensitive to oxidative stress are less clear, but may preliminarily include midbrain and thalamus. We have also developed a technique to stimulate all areas of the brain simultaneously with glutamate. By imaging the turnover of endogenous ($FADH_2$ to FAD^{2+}) we can fit rates of consumption and regeneration of FAD^{2+} in multiple areas of the brain simultaneously.
Ultimately, for all of these methods, we extract quantitative parameters of redox changes in response to activation, hypoxia or oxidative stress and then display the values of these parameters as a heat map image overlaid on an anatomical image of the brain, such as a coronal section. These images will provide a useful way of understanding, visually, complex parameters of brain metabolism. The quantitative nature of these extracted parameters allows them to be tested statistically. We show which parameters are most altered in aging and therefore which would be most useful in detecting the potential protective effects of a variety of interventions , such as exercise in the form of free wheel running, which may preserve brain health. We also report several other indicators of internal and external health including a calculation of metabolic efficiency in whole animals from the CLAMS system, mDNA mutation load with deep sequencing and hearing loss as assessed by auditory brainstem responses.

Title: The impact of cofilin1 on mitochondrial dynamics and function in neuronal HT22 cells

Authors: *L. HOFFMANN[1], K. REHKLAU[2], J. GROHM[1], M. RUST[2], C. CULMSEE[1]

Abstract: Mitochondria are dynamic organelles which undergo permanent fission and fusion to maintain their functions in energy metabolism, calcium homeostasis and regulation of reactive oxygen species (ROS). Genetic defects affecting mitochondrial fission and fusion mediate Charcot-Marie-Tooth neuropathy, and impaired mitochondrial dynamics were also associated with age-related neurological disorders, such as Parkinson's and Alzheimer's disease [1, 2]. Enhanced oxidative stress is considered as a major consequence of mitochondrial dysfunction, and the resulting oxidative stress is also regarded as a major trigger for neuronal dysfunction and cell death in the ageing brain and in multiple neurodegenerative disorders. How oxidative stress mediates neuronal dysfunction and whether the associated mechanisms are accessible for therapeutic intervention strategies is not clarified. Here, we investigated the role of cofilin1, a key regulator of actin and, thereby, mitochondrial dynamics in models of detrimental oxidative stress induced by erastin or glutamate, which induce cell death through increased mitochondrial ROS production and loss of mitochondrial membrane potential. Cofilin1 knockdown was achieved in neuronal HT22 cells by siRNA. Depletion of cofilin1 resulted in increased fission of the mitochondria, without affecting its function in standard culture conditions. Further, we found evidence that cells with fragmented mitochondria upon cofilin1 depletion showed increased cellular resistance against oxidative stress and cell death in paradigms of glutamate and erastin toxicity. Additionally, these cells preserved an intact mitochondrial membrane potential, unaltered ATP production and decreased mitochondrial ROS level despite glutamate or erastin challenges, indicating that cofilin1 knockdown affected mitochondrial resilience against oxidative stress. In contrast, cofilin1 silencing by siRNA could not prevent lipid peroxidation, supporting that cofilin1 knockout mediated effects at the level of mitochondria and did not interfere with upstream mechanisms of glutamate or erastin toxicity. Our findings suggest an important role of actin dynamics regulating mitochondrial fission and homeostasis in paradigms of oxidative stress. In contrast to pathological mitochondrial fragmentation, actin-regulated mitochondrial fission was not associated with impaired mitochondrial function, but may rather

attenuate ROS-induced mitochondrial damage and associated cell death pathways, thereby providing new therapeutic targets for neurodegenerative diseases.

Title: Induced pluripotent stem cell derived excitatory neurons as a neuropsychologic model of MELAS disease

Authors: T. KLEIN GUNNEWIEK[1], D. CASSIMAN[3], E. MORAVA KOZICZ[5,4], N. NADIF KASRI[2], *T. L. KOZICZ[1,5]
[1]Anat., [2]Human Genet., Radboud Univ. Nijmegen Med. Ctr., Nijmegen, Netherlands; [3]Hepatology, [4]Pediatrics, Uz Leuven, Leuven, Belgium; [5]Pediatrics, Hayward Genet. Ctr., Tulane Univ., New Orleans, LA

Abstract: Most individuals diagnosed with the common mitochondrial phenotype of MELAS carry the pathogenic variant 3243A>G in their mitochondrial DNA (mtDNA). Patients show a broad range of symptoms, involving mainly the skeletal muscle and the central nervous system. The mutation being present in the maternally inherited mtDNA, makes generating a knockdown/knockout animal models problematic. In order to increase our understanding on the neuropathobiology of mt.3243A>G we created human cortical neurons (iNeurons), derived from inducible pluripotent stem cells (IPSCs) and studied the impact of mt.3243A>G on mitochondrial- and neuronal (including synaptic) function. Patient-derived fibroblasts were reprogrammed to IPSCs, which were tested for heteroplasmy by sanger sequencing; three clones from the same patient, with different heteroplasmy levels (0%, 72%, and 83%) were expanded. These IPSC's were differentiated into excitatory iNeurons by lentiviral rtta- and Neurogenin 2 (Ngn2) expression. Here we report on the characterization of the iNeurons both at the single-cell and neuronal network level. We also describe whole-cell patch clamp recordings assessing spontaneous excitatory post-synaptic currents (sEPSC's), as well as intrinsic properties, combined with Mitotracker, MAP2- and Synapsin immunocytochemical staining. Additionally, we report on multi-electrode arrays (MEA's) used to study the effects of the 3245G>G mutation on the network activity of the iNeurons. Our study illustrates the relevance of our patient-specific in vitro neurophysiologic model of mitochondrial involvement, which will enhance our

understanding of the role of mitochondrial dysfunctions in neurological manifestations of MELAS disease.

Abstract: Ginseng has already been proved to exert potential benefits on antitumor activity via its antioxidant properties from other cancer cell lines. In this study, we investigated the potential pharmacological activity of several minor ginsenosides in neuroblastoma cell lines. Among all tested ginsenoside compounds, four minor ginsenosides had strong cytotoxicity and became more effective agents to display the protective effects. As a result, these compounds were significantly increased the apoptosis rate in dose dependent manner which was accompanied by mitochondrial membrane potential (MMP, $\Delta\Psi m$) loss. We found that the expression levels of cleaved caspase 3, cleaved PARP, PUMA and Noxa were upregulated, whereas the expression levels of survivin, Bcl-2, Bcl-xL, MMP-2, MMP-9 protein were down-regulated by treatment of minor ginsenosides. These results suggest that four minor ginsenosides might be promising compounds to have therapeutic effect on neuroblastoma cell lines.

Title: Activation of AMPK affects metabolism of amino acids

Authors: C. M. VOSS, J. V. ANDERSEN, *H. S. WAAGEPETERSEN
Univ. of Copenhagen, Copenhagen, Denmark

Abstract: Astrocytes and neurons rely on continuous supply of energy substrates in order sustain normal brain function. Therefore mechanisms capable of maintaining energy equivalents are required. AMP-activated protein kinase (AMPK) has until now mostly been investigated in the periphery where it has been described as a master metabolic switch. It was shown previously that AMPK is activated by low energy status in peripheral cells and in turn activates catabolic pathways and inhibits anabolic pathways. The amino acids glutamate (glu) and glutamine (gln) are taken up by astrocytes and neurons and may either enter the Krebs cycle or take part in glutamatergic neurotransmission. How AMPK regulates the metabolism of these important amino acids in brain is however, poorly understood. Pharmacological activation of AMPK was accomplished using the AMP-analogue 5-aminoimidazole-4-carboxamide 1-β-D-ribofuranoside (AICAR). To investigate the metabolic impact of AMPK activation in astrocytes and neurons, acutely isolated hippocampal slices from female NMRI mice were prepared. Slices were incubated in aCSF containing glucose (5 mM) and ^{13}C-labeled glu (0.5 mM) or gln (1 mM) in absence or presence of AICAR (2 mM). Krebs cycle metabolism of glu and gln was assessed with high-performance liquid chromatography supplemented with gas chromatography-mass spectrometry. Increased uptake of ^{13}C-labeled gln and increased metabolism in the Krebs cycle as a response to AMPK activation was observed. Using ^{13}C-labeled glu we observed the same tendency, however not statistically significant. The entrance of glu and gln into the Krebs cycle has an anaplerotic function, since the breakdown of the substrates to Krebs cycle metabolites replenishes the intermediary metabolite pool. However, the Krebs cycle cannot function as a carbon reservoir and therefore cataplerotic mechanisms allowing glu and gln derived carbons to leave the cycle exist. Cataplerosis may be exerted by the action of malic enzyme (ME), which plays an important role in the complete oxidation of glu and gln. Pyruvate recycling is a way for the cells to oxidize amino acids completely, where pyruvate formed in the reaction catalyzed by ME reenters the Krebs cycle via pyruvate dehydrogenase. Increased pyruvate recycling was observed upon AMPK activation when ^{13}C-labeled glu and gln were provided as substrates. These results show that amino acid metabolism in the brain is affected by AMPK activation. Astrocytes and neurons seem to increase their uptake and oxidation of glu and gln thereby maximizing their energetic outcome from these substrates when AMPK is activated and may have consequences for glutamatergic neurotransmission.

Title: calcium dyshomeostasis mediates neural developmental abnormalities in SOD2 deficient cortical neurons

Authors: *A. CHENG[1], Q. ZHAO[2], D. LU[2], M. P. MATTSON[2]
[1]Lab. of Neurosciences, NIA Biomedial Res. Ctr., Baltimore, MD; [2]Lab. of Neurosciences, NIA Biomedial Res. Ctr., Baltimore, MD

Abstract: Superoxide dismutases (SODs), including cytosolic and extracellular SODs (SOD1 and SOD3) and mitochondrial SOD (SOD2), are major antioxidant defense enzymes. Germline deletion of SOD2 results neonatal lethality. However, the function of SOD2 in brain development is unknown. We found that brain growth is markedly stunted in $SOD^{-/-}$ mice during the second half of embryonic development. Primary cortical neurons in cultures established from embryonic day 15 $SOD2^{+/+}$ and $SOD2^{-/-}$ mice appear similar during the first 24 hours in culture. During the ensuing two days in culture $SOD2^{-/-}$ neurons in ambient oxygen levels (20%), but not in a reduced oxygen level (3 %), exhibit a profound reduction of neurite outgrowth and subsequently die such that less than 10% of the $SOD2^{-/-}$ neurons remain alive at culture day 5. The mitochondria in $SOD2^{-/-}$ neurons become fragmented and accumulate in cell body well prior to cell death. The structural abnormalities of the mitochondria are associated with reduced levels and phosphorylation (S637) of dynamin related protein 1 (Drp1), a major mitochondrial fission regulating protein, whereas mitochondrial fusion regulating proteins (OPA1 and MFN2) were relatively unaffected. The latter mitochondrial alterations coincide with impaired mitochondrial calcium buffering capacity and an elevation of cytosolic calcium levels. Treatment of $SOD2^{-/-}$ neurons with the Ca^{2+} chelator BAPTA-AM significantly rescues the expression level and phosphorylation of Drp1, as well as neurite outgrowth and cell survival. Collectively, these findings reveal critical roles for SOD2 in maintaining calcium homeostasis in newly generated embryonic cerebral cortical neurons, which is essential for mitochondrial function, neurite outgrowth and cell survival. Abstract: Methylmercury is known as a causal substrate of Minamata disease which is a neurological syndrome, and their symptoms include ataxia, numbness, loss of peripheral vision and damage to hearing and speech. The onset mechanism of Minamata disease, which shows neural degeneration in the specific region including central and peripheral nervous system, has been mainly investigated in the central nervous system; however, the mechanism of neural degeneration in the peripheral nervous system is largely unknown. In the present study, we investigated the molecular mechanism of neural degeneration in the peripheral nervous system using dorsal root ganglion (DRG). Methylmercury chloride solution (2.0 mg/ml) was administrated transgastrically to 9 weeks old Wistar rats at a daily dosage of 6.7 mg/kg/day. The administration cycle, 5 days administration and subsequent 2 days non-administration was used. For immunohistochemistry, the animals were deeply anesthetized by carbon dioxide at 7 or 14 days after first methylmercury administration, and perfused transcardially with PBS followed by 4% PFA. DRG, sensory and motor nerve fibers were prepared from lumber cord (L1-5). For DNA microarray assay, perfusion step was excluded. DRG and nerve fibers were immunostained by neuronal markers (neurofilament, NeuN), myelin marker (MBP), the markers of neuronal subtype in DRG (LDBP, PLXNC1, TrkA, TH). DRG and nerve fibers were unchanged in 7 days sample, however, large number of DRG neurons were degenerated and sensory nerve fiber were disrupted in 14 days sample. Next we prepared non-fixed L1-5 DRG sample from 7 and 14 days after first methylmercury administration for DNA microarray assay. The 1401 and 14858 genes were altered in 7 and 14 days sample compared to control, respectively. The altered genes especially in 7 days were analyzed by The Database for Annotation, Visualization and Integrated Discovery (DAVID) and some key pathways were picked up from the database. Further

investigation is required to clarify the mechanism of neural degeneration in DRG induced by methylmercury and we will show the proceedings at the meeting.

Title: Novel mouse model of GWI optimized for the study of the cholinergic system

Authors: *I. CARRERAS[1], N. AYTAN[2], T. MELLOTT[2], L. CRABTREE[3], B. JENKINS[4], J. K. BLUSZTAJN[2], A. DEDEOGLU[1]
[1]VA Boston Healthcare Syst., Boston, MA; [2]Boston Univ. Sch. of Med., Boston, MA; [3]Exeter Univ., Exeter, United Kingdom; [4]MGH-East, Boston, MA

Abstract: The etiology and pathophysiology of Gulf War Illness (GWI) is poorly understood and treatments are lacking. Three drugs used in the Gulf war have been consistently identified as risk factors for the GWI: pyridostigmine bromide (PB), *N*, *N*-diethyl-*m*-toluamide (DEET), and permethrin (PET). These drugs target the nervous system and, via the inhibition of acetylcholine esterase (AChE), the cholinergic system. Although these drugs are considered safe at the doses prescribed, it has been hypothesized that their combination and the stress encountered during the Gulf war deployment may have contributed collectively and synergistically to generate the GWI. It is a priority to design treatments that could reverse the nervous system and the cholinergic defects caused by exposure to these toxins. Here we report a new mouse model of GWI optimized for the study of the cholinergic system. This GWI model is founded on a previously validated one based on the combined exposure to low and relevant doses of PB (1.3 mg/kg/day), DEET (40 mg/kg/day) and PET (0.13 mg/kg/day) and mild restraint stress. The novelty of the model resides on the use of the $ChAT^{BAC}$-eGFP mouse line that express the green fluorescent protein (GFP) exclusively in cholinergic cells allowing to visualize all cholinergic elements of the peripheral and central nervous system. Three months after exposure, mice exposed to the chemicals and stress exhibited memory impairments and increased anxiety compared to control mice that received vehicle only and no stress. Changes in behavior were accompanied with changes on the level of choline acetyltransferase and GFP in the septum. In the hippocampus we found that exposure affected microglial activation, neurogenesis and the neurotrophin BDNF/TrkB and NGF systems. By in vitro magnetic resonance spectroscopy we found

decreased levels of N-acetyl aspartate and GABA in the hippocampus of exposed mice. Experiments were performed in both male and female mice and we report sex differences that will need further investigation. These results support the cholinesterase-inhibiting drug hypothesis of GWI and offer a new animal model that is advantageous in evaluating the effects of cholinesterase inhibiting drugs on the central and peripheral cholinergic systems and provide a model that could expedite the development of treatments for veterans suffering from GWI.

Title: Investigation the role of TDP-43 oligomers in neurodegenerative diseases

Authors: *T.-Y. WENG, Y.-S. FANG, Y.-R. CHEN
Academia Sicica, Tapiei, Taiwan

Abstract: The TAR DNA binding protein 43 (TDP-43) resides mainly in nucleus and plays important roles in the neurodegenerative diseases, such as amyotrophic lateral sclerosis (ALS) and frontotemporal lobar dementia (FTLD). These neuropathology are characterized by deposition of TDP-43-positive cytoplasmic inclusions. In our previous research, we found that the recombinant full-length TDP-43 can form stable oligomers that are neurotoxic *in vitro* and *in vivo*. Such oligomers are also detected in brains of transgenic TDP-43 mice and FTLD-TDP patients using our specific antibody (TDP-O) against TDP-43 oligomers. We next employ our recombinant TDP-43 and TDP-O as the model to investigate the effect of oligomers may involve. Our preliminary data show that the refolded TDP-43 is a TDP-O positive species, and it is more toxic than the TDP-43 S5D or S5A whose TDP-43 exhibits mutation of serine (379,403,404,409,410) to alanine (S5A) for eliminating phosphorylation or mutation of serine (379,403,404,409,410) to aspartic acid (S5D) for simulating hyperphosphorylation. Also, TDP-O antibody shows the neutralization ability by eliminate the cellular toxicity of the refolded TDP-43 in the cell models. Recently, TDP-43 is found to be located in the mitochondria, therefore, we are also interested whether there are other cellular compartments that TDP-43 oligomers may attend. The subcellular localization of endogenous TDP-43 and exogenous TDP-43 oligomers were examined using immunofluorescence. Future directions will be focused on how the TDP-43

oligomers are formed and the cellular localization of these oligomeric TDP-43, and what are the subsequent consequences and its binding partners.

Title: Adult hippocampal neurogenesis impairment in familial hypercholesterolemia: evidence for a role of the LDL receptor and cholesterol metabolism in adult neural stem cells

Authors: *D. F. ENGEL[1], J. DE OLIVEIRA[3], A. GRZYB[4,5], P. S. BROCARDO[2], G. KEMPERMANN[4,5], A. F. DE BEM[1]
[1]Dept. de Bioquímica, [2]Dept. de Ciências Morfológicas, Univ. Dresden, Dresden, Germany

Abstract: Familial hypercholesterolemia (FH) is a disorder of lipoprotein metabolism caused by genetic abnormalities of the low-density lipoprotein (LDL) receptor. The consequent defective catabolism of LDL results in increased plasma cholesterol levels from early age. Recently, clinical and preclinical studies have demonstrated an association between FH, cognitive and mood impairments and neurodegeneration. Since adult hippocampal neurogenesis is implicated in mood and cognition regulation, we hypothesized that the well described cognitive impairments in $LDLr^{-/-}$ mice, a widely used rodent model of FH, may be related to impairment in hippocampal region-dependent behaviors and reduced neurogenesis. Additionally, to dissociate the effects of hypercholesterolemia and of the LDLr absence, we proceeded LDLr gene

knockdown and isolated LDL treatment in adult dentate gyrus (DG) neural stem cells (aNSCs) in vitro. The DG-dependent metric change behavioral test revealed that the $LDLr^{-/-}$ mice presented impairment in DG-dependent cognitive task, compared to C57BL/6 controls. This was corroborated by a reduction in DG cell proliferation and neurogenesis, as assessed 24 h and 28 days following BrdU injections, respectively. Analysis of aNSCs primary cultures, isolated from the DG of adult C57BL/6 mice, demonstrated that the gene expression of enzymes involved in cholesterol synthesis (HMG-CoA reductase and squalene synthase) and of the LDLr peaks during the proliferation stage of the neurogenic process. On the other hand, the gene expression of LRP1, cholesterol 24-hydroxylase, and sterol 27-hydroxylase is up-regulated during the differentiation stage. In agreement with the observations from the $LDLr^{-/-}$ mice, exposure to both human LDL as well as silencing of the LDLr (LDLr siRNA) reduced cell proliferation and/or neuronal differentiation of aNSCs monolayers. LDL treatment was also associated with an increase in the number of lipid droplets and a down-regulation of mRNA levels of the LDLr and enzymes involved in cholesterol synthesis, whereas LDLr siRNA also reduced LRP1 gene expression. The transcriptome differential expression analysis revealed, mainly, that LDL down-regulated cholesterol metabolism processes. Overall, these data indicated a DG-dependent impairment in spatial processing associated to decreased neurogenesis in an animal model of FH. Furthermore, according to our in vitro study both the high cholesterol levels and the LDLr absence might have a role in this outcome. Those results help to underline the function of the LDL receptor and cholesterol metabolism in adult neural stem cells proliferation and differentiation.

Title: A novel ALS and FTD model mouse expressing cytoplasmic mutant FUS leads neurodegeneration via synaptic disruption

Authors: *G. SHIIHASHI[1], D. ITO[1], I. ARAI[2], Y. KOBAYASHI[4], K. HAYASHI[3], S. OTSUKA[2], K. NAKAJIMA[3], M. YUZAKI[2], S. ITOHARA[4], N. SUZUKI[1]
[1]Neurol., [2]Physiol., [3]Anat., Keio Univ. Sch. of Med., Tokyo, Japan; [4]Lab. for Behavioral Genet., RIKEN Brain Sci. Inst., Saitama, Japan

Abstract: Cytoplasmic FUS aggregate is one of the pathological hallmarks in ALS (amyotrophic lateral sclerosis) and FTD (frontotemporal dementia) brain tissue. A major question is whether neurodegeneration is caused by a toxic gain-of-function of cytoplasmic FUS aggregate or a loss of normal FUS function in the nucleus. Therefore, we generated transgenic (tg) mouse line overexpressing exogenous FUS with nuclear localization signal deletion (ΔNLS-FUS tg) related with juvenile ALS with cognitive dysfunction under the control of a neuron specific-promotor Thy-1. ΔNLS-FUS was expressed in the frontal cortex and hippocampus and led age-dependent neuronal loss. ΔNLS-FUS was localized in the cytoplasm while the endogenous FUS did not change in the expression level, nuclear distribution and function for RNA regulation, indicating no loss-of-function of endogenous FUS in ΔNLS-FUS tg mice. ΔNLS-FUS tg mice showed ALS and FTD phenotypes such as progressive motor deficits, hyperactivity, abnormal social interaction, and memory deficit. Golgi staining and immunohistochemistry of synaptic marker revealed decreased dendritic spine and synaptic density in the frontal cortex and hippocampus of ΔNLS-FUS tg mice before neuronal loss. Whole-cell patch-clamp recording from the frontal cortex also showed decreased excitatory synaptic inputs in ΔNLS-FUS tg mice. These results indicate synaptic deficits in ΔNLS-FUS tg mice. ΔNLS-FUS tg mice showed cytoplasmic FUS aggregates positive for ubiquitin and p62. The signal of FISH (fluorescence in situ hybridization) for poly-A-tails of mRNA was colocalized with the cytoplasmic FUS aggregate while the total mRNA levels were decreased at the dendrites of primary culture neurons expressing ΔNLS-FUS. Puromycin labels the newly synthesized proteins, and its intensity was decreased at the dendrites of the cultured neurons expressing ΔNLS-FUS. Collectively, toxic gain-of-function of cytoplasmic FUS is sufficient to lead ALS and FTD phenotypes. Moreover, cytoplasmic FUS aggregate traps the mRNA and impairs its dendritic transport and translation, which leads neurodegeneration via synaptic disruption.

Title: The effect of CDNF in the Quinolinic acid toxin model of Huntington`s disease

Authors: *P. STEPANOVA[1], R. K. TUOMINEN[2], D. LINDHOLM[3], M. H. VOUTILAINEN[1]
[1]Inst. of Biotech., [2]Div. of Pharmacol. and Pharmacotherapy, [3]Inst. of Biomedicine, Univ. of Helsinki, Helsinki, Finland

Abstract: Huntington`s disease (HD) is an autosomal dominantly inherited progressive neurodegenerative disorder characterized by motor and non-motor symptoms. Neuropathology of HD is described mostly by degeneration of striatal neurons. Protein folding stress at the ER may contribute to HD-related neurodegeneration. The actual causes of ER stress in HD are poorly understood. Currently, no effective treatment for HD is yet available. The clinical trials of drugs that were used in HD mouse models have failed to delay progression of disease in HD patients. Neurotrophic factors (NTFs) protect and repair injured neurons. It has been shown that several NTFs improve the morphological differentiation and increase the survival ability of striatal neurons *in vitro*. Furthermore, many NTFs were applied in the toxin and genetic models of HD. We have discovered a protein and named it Cerebral Dopamine Neurotrophic Factor (CDNF). CDNF is a secreted protein that is a member of a novel conserved NTFs family, protecting and repairing mammalian dopaminergic neurons *in vivo*. CDNF may regulate ER stress and UPR intracellularly, secreting from the cells to extracellular space during ER-stress. We have shown the therapeutic potential of CDNF in rodent and non-human primates models of PD and showed that CDNF is a potent molecule to protect DA neurons and more importantly restore their function. Importantly, CDNF is a stable protein, which diffuses in brain tissue better than any other neurotrophic factor. Our present results strongly suggest that CDNF regulates endoplasmic reticulum (ER) stress and unfolded protein response (UPR). Moreover, CDNF rescues the only ER-stressed or degenerating neurons and does not influence naïve neurons.
This report represents the first positive neuroprotective effects of a single CDNF administration in QA (Quinolinic acid) rat model of HD. Wistar male rats were received a single unilateral intrastriatal QA-injection (225nmol) and in two weeks after lesion CDNF (10 µg) or vehicle were injected into the same site. Motor coordination and muscle strength were improved in the CDNF-treated group. CDNF significantly increased the number of NeuN-positive neurons in the striatum in comparison with control group. CDNF has significantly postponed the appearance of clinical symptoms in a rat model of HD. Therefore, it seems that CDNF is a potential new drug candidate for treating motor, which is related to Huntington`s diseases.

Title: Transcriptomic changes in parvalbumin positive interneurons expressing Cre recombinase

Authors: *X. D'ANGLEMONT DE TASSIGNY, D. ENTERRIA-MORALES, I. LOPEZ-LOPEZ, J. LOPEZ-BARNEO
Inst. de Biomedicina de Sevilla, Sevilla, Spain

Abstract: The use of Cre-lox technology has considerably improved our knowledge in neurobiology. Expressing the bacteriophage-derived, site-specific Cre recombinase in neural cell subsets, allows the conditional deletion, induction or detection of target genes. However, Cre-driver cells may undergo undesired stress that could modify their physiological and metabolic function, and therefore affect the final outcome of a given experiment. In this study, we sought at investigating the transcriptional responses caused by the presence of an active Cre recombinase in the GABAergic interneuron subgroup expressing the Ca^{2+} buffer parvalbumin (PV). For this, we used two reporter mice expressing the red fluorophore tdTomato to capture the PV cells by fluorescence-activated cell sorting (FACS): i) a constitutive *tdTomato* gene inserted in the *Pvalb* locus, and ii) a *PV-Cre-tdTomato* model in which fluorescent cells are Cre-positive. We compared by microarray analysis the transcriptional differences in PV neurons expressing Cre (PV^{Cre}), or not (PV^{wt}), in two anatomically and functionally distinct brain regions: the motor cortex and the dorsal striatum.
Of the 26336 coding and complex genes analyzed, < 4% and < 13% were up- and down-regulated respectively in both PV^{Cre} cortex and striatum. Cortical and striatal PV neurons exhibited a coordinated response to Cre, manifested by a strong up-regulation of genes related to inflammation. This was accompanied by a pronounced decrease in the mRNA expression of ion channels and membrane receptors to GABA, glutamate, serotonin and acetylcholine. These changes differed between cortical and striatal PV neurons as their network, input and function are somewhat different. Gene ontology enrichment analysis also indicated high perturbation of important pathways, such as proteasome degradation, FoxO signaling, HIF-signaling or PI3K-Akt. We have confirmed the microarray differences of selected genes by quantitative RT-PCR, and compared the gene expression in PV neurons versus whole-brain region. Finally, we evaluated the differences observed at the mRNA level of selected proteins (IL1alpha) by ELISA, immunohistochemistry or western blot.
In summary, we provide here a comprehensive transcriptomic analysis showing the adverse effects of Cre expression by PV interneurons, which develop an important inflammation-like response and potential phenotypic changes at the cellular and system levels.

Title: The role of infiltrating myeloid cells in alpha-synuclein neurotoxicity

Authors: *T. N. MALTBIE[1], A. B. WEST[2], A. HARMS[1]
[1]Neurol., Univ. of Alabama At Birmingham, Birmingham, AL; [2]Neurol., UAB, Birmingham, AL

Abstract: Parkinson disease (PD) is a common neurodegenerative movement disorder and results in the loss of dopaminergic neurons in the substantia nigra pars compacta. PD is diagnosed clinically by motor symptoms responsive to dopamine replacement therapies. Pathologically, PD is diagnosed by proteinaceous aggregates called Lewy bodies and neurites in the brain, which consist mainly of the PD-linked protein α-synuclein (α-syn). Analysis of post-mortem tissue in PD demonstrates the accumulation of CD4-postive immune cells from the periphery that infiltrate into susceptible brain tissue. PET-neuroimaging using TSPO ligands shows that inflammation occurs early in PD and does not rescind through the course of disease. However, the contribution of peripherally-derived immune cells in the brain and their impact on neurodegeneration in PD has been difficult to understand. Here, we examine neuroinflammation in the rodent brain after the formation of α-syn inclusions in neurons caused by intra-cranial injections of α-syn fibrils. We find evidence for peripheral immune cell invasion that occurs prior to neurodegeneration. *Ex vivo*, we find that macrophages readily internalize and degrade α-syn fibrils, and in the process, elicit pro-inflammatory responses that may be damaging to nearby neurons. Through correlational observations *in vivo* and mixed immune-cell and primary neuronal cultures *in vitro*, we hope to establish how different inflammatory responses may influence neurodegeneration and the spread of α-syn pathology through the brain.

Title: Effects of neonatal sevoflurane exposure on the plastic changes in the hippocampus

Authors: Y. SATO, *M. MAEKAWA, S. YAMAGUCHI, Y. HORI
Dokkyo Med. Univ. Sch. Med., Tochigi, Japan

Abstract: Sevoflurane, a widely used anesthetic, affect $GABA_A$ receptor-mediated tonic inhibition. Sevoflurane exposure in an early stage of life induces cognitive dysfunction later in life. However, the mechanisms underlying sevoflurane-induced cognitive impairment are still unclear. In the immature brain, dominant NKCC1 expression leads to high $[Cl^-]i$, which induces a depolarizing GABA response. We observed the behavioral effects of bumetanide, a NKCC1 inhibitor, on sevoflurane-induced cognitive impairment. We also observed the effects of neonatal sevoflurane exposure on functional plastic changes in the hippocampal area CA1.
Neonatal mice (3-5 days old) received an intraperitoneal injection of bumetanide or saline. Just after the injection, the mice were exposed to 2.1% sevoflurane in O_2 for 4 hours. These mice were examined with behavioral tests and electrophysiological recording from 49 days old. The water maze consisted of a 1.2 m diameter circular pool with a hidden platform, and the size of the open-field arena was 40 x 40 x 20 cm. We recorded population spikes (PS) in the hippocampal area CA1 before and after tetanus stimulation (25 Hz, 1 s) of the Schaffer collateral-commissural fibers, and the amplitude ratio (PPR) of the second to the first postsynaptic response after paired pulse stimulation (60 ms interval).
Mice exposed to sevoflurane at P3-5 (P4 mice) showed longer escape latency in the water maze test and spent less time in the target quadrant in the probe test, showing less traveling distance and vertical movement in the novel open-field arena as compared to the control mice. The P4 mice with bumetanide pre-injection showed behaviors similar to those of the control mice. The relative amplitude of PS 30 to 60 minutes after tetanus stimulation in P4 mice was comparable to that in control mice. On the other hand, the relative amplitude of PS 0 to 10 minutes after tetanus stimulation in P4 mice was significantly smaller than that of the control mice. The second postsynaptic response after paired pulse stimulation was facilitated in P4 and control mice, and PPR in P4 mice was significantly less than that of the control mice.
Our results suggest that the effects of neonatal sevoflurane exposure on cognitive behaviors depend on the functional NKCC1 expression, and that neonatal sevoflurane exposure results in the impairment of short-term plasticity in the hippocampal area CA1.

Title: FAIM2 stability controls the balance of cell death and survival in adult neural stem cells by regulating autophagy

Authors: *C. J. HONG, H. WOO, H. RYU, B. YEO, K. CHUNG, S. HA, S. JUNG, H.-K. AN, S.-W. YU
Brain and Cognitive Sci., DGIST, Daegu, Korea, Republic of

Abstract: Adult neural stem cells maintain self-renewal capacity and multipotency in the adult brain, thus regulating the output of neurogenesis. Autophagy thought to play a pro-survival role in the cells can kill cells as we have previously shown that autophagic cell death (ACD) is a dominant programmed cell death mode in adult hippocampal neural stem cells subjected to insulin withdrawal in vitro. In postnatal mouse hippocampus, Fas apoptotic inhibitory molecule 2 (FAIM2) gradually increases with age. We found that FAIM2 is expressed in adult hippocampal neural stem cells. Decrease in FAIM2 protein is accompanied by ACD following insulin withdrawal. Prevention of protein synthesis by cyclohexamide showed shorter half-life of FAIM2 in ACD in comparison to that in basal state. Indeed, FAIM2 was post-translationally degraded via autophago-lysosomal pathway. FAIM2 knockdown via siRNA augmented cell death and increased autophagy markers. In summary, our result suggests that FAIM2 protein stability is a critical determinant of neural stem cells' susceptibility to ACD. Our results expand the role of FAIM2, which was previously established as a neuron-specific anti-apoptotic protein, to regulation of autophagy in neural stem cells.

Title: Neuroprotective effects of sodium orthovanadate against oxidative injury in organotypic hippocampal slice culture

Authors: *K. LEE[1], U. KIM[2], B. LEE[2]
[1]Dongseo Univ., Dept. of Dent. Hygiene, Div. of Hlth. S, Busan, Korea, Republic of; [2]Dept. of Physiology,, Yonsei Univ. Col. of Med., SEOUL, Korea, Republic of

Abstract: Oxidative injury leads the neuronal cell death due to increased efflux of the excitatory amino acid neurotransmitter glutamate and consequent activation of its receptors. Sodium orthovanadate (Na3VO4, SOV) competitively inhibits the protein tyrosine phosphatases that affected the intracellular proteins phosphorylation. Thus, the present study was conducted to observe the neuroprotective effects of SOV, a protein tyrosine phosphatases inhibitor, on KA-induced neuronal death in OHSC. In addition, we evaluated electrophysiology and behavior study *in vivo* to observe the function of surviving cells by synaptic plasticity in epileptogenesis after SOV treatment in the KA-induced epilepsy model. Neuronal cell death, as assessed by propidium iodide (PI) uptake, was reduced by SOV treatment (24 and 48 h) compared with KA treatment. In the activation of survival signals, the treatment of SOV appears to increase the amount of phospho-Akt and regulate activation of SOD caused by KA-induced injury. In addition, the SOV were resistant to KA-induced behavioral seizure and significantly reduced the epileptiform discharges from the hippocampal neurons. Thus, SOV blocks the acute effects of KA, thereby leading to its neuroprotective effects. These results suggest that SOV may protect hippocampal neurons against oxidative stress and the survived neurons may functional to synaptic plasticity changes (NRF-2016R1D1A3B2008194).

Title: Intriguing mixed neuropathology in a case of Lewy body disease

Authors: *C. J. HAMMOND[1,2], B. J. BALIN[3,2]
[1]Div. of Res., [2]Ctr. for Chronic Disorders of Aging, [3]Bio-Medical Sci., Philadelphia Col. of Osteo. Med., Philadelphia, PA

Abstract: Objective: To determine the extent of neuropathology found in a case of dementia with Lewy bodies. We obtained the brain from a 78 year old deceased male that had been diagnosed with Lewy body disease by exclusion 9 years prior to death. Symptoms exhibited during the course of disease included those typically described in dementia with Lewy bodies with later onset of parkinsonian changes. Lewy body disease is clinically characterized by the following symptoms: dementia, fluctuation, visual hallucinations, and disturbances in attention and executive function. Neuropathological characterization is noted typically by cytoplasmic Lewy body inclusions in cortical and subcortical neurons with alpha-synuclein being the major protein constituent.
Methods: The brain was formalin-fixed and olfactory bulbs, olfactory tracts, optic nerve, optic chiasm, cortical and subcortical regions were prepared for paraffin embedding. Sections from these regions were stained with Periodic Acid Schiff (PAS) with or without diastase digestion as well as immunolabeled with antibodies for a variety of different proteins and infectious agents (Herpes Simplex Viruses 1 and 2, *Chlamydia* species and *Borrelia burgdorferi*). The various proteins included: tau and ptau, GSK3beta, alpha synuclein, TDP43, Abeta 1-42, GFAP, and beta tubulin.
Results: Remarkably, most regions examined demonstrated mixed neuropathology as reflected by immunolabeling with multiple antibodies and PAS staining. Alpha-synuclein presence was notable in both cytoplasmic Lewy bodies and neurites in numerous areas including the amygdala, and temporal cortex. PAS staining of membrane-bound inclusions was very prominent in both olfactory bulbs and tracts as well as in the optic nerve and chiasm. Diastase treatment demonstrated limited digestion of glycogen found in the PAS-positive inclusions. Limited labeling was also observed for Herpes and *Chlamydia* specifically in olfactory and hippocampal regions.
Conclusions: In this particular case of Lewy body disease, neuropathological inclusions were

prominent consisting of those typically found in this disease such as alpha synuclein, but also Alzheimer's disease and other neurodegenerative processes. Intriguingly, because of the extensive amount of PAS-positive inclusions found throughout the brain, this subject may also have had polyglucosan body disease as a comorbid condition. Immunolabeling for infectious agents was also interesting in this case, although the significance of this labeling is inconclusive.

Title: Operant learning in adult rats is impaired following postnatal GABAa receptor blockade

Authors: *O. J. SURGENT, S. ROBINSON
Psychology, Hamilton Col., Clinton, NY

Abstract: Autism Spectrum Disorder (ASD) is a neurologic disorder often characterized by repetitive behaviors, impairments in social functioning and muted affect. It has been hypothesized that these behavioral manifestations in ASD may be due to atypical sensory perception brought about by an altered framework of neural computation employed by the brain. Neurotypically, perception of sensory stimuli is used to initiate learning which leads to appropriate execution of specific behaviors. Sensory learning is dependent upon a critical balance of excitatory and inhibitory signaling in the brain. Drawing from evidence that suggests that inhibitory (GABAergic) signaling is impaired in ASD, it is likely that this critical balance is shifted and that individuals with the disorder employ an alternative system of neural computation for sensory perception and thus sensory learning. The present study investigated sensory learning in a potential animal model of ASD by inducing GABAergic deficiencies in rats during a critical period of neural development and subsequently testing sensory-based discrimination learning during adulthood. Male rat pups were injected daily with the GABAa receptor antagonist, bicuculline (3 mg/kg), for two weeks and left undisturbed until young adulthood. At approximately 2 months of age the first phase of operant conditioning began. Responses on the left lever were reinforced following presentations of one visual stimulus whereas responses on the right lever were reinforced following presentation of a second, distinct visual stimulus. In the second phase of testing, the two-lever discrimination paradigm was similar with the exception that a third visual stimulus or an auditory stimulus was presented instead of 2 visual stimuli. Rats with GABAergic deficiencies were unable to make stimulus-response associations when stimuli within a pair were of the same modality (i.e., two visual cues), however they were not impaired in the discrimination task when stimuli were different modalities (i.e., a visual stimulus vs. an

auditory stimulus). These results inform the understanding of how disruptions in GABAergic signaling during development may influence sensory decision making in adulthood. Moreover, because animals with GABAergic deficiencies show impairment in sensory learning in some cases but not in others, it can be concluded that sensory learning is itself a spectrum and can be assisted through certain interventions. Results may be generalizable to some members of the ASD population and underscore the need for more specific learning interventions to aid sensory-based decision-making.

Title: LPS-mediated kynurenic acid and neurogranin-NFAT signaling decrease attentive and cognitive function in mice

Authors: K. WININGER[1], A. OLIVEROS[2], J. SENS[3], S. CHOI[2], S. K. ERHARDT[4], *D.-S. CHOI[2]
[1]Neurobio. of Dis., [2]Mol. Pharmacol. and Exptl. Therapeut., Mayo Clin. Col. of Med., Rochester, MN; [3]Neurobio. of Dis., Mayo Clin. Col. of Med., Jacksonville, FL; [4]Karolinska Inst., Stockholm, Sweden

Abstract: Recent studies implicate neuroinflammation in several neurologic and neuropsychiatric disorders including Alzheimer's and schizophrenia and depression. However, the fundamental role it plays in the development of the symptoms is not well understood. Recent discoveries uncover some of the potentially damaging effects of the inflammatory pathways in the brain. The kynurenine pathway is activated by pro-inflammatory cytokines, and kynurenine as well as its metabolite kynurenic acid (KYNA) is increased in these disorders and has been associated with cognitive decline. KYNA is a known non-competitive N-methyl-D-aspartate

(NMDA) receptor antagonist. Given that dysfunctional glutamate signaling is often a correlate of these disorders it is possible that NMDA receptor signaling contributes to the presentation of symptoms. In this study we induce neuroinflammation in C57Bl/6J mice by 2x injections of lipopolysaccharide (LPS) or vehicle (0.83 mg/kg i.p.) 16 hours apart. At 24 hours, mice were either sacrificed and brains were extracted for tissue analysis via western blot, or they underwent behavior (pre-pulse inhibition, rotarod, and pavlovian conditioning). We demonstrate that inducing neuroimflammation through systemic injections of duel-lipopolysaccharide (LPS) impaired stimulus processing during Pavolovian conditioning. These mice concurrently showed increases of N-Methyl-D-Aspartate receptor (NMDAR) antagonist kynurenic acid (KYNA) as well as an increase of NFκB and post-synaptic calmodulin binding protein neurogranin (Nrgn) phosphorylation in medial prefrontal cortex (mPFC) and ventral hippocampus (vHip). This was accompanied by a decreased phosphorylation of calmodulin kinase II (CAMKII) and nuclear factor of activated T-Cells (NFAT).Our results suggest that neuroinflammation, through activation of the KYNA- NMDA-Nrgn pathway, may be associated with attentional processing and cognitive dysfunction. This may provide a novel avenue of investigation for understanding the effects of NMDAR dysregulation in central nervous system (CNS) disorders.

Abstract: The microtubule-associated protein tau becomes abnormally aggregated and hyperphosphorylated in various neurodegenerative diseases, which are collectively referred to as tauopathies. Since tau pathology spreads through anatomically connected neural networks, it has been hypothesized that pathological tau species can be released into the extracellular space and

taken up by neighboring naïve cells to initiate tau seeding and propagation. While exact mechanisms underlying cell-to-cell transmission of pathological tau species still remain elusive, recent evidence has proposed extracellular vesicles (EVs) as one of the potential mechanisms of tau seeding and propagation. In an effort to evaluate the effect of tau-associated EVs (tau-EVs) from different tauopathies on tau seeding in a more sensitive and quantitative manner, we utilized the tau RD P301S FRET biosensor cell line that forms punctae of closely associated tau RD-CFP and tau RD-YFP, resulting in a FRET signal that is indicative of tau seeding activity. We first demonstrated that tau seeding can be induced in this biosensor cell line in a dose-dependent manner following treatment with tau-EVs isolated from brain tissues of a tauopathy mouse model rTg4510, which is in keeping with findings from previous reports. Next, we isolated EV fractions from post-mortem brain tissue samples of Alzheimer's disease (AD) and other tauopathy patients, and found that these EV fractions differentially induced tau seeding *in vitro*. Furthermore, to investigate these observations under physiological conditions, we took advantage of our well-established somatic brain transgenesis technique, injecting a novel AAV2/9-TauFRET2 construct into postnatal day 0 (P0) mouse pups by means of intracerebroventricular (ICV) injection. The whole brain transduction of this construct, followed by the injection of EV fractions isolated from different tauopathies, allows for the quantitative and qualitative analysis of tau seeding activity *in vivo*. Taken together, our data suggest that tau-EVs from various tauopathies can modulate tau seeding in a distinct manner. Future studies aimed at identifying the contents of tau-EVs derived from primary tauopathy brains will further aid the development of tau-EVs as a potential biomarker for AD and associated tauopathies.

Title: The effect of short-duration of the gamma-wave tACS on concentrations of glutamine and glutamate in the dorsolateral prefrontal cortex: An MRS study

Authors: *K. OMATA[1,2], Y. TAKATA[3], S. ITO[4], Y. OUCHI[2]
[1]Natl. Ctr. of Neurol. and Psychiatry, Tokyo, Japan; [2]Hamamatsu Univ. Sch. of Med., Hamamatsu, Japan; [3]Central research laboratory, Hamamatsu photonics K.K., Hamamatsu, Japan; [4]Hamamatsu PET Imaging Center, Hamamatsu Med. Photonics Fndn., Hamamatsu, Japan

Abstract: Purpose: Transcranial alternating current stimulation (tACS) is a noninvasive brain stimulation method with alternating electrical currents applied through electrode pads on the skull at a specific-frequency. Although transcranial direct current stimulation (tDCS) was reported to alter neurotransmitter concentrations such as GABA and glutamate (Glu) measured by magnetic resonance spectroscopy (MRS), the influence of tACS in the concentrations of these chemical substances still remains unclear. Here, we examined the effect of the gamma-wave tACS by measuring the chemical concentrations in the dorsolateral prefrontal cortex (DLPFC) with MRS. Methods: Twenty-four healthy volunteers participated in the tACS-MRS study. Two MRS measurements were conducted before and after the long-duration gamma-wave tACS, and the short-duration one (like a sham stimulation). The tACS delivered an alternating electrical current of 1mA amplitude of gamma frequency (40 Hz) to the brain via 2 electrodes over the bilateral DLPFC. The electrodes were placed on the F3 and F4 by the 10/20 EEG coordinates. In the real stimulation condition, the current with a ramp-up time of 4 s was applied for 10 min. In the short stimulation condition, the current ramped up over 4 s was applied for 20 s. The MEGA-PRESS sequence was used to measure the concentrations of chemical substances, GABA, Glu, Glx, GSH and NAA. LC-model was applied to the analysis of the concentrations of these substances. Results: There was no significant change in chemical concentrations as for the long gamma-wave tACS application, but a significant interaction effect was found in Glx concentration (repeated-ANOVA, $p < 0.017$). The post-hoc analysis showed a significant difference of the Glx concentration between before and after the short-duration application (*t*-test, $p < 0.026$). Discussion: The results showed that the continuous gamma-wave tACS did not alter the cortical chemical conditions significantly unlike the tDCS. Since the tACS generates the cyclic change of electric potentials over the surface of neocortex, this type of cyclic stimulation might keep the chemical concentrations unchanged within the range of the cyclic change. In addition, the two electrodes were symmetrically placed on the both sides of the brain. Hence, an inter-connection effect between the two hemispheres might cancel out significant changes in the chemical states under the tACS. In contrast, there was a significant change of Glx concentration for the short-duration stimulation, suggesting that the small perturbation would affect the chemical state of Glx rather than a typical long application of tACS.

Title: Quantitative proteomic analysis of human trabecular meshwork (hTM) in response to Rho-associated protein kinase ROCK inhibitor

Authors: *S. SHAN[1], T. C. LAM[1], W. D. STAMER[2], C. DO[1], C. TO[1]
[1]Sch. of Optometry, The Hong Kong Polytechnic Univ., HungHom, Hong Kong; [2]Duke Eye Center, Sch. of Med., Duke Univ., Durham, NC

Abstract: Objective: The trabecular meshwork (TM) is a tissue located in the irido-corneal angle of the eye. It plays an important role in regulating intraocular pressure (IOP) by controlling resistance to aqueous humor drainage and dysfunction results in ocular hypertension/glaucoma. Currently, lack of specific drugs that targets the TM is a set-back for effective glaucoma treatment. Recently, Rho-associated coiled coil-forming protein kinase (ROCK) inhibitors are under development as candidates for TM-targeting, IOP-lowering anti-glaucoma drugs. To better understand the underlying biological mechanisms of ROCK inhibitors, differential protein expression profiles of human TM (hTM) cells in response to treatment by Y39983, a ROCK inhibitor, is investigated by discovery based label-free SWATH-MS approach applied by using a high-resolution Quadrupole-time-of-flight (QTOF) instrument. **Methods**: Primary hTM cell cultures from normal donors were incubated with and without 1μM Y39983 for 48 hours. Staining for actin was performed by using fluorescein phalloidin. Differentially expressed proteins with and without Y39983 were also identified and quantified by liquid chromatography tandem mass spectrometry (LC-MS/MS) using SWATH^{TM} technologies. **Results**: Immunocytochemistry data showed that the intensity of actin staining and number of stress fibers was reduced following Y399833 treatment. By LC-MS/MS, a total of 3949 non-reductant hTM proteins were identified (at 1% FDR). Under specific criteria (p value ≤ 0.05, fold change ≥ 1.5 folds and not less than 2 peptide matches per protein) in SWATH data analysis, 20 proteins were regulated in Y39983-treated hTM cells. The molecular functions of these proteins, as deduced by PANTHER gene list analysis, were related to binding, structural molecule and catalytic activities. In addition, by using STRING v.10 online platform, PI3K-Akt signaling pathway, focal adhesion and ECM-receptor interaction were grouped. **Conclusions:** The ROCK inhibitor, Y39983 alters hTM intracellular actin architecture. The majority of the protein changes in response to Y39983 is novel, including GUSB which may facilitate the breakdown of

glycosaminoglycan. This study demonstrated an exhaustive picture of protein changes by ROCK inhibitor on hTM cells, enhancing the understanding of its mechanistic actions as well as developing potential clinical application as an anti-glaucoma agent.

Abstract: 3, 4-methylenedioxymethylamphetamine (MDMA) and Nicotine in take affect several brain centers that has to do with serotonin, dopamine and glutamate transmissions which are used in motor coordination and cognition. We elucidated the effect of chronic injections of MDMA, nicotine and a combined Nicotine-MDMA treatments on motor-cognitive neural functions. In addition, we evaluated the associations between the observed behavioural and neural structural changes induced by these treatments in BALB/c male mice with these two drugs. Sixty (60) young male BALB/c mice weighing 20.5 - 23.5 g were used for this study. The mice were randomly divided into six (6) groups (NIC, MDMA, NIC/ MDMA, NIC + MDMA, MDMA + NIC and Vehicle) of ten (10) mice each; group 1 (NIC) were given 2.0 mg/Kg (s.c.) of nicotine every day for 4 weeks, group 2 (MDMA) were given 2.0 mg/Kg (s.c.) of MDMA twice a week for 4 weeks, group 3 (NIC/MDMA) were given 2.0 mg/Kg (s.c.) of nicotine every day and 2.0 mg/Kg (s.c.) of MDMA twice a week for 4 weeks, group 4 (NIC+MDMA) were given 2.0 mg/Kg (s.c.) of nicotine every day for the 1st 2 weeks follow by 2.0 mg/Kg (s.c.) of MDMA twice a week for the 2nd 2 weeks while group 5 (MDMA+NIC) were given 2.0 mg/Kg (s.c.) of MDMA twice a week for the 1st 2 weeks follow by 2.0 mg/Kg (s.c.) of nicotine every day for the

2nd 2 weeks. The control (group 6) were given 0.2 mL of normal saline (s.c) throughout the 4 weeks. We observed that MDMA caused a decline in motor function, whereas nicotine improved motor function. There was no significant difference in motor coordination/activities for the combined treatment versus the control. Individual treatment with Nicotine and MDMA compact cognitive function and altered dopaminergic, serotonergic and glial activities in prefrontal cortex and dentate gyrus. Also, a combined Nicotine-MDMA treatment also reduced memory activities when compared with the control. This study reviled that Nicotine, MDMA and Nicotine-MDMA treatments significantly reduced memory function and caused structural changes in prefrontal cortex and hippocampus of mice. This study unveiled that MDMA and nicotine induce gliosis and degeneration of neuronal cells of dopaminergic system.

Title: JZ101 deficiency promotes tau pathology

Authors: *F. GAO, ***F. GAO**, J. YANG, J. ZHANG
Peking Union Med. Col., Beijing City, China

Abstract: Microtubule-associated protein Tau (MAPT), a component of the cellular cytoskeleton responsible for microtubule assembly and neuronal stability, is involved in a wide range of neurodegenerative diseases known as Tau pathologies. Here we identified a novel protein named as JZ101, a mitochondrial out membrane protein with great importance in the maintenance of mitochondrial function. We also found a crucial role of JZ101 in the regulation of tau pathologies. The mouse model of forebrains specific depletion of JZ101 demonstrated substantial neurodegeneration accompanying with Tau hyperphosphorylation. The level of AT180 was specifically increased in the forebrains of JZ101 KO mice. However, the levels of phosphorylated AT8 and total tau showed no significant difference between JZ101 KO mice and WT littermates. In conclusion, our findings demonstrate that JZ101 deficiency promotes Tau hyperphosphorylation, and JZ101 might be involved in the pathogenesis of neurodegenerative diseases such as Alzheimer’s disease and Parkinson disease. Our study would also give a new implication for Tau pathologies.

Title: Brain-derived exosomes from dementia with lewy bodies propagate alpha-synuclein pathology

Authors: *J. NGOLAB, I. TRINH, E. ROCKENSTEIN, J. FLORIO, M. TREJO, A. ADAME, E. MASLIAH, R. A. RISSMAN
Dept. of Neurosciences, Univ. of California San Diego, La Jolla, CA

Abstract: Proteins implicated in neurodegenerative diseases such as Alzheimer's Disease (AD) and Dementia with Lewy Bodies (DLB) have been identified in bodily fluids encased in extracellular compartments called exosomes. Whether exosomes found in DLB patients can seed aggregation is not clear. In this study, exosomes were successfully harvested through ultracentrifugation from brain tissue from DLB and AD patients as well as non-diseased brain tissue. Exosomes extracted from brains diagnosed with either AD or DLB contained aggregate-prone proteins identified in brain tissue through immunohistochemistry. Furthermore, non-diseased mouse brains injected with brain-derived exosomes from DLB patient exhibited prominent alpha-synuclein (α-syn) aggregation. As assessed through immunofluorescent double labeling, α-syn aggregation was observed in $MAP2^+$, $Rab5^+$ neurons. Using a neuronal cell line, we also determined intracellular α-syn aggregation mediated by exosomes is dependent on recipient cell endocytosis. Together, these data suggest exosomes from DLB patients are sufficient for seeding and propagating α-syn aggregation *in vivo*.

Title: The neuroretina in multiple system atrophy: Morphological implications of Plp-α-Syn mice

Authors: *K. KAEHLER[1], H. SEITTER[1], A. SANDBICHLER[2], N. STEFANOVA[3], A. KOSCHAK[1]
[1]Dpt. of Pharmacol. and Toxicology, Univ. of Innsbruck, Innsbruck, Austria; [2]Dpt. of Zoology, Univ. of Innsbruck, Innsbruck, Austria; [3]Dep. of Neurol., Innsbruck Med. Univ., Innsbruck, Austria

Abstract: Neurodegenerative diseases like Parkinson's disease (PD) and Multiple System Atrophy (MSA) have been shown to exhibit physiological and morphological neuronal abnormalities. These abnormalities can result from exceeding aggregation of α-synuclein (α-SYN), a 140aa presynaptic protein that exerts toxic function in case of dysregulation. Both PD and MSA are associated with a variety of visual symptoms and a potential role of the retina as a biomarker for progression of Parkinson's disease is recently discussed. We therefore aimed at investigating the underlying mechanisms in homozygous transgenic mice overexpressing human α-SYN under the proteolipid protein (PLP)-promoter (PLP-α-SYN) compared to wild type (WT) animals of two different age groups (two months, one year). By performing immunohistochemical analyses on vertical retinal sections we discovered that distinct α-SYN signal occurred in different retinal cell layers of PLP-α-SYN mice, but not in WT mice. This is remarkable as the PLP promotor driving the α-SYN expression in oligodendrocytes was reported to be inactive in the retina. PLP expression stopped at the optic nerve/retina junction, where we observed a colocalization with α-SYN. Notably one cell type distinctly stained in the inner retina appeared to be rod bipolar cells, an assumption confirmed by PKCα co-staining. Quantitative real-time PCR using specific TaqMan® probes will help to verify the specificity for α-SYN immunoreactivity in rod bipolar cells. Interestingly, immunoreactivity for α-SYN was more distinct in peripheral rod bipolar cells than in central ones. Additional immunohistochemical experiments included the investigation of the glial fibrillary acidic protein (GFAP), a marker for activation of Müller glia that can indicate neuroinflammatory processes, and Iba1, a marker for microglial activation. GFAP-positive fibers spanning the peripheral retina were pronounced in aged animals in WT and even more in PLP-α-SYN. This might reflect also the direction of accumulation human α-Syn in rod bipolar cells, which proceeds in the same way. In preliminary experiments Iba1 expression seemed comparable. Due to the known impairments of the dopaminergic system in α-synucleinopathies we investigated also dopaminergic neurons. Although the cell bodies seemed deformed in PLP-α-SYN animals their number was comparable. Tyrosine-hydroxylase-positive processes however appeared to reach into deeper strata of the inner plexiform layer. Our finding clearly implicated an impairment of retinal neurons in the PLP-α-SYN MSA model, which may also underlie visual deficits reported in MSA patients.

Title: Effects of retigabine on endoplasmic reticulum stress induced by thapsigargin and tunicamycin in PC12 cells; a comparative study

Authors: *S. KARADENIZLI[1,2], D. SAHIN[2], H. KENAR[3], C. YILMAZ OZDOGAN[3,4], N. ATES[2]
[2]Med. Faculty, Dept. of Physiol., [3]Exptl. and Clin. Res. Center, Diabetes and Obesity Res. Lab., [4]1Department of Biology, Grad. Sch. of Natural and Applied Sci., [1]Kocaeli Univ., Kocaeli, Turkey

Abstract: Retigabine (RTG) is an anticonvulsant drug used in the treatment of partial seizures and acts through the activation of M-type current dependent on KCNQ channels. Valporic acid (VPA) enhances GABA B receptor levels and decelerates glutaminergic transmission. Thapsigargin (Tg) is commonly used as an ER (Endoplasmic Reticulum) stress agent conducting calcium depletion by blocking SERCA. Tunicamycin (Tun) blocks N-glycosilation reactions in protein folding process. The aim of this study was to compare effects of RTG and VPA on Ca^{2+} influx and cell death in PC12 cells under ER stress induced by Tg and Tun.
$8x10^4$ cells were seeded per well on poly-L-lysine coated 96-well cell culture plates. The cells were cultured in DMEM supplemented with 5% fetal bovine serum, 5% horse serum and 1% Pen-Strep for three days to obtain confluency. Then the cells were threated with 1% NGF in DMEM for 72 hours to induce differentiation. Following treatment, the media were removed and the cells were incubated with 100 µl 20 mM glucose KRB buffer and 100 µl FLIPR Ca^{2+} assay kit (Molecular Devices) for 2 hours. 25 µM RTG or 10 nM VPA were added and incubated for 20 min prior to measurement of Ca^{2+} influx. Fluorimetric data (n=3) was acquired on the FlexStation3 (Molecular Devices) with an excitation wavelength of 485 nm and an emission wavelength of 525 nm. The FlexStation3 was set to run for 10 min, collecting data at 2.5-second intervals, with stimulation of the cells (1000 nM Tg or 1µg/mL Tun) occurring at 60 s. Cell proliferation (n=4) was measured after 24 hours of ER stress by using WST-1 assay (Roche). One way Anova was used to compare cell viability results.
Tg and Tun treatment decreased cell viability when compared to the control group. Tg dramatically increased cell toxicity and Ca^{2+} influx. Vacoulization and loss of cell adhesion were

observed. RTG and VPA treatment decreased the detrimental effects of Tg and Tun, respectively, on cell viability. Tun enchanced cell toxicity but had no effect on Ca^{2+} influx. Compared to the control group, especially VPA and Tun enhanced cell proliferation when applied together.
The protective effect of VPA against ER stress was known, but the effect of RTG on ER stress is still unclear. According to our results, RTG has protective effects on cell viability and Ca^{2+} influx regulation in ER stress induced by Tg.

Title: Loss of Nlrp3 protects neurons against environmental toxicant exposure *In vitro*

Authors: *F. ANDERSON[1], A. L. YOUNG[3], H. H. YEH[2], M. C. HAVRDA[4]
[1]Dartmouth Col. Geisel Sch. of Med., Hanover, NH; [2]Physiol. and Neurobio., Dartmouth Col. Geisel Sch. of Med., Lebanon, NH; [3]Dartmouth Col., Hanover, NH; [4]Geisel Sch. of Med. at Dartmouth, Lebanon, NH

Abstract: Inflammation has long been associated with age-related neurodegenerative diseases and there is increasing evidence of an environmental component influencing the incidence and progression of brain disorders. In this context, there is a great interest in sterile inflammatory mechanisms triggered by exposure to environmental toxicants, including pesticides, heavy metals, and industrial solvents. The NLRP3 inflammasome complex is an innate immune pro-inflammatory mediator involved in the maturation of pro-inflammatory cytokines that can be activated by non-pathogenic triggers such as oxidative stress and misfolded proteins. NLRP3 has been shown to be upregulated in neurons following cerebral infarction and our laboratory has found evidence of elevated NLRP3 expression in mesencephalic neurons in tissues obtained from Parkinson's disease patients. These data suggest that distressed neurons may operationalize the inflammasomes initiating, or contributing to, the neuroinflammatory state. Our laboratory and others have found activation of the *Nlrp3* inflammasome resulting from exposure to the Parkinson's disease-associated pesticide rotenone and evidence suggesting that abolishing its function may be neuroprotective. Here we screen a panel of environmental neurotoxins to determine if *Nlrp3* is required for neurotoxicity using primary cortical neurons established from

wild type (WT) and *Nlrp3*$^{-/-}$ mice. The effects of *Nlrp3* loss-of-function varied across the different groups of toxicants. *Nlrp3*$^{-/-}$ cultured neurons were resistant to toxicity elicited by high doses of organophosphate and organochloride pesticides including diazinon, chlorpyrifos, and dieldrin as compared with identically treated wild type neurons. The results indicate that inhibition of *Nlrp3* is a rational neuroprotective strategy and suggest that further analysis will identify pathways of interest for understanding the impact of environmental toxicant exposure on the central nervous system.

Abstract: Iron, A-beta, and Tau Colocalization in the Subiculum During Braak Stage Progression in Progressive AD and Cardiovascular Disease Pathologies.

Introduction

Alzheimer's Disease (AD) is associated with several pathological protein aggregates in the brain, particularly in the hippocampus. We have demonstrated that excessive non-heme iron deposits co-localizing with amyloid-beta (Aβ) plaques and hyperphosphorylated tau (HP-Tau) are a hallmark of AD pathology. The goal of this project is to investigate the timing of amyloidosis and taopathy with iron dysregulation through Braak stage progression, and with added presence of cerebrovascular disease (CVD). We hypothesized that in the subiculum of the hippocampus, the relationship between neuropathology and iron dysregulation will be similar between both diseases.

Methods
We histologically processed medial temporal lobe biopsies of 35 subjects and analyzed those classified as Braak stage I-III (3 subjects), IV-V (4 subjects) VI (2 subjects), CVD (1 subject), IV-V+CVD (4 subjects), VI+CVD (5 subjects) and control (3 subjects). We used the DAB-enhanced stains for non-heme iron (Perls'), anti-Aβ-42, anti-Tau and anti-CD68 on 6 micron coronal slices, and scanned followed by visualization using a Leica SCN400 and Leica Digital Image Hub environment, respectively. Images were qualitatively analyzed for the presence of each stain in the EC using 15x-25x magnification.
Results
The subiculum exhibited deposition of (Aβ) plaques and HP-Tau with non-heme iron as early as Braak I-III, and throughout stages IV-V and V. This is similar with CVD and the addition of CVD at any of the Braak stages. Control subjects did not exhibit any pathology.
Conclusions
The subiculum is an important gateway of the entorhinal cortex to hippocampus functional anatomy. Iron dysregulation accompanies amyloidosis and tauopathy in the subiculum at all Braak stages, CVD alone, and CVD with AD, indicating that non-heme iron may play an important role in the early as well as late in the neurodegenerative process.

Abstract: Introduction:
Alzheimer disease (AD) is a neurodegenerative disease leading to dementia that causes problem with memory, cognition and social behavior. Depositions of iron in the brain have been thought to be an important event in the neurodegenerative process, and are associated with beta-amyloid

plaques and tau proteins in AD brains. Iron can catalyze free radical reactions and contribute to oxidative damage as seen in such disease. Hence, MR imaging of such iron deposition was proposed as a biomarker to evaluate the pathogenesis and progression of AD.
Methods:
T2-weighted turbo-spin echo (TSE) MR images acquired at 1, 3, 6 and 9 months of age of transgenic mice producing higher amount of amyloid beta (APP/PS1) or Tau proteins, and age-matched wild types (WT) were analyzed for signal intensity in a hippocampal ROI (region of interest). Sub-cohorts of mice received an oxidative insult and were rescued with Metformin, clioquinol or zinc, all through ad libitum diet. We used a Litz birdcage coil sized specifically for a mouse to acquire the images on a Siemens Trio. Voxel size was small (0.27 x 0.27 x 0.9mm), which allowed 16 averages to achieve adequate SNR. The TR/TE = 8000/115 ms, and flip angle was 150 deg. Images were visualized and analyzed on the Osirix platform. Mean pixel values of a ROI (Area: 2.001 mm^2, W: 1.694 mm H: 1.504 mm P: 5.0 mm) from hippocampus as a ratio of maximum pixel values of the ipsilateral eye were statistically analyzed using a repeated measures one-way ANOVA.
Results:
Eighteen APP/PS1 mice, 18 Tau, and 18 WT mice were imaged and analyzed separately for the effect of time on mean T2 TSE signal. APP/PS1 [$F(3, 21) = 5.410$, $p=0.006$] and Tau [$F(3, 21) = 11.861$, $p<0.001$], but not WT [$F(3, 21) = 0.705$, $p=0.560$] mice showed a significant signal decline with age in the left hippocampus. Likewise, APP/PS1 [$F(3, 21) = 4.720$, $p=0.011$] and Tau [$F(3, 21) = 8.384$, $p=0.001$], but not WT [$F(3, 21) = 0.493$, $p=0.691$] mice showed a significant signal decline with age in the right hippocampus. There was no effect of oxidative insult or diet rescue on T2 TSE signal.
Conclusions:
Expected accumulation of the pathological proteins beta-amyloid and tau in the hippocampus of the respective APP/PS1 and Tau transgenic mice appeared to result in a measurable T2 signal decay compared with that of WT mice. However, the oxidative stress and rescue treatments didn’t affect the outcome. Future studies include histological and Western blot confirmation.

Abstract: Introduction:
Pathological deposition of amyloid-beta (Aβ) plaques followed by neurofibrillary tangles comprised of hyperphosphorylated tau (HP-Tau) in the hippocampus and entorhinal cortex (EC) is a hallmark of Alzheimer's disease (AD). Our working hypothesis is that non-heme iron co-localizes with the Aβ plaques in early Braak stages, but will associate with HP-Tau tangles in later stages. Changes in co-localization of iron with these proteins in the EC across Braak stages is not well-known. In addition, the activation of microglia in relation to the iron response pathology in the EC is not well-characterized. We hypothesize for this experiment that as Braak stages progress, non-heme iron will co-localize with Aβ initially, then additionally with HP-Tau in the EC, and that this progression is concomitant with activation of microglia. We contrasted this with the pathology of frontotemporal dementia with cerebrovascular disease (FTD+CVD) in the EC.
Methods:
We histologically processed medial temporal lobe biopsies of 35 subjects and analyzed those classified as Braak stage I-III (3 subjects), IV-V (4 subjects), VI (2 subjects), FTD+CVD (2 subjects), and control (3 subjects). We used the DAB-enhanced stains for non-heme iron (Perls'), anti-Aβ-42, anti-Tau and anti-CD68 on 6 micron coronal slices, and scanned followed by visualization using a Leica SCN400 and Leica Digital Image Hub environment, respectively. Images were qualitatively analyzed for the presence of each respective stain in the EC using 15x-25x magnification.
Results:
Aβ and HP-Tau were present in the EC as early as Braak I-III, in addition to co-localized non-heme iron and activated microglia. This spatial relationship is also present in Braak IV-V and VI. FTD+CVD subjects exhibited a similar pattern, but in the absence of Aβ plaques.
Conclusions:
Tauopathy associated with non-heme iron deposition and microglial activation are events that occur early in AD and FTD+CVD pathology, but only AD includes Aβ plaque formation. This indicates that iron dysregulation and inflammatory processes are non-specific for these two different neurodegenerative processes, and corroborates the specificity of the formation of Aβ plaques to AD.

Abstract: INTRODUCTION
The buildup of amyloid-beta (Aβ) plaques and tau tangles in the brain, particularly in the hippocampus, is a hallmark of Alzheimer's disease (AD). We previously showed that extracellular non-heme iron deposits co-localize with these aggregates. However, the degree to which this co-localization varies according to the separate architectonic hippocampal areas, and according to Braak I-VI progression, is not well documented. To this end, we compared the CA1 and subiculum hippocampal subfields. We hypothesized that iron co-localization with Aβ precedes tau through advancing AD and will be more pronounced in CA1 compared with the subiculum based on the perforant pathway connectivity.
METHODS
We histologically processed medial temporal lobe biopsies of 35 subjects and analyzed those classified as Braak stage I-III (3 subjects), IV-V (4 subjects) VI (2 subjects), and control (3 subjects). We used the DAB-enhanced stains for non-heme iron (Perls'), anti-Aβ-42, and anti-

Tau on 6 micron coronal slices, and scanned followed by visualization using a Leica SCN400 and Leica Digital Image Hub environment, respectively. Images were qualitatively analyzed for the presence of each respective stain in the EC using 15x-25x magnification.
RESULTS
The subiculum, along with the entorhinal cortex, exhibited co-localization of non-heme iron with (Aβ) plaques first, followed by HP-Tau as early as Braak I-III, and throughout stages IV-V and VI. This pattern was similar in CA1, but lagged behind the pathology progression of the subiculum. By stage VI, none-heme iron co-localizes with HP-Tau more than with Aβ. Control subjects did not exhibit any pathology.
CONCLUSIONS
The subiculum is anatomically adjacent to the entorhinal cortex, but follows CA1 in the perforant pathway. The chronological order of Aβ deposition followed by the formation of HP-Tau tangles, and the concomitant none-heme-iron deposition, however, does not appear to follow this pathway. This suggests that the subiculum and entorhinal cortex should be considered together in the progression of AD pathology.

Title: The change of cell death signaling in the hippocampus of alcoholic human and rat brain following adolescent intermittent ethanol exposure

Authors: ***W. LIU**[1], F. T. CREWS[2]
[1]Bowles Ctr. for Alcohol Studies, Univ. of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Prof Pharmacol & Psychiat, Bowles Ctr. Alcohol, Chapel Hill, NC

Abstract: We previously found that adolescent intermittent ethanol (AIE) exposure decreased neurogenesis, and increased apoptosis of neuronal cells in the hippocampus. Apoptosis can be induced by activation of death receptors, including DR3, Fas, DR4 and DR5 by their individual ligands. To investigate the impact of AIE exposure on cell death signaling pathway in adult rat and human post-mortem alcoholic brain, the protein expressions of cell death cascade were assessed in the granular cell layer (GCL) of the hippocampus using immunohistochemistry

(IHC). For animal brain study, male Wistar rats were exposed with ethanol (5 g/kg, i.g., 2 days on-2 days off, PND25-54). Animals were sacrificed at P95 for brain sectioning and IHC with active caspase-3, death receptor 3 (DR3/TNFRSF25) and TL1A/TNFSF15, the ligand of cell death receptor. For human brain study, the paraffin sections of human post-mortem hippocampus were obtained from the New South Wales Tissue Resource Center at the University of Sydney in Australia. Markers of cell death signaling pathway were assessed in human hippocampus with IHC. We found that AIE exposure remarkably increased DR3+IR (204% of control, $p<0.01$), TL1A+IR (184%, $p<0.01$) and active caspase-3+IR (138%, $p<0.01$) in the GCL of rat brain. These findings prompted the further investigate of death receptor signaling cascade in the human post-mortem alcoholic brain. Our data have indicated that DR3+IR (267 %, $p<0.05$) and TL1A+IR (364%, $p<0.01$) were significantly increased compared to controls in the human post-mortem alcoholic GCL, respectively. The expression of the two pivotal Death Domain (DD), FADD+ (469%, $p<0.05$, Fas-associated DD), pFADD+ (342%, $p<0.01$) and TRADD+IR (414%, $p<0.05$, TNF receptor-associated DD), were also increased. We found that active caspase-8+IR in the GCL of alcoholic brain was significantly increased (292% of control, $p<0.05$) with active caspase-9 showing a trend increase. The two executioner caspases were also increased, active caspase-3+ (356%, $p<0.05$) and caspase-7+IR (385%, $p<0.05$). The expression of DR3, its ligand and active caspase-3 in alcoholic GCL are consistent increase with ethanol exposure in rat brain following AIE. Fas+IR expression did not show any change, but its ligand, FasL+IR expression was remarkably increased in the Alcoholic GLC. Further NFκB p65+ and IL8+IR expression were significantly increased in the Alcoholic GLC. The these data indicate that human post-mortem alcoholic brain and adult rats following AIE exposure show increased expression of DRs, activated caspases and DR signaling proteins in hippocampus. Abstract: The pathophysiological mechanisms underlying neuronal death following a stroke occur through the temporal, concerted dysregulation of many cellular processes. ER calcium is important for many cellular functions, such as protein folding, lipid metabolism, and signaling pathways. Disruption of ER calcium homeostasis has been implicated in multiple neurological diseases, including stroke. We used secreted ER calcium-modulated proteins (SERCaMPs) to monitor ER calcium depletion using in vitro and in vivo models of stroke. Using a previously described Gaussia luciferase (GLuc)-SERCaMP in vitro, we demonstrate here that oxygen and glucose deprivation increased ER calcium depletion and decreased cell viability. Additionally, we developed and screened a series of GLuc-based SERCaMP reporters representing ~80 ER resident proteins. The observed changes in reporters indicate a significant departure of proteins from the ER in response to ischemia-induced ER calcium depletion which we have termed “ER exodosis.” This increase in SERCaMP response was attenuated by treatment with the RyR antagonist dantrolene, which also attenuated ER calcium depletion and increased cell viability. Rats injected with AAV vectors expressing GLuc-SERCaMP in the cortex showed evidence of ER calcium depletion following occlusion of the middle cerebral artery. Furthermore, dantrolene treatment reduced the infarct volume in rats. Collectively, our data supports a model in which ischemic injury causes ER calcium depletion and ER exodosis. These effects can be attenuated by stabilizing ER calcium and preventing loss of ER resident proteins.

Abstract: Deep brain stimulation (DBS) is used to treat drug resistant pathologies such as movement disorders, epilepsy, and pain and is being trialed for managing psychiatric disorders. Unlike movement disorders and epilepsy which are characterized by well-defined symptoms, psychiatric disorders have heterogeneous presentations with overlappting functional deficits across disorders. Cognitive rigidity and impaired top-down control are found across anxiety and mood disorders. A DBS paradigm that directly improved cognitive flexibility might effectively treat multiple disorders.Cognitive flexibility includes the ability to rapidly shift attention and behavioral strategies in response to changes in the environment. We assessed flexibility with a Multi-Source Interference Task (MSIT). MSIT requires subjects to identify which of three stimuli (numbers) is different than its neighbors. In Interference (I) trials, the number is out of position and is flanked by valid-target distractors. Patients undergoing invasive monitoring for epilepsy surgery performed the MSIT over several blocks of trials. Short trains of dorsal and ventral striatal stimulation at 130 Hz, 6 mA were delivered during a pseudo-randomized 50% of trials. We found a significant effect ($p<0.01$, multivariate regression) of right dorsal striatal stimulation in improving cognitive flexibility in all 6 patients who received right dorsal striatal stimulation. In 5/6 patients, left dorsal striatal stimulation had a similar effect. On a group level, left dorsal, left ventral and right dorsal had a significant effect on improving cognitive flexibility, while right ventral stimulation did not. We calculated a Spearman's correlation coefficient between the cognitive flexibility state (estimated from reaction time) and High Gamma Power (HGP, 65-200 Hz) in dACC during the first 0.5 seconds after image onset. In 4/6 patients, HGP in left and right dACC channels correlated with behavioral flexibility. These were also the same patients who had a significant improvement in flexibility with stimulation. The two patients that showed a negative correlation between dACC HGP and behavior were unaffected by striatal stimulation. From initial analysis, we conclude that dorsal striatal stimulation improves cognitive flexibility by modulating neural firing (reflected in HGP) in the dACC. This feature can be used to design closed loop stimulation strategies for improving cognitive flexibility in patients with mood and anxiety disorders.

Title: Recovery of cortical delta band functional connectivity after focal ischemia

Authors: *Z. P. ROSENTHAL[1], J.-M. LEE[2]
[1]Write A Reply..., Saint Louis, MO; [2]Washington Univ. in St Louis Sch. of Med., St. Louis, MO

Abstract: Stroke, a leading cause of disability, has a $34 billion economic burden annually. Recovery from stroke, though often limited, is associated with repair of microcircuits in peri-infarct tissue (termed remapping), as well as re-establishing functional connectivity (fc) with larger brain networks. Prior studies have examined these changes in network connectivity using hemodynamic signals (e.g. BOLD fMRI), which are limited to slow activity (<0.5Hz) and may be contaminated by neurovascular uncoupling. In this study, we use a fluorescent calcium-based indicator (GCaMP) to circumvent these shortcomings by directly reporting on neuronal activity, and reveal distinct changes in delta band (0.5-4 Hz) connectivity in a mouse model of stroke. Sixteen male *Thy1*-GCaMP6f transgenic mice underwent photothrombosis of the forepaw sensory cortex ($S1_{FP}$). Cortical neuroimaging was performed serially, before and after photothrombosis. At each time point, we measured awake spontaneous GCaMP activity, as well as evoked responses to forepaw electrical stimulation to track remapping of the $S1_{FP}$ cortex. Resting state activity was analyzed for pixel-by-pixel correlations (fc matrices), maps of fc with key seed regions, and similarity between correlation maps over time. At baseline, we observe focal activation of the left $S1_{FP}$ during right forepaw stimulation; activity at rest shows strong local ipsilateral and homotopic (contralateral) fc. One week after stroke, evoked maps reveal a greatly attenuated $S1_{FP}$ map, which remaps posterior to the infarct by week 4. Likewise, fc maps at week 1 show weakened homotopic connectivity, primarily around the infarct, with recovery of an fc structure similar to baseline by week 4. These results suggest that recovery after stroke is associated with both remapping of $S1_{FP}$ and reintegration of remapped regions into global delta band fc networks. This study will lay the foundation for future work on the molecular and cellular mechanisms underlying network plasticity, which may enable targeted therapy to enhance stroke recovery.

Title: Whole-brain indirect structural connectivity detects loss of cerebellar connectivity after stroke

Authors: ***M. R. SOTELO**[1], B. D. SCHMIT[2]
[1]Biomed. Engin., Marquette Univ., Milwaukee, WI; [2]Dept. of Biomed. Engin., Marquette Univ. Dept. of Biomed. Engin., Milwaukee, WI

Abstract: Introduction: The impact of a stroke on overall brain connectivity depends on lesion disruption of structural connections in the brain. This structural connectivity has been characterized using diffusion tensor imaging to model white matter integrity; however, these techniques do not take into account whole-brain connectivity. We have developed a novel approach to objectively analyze whole-brain structural connectivity to identify global effects of stroke and uncover underlying mechanisms influencing functional outcome.
Methods: Diffusion MRI scans were obtained using the qball-HARDI, 2mm, 150 directions protocol (b-value=1500 s/mm^2). FMRIB Software Library (FSL) was used for processing the images. Cortical and subcortical regions were segmented from the MNI template using Freesurfer, and cerebellar segmentation was obtained from FSL, resulting in 114 nodes in the brain. Probabilistic tractography using the ball-and-sticks model was performed, and weighted-undirected networks were binarized at sparsity levels from 1-10% of the maximum connectivity. The voxel-wise indirect structural connectivity (VISC) algorithm[1] was implemented on a regional level in MATLAB. A Student's T-test was used to compare the chronic stroke group (n=11) with the control group (n=8). Separately, a percent difference threshold (10%) identified regions with reduced VISC in each subject. At each sparsity level, these regions were group-averaged to show the median for the group.
Results: Structural connectivity identified using this regional application of the VISC metric indicated significantly lower structural connectivity in the cerebellum, pons, and the thalamus in the stroke group. The matrix sparsity had an effect on identifying regions with reduced VISC, showing the importance of using a range of sparsity levels in connectivity matrix analyses. In an individual case, a left basal ganglia and brain stem lesion resulted in lower VISC in the contralesional thalamus and cerebellum. A left cerebellar lesion resulted in reduced VISC in the contralesional cerebellar and on both hemispheric basal ganglia. The median reduction in VISC at the 1% sparsity level showed reduced VISC in the vermis and ipsilesional cerebellum not found in the control group.
Conclusion: Indirect structural connectivity indicated reduced connectivity to cerebellar regions after stroke, suggesting its role in functional outcome.

Abstract: Compared to motor recovery, we know little about sensory recovery after stroke. Recent findings indicate that motor and proprioceptive deficits in the arm recover at different rates after stroke. This has implications for developing targeted treatments. Motor and sensory brain areas are highly connected; however, we query whether anatomical distinctions underlie the differences observed in motor and proprioceptive recovery. Motor and proprioceptive performance was assessed at 26 weeks in 140 subjects after stroke with a KINARM exoskeleton robot. Motor performance was measured with an 8-target centre-out reaching task (Visually Guided Reaching, VGR). Proprioception was assessed with 2 mirror-matching tasks conducted without vision. Position Matching (PM) assesses static limb position sense and Kinesthesia (KIN) assesses limb movement sense. Each task yields a composite task score and several parameter scores that measure speed and spatial errors. Normative control ranges based on 231 healthy subjects were used to determine impairment. Statistical region of interest (sROI) analyses compared motor and sensory performance with stroke lesion location across 150 brain regions using a general linear model. Task Score Maps: Preliminary results revealed that damage to the corticospinal tract (CST) and Heschl's gyrus was associated with poor Task Scores for VGR, PM and KIN. Damage to the postcentral, supramarginal, inferior parietal gyri and arcuate fasciculus was associated with poor Task Scores for PM and KIN. Parameter Score Maps: Unique lesion locations were associated with parameter scores for VGR (Heschl's gyrus and CST lesions were associated with initial direction error; putamen, caudate and CST were associated with poor movement time). For PM, lesions in the Rolandic operculum and insula were associated with poor variability while lesions in the superior parietal lobe and CST were associated with poor perception of workspace area. For KIN, cortical lesions (Heschl's, postcentral, supramarginal, inferior and superior parietal gyri) were primarily associated with poor initial direction error whereas white matter regions (e.g. arcuate fasciculus, optic radiations, CST) were associated with poor response latency scores. Overall, sROI detected differences in brain regions associated with poor motor compared to poor proprioceptive performance. Parameter scores identified more distinct lesion/behaviour relationships. These findings add to evidence that motor and proprioceptive function after stroke are dissociable. Further, these findings may be of use in developing targeted treatments for specific impairments after stroke.

Title: Efficacy of resting-state biomarkers versus behavioral measures in discriminating hemispatial neglect in stroke patients

Authors: *E. PIRONDINI[1], N. ZINGER[2], L. Y. DEOUELL[3], D. VAN DE VILLE[1]
[1]Med. Image Processing Lab., Univ. of Geneva, Geneva, Switzerland; [2]Dept. of Psychology, The Hebrew Univ. of Jerusalem, Edmond and Lily Safra Ctr. for brain sciences (ELSC), Jerusalem, Israel; [3]The Hebrew Univ. of Jerusalem, Jerusalem, Israel

Abstract: Hemispatial neglect is a highly heterogeneous perceptual disorder that often follows stroke, especially after right hemisphere lesion. Its most typical characteristic is failure to report or respond to visual, somatosensory, and auditory stimuli presented in the contralesional space. Standard clinical evaluations include “pencil-and-paper” (PnP) tests that consist in drawing and cancelation tasks. Recent studies showed that computer-based assessments have several advantages over PnP tests offering a major methodological improvement in studies of neglect rehabilitation. While computer-assisted measurements reduce the chances for ceiling effects and allow evaluating performance changes through repeated assessments, combination of classical approaches to brain recordings might increase the sensitivity of clinical tests. An increasing number of studies showed that spontaneous brain activity could be of great clinical value potentially providing novel, rich, and sensitive biomarkers to delineate neurological disorders and responses to treatment. In particular, electroencephalography (EEG) recordings are safe, inexpensive, and accessible in complex medical settings and they could, thus, be ideal for biomarkers definition.
Here we aimed at comparing the sensitivity of spontaneous brain activity measured at rest with EEG to a computerized task in discriminating unilateral neglect. As computer-based task, we used the Starry Night Test (SNT), which presented a higher sensitivity than Behavioral Inattention Test at the individual level. Twenty patients between 1 and 3 months post-stroke and 6 healthy control subjects were enrolled in the study. Lesion location was confirmed by Computer Tomography images. EEG activity during resting-state (RS) was recorded before the SNT task. In order to assess the reproducibility of these tests, SNT and RS were repeated

multiple times per day in two different days. Spontaneous alpha and beta oscillations resulted in a higher accuracy (overall accuracy average ± std over days and sessions: 0.88 ± 0.03) in discriminating patients and healthy subjects as compared to reaction time measures from the SNT test (overall accuracy: 0.73 ± 0.03). Moreover, cortical oscillatory activity recorded at rest predicts behavioral deficits in the SNT task.
In conclusion, this data suggests that evaluation of resting-state brain recordings could benefit the evaluations of unilateral neglect beyond traditional PnP and computerized tests. Moreover, resting-state EEG has the potential to provide an index of the dynamics of spontaneous recovery and effects of rehabilitation interventions.

Title: Corpus callosum anatomy in chronic stroke, revealed through structural segmentation

Authors: *J. K. FERRIS, K. S. HAYWARD, J. L. NEVA, L. A. BOYD
Physical Therapy, Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Introduction: The corpus callosum (CC) is the principle neural structure mediating interhemispheric interactions. The CC can be subdivided into segments, containing tracts from distinct cortical regions. Previous anatomical subdivisions of the CC have divided this structure into five to ten sections by manual segmentation. However, these divisions do not reflect individual functional or anatomical differences in the CC. After stroke resulting in motor impairment, there is evidence that both descending motor pathways and interhemispheric connections are impacted. Yet, previous studies of individuals with chronic stroke relied on division of the CC into fixed segments, which may underestimate variability in individual anatomy. Here, we use probabilistic tractography to subdivide the CC on the basis of connectivity with cortical targets, in order to determine how CC anatomy is altered in individuals with chronic stroke
Methods: Four groups of individuals (healthy younger adults, healthy older adults, individuals with chronic stroke with mild upper-limb impairment, chronic stroke with severe upper-limb impairment) underwent T1-weighted anatomical, and 60-gradient high-angular resolution diffusion imaging (HARDI) scans on a 3.0T Philips Achieva scanner. MRI analyses were carried

out by tools from FSL and Freesurfer. Bilateral masks of the following cortical targets are being acquired: precentral gyrus, postcentral gyrus, premotor cortex, prefrontal cortex and parietal cortex. Probabilistic tractography will be performed to define connectivity between cortical targets and corpus callosum. The number of voxels within the CC with ≥ 95% probability of connectivity to each cortical target will be calculated. To determine if the number of voxels per CC segment differed between groups, we plan to perform a one-way analysis of variance (ANOVA), with Group as a between subject factor. ANOVAs will be performed separately for each cortical target. To explore the functional relevance of the identified CC segments, fractional anisotropy (FA) of cortical tracts will be related to motor function (Wolf Motor Function Task) and impairment (Fugl-Meyer) using Spearman's correlation coefficients.
Results: Results of the planned analyses will be presented at the 2017 SFN meeting
Conclusions: This analysis will show whether an anatomically determined segmentation of corpus callosum projections is impacted differently by stroke. Our work will reveal nuanced neuroanatomical changes after stroke resulting in mild or severe upper limb impairment, and stands to increase our understanding of how corpus callosum integrity relates to motor outcomes after stroke.

Title: Investigating the role of contralesional cortex activation in post-stroke recovery

Authors: *M. ITO, M. Y. CHENG, D. L. SMERIN, S. L. LEVY, T. C. CHIANG, G. K. STEINBERG
Dept. of Neurosurgery, Stanford Univ., Stanford, CA

Abstract: Background: Functional neuroimaging studies have reported increased activation in the contralesional primary motor cortex (cM1) in both experimental and clinical settings of stroke. However, the cM1 activation with cellular resolution and its role in post-stroke recovery is unclear. In this study, we characterized the time course of active neuronal network after experimental stroke in mice by immunostaining with neuronal activity-dependent markers. Furthermore, we investigated the role of cM1 activation in post-stroke recovery using the chemogenetic inhibitory DREADD system. Methods: Adult male C57Bl6 mice (6-7 weeks) were subjected to stereotaxic injection of AAV-CamKIIa-hM4D-mCherry into the cM1. After 4-5

weeks, ischemic stroke was induced by transient MCAO. For the time course study, mice were sacrificed at post-stroke days (PD) 3, 5, 14 and 28 (n=5, 4, 5 and 3, respectively). Brains were processed for immunostaining using pCREB antibody (neuronal activity-dependent marker). In another cohort, stroke mice received either clozapine-N-oxide (CNO) or saline (SAL) intraperitoneally from PD 5-14. Functional recovery was evaluated using the rotating beam test at pre-stroke baseline and PD 4, 7, 10, and 14. All mice were sacrificed at PD15 for histology. All mice analyzed in this study showed comparable cortico-striatal infarct in the left hemisphere and hM4D-mCherry expression in cM1. Results: After stroke, pCREB was predominantly expressed in cM1 when compared to ipsilesional M1 (iM1). The expression of pCREB in cM1 was observed as early as PD3 and gradually increased at PD5 and 14, indicating interhemispheric imbalance of cellular cortical activity after stroke. Neuronal silencing of cM1 via the inhibitory DREADD (CNO-treated mice) showed a trend of maladaptive effect on functional recovery after stroke when compared to control group (CNO n=5, SAL n=4, P=0.3 (treatment*time), two-way repeated measure ANOVA of speed). Immunohistological staining with pCREB at PD15 showed that CNO-treated mice exhibited reduced cellular activity in cM1, indicating the silencing effect of the hM4D. Conclusions: Our results showed that basal cM1 neuronal activity increased after stroke and interhemispheric cortical imbalance persisted until at least PD14. Chemogenetic inhibition of cM1 during PD5-14 exacerbated recovery, suggesting that early cM1 activation may be beneficial for functional outcome. Current studies investigate the effect of chemogenetic inhibition in late phase after stroke, since activation of cM1 may have time-dependent role. Ongoing studies also examine which neuronal subtypes are predominantly activated in cM1 after stroke.

Title: Resting-state functional connectivity changes in photothrombotic ischemic stroke rat model

Authors: *H.-S. LEE, J.-H. YOON, O.-H. CHEONG, S.-H. PARK, Y. JEONG
Bio and Brain Engin., KAIST, Daejeon, Korea, Republic of

Abstract: Introduction: Ischemic stroke is one of the major causes of death and disability. A number of papers have been studied focused on global functional connectivity changes after large, nonspecific ischemic stroke during task and in the resting-state. However, there is no study

on how global resting functional connectivity (rsFc) changes with specific cortical region damage. Photothrombotic ischemic (PTI) stroke is a focal cerebral ischemia model which utilizes a photocoagulation process of Rose Bengal with light at target area. Adjusting the duration of light and dye concentration, focal infarct size is controllable. Here, we focally induced stroke on primary motor cortex (M1) using rat PTI model and examined longitudinal changes in rsFc as well as their motor ability and infarct volume changes. **Methods:** Sprague-Dawley rats were used in this study. Rose Bengal was intravenously injected and cranial windows were made. The animals grouped into PTI and Sham group and light for thrombosis was only illuminated to PTI group on motor cortex (M1). Motor task (Rotarod), and T2-weighted and resting-state fMRI (rsfMRI) scanning with 3T MRI under light isoflurane anesthesia were performed before (day 0) and on 1, 3, and 6 days after thrombosis. Ischemic volumes were measured with T2-weighted images and functional connectivity was assessed with rsfMRI. **Results:** On Rotarod, PTI group showed significantly decreased latency on day 1 but progressively recovered on days 3 and 6. The infarct size also gradually reduced to half the size of day 1 on day 6. rsfMRI results showed reduced functional connectivity in 64 whole brain regions of interest (ROIs) on day 1, especially with M1 and gradually improved with recovery. Accordingly, network theory based analysis revealed disrupted network properties in the PTI group. All properties were recovered simultaneously with recovery. **Conclusions:** After photothrombosis on M1, motor performance and functional connectivity of M1 were significantly decreased. Afterward they were recovered in some degree without any treatment. Our results showed that focal lesion can induce changes of global functional connectivity and the changes are related with behavioral performance. Further research on relationship between recovery and functional connectivity by local damage will provide knowledge on better motor rehabilitation.

Title: Elevated functional connectivity within injured cortical regions after focal stroke

Authors: *F. TIAN[1], T. SHICK[1], A. SAJJAD[1], M. WANG[1,2], J. BORJIGIN[1]
[1]Univ. of Michigan, Ann Arbor, MI; [2]Veterans Admin. Ann Arbor Healthcare Syst., Ann Arbor, MI

Abstract: Focal stroke, one of the major causes of mortality and morbidity, affects millions of individuals around the world. Very little, however, is known about the temporal changes in the intrinsic electrical activity of the brain following focal stroke. The objective of this study is to explore how the injured region interacts with the healthy region of the brain during focal stroke. A total of 10 Sprague Dawley rats were included in this study. Baseline EEG (from 8 cortical loci) and EKG signals were recorded for 1 hour. Online recording was continued for a maximum of 20 hours after right middle cerebral artery occlusion (RMCAO). All rats showed large infarcts on the right side of the brain, half of which died suddenly with a mean survival length of 13.58 hours. Dead rats were found to have suffered subarachnoid hemorrhage (SAH), in addition to the ischemic stroke. In all 10 rats following RMCAO, there was a marked reduction of EEG power for all 8 EEG channels. As expected, all 4 channels located on the right side of the brain (injured side) demonstrated more significant reduction of EEG power than the left side, especially for the site of injury. EEG coherence (functional connectivity) for signals recorded from the left side of the brain gradually decreased after RMCAO. Interestingly, EEG coherence gradually increased after the stroke on the right side of the brain. In addition, heart rate variability showed distinct patterns in rats that died versus those that survived, suggesting that the autonomic nervous system regulation is different in these two conditions. This study is expected to contribute to our understanding on the temporal dynamics of cortical power, functional connectivity, and the regulation of autonomic nervous system during focal stroke.

Abstract: Motor impairment is one major symptom of patients after cortical strokes. Current neuromodulatory strategies to enhance motor recovery often target large brain areas non-specifically and without sufficient understanding of their interaction with internal repair mechanisms. Here we developed a novel therapeutic approach in an animal model of stroke by specifically activating corticospinal circuitry using optogenetics. Rats were subjected to a photothrombotic stroke destroying >95% of the sensorimotor cortex. Optogenetic stimulation of corticospinal neurons, in combination with intense subsequent rehabilitation, led to full recovery of lost motor functions, similar to an Anti-Nogo immunotherapeutic approach. A new computer vision based automatic behavior analysis revealed that recovery in a grasping task represented true restoration of baseline movement patterns rather than compensatory actions. Optogenetic stimulation of the corticospinal neurons induced their axona to sprout from the intact to the denervated cervical hemi-cord. In recovered animals, optogenetic silencing of these corticospinal projection neurons in premotor and primary motor area resulted in too long or too short targeting movements of the restored grasping function, thus identifying the reestablishment of specific and anatomically localized cortical microcircuits induced by successful rehabilitative strategies. These results provide a conceptual framework to improve established clinical techniques such as transcranial magnetic or transcranial direct current stimulation in stroke patients.

Title: Automated assessment of dynamic changes in the cortical vascular network architecture after ischemic stroke

Authors: *R. RUST[1,2], M. E. SCHWAB[1,2]
[1]Brain Res. Inst., Zuerich, Switzerland; [2]ETH Zurich, Dept. of Hlth. Sci. and Technol., Zurich, Switzerland

Abstract: Recovery after stroke can occur by compensation of lost capabilities by functionally related regions or restoration of the functionality of the perilesional, partially affected cortical tissue in the ischemic penumbra. The latter mechanism strongly depends on the revascularization of the ischemic border zone, a process which significantly contributes to the final lesion size and the severity of the clinical deficit. We developed a multi parametric system to reliably analyze dynamic changes and their consequences in the cortical vascular network including (1) stroke size, (2) blood vessel density and distribution (3) neoangiogenesis, (4) perfusion of vessels, and (5) behavior. We evaluated different vascular endothelium-specific antigens (CD31, Glut1, Isolectin B4, Laminin, and Collagen IV) together with the proliferation marker EdU to measure neo-angiogenic activity and distribution. Perfusion of vessels was assessed by a set of intracardially applied vascular tracers (dextran, lectins, and albumin) that were compared on the basis of penetration depth and leakage into the tissue. These tracers can be combined with genetic mouse models with fluorescent markers in the vascular endothelium. A big advantage of transgenic marker mice is the compatibility for 3D applications with cleared whole brain samples that require no additional immunohistochemistry. All data are analyzed automatically with the public domain software ImageJ in an unbiased, trackable and time saving approach to determine the vascular network architecture and its dynamic changes following an ischemic event as well as therapeutic interventions, e.g. with anti-Nogo-A antibodies.

Title: Compensation of the cortico-reticular tract against cortico-rubral tract block after capsular hemorrhage in intensive rehabilitation-induced recovery

Authors: *A. ISHIDA[1], Y. UEDA[1], K. KOBAYASHI[2], T. ISA[3], H. HIDA[1]
[1]Nagoya City Univ. Grad. Sch. of Med. Sci., Nagoya, Aichi, Japan; [2]Natl. Inst. For Physiological Sci., Okazaki, Japan; [3]Dept. of Neuroscience, Grad. Sch. of Med. & Fac. of Med., Kyoto Univ., Kyoto, Japan

Abstract: Various forms of reorganization are often shown in the residual central nervous system after cortico-spinal tract (CST) lesion by stroke, which could be enhanced by the poststroke rehabilitation. We reported that forced impaired limb use (FLU) increased the sprouting of the cortico-rubral tract (CRT) in CST-damaged intracerebral hemorrhage (ICH) resulting in the recovery of disturbed forelimb functions. However, the precise role of the CRT in FLU-induced functional recovery is still unclear. To clarify the question, we selectively blocked CRT at the chronic or the early phase after FLU following to ICH and then compared the FLU effect on functional recovery. The FLU effect on the recovery was also investigated in CRT selective blockage during FLU. To block CRT selectively, adult male Wistar rats were first injected lentivirus vector (NeuRet-TRE-EGFP.eTeNT) into the red nucleus and adeno-associated virus vector (AAVdj-CaMKII-rtTAV16) into the ipsilateral motor cortex. Thus, CRT neurons were double-infected, enabling to block synaptic transmission by doxycycline (DOX) administration. Four weeks after virus injections, ICH was made by collagenase injection into the internal capsule, and FLU was given at 1-8 day after ICH. DOX was orally administered for all rats on days 1-28 (during FLU) or 13-20 (early phase) or 92-99 (chronic phase). Skilled reaching task was perfomed as behavioral assessments. ICH rats demonstrated severe impairment of motor function at 24 hours after ICH. In case of the CRT block in the chronic phase, the recovered forelimb function was severely impaired. FLU-induced functional recovery was similarly blocked in CRT block in the early phase. However, in the CRT blockade during FLU, FLU-induced regain of forelimb function was not disturbed. Histological analysis revealed that the change of neurite projection was not observed in CRT, but the cortico-reticular projection was significantly increased. Data suggest that the CRT is a promising substrate for poststroke rehabilitation, but CRT could be quickly compensated by other descending projections such as the cortico-reticular tract.

Title: Changes in functional connectivity due to repeated transcranial magnetic stimulation and botulinum toxin treatment-Discussion on two cases with different functional connectivity changes-

Authors: *R. SAKAI[1], T. ISHIKURA[2], Y. KOBAYASHI[3]
[1]Fukui Col. of Hlth. Sci., Fukui-Shi, Japan; [2]Osaka Hlth. Sci. Univ., Osaka, Japan; [3]Fukui Gen. Hosp., Fukui, Japan

Abstract: Introduction
Concomitant treatment with repeated transcranial magnetic stimulation (rTMS) and botulinum toxin was administered for upper limb paralysis in two patients with chronic stroke. Examination of the functional connectivity (FC) before and after treatment revealed contrasting changes. We report these cases with consideration.
Materials and Methods
The subjects were two patients with chronic stroke: case 1, a man in his sixties with left brain-stem hemorrhage; case 2, a man in his fifties with left putaminal hemorrhage. Prior to admission, botulinum toxin was administered to the paralyzed side of the upper limb flexor muscles. After that, a 2-week intensive in-hospital treatment was administered. In the morning and afternoon, low-frequency rTMS was performed in the unimpaired brain followed by task-orientated training. Before and after the treatment, upper limb function assessments such as Wolf motor function test (WMFT), simple test for evaluating hand function (STEF), and modified Ashworth scale (MAS) were used. FC imaging was performed using 1.5T optimaMR360 (GE Co., Inc.). The conditions for the imaging before and after the treatment were T2-weighted EPI, TR/TE/FA = 3000/40/90, resting-state eyes-open visual fixation, and imaging time of 5 min. For the analysis, band-pass-filter (0.008-0.09 Hz) and linear trend removal were performed after the pretreatment; FC with each anatomical brain site was calculated with the primary motor cortex of the damaged hemisphere (M1) as the starting point. Further, rsfMRI imaging was performed in 10 healthy adult volunteers under the same conditions.
Results
In both cases, WMFT, STEF, and upper limb function improved. In MAS, case 1 showed no notable change, while attenuation of spasms centered in the elbow joint flexor was observed in case 2. In the pretreatment/post-treatment, FC between the right and left primary motor cortices improved to 0.11/1.01 in case 1, but decreased to 0.86/0.35 in case 2.
Discussion
In case 1, there was no change in MAS, and FC increased; thus, interhemispheric interaction was normalized by rTMS. In case 2, MAS improved, but FC decreased; hence, attenuation of spasms by botulinum toxin treatment was involved in the improvement of upper limb function. Motor function prior to treatment was similar for both cases, and despite receiving the same treatment procedure, FC showed contrasting changes. These results demonstrated that even when motor function is almost the same, the FC pattern differs according to the site of injury. Moreover, in treatments for normalizing interhemispheric interaction, such as rTMS, attention needs to be paid to FC before the treatment.

Title: Correlation between brain microstructure revealed by NeuriteOrientation Dsipersion and Density Imaging and cerebral hemodynamics and metabolism measured with positron emission tomography in patients with moyamoya disease

Authors: *S. HARA[1,2], M. HORI[2], M. INAJI[1,3], T. MAEHARA[1], K. ISHII[3], S. AOKI[2], T. NARIAI[1,3]
[1]Dept. of Neurosurg., Tokyo Med. and Dent. Univ., Tokyo, Japan; [2]Juntendo Univ., Tokyo, Japan; [3]Tokyo Metro Inst. Gerontology, Tokyo, Japan

Abstract: *Purpose*: Neurite Orientation Dispersion and Density Imaging (NODDI) is a diffusion MRI model which can evaluate brain microstructure excluding the influence of water component. We investigated the correlation between NODDI measured brain microstructure and PET measured cerebral hemodynamics and metabolism in patients with moyamoya disease, a progressive occlusive cerebrovascular disease that usually cause chronic cerebral ischemia in younger population.*Methods:* From Sep 2015 to Jan 2017, 11 consecutive patients with moyamoya disease underwent 15 O gas positron emission tomography (PET) and MRI. By the analysis of the clinical presentation and the morphological MRI, all hemispheres were categorized as affected (A) or non-affected (N) by the attending neurosurgeon. The diffusion MRI was acquired using a 3.0-T MRI system with 3 b values (0, 700: 30axes, 2850: 60 axes) and fitted to the NODDI model by the NODDI Matlab Toolbox. PET data were acquired using a Discovery 710 PET/CT scanner with inhalation of [15O]CO2 and [15O]O2. Hemispheric cortical ROIs were created from T1 weighted-images in each patient.*Results*: Intracellular volume fraction (Vic) and Orientation Dispersion Index (OD) of NODDI revealed significant correlation with cerebral blood flow (CBF) and metabolic rate of oxygen (CMRO2) in the cortex (Figure1). OD of affected hemispheres were significantly lower than unaffected hemispheres. Discussion: Vic and OD is presumed to correlate with the neuronal density and the network complexity of dendritic spines, which reported to decrease by chronic ischemia. It is reasonable that the decreased CBF lead to decreased Vic, OD and CMRO2, and that OD was lower in the affected hemispheres than in the non-affected ones. It is noteworthy that noninvasively obtained brain microstructure status by NODDI correlated well with cerebral hemodynamics and metabolism which can only be evaluated by 15 O gas PET. *Conclusions*: NODDI may reveal the

progressive neuronal damage caused by chronic ischemia , which is undetectable by the conventional MRI in patients with moyamoya disease.

Title: Trans-synaptic retrograde retinal ganglion cell degeneration after stroke coincides with the stable blind field and with areas of decreased representation in V1

Authors: *C. L. SCHNEIDER[1,3], E. K. PRENTISS[1], Z. R. WILLIAMS[4], B. SAHIN[5], B. Z. MAHON[1,2,6]
[1]Brain and Cognitive Sci., [2]Ctr. for Visual Sci., Univ. of Rochester, Rochester, NY; [3]Med. Scientist Training Program, [4]Ophthalmology, [5]Neurol., [6]Neurosurg., Univ. of Rochester Sch. of Med. and Dent., Rochester, NY

Abstract: Stroke in the territory of the posterior cerebral artery leads to blindness in all or part of the contralesional visual field. While about 50% of patients experience some degree of visual recovery within the first 6 months after stroke, only 12.5% recover completely (Tiel K., Kolmel, 1990). One limiting factor that may prevent further visual recovery is trans-synaptic retrograde degeneration of retinal ganglion cells (RGC), which has been observed in stroke patients starting as early as 3 months after stroke (Jindahra, Petrie, & Plant, 2009, 2012; Park, Park, Cho, & Park, 2013; Tanito & Ohira, 2013; Yamashita & Miki, 2012). It is still unknown, however, whether RGC complex thinning after stroke is localized to areas of the retina that correspond (retinotopically) to damaged cortical regions. Here we bring into register optical coherence tomography of RGC complex thickness, perimetry, and functional magnetic resonance imaging of visual cortex activity by dividing visual space into the same 12 wedges for all three measures. In both a cross-sectional and a longitudinal study of recent stroke patients (within 1.5 years since stroke) we found that RGC degeneration after stroke occurs across the entire macula, but at a significantly faster rate in areas of the macula corresponding to the blind field. In addition, variability in RGC degeneration across sub-regions of the macula can be explained by the number of active voxels in visual cortex that maximally responded to visual stimulation in the corresponding regions of the visual field. RGC degeneration is negatively correlated with the number of active voxels in visual cortex in all locations, but the relation was significantly stronger for blind areas of the visual field. These results suggest that attempts to increase residual visual cortical activity may prevent RGC degeneration, which could remove one of the barriers to and lengthen the window of spontaneous visual recovery.

Abstract: Stroke is a leading cause of adult long-term disability worldwide. Large-scale neuroimaging studies have shown promise in identifying robust biomarkers of stroke recovery. However, analyzing these large datasets is problematic due to barriers in accurate stroke lesion segmentation. Lesion segmentation allows us to account for the size, location and number of each individual's lesions and to understand how these factors impact recovery. Manually traced lesions are the gold standard for lesion segmentation, but require anatomical expertise and can be prohibitively time consuming. While algorithms have been developed to automate this process, the results often lack accuracy. Promising newer algorithms employ machine learning techniques, but these require large training datasets to optimize performance.
To address these issues, we developed ATLAS (Anatomical Tracings of Lesions After Stroke), a publically-available dataset of 316 manually segmented lesions on T1-weighted MRIs with metadata. This large, diverse dataset can be used to train and test lesion segmentation algorithms and act as a standardized dataset for comparing the performance of different segmentation methods.
ATLAS lesions were traced by a team of 11 individuals. All team members were trained by an expert tracer on an identical set of lesions and followed detailed written and video protocols. We assessed inter- and intra-rater reproducibility by averaging the dice correlation coefficient (DCC) between and within tracers, across the lesion training set (inter-rater DCC = 0.76±0.17; intra-rater DCC = 0.83±0.13). All lesion segmentations were quality checked by a second tracer. An experienced neuroradiologist reviewed all lesions to create metadata, including the number and location of lesions (left/right hemisphere; cortical/subcortical), type of stroke (embolic, hemorrhagic), primary stroke location, vascular territory, and severity of periventricular and deep white matter hyperintensities. This metadata allows for sorting of the ATLAS dataset based on specific categories of stroke, and provides lesion characteristics during the evaluation of algorithms (e.g., an algorithm might fail primarily on cortical lesions, or in brains with multiple lesions, etc.).
ATLAS is deposited on the Archive of Data on Disability to Enable Policy (ADDEP) and hosted by the Interuniversity Consortium for Political and Social Research (ICPSR), the world's largest social science data achieve, which supports rehabilitation. We anticipate that ATLAS will become a useful resource to standardize the segmentation protocol, and improve the accuracy of current lesion segmentation methods.

Title: Retrograde Neurodegeneration of Substantia Nigra Projections to the striatum following long term survival after Ischemic Stroke

Authors: *A. PANTA, F. SOHRABJI
Neurosci. And Exptl. Therapeut., Texas A & M Hlth. Sci. Ctr., College Station, TX

Abstract: Introduction: Stroke survivors suffer from long-term physical, cognitive and affective disabilities. These disabilities lower the quality of life, contribute to social isolation and anhedonia, and clinical disorders such as post-stroke depression (PSD), which disproportionately affects women. Preclinical studies show that lesions of the substantia nigra (par compacta) impair both motor performance and reward seeking behavior. Neurons from the SNc project to the striatum, a region that is significantly infarcted by middle cerebral artery occlusion (MCAo).
Hypothesis: Ischemia induced by MCAo leads to retrograde degeneration of the SNc pathway projecting to the striatum.
Methods: Middle-aged Sprague-Dawley female rats (12 months old) were subjected to ischemic stroke using a silicon-coated nylon filament suture to occlude the middle cerebral artery (MCA) which was removed 75min after to allow for reperfusion. After 14 weeks of survival, rats were again anesthetized and Fluorogold (Flg) was injected into the left and right striatum. Four days later, animals were overdosed with anesthetic, perfused with saline and formaldehyde and the brain removed for cryosectioning. In three sections per animal, Flg-labeled cells in the SNc were counted on both hemispheres, using fluorescent illumination.
Results: Flg-injections into the striatum retrogradely labeled neurons in the midbrain. There was a 35% decrease ($p<0.009$) in the number of Flg labeled SNc cells in the ischemic hemisphere (85.5+18.2) as compared to the non-ischemic hemisphere (132.4+22.7). The reduced number of projection neurons in the ischemic henmisphere is consistent with the loss of trophic support from the striatum.
Conclusions: SNc neurons are a critical component of reward pathway and motor function,

hence degeneration of these neurons could lead to long term motor deficits and depressive symptoms including anhedonia that are common after stroke.

Title: Unmasking the complex systems biology of tissue remodeling after ischemic brain injury in rats using multiplex fluorescence biomarker immunohistology and multispectral imaging

Authors: *D. MARIC, J. D. BERNSTOCK, A. B. SEDLOCK, Y. MOU, D. YE, J. M. HALLENBECK
NINDS/NIH, Bethesda, MD

Abstract: Stroke is a leading cause of death in the United States and even when non-lethal it can lead to complex and widespread debilitating changes in the brain, with marked deterioration of quality of life and potentially long recovery times required to restore lost functions. While extensive stroke research conducted thus far has aimed to better characterize the complex processes mediating brain tissue damage and recovery after stroke, our full understanding of these processes and designing comprehensive drug treatments to elicit most beneficial clinical outcomes are still in their nascent stages. To further advance this field of research, we used a systems biology approach by combining large-scale multiplexed fluorescence immunohistology of rat brains after focal ischemic injury with whole brain slide scanning using a customized multispectral imaging platform. We processed 10-micron thick serial whole brain coronal sections collected from male Sprague Dawley rats at 72 hours following focal brain ischemia using a medial cerebral artery occlusion (MCAO) model. Sections were repeatedly probed and sequentially imaged using a panel of up to 50 fluorescent biomarkers relevant to cellular and molecular processes mediating neuroinflammation, neuroplasticity, neurogenesis, gliogenesis and angiogenesis in response to MCAO. Unique combinations of these biomarkers enabled a comprehensive identification and quantitation of all relevant cell types (neurons, astrocytes, oligodendrocytes, endothelial cells, microglia, immune cells, etc.) and their changing functional states (reactive, resting, apoptotic, proliferative, etc.) in the brain after injury. The results show dynamic and highly complex spatiotemporal changes in brain tissue remodeling and recovery after ischemic injury eliciting distinct cellular/molecular and specific niche responses that develop both proximally and distally to the site of injury. This work demonstrates the crucial

need and a workable solution to apply comprehensive multiplex fluorescence biomarker screening and multispectral imaging to study the systems biology of brain in response to ischemic injury. The practical computational solutions pertaining to processing very large image datasets (including those involving multiplex 3D imaging of the entire brain using array tomography) and multi-parametric computational image analysis of these datasets are currently in development.

Title: Neuroplasticity mechanisms that lead to stroke recovery

Authors: *M. T. JOY[1], A. J. SILVA[2], S. T. CARMICHAEL[3]
[2]Neurobiology, Psychiatry and Biobehavioral Sciences, Psychology, Integrative Ctr. for Learnin, [3]Neurol., [1]UCLA, Los Angeles, CA

Abstract: Stroke is the leading cause of long-term adult disability in the US. With the exception of clot busting drugs (tPa) and endovascular therapies, neurorehabilitation is the only therapy in clinical use. Pharmacological attempts to improve recovery have included the use of molecular effectors of neuroplasticity as targets. Molecular mechanisms that underlie stroke recovery remain largely unknown. C-C chemokine receptor 5 (CCR5) was recently identified as a regulator of synaptic plasticity in hippocampal learning and memory circuits[1]. We investigated if CCR5 signaling regulates stroke recovery. We show that CCR5 knockdown in specific motor circuits induces early and sustained motor recovery following an ischemic stroke in the motor cortex. Pharmacological blockade of CCR5 also produces similar recovery effects in motor function, paving the possibility of using CCR5 as a druggable target for stroke recovery. The mechanism through which CCR5 signaling augments changes in synaptic plasticity effecting recovery were investigated. As CCR5 knockdown leads to early recovery, within the first week of stroke, we monitored changes in dendritic spine dynamics in pre-motor cortex, anterior to the stroke site. Our data shows that CCR5 knockdown reduces spine loss and preserves ~80% of

dendritic spines when compared to control-stroke groups that showed a 50% loss of spines. Moreover, CCR5 knockdown induces robust changes in structural plasticity. Using a quantitative cortical mapping approach, our data shows that CCR5 knockdown causes sprouting of axons into the contralateral hemisphere from pre-motor cortex ipsilateral to the stroke site. Taken together, our data shows that CCR5 knockdown induces changes in synaptic plasticity that underlie motor recovery post-stroke, acting as a potent target for stroke recovery. Reference 1. Abstract: Neuro-rehabilitative research is developing novel strategies to enhance the effectiveness of therapies after stroke by using physical and plasticizing treatment. Previous studies have shown that repeated neuronal stimulation of the peri-lesioned area with optogenetics induces a significant improvement in cerebral blood flow and neurovascular coupling response. Up to now the mechanisms underneath the reshaping of brain circuitry induced by rehabilitation after stroke are still unknown. By performing *in vivo* imaging of Thy1-GCaMP6f mice we want to investigate how different rehabilitative therapies shape new cortical maps in the peri-infarct area. In order to promote the functional recovery after stroke we use either an optogenetic

strategy to stimulate targeted excitatory neurons in the peri-lesional region or motor training on a robotic platform. In the first case, we repeatedly stimulate with a 473 nm laser ChR2-transfected neurons five days a week. In the second paradigm, we investigate the effects of motor rehabilitation by performing wide field cortical imaging while the animals execute a motor task on a robotic device. We investigate how light-stimulation moulds cortical maps, and compared it with remodelling induced by motor training. We analyse the spatio-temporal calcium dynamic and the reshaping of cortical activation area during the movement in a month. We then evaluated how the interhemispheric connectivity changes in response to the different rehabilitation approach. Our combination of techniques allows obtaining unprecedented views on cortical plasticity induced by rehabilitative therapies.

Title: Does tonic inhibition in the sub-acute period after stroke alter the trajectory of upper limb recovery?

Authors: *J. CIRILLO[1,2], R. A. MOONEY[1,2], V. M. BORGES[2,3], P. A. BARBER[2,3], A. N. CLARKSON[4], S. J. ACKERLEY[2,3], M.-C. SMITH[2,3], C. MANGOLD[2], C. M. STINEAR[2,3], W. D. BYBLOW[1,2]
[1]Dept. of Exercise Sci., [2]Ctr. for Brain Res., [3]Dept. of Med., Univ. of Auckland, Auckland, New Zealand; [4]Dept. of Anat., Univ. of Otago, Dunedin, New Zealand

Abstract: Evidence from experimental animal models of stroke indicates that reducing the level of tonic inhibition present in motor cortex may facilitate neural plasticity, learning, and motor recovery. The present study is examining primary motor cortex (M1) inhibition in patients over the first 12 weeks after stroke, and in a cohort of age-similar healthy controls. Gamma aminobutyric acid (GABA) concentration and neurotransmission in M1 are assessed using magnetic resonance spectroscopy (2 and 6 weeks after stroke) and threshold tracking paired-pulse transcranial magnetic stimulation (TMS) (2, 6, and 12 weeks after stroke). Upper limb impairment is assessed with Fugl-Meyer Upper Extremity Scale at 2, 6, 12 and 26 weeks after stroke. Similar to recent studies, patients with a functionally intact corticospinal pathway exhibit

a proportional recovery such that upper limb impairment resolves by ~70% of the maximum possible. MRS indicates that compared to age-similar controls, GABA concentration are reduced within contralesional, but not ipsilesional, M1 6 weeks after stroke. Short- and long-latency intracortical inhibition examined with TMS indicate greater inhibition in the ipsilesional hemisphere during the spontaneous recovery period after stroke compared to controls. Patients with higher tonic inhibition in ipsilesional M1 tend to have a longer recovery period. The extent of postsynaptic GABAergic inhibition is similar to controls during the early spontaneous recovery period, but disinhibition is present by 12 weeks post-stroke. These findings indicate that the ability to modulate tonic inhibition levels early after stroke may have implications for upper limb recovery during the spontaneous recovery period.

Title: Position and movement sense in stroke patients; pilot study

Authors: *Y. ACOSTA-SOJO, B. J. MARTIN
Industrial and Operations Engin., Univ. of Michigan, Ann Arbor, MI

Abstract: Asymmetries in upper limb position and movement sense have been identified in healthy participants. However, traditional and current rehabilitation procedures have ignored intrinsic asymmetries and rarely differentiate the specific sensory and/or motor needs after stroke. The brain damage suffered during the stroke can limit the functionality of the right and left hemisphere of the brain, causing motor and sensory deficits. As a result, alteration of asymmetries observed in healthy patients is expected to occur in stroke patients. For this reason, the aim of this pilot study was to investigate the alteration of sensory information received from the same or opposite limb/hemisphere system in mildly/moderately affected stroke patients. The sensory system was tested by proprioceptive perception of upper limb position and movement. Position sense was tested with eyes closed while participants matched a reference position imposed by a robotic arm in two different conditions: ipsilateral remembered and contralateral concurrent. Movement sense was tested with eyes closed while participants matched with the opposite arm the perceived movement elicited by a vibration applied to the triceps of the reference arm. The preliminary results indicate an exacerbation of position and movement sense

asymmetry between the right and left limb systems. The matching position errors are greater for the affected limb when the matching and reference movements are performed with the same limb and matching errors are greater when memorization of perception is required. The amplitude and velocity of movement matching vibration-induced illusion is lower for the affected than non-affected limb. It is worth noting that "greater error and exacerbation" are to be considered in the context of intrinsic asymmetries in healthy controls.

Title: Tailoring non-invasive brain stimulation to enhance bimanual arm coordination in individuals with chronic stroke

Authors: *W. LIAO[1], J. WHITALL[1], J. E. BARTON[2], S. MCCOMBE WALLER[1]
[1]Physical therapy rehabilitation Sci., Univ. of Maryland,Baltimore, Baltimore, MD; [2]Neurol., Univ. of Maryland Baltimore, Baltimore, MD

Abstract: Using non-invasive brain stimulation (NIBS) as an adjunctive therapy has become increasingly popular in stroke rehabilitation. Current protocols have focused on the interhemispheric competition model which emphasizes facilitation of the lesioned hemisphere or inhibition of the non-lesioned hemisphere. Few studies have examined the effects of NIBS on bimanual arm function. The purpose of this study was to examine the neuro-modulation effects of ipsilesional primary motor cortex (iM1) vs. contralesional dorsal premotor cortex (cPMd) on interlimb coordination and cortical function in individuals with chronic stroke. We hypothesized that subjects would show differential responses to these two types of stimulation and that these differences may be associated with their level of paretic arm function. **Subjects:** Eight subjects with chronic stroke. **Methods:** Using a repeated measures design, subjects received a single session of 5Hz repetitive transcranial magnetic stimulation (rTMS) on either iM1 or cPMd. During each session, subjects performed isometric elbow flexion tasks with a single arm or both arms while matching a visual target corresponding to 20% of their maximal voluntary contraction. Outcomes included motor evoked potential amplitude (MEPs) of M1 bilaterally, force performance, and muscle coherence of the two arms during the bimanual task. **Results:** Six subjects showed greater MEP amplitudes in the lesioned M1, and decrease of MEPs in the non-lesioned M1 after iM1 stimulation ($p<.05$). Muscle coherence between two arms during the bimanual task also increased after iM1 stimulation ($p<.05$). In contrast, two subjects

demonstrated greater MEP amplitudes in the lesioned M1 after cPMd compared to iM1 stimulation. Muscle coherence between the arms during bimanual tasks also increased after cPMd, but not iM1 stimulation. A regression model showed the percentage change of MEP amplitude of lesioned M1 was significantly correlated with distal arm function of Fugl-Meyer assessment scores (p=.03, R^2=.63). **Conclusion:** Our study identified two different patterns of response after rTMS to iM1 and cPMd in subjects with chronic stroke. Subjects with more impaired distal arm function, may benefit more from direct enhancement of cPMd than lesioned M1. Our preliminary findings indicate that protocols of NIBS should be individualized to each subject.

Title: Exercise ameliorates the effects of compensatory limb training in a mouse model of stroke

Authors: *A. L. KERR, E. M. HAAN, R. MAVROS, V. NEMCHEK
Psychology, Illinois Wesleyan Univ., Bloomington, IL

Abstract: Stroke is a leading cause of disability worldwide. However, current rehabilitative therapies are insufficient in restoring pre-injury function. Upper-limb deficits are among the most common, chronic deficits associated with stroke. A common consequence of this deficit is compensatory over-reliance on the less-impaired limb (contralateral to the injured hemisphere). However, previous research in humans and animal models suggests that these post-stroke compensatory behaviors limit the recovery potential of the impaired limb. The current study was conducted using a mouse model of stroke to investigate the impact of aerobic exercise on the ill effects of compensatory limb training. C57BL/6 mice were trained pre-operatively with their preferred limb on the Pasta Matrix Reaching Task (PMRT) to establish skilled reaching behavior (18-20 days). All mice then received a unilateral ischemic stroke (photothrombotic) of the sensorimotor cortex contralesional to the trained limb. Four days after lesion, reaching performance (preferred limb/ impaired limb) was assessed on the PMRT. Mice were then equally divided into three groups: compensatory limb training (CLT), exercise and compensatory limb training (Ex-CLT), and control. Mice were trained in these groups for 14 consecutive days (post-operative training). Mice in the Ex-CLT group had 22-hour access to running wheels in their home cage during post-operative training. Animals receiving CLT training received a daily

training session (PMRT) of their less-impaired limb during the same period. Control animals spent an equivalent amount of time in reaching chambers but were not trained with either limb during post-operative training. Following post-operative training, all mice received daily assessment of the impaired limb (contralateral to the lesion) for five consecutive days (PMRT). Our results indicate that aerobic exercise ameliorates the negative effects of compensatory limb training and permits functional recovery of the impaired limb when paired with focused training of the less-impaired limb. Aerobic activity may be an effective adjunctive therapy that extends the recovery potential of the impaired limb.

Title: Trade-off between efficacy and efficiency of motor training post-stroke

Authors: *N. SCHWEIGHOFER[1], C. WANG[1], C. J. WINSTEIN[2]
[2]Div. Biokinesiol/Physical Ther, [1]USC, Los Angeles, CA

Abstract: It is well known from motor learning research that motor performance depends on the amount of practice, but also that the gains follow diminishing returns: each additional unit of training yields smaller and smaller gains. Recent results from the DOSE trial, a single blind, phase I, randomized controlled trial of four doses (0, 15, 30, or 60 hours) of upper extremity therapy during the chronic phase after stroke, showed a robust dose-response relationship for the Motor Activity Log-Quality of Movement (MAL-QOM) (Winstein et al., in preparation). **Here,** we test the hypotheses that: 1) increasing the dose of training leads to an increase in the efficacy of training but a decrease in the efficiency of training, and 2) increasing the duration of training will also decrease the efficiency of training. We modeled the changes in the MAL during the train-wait-train-wait-train schedule used in the DOSE trial with novel dynamical mixed-effects models that account for individual response in changes in MAL both during and between training bouts. Using dose as input, we modeled the efficiency of training with dose; using time varying learning rates, we modeled the efficiency of training with duration; with the forgetting term, we modeled the decrease in MAL following training. Results confirmed the dose-response relationship previously found with regression models. The models also showed a decrease of efficiency with dose (the greater the doses, the less the gain per hour) and decrease in efficiency

with time (the longer the duration of training, the less the gain per hour). In addition, the greater the dose, the more the forgetting following training. However, the random learning and forgetting coefficients showed a large between subject variability in both increase and decrease in MAL as a function of dose and time. In conclusion, our novel model well accounted for the individual effects of motor training post-stroke and exhibited a trade-off between the gains due to training on one hand and the intensity and duration of motor training on the other hand.

Abstract: According to muscle synergy hypothesis, movement's generation is achieved through a modular organization of the neuromuscular system, which is able to co-activate groups of muscles as single units, possibly thanks to the existence of spinal interneuronal structures. After a cerebrovascular accident, disruptions of the activation signals descending from the motor cortex may lead to abnormal muscle activation's patterns, with consequent motor impairment. Proper rehabilitation strategies are of crucial importance for motor recovery after a stroke event. The present work aims to study the effects induced by a new, actuated lower-limb exoskeleton on muscle activations during walking.
Healthy adults (N=5) and chronic stroke survivors (N=1) were asked to perform walking trials in 3 different experimental conditions: 1) natural walking, 2) walking wearing the inactive exoskeleton; 3) walking wearing the active exoskeleton. Electromyographic data (EMGs) of 14 lower limb and trunk muscles were recorded; the muscle synergies associated with each walking condition were extracted from filtered, rectified and normalized EMGs through Non-Negative Matrix Factorization Algorithm (NNMF). The similarity between synergy sets extracted from the three different conditions was assessed through their scalar products.

In healthy subjects, wearing the active or inactive exoskeleton did not alter the number of activated muscle synergies, when compared with natural walking; however, the exoskeleton was associated with changes in the muscular composition of >1 synergy, which involved muscles contributing to hip and pelvis stabilization. These motor adaptation strategies may be seen as a reactive balance response to the exoskeleton-induced external perturbations.
In the post-stroke patient, merging and fractionation of synergies were detected in the affected limb, when compared with the unaffected side's set. The activation of the exoskeleton reduced the number of muscles composing the merged synergies and was also associated with an increase in similarity between the synergies of the affected and unaffected-limb.
These findings suggest that the investigated exoskeleton does not interfere with the healthy natural muscle activations and motor adaptation strategies, and may stimulate effective neuromuscular responses in stroke survivors.

Title: Characteristics of sequential force development in stroke

Authors: *J. ROH[1,2], S. LEE[3,4], P. RAGHAVAN[5], W. Z. RYMER[6,2]
[1]Kinesiology, Temple Univ., Philadelphia, PA; [2]Dept. of Physical Med. and Rehabil., Northwestern Univ., Chicago, IL; [3]Biomed. Engin., Catholic Univ. of America, Biomed. Eng., Washington, DC; [4]4Center for Applied Biomechanics and Rehabil. Res., MedStar Natl. Rehabil. Hosp., Washington, DC; [5]Rehabil. Med., New York Univ. Langone Med. Ctr., New York, NY; [6]Rehabil. Inst. of Chicago, Chicago, IL

Abstract: Previous studies suggest that activation of a small number of motor modules (i.e., coordinated patterns of muscle activity that flexibly combine to produce functional motor behaviors) underlies isometric force generation in stroke survivors and neurologically intact individuals. Our previous study demonstrated that stroke induces alterations in the composition of motor modules in the way that activation of some muscles is abnormally coupled. As we identified the 'post-stroke' alteration of modular organization of multi-directional force production during the stable force match phase, it remains unclear whether similar changes also

occur during the ‘dynamic’ phase of converging to solution (i.e., during force development). We thus examined whether stroke-specific motor module patterns also emerge over the exploratory course of isometric force matches. EMG was recorded from eight major muscles of the affected arm of eight chronic stroke survivors with severe impairment (Fugl-Meyer UE score < 25) and both arms of six age-matched control participants, during a 3-dimensional isometric force matching task. A non-negative matrix factorization algorithm identified motor modules in two time windows: exploratory force ramping phase, and stable force match. Correlation coefficients between any potential pair of end-point force components were also computed for the same time windows. Motor modules are conserved throughout the entire duration of isometric force development in both subject groups, as the same set of motor modules was identified during both phases of force generation. In stroke, the atypical co-activation of the three heads of the deltoid was conserved throughout force development. In both groups, all computed force correlations were significantly higher ($p < 0.05$) during the force ramping phase compared to stable force generation. In stroke, a higher force directional error was observed during the force ramp phase ($p < 0.05$). For both stroke and control groups, the CNS modulated the activation of the same set of motor modules to ramp up and stably maintain force, and the ‘abnormality’ in the composition of motor modules and their improper tuning appears to have contributed to the performance degradation post-stroke.

Title: Motor cortex excitability in a simple reaction time task in post-stroke fatigue: Preliminary data

Authors: W. DE DONCKER[1], ***A. KUPPUSWAMY**[2], S. ONDOBAKA[1], *A. KUPPUSWAMY[2]
[1]UCL, London, United Kingdom; [2]Inst. of Neurology, UCL, London, United Kingdom

Abstract: *Background:* Post-stroke fatigue is a debilitating, persistent symptom with significant impact on stroke survivors. We previously showed that post-stroke fatigue is associated with low levels of motor cortex excitability at rest. In this study we map the motor cortex excitability over time during the performance of a simple reaction time task and correlate excitability profile to

fatigue levels. The prediction is that those with high fatigue will show decreased excitability prior to movement. *Methods:* First time non-depressed stroke survivors, at least 3 months post-stroke, with minimal physical and cognitive impairment were recruited into the study. Fatigue levels were measured using the Fatigue Severity Scale - 7. Single pulse transcranial magnetic stimulation was used to measure excitability of the motor cortex as follows. Standard protocols as previously described was used to measure hotspot and threshold for eliciting a response in the affected side FDI. The intensity to obtain a 0.5 mV response in the affected side FDI was determined. The individual's reaction time was measured when the participant performed a ballistic finger abduction in response to an auditory 'go' cue. 70 trials of finger abduction were performed when TMS was delivered. Participants prepared to move when they heard the warning cue 500ms prior to the 'go' cue, which was the signal to perform a ballistic finger abduction. TMS was delivered at the warning cue, 333ms prior to 'go' cue, 167ms prior to 'go' cue, at the 'go' cue and 70% into the reaction time of the participant. Two more conditions, one where no warning cue was provided and other where no 'go' cue was provided. There were 10 trials in each condition delivered randomly. *Results:* We have currently tested 5 stroke survivors. Preliminary analysis show that stroke survivors with high levels of fatigue as measured by FSS-7 questionnaire have reduced excitability in the time leading up to the movement after presentation of the 'go' cue. Based on our previous results we proposed that post-stroke fatigue may be a disorder of sensorimotor control and less of a psychiatric problem. The data from our current study, thus far, lends support to this idea.

Title: Backward ArteriogeneSIS (BASIS) by mechanical barrier disruption and systemic erythropoietin pretreatment in mild and severe ischemic rat model

Authors: *G. PARK, E. CHOI, Y. KWON, K.-E. LEE, J. LEE, J. HONG
Dept. of Neurology, Ajou Univ. Sch. of Med., Suwon, Korea, Republic of

Abstract: BACKGROUND: Stroke is one of the most disabled condition requiring restoration and revascularization is a promising strategy for the acute stroke. To achieve a successful backward arteriogenesis from healthy extracranial milieu, a simple combination therapy was performed with mechanical barrier disruption (MBD: skull and dura mater) and systemic erythropoietin pretreatment in rat model with cerebral perfusion impairment. **METHODS:** Mild

ischemia was assessed in male Sprague-Dawley rats (250 to 270g) with bilateral internal carotid artery ligation (bICAL). Severe ischemia was evaluated in male Wistar rats (230 to 250g) with bICAL and 90-min transient middle cerebral artery occlusion (tMCAO). Recombinant human EPO (5,000 U/kg) or saline was intraperitoneally injected for 3 consecutive days and then MBD was generated with a 2.5 mm burr-hole at the right side. In combination group and MBD-only group, we compared histology, vessel density, flow cytometry, gene expressions at different timeframes: acute for vasculogenesis (1 day and 4 days), subacute for angiogenesis (2 to 4 weeks), and chronic for arteriogenesis (4 to 12 weeks). **RESULTS**: (vs. hemisphere without MBD), hemisphere with MBD had microglial activation ($P < .05$) and upregulations of pro-inflammatory factors (*Tnf-α, Il-6, Il-1β,* $P < .001$) and Matrix metalloproteinase-9 (Mmp-9, $P < .01$) for increased vascular permeability, while EPO-combination group suppressed inflammatory responses (IBA-1, $P < .05$; *Tnf-α,* $P < .001$; *Il-6*, $P < .05$ vs. MBD-only group) and increased the prevalence of endothelial progenitor cells (EPCs) in acute period. Combination group had a successful transdural anastomosis with relative upregulations of proangiogenic factors in subacute period. Combination group also showed upregulation of proangiogenic factors (*Vegf*, $P < .001$; *Ang-2*, $P < .05$; *Vegfr-1*, $P < .05$) and increased vessel maturation (*Pdgf-β,* $P < .001$; *Tie-2*, $P < .05$) presenting the activation of MMP-2 ($P < .001$) in chronic period. Additionally, minocycline (blockade of MMPs) administration (45mg/kg, i.p.) decreased vascular maturation ($P < .05$) which is explained as the blockade of MMP-2 even in combination group ($P < .01$). Severe ischemic model with profound cerebral perfusion impairment showed more rapid backward arteriogenesis than mild ischemic model, which is presenting with the severity of cerebral perfusion as an environmental determinant for revascularization. **CONCLUSIONS:** Our data demonstrate that a combination method of MBD and systemic EPO pretreatment enhances vessel maturation without regression, which can be a promising therapeutic strategy for acute ischemic stroke victims.

Title: 90 or over-year-old subarachnoid hemorrhage patients

Authors: *N. KUTSUNA[1,2], K. MAKITA[1,2], G. KIDO[1], Y. KAGAWA[1]
[1]neurological surgery, Sonoda daiichi hospital, Tokyo, Japan; [2]Neurolog. surgery, Nihon university school of medicine, Tokyo, Japan

Abstract: There will be more frequent incidence of clinical therapeutic judgement on 90 or over-year-old subarachnoid hemorrhage (SAH) patients while aging society has been expanding in the world. However, there are few evidence on therapeutic possibility for those patients. It is our purpose to report the possibility and features through consecutive 15 cases at two centers. Mean age was 91.5 ± 1.7 years old. World Federation of Neurological Surgeons grade on arrival was 3.5 ± 1.4 and average Fisher group was 3.8 ± 0.4. Mortality calculated from all patients was 66.7%. One case was suffered from symptomatic vasospasm. Five cases among all patients underwent surgical treatment including clipping or intervention. As a whole, Odds ratio was 0.0028 ($P < 0.05$, 95% confidence interval $0.0013 \leqq OR \leqq 0.5645$) in relation to survival between conservative therapy and surgery. The result supported surgical possibility for their longer life. However, mRS in all patients was very high at discharge, which indicated prevention of aneurysm rupture was important for them. As same as younger cases appropriate indication of surgery may be important for super-aged SAH patients despite of ruptured or unruptured aneurysm.

Title: Myoelectric computer interface training improves arm movement after stroke

Authors: *M. W. SLUTZKY[1], A. SINGH[2], S. HAMEED[2], E. M. MUGLER[1]
[1]Neurol., [2]Northwestern Univ., Chicago, IL

Abstract: Impaired arm function after a stroke is due not only to weakness, sensory impairment, and spasticity, but also to abnormal co-activation patterns of arm muscles. We designed a paradigm that uses a myoelectric computer interface (MCI) to help stroke survivors reduce this abnormal co-activation. The MCI maps the activity of a pair of abnormally-coupled muscles to orthogonal components of cursor movement in a computer game, and the user learns to decouple

the muscles by moving the cursor to targets along the mapping directions. We evaluated the effects of in-laboratory training for over 18 sessions in 31 chronic stroke survivors. We compared the effects of training duration (60 vs. 90 minutes per session) as well as isometric vs. movement-based training conditions, for a total of 3 subject groups. We measured the degree of co-activation, arm joint kinematics, and clinical outcome metrics. All subject groups were able to reduce abnormal co-activation in targeted muscles using the MCI training. Each group showed a trend of reduced arm impairment after 6 weeks of training—Fugl-Meyer Assessment, improvement of 3.4±2.8 (mean±SE) for 60-min. group, 3.8±3.6 for 90-min. isometric group, and 3.5±3.4 for the 90-min. movement group). MCI training also appeared to improve subjects' arm function as measured by the Wolf Motor Function Test (-4.0 s, -7.8 s, and -6.9 s for the 60, 90, and isometric groups, respectively) and Motor Activity Log (3.9, 5.5, and 1.2 point gains for the 3 groups). Overall, there was a trend to improved function with longer training; no statistical difference was seen between movement-based and isometric training. Moreover, gains persisted at one month after training stopped. We are currently developing a wearable version of the MCI. We are testing the hypothesis that more frequent training, in the home setting, will translate to even greater gains in arm function. Subjects wear the electrodes home, play the MCI games daily using their abnormally co-activating muscles, and return to the lab weekly for testing. If successful, this paradigm could ultimately synergistically help patients undergoing more traditional rehabilitation, as well as those who have completed physiotherapy.

Title: Acute vagal nerve stimulation reduces infarct size but not motor impairment after stroke

Authors: K. OKADA[1], E. MARSCHALL[1], T. LITTLE[1], C. ROWAN[1], *J. A. KLEIM[2]
[1]SBHSE, [2]Sch. Of Biol. and Hlth. Systems Engin., Arizona State Univ., Tempe, AZ

Abstract: Stroke remains a major source of adult disability. More than 80% of stroke survivors will exhibit motor impairments and most will live with enduring deficits. Recent work has demonstrated that chronic vagal nerve stimulation (VNS) can enhance the efficacy of motor rehabilitation for reducing motor impairments. Here we examined whether VNS during the induction of cortical ischemia could alter both infarct size and post stroke motor impairment. Adult male rats were first trained to criterion on an automated isometric force task. Following training, animals were then assigned to one of three groups in a manner that counterbalanced pre-

stroke motor performance: Stroke, Stroke+VNS and Control. Animals in the Stroke condition received a cortical infarction via injections of endothelin 1 into the forelimb motor cortex contralateral to the trained limb. Animals in the Stroke+VNS group received the same cortical infarction in combination with thirty minutes of VNS and Control animals received neither a stroke nor VNS. Performance on the force task was then assessed for two weeks post stroke. Results showed that animals in the Stroke+VNS condition had significantly smaller cortical infarcts than animals in the Stroke condition. Both the Stroke and Stroke+VNS animals were significantly impaired on the force task compared to Controls for the entire two weeks of testing. Despite the differences in infarct volume, there were no differences in performance between the Stroke and Stroke +VNS animals. The results demonstrate that while acute VNS can reduce infarct volume, the protective effects do not translate to reductions in motor impairment. Current work is examining how cortical physiology may be altered during VNS.

Title: A novel rat model of lacunar stroke targeting the forelimb area of the internal capsule

Authors: *A. SINDHURAKAR[1], V. C. RAMIREZ[1], T.-C. WEN[1], H. PARK[1], J. B. CARMEL[1,2]
[1]Burke Med. Res. Inst., White Plains, NY; [2]Neurol. and Pediatrics and Brain Mind Res., Weill Cornell Med., New York, NY

Abstract: Lacunar strokes of the internal capsule (IC) are common in people and often cause substantial and lasting motor impairments. Current rat models of IC stroke produce lesions that are inconsistent in their location and size. We describe the organization of the IC in the rat and a technique to specifically and reproducibly lesion the forelimb representation. We developed a 3-dimensional model of the rat IC that combines microstimulation mapping with anatomical tracing of axons from forelimb and hindlimb motor cortex. Both anatomy and physiology showed separate representations of the forelimb (Figure, green) and hindlimb (red) with a small overlap. We used an optrode (a sharp electrode and optical fiber) first to identify the forelimb representation using microstimulation and then, to lesion it. For the lesion, we systemically

injected Rose Bengal and delivered green light focally using a laser to activate the Rose Bengal only within the forelimb representation of IC. We found that the lesions were localized to forelimb area of the IC with minimal to no extension to adjacent areas, including the hindlimb region. Rats that underwent the procedure demonstrated significantly decreased forepaw movements contralateral to lesioned hemisphere compared with the non-targeted forepaw movements, as measured by the pasta manipulation task ($N=17$, $p<0.01$). The production of selective and reproducible lesion allows us to investigate changes in adjacent neural circuits. In sum, we can reproducibly achieve anatomically precise and behaviorally consistent changes that enable us to test hypotheses about how the corticospinal system adapts to lacunar stroke.

Title: A cerebral artery stress test to assess regulation of cerebrovascular pulsatility during acute aerobic exercise in overt and covert stroke

Authors: *A. D. ROBERTSON[1], S. ATWI[2], K. KOSTOGLOU[3], R. XU[2], G. D. MITSIS[4], B. J. MACINTOSH[2]
[1]Canadian Partnership for Stroke Recovery, [2]Med. Biophysics, Sunnybrook Res. Inst., Toronto, ON, Canada; [3]Electrical and Computer Engin., [4]Bioengineering, McGill Univ., Montreal, QC, Canada

Abstract: Ischemic stroke and cerebral small vessel disease (CSVD) are associated with highly pulsatile cerebral hemodynamics. Whereas habitual exercise is believed to benefit neurovascular

health, acute exercise is a physiological stressor involving increased pulse pressure (PP). Healthy young adults protect the microcirculation from hypertensive injury during exercise through corresponding increases in cerebrovascular tone. Regulation of tone in older adults with vascular disease, however, is less characterized. This study examined pulsatile hemodynamics in relation to moderate intensity aerobic exercise in adults with cerebrovascular disease. Healthy young (n=17) and old adults (n=9), as well as old adults with CSVD (n=9) and chronic stroke (n=11), participated. We recorded arterial blood pressure and blood flow velocity through the middle cerebral arteries across resting (5 min), moderate intensity cycling (20 min), and recovery (5 min) phases. We used pulsatility index (PI) to characterize cerebrovascular hemodynamics, and critical closing pressure (CrCP) and resistance area product (RAP) to characterize regulatory mechanisms of cerebrovascular tone. Resting PP was greater in Stroke compared to Young (units - mm Hg; Young: 35±10; Old: 45±13; CSVD: 40±10; Stroke: 47±14; P=.035); whereas, we observed a non-significant group trend in baseline pulsatility index (PI) (units - ratio; Young: 0.89±0.12; Old: 0.92±0.16; CSVD: 0.93±0.15; Stroke: 1.06±0.23; P=.07). We did not observe group differences for the change in PI during exercise (P=.37). There were, however, group differences in the regulatory mechanisms underlying PI. Notably, group differences existed relating to the influence of RAP (P<.001) and CrCP (P<.001) on PI (Figure 1). These findings suggest hypertensive hemodynamic stresses during moderate intensity exercise do not present heightened risk for cerebrovascular patients. The mechanisms involved in regulating pulsatile hemodynamics, however, may vary with aging and cerebrovascular disease. Future non-linear time series analysis is warranted.

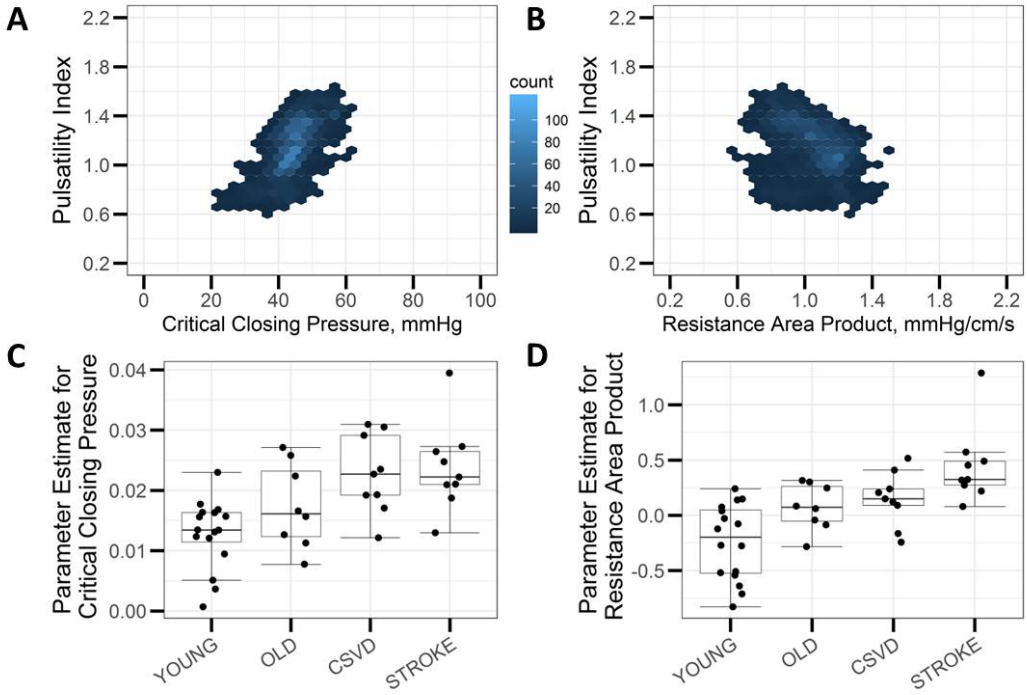

Figure 1. Scatterplots showing how middle cerebral artery pulsatility relates to critical closing pressure (A) and resistance area product (B) in a representative young participant. Group comparison of parameter estimates relating the independent effect of critical closing pressure (C) and resistance area product (D) on pulsatility index.

Title: Localized optogenetic stimulation and label-free imaging of neuronal cell activation

Authors: ***C. HU**, R. SAM, M. WANG, M. GILLETTE, P. SENGUPTA, G. POPESCU
Beckman Inst. for Advanced Sci. and Technol., Univ. of Illinois at Urbana-Champaign, Urbana, IL

Abstract: Imaging activation of cells typically requires exogenous fluorescent labels or sensors that change their properties when cells are activated. These sensors are either genetically encoded or delivered to the cells using a vehicle that that can pass through the plasma membrane. This process of labeling cells is often slow, tedious and inefficient. Additionally, it limits the reach of activity imaging in living cells as these sensors interfere with cellular pathways and are often toxic. In this study, we present a novel optical imaging system that enables label-free noncontact detection of neuronal cell activation induced by spatially-localized optogenetic stimulation of cells. We used transient transfection to express channelrhodopsin-2 (ChR2) in cells that enabled cell activation with a short pulse of blue light. We built a white-light Diffraction Phase Microscopy (wDPM) setup as an add-on module upon a commercial bright field microscope. By coupling a projector at the reflection port, this system allows spatially-resolved optical stimulation on specific cells in the field of view. For our experiments, we differentiated PC12 cells into neuronal lineage using nerve growth factor (NGF). Differentiated cells developed networks with neighboring cells when cultured in this fashion. We recorded wDPM videos from ChR2 transfected PC12 cell networks under three different conditions: no stimulation, blue (~460 nm) and red (~ 650 nm) light stimulation, in this order. For the control group, non-transfected networks were also subjected to the same stimulation conditions. Using the data outputted by our label-free method, we studied intracellular transport. Our experimental results indicate that ChR2 positive PC12 cell networks show enhanced mass transport after blue light stimulation, compared with red light stimulation, no stimulation and non-transfected cells.

To the best of our knowledge, this is the first demonstration of label-free imaging of cell activation with optogenetic stimulation.

Title: Murine cell and layer-specific distribution abnormalities in the hippocampus following trauma

Authors: ***Y. LEE**[1], M. E. KANDEL[2], S. JOUNG[3], I. UZCANGA[5], J. DE JESUS ASTACIO[6], C. BEST[4]
[1]Neurosci., Univ. of Illinois Urbana-Champaign, Urbana, IL; [2]Electrical and Computer Engin., Univ. of Illinois At Urbana-Champaign, Champaign, IL; [4]Dept. of Bioengineering, [3]Univ. of Illinois Urbana Champaign, Champaign, IL; [5]Inst. Tecnologico de Santo Domingo(INTEC), Santo Domingo, Dominican Republic; [6]Univ. of Puerto Rico, Mayaguez, Dominican Republic

Abstract: The hippocampus, a seahorse-shaped region of the brain, is responsible for emotions, learning, and memory. Compared to the rest of the brain, the hippocampus along with other mesial temporal structures is selectively vulnerable to Traumatic Brain Injury (TBI). This explains why memory impairment is one of the leading residual TBI-induced deficits and why forgetfulness is among the most frequent complaints heard from TBI patients and their relatives. The hippocampus has a characteristic anatomical organization comprised of multiple distinct areas and their respective layers, including the dentate gyrus (DG), Cornu Ammonis (CA3, CA2, CA1), subiculum (Sub), and entorhinal cortex (EC). Each region is composed of different cell types, distribution patterns and varied regional wiring. Here, we examine experimental trauma-induced hippocampal architectural alterations, and provide a detailed quantification of cellular and neurite morphology, fiber orientation, tomographic volumes and connectivity changes associated with trauma. The experimental trauma model is an adopted fluid percussion Instrument (Model FP301) injury model that supplies a reproducible impact. We visualize and quantify trauma-induced layer-specific and rostral to caudal structural shifts in stained and cleared *ex vivo*, and *in situ* hippocampi via light sheet microscopy (Carl zeiss Light sheet Z1 and Zen lite imaging software), and Spatial Light Interference Microscopy (SLIM) (Zeiss Axiovert, ImageJ and in-house software).

Title: Neural structure and dynamics using halo-free phase-sensitive microscopy

Authors: ***G. POPESCU**[1], M. KANDEL[1], S. JOUNG[2], C. A. POPESCU[2]
[1]Univ. of Illinois At Urbana-Champaign, Urbana, IL; [2]Bioengineering, UIUC, Urbana, IL

Abstract: Although phase contrast is extremely sensitive among transmitted light modalities, features of interest such as neurons near cell bodies are often obscured by a strong “halo” artifact, perturbing quantitative analysis. Recent advances in modeling image formation in common-path interferometers have shown that this artifact is due to the coherent addition of many waves at the image plane - and the halo effect arises due to the limited spatial coherence of the illumination. Thus, microscope manufacturers face an unfortunate trade-off between high detail (incoherent) and low detail (coherent) optimized systems. In this work, we propose a method to break this dichotomy, by carefully mixing corrupt low-frequency data corresponding to the outline of the cell with high-fidelity intracellular details in a way that completely preserves the quantitative nature of the high-frequency content. Specifically, we propose a digital filtering technique for quantitative phase images that is deterministic, requires no manual interaction or point spread function measurements and operates at video rates. To validate our technique we study the time evolution of adherent neuron cultures whose neurites were obscured by the halo artifact.

Abstract: Traumatic Brain Injury (TBI) may cause severe neuronal damage, alterations in cerebral blood flow and metabolism, and ultimately consequent long-term cognitive and memory deficits, disturbances in mood and behavior, as well as impairments in motor coordination. Thus, TBI represents an important healthcare concern with an estimated 5.3 Million Americans living with a TBI-related disability. Additionally, TBI is a contributing factor in a third (30.5%) of all injury-related deaths in the United States. Despite more than 50 clinical trials, and at least 30 proposed pharmacological compounds, there have been few advances in TBI patient management over the last twenty years. Here, we study two therapeutic approaches, *Docosahexaenoic Acid* (*DHA*, 25 μM and 50 μM) treatment and *Therapeutic Hypothermia* (TH, 24^0C, 34^0C, and 37^0C), and we investigate their relative effectiveness as neuroprotectants in a neuronal cell trauma model of TBI. DHA treatment and TH are thought to limit and prevent the secondary pathological effects of TBI following the initial acute stage neural trauma caused by the mechanical forces of impact. The mechanisms of action of both DHA and TH include the regulation of physicochemical properties such as neural membrane fluidity, permeability and viscosity in synaptic membranes; the modulation of neurotransmission, gene expression, and activities of enzymes, receptors and ion channels. These processes are closely associated with activation of signaling pathways that sustain synaptic function and neuronal survival via limiting oxidative stress, inflammation and apoptosis. Using a standard cell survival assay, trypan blue, and in combination with a novel quantitative form of microscopy Spatial Light Interference Microscopy (SLIM), Dispersion-Relation Spectroscopy, a cell trauma device (AMScien Instruments), an Arduino based temperature regulator, and *in vitro* murine neuronal cell cultures, we characterize and quantify DHA and TH-induced changes in cell survival, neuronal structural integrity (neurite length and width, and number of branch points), membrane dynamics (transport

rates) after cell culture exposure to mechanical impact (2.5 and 5atm). We show that *DHA* (25 μM) and TH (24^0C, 34^0C) impart significant neuroprotection in our cell trauma model.

Title: Gradient light interference microscopy (GLIM) for label-free imaging of acute brain slices

Authors: *M. E. KANDEL[1], G. N. KOUZEHGARANI[2], M. U. GILLETTE[2], G. POPESCU[1]

Abstract: Turbid structures such as acute brain slices are difficult to image with visible light, as incoherent contributions from out of focus planes obscure the sample. To improve the contrast of a conventional patch clamp setup, we construct an add-on module capable of introducing four controlled phase shifts between the laterally sheared beams in DIC. Our interferometer, referred to as GLIM, enables us to record phase maps, which implicitly cancel background contributions from out of focus planes. The resulting phase map is a relief style image that can be used to assay quantitative microscopy parameters such as mass transport or cell growth. GLIM is presented as a fully automated add-on to a conventional DIC microscope performing the interferometric reconstruction at video rates. Here we show our early work on characterizing the transport phenomena in acute brain slices over comparably long periods of times that would be otherwise difficult to achieve using conventional techniques.

Abstract: Glioblastoma Multiforme (GBM) is a common and hyper aggressive brain cancer which has a median survival time of 12 to 15 months after diagnosis. Typical treatment includes partial resection, followed by a combination of radiotherapy and chemotherapy in an attempt to kill the remaining cancerous cells. A primary characterization of this tumor is a high inflammatory response that is aided by a hypoxic environment the growing tumor creates. In combination with this high inflammatory response, the tumor's aggressive, expansive, and random nature, it extremely unlikely to eradicate the whole tumor. The aim of this study is to examine the effects that a newly emerged family of synthetic carbon nanoparticles, known as dendrimers, has on the Glioma 261 mouse and F98 rat cell line *in vitro.* Mesenchymal stem cells, neuronal stem cells and primary cortical neurons derived from mouse were used as control cells to also observe the particles effects on non-cancerous cells. Confocal images were also taken of these cell lines to observe the pattern and distribution of the dendrimer after it is taken up. These dendrimers, which are 3-dimentional and can have different surface groups, have exhibited many unique properties, such as anti-inflammatory properties. To be able to thoroughly study the effects of the dendrimer, we used a modified fourth generation that was comprised of 90% OH

(neutral) groups and 10% NH_2 (cationic) groups, which is approximately 4nm in diameter. Two compositions of the same dendrimer were used in two different experiments; the first composition of dendrimer with the FITC fluorescent marker attached to the NH_2 groups, while the other composition lacked the FITC marker. The first experiment conducted was to introduce the two compositions of dendrimers into a cell culture of the respective cells to observe the effects it has on cell proliferation and adhesion. The second experiment was administering an MTT assay on the two cancer cell lines and the control cell lines previously listed to assess the mitochondrial metabolism and if the effects were significant enough to reduce the viability of the cells. The findings showed that both compositions had negative effects on the cells while in culture, and showed a significant reduction of tumor cell viability in the MTT assay.

Title: Restoring large scale brain activity and consciousness with vagus nerve stimulation

Authors: *A. SIRIGU[1], M. CORAZZOL[1], G. LIO[1], A. LEFEVRE[1,2], N. ANDRÉ-OBADIA[2], P. BOURDILLON[2], J. LUAUTE[2], M. GUENOT[2]

Abstract: Vegetative state is a severe disorder of consciousness characterized by a disruption in thalamo-cortical ascending pathway and fronto-parietal functions. We hypothesized that stimulation of the vagus nerve a neural pathway which provides bodily inputs to the brain and is widely distributed throughout the CNS, promotes the return of consciousness. We investigated the effects of chronic VNS in a patient in a vegetative state since 15 years. Within four weeks after VNS, the patient's ability to respond to and follow external stimulation increased and his state transitioned from vegetative to minimally conscious as assessed by standard coma tests. Importantly, VNS induced improvements in consciousness were correlated to several brain measures of sub-cortical and cortical activity. A significant increase of information sharing, a

measure previously identified as a sensitive index of consciousness, was observed after VNS over a parietal region within a cluster including the right centrotemporooccipital electrodes. Interestingly, this improvement in cortical communication overlapped within regions previously identified as hot zones for consciousness. Our study demonstrates the therapeutic potential of VNS to modulate large-scale human brain activity and alleviate disorders of consciousness.

Title: Repeat concussive TBI and prevention by paclitaxel is characterized by imaging biomarkers with pathologic confirmation in mice

Authors: *C. G. CROSS[1], J. S. MEABON[2], M. M. CLINE[2], M. A. OSTLIE[1], D. G. COOK[2], D. J. CROSS[1], S. MINOSHIMA[1]
[1]Univ. of Utah, Salt Lake City, UT; [2]VA Puget Sound, Seattle, WA

Abstract: Introduction
We previously showed that intranasal paclitaxel (PTX) was neuroprotective for cognitive deficits in repeat concussive brain injury (rcTBI). PET and MR imaging have been proposed as biomarkers to evaluate rcTBI clinically. In this study, we hypothesized that imaging could be used in mice to characterize rcTBI as well as response to therapeutic intervention by paclitaxel.
Methods
Intranasal PTX (0.6 mg/kg; n=6) or saline (SAL) (n=9) was administered only after the first repeat concussive controlled cortical impact (rcCCI) in a series of one impact/day for five days (n=15) or sham rcCCI (n=8). Diffusion tensor imaging (DTI), T1-weighted (T1W) and T2-maps were acquired on 14T high res MR scanner at 9 days post rcCCI. Fractional anisotropy (FA) was compared using manual ROIs as well as FSL tract-based spatial statistics (TBSS). Glucose metabolism was assed via SUV corrected 18F-flurodeoxyglucose (FDG) PET imaging as a biomarker for synaptic activity at 35 days. At 45 days, brains were evaluated for pathologic evidence of axonal injury (silver stain) and synaptic loss (PSD-95) in the external capsule and hippocampus respectively.
Results
FA in the external capsule was decreased in SAL-rcCCI by 17% compared to SHAM (0.21±0.01 vs 0.25±0.01, $p \leq 0.05$) and extensive areas of white matter injury were seen by TBSS. However, PTX-rcCCI was not significantly different from SHAM or SAL-rcCCI with either analysis. With

silver stain, axonal degeneration was seen in cortical white matter of the external capsule in 5/6 SAL-rcCCI but not PTX-treated (n=0/5). A single, dystrophic axon was observed in 1/8 shams. T1W and T2 images revealed focal abnormalities in the cortex below area of repeat impact in all SAL-rcCCI mice that were not apparent in PTX-rcCCI. SAL-rcCCI showed significantly decreased brain FDG uptake, which was "normalized" in PTX mice. Whole brain SUVs, were 120.5±30.1, 90.3±18.7 and 129.2±23.0, for SHAM, SAL- and PTX-rcCCI respectively, $p \leq 0.05$. In SAL-rcCCI, hippocampal PSD-95 immunofluorescence was reduced compared to both SHAM and PTX.

Conclusion

Paclitaxel prevented alterations in white matter structure and glucose metabolism from rcCCI that were detected by both MRI and PET imaging modalities. However, only FDG-PET confirmed that PTX resulted in improvement when pathology indicated both synaptic loss AND axonal injury were prevented with PTX. DTI may not be sensitive enough or may have more inherent variability to detect treatment-related benefit in rcTBI. Further research is needed to distinguish these factors.

Abstract: Rett syndrome is a rare neurological disorder associated with a mutation in the X-linked gene MECP2. This disorder mostly affects females, who typically have normal early development followed by a regression of skills. The recently developed MeCP2 transgenic rat

model exhibits symptoms commonly observed in of Rett syndrome patients, including seizures, breathing abnormalities, motor abnormalities, anxiety, and communication deficits. Extensive behavioral therapy can improve language, cognitive, and social functioning for individuals with autism. More recently, behavioral training in Rett Syndrome patients also provided improvements in cognitive performance. Insulin-like growth factor 1 (IGF-1) therapy has also been successfully utilized in both human clinical trials and in rodent models, with improvements in apnea, anxiety, and restoration of plasticity deficits. We first sought to characterize the ability of MeCP2 heterozygous (Het) rats to perform a complex speech discrimination task and a skilled motor task. Mecp2 and WT rats were trained to discriminate human speech sounds (i.e., /dad/ v. /bad/) in quiet and in various levels of background noise. Additionally, rats were also trained on a skilled lever press task to evaluate motor learning. Preliminary data indicates behavioral impairments in both the perceptual and motor tasks. As expected, MeCP2 rats also exhibit atypical social and anxiety behaviors compared to WT littermates.
Ongoing experiments are directed at investigating whether behavioral therapy and/or IGF-1 therapy can improve the observed deficits in perceptual, motor, and cognitive function. These studies may lead to the development of novel therapies to improve the quality of life of Rett syndrome patients.

Title: Mechanisms of VNS-induced extinction enhancement and PTSD symptom reduction in rats

Authors: *L. J. NOBLE[1], J. E. CHILDS[2], A. V. CHUAH[2], V. B. MERUVA[2], S. KROENER[3], C. K. MCINTYRE[4]
[1]Univ. of Texas At Dallas, Dallas, TX; [3]Sch. of Behavioral and Brain Sci., [4]Sch. Behav and Brain Sci., [2]Univ. of Texas at Dallas, Richardson, TX

Abstract: Posttraumatic stress disorder (PTSD) can develop following a traumatic event. Symptoms of PTSD include hypervigilance, avoidance, and increased anxiety. Exposure therapy is a form of cognitive behavioral therapy that is commonly used to treat these symptoms. During exposure therapy, patients are repeatedly exposed to cues that remind them of the trauma until they learn healthier responses to those cues. However, PTSD patients show impairments in extinction learning, which may increase dropout and nonresponse rates. Adjuncts to exposure therapy could be utilized to enhance its effectiveness by promoting successful extinction learning and accelerating the course of treatment. Vagus nerve stimulation (VNS) is an FDA-approved treatment for the prevention of seizures. VNS shows promise as an adjunct for exposure therapy because it enhances memory consolidation in rats and in humans, and we recently found that pairing VNS with unreinforced exposures to a conditioned stimulus enhanced extinction learning and protected against relapse in the extinction-resistant single prolonged stress (SPS) rat model of PTSD. Furthermore, we found that administration of VNS during extinction led to subsequent elimination of PTSD-like symptoms one week later. These results indicate that extinction impairments contribute to general symptoms of PTSD and, therefore, treatments that promote successful extinction should produce benefits that reach beyond the cue-induced fear. Alternatively, VNS may generally reduce symptoms of fear, arousal, and anxiety. The current studies are designed to examine the mechanisms by which VNS enhances extinction of conditioned fear, and reduces PTSD-like symptoms in rats subjected to SPS. Unpaired administration of VNS in the homecage prior to elevated plus maze testing increased time spent in open arms, and this effect was attenuated by peripheral administration of methylscopolamine, a muscarinic antagonist that does not cross the blood brain barrier, indicating that VNS alone produces an anxiolytic effect that depends on peripheral parasympathetic effects. However, methylscopolamine did not interfere with VNS enhancement of extinction. These results indicate that VNS-induced extinction enhancement does not depend on peripheral vagal activation. Rats subjected to SPS show alterations in synaptic plasticity in the pathway from the medial prefrontal cortex to the basolateral complex of the amygdala. Current studies are aimed at elucidating the mechanisms by which VNS acts within the central nervous system to enhance extinction and alleviate PTSD-like symptoms in rats.

Title: Pairing vagus nerve stimulation with motor training to enhance motor recovery after stroke: Effects of parametric variations of stimulation intensity

Authors: *D. PRUITT[1], ***D. PRUITT**[1], T. DANAPHONGSE[2], M. LUTCHMAN[2], R. L. RENNAKER[2], M. P. KILGARD[2], S. A. HAYS[2]

Abstract: Stroke is a leading cause of long-term disability. Currently, there are no effective rehabilitative therapies for chronic stroke patients. Previously, we have determined that pairing vagus nerve stimulation (VNS) with motor training enhances recovery of motor function is multiple models of stroke. VNS provides a new therapeutic avenue to treat patients suffering from a stroke, but it is necessary to investigate what stimulation parameters provide the optimal benefit. In this study, we tested multiple intensities of VNS paired with motor training to determine the stimulation intensity that is most effective at enhancing functional recovery. We trained animals on a supination task. After proficient at the task, animals received an ischemic stroke with endothelin-1 (ET-1). Animals then continued motor training while receiving VNS at an intensity of 0.4 mA, 0.8 mA, 1.6 mA, or no VNS at all. We found that VNS was successful at enhancing motor recovery, and we expand upon the effects of each stimulation intensity on motor recovery.

Title: Optimizing vagus nerve stimulation paired with rehabilitation to enhance recovery following spinal cord injury

Authors: ***M. DARROW**[1,5], A. D. RUIZ[2], P. D. GANZER[3], L. BARRON[6], A. BERRY[6], M. BILAL[6], R. L. RENNAKER[7], M. P. KILGARD[4], S. A. HAYS[3]
[1]Texas Biomed. Device Center/Bioengineering, Univ. of Texas At Dallas, Plano, TX; [2]Texas Biomed. Device Ctr., [3]Bioengineering, [4]Behavioral and Brain Sci., Univ. of Texas At Dallas, Richardson, TX; [5]Texas Biomed. Device Ctr., Richardson, TX; [6]The Univ. of Texas at Dallas, Richardson, TX; [7]ECSS3.907, UT Dallas, Richardson, TX

Abstract: There are approximately 17,000 cases of spinal cord injury (SCI) each year in the United States. Despite extensive rehabilitation, most patients are left with chronic impairments in motor function. Therapeutic interventions to improve recovery of function after SCI are needed. Recent evidence suggests that repeatedly pairing vagus nerve stimulation (VNS) with rehabilitation can drive plasticity in motor circuitry in the central nervous system and enhance forelimb recovery in models of neurological injury and disease. However, little is known about the optimal delivery strategy for this potential therapy. We evaluated the capacity of four distinct VNS delivery paradigms to enhance motor recovery in a model of SCI. Rats were trained on the isometric pull task, an automated, quantitative measure of forelimb strength. Animals received a right side cervical spinal contusion at level C5/C6 to impair function of the trained forelimb. Starting on the sixth week post-injury, animals were assigned to balanced treatment groups to receive either rehabilitative training without stimulation (Rehab), equivalent rehabilitative training in which VNS was paired with forelimb movement on trials with the strongest sixth of pull forces(VNS + 17% Best Rehab), equivalent rehabilitative training in which VNS was paired with forelimb movement on every trial independent of pull force (VNS + 100% Rehab), equivalent rehabilitative training in which VNS was paired with forelimb movement on trials with the weakest sixth of pull forces(VNS + 17% Worst Rehab), or equivalent rehabilitative training in which VNS was paired with forelimb movement on trials with the strongest sixth of pull forces but delayed 2 seconds (VNS + 17% Best Rehab Delayed). Forelimb function was evaluated over the course of six weeks of rehabilitative training. Rats were then placed in their home cage and returned for an additional week of behavioral testing four weeks later to allow assessment of lasting effects. At the completion of forelimb testing, all animals underwent intracortical microstimulation motor mapping. The VNS + 17% Best Rehab, VNS + 100% Rehab, and VNS + 17% Best Rehab Delayed paradigms improve motor recovery beyond rehabilitation alone. Also, VNS + 17% Worst Rehab is not better than Rehab and is significantly worse than the other groups receiving VNS. Preliminary ICMS data indicates that enhanced plasticity in motor cortex is associated with improved recovery of function. Consistent with our previous studies, VNS delivered during rehabilitation enhances motor recovery after SCI. Ongoing studies are directed at evaluating the stability and generalizability of VNS-dependent benefits.

Abstract: Long-term impairment of hand function is a common consequence following peripheral nerve injury. Insufficient plasticity in central networks has been implicated in poor recovery. Here we tested the hypothesis that enhancing central plasticity could improve recovery after forelimb nerve injury. We utilized a targeted plasticity therapy consisting of short bursts of vagus nerve stimulation (VNS) paired with rehabilitative training following median and ulnar nerve transection and repair. Subjects receiving VNS paired with rehabilitation displayed significantly increased forelimb strength and improved mechanosensation compared to subjects receiving a matched amount of rehabilitative training without VNS. Physiological and anatomical studies revealed that pairing VNS with rehabilitation increased functional connectivity in descending motor networks. Furthermore, a matched amount of VNS delivered after daily rehabilitation sessions failed to improve recovery or enhance plasticity. VNS did not affect the morphology of the injured nerves suggesting that peripheral nerve changes did not mediate recovery. Finally, disrupting the cortical cholinergic system blocked the plasticity enhancing effects and the improved recovery observed in paired VNS subjects. Together, these findings highlight the importance of plasticity in recovery after peripheral nerve injury and suggest that strategies to enhance plasticity may provide an additional avenue to improve sensory and motor recovery.

Title: Identification of axon growth promoting small molecules using a high throughput phenotypic assay exploiting hiPSC derived human sensory, motor and cortical neurons

Authors: *B. SINGH, T. HO, Y.-C. CHENG, J. MERCIER, C. J. WOOLF
FM Kirby Neurobio. center, Boston Children's Hosp. Harvard Med. Sch., Boston, MA

Abstract: Central nervous system (CNS) injuries are debilitating and lead to permanent disability because of the limited growth of axons after injury, attributable both to a lack of an intrinsic growth capacity and presence of extrinsic growth inhibitory cues. Previous preclinical screens for compounds to promote axonal growth in the CNS using heterologous expression systems have not translated to the clinic because the assay does not recapitulate the natural molecular architecture of neurons or their post-translational state. Similarly, mouse primary neurons are difficult to generate in sufficient numbers for high throughput screening (HTS) and they have large variances in axonal growth, making screening problematic (low Z').
We have generated standardized protocols to differentiate sensory, motor and cortical neurons from hiPSCs and also have developed a robust, sensitive and reproducible phenotypic neurite outgrowth assay (Z'>0.5) that recapitulate PNS and CNS specific growth phenotypes *in vitro.* This provides us with a means to screen for regeneration-promoting compounds in a high throughput mode. We are currently screening a diverse annotated bioactive compound libraries (>3,000 compounds) for neurite outgrowth promotion in human sensory, motor and cortical neurons on permissive (laminin) and inhibitory (CSPG and myelin) substrates. Neurite outgrowth and neuronal survival is measured using the Thermo Cellomics Arrayscan XTI following exposure to test compounds. We have achieved a Z'>0.5 using Y-27632 (Rock inhibitor) for cortical neurons on myelin and BDNF for sensory neurons on laminin, as positive controls. Positive hits will be classified as any compound that results in neurite outgrowth levels significantly higher than DMSO controls ($p<0.05$). Once we identify hits, we will execute target identification by deconvolution, and then target validation using CRISPR KO or overexpression, as the first stage towards identifying targets suitable for developing novel therapeutics to treat CNS and PNS injuries.
We will identify targets involved in promoting growth of CNS neurons in an inhibitory environment and growth of PNS neurons in a permissive environment. These will represent the foundation for further studies; test activity in primary rodent neurons and in models of spinal cord and peripheral nerve injury; conduct target based HTS. The combination of stem cell technology enabling differentiation of defined human neurons combined with high content screening capacity offers an opportunity for a transformative change in regeneration target identification - one that is both unbiased and human focused. This work is supported by Adelson foundation.

Abstract: Traumatic brain injury (TBI) is a leading cause of death and disability. The majority of therapeutic strategies has failed in clinical trials and was attributed to the heterogeneous pathophysiology. Recently, multimodality treatments have been considered to be an area of promising future endeavors. Transcranial magnetic stimulation (TMS) has been shown as a promising noninvasive therapeutic intervention for neuropathological diseases, stroke, as well as TBI (Lu H et al., 2015; Shin SS and Pelled G, 2017). Nevertheless, we demonstrated that pairing TMS with another mode of stimulation may augment its long-lasting effect (Banerjee et al., 2017). Since environmental enrichment (EE) was shown to improve motor and memory function, we tested if TMS paired with EE will facilitate recovery to a greater degree compared to each of the modalities alone. We subjected rats to controlled cortical impact, and then assigned them to one of the four groups: 1. no further treatments (TBI), 2. environmental enrichment after injury (TBI-EE), 3. TMS for 1 week after injury (TBI-TMS), and 4. TMS and environmental enrichment (TBI-TMS-EE). Rats receiving EE were housed in a communal cage with various stimuli such as toys and ladders. The TMS group had 10Hz repetitive TMS over 7 days. Functional outcomes were assessed at short term (7 days) and long term (6 weeks) by a battery of sensory and motor tests: primary somatosensory cortex local field potential (LFP), bicep motor evoked potential (MEP) assessed by electromyography, and beam walk test as well as challenge ladder test. At short term, TBI-TMS and TBI-TMS-EE groups had significantly LFP amplitudes compared to TBI and TBI-EE groups ($P<0.05$). Additionally, TBI-TMS-EE group had significantly improved performance on beam walk test compared to TBI group ($P<0.001$). However, no differences were detected by MEP. To investigate the long term effect of multimodality treatment, TBI-TMS-EE group was compared to TBI-TMS group at 6 weeks. There was significantly improved performance in challenge ladder by the TBI-TMS-EE group compared to TBI-TMS group ($P<0.01$). Additionally, there was higher somatosensory cortex

LFP amplitude (P<0.05) as well as MEP (P<0.05) in TBI-TMS-EE group compared to TBI-TMS group. When the rats from both groups were compared using evoked-functional MRI (fMRI) to a forepaw stimulation, TBI-TMS-EE group had higher number of activated pixels (P<0.01). This study explored the idea of combining a noninvasive magnetic stimulation with rehabilitative training in an EE. We demonstrate here for the first time that combined therapy using TMS and EE enhances both motor and sensory function following TBI compared to TMS or EE alone.

Title: Novel non-viral knockdown strategies targeting retinoblastoma protein for rescue and regeneration of peripheral axons

Authors: *K. ZUBKOW[1], T. M. POITRAS[1], A. CHANDRASEKHAR[1], D. W. ZOCHODNE[2]

Abstract: Retinoblastoma protein (Rb1) is a tumor suppressor protein that acts as a cell cycle inhibitor through its interaction with the transcription factor E2F. In previous work (Christie, Krishan et al., Nat Commun, 2014), we identified its expression in peripheral sensory neurons and the impact of its knockdown on regeneration. In the adult peripheral nervous system, tumor suppressor proteins such as Rb1 hinder neuroplasticity, a disadvantage when regeneration and rescue of neurons and axons is critical. Here we addressed whether two novel strategies for non-viral siRNA delivery in two differing models of peripheral nerve damage had the ability to enhance recovery. In the first paradigm, we assessed whether delayed local Rb1 siRNA delivery to the hindpaw using an electroporation protocol might confer pro-regeneration benefits following a nerve crush injury. The protocol was associated with robust knockdown of Rb1 in ipsilateral dorsal root ganglia (DRG) sensory neurons, indicating an impact of the siRNA through retrograde transport. The second model was a chronic model of diabetic neuropathy induced by streptozotocin injection and persistent hyperglycemia over 3 months. Rb1 was knocked down in lumbar DRGs by intranasal administration. Both studies used male CD1 mice,

mechanical and thermal sensory testing, and electrophysiological testing. Two weeks after sciatic nerve crush, mice received a total of 8 hindpaw injections with local electroporation of either Rb1 or control scrambled sequence siRNAs over 2 weeks. 28 days following injury, motor conduction velocities in Rb1 siRNA-treated mice, but not controls given scrambled siRNA, showed recovery to pre-injury levels indicating more rapid maturation of regenerating myelinated motor axons. There was also preliminary evidence of greater recovery of thermal and mechanical sensation in mice given Rb1 siRNA. In diabetic mice with neuropathy, those treated with Rb1-targeted siRNA had higher motor and sensory conduction velocities at endpoint, comparable to values in non-diabetics. Rb1, but not scrambled, siRNA appeared to restore thermal sensitivity to baseline levels. Suppression of Rb1 may enhance plasticity and functional recovery of thermal sensitivity and nerve conduction velocity in models of peripheral nerve damage. While our preliminary findings require additional investigation, we note that novel forms of siRNA delivery may offer important benefits.

Title: Cellular dynamics in adult dorsal root ganglia

Authors: *A. KRISHNAN[1], D. W. ZOCHODNE[2]
[1]Neurosci and Mental Hlth. Inst., and Div. of Neur, Edmonton, AB, Canada; [2]Neurosci. and Mental Hlth. Institute, and Div. of Neurol., Edmonton, AB, Canada

Abstract: The identity, fate and role of the wider repertoire of perineuronal cells in dorsal root ganglia (DRG), other than satellite glial cells (SGCs), are largely unexplored. Here we examine dynamic cycling in DRGs of adult rats with or without remote axotomy injuries. We employed a well known marker of DNA turnover, ki67 and incorporation of Brdu to characterize cycling populations, emphasizing 3 day axotomized DRGs in SD rats. Brdu was given intraperitoneally immediately, then two days later following sciatic nerve transection. Cellular characterization was done using immunohistochemistry. As expected both ki67 and Brdu marked a subpopulation of $GFAP^+$ cells indicating SGC turnover, and that this turnover is enhanced after axotomy. Strikingly, they also marked selected cells of the $Iba1^+$ or $ED1^+$ macrophage population, indicating unappreciated local turnover of these populations. A striking observation was the

presence of the stem cell/dedifferentiation marker sox2 in perineuronal satellite cells. Sox2 was highly expressed in a majority of SGCs, irrespective of the cell cycle status, but was also colocalized to a smaller group of $Iba1^+$ or $ED1^+$ cells. A small proportion of sox2 expressing cells also co-expressed Brdu or ki67 indicating that they are actively cycling. We noted intimate contact between SGCs and macrophages in axotomized DRGs after 3 days of sciatic nerve transection. A time course analysis, post transection, showed that SGC activation precedes macrophage contact, rendering it unlikely that there is an initiating role for macrophages on SGC activation. However, *in vitro* co-culture of axotomy primed neurons, SGCs and macrophages identified macrophages wrapping around areas of neuronal debris indicating phagocytosis. Overall, the injured DRG perineuronal milieu favors multi-lineage cellular turnover, some of which involves sox2 and, involving SGCs and macrophages. Additionally, macrophages may play an important role in scavenging byproducts from rapid turnover of cells in the DRGs post axotomy. [Supported by CIHR]

Title: Conditioning with botulinum toxin enhances motor axon regrowth in mouse and human models of injury

Authors: *C. K. FRANZ[1], L. JORDAN[1], J. A. ORTEGA[2], E. KISKINIS[3], C. HECKMAN[4]
[1]Physical Med. and Rehabil., Shirley Ryan Abilitylab, Chicago, IL; [2]Neurol., [3]Neurol. and Physiol., [4]Dept. of Physiol., Northwestern Univ., Chicago, IL

Abstract: Peripheral axon regeneration is improved when the nerve lesion under consideration has recently been preceded by another nerve injury. This is known as the conditioning lesion effect (CLE). While the CLE is one of the most well robust and well characterized means to enhance motor axon regeneration in experimental models, it is not considered a clinically feasible strategy. It is likely that the mechanism of the CLE is related to acute denervation changes. Therefore, we decided to test whether chemo-denervation with an FDA approved formulation of botulinum toxin A (BoTX-A) would be sufficient to reproduce the CLE with the goal of eventual clinical application. We examined the effects of a 1-week pre-conditioning administration of BoTX-A on motor axon regrowth in both a mouse tibial nerve injury and human stem cell-based model. We assessed axon regeneration in vivo (mice) with retrograde

tracers and histological analysis of peripheral nerve tissue after injections into the triceps surae muscle group. We assessed motor neurite outgrowth in vitro (human) by dissociation and re-plating stem cell-derived motor neurons for morphometric analysis. We found that BoTX-A conditioning treatment significantly enhanced outgrowth of motor axons/neurites in both our mouse and human models, which supports further preclinical development of this novel approach to enhance motor axon regeneration.

Title: Activation of TRPV1 receptors improves the regenerative capacity of adult sensory neurons

Authors: *T. M. POITRAS[1], A. CHANDRASEKHAR[1], L. MCCOY[1], C. A. WEBBER[2], D. W. ZOCHODNE[3]
[2]Div. of Anat., [3]Med. and Neurol., [1]Univ. of Alberta, Edmonton, AB, Canada

Abstract: The influx of calcium generated by activation of TRPV1 neuron channels is generally linked to toxic axonal degeneration. However, subtoxic rises in axonal calcium, such as that generated by extracellular electrical stimulation paradigms, may be supportive of axon growth, and intracellular calcium gradients are known to influence growth cone behaviour. Here we asked whether subtoxic TRPV1 activation influenced the growth properties of adult sensory neurons and sensory axon regeneration after injury. TRPV1 activation through high dose (1 mM) capsaicin exposure of dissociated adult sensory neurons from rats rendered expected neuronal death and axon retraction. However, lower doses (10-100 µM) enhanced neurite outgrowth. Using calcium imaging, we confirmed that this degree of activation was associated with heightened calcium flux within neurons. We next tested whether or not a similar relationship between TRV1 activation and regeneration exists *in vivo.* We used a high sciatic crush mouse model, immediately followed by a single application of either a low (200uM) or high (2mM) dose of capsaicin directly to the site injury. At 28 days following injury and capsaicin, the low dose group showed a more rapid recovery of thermal but not mechanical sensation compared to vehicle treated controls. There were no significant improvements in animals treated with higher doses but instead we observed a further decline in sensory nerve conduction velocity. There was

no impact on sensory conduction velocity after low dose exposure and injury and neither dose improved motor function. Taken together, TRPV1 activation by sub-toxic doses of capsaicin causes increases in neuronal calcium influx, enhanced regeneration of injured sensory neurons, and improved behavioural recovery similar to that observed with paradigms of extracellular electrical stimulation.

Title: Electrical stimulation as a conditioning lesion for promoting peripheral nerve regeneration

Authors: *K. CHAN[1], J. L. SENGER[2], J. L. OLSON[2], C. A. WEBBER[3]
[1]Univ. Alberta, Edmonton, AB, Canada; [2]Surgery, [3]Div. of Anat., Univ. of Alberta, Edmonton, AB, Canada

Abstract: The beneficial effects of a preinjury crush conditioning lesion (CL) on peripheral nerve regeneration have been well-documented in animal models. Despite, that, no human studies have been attempted to date. Principle reasons are the ethical dilemma of deliberately injuring an intact nerve and the difficulty in predicting the timing of a nerve injury. Recent studies demonstrated that 1 hour of electrical stimulation (ES) produces effects similar to CL in neuronal cultures. This, coupled with the increasing use of nerve transfers, in which an intact nerve is deliberately cut to reinnervate a denervated muscle, means that ES may be clinically translatable to enhance regeneration. This study hypothesizes that ES prior to nerve injury will enhance nerve regeneration. Twenty-Four Sprague-Dawley rats were divided into four groups of 6 based on conditioning-type to the common peroneal (CP) nerve: ES, crush, sham-ES, and naïve. One week following conditioning, they underwent a cut/coaptation of the CP nerve at the sciatic trifurcation. On post-cut day 14, nerves and dorsal root ganglia (DRGs) were collected. Axonal counts of nerves stained with NF-200 revealed similar lengths of regeneration between ES and crush (4.2±0.6 mm vs. 4.3±0.4 mm, $p=0.66$) that were superior to sham-stimulation (1.2±0.4 mm) and naïve (1.1±0.3 mm, $p<0.05$). A greater number of axons at the distal tip were present in animals that received either ES or crush conditioning compared to the unconditioned

cohorts. To evaluate mechanisms, DRGs were stained with neuronal injury marker growth associated factor-43 (GAP-43), and satellite glial cells with glial fibrillary acidic protein (GFAP). Significant increase in GAP-43 expression at three days was observed in ES and crush cohorts compared to sham or naïve ($p<0.001$). The satellite glial cells of ES and crush conditioning showed a significant increase in GFAP expression (29.3% and 39.3% respectively) compared to sham (8.6%) and naïve (13.5%) DRGs. By demonstrating similar improvements in axon regeneration, this proof of principle study suggests that ES conditioning may produce regenerative outcomes comparable to the crush injury model. This would open the possibility of testing ES for conditioning lesion like effects in clinical trials prior to nerve surgery to enhance nerve regeneration.

Title: A novel local FK506 delivery system enhances axon regeneration

Authors: *K. TAJDARAN[1], K. CHAN[2], M. S. SHOICHET[3], T. GORDON[4], G. H. BORSCHEL[5]
[1]Univ. of Toronto/Sickkids Hosp., North York, ON, Canada; [2]Chan, [3]Chem. Engin. and Applied Chem., Univ. of Toronto, Toronto, ON, Canada; [4]Dept of Surgery, Div. of Plastic Reconstructive Surgery, Hosp. for Sick Children, Toronto, ON, Canada; [5]Plastic and Reconstructive Surgery, The Hosp. For Sick Children, Toronto, ON, Canada

Abstract: Purpose: Administration of FK506, an FDA approved immunosuppressant, has shown to enhance nerve regeneration following peripheral nerve injuries. However, the severe side effects of the systemically delivered FK506 has prevented clinicians from using this drug routinely. Therefore, we have developed a novel fibrin gel based local delivery system for FK506. In this study, we analyzed the effectiveness of the FK506 local delivery system to promote axon regeneration. In addition, we analyzed FK506 transport to the surrounding tissues, *in vivo*, from the delivery system at the nerve injury site. **Methods:** FK506 was incorporated into fibrin gel in solubilized, particulated or poly(lactic-*co*-glycolic) acid microspheres-encapsulated forms. A rat nerve transection model was used, where the proximal tibial nerve stump was cross-sutured to the distal stump of a cut common peroneal nerve. Rats in the negative control groups either did not receive any delivery system treatment or received fibrin gel with empty microspheres. The experimental groups included rats treated with fibrin gel loaded with the three forms of FK506 formulation. Three weeks after repair, nerve regeneration was assessed using

retrograde labeling and histomorphometric analysis. Using mass spectrometry, FK506 tissue concentrations were analyzed at the site of the nerve injury, in sciatic nerve, dorsal root ganglia (DRGs), spinal cord, brain, heart, liver, kidney, and plasma at 7, 14, and 28 days post repair. **Results**: Rats in experimental groups receiving FK506-loaded microspheres and the particulated FK506 had significantly highest number of motor and sensory neurons that regenerated their axons and allowing *all* tibial motoneurons regeneration. Histomorphometric analysis indicated increased number of myelinated axons following particulated FK506 and FK506 microspheres treatment compared to the negative control groups. The most prolonged period of FK506 *in vivo* release at the site of nerve injury was seen with the PLGA microsphere-encapsulated form for 28-days. The highest FK506 tissue concentration was detected within the entire spinal cord at day 7 regardless of the delivery system formulation. FK506 was also found at the nerve injury site, sciatic nerve, DRGs, and the gluteal muscles, decreasing in concentration over time, with little to no drug detection in other vital organs. **Conclusion**: The local application of FK506 via our proposed delivery systems resulted in excellent axon regeneration while minimizing the toxicity of systemic FK506 that has prevented clinicians from using FK506 routinely for treating severe cases of peripheral nerve injuries.

Title: MRI tracking of Gadoteridol-labeled mesenchymal stem cells in a spinal cord injury murine model

Authors: *M. M. BOIDO[1], M. FILIPPI[2], C. PASQUINO[3], F. GARELLO[2], C. BOFFA[2], E. TERRENO[2]
[1]Univ. of Turin, Orbassano (TO), Italy; [2]Mol. and Preclinical Imaging Ctr., Torino, Italy; [3]Mol. Biotech. Ctr., Torino, Italy

Abstract: Mesenchymal Stem Cells (MSCs) are multipotent stromal cells, able to deliver neurotrophic, anti-inflammatory and immunomodulatory molecules: for these reasons, their effects are exploited for the treatment of a multitude of pathologies, including neurodegenerative diseases and traumatic CNS lesions. In case of spinal cord injury (SCI), the regrowth of severed axons is limited, but cell therapy can promote circuit repair, reorganization and axonal sprouting.

Imaging-supported in vivo cell tracking provides a reliable method to assess the characteristics of cell grafts and to monitor the cell growth/movement after transplantation. In this study, murine MSCs were labeled with the clinically approved MRI agent Gadoteridol through a procedure based on the hypo-osmotic shock (hypo-MSCs), in order to be tracked in vivo in a murine model of SCI. Moreover in vitro and in vivo analysis have been performed to evaluate cell viability, proliferation and surface marker expression of MSCs. With respect to iso-osmotic incubations, the hypo-osmotic labeling did not alter the biological and functional profile of MSCs in vitro, but significantly increased the Gadoteridol cellular uptake. In vivo imaging on SCI mice revealed a substantial T1 contrast enhancement after transplantation of 300,000 labeled MSCs, enabling to circumscribe their spinal distribution and to follow their migratory dynamics for about 10 days. Histological validation of in vivo data corroborated the imaging results, highlighting the opportunity to perform a precise and reliable monitoring of the cell-based therapy. Finally, animals treated with labeled MSCs were monitored by behavioral tests and showed motor improvements, confirming the unaltered therapeutic efficacy of hypo-MSCs. Our results suggest that the presented cell labeling procedure is endowed with high efficacy and clinical translatability, and could possibly be beneficial for stem cell-based medical protocols required in tissue repair.

Title: Modeling epidural spinal cord stimulation to predict paraplegic patients' responses and identify critical features of the electrical activity

Authors: *E. R. FELDMAN, Y. SUI, J. W. BURDICK
Computing and Mathematical Sci., Caltech, Pasadena, CA

Abstract: Spinal cord stimulation (SCS) applied by multi-electrode epidural arrays implanted over the lumbosacral spinal cord has enabled paraplegics to stand and regain partial motor control. This work links computational SCS models to experimental data obtained by testing

paraplegic subjects' standing performance under various stimuli. Machine learning techniques applied to the dataset and simulation results isolate stimulation characteristics associated with good empirical motor recovery via SCS. These results may help to clarify some of the mechanisms underlying the success of SCS and to suggest new methods to guide the selection of effective stimuli for each patient.

The standing skill of two paraplegic subjects implanted with 16-electrode epidural implants was tested in response to 90 and 117 different stimuli respectively over two non-consecutive weeks. Using a volume conductor model of the spinal cord, we calculated by finite element analysis the electric field and current densities that should occur within the spinal tissues under each experimentally-tested stimulus. We constructed a set of features from the average values of the voltage amplitude, gradient, and Hessian in tissue voxel grids of several granularities. Via random forest and elastic net regression, we show that these features can predict the subjects' empirical responses. We also applied feature selection methodology to identify the features most correlated with, and that most likely influenced, the subject responses.

We find that the key electric field features are anatomically structured (see figure) and agree with neural activation theory. Further analysis, using a novel feature selection approach, highlights groups of spinal tissue locations that may be co-activated during effective posture control. Finally, we show that Gaussian process regression can effectively model a probability distribution on the performance of candidate stimuli, allowing more informative performance prediction for untested stimuli. This result could help clinicians identify stimuli with a high probability of success.

Title: Cortex-dependent recovery of unassisted hindlimb locomotion after complete spinal cord injury in adult rats

Authors: *K. A. MOXON[1,2], G. FOFFANI[3], P. D. GANZER[4], V. BRACCHI-RICARD[2], J. R. BETHEA[2], A. MANOHAR[2]
[1]Biomed. Engin., Univ. of California Davis, Davis, CA; [2]Drexel Univ., Philadelphia, PA; [3]Hosp. Nacional De Parapléjicos, Toledo, Spain; [4]Bioengineering, Univ. of Texas At Dallas, Richardson, TX

Abstract: After paralysing spinal cord injury the adult nervous system has little ability to "heal" spinal connections, and it is assumed to be unable to develop extra-spinal recovery strategies to bypass the lesion. We challenge this assumption, showing that completely spinalized adult rats can recover unassisted hindlimb weight support and locomotion without explicit spinal transmission of motor commands through the lesion. This recovery is achieved with combinations of pharmacological and physical therapies that maximize cortical reorganization, inducing an expansion of trunk motor cortex and forepaw sensory cortex into the deafferented hindlimb cortex. This cortical reorganization is characterized by altered levels of proteins associated with synaptic plasticity supported by astrocyte function, and sprouting of corticospinal axons. Lesioning the reorganized cortex reverses the recovery. Adult rats can thus develop a novel cortical sensorimotor circuit that bypasses the lesion, likely through biomechanical coupling, to partly recover unassisted hindlimb locomotion after complete spinal cord injury. These results demonstrate the importance of plasticity along the entire neural axis to optimize recovery of function.

Title: Stretch-induced activation of muscles paralyzed by spinal cord injury

Authors: *C. K. THOMAS, L. MONTOYA, K. GANT
Miami Proj Cure Paralysis, Univ. of Miami Sch. of Med., Miami, FL

Abstract: Many people with spinal cord injury (SCI) report that repeated, sustained passive stretch is an effective way to manage muscle spasms because the stretch triggers spasms then reduces them. Physical therapists often use this stretch approach to manage contractures. Our aim was to examine how paralyzed muscles (under no voluntary control) respond to repeated, sustained passive stretch by recording surface electromyographic (EMG) signals (vastus lateralis, hamstrings, tibialis anterior, medial gastrocnemius, soleus) and joint angles (knee, ankle) during experimenter-induced passive stretch of the four muscle groups (10 static stretches, each held for 30 seconds, release, 15 seconds rest between stretches). The recordings were repeated on a different day but without stretch. Data were compared to results obtained from uninjured (control) subjects. Most muscles responded to the changes in muscle length (lengthening or shortening). The EMG responses were usually stronger in SCI participants, particularly during the rest phase, suggesting a lack of inhibition. The EMG responses occurred with each stretch, without habituation, and spread to arm and hand muscles in SCI individuals. Thus, repeated stretch of muscles is an effective way to exercise paralyzed muscles. Contraction intensity was not related to the maximal soleus H-reflex to M-wave ratio, suggesting that small diameter afferents, not necessarily Ia afferents, underlie the muscle responses to stretch.

Title: Robotic upper-limb assessment of bilateral asymmetries after spinal cord injury

Authors: *A. WILSON[1,2], Y. LEI[1,2], M. A. PEREZ[1,2]
[1]Dept. of Neurolog. Surgery, The Miami Project to Cure Paralysis, Univ. of Miami, Miami, FL; [2]Bruce W. Carter Dept. of Veterans Affairs Med. Ctr., Miami, FL

Abstract: Cervical spinal cord injury (SCI) in humans largely damages both sides of the spinal cord resulting in asymmetrical impairments in arm function (Oxland et al., 2010; Calabro and Perez, 2016). The purpose of our study was to use the Kinesiological Instrument for Normal and Altered Reaching Movement (KINARM) exoskeleton device to assess asymmetries in upper-limb function in individuals with chronic incomplete cervical SCI. Maximum isometric voluntary contraction (MVC) was quantified in upper-limb muscles including the first dorsal interosseous, abductor pollicis brevis, extensor and flexor digitorum communis, biceps and triceps brachii and anterior and posterior deltoid to determine the stronger and weaker arm in SCI participants. Using the KINARM arm position matching task we quantified the systematic shift between the passive and active hands, the spatial contraction/expansion area of the active hand relative to the passive hand, and trial-to-trial variability of the active hands end position between trials. While all variables were affected in SCI participants compared with control subjects, we found that the systematic shift was the variable that better reflected asymmetries in MVC between the arms of SCI subjects (controls: right arm= 4.3±2.1 cm, left arm=2.8±1.2 cm; SCI: weaker arm=7.1±2.1 cm, stronger arm=6.5±2.3 cm). Our findings suggest that the KINARM can effectively detect functional asymmetries in upper-limb function in humans with chronic SCI. This new assessment tool may increase the sensitivity of current upper-limb clinical assessment following SCI.

Abstract: Spasticity is one of the most common symptoms in humans with spinal cord injury (SCI). The neurophysiological and behavioral outcomes related to its clinical assessment, however, remain poorly understood. Here, we examined the Modified Ashworth Scale (MAS; a gold standard clinical assessment of spasticity), Wartenberg's Pendulum Test, and the H-reflex (H-max) and maximal motor response (M-max) in the quadriceps muscle in individuals with SCI who had residual voluntary activity (incomplete SCI, n=18) and in those unable to voluntarily activate muscles below the level of injury (complete SCI, n=18). We found that the MAS was higher in individuals with incomplete (2.34±1.15, $p<0.001$) compared with complete (0.76±0.74) SCI. The H-max and M-max were larger in individuals with incomplete compared with complete SCI and control subjects. The knee joint angular velocity was less pronounced in individuals with incomplete compared with complete SCI, suggesting that individuals with incomplete SCI had more pronounced spasticity. To further understand the physiological mechanisms contributing to spasticity in individuals with complete SCI who showed spasticity (MAS=3) and no spasticity (MAS=0) we examined the integrity of the corticospinal pathway by using transcranial magnetic and electrical stimulation over the leg motor cortex and measuring motor evoked potentials (MEPs) in the quadriceps muscle. Notably, we found that MEPs elicited by magnetic and electrical stimulation were present in individuals with complete SCI who had severe spasticity but absent in individuals with complete SCI without spasticity. Altogether our results suggest that transmission in the corticospinal pathway contributes to spasticity in humans with chronic incomplete SCI.

Title: GLP-1 receptor agonist enhances the ER stress response and improves functional recovery after spinal cord injury in a rat model

Authors: *S. NOMURA[1], H. KATOH[2], S. YANAGISAWA[2], T. IMAI[3], M. KUROIWA[4], M. WATANABE[2]
[1]Dpt of Orthopaedic Surgery, Tokai Univ. Sch. of Med., Isehara, Kanagawa, Japan; [2]Tokai Univ., Kanagawa, Japan; [3]Dept. of Orthopaedic Surgery Tokai Universit, Isehara/Kanagawa, Japan; [4]Tokai Univ. Sch. of Med., Kanagawa, Japan

Abstract: After spinal cord injury (SCI), oligodendrocyte precursor cells (OPC) residing in the spinal cord have been shown to actively proliferate, but many these cells succumb to apoptosis instead of differentiating into functional oligodendrocytes. One of the factors involved in neural cell apoptosis is endoplasmic reticulum (ER) stress, which arises from the accumulation of misfolded proteins in the ER. We previously reported that enhancing the ER stress response by administering amiloride improved OPC survival and differentiation, enhanced remyelination, and improved hind limb motor and sensory dysfunction.
Glucagon-like peptide-1 (GLP-1) receptor agonists, which are used in the treatment of type 2 diabetes, have recently been shown to exhibit neuroprotective effects and to decrease ER stress. The aim of this study is to examine the effect of the GLP-1 receptor agonist exenatide on the ER stress response in the injured spinal cord and on functional recovery.
A moderate contusive SCI was induced in 10-week-old female Sprague-Dawley rats using an IH-impactor (200 Kdyne). The GLP-1 group received subcutaneous injections of 10 μg exenatide immediately after and 7 days after SCI, while the control group received no treatment. Blood glucose levels were monitored and hind limb motor function was evaluated using the BBB score. At 1, 3, 7, and 14 days after SCI, spinal cords were excised (n=5 per group) and the expression of GRP78, which acts to decrease ER stress, and CHOP, which induces apoptosis in response to severe ER stress, were examined using Western blot.
Blood glucose levels rose sharply immediately after SCI and then gradually descended to approximately 100 mg/dl by 12 hours after SCI. No significant difference was observed between the two groups, and hypoglycemia was not observed in the GLP-1 group. Western blot revealed a significant increase in GRP78 expression on Day 3 ($p<0.01$), and a significant decrease in CHOP expression on Day 14 ($p<0.05$) in the GFP1 group compared to the control group. BBB scores revealed significantly higher motor scores in the GLP-1 group from day 7 and later ($p<0.01$).
Our results show that administration of the GLP-1 receptor agonist exenatide decreased ER stress and led to significant improvement of hind limb motor function. Since GLP-1 receptor agonists are in clinical use with other documented characteristics that would potentially be beneficial to the recovery after SCI, we believe that GLP-1 receptor agonists are a very promising candidate for the pharmacological treatment of SCI.

Title: Gene therapy to alleviate hyperreflexia after spinal cord injury

Authors: C. A. BENSON, M. HILL, S. LIU, F. DIB-HAJJ, S. G. WAXMAN, S. DIB-HAJJ, *A. M. TAN
Neurol., Yale University/VA Connecticut Healthcare Syst., West Haven, CT

Abstract: Spasticity is a symptom of *hyperexcitability* within the spinal stretch reflex system (e.g., H-reflex), and is a frequently observed secondary impairment following spinal cord injury (SCI) and other insults to the CNS. Spasticity generally presents as a velocity-dependent increase in muscle tone and uncontrolled, repetitive, involuntary contractions of skeletal muscles. Despite its prevalence and negative impact on quality-of-life, spasticity is only incompletely understood and represents and unmet medical need. Conventional anti-spasticity drugs, such as baclofen, can provide relief of spastic symptoms, but have significant limitations. In contrast, the availability of viral-mediated gene manipulation in the nervous system offers three distinct advantages: 1) increased target tissue specificity, 2) reduced off-target effects, and 3) prolonged therapeutic efficacy.
Over the past decade, we have gathered a large body of evidence demonstrating a strong correlation between abnormal dendritic spine morphology and hyperexcitability disorders associated with SCI, i.e., neuropathic pain and spasticity. Dendritic spine changes associated with pain or a loss of H-reflex rate-dependent depression (RDD) indicative of spasticity, include 1) an increase in spine density, 2) a redistribution of spines to regions closer to the cell body, and 3) an increase in dendritic spine head surface area. Collectively, our findings support the premise that dendritic spine dysgenesis serves as a morphological correlate to understand and address spasticity following SCI. We have recently identified the Rac1-Pak1 molecular pathway as a potential candidate for pharmacological intervention.
Here we will present our data in developing a novel gene therapy to elucidate the abnormal

cellular mechanisms that underlie H-reflex circuit hyperexcitability. Our data show that intramuscular delivery of an adeno-associated virus (AAV) targeting Rac1 expression infects motor neurons of the spinal cord and permits fluorescent image analysis of dendritic spine dysgenesis. Using EMG recordings, we show that viral-mediated treatment appears to reduce hyperexcitability in the stretch reflex system. This preclinical study is in-progress with an overall objective of deconstructing the mechanisms underlying spasticity at the circuit-level within the injured spinal cord.

Title: Recovery of sensory-motor integration after dorsal rhizotomy and repair with platelet-rich plasma (PRP)

Authors: *M. V. DE CASTRO, B. B. VOLPE, Â. C. M. LUZO, A. L. R. OLIVEIRA
Univ. of Campinas (UNICAMP), Campinas, Brazil

Abstract: Motor coordination involves specific neural processes ranging from the perception of stimuli to the achievement of the response, being dependent on delicate sensory-motor integration, which is particularly evident in the spinal cord. Spinal root injuries can lead to motor, sensibility and autonomic losses. This type of lesion constitutes a significant medical problem and usually affects the brachial plexus in consequence of high energy trauma. However, due to the possibility of generating further inflammation and neuropathic pain, surgical procedures do not prioritize the repair of the afferent component. In this context, new therapies need to be developed for dorsal root repair. A promising treatment would be the use of platelet-rich plasma (PRP). Nowadays, PRP is used in a wide range of surgical procedures, and there are several scientific studies demonstrating benefits in treating various types of injuries. Therefore, to investigate the effectiveness of PRP as adhesive and inductive element for nerve regeneration, adult female Lewis rats (LEW/HsdUnib; n=5 per group) were subjected to unilateral rhizotomy

(RZ) of the L4–L6 dorsal roots and divided into two groups: (1) RZ without repair; (2) RZ followed by root repair with PRP (RZ+PRP). The reflex arc recovery was evaluated daily through the electronic von-Frey method, during eight weeks, while the expression of VGLUT1 (vesicular glutamate transporter 1), GFAP (astrocyte marker) and Iba-1 (microglial marker), was evaluated in the spinal cord by immunofluorescence, eight weeks after lesion. Taken together, our results indicate that PRP is efficient to repair transected spinal roots, restoring the reflex of paw withdrawal, without signs of allodynia (8th-week post-lesion*: RZ+PRP= 65.13% better than RZ*). Also, the use of PRP for this type of injury allowed the reentrance of primary afferents within the spinal cord and did not exacerbate the glial reactivity, promoting the restoration of spinal circuits. We believe that our results will serve as a basis for the use of PRP in accelerating nerve regeneration and may contribute to the future clinical use of this therapeutic approach, fulfilling a critical gap in reparative procedures after this type of injury.

Title: Therapeutic targeting of Pak1 signaling alleviates neuropathic pain after traumatic 2nd degree burn injury

Authors: Y.-Q. GUO[1], *P. EFFRAIM[2,3], C. BENSON[1], S. HENRY[1], S. G. WAXMAN[4], S. D. DIB-HAJJ[5], A. M. TAN[6]
[1]Neurol., Yale Univ., West Haven, CT; [2]Yale Univ. Sch. of Med., West Haven, CT; [3]VA Connecticut Healthcare Syst., West Haven, CT; [4]Neurol., Yale University, Neurosci. and Regeneration Res. Ctr., West Haven, CT; [5]Neurol., Yale Sch. of Med., West Haven, CT; [6]Neurol., Yale University/VA Connecticut Healthcare Syst., West Haven, CT

Abstract: Across the globe, 11 million individuals per year require medical treatment due to severe burn injuries. However, chronic intractable pain that arises following cutaneous burn trauma is rarely studied in preclinical models. To investigate mechanisms related to burn-injury neuropathic pain, we developed a highly-reproducible model in mice, which produces persistent

pain. In this model, histological assessment of the burned glabrous skin of the hind paw confirmed that the procedure results in a 2nd degree burn-injury that fully penetrates the epidermis and portions of the dermis. Within three days after burn injury, mice exhibit significant mechanical allodynia and heat hyperalgesia that persists for up to 4 weeks. Dendritic spine dysgenesis, a morphological correlate of nociceptive hyperexcitability and neuropathic pain, appeared within the intermediate zone of the dorsal horn. In addition, we observed an increase in the ipsilateral expression of c-fos, GFAP (astrogliosis), and Iba1 (microgliosis). Our previous work has implicated a role for the Rac1 molecular signaling pathway in dendritic spine dysgenesis underlying neuropathic pain in several models of neuropathic pain, including SCI, peripheral nerve injury, and diabetic neuropathy. Rac1 belongs to the Ras superfamily, a class of GTPases which are generally considered poor clinical targets due to their complex intracellular dynamics. To accelerate translation of our preclinical findings, we sought to establish a proof-of-principle that targeting Pak1, a downstream effector of Rac1, can disrupt abnormal dendritic spine remodeling and alleviate neuropathic pain symptoms. FK228 (romidepsin) at 0.1-1nM concentrations significantly reduces PAK1 kinase activity. Our interim data in our model of burn injury demonstrate that systemic administration of romidepsin can downregulate expression of p-raf1, a Pak1 effector target, reduce the degree of dendritic spine dysgenesis, and partially rescue thermal or mechanical pain thresholds. Finally, we observed a significant decrease in burn-injury induced c-fos and GFAP expression ipsilateral to the side of the burn following romidepsin treatment. Taken together, our findings merit further investigations of Pak1 signaling as a potential molecular target for therapeutic intervention in traumatic burn-injury induced neuropathic pain.

Title: Effects of injury-induced histamine release on fibroblasts and the extracellular matrix in peripheral nerves

Authors: *J. RAUCH, M. ANEX-SCHNAUSS, C. GILL, J. CASTORINO
Hampshire Col., Amherst, MA

Abstract: Histamine secreted by mast cells promotes fibrosis by increasing type I collagen production and inducing fibroblast proliferation and migration. Peripheral nerve fibroblasts share many of the same characteristics as fibroblasts in these tissues; therefore, histamine may affect peripheral nerve fibroblasts in a similar way. The aim of this experiment was to study the effect of histamine on collagen, fibronectin, laminin, and transforming growth factor-β; mRNA expression in 3T3 fibroblasts and to determine a role for histamine in peripheral nerve regeneration following injury. NIH-3T3 fibroblasts were starved in medium containing 1% DBS and DMEM for 36 hours, prior to induction for 12 hours with 2% DBS and DMEM ± 10^{-4} M histamine. Total RNA extractions and qRT-PCR were performed to determine mRNA expression. Our results show that histamine-treatment increased Col1a1 (p = 0.158), Fn1 (p = 0.222), and Lamb1 (p = 0.048) mRNA expression and decreased Tgfb1 (p = 0.360) mRNA expression in 3T3 fibroblasts. No significant difference in fibroblast number was observed between control and histamine-treated cultures. Furthermore, adult rat sciatic nerves were cultured over a confluent layer of 3T3 fibroblasts and completely transected with or without histamine. After 5 days of live tissue imaging, nerves were fixed, stained with collagen type I alpha 1 chain and laminin subunit beta 1 primary antibodies, and imaged by fluorescence microscopy. We show nerve outgrowth over the course of 5 days and demonstrate differences in ECM matrix deposition between histamine-treated and control nerves. The observed significant upregulation of LAMβ;1 mRNA expression in response to histamine is a novel finding. Contrary to previous research, our data indicates that histamine has no significant effect on cell number and type I collagen production. Furthermore, our results provide additional evidence that the histamine released by mast cell activation plays a critical role during peripheral nerve injury.

Title: Bidirectional paired-associative synaptic plasticity at spinal motoneurons

Authors: *A. YAMASHITA
Neurorehabilitation Res. Institute, Morinomiya, Osaka-Shi, Japan

Abstract: Introduction: Paired-associative stimulation (PAS), repeated transcranial magnetic stimulation (TMS) pairing with electrical peripheral nerve stimulation (ES), leads to synaptic plasticity at the cortical level. The direction and magnitudes of induced plasticity are dependent on interstimulus intervals. Here we investigated synaptic plasticity at spinal motoneurons (SMs) using a modified PAS protocol, named as SM-PAS.

Methods: Eleven right-handed healthy volunteers participated in this study. Motor-evoked potentials (MEPs) were recorded from right first dorsal interosseous muscle (FDI). Peripheral ES was delivered on right ulnar nerve at the wrist, and stimulus intensity was set at supramaximal intensity. TMS was applied over the left primary motor cortex (M1) hand area, and stimulus intensity was set at 120% resting motor threshold for the right FDI. We measured TMS-evoked MEP and F-wave latencies in each subject and calculated difference in latencies to determine an appropriate timing which overlaps TMS-induced descending volleys with ES-induced antidromic inputs at the SM synapses. We performed SM-PAS (180 pairs at 0.2 Hz) at different intervals of TMS and ES pairing. For evaluating corticospinal-motoneuronal synaptic excitability, single-pulse TMS was delivered at cervicomedullary junction level during brief contraction of the right FDI, and cervicomedullary MEP (CMEP) was recorded from the right FDI before and after SM-PAS every 10min for 1 hour. Cortical MEP by TMS of the left M1 hand area, compound muscle action potential (CMAP) and F-waves by ulnar nerve stimulation were also measured from right FDI.
Results: When the interval was set at the timing at which antidromic inputs in the motoneurons axons reached the neurons just before the corticospinal descending volley arrived at the presynaptic terminal, SM-PAS facilitated CMEPs for 60 min. Inversely, SM-PAS reduced CMEPs for 60 min when antidromic inputs reached the postsynaptic terminal 9 ms after the descending volleys arrival. MEP tend to increase after facilitatory SM-PAS, but this effect was not statistically significant. F/M ratio remained unchanged after SM-PAS.
Discussion: Here we successfully induced the synaptic plasticity at the corticospinal-motoneuronal synapses by applying SM-PAS. The direction and magnitudes of induced plasticity are in line with spike-timing dependent plasticity rule. Lack of significant increase of cortical MEP after SM-PAS may reflect homeostatic compensatory changes in cortical excitability to cancel out the altered spinal excitability.

Title: Semaphorin3A inhibits axon regeneration after trigeminal nerve transection

Authors: *H. KANEMARU[1], K. SEO[2], Y. YAMADA[3], A. OHAZAMA[4], T. MAEDA[5]
[1]Div. of Dent. Anesthesiol., Niigata Univ., Niigata-city, Japan; [2]Niigata Univ. Grad Sch., Niigata 951-8514, Japan; [3]Dent. Anesthesiol., Grad. Sch. of Niigata Univ., Niigata, Japan; [4]Div. of Oral Anat., Niigata Univ. Grad. Sch. of Med. and Dent. Sci., NIigata, Japan; [5]Ctr. for Advanced Oral Sci., Niigata Univ. Grad Sch. Med. Dent., Niigata-shi, Japan

Abstract: [Introduction]
Semaphorin 3A (Sema 3A) is one of secreted proteins involved in axonal guidance during embryo as well as in regeneration of spinal cord injury after birth and detrimental. Although the expression of Sema 3A has been found in human neuroma after spinal nerve injury (Tannemaat 2007), functional significance of Sema 3A remains unclear in detail during the peripheral nerve regeneration.
[Aims]
The present study examined a chronological change in expression of Sema 3A in the injured lesion after inferior alveolar nerve (IAN) transection to reveal its roles in the process of peripheral nerve regeneration.
[Material and methods]
This study used a nerve injury model using male C57BL6 mice (7~8 weeks) as we have previously reported. Briefly, under deep anesthesia by 4% chloral hydrate, after the masseter muscle was tone to expose the surface of the mandible, its bone was removed by a dental drill to expose the IAN. Then, IAN was cut at distal site of mandibular formation.
(1) Expression of Sema 3A; mice were allowed to survived for 1, 3, 7, 14 days after the operation, and they were perfused with fixative. Cryostat sections of the IAN were processed for Sema 3A immunohistochemistry (antibody ab23393) with by TSA amplify Kit.
(2) Immunohistochemical observation of effects by Sema 3A antagonist; either antibody to Sema 3A or vehicle (physiological saline) was locally administered to the legion at postoperative day (PO) 1 and 2. Animals were perfused with fixative at PO3. Cryostat sections were immunostained with an antibody to PGP9.5, a general marker for nerve fibers, to examine the regeneration lesion.
(3) Retrograde tracer study on effect of Sema 3A antagonist; Either Fluoro-Gold or DiI was injected to the mental area prior to IAN cut and at PO5, respectively. At PO7, the expression of the tracers was observed in the trigeminal ganglion.
[Results]
(1) Sema 3A expression was detectable only at the medial site of the IAN lesion. This expression could be found at PO1, but it decreased at PO3. No expression appeared after PO7.
(2) The vehicle control animals demonstrated widely-randomized axon sprouting from the medial bulb of the transected IAN at PO3. However, Sema 3A antagonist suppressed such axon sprouting.
The animals administrated with Sema 3A antagonist appeared to exhibit more FG expression in the trigeminal ganglion, suggesting an acceleration of axon regeneration.
[Conclusion]
Immunoexpression of Sema 3A was recognizable at the medial site of the damaged nerve immediately after the injury, and thereafter diminished. It is implicated that Sem 3A contributes

to inhibit axon regeneration only at the early stage of nerve regeneration.

Title: Axon regeneration promoted by signaling of the unfolded protein response in peripheral nerve injury

Authors: *Y. OHTAKE[1,2], A. SAITO[2], K. IMAIZUMI[1]
[1]Dept. of Biochem., [2]Dept. of Stress Protein Processing, Hiroshima Univ., Hiroshima-Shi, Japan

Abstract: The endoplasmic reticulum (ER) has a dynamic interconnected network responsible for maintaining cellular homeostasis including local calcium ion concentration, lipid metabolism and protein synthesis. Multiple cellular malfunctions such as disturbance of calcium ion homeostasis and expression of mutated proteins perturb ER functions. The abnormalities are known as ER stress. The three major ER stress transducers IRE1, PERK and ATF6 recognize ER stress, followed by transducing signals to activate protein quality control system and avoid cellular damages. This signaling pathway is referred to as unfolded protein response (UPR). The UPR is involved not only in ER homeostasis but also in regulating biological functions. Recent studies indicate that the UPR is activated in response to axonal injury, suggesting the prospective association of the UPR derived from the developed axonal ER network with axon regeneration and degeneration. In this study, we investigated the mechanisms for inducing ER stress in response to axon injury and the roles of UPR in regulating axon regeneration in sensory neurons. To assess the effect of the UPR signaling on axon regrowth, we used axotomized neurons of mouse dorsal root ganglion (DRG) at embryonic day 13 and a mouse model of sciatic nerve crush. The phosphorylation levels of IRE1 and PERK were up-regulated in primary cultured DRG after axonal injury. The inhibition of calcium ion release from ER by 2-APB and dantrolene reduced the phosphorylation of those transducers. These data suggest that at least one of the underlying factors for the activation of UPR after the injury is calcium ion release from ER and its depletion in axonal ER lumen. We observed the activation of IRE1 and PERK in distal sites of axons in response to sciatic nerve crush. The attenuation of those was exhibited by the pre-treatment of axons with 2-APB and dantrolene after sciatic nerve crush, consistent with those in primary cultured DRG neurons. Axonal regrowth of primary cultured DRG neurons and sciatic nerve was reduced by the pre-treatment of axons with specific inhibitors of ER stress

transducers. We found that the blocking of UPR signaling by the inhibitors of ER stress transducers promoted the ER fragmentation in distal axons. Consequently, axonal injury-induced UPR signaling at an axonal segment has a potential to promote axon regeneration through the proper manipulation of axonal ER dynamics, that could maintain the ER functions and the integral ER-derived signaling pathways for eliciting the regeneration.

Title: GMFb may regulate the Schwann cell repair phenotype after acute and chronic denervation

Authors: *J. SCHEIB[1], A. HOKE[2]
[2]Dept. of Neurol., [1]Johns Hopkins Univ., Baltimore, MD

Abstract: The peripheral nervous system (PNS) has the capability of regenerating over long distances. However, full functional recovery is often limited, especially when the target tissue is far away. After injury, Schwann cells take on a repair cell phenotype, resulting in debris clearance, growth factor secretion, and maintenance of basal lamina tubes to guide axons. In nerve injuries where axons must regenerate long distances, the chronically denervated distal Schwann cells become atrophied and less supportive of regeneration, but the molecular mechanisms of this atrophy are unknown. In this study, we hypothesize that glia maturation factor beta (GMFb), a pro-inflammatory mediator mostly studied in astrocytes, is involved in the repair cell phenotype of Scwhwann cells. Our preliminary data suggest that GMFb expression is increased in rat sciatic nerves after injury, but this upregulation is not maintained after chronic denervation. GMFb overexpression in cultured rat Schwann cells protects them from apoptosis, and may alter debris clearance. We are further analyzing the phenotypic changes of cultured Schwann cells with overexpression of GMFb, and we are using mouse models to study the effects of altered GMFb expression on nerve regeneration in vivo.

Title: 3D printing aligned scaffold immobilizing bioactive cue for neural regeneration

Authors: *W. ZHU[1], F. MASOOD[3], B. T. HARRIS[4], L. ZHANG[2]
[1]Mechanical and Aerospace Engin., [2]Mechanical Engineering, Medicine, and Biomed. Engin., The George Washington Univ., Washington, DC; [3]Mechanical Engin., Univ. of Maryland, Collage Park, MD; [4]Neurol., Georgetown Univ. Med. Ctr., Washington, DC

Abstract: Nerves are ease of getting damaged through disease, trauma, and congenital defects. The self-regenerative capacity of nervous system is extremely limited. Therefore, artificial intervention is usually needed to address most severe nerve injuries. Although the use of autograft (a nerve harvested from a less important site of a patient), presents partially regenerative outcomes, it often leads to complication including donor site morbidity. Tissue engineered scaffolds which involve biomaterials, cells and bioactive cues are showing promise to repair damaged neural tissues with functional recovery. In this present study, we utilized a stereolithography based 3D printing technique to generate novel tissue engineered scaffolds containing highly aligned micro channels for neural regeneration. The printable bioink is composed of natural plant oil based biomaterial which is sustainable and biocompatible. In addition, bioactive cues, such as bFGF (basic fibroblast growth factor) and EGF (epidermal growth factor), were immobilized on the printed scaffolds by polydopamine (PD) in an effort to promote neural cell adhesion, and direct neuronal differentiation. The 3D printed scaffolds we fabricated with varied channel densities and infills demonstrated well-defined highly aligned microstructure. Confocal microscopy images indicate the plant oil based bioink presents exceptional biocompatibility and the high channel densities on the scaffolds aid mesenchymal stem cell growth with aligned orientation. PD coating is able to enhance surface adsorption of protein, improve scaffold hydrophilicity, and promote cell proliferation after 5 day culture. Additionally, neural differentiation of mesenchymal stem cells was observed on bioactive cues immobilized scaffolds. In conclusion, stereolithography based 3D printing technique is able to print aligned scaffolds by using plant oil based biomaterial. By immobilizing bioactive cues, the resultant scaffolds present the capacity in directing cell alignment, promoting cell proliferation and inducing neural differentiation of stem cells, providing great potential for neural tissue engineering applications.

Title: Temporal relationships of behavioral, electrophysiological and pathological outcomes with *In vivo* muscle physiology during motor unit reconnectivity

Authors: *C. G. WIER[1,2], A. R. KNAPP[2], P. L. HEILMAN[2], W. ARNOLD[3], S. J. KOLB[4,2]
[1]Chris Wier, Columbus, OH; [2]Dept. of Biol. Chem. and Pharmacol., Ohio State Univ., Columbus, OH; [3]Neurol., The Ohio State Univ., Columbus, OH; [4]Neurol., The Ohio State Univ. Wexner Med. Ctr., Columbus, OH

Abstract: Background: Peripheral nerve injury (PNI) results in weakness by disrupting the connection of motor axons with muscle fibers. Complete functional recovery of the motor axonal connectivity is rarely achieved in patients with more severe PNI. One critical gap in our current knowledge is the molecular determinants of motor neuron repair. To address this gap, there is a need to have a reliable, comprehensive and longitudinal understanding of motor unit physiology that is paired with behavioral and pathological outcomes. Standard electrophysiological measures such as compound muscle action potential (CMAP) or motor unit number estimation (MUNE) allow tracking of recovery and commonly used in both clinical and preclinical studies. Here we aimed to understand the relationship in recovery between electrophysiological and muscle physiological outcomes.
Objective: To determine the longitudinal relationships between standard peripheral nerve recovery outcome measures and *in vivo* muscle physiology.
Design: Sciatic nerve was performed in adult FVB mice. Behavioral motor assessment (sciatic function index), electrophysiological assessment of motor unit connectivity (CMAP and MUNE), and muscle physiological status (tetanic plantar flexion torque) were monitored longitudinally during recovery. Outcome measures were followed up to 28 days post-injury (28dpi). Pathological characterization of neuromuscular junction (NMJ) reinnervation was performed at 21dpi. Statistical comparison was performed from functional nadir at 7dpi. Correlation between measures was assessed using Pearson correlation coefficient.
Results: At 18 dpi, significant improvement was noted in both CMAP amplitude and the SFI ($p<0.01$). In contrast, MUNE and plantar flexion torque did not show significant improvement until 21dpi ($p<0.05$ and $p<0.01$, respectively). There was good correlation between the plantar flexion torque measurements and both CMAP ($r=0.60$, $p<0.01$) and MUNE ($r=0.62$, $p<0.01$). Quantification of NMJ reinnervation is ongoing.

Conclusion: In our studies, CMAP and behavioral outcomes were able to identify the earliest signs of recovery. In contrast, our findings suggest that assessment of muscle physiology and motor unit electrophysiology may be more effective at identifying persistent neurological deficits in mouse models of nerve injury and repair.

Title: Peripheral nerve repair with magnesium metal filaments providing contact guidance support

Authors: X. AN[1], T. M. HOPKINS[2], J. J. VENNEMEYER[2], A. M. HEILMAN[2], K. J. LITTLE[4], D. B. HOM[3], *S. K. R. PIXLEY[2]

Abstract: To repair peripheral nerves after injuries that cause gaps, optimized biomaterial scaffolds are sought to replace the current gold standard, autografts. To perfect scaffolds, we hypothesized that biodegradable metallic magnesium (Mg) filaments (<1mm diameter), placed inside nerve conduits, would provide contact guidance support for regenerating cells and axons. *Methods:* To determine if this was possible, experimental gaps made in one sciatic nerve of adult Lewis rats were repaired by placing nerve stumps in hollow poly(caprolactone) (PCL, immersion dipped) or silicone conduits. Groups received either a single Mg filament (99.9% Mg, d=250μm) touching both nerve stumps inside a saline filled conduit, a similar titanium (Ti) filament (same d), no filaments (empty, negative controls) or isografts (positive controls). Imaging via microCT was done at 6 weeks to assess Mg degradation, in either tissues or living animals. Animals were sacrificed at 6 weeks for 10 mm gaps and after 14-16 weeks for gaps of 15 mm (supposedly a critical gap length with conduits alone). For all animals, behavioral testing included foot sensory

and motor function tests and measurements of the widest calf circumference to monitor muscle atrophy. At sacrifice, calf muscles were weighed and nerves and conduits were either osmicated or treated with iodine for soft tissue imaging by microCT. Tissues (some after iodine removal) were paraffin or resin embedded and processed for histological and antibody staining. *Results:* Significant gaps were seen in almost all Mg filaments by 6 weeks, with few conditions showing slower degradation, i.e., intact filaments. In all cases, regenerating tissues clearly encapsulated and surrounded Mg filaments, with no signs of necrosis and very low stimulation of macrophages. Improved axon amounts and size (determined by neurofilament 200 protein immunostaining) occurred with Mg filaments and a 10 mm gap, compared to Ti filaments or empty conduits. With longer gaps of 15 mm and after 14-16 weeks, Mg filaments were completely resorbed. Functional improvement and muscle atrophy reversal occurred only with isograft groups, not with Mg or empty conduits. Nerve tissue spanned the gaps in most animals (including empties). No scarring or increased fibrosis was found after Mg degradation was complete. General tissue health was significantly enhanced with Mg over empty conduits, with less inflamed blood vessels. Overall, biodegradable Mg filaments are biocompatible and show promise for providing contact guidance and improving tissue regeneration in peripheral nerve repair.

Title: Two-photon imaging of human neuromuscular junction degradation after traumatic peripheral nerve injury

Authors: *J. P. CHAN, W. A. PALISPIS, O. STEWARD, R. GUPTA
Univ. of California, Irvine, Irvine, CA

Abstract: Introduction: The study of the neuromuscular junction as a model for synaptogenesis as well as other disease states is fundamental in neuroscience. Remarkably there is NO information about the time course and nature of human neuromuscular degeneration. Patients with traumatic peripheral nerve injuries provide a unique opportunity to capture this invaluable data as we sought to provide the novel data about human motor endplate degeneration at the neuromuscular junction (NMJ).
Methods: IRB approval was obtained so as to permit biopsies from denervated muscles in patients with injuries ranging from complete pre-ganglionic C5-T1 brachial plexus injuries to

less severe, but distinct, traumatic nerve injuries. Specimens were processed for immunohistochemistry and visualized with two-photon excitation and confocal microscopy. Human muscle samples from multiple timepoints after injury were analyzed along with control specimens from innervated muscles so as to create a temporal sequence of events for human motor endplate degradation following traumatic nerve injury.
Results: Denervated muscle samples show distinct differences from innervated muscles, including fragmentation and dispersion of acetylcholine receptors. There is also a noted decrease in NMJ volume as seen in 3D reconstruction, and a trend towards plaque endplate morphology. Moreover, comparison of denervated muscles shows signs of temporal degeneration. NMJs from early denervated muscles still show well preserved circular morphology with definite acetylcholine receptors arranged in distinct folding patterns. By one year status post traumatic brachial injury, NMJs begin to present with greater fragmentation. Moreover, synaptic gutters start to fade, and asymmetry in acetylcholine receptor distribution is noted. Interestingly, even after one year of denervation, NMJs were able to retain their overall circular shape.
Conclusion: This study details the novel and critically important qualitative data about the sequence of events involved in human motor endplate degradation after a clearly defined traumatic nerve injury. Surprisingly, human NMJs persist and retain their structures even after the 6-month window of opportunity for meaningful functional recovery has elapsed, which may indicate a limited utility of animal models for traumatic peripheral nerve injuries. This temporal profile highlights the importance of species-specific findings and provides invaluable data that can answer important questions pertaining to the optimal timing of surgical intervention and timing of any adjuvant treatments for peripheral nerve injuries.

Title: Tissue engineered nerve grafts maintain distal pro-regenerative Schwann cells in a rodent model of chronic axotomy

Authors: *D. BROWN[1,2], Z. ALI[2], J. BURRELL[2], K. KATIYAR[2], K. BROWNE[2], D. CULLEN[2]
[1]Neurosurg., [2]Ctr. for Brain Injury and Repair, Dept of Neurosurg., Univ. of Pennsylvania, Philadelphia, PA

Abstract: Peripheral nerve injury (PNI) is a common affliction that affects individuals of all age groups and socioeconomic backgrounds. However, current repair strategies yield limited functional restoration, especially when axon s are tasked with regenerating over long distances that require many months to reach targets. A primary reason for insufficient regeneration involves the breakdown of distal Schwann cells (SCs), the resident glial cells that provide trophic and structural support for regenerating axons. After axotomy and subsequent Wallerian degeneration, distal SCs become temporarily pro-regenerative, but absent regenerating axons and associated molecular cues the chronically denervated SCs lose their pro-regenerative capabilities over several months. To address this need, we are exploring the potential of “satellite” transplants containing living neurons and axonal tracts as a means to integrate with otherwise axotomized SCs and thereby maintain their pro-regenerative capacity. To test this concept, the sciatic nerve was transected and the proximal nerve stump was capped to block regenerating host axons from reaching the distal stump. Custom three-dimensional neuronal/axonal constructs were placed within nerve guidance tubes (NGTs) and implanted in-line with the distal stump either at the time of transection or following a delay of 6 or 10 weeks (negative control animals received a NGT without cells). All animals were euthanized at 16 weeks after the initial transection and the distal nerves were processed for immunohistochemical examination of SC presence and morphology. We found that implants exhibited robust neuronal survival and axonal growth throughout the otherwise axotomized sciatic, tibial, common peroneal, and sural nerves in animals with acute or delayed implants. The presence of TENG axons correlated with increased levels of pro-regenerative SCs in each of the nerves relative to NGT controls, as indicated by SC alignment and immunoreactivity for p75 and S100. The area of pro-regenerative SCs was quantified in fascicles of each nerve, revealing that the effects of neuronal/axonal implants versus NGTs in preserving SCs was most pronounced in the tibial, common peroneal, and sural branches over 3 cm distal to the transection site, indicating that these constructs successfully “babysat” SCs far afield from the implantation site. We are currently coupling this distal SC “babysitting” strategy with additional tissue engineered constructs designed to bridge segmental defects to ascertain the ability of this dual approach to accelerate axonal regeneration and enable functional recovery following currently intractable PNI.

Abstract: mRNA translation is an essential process for successful axon regeneration. This machinery controls local protein synthesis at the injury site and generates newly synthesized proteins in the cell body to promote axon ourgrowth. Although the spatiotemporal protein abundance is determined by a sophisticated coordination of transcriptional levels and translation efficiency, the underlying mechanisms that direct translational regulation of intrinsic growth ability remain unclear. In this study, we examined whether N6-Methyladenosine (m6A), an RNA modification involved in regulating mRNA translation and stability, was involved in axon regeneration. We performed m6A-Seq of naïve and axotomized dorsal root ganglions (DRGs) and found that RNA methylation occurred on a repertoire of regeneration-associated genes (RAGs). Mettl14 is one of the methylases that catalyze the methylation of mRNA. In Mettl14KO mice, the m6A containing transcripts are reduced. Moreover, we revealed an impairment of axon outgrowth upon injury in the DRGs of Mettl14 KO mice. Taken together, our results suggest that m6A may play an important role in the of the regulation of growth capacity and uncover new potential targets for promoting axon regeneration.

Title: Tau induces formation and dysfunction of small diameter capillaries in aged tau P301L mice

Authors: *R. E. BENNETT, A. B. ROBBINS, B. T. HYMAN
Neurol., Massachusetts Gen. Hosp. Dept. of Neurol., Charlestown, MA

Abstract: Alzheimer's disease pathology is characterized by amyloid beta plaques, tau-containing neurofibrillary tangles and neuronal cell death. Mounting evidence indicates that these changes are exacerbated by vascular abnormalities with cerebral amyloid angiopathy, hypertension, cholesterolemia, and diabetes being among the best known contributors to weakened and dysfunctional cerebral vasculature (BUÉE et al., 1997; Kalaria, 1999; Zipser et al., 2007). The contribution of tau neurofibrillary tangle pathology to vascular change is less clear. To examine this relationship between tau and blood vessels, we performed in vivo two-photon imaging to assess blood vessel changes in tau-overexpressing mice carrying the P301L tau mutation (rTg4510). Aged transgenic mice exhibited a significant increase in blood vessel density at 15-18 months and a reduction in average blood vessel diameter from 5.8 ± 1.5 microns in controls to 3.9 ± 0.1 microns in Tg4510 mice. These small diameter vessels were also blocked by rhodamine 6G-labeled leukocytes in 25% ± 4% of capillaries in Tg4510 mice compared to 7% ± 3.5% in control mice. Blocked vessels contained plasma only and were not observed to have red blood cell flow. We hypothesized that these small diameter, apparently non-functional vessels were either collapsed "string vessels" or were newly formed capillary tubes. To test this, we then isolated CD31+ endothelial cells from the brain and performed qPCR analysis which indicated gene expression changes related to angiogenesis including increased *VegfA, Serpine1*, *Plau*, and *Mmp9*. Similar changes were confirmed in human gene expression data sets comparing patients with high tau tangle pathology versus low tangle pathology. Altogether, this indicates a novel pathway whereby pathological changes due to tau accumulation induce aberrant angiogenesis in the brains of Alzheimer's disease mouse models and human patients. Further, blockage of small diameter blood vessels by leukocytes could explain, in part, observed cerebral hypoperfusion in Alzheimer's disease.

Title: TREM2 deficiency results in early exacerbation of tau pathology and leads to enhanced neurodegeneration with cognitive deficits in hTau mice

Authors: *S. M. BEMILLER[1], T. J. MCCRAY[1], K. ALLAN[2], A. L. OBLAK[1], G. XU[1], O. N. KOKIKO-COCHRAN[3], S. D. CRISH[4], R. M. RANSOHOFF[5], G. E. LANDRETH[1], B. T. LAMB[1]

Abstract: Recent identification of the R47H coding variant of the Triggering Receptor Expressed on Myeloid Cells-2 and its conferral of increased risk of developing late onset Alzheimer's Disease (LOAD) has led to a surge of research investigating the role of TREM2 in regulating CNS pathologies. TREM2 is a critical immune regulating protein normally expressed exclusively in the CNS on microglia and infiltrating peripheral myeloid populations which enter the diseased CNS. Recent work by the Lamb lab has identified a role for TREM2 in regulating amyloid pathology in transgenic APPPS1 and 5XFAD mice by using novel *Trem2*$^{LacZ/+}$ and *Trem2*$^{lacZ/LacZ}$ mice (*Trem2*$^{-/-}$). We demonstrated that TREM2 deficiency leads to time dependent alterations in plaque load, decreasing hippocampal plaque load at 4-months of age, and ultimately exacerbates widespread regional plaque pathology later in disease. Additionally, TREM2 deficiency results in chronic altered inflammatory gene expression profiles and decreased microglial survival late in pathology. Despite the advances in understanding the role of TREM2 in regulating amyloid pathologies, very little is known regarding the role of TREM2 in regulating the other cardinal hallmark of Alzheimer's Disease pathology, namely the intraneuronal inclusion of hyperphosphorylated and aggregated microtubule associated protein tau (Tau). In order to explore the hypothesis that TREM2 signaling plays protective roles in modifying tauopathy, we crossed the *Trem2*$^{-/-}$ mice to humanized tau mice which express all six isoforms of human tau and are lacking endogenous murine tau (hTau mice). Here we demonstrate that TREM2 deficiency results in exacerbated and hastened tau phosphorylation and aggregation by 6-months of age along with dysregulated kinase activity. This phenomenon persists throughout pathology and results in modest cognitive dysfunction by 12-months of age, and ultimately dramatic neurodegeneration by 18-months. Further, these phenomena are directly related to inefficient microglial mediated inflammatory responses due to TREM2 deficiency. Our results suggest a critical role for TREM2 in regulating the pathological outcomes in tauopathy and represent an exciting potential novel therapeutic target.

Title: Investigating combinatory phosphorylation of tau in propagation models of tauopathy

Authors: *N. SAHARA[1], T. KIMURA[1], G. MATSUMOTO[2]
[1]Natl. Inst. of Radiological Sci., Chiba, Japan; [2]Nagasaki Univ. Sch. of Med., Nagasaki, Japan

Abstract: Filamentous tau aggregates are the histopathological hallmark of tauopathy. Recently, the hypothesis of tau protein propagation in tauopathy is widely accepted. However, it is still unclear whether tau phosphorylation can be propagated in a clonal fashion. The purpose of this study is to verify if there is a combinatory tau phosphorylation pattern during the transduction of tau inclusions in both cells and mice. We developed stable cell lines expressing both full-length four repeat tau isoform and K18-GFP (GFP tagged 4 repeat domain of tau) with P301L FTDP-17 mutation. To introduce intracellular inclusions, heparin induced tau aggregates consisting of P301L mutated K18 were transduced into stable cell lines. After subcloning, stable cell lines with intracellular inclusions were established. Phosphorylation and insolubility of tau protein in each cell line was examined by Phos-tag SDS-PAGE and sedimentation assay, respectively. As a result, we found different phosphorylation pattern with distinct intracellular inclusions. Once a specific phosphorylation pattern of propagating tau protein is defined, findings will provide useful information to control prion-like transmission and spreading of tau pathology. Further examinations are ongoing to validate the propagation of tau phosphorylation in vitro and in vivo.

Abstract: Tauopathies are a group of neurodegenerative diseases characterized by pathognomonic protein inclusions formed by abnormal accumulation of microtubule-associated protein named tau. Tau inclusions are observed as intracellular neurofibrillary tangles. Clinical phenotypes of tauopathies manifest as cognitive impairment and behavioral disturbance. The aggregation of tau remains a central target for drug discovery, however no disease-modifying treatments exist. The mechanistic target of rapamycin (mTOR) signaling has emerging evidence in regulating all aspects of cellular proteostasis in response to diverse stresses through the uncovered cytosolic and lysosomal L-arginine sensing pathways, respectively. Our group has discovered a unique interaction between tau aggregation and mTOR signaling linked to L-arginine metabolism. In both human Alzheimer’s disease patient samples and tau transgenic mice, we observed dysregulated L-arginine metabolism and uncoupled mTOR signaling proteins associated with tau pathology. The depletion of L-arginine by overexpressing arginase 1 significantly reduced tau pathology in transgenic mice. We speculate that hyperactivity of mTOR signaling impairs proteostasis and exacerbates neuropathology. G protein coupled receptor (GPCR) family C, group 6 member A (GPRC6A) was recently deorphanized by basic L-amino acids, especially L-arginine. Although the exact role of GPRC6A remains unknown, we posit that GPRC6A mediates extracellular sensing of L-arginine to regulate mTOR complex 1 (mTORC1) signaling. We hypothesize that decreased GPRC6A signaling inhibits mTORC1 activation, thus clearing tau during tauopathies. We posit that GPRC6A remains tonically active and senses extracellular L-arginine in tauopathies. By utilizing tau overexpressing cell lines and tau transgenic mice, we blocked GPRC6A activity with novel allosteric antagonists and downregulated GPRC6A expression via shRNA constructs. We found that both pharmacological allosteric antagonism and genetic downregulation of GPRC6A inhibited mTORC1 signaling, promoted proteostasis and significantly reduced total monomeric and oligomeric tau in tauopathy

cells. Overall, our data suggests that decreased GPRC6A signaling reduces tau pathology. This is the first study to uncover the mTORC1 signaling mediated by extracellular sensing of L-arginine through GPRC6A. Further studies are required to warrant the exact mechanism of GPRC6A in maintaining proteostasis in tau transgenic mice. Therapeutics that modulate GPRC6A activity may potentially provide new treatments to clear protein aggregates in tauopathies and other proteinopathies.

Title: Hexosamine pathway metabolites ameliorate tauopathy in *C. elegans* neurons

Authors: *E. PARK, I. TARIQ, C. RONGO
The Waksman Institute, Rutgers Univ., Piscataway, NJ

Abstract: The microtubule-associated protein Tau is implicated in Alzheimer's Disease (AD) and various tauopathies, often forming hyperphosphorylated aggregates and fibrillary tangles, yet the mechanism by which Tau impairs neuron function remains controversial. One well-characterized tauopathy is frontotemporal dementia with parkinsonism-chromosome 17 (FTDP-17), patients with which have Tau mutations, including V337M (hTauV337M). In *C. elegans*, neuronal overexpression of hTauV337M combined with an aggregation-promoting fragment of Tau (F3ΔK280, which includes amino acids 258-360 but deleted for K280) results in Tau aggregation and uncoordinated locomotive behavior with multiple axonal defects[1]. Here we examine the effect of expressing hTauV337M and F3ΔK280 on microtubule-based transport in the command interneurons. Animals that express mutant Tau have fewer mitochondria, as well as defective transport of presynaptic synaptobrevin-1 (SNB-1) and postsynaptic AMPA receptors (GLR-1) to glutamatergic synapses. Interestingly, introduction of a Kinesin-Tom7 chimeric protein, which directly couples mitochondria to the microtubule track without the need of motor adaptors, improves mitochondria distribution in motor neurons, suggesting that mutant Tau acts by impairing the ability of mitochondria to associate with kinesin motors. To examine the role of Tau aggregation in this process, we exposed animals to conditions that reverse protein aggregation, including manipulation of the hexosamine pathway. The hexosamine pathway can

be activated by increasing the synthesis of N-acetyl glucosamine, resulting in enhanced proteostasis and the reduced effects of age-related diseases [2]. We found that the genetic activation of the hexosamine pathway or supplementation with the pathway metabolite N-acetylglucosamine reduces Tau aggregation, improves locomotion, and increases neuronal mitochondrial number compared to the untreated group. Our study suggests that promoting proteostasis by enhancing the hexosamine pathway could be potential therapeutic strategy to treat Tauopathy.

Abstract: Alzheimer's disease (AD) is a devastating neurodegenerative disease characterized by severe deficits in memory, thinking and behavior. At the molecular level, AD is characterized by two hallmark pathologies: the development of extracellular amyloid plaques and intracellular neurofibrillary tangles (NFTs). In particular, NFTs are formed from tau, a microtubule binding protein expressed in neurons throughout the brain. During AD pathogenesis, hyperphosphorylated tau aggregates into oligomers and eventually pathological fibrils. However, the molecular mechanisms which drive the development of tau pathology remain elusive. Recently, the Wolozin lab has identified ribonucleoprotein granules, particularly stress granules (SGs), as major components of AD pathology which coincide with the development of tau pathology. For instance, T-cell intracellular antigen 1 (TIA1) is a primary SG nucleating protein which co-localizes with neuropathology in Amyotropic Lateral Sclerosis (ALS), AD, and frontotemporal dementia (FTD).

Following this discovery, we bred TIA1 heterozygous and homozygous knockouts of the PS19 P301S tau mouse model of tauopathy to determine if TIA1 reduction could ameliorate the development of tau pathology. We report that both heterozygous and homozygous deletion of TIA1 in PS19 mice improved memory performance, using the Y maze spontaneous alternation and novel object recognition tasks. Additionally, immunohistochemical (IHC) analysis indicated that loss of TIA1 also rescued the loss of synaptic markers such as synaptophysin. Further signs of rescue was observed with RNAseq. Analysis of transcription and splicing by RNAseq revealed a profound disturbance of RNA splicing in the PS19 model, which was rescued by deletion of TIA1 in the +/- and -/- mice. Analysis of tau pathology, though, showed a surprising result. The PS19 x TIA1+/- and -/- mice exhibited a striking increase in the number of NFTs in the brain, observed with antibodies to phospho-tau (PHF1, CP13) as well as with the pathological NFT markers, the Gallyas silver stain and Thioflavine, despite the behavioral rescue observed. Biochemical fractionation revealed a corresponding increase in insoluble tau with a notable decrease in tau oligomers. Studies of in vitro tau aggregation using electron microscopy demonstrated the ability of tau TIA1 to stabilize tau oligomers while inhibiting tau fibrillization. These results suggest that TIA1 preferentially binds and stabilizes oligomeric tau, while inhibiting the formation of fibrillar tau. This suggests a novel mechanism for regulating the pathophysiology of tau pathology that involves RNA and RNA binding proteins.

Title: Aberrant interaction between FUS and SFPQ in 4R-tau dominant tauopathy brains

Authors: *S. ISHIGAKI[1], Y. RIKU[1,2], Y. FUJIOKA[1], D. HONDA[1], S. YOKOI[1], K. ENDO[1], K. KAWAI[1], H. WATANABE[3], M. KATSUNO[1], M. YOSHIDA[2], G. SOBUE[1]

Abstract: Fused in sarcoma (FUS) is genetically and clinicopathologically linked to frontotemporal lobar degeneration (FTLD) and amyotrophic lateral sclerosis (ALS). We have previously reported that FUS and SFPQ regulate alternative splicing of Mapt gene at exon10 which generates two pathogenic isoforms of neural microtubule-associated protein tau (Tau) protein. Silencing of FUS or SFPQ resulted in the increased ratio of 4-repeat tau (4R-tau)/ 3-repeat tau (3R-tau) followed by abnormal FTLD-like behavioral impairments, accumulation of phosphorylated tau, and neuronal loss. Therefore, we investigated the interaction between FUS and SFPQ in postmortem autopsied brains of FTLD and progressive supranuclear palsy (PSP) patients. The immunohistological analysis revealed that both FUS and SFPQ were localized in frontal neuron nuclei and hippocampal dentate gyrus (DG) neurons in all cases. Detailed quantification of the fluorescent signal intensities in the respective nuclei revealed that intra-nuclear co-localization of FUS and SFPQ was significantly reduced in FTLD and PSP compared to controls. The protein expression of FUS and SFPQ in postmortem brain tissue from FTLD, PSP, and control cases was also investigated. Immunoprecipitation analysis showed reduced interactions between FUS and SFPQ in the brains of FTLD and PSP patients. Our findings suggest that a pathophysiological link between FUS/SFPQ involved in the pathogenesis of FTLD and 4R-tauopathy.

Title: Utilizing fly primary neurons to study htau propagation: An *In vitro* model of alzheimer's disease

Authors: E. MURPHY, C. QIAN, C. QI, M. SMARELLI, R. YAVORSKY, A. LEE, D. LEE, *R. A. COLVIN
Dept Biol. Sci., Ohio Univ., Athens, OH

Abstract: Aggregates of the microtubule stabilizing protein, tau, are found in the neurofibrillary tangles (NFTs) of Alzheimer's Disease (AD) patients. When phosphorylated, the protein is altered from an endogenous form to a pathogenic form. These aggregations, or tauopathies, are known to disrupt cell transport and destabilize the microtubule in its diseased state. Although these tauopathies have been accepted by the scientific community as a potential cause of AD, the mechanisms behind which this aggregated tau protein can spread and further the progression of the disease are unknown. New evidence suggests that these pathogenic forms of tau can infect neighboring neurons in a prion-like manner, meaning they have the potential to induce a conformational change in a normal tau protein, altering it to a diseased state. This trans-synaptic propagation is a hypothesized method of propagation in AD neurons. The purpose of this research project is to investigate the cellular mechanisms of propagation of tau in a cellular model of Alzheimer's Disease. Our preliminary results have shown that a *Drosophila* primary cell model can be used to express an aggregation prone pathogenic version of human tau protein (2N4R) in cholinergic neurons *in vitro*. This human tau isoform was integrated with a FLAG tag to allow for immunofluorescent visualization. Expression of hTau was confirmed by western blot of highly specific immunoprecipitated adult fly brain protein and in primary culture neurons by immunofluorescence using an anti hTau antibody. Tau protein was released extracellularly by inducing membrane depolarization in primary cultured neurons after incubation with KCl in the

media (conditioned media). Neurons were incubated with 50 mM KCl for four hours or 10 mM KCl for 24 hours. A fluorescence intensity assay measuring tau protein level after KCl treatment suggested that these neurons had a lower level of intracellular hTau when compared with untreated, 2N4R expressing neurons. Western blot analysis of the immunoprecipitated conditioned media (using hTau antibody) and then probed with AT180 demonstrated that released tau was phosphorylated. Addition of this conditioned media to control neurons (Cha-GFP) demonstrated cellular uptake of hTau protein into the soma. These results suggest that our model may be useful for studying the release and uptake of tau protein occurring in AD pathogenesis.

Title: miR-125b contributes to Tauopathy in Presenilin1/2 conditional knockout dementia model mice via NCAM

Authors: *B. MENG, L. ZHANG, H. DONG, B. MEI
Key Lab. of Brain Functional Genomics, Ministry of Educ., East China Normal Univ., Shanghai City, China

Abstract: Presenilin1 (PS1) and presenilin2 (PS2) are two members of γ-secretase, which notably processes Amyloid β precursor protein (APP), highly involved in familial Alzheimer's disease (FAD) pathology. Conditional forebrain PS1/PS2 double knockout (DKO) mice show cognitive capability impairments, affective disorder, severe forebrain shrinkage, inflammation, tau hyper-phosphorylation etc., but no Aβdeposition because of the complete dysfunction of γ-secretase, therefore was regarded as a unique Aβ-independent dementia mice model.
Among the dys-regulated microRNAs, miR-125b showed a significant up-regulation in prefrontal cortex (PFC) of DKO mice. We further confirmed that neural cell adhesion molecule (NCAM) was one of its targets by Dual Luciferase Reporter Assay. NCAM protein level was decreased when miR-125b was over-expressed (OE) in NGF-induced differentiated PC12 cells.

Moreover, with serum deprivation, up-regulation of pGSK3β-Ser9 resulted in a high activity of GSK3β in differentiated mir-125b-OE PC12 cells; which further led the hyper-phosphorylation of Tau, as well as the increased Caspase-3 activation, which were consisted with the situation in DKO mice. Finally, we introduced retroviral mediated miR-125b over-expression in the PFC of wildtype C57B/L6 mice which resulted learning deficiency in the Novel Objective Recognition task with a decreased density of dendritic spines. And similarly as in vitro, elevated activity of GSK3β and hyper- phosphorylation of tau protein were confirmed.
Taken together, with γ-secretase dysfunction, abnormally increased miR-125b inhibits the expression of NCAM that further caused the increase of downstream molecule GSK3β activity and tau hyper-phosphorylation further. Our results revealed mechanism of PS1/PS2 dysfunction effect on Tauopathy via microRNA regulation in an Aβ-independent manner in dementia.

Title: Microtubule affinity regulating kinase 2 inhibition: Synthetic peptide mimetic of human tau repeat domain reduces tau phosphorylation in rat primary cortical neurons

Authors: *C. QIAN[1], N. AL QAEISOOM[2], J. M. HOLUB[2], R. A. COLVIN[1]
[1]Biol. Sci., [2]Chem. and Biochem., Ohio Univ., Athens, OH

Abstract: The microtubule-associated protein tau stabilizes microtubules by interacting with tubulins in neurons. Tau that is post-translationally phosphorylated can dissociate from tubulin, leaving polymeric microtubule structures in highly dynamic states. Tau phosphorylation at specific amino acids is precisely regulated by tau kinases and tau phosphatases. When this machinery is dysregulated, tau can be hyper-phosphorylated. Prolonged dissociation of hyper-phosphorylated tau induces microtubule collapse and disrupts axonal transport. More critically, diffusible tau can form prion-like oligomers, which have been implicated in the pathogenesis of age-dependent neurodegenerative diseases such as Alzheimer's disease (AD). Elevated activity of tau kinases, including microtubule affinity regulating kinase 2 (MARK2), has been demonstrated during AD pathogenesis. MARK2 is known to phosphorylate tau in one of four repeat (R) domains. Our objective was to develop synthetic peptide mimetics of human tau R1 domain (tR1) as non-cytotoxic, cell-permeable ligands to selectively inhibit MARK2-mediated phosphorylation of the endogenous tau. tR1 peptides showed minimal effects on viability when added to primary cortical neurons at concentrations up to 100μM. Antibody-based fluorescence polarization assays were used to demonstrate that our tR1 peptide mimetic was a ligand of

MARK2 *in vitro*. We observed that fluorescently labeled tR1 peptides were internalized by primary cortical neurons and localized in endosome-like vesicles throughout the soma and neurites, which can be inhibited by sodium azide, suggesting internalization by an endocytotic pathway. Phenylarsine oxide (PAO) treatment upregulated MARK2 activity and increased endogenous tau Ser262 phosphorylation significantly over untreated controls. Interestingly, co-treatment of PAO-treated cells with tR1 peptide and endosomal disruptors bafilomycin A1 or chloroquine reduced MARK2-dependent tau phosphorylation at Ser262 partially but significantly. Notably, tR1 peptide did not change phosphorylated tau level at Thr231. Taken together, these data suggest that tR1 peptides are internalized by cortical neurons and inhibit MARK2-dependent phosphorylation of endogenous tau at Ser262 when delivered to the cytosol. Importantly, these results show that the synthetic tR1 peptide mimetics are capable of selectively inhibiting tau phosphorylation at specific kinases-dependent sites. We anticipate that synthetic tR1 peptide will serve as strong leads in the development peptide-based AD therapeutics and as tools to study the complex nature of tau biology.

Title: Copper binding regulates cellular prion protein function

Authors: *X. T. NGUYEN[1], H. T. TRAN[1], D. COJOC[2], G. LEGNAME[1]
[1]Dept. of Neuroscience, Lab. of Prion Biol., Scuola Internazionale Superiore Di Studi Avanzati, Trieste, Italy; [2]Optical Manipulation Lab., Inst. of Materials, CNR, Trieste, Italy

Abstract: The cellular prion protein (PrP^C), mainly known for its role in neurodegenerative diseases, is involved in several physiological processes including neuritogenesis. By combining genomic approaches, different cellular assays and a novel focal stimulation technique, we have explored the molecular mechanism underlining its function as a signaling molecule in neuritogenesis. Different recombinant mutant prion proteins are obtained to treat the primary hippocampal cultures or exposed near the hippocampal growth cones (GC) in a local stimulation manner. While focal stimulation of GC with wild-type recombinant PrP (recPrP) induced neurite outgrowth and rapid GC turning towards the source, N-terminal mutants fail to support this

function.
In particular, the copper-binding sites mutants present at the N-terminus of PrP^C are toxic to neurons indicating this region being crucial for the function of the protein. Mutants of recPrP including a key mutation for prion conversion H95Y (Giachin, Mai et al. 2015) or the GSS-linked mutation abolish the function on neuritogenesis. Altogether, our findings indicate the functional regions for PrP^C in neuritogenesis and suggest a potential link between loss-of-function of the protein and disease initiation.

Abstract: The pathological accumulation of tau is associated with a number of diseases including Alzheimer's Disease (AD). Tau is predominantly a microtubule stabilizing protein, enabling the replenishment and regulation of the key transport route for axonal cargoes. Tau can become hyperphosphorylated, becoming aggregative and toxic, spreading throughout the brain forming intracellular neurofibrillary tangles. Uncovering the functional elements that could underpin the synapse loss and cell death observed in tauopathies is crucial in slowing down or reversing these diseases. Mitochondria are crucial for neuronal health and maintenance of synaptic function, and have been linked to degenerative pathologies. Mitochondrial dysfunction can lead to changes in ATP production, Reactive Oxygen Species deregulation, disruption in calcium buffering and apoptosis control. These dysfunctional pathways can lead to synaptic damage and cell death. The changes and the time course of mitochondrial function and its relationship to synapse loss in tauopathies, AD patients and animal models is not well known. Here, longitudinal in vivo two-photon microscopy is performed in rTg4510 mice, which express a repressible form of human tau containing the potent P301L mutation. rTg4510 mice and control littermates were transduced with an AAV driving expression of cytosolic & mitochondrial-targeted fluorescent proteins in a subset of excitatory cortical neurons. Repeated

imaging of the distribution and motility dynamics of axonal mitochondria was performed in head-fixed, anaesthetized mice. These results show the changes in mitochondria occurring with increasing tau pathology. Transgenic mice show decreased chances of motility and in the ratio of motile mitochondria vs total mitochondria. An initial increase in mitochondrial density along the axon is seen in the rTG4510 mice, followed by a decrease against control mice. An increase the pause ratio of the mobile mitochondria is seen along with an increase in the average pause time. Age related decreases mobile mitochondria speed are also seen in the rTg4510 mice. The data indicates mitochondria may have a key role in the tau related neurodegeneration from an early age.

Title: Optimization of structure-based tau aggregation inhibitors

Authors: *J. J. TREANOR[1], M. APOSTOL[1], A. WRIGHT[1], S. TANAKA[1], J. SCHERRER[1], D. S. EISENBERG[2]
[1]ADRx Inc., Thousand Oaks, CA; [2]UCLA, Los Angeles, CA

Abstract: Although the cause of Alzheimer's disease (AD) is not known, the aggregation of tau is believed to be a key step in the pathobiology of AD. Disease severity, cognitive dysfunction, and neuronal cell death are correlated with the presence of neurofibrillary tangles, which are composed of aggregated tau. Approaches to design tau aggregation inhibitors (TAIs), however, have been hampered by the lack of structural understanding of these toxic aggregates. To enable the in silico structure-based design of Tau aggregation inhibitors detailed atomic structures and computational models that identify the domains within Tau that drive aggregation have been developed (Sawaya et al. 2007, Colletier et al. 2011, Thompson et al. 2005, Laganowsky et al. 2012, Goldschmidt et al. 2010). Two small protein segments ^{306}VQIVYK^{311} and ^{275}VQIINK^{280} have been proven to be responsible for tau aggregation both *in vitro* and *in vivo*, and modulate its toxicity. The atomic structure of VQIVYK has been determined and, with the use of Rosetta computational design software, a series of peptide inhibitors of tau fiber formation were designed. Natural and non-natural amino acid containing peptides have served as starting points for the further optimization of inhibitors. High-throughput biochemical assays have been used to screen libraries of TAIs synthesized to increase the potency and selectivity of the original warheads. The ability of TAIs to block aggregation of full length and mutated tau isoforms,

containing both the VQIVYK and VQIINK amyloidogenic repeats, have been used to confirm the mechanism of action of these inhibitors. Data will be shown that also demonstrates cellular disruption of Tau aggregation by these TAIs using a luciferase-based reporter assay. In summary, potent Tau aggregation inhibitors have been designed utilizing a structure-based model of Tau aggregation that are now being evaluated for *in vivo* efficacy in mouse models of Tau-induced neurodegeneration.

Title: Impaired autophagy exacerbates neurotoxicity induced by general anesthetics in a culture model of familial Alzheimer's disease

Authors: C. WARD[1], M. YANG[2,4], Y. WANG[2,5], G. LIANG[2], Z. XU[2,6], *C. T. CHU[7], H. WEI[3]
[1]Children's Hosp. of Philadelphia, Philadelphia, PA; [3]Dept Anethesiol & Critical Care, [2]Univ. of Pennsylvania, Philadelphia, PA; [4]Shanghai Jiaotong Univ., Shanghai, China; [5]Shandong Univ.,

Jinan, China; [6]Tongji Univ. Sch. of Med., Shanghai, China; [7]Div. of Neuropathology, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: General anesthetics have been shown to worsen pathology and cognitive dysfunction in Alzheimer's disease animal models, but the mechanisms remain unclear. Our previous work suggests that isoflurane causes neurotoxicity in a culture model of familial Alzheimer Disease (FAD) through abnormal calcium release from the endoplasmic reticulum (ER). We hypothesize that the general anesthetic propofol induces cell death through disruption of intracellular calcium homeostasis and dysregulation of lysosome and autophagy function in Alzheimer's disease.
PC12 cells stably transfected with wild type (WT) or mutated presenilin-1 (L286V) were treated with different concentrations of propofol for 6 or 12 hr. The effects on cell survival, cytosolic calcium concentration ($[Ca^{2+}]_c$) and autophagy induction and flux were investigated. The stable and sensitive Cell Counting Kit-8 (Sigma) was employed to measure cell viability. Changes in $[Ca^{2+}]_c$ were determined by Fura-2 AM dye. We evaluated $[Ca^{2+}]_c$ after exposing both cell lines to propofol in the presence or absence of the ryanodine receptor (RYR) antagonist (dantrolene), the inositol 1,4,5-trisphosphate ($InsP_3$) receptor antagonist, (xestospongin C, Xc), and intracellular calcium chelator (BAPTA-AM). We used LysoTracker probes to determine the effects on lysosome acidification in WT and L286V cells. V-ATPase localization to the lysosome or ER was determined by immunofluorescence.
Propofol dose- and time- dependently induced cytotoxicity in both L286V and WT PC12 cells, while bafilomycin, an inhibitor of autophagy flux, significantly aggravated the propofol-mediated cell death in L286V but not WT cells. BAPTA-AM, dantrolene and Xc significantly inhibited propofol-induced elevation of $[Ca^{2+}]_c$ and cell damage. However, combined use of dantrolene and Xc, paradoxically and abnormally increased $[Ca^{2+}]_c$ by calcium influx from the extracellular space and potentiated propofol induced cell damage. Compared to WT cells, L286V cells demonstrated significantly reduced lysosome acidification. The effects of RYR- or $InsP_3$-antagonists on anesthetic effects on autophagic flux and on ER and lysosomal distribution of V-ATPase were studied.
Our results suggest that autophagy plays an important role in regulating cell death induced by the general anesthetic propofol in a culture model of FAD, and highlight the importance of understanding how excessive calcium release from the ER mediated by RYR or $InsP^3R$ impact different stages of autophagy.

Title: Atg-5 plays important role on propofol regulation of autophagy and cell survival

Authors: *H. WEI[1], Z. XU[3], Y. WANG[4], G. LIANG[2], Z. LIU[6], W. MA[5], C. WARD[7]
[1]Dept Anethesiol & Critical Care, Univ. of Pennsylvania, Philadelphia, PA; [2]Univ. of Pennsylvania, Wynnewood, PA; [3]Dept. of Anesthesiol. and Critical Care, Perelman Sch. of Med., Univ. of Pennsylva, Philadelphia, PA; [4]Dept. of Anesthesiol., [5]The First Affiliated Hosp. of Guangzhou Univ. of Chinese Med., Guangzhou, China; [6]Shanghai First Maternity and Infant Hosp., Shanghai, China; [7]Dept. of Anesthesia and Critical Care, Children's Hosp. of Philadelphia, Philadelphia, PA

Abstract: In fibroblasts with total knock out of Atg 5 ($ATG5^{-/-}$), a key regulator on autophagy activity, we studied the role of Atg5 on the effects of propofol on autophagy and cell proliferation and survival. Cell viability and death were measured by MTT reduction and lactate dehydrogenase (LDH) release assays respectively. Cell proliferation was determined by Bromodeoxyuridine incorporation. Autophagy activity was determined by measuring changes of LC3 II protein levels in the presence or absence of Bafilamycin. The cytosolic calcium concentrations ($[Ca^{2+}]_c$ were measured using dye Fura-2, in the presence or absence of xestospongin C or dantrolene. Propofol dose-, time- and Atg5-dependently affected cell proliferation and death. Propofol at 200 µM for 6 or 12 hours did not affect cell viability in either type of cells. However, a 24 hour treatment of propofol at 10 µM significantly increased MTT. Propofol at 200 µM decreased MTT in the $ATG5^{-/-}$ but not WT cells. Propofol at 100 and 200 µM induced cell death more significantly in $ATG5^{-/-}$ cells. Dantrolene or Xc significantly worsen or inhibited propofol-induced cell death in WT or $ATG5^{-/-}$ deficient cells respectively. Furthermore, propofol at 10 µM significantly increased proliferation, while propofol at 200 µM significantly decreased cell proliferation only in $ATG5^{-/-}$cells. Propofol dose-dependently increased the autophagy biomarker LC3 II and was potentiated by bafilamycin, only in WT but not $ATG5^{-/-}$ cells. Propofol increased $[Ca^{2+}]_c$ in both types of cells, but significantly more in $ATG5^{-/-}$ cells, which could be inhibited significantly by dantrolene or Xc. Propofol causes Ca^{2+} release from the endoplasmic reticulum via $InsP_3$ and or ryanodine receptors more dramatically in $ATG5^{-/-}$ then WT cells. Propofol promotes or suppresses cell proliferation at low and clinically relevant or high pharmacological concentrations respectively in an Atg5-dependent manner. Propofol induced cell death only at high pharmacological concentrations more significantly in $ATG5^{-/-}$ than WT cells. This study suggests that Atg5 plays a crucial role in propofol regulation of autophagy and associated cell survival and proliferation via differential activation of $InsP_3R$ or RYR.

Title: Isoflurane inhibition of exocytosis coupled to P/Q- and N-type voltage-gated Ca^{2+} channels

Authors: *Y. KOYANAGI[1,2], Z.-Y. ZHOU[1], H. C. HEMMINGS, Jr.[1]
[1]Anesthesiol., Weill Cornell Med., New York, NY; [2]Anesthesiol., Nihon Univ. Sch. of Dent., Tokyo, Japan

Abstract: The general anesthetic ether isoflurane inhibits voltage-gated Na^+ channels, which results in reduced Ca^{2+} influx through voltage-gated Ca^{2+} channels (VGCCs) at synaptic terminals and suppression of synaptic vesicle (SV) exocytosis. It remains unclear what contribution direct inhibition of presynaptic VGCCs by isoflurane makes to the reduced SV exocytosis observed in central nervous system nerve terminals. We used the calcium sensitive dye, Magnesium Green, together with the red-shifted reporter of vesicle recycling mOrange2 coupled to the vesicular glutamate transporter vGLUT1 to quantitate Ca^{2+} influx and SV exocytosis by live-cell imaging of rat hippocampal neurons. Using real-time imaging of both reporters loaded/expressed in the same neurons, we tested isoflurane effects on Ca^{2+} influx and SV exocytosis. The selective VGCC blockers conotoxin-GVIA and agatoxin-IVA were used to isolate P/Q- and N-type VGCC effects, respectively. In the presence of 1 μM conotoxin-GVIA, 2MAC isoflurane inhibited 50 mM KCl evoked Ca^{2+} influx (by 58 ± 9%; n = 13, $P < 0.01$, paired *t*-test) and SV exocytosis (by 51 ± 7%; n = 13, $P < 0.001$). In the presence of 400 nM agatoxin-IVA, Ca^{2+} influx and SV exocytosis were inhibited by isoflurane by 72 ± 8% (n = 13, $P < 0.01$) and 71 ± 7% (n = 13, $P < 0.001$), respectively. Isoflurane inhibited Ca^{2+} influx and SV exocytosis mediated by P/Q-type VGCC more than by N-type VGCC. These results suggest that isoflurane also reduces Ca^{2+} influx in a voltage-gated Na^+ channel independent manner to suppress SV exocytosis. Together with previous findings showing cell type dependent VGCC expression, VGCC subtype-selective inhibition might contribute to cell type-specific modulation of SV exocytosis by volatile anesthetics.

Abstract: Impaired glucose metabolism, decreased levels of thiamine (vitamin B1) and its phosphate esters, and downregulated activity of thiamine-dependent enzymes, such as pyruvate dehydrogenase, alpha-ketoglutarate dehydrogenase, and transketolase have been linked to Alzheimer's disease (AD). Thiamine-deficient mice exhibit increased amyloid deposition, tau hyperphosphorylation, and oxidative damage**[1]**. Experimental evidence has shown that benfotiamine (BFT), a synthetic S-acyl derivative of thiamine, rescued cognitive deficits and reduced amyloid burden in APP/PS1 mice**[2]**. We investigated whether BFT confers neuroprotection against tau phosphorylation and the generation of neurofibrillary tangles (NFTs) – which causes frontotemporal dementia in humans – in a mouse model of tauopathy. Exposure to BFT resulted in increased lifespan, behavioral improvement, reduced and glycated tau and

NFTs, and prevented neuronal death in P301S transgenic (TG) mice. In addition, BFT administration significantly ameliorated mitochondrial dysfunction, attenuated oxidative damage, and decreased the expression of several proinflammatory mediators, consistent with a possible activation of the Nrf2/ARE neuroprotective pathway. Accordingly, we found that BFT (but not thiamine) triggers the expression of Nrf2/ARE-dependent genes in wild-type (WT) but not in Nrf2-deficient fibroblasts. Our findings suggest that BFT is a promising therapeutic agent for the treatment of tauopathies.

Title: Sex differences in the microRNA-mediated regulation of microglia function in a mouse model of Alzheimer's Disease

Authors: *L. KODAMA[1], J. I. ETCHEGARAY[2], Y. ZHOU[2], E. GUZMAN[3], K. S. KOSIK[4], L. GAN[5]
[1]Neurosci., UCSF, San Francisco, CA; [2]UCSF Gladstone, San Francisco, CA; [3]UCSB, Santa Barbara, CA; [4]Univ. of California Santa Barbara, Santa Barbara, CA; [5]Gladstone Inst. of Neurolog. Dis., San Francisco, CA

Abstract: MicroRNAs are a class of small non-coding RNAs that suppress translation of their mRNA targets and have been implicated in modulating gene expression of immune cells. Recent studies have found miRNAs are also important in the regulation of the innate immune system of the central nervous system, namely in controlling microglia function. Dysregulation of microglia function is seen in many CNS pathologies, including tauopathies such as Alzheimer's Disease (AD), but how microglial miRNAs play a role in tau pathology is not known. In this study, we show that downregulating microglial microRNAs by conditionally floxing out dicer specifically in microglia (Cx3cr1Cre-ERT2/+; DicerF/F) exacerbates tau burden in male P301S (PS19) AD mice but not in female mice at 8 months of age. Pathology is especially increased in the entorhinal cortex region. To study the underlying sex differences and miRNA regulation of microglia function, we analyzed microglia density and morphology. Cx3cr1Cre-ERT2/+; DicerF/F male and female mice both show a decrease in microglia density but do not seem have

a defect in proliferative response to aggregated tau. Morphological analysis, however, shows female but not male Cx3cr1Cre-ERT2/+; DicerF/F mice have microglia with shortened processes and larger cell bodies, reminiscent of activated cells. We also did RNA sequencing specifically for miRNAs isolated from control and PS19 adult microglia to better understand the expression profile and functional changes in PS19 mice. Preliminary results show differential expression of several miRNAs, including upregulation of miR155 involved in the proinflammatory response pathway, and miR380-5p involved in apoptosis. Together, these data provide an entry point to further characterize the role of gender and miRNA in regulating microglia function and how microglia may be involved in sexual dimorphic neurodegenerative phenotypes.

Abstract: Abnormal aggregates of hyper-phosphorylated tau are a characteristic feature of several neurodegenerative disorders including Progressive Supranuclear Palsy (PSP) and Alzheimer's disease (AD), but factors contributing to this pathologic tau phosphorylation are not well understood. In the present investigation, we studied the regulation of the phosphatase responsible for dephosphorylating tau in the brains of patients with PSP and AD. Protein phosphatase 2A (PP2A), which is a family of conserved enzymes that constitute the majority of serine/threonine phosphatase activity in the brain, is a holoenzyme composed of a catalytic C subunit, a scaffold-like A subunit, and one of several regulatory B subunits that confer substrate specificity. The major tau phosphatase is B55α subunit-containing PP2A, the assembly and activity of which are regulated by reversible carboxyl methylation of the C subunit. In AD brains, reduction in PP2A methylation and PP2A phosphatase activity, as well as decreases in

B55α containing holoenzyme and PP2A methylation methylating enzyme have been noted. HoweverHere, we sought to address whether those findings relate to tau pathology or to the prominent concomitant amyloid pathology of AD by comparing them in the relatively pure tauopathy PSP. The state of PP2A methylation, as well as the expression of its methylating enzyme, leucine carboxyl methyltransferase (LCMT-1), and demethylating enzyme, protein phosphatase methylesterase (PME-1), were studied in the frontal cortex of postmortem brains from PSP and AD cases as well as age-matched non-neurological controls using immunohistochemical stains. Results showed that methyl-PP2A is reduced, particularly in AD brains, while demethyl-PP2A is increased, with no changes in total PP2A or B55α subunit, resulting in a reduction in the ratio between methyl/demethyl PP2A of 63% in PSP and 75% in AD compared to controls. This is associated with a significant decrease in LCMT-1 expression, and a two-fold increase in PME-1 in both PSP and AD brains. These findings suggest that PP2A dysregulation in tauopathies may contribute to the accumulation of hyper-phosphorylated tau and to neurodegeneration, raising the possibility that boosting PP2A phosphatase activity may be a disease modifying therapeutic strategy for these disorders.

Title: Dysregulation of Fgf14 by the tau transgene array is required for neurodegeneration in the rTg4510 mouse model of tauopathy

Authors: *J. GAMACHE[1], K. BENZOW[1], E. FURROW[2], K. H. ASHE[2], M. KOOB[2]
[1]Neurosci., Univ. of Minnesota Twin Cities Campus, Minneapolis, MN; [2]Univ. of Minnesota, Minneapolis, MN

Abstract: Tauopathies such as Alzheimer’s disease are neurodegenerative diseases in which the microtubule-associated protein tau (MAPT) is abnormally regulated. The rTg4510 mouse model, which harbors a tau transgene with a mutation known to cause tauopathy (P301L), is one of the most widely used models of these diseases. These mice recapitulate key features of human

disease in that they develop neurofibrillary tangles, experience cognitive deficits, and exhibit dramatic loss of neurons. This model was conventionally made using pronuclear injection, resulting in random integration of the transgene into the mouse genome. We have now generated a precision-engineered equivalent of the rTg4510 line in which a single copy of the same tau transgene cassette is integrated into a predetermined, intergenic locus (T2/T2). Although this precision-engineered line expresses even more human tau than rTg4510, we found that these mice do not exhibit any significant loss of neurons, and therefore performed whole-genome sequencing analyses of rTg4510 mice to determine the underlying cause of neuron loss in this transgenic model. We found that approximately 70 tau transgene copies replaces a 244 kb segment of chromosome 14, resulting in a deletion of the first exons and promoter regions of the longer variants of the fibroblast growth factor 14 (Fgf14) gene (splice variants V2, X1, and X2). Only the shortest variant of the Fgf14 gene (V1) remains intact. We measured Fgf14 mRNA expression levels of these splice variants in rTg4510 brains and found that the V2, X1, and X2 levels were decreased, while expression levels of V1 were dramatically increased in comparison to non-transgenic controls. Disruption of the FGF14 gene has been linked to a range of neurological abnormalities, including microcephaly, and the dysregulation of this gene in rTg4510 mice is likely to make a significant and perhaps even primary contribution to the cognitive deficits and neuron loss that develop in these mice as they age. In light of these findings, we believe that it is critical to reevaluate all studies using the rTg4510 model, and encourage the use of models made using precise transgene targeting for any future animal studies to avoid similar confounds that may impede the development of disease-modifying treatments.

Title: Deciphering HDAC6 interaction with human Tau using zebrafish

Authors: N. RIBEIRO PALHA[1], C. QUEVEDO[2], *A. DEKEYNE[1], B. PUVION[1], A. MURIANA[2], A. AZUALDE[2], C. LOUIS[1], J. P. KISS[1]
[1]Inst. De Recherches Servier, Croissy Sur Seine, France; [2]Biobide, San Sebastian, Spain

Abstract: HDAC6 is a Zn^{2+}-dependent class IIb lysine deacetylase which deacetylates and regulates cytoplasmic non-histone proteins (e.g. α-tubuline, cortactin, HSP90). In neurons, HDAC6 might play a role for their integrity and survival *via* activation of proteostatic mechanisms and inhibition of toxic downstream events (apoptosis, Tau oligomerization,

microtubule destruction) (d'Ydewalle et al., 2012, *Traffic* 13:771-779). In Alzheimer's disease (AD) patients, it has been shown that Tau binds and inhibits deacetylase activity of HDAC6, as revealed by hyperacetylation of α-tubulin (Perez et al., 2009, *J Neurochem* 109:1756-66). On the other hand, the protein level of HDAC6 in AD brains – although functionally impaired - is increased compared to normal brain (Ding et al., 2008, *J Neurochem* 106:2119-30). The assumption then is that α-tubulin is hyperacetylated in AD patients because Tau binds and inhibits the activity of HDAC6. Therefore, disrupting the interaction between Tau and HDAC6 in order to restore its activity could be of therapeutic interest.
Here we report a characterization of the functional link between Tau and HDAC6 in zebrafish (zf) larvae. *First*, the conserved role of zfHDAC6 in tubulin deacetylation was verified by western blot using either pharmacological (SAHA and tubastatine A) or genetic (morpholino-mediated knockdown) inhibition of zfHDAC6. Furthermore, overexpression of human HDAC6 decreased the acetylation of zebrafish α-tubulin. *Second*, co-immunoprecipitation data suggests that zfHDAC6 interacts *in vivo* with human Tau in transgenic zfTAUP301L larvae, a zebrafish tauopathy model (Paquet et al., 2009, *J Clin invest* 119:1382-95). Interestingly, experimental data from human cell lines and cell-free assays also supported a physical interaction between these two proteins. *Third*, zfHDAC6 morpholino-induced knockdown did not modify tau pathology phenotypes displayed by this transgenic line, namely neuronal cell death and shortened motoneuron axonal extensions. *Finally*, pharmacological inhibition of HDAC6 in tauopathy fish did not modify axonal length defects and - not in line with the working hypothesis - *rescued* neuronal death. As such, our zebrafish results do not support a role for HDAC6 in modulation of tau pathology, in line with recent data from human AD brain samples also pointing to an absence of any functional link between AD pathology and HDAC6 dysfunction. Together, our data illustrates how the zebrafish model organism can play an important role in proteinopathy drug discovery programs.

Title: Study of the astrocyte-neuron relationship in a novel gene transfer-based rodent model of tauopathy

Authors: *K. CAMBON, A. MATÉ DE GÉRANDO, M. D'ORANGE, G. LIOT, L. STIMMER, G. AURÉGAN, C. JOSÉPHINE, M.-C. GAILLARD, E. BROUILLET, P. HANTRAYE, A.-P. BEMELMANS
CEA- MIRCEN, Fontenay Aux Roses, France

Abstract: Tauopathies are neurodegenerative diseases characterized by the aggregation of Tau protein. These pathologies exhibit a wide variety of clinical and anatomo-pathological presentations, which may result from different pathological mechanisms. While in Alzheimer's disease it is essentially neurons which accumulate fibrillary tangles, glial inclusions in the shape of astrocytic plaques or tufted astrocytes are also observed in corticobasal degeneration and progressive supranuclear palsy respectively. However, to date, the mechanisms leading to the presence of tau aggregates in astrocytes have been little investigated. Furthermore, the functional consequences of such astroglial tauopathies are still unclear. Our aim was to study the relationship between neurons bearing soluble and/or aggregated Tau species and their neighboring astrocytes. To that purpose, we generated a fast-developing model of tauopathy in rodents by injecting adeno-associated viral vectors (AAV) encoding the human 1N4R Tau isoform in the hippocampus of adult rats and mice. At one month post-injection, overexpression of P301L mutant-Tau or of a pro-aggregating vector lead to the formation of AT100- and AT8-positive aggregates not only in neurons but also in astrocytes. In situ hybridization showed that most Tau positive- astrocytes were not transduced by the vectors, suggesting that astroglial tauopathy was secondary to the presence of neurofibrillary tangles. In order to better understand this effect, we will use co-cultures of neurons and astrocytes to determine whether astrocytes are able to take up aggregates either released from neurons or from phagocytosis of tangle-bearing neurons. The functional consequences of exposure to neurofibrillary tangles on astrocytic functions will also be evaluated.

Title: Silencing of FUS in the non-human primate brain via stereotaxic injection of an adeno-associated virus encoding shRNA

Authors: *K. ENDO, S. ISHIGAKI, Y. FUJIOKA, H. WATANABE, M. KATSUNO, G. SOBUE
Nagoya Univ. Grad. Sch. of Med., Nagoya, Japan

Abstract: Frontotemporal lobar degeneration (FTLD) is one of the devastating dementia syndromes which show an abnormality in social cognition or social behavior. FUS, an RNA binding protein has been identified as a causative molecule which is dislocated from the nucleus to the cytoplasm in the affected neurons of FTLD or amyotrophic sclerosis (ALS). Based on the hypothesis that aberrant RNA metabolism could be one of the major causes for the diseases, we have shown that the FUS-silencing in the hippocampus of mice could be a good candidate animal model for FTLD. However, due to the limitations to study social abnormalities in rodents, it would be desirable to establish a non-human primate model of FTLD. For this purpose, we established FUS-silencing method using stereotaxic injection of AAV to non-human primate (Callithrix jacchus). We designed shRNAs against marmoset FUS gene and generated AAV9 virus encoding the most effective shRNA against FUS (shFUS). The AAV encoding shFUS (AAV-shFUS) was injected into the frontal cortex or caudate of a young adult marmoset, whereas AAV encoding control shRNA was injected into the contralateral side. We obtained approximately 80% of silencing of FUS by the injection of AAV-shFUS. These techniques would enable us to establish a non-human primate model of FUS-silencing in various brain tissues for investigating the pathomechanism of FTLD.

Title: Creating a *Drosophila melanogaster* model of prion-like tau protein spread

Authors: *S. A. LEVY[1], B. FROST[2]
[2]Cell Systems and Anat., [1]UT Hlth. San Antonio, San Antonio, TX

Abstract: Tauopathies are a class of neurodegenerative diseases pathologically characterized by the accumulation of fibrillar tau protein aggregates. In Alzheimer’s disease, the most prevalent

tauopathy, these aggregates form neurofibrillary tangles, one of the major pathological hallmarks of the disease. Strikingly, tau pathology propagates hierarchically over time and appears to spread along the brain circuitry. In recent years, an increasing amount of evidence has surfaced to support the hypothesis of a prion-like mechanism for tau spread. Tau is now known to spread between cells and form a variety of stably transmitted strains *in vitro* as well as *in vivo*. The cellular mechanisms mediating and regulating tau spread have not been well characterized. Here, we propose to create a *Drosophila melanogaster* model of the prion-like spread of pathogenic tau. This model will provide a tool to study the processes involved in prion-like tau propagation in a short-lived, cost-effective animal model for which a wide variety of genetic tools are available. We will make use of the well-described circuitry of the *Drosophila* olfactory system, part of which consists of output neurons in the mushroom body projecting to five target regions. Based on this circuitry, a two-pronged approach will be employed to model the two key features of prion-like protein transmission: 1) spreading of tau to other cell populations and 2) a capacity to recruit native tau to seed aggregation. A split-Gal4 system will direct expression of tau^{R406W}, a tau mutant associated with familial tauopathy, to a small subset of mushroom body output neurons. The spread of tau beyond the neurons where it is expressed will be assessed by immunofluorescence. To detect the capacity of tau seeds to spread to synaptically connected regions and seed aggregation of tau in downstream neurons, the same split-Gal4 system will be used to express tau^{R406W}-CFP in mushroom body output neurons, while a LexA system will drive tau^{WT}-YFP expression in the target regions. CFP-labeled tau spreading along neuronal projections and recruiting the local YFP-tagged tau to seed aggregation in target regions will emit a FRET signal. A *Drosophila* model of tau spread will allow us to investigate the mechanisms controlling this phenomenon in adult brains, with the long-term goal of developing treatment strategies targeting the prion-like spread of pathogenic tau protein. In this context, a FRET-based model of tau seeding is well suited for screening of genetic and pharmacological interventions that interfere with putative transmission mechanisms.

Title: Proteinase K-resistant proteins linked with the different types of advanced glycation end products in the 263K prion-infected brain

Authors: *Y.-G. CHOI[1], J.-I. KIM[2], E.-K. CHOI[1], J. CASTILLA[3,4], Y.-S. KIM[1,5]
[1]Ilsong Inst. of Life Science,Hallym Univ., Anyang, Korea, Republic of; [2]Bukyong Natl. Univ., Busan, Korea, Republic of; [3]CIC bioGUNE, Derio, Spain; [4]IKERBASQUE, Basque Fndn. for Sci., Bilbao, Spain; [5]Dept. of Microbiology, Col. of Medicine, Hallym Univ., Chuncheon, Korea, Republic of

Abstract: In the previous studies it was shown that advanced glycation end product (AGE) is linked into the N-terminus of pathogenic prion isoform (PrP^{Sc}), probably at one or more of the three Lys residues (23, 24 and 27) on its N-terminus, and that the linked AGE type into the pathogenic prion isoform is N^{ε}-(carboxymethyl)lysine (CML), which is a major AGE form specific to Lys residue produced by nonenzymatic glycation. In this study, we investigated whether the other types of AGEs are linked into the pathogenic prion isoform, and whether there are the AGE-linked pathogenic prion isoforms in the brains of some transgenic mice with transgened PrP. The insoluble fractions that PrP^{Sc} could be enriched were isolated in the brains of 263K-infected hamster, 139A scrapie prion-infected mice (C57BL and tga20), PrP KO mouse and bank vole PrP^{109I} tg mouse. R3 anti-AGEs, anti-pentosidine, anti-pyrraline, anti-CML, anti-N^{ω}-(carboxymethyl)arginine (CMA), and 3F10 anti-PrP antibodies were used. As reported in the previous studies, AGE was linked into the pathogenic prion isoform in the 263K scrapie prion-infected hamster brain. Among the known AGE types, it was identified that pentosidine, pyrraline, and CMA which is a CML analogue as well as CML were linked into the proteinase K (PK)-resistant proteins, which might be the pathogenic prion isoforms because there would be only the PK-resistant pathogenic prion isoforms in the insoluble fraction isolated from the infected brain following PK digestion. As the different types of AGEs-linked proteins were detected even after PK digestion, the position of the different types of AGE linkage would be the C-terminal position of the pathogenic prion isoform (PrP90-231 of 263K scrapie prion isoforms) if the PK-resistant proteins were the pathogenic prion isoforms. In addition, the pathogenic prion isoforms both in the 139A scrapie prion-inoculated tga20 mice and in the bank vole PrP^{109I} tg mice are also linked with one or more of the AGEs types. The AGE linkage into the pathogenic prion isoforms in the brains of the PrP transgened mouse models was not dependent on their glycosylated types, as observed in the brains of 263K-infected hamster and 139A-infected C57BL mouse. Although it failed to show that the different types of AGE-linked PK-resistant proteins are the pathogenic prion isoforms by immunoprecipitation analysis, it is suggested that some of PrP^{Sc} isoforms would be post-translationally modified with the different types of AGEs in the pathologically affected brains (2016R1D1A1B02011328; HI16C0965).

Title: The expression of the neurotoxic tau45-230 fragment leads to changes in the cytoskeleton associated with defects in neurite elongation and synapse formation in hippocampal neurons

Authors: *A. B. FERREIRA[1], S. AFREEN[2]
[1]Cell & Mol. Biol., [2]Cell and Mol. Biol., Northwestern Univ., Chicago, IL

Abstract: We have shown that tau_{45-230} induces neurodegeneration followed by cell death in the context of AD and related disorders. In addition, our previous results indicated that a subset of tau_{45-230} was associated with the cytoskeleton of hippocampal neurons. In the present study, we assessed whether this subcellular localization could underlie the neurotoxicity of this tau fragment. To identify tau_{45-230} effects on the cytoskeleton, we determined the composition of the microtubular system as well as the monomeric to filamentous actin ratio in: 1- cultured hippocampal neurons obtained from embryonic day 16 (E16) pregnant wild type mice transfected with tau_{45-230}-GFP; 2- cultured hippocampal neurons obtained from E16 transgenic tau_{45-230} pregnant mice; and 3- wild type and transgenic tau_{45-230} hippocampal neurons that develop *in situ* (postnatal month 3 to 9). Untransfected cultured hippocampal neurons obtained from E16 wild type mice were used as additional controls. These experiments were performed by means of quantitative Western blot and immunocytochemistry analyses. Our results showed that the expression of tau_{45-230} in hippocampal neurons that develop either *in situ* or in culture induced a transient increase of tyrosinated tubulin, a marker of unstable microtubules. Furthermore, the presence of this neurotoxic tau fragment was associated with a significant reduction in actin filaments under these experimental conditions. These changes in the composition of microtubules have been correlated with decreased elongation and maintenance of axons and dendrites in central neurons. On the other hand, decrease in actin filaments has been associated with altered growth cone motility and synapse formation in hippocampal neurons. Together, these results suggest that tau_{45-230} could exert its toxic effects, at least in part, by modifying the composition of the neuronal cytoskeleton, and in turn, inducing neurite degeneration and synapse loss in AD and other neurodegenerative diseases. *This work was supported by NIH grant NS090993 to AF.*

Title: The Role of 5-lipoxygenase on tau pathology, synaptic integrity, and cognition in a mouse model of tauopathy

Authors: *A. VAGNOZZI[1], P. F. GIANNOPOULOS[2], D. PRATICO[1]
[1]Lewis Katz Sch. of Med. At Temple Univ., Philadelphia, PA; [2]Ctr. for Neural Sci., New York Univ., New York, NY

Abstract: Neurodegenerative tauopathies are characterized by pathological accumulation of highly phosphorylated isoforms of tau protein, which leads to progressive neuronal loss. Neuroinflammation often accompanies these diseases; however, the direct role of neuroinflammation in tauopathies remains unknown. 5-lipoxygenase (5LO) is a pro-inflammatory enzyme, which produces several bioactive metabolites and is widely expressed in the central nervous system. Previously, our group showed that 5LO modulates the Alzheimer's disease (AD) phenotype of APP transgenic mice as well as a mouse model with plaques and tangles. However, whether this protein modulates tau phosphorylation and subsequent pathology independently from its effect on APP metabolism remains to be fully investigated. In the current study, we provide evidence for an age-dependent and region-specific upregulation of the 5LO pathway in a transgenic mouse model of tauopathy, the P301S line. In addition, we demonstrate that genetic deletion of 5LO in this mouse model results in significant memory improvement, reduces tau phosphorylation at specific epitopes, and rescues synaptic pathology and neuroinflammation. In vitro studies confirm that 5LO directly modulates tau phosphorylation at the same epitopes as in brain tissues. Taken together, our data reveal an active involvement of the 5LO pathway in the development of the tauopathy phenotype and provide strong support to the hypothesis that this enzymatic protein should be considered a novel and viable therapeutic target for the treatment of human tauopathy.

Title: Investigating the effects of nuclear calcium signaling in the pathogenesis of tauopathies

Authors: *R. E. MAHONEY, M. GAMEZ, B. FROST
Barshop Inst., UTHSCSA, San Antonio, TX

Abstract: Calcium is required for the function of all cells in the body, including neurons. The pivotal role of calcium in so many neuronal processes dictates the need for precise regulation of its intracellular levels. Any dysregulation, however subtle, could lead to dramatic changes in normal neuronal function. For example, during adaptive processes such as learning and development, changes in transmembrane calcium fluxes correlate with changes in neuronal excitability and structural connectivity. Calcium thus is likely to have key roles in the cellular processes underlying aging-related changes in the brain, including normal age-associated memory impairments as well as more severe dementias, including Alzheimer's disease. Central to this question we have investigated the role of nuclear calcium in the progression of tauopathies in the fruit fly *Drosophila melanogaster*. Preliminary studies suggest that pathological tau reduces calcium levels, possibly through a decrease in the expression of the *Drosophila* BK channel homolog, *Slowpoke*, specifically within the neuron. We will further investigate tau-mediated reduction of nuclear calcium, and will determine if genetically increasing nuclear calcium along with neuronal *Slowpoke* expression alleviates tau-induced neurotoxicity, and increases healthspan and lifespan *in vivo*.

Title: Genetic ablation of tau reduces oxidative damage and improves mitochondrial bioenergetics during the aging

Authors: *R. A. QUINTANILLA, C. JARA, C. TAPIA-ROJAS, E. VERGARA-HERNANDEZ
Inst. de Ciencias Biomédicas, Univ. Autónoma de Chile, Ctr. de Investigación Biomédica, Univ. Aut, Santiago, Chile

Abstract: Mitochondrial impairment has been proposed as an important factor in cerebral aging and neurodegenerative diseases. In this context, recent studies have shown an association between mitochondrial failure and tau pathology in the brain. Tau is a protein involved in the microtubule function and also play an important role in synaptic plasticity. Important studies have shown that during aging, pathological forms of tau can be accumulated and that these tau forms may directly affect mitochondrial function with negative consequences for neurons. Therefore, we determined whether the absence of tau may prevent the mitochondrial structural and functional impairments using wild-type and knock-out tau (-/-) mice of 18 months of age. We analyzed the protein expression of principal mitochondrial dynamics regulators (Drp1, pDrp1, for mitochondrial fission and Mfn1/2, Opa1, for fusion) in hippocampal extracts obtained from these mice. Analysis of the expression levels indicated not significant differences in mitochondrial fission regulators (Mfn1/2 and Opa1) in wild-type and tau (-/-) samples. In addition, pDrp1 levels were significantly reduced in tau (-/-) hippocampal samples. Interestingly, we detected a significant reduction in Cyclophilin D (CyPD) levels in hippocampal extracts from tau (-/-) mice. This is an important observation because CyPD facilitates the activation of the mitochondrial permeability transition pore (mPTP), a structure which opening compromises the entire mitochondrial function. In addition, hippocampal extracts from tau (-/-) mice showed a reduction in protein oxidative damage, detected with the 4-HNE antibody and N-tyr, and more importantly tau (-/-) hippocampal samples showed a significant increase in total ATP levels compared to wild-type. Complementary studies in hippocampal slices showed that wild-type mice presented a reduction in mitochondrial potential levels and an increase in ROS levels compared to tau (-/-) mice, indicating that tau presence affects mitochondrial health during aging. Altogether these results indicate that pathological modifications of tau may contribute to brain aging process by affecting mitochondrial dynamics and bioenergetics.

Title: Tau aggregation causes nucleocytoplasmic transport disruption in FTD and other tauopathies

Authors: *J. G. DAIGLE[1], B. EFTEKHARZADEH[2], B. T. HYMAN, MD,PhD[3], J. D. ROTHSTEIN[4]
[1]Neurology/Neurosurgery, Brain Sci. Inst., Johns Hopkins Sch. of Med., Baltimore, MD; [2]Neurol., MGH, Charlestown, MA; [3]Massachusetts Gen. Hosp., Charlestown, MA; [4]Brain Sci. Inst., Johns Hopkins Univ., Baltimore, MD

Abstract: Tau pathological aggregation is found in several neurodegenerative diseases including ALS, AD and FTD. However, the cellular pathways disrupted due to tau aggregation are poorly understood. Here, we discovered nucleocytoplasmic trafficking defects in preclinical mouse model of FTD and human postmortem tissues. Additionally, we observe similar disruptions in primary mouse neuronal cultures treated with different toxic tau species. We find that phosphorylated Tau species in the cytoplasm sequester nuclear pore complex proteins and disrupt nuclear/cytoplasmic ran gradients. Using several quantitative high resolution imaging methods we are able to detect Tau binding to the nuclear pore complex at the molecular level. Tau accumulation in the perinuclear space interferes with nucleocytoplasmic transport, likely through direct interactions of tau with Nuclear pore complex elements. We believe that abnormal nuclear transport is a key pathological even in tauopathies that may extend to many neurodegenerative diseases. Targeting this pathway could prove to be a novel strategy in developing therapeutics for neurodegeneration.

Title: Influence of hyperphosphorylated tau in the hippocampal CA1 region in tau transgenic mice

Authors: *L. MUELLER-THOMSEN[1], H. SCHRODER[2], T. SCHNEIDER[3], J. GOETZ[4], S. HUGGENBERGER[5]

Abstract: Alzheimer's disease (AD), the most frequent form of dementia, is characterized by a significant loss of brain mass mainly in hippocampal and cortical areas. The brains of patients with AD are histopathologically characterized by two hallmark lesions: extracellular amyloid-beta containing plaques and neurofibrillary tangles (NFTs) which are hyperphosphorylated forms of intracellular microtubule-binding protein tau. Under pathological conditions there is a mislocalisation of hyperphosphorylated tau and NFTs to somatodendritic compartments and spines. There is mounting evidence that hyperphosphorylated tau species drive neuronal dysfunction and degeneration in tauopathies. The impact of the pathological modified tau protein on the functions of neuronal networks was sparsely studied so far. To investigate how hyperphosphorylated tau affects neuronal functions we examined the electrophysiological properties of hippocampal network activity of mice expressing human tau (P301L htau transgenic pR5 mice) by extracellular field potential measurements using a long time potentiation (LTP) protocol. LTP is widely accepted as a cellular mechanism underlying synaptic plasticity responsible for learning and memory. The LTP mechanism is divided into two phases: the early phase is characterized by the activation of NMDA and AMPA receptors and the resulting cation influx. The late phase is characterized by gene transcription, new protein synthesis and changes in the number of single-channel conductance of AMPA glutamate receptors in spines. Here we found a significant amplitude reduction in LTP in senescent pR5 mice in contrast to their non-transgenic littermates 10 minutes after LTP induction. These finding indicates the relationship between hyperphosphorylated tau protein within hippocampal neurons and the resulting memory deficits within the second phase of LTP. For this reason our next goal is the assessment of changes of AMPA-R conductance due to the intracellular presence of hyperphosphorylated tau.

Abstract: Age, itself, is by far the single greatest common risk factor for chronic progressive neurodegenerative conditions, but the underlying mechanisms are not completely understood. We and others previously reported the existence of large aggregates of undigested lysosomal protein "cargo" in the brains of aged wild-type mice. This accumulation of extracellular protein aggregates and presence of lipofuscins in old brains highlight an age-dependent decrease in handling of cellular and tissue garbage. Here we show that lysosomes, labeled by LAMP-1 or Cathepsin D, are significantly larger in hippocampal pyramidal neurons and inhibitory parvalbumin interneurons in 20-month-old mice than in 5-month-old mice. Motivated by our previous finding that there was increased neuronal NADPH oxidase 2 (Nox2) expression in brains of aged wild-type mice, and by reports that superoxide derived from NADPH oxidase (Nox) impairs lysosomal protein degradation, we asked whether Nox activation could be contributing to lysosomal changes by treating mice long-term with the Nox inhibitor, apocynin (100 mg/kg/day). We found a significant improvement in lysosome function, as demonstrated by a reduction of both the number and total area of p62-positive clustered aggregates in the hippocampus. We are investigating whether lysosome enlargement has also been normalized in these mice. These data are significant because they directly link Nox activity with decrease in lysosomal clearance of material. Such decrease can lead to the accumulation of extracellular and intracellular aggregates that may promote tissue injury, local inflammation, and deposition of disease-specific proteins.

Title: Ovariectomy and hormone treatment modulates female brain bioenergetic function in an endocrine status dependent manner

Authors: *Z. MAO[1,2], F. YIN[2], J. YAO[2], R. BRINTION[1,2]
[1]Ctr. for Innovation in Brain Science, Dept. of Pharmacol., Univ. of Arizona, Tucson, AZ;
[2]Pharmacol. and Pharmaceut. Sci., USC, Los Angeles, CA

Abstract: The perimenopause is an aging transition unique to the female that is associated with multiple neurological symptoms. Our recent study in a rodent model of human perimenopause revealed the perimenopausal transition as a critical period characterized by a significant decline in bioenergetic and synaptic functions, that is reminiscent of early stage of Alzheimer's disease (AD). Combinations of 17β-estradiol (E2) and progestogens (P4) in varying regimens are widely used as hormone therapy for menopause-related climacteric symptoms. The present study was aimed to determine the efficacy and optimal intervention window of the E2 in combination of cyclic P4 therapy on female rat brain at different stages of the perimenopausal transition, against bioenergetic deficits and AD risks. Placebo or E2+CyP4 therapy was initiated on female rats at 9-10 months with either regular cycling or irregular cycling, and for each cycling status, ovariectomy (OVX) or Sham OVX surgery was performed before the intervention. Hormone therapy consisted of two 30-day cycles of continuous E2 and cyclic P4 (10 days/cycle) delivered by silastic capsules. Upon completion of the regime, rats were subject to genomic, biochemical and brain metabolic investigations. We previously reported that a two-month treatment of E2+CyP4 on (OVX) young rats induced a bioenergetic gene-expression profile comparable to the ovary intact females. Our data from this study suggest that E2+CyP4 therapy improves brain bioenergetic functions in terms of increased pyruvate dehydrogenase (PDH) activity and elevated mitochondrial respiratory capacity, but the effect was differentially affected by the endocrine status of the rats when the intervention was initiated. Interestingly, our data suggested that OVX initiated on regular or irregular cyclers elicited opposed effects on bioenergetic-, inflammatory- and AD-related gene expressions. Outcomes of this study determine the window of opportunity for preventing the at-AD-risk bioenergetic phenotype by hormone intervention and will provide mechanistic details for developing novel strategies to maintain neurological health and function throughout menopausal aging.

Title: Estradiol improves metabolic and cognitive outcomes of obesity in female APOE3 and APOE4 mice at early middle age

Authors: *A. CHRISTENSEN[1], C. J. PIKE[2]
[1]Dept. of Gerontology, [2]USC Leonard Davis Sch. of Gerontology, USC, Los Angeles, CA

Abstract: Alzheimer's disease (AD) is a multifactorial neurodegenerative disease that is more prevalent in females. AD risk is significantly affected by genetic, environmental, and modifiable factors. The most significant genetic risk factor for AD is the ε4 allele of apolipoprotein E (*APOE4*). Interestingly, AD risk associated with *APOE4* disproportionately affects women. Further, human and rodent studies indicate that neuropathology and cognitive deficits associated with *APOE4* are greater in females. Modifiable lifestyle factors also affect AD risk. One such factor is obesity during middle-age, which significantly increases AD risk in late life. Given that ~65% of US adults are overweight or obese, it is important to understand not only how obesity independently affects AD risk but also (a) how it interacts with *APOE4* to affect AD and (b) the extent to which these interactions can be reduced by therapeutic strategies. A widely used intervention in middle-aged women is estrogen-based hormone therapy, which can exert wide-ranging health benefits when administered in early middle-age at perimenopause, but is potentially harmful in late middle-age. No experimental studies have explored the interactions among *APOE4*, obesity, and hormone therapy in aging females. To begin investigating these issues, we considered how obesity outcomes are affected by treatment with estradiol at the onset of middle-age in female mice with human *APOE3* and *APOE4*. The utilized transgenic mice (called EFAD non-carriers, EFAD-NC) have targeted replacement of mouse *APOE* with human *APOE3* or *APOE4* and are generated from breeding of EFAD-Tg mice, which are homozygous for human *APOE3* or *APOE4* against a hemizygous background of 5xFAD-Tg mice. Female EFAD-NC mice were examined over a four-month period that spans the transition into reproductive senescence, which models many aspects of human perimenopause. Beginning at age 5 months, mice were maintained on a control diet (10% fat) or nutrient-matched high-fat diet (60% fat). After 2 months of diet, by which time obesity was present in high-fat groups, all mice were implanted with either estradiol or vehicle that was maintained for the final two months of the experimental period. Animals were assessed on a wide range of metabolic and neural measures. In general, hormone therapy improved metabolic outcomes and cognitive performance in both *APOE3* and *APOE4* mice, although the efficacy sometimes differed across genotype and diet condition. Collectively, these findings begin to define how *APOE4* interacts with female sex, perimenopause and obesity to regulate neural outcomes and the extent to with hormone therapy provides benefits.

Title: Impact of APOE genotype on the sex-differentiated bioenergetic trajectories and AD risks in aging mouse brains

Authors: *F. YIN[1], Y. WANG[1], A. MISHRA[1], Z. MAO[1,2], R. D. BRINTON[2,1]
[1]Sch. of Pharm., USC, Los Angeles, CA; [2]Ctr. for Innovation in Brain Sci., Univ. of Arizona, Tucson, AZ

Abstract: Age, APOE4 genotype, and female sex are top risk factors for AD. Our previous studies demonstrated that the bioenergetic shifts occurring in the perimenopausal female brain could contribute to an increased AD risk in women. We also observed substantial sex disparities in brain bioenergetic trajectories in normal aging mice. The goal of this study is to determine the sex differences in the impact of APOE genotype on AD at-risk phenotypes during brain aging. Female and male, APOE3- and APOE4 targeted replacement (TR) mice were assessed for: (a) bioenergetic-, inflammatory-, and AD pathology-related gene expression in hippocampus followed by bioinformatic analysis, and (b) key metabolic parameters in the periphery. Gene expression analyses revealed that female APOE4 mice at pre-menopause age (6-month old) exhibited a significantly different bioenergetic profile relative to APOE3 controls: APOE4 mice showed a higher expression of genes involved in mitochondrial oxidative phosphorylation, mitochondrial membrane transport, and mitochondrial fusion. These changes in female APOE4 brains may represent an adaptive response to deficits in brain glucose availability and a shift in energy fuels from glucose to ketone bodies and glucose. This hypothesis is further supported by: (a) APOE4 mice had lower levels of plasma glucose in both sexes while the higher levels of ketone bodies and triglycerides were only seen in the females; (b) both APOE3 and APOE4 females had lower peripheral glucose levels and higher ketone body levels than their genotype-matched male counterparts, indicating a potential earlier shift in bioenergetic fuel usage in females. These findings suggest that APOE4 genotype interacts with the age-related decline in glucose metabolism and the bioenergetic shift to alternative fuels, particularly in females. Functional assessments of these mice including: (a) FDG-microPET for cerebral glucose metabolism, (b) brain mitochondrial function, and (c) glucose tolerance test for peripheral metabolism, are undergoing. Outcomes of this study will provide mechanistic details of the APOE4 genetic burden on the sex-differentiated bioenergetic fluctuation during aging and its contribution to higher AD risks in women. Title: Epigenetic control of the perimenopausal brain in hypothalamus

Authors: *E. BACON[1], A. MISHRA[2], Y. WANG[2], F. YIN[1], R. D. BRINTON[1,3]
[1]Sch. of Pharm., [2]Clin. and Exptl. Therapeutics, Sch. of Pharm., USC, Los Angeles, CA; [3]Ctr. for Innovation in Brain Sci., Univ. of Arizona, Tucson, AZ

Abstract: To better understand the potential underlying mechanisms of neurological symptoms associated with perimenopause transition, as well as the temporal control of the onset and completion of perimenopause, the current study aims to characterize the transcriptional and epigenomic changes that occur during the transition using a rat model recapitulating fundamental characteristics of human perimenopause. RNA-seq analysis of hypothalamic tissues from rats at various ages and endocrine status showed that the majority of differentially expressed genes occurred between 6-9 months of age, prior to perimenopause, when animals were still regularly cycling. E2, GnRH, and KISS1 were identified as upstream regulators involved in the transition between each endocrine status suggesting that hypothalamic aging begins before the onset of perimenopause and progresses through the transition into menopause. One-carbon key players SAM and homocysteine were identified as regulators of transcriptional changes during 6-9 months, suggesting that impaired one carbon metabolism precedes irregular cycling. Pathway analysis of RNA-seq and reduced representation bisulfite sequencing (RRBS) genome wide DNA methylation data identified GnRH signaling and the hypothalamic-pituitary-gonadal axis (HPG axis), prolactin, glutamate and GABA signaling, melatonin and circadian rhythm, as well as epigenome maintenance and one-carbon metabolism, as pathways that undergo dramatic changes during perimenopause. Hypothalamic global DNA methylation declined at the onset of irregular cycling in 9 month animals, and two distinct populations of high and low methylation were observed at 6 months of age demonstrating differences in epigenome “age”. To determine if DNA methylation directly influences onset and progression of perimenopause, we treated pre-menopausal rats with 5-aza-2’-deoxycitidine (5-aza), a de-methylating agent, and assessed cyclicity and perimenopause timing. 5-aza treatment significantly accelerated the completion, but not initiation, of perimenopause, as characterized by acyclicity. Conversely, methionine supplementation delayed the initiation of perimenopause, and resulted in a larger proportion of animals still cycling regularly at 9 months of age. These data together provide evidence that endocrine aging in hypothalamus begins before the onset of the physical manifestation of

perimenopause (i.e. irregular cycling) and that epigenetics, including DNA methylation, regulate the onset and completion of the perimenopause transition.

Title: PhytoSERM for management of menopause-associated vasomotor symptoms -- effect of APOE genotype and mitochondrial haplogroup

Authors: *Y. WANG[1], G. HERNANDEZ[1], W. MACK[2], L. S. SCHNEIDER[2], F. YIN[1], R. D. BRINTON[1,3]
[1]Sch. of Pharm., [2]Sch. of Med., USC, Los Angeles, CA; [3]Ctr. for Innovation in Brain Sci. and Dept. of Pharmacol., Univ. of Arizona, Tucson, AZ

Abstract: PhytoSERM is a selective estrogen receptor beta (ERβ) modulator comprised of three clinically relevant phytoestrogens: genistein, daidzein, and equol. Earlier *in vitro* and *in vivo* studies demonstrated neuroprotective effect of PhytoSERM, without side effect on the reproductive system. In a mouse model of hot flash, 8-week PhytoSERM diet prevented surgical menopausal-induced rise in tail temperature. In the present study evaluating safety and efficacy of PhytoSERM for menopause-associated hot flashes (ClinicalTrial.gov ID: NCT01723917), 44 post-menopausal women aged 48 to 58 years old with a vasomotor symptom such as hot flash and a memory complaint were included. Participants were randomized into placebo (N=16), 50mg (N=17), or 100mg (N=11) daily dosage groups. Frequency and severity of hot flash were self-reported throughout the 12-week trial period. Changes in hot flash frequency within each treatment group were analyzed using non-parametric paired t-test between week 1 and week 12, and changes among treatment groups were analyzed using non-parametric ANOVA followed by unpaired t-test. Results were then stratified based on the APOE genotype and mitochondrial haplogroup of the participants. At week 12, participants on both the 50mg and the 100mg PhytoSERM groups had significantly lower hot flash frequencies compared to week 1. However, only the 50mg group demonstrated significant reduction compared to the placebo group, supporting 50mg daily as a more effective dosage for management of hot flash. When stratified

by APOE genotype, non-APOEε4 carriers on 50mg group had significantly reduced hot flash frequencies compared to those from the placebo group. APOEε4 carriers on 50mg of PhytoSERM also had a trend of reduced hot flash frequency, but failed to reach statistical significance, likely due to limited sample size. When stratified by mitochondrial haplogroups, haplogroup H on 50mg of PhytoSERM had significantly reduced hot flash frequency compared to those on placebo, whereas non-H haplogroups had a trend of reduction but failed to reach statistical significance. Collectively, daily treatment of PhytoSERM at 50mg significantly reduced hot flash frequency in post-menopausal females, with non-APOEε4 carriers and haplogroup H more responsive to the treatment. A larger cohort is necessary to further identify and confirm responders based on APOE genotype and mitochondrial haplogroups. Title: Mechanistic role of brain hypometabolism and mitochondrial uncoupling in perimenopausal hot flash

Authors: *R. D. BRINTON[1,2], F. YIN[1], J. YAO[1], Q. DENG[1], A. MISHRA[1], Z. MAO[1,2]

Abstract: The goal of the current study is to determine the mechanism of the signature symptom of the menopausal transition, the perimenopausal hot flash. We hypothesized that loss of ovarian hormone regulation of bioenergetics in brain induces a series of adaptive responses in the brain, which are initiated by decline in glucose metabolism, followed by activation of alternative fuel sources, ketone bodies and free fatty acids, which lead to mitochondrial uncoupling and temperature dysregulation. We used the ovariectomy (OVX) rat model as a reliable and predictive inducer of temperature dysregulation. Loss of ovarian hormones in the OVX rats led to decreased uterine weight, increased body weight and a significant increase in peripheral (tail skin) temperature. Further, our analyses in the OVX rat model indicated that peripheral temperature dysregulation coincided with systemic glucose intolerance and decreased cerebral glucose metabolism (FDG-PET). We further tested our hypothesis that loss of ovarian hormones

leads to disruption and uncoupling of the proton motive force-dependent energy conservation systems and the consequent dissipation of energy as heat. Results of these analyses indicated that mitochondrial respiratory control ratio (RCR) was decreased in OVX rats accompanied by increased mitochondrial uncoupling, the upregulation of mitochondrial uncoupling proteins (UCPs), and enhancement of mitochondrial fragmentation in multiple brain regions. These OVX-induced changes were completely or partially prevented by 17beta-estradiol treatment, suggesting an obligatory role of estrogen signaling in these events. Finally, to investigate the relationship between mitochondrial uncoupling in the brain and the increase in peripheral temperature, mitochondrial uncoupling was induced by 2,4-dinitrophenol (2-DNP), a mitochondrial uncoupler. Our analyses indicate that intracerebroventricular injection of 2-DNP induced sequential fluctuations in brain temperature, core temperature and tail skin temperature, with the endogenous mitochondrial uncouplers (UCP2 and UCP3) downregulated in the brain, likely a negative feedback to the 2-DNP-induced mitochondrial uncoupling. Collectively, we established the physiological and bioenergetic phenotype of a rat model of hot flash, and our findings provide new mechanistic details of hot flash by connecting loss of ovarian hormones, brain hypometabolism, mitochondrial uncoupling and dysfunction, and peripheral temperature dysregulation. Title: Sex differences in metabolic and neurological outcomes in humanized APOE-E4 knock-in rats

Authors: *A. MISHRA[1], F. YIN[2], Z. MAO[2,3], R. D. BRINTON[2,3]
[1]Clin. therapeutics, [2]Sch. of Pharm., USC, Los Angeles, CA; [3]Ctr. for Innovation in Brain Sci., Univ. of Arizona, Tucson, AZ

Abstract: Women APOE-ε4 carriers are at increased risk of developing Alzheimer's disease (AD) than men, and are susceptible to accelerated aging and undergo faster rates of cognitive

decline from Mild Cognitive Impairment (MCI) to AD. Using a novel rat model with humanized APOE-**ε**4 gene knock-in (Horizon Discovery), we conducted a 9-month longitudinal study (between age 6-15 months) to characterize the individual and combinational impact of sex and APOE-ε4 genotype on the brain aging process by evaluating metabolic and neurological outcomes. APOE-ε4 and wildtype (WT), male and female rats, were metabolically assessed at four aging windows during the study: 7-8 months (m), 9-10 m, 12-13 m and 15-16 m. Vaginal lavages were collected from APOE-ε4 and WT rats during the following aging windows 6-7 m, 9-10 m and 12-13 m to correlate reproductive aging with corresponding changes in metabolic and neurological outcomes. Across these aging windows**,** we conducted micro ^{18}FDG-microPET/CT (18-fludeoxyglucose micro Positron Emission Tomography / Computational Tomography) to measure brain glucose uptake, and established peripheral metabolic- and inflammatory profile consisting of ketone bodies, triglycerides, insulin, lipidomics as well as circulating cytokines: IFN-γ, IL-1β, IL-4, IL-5, IL-6, IL-10, IL-13, TNF-α. Longitudinal follow-up revealed that in comparison to WT rats, APOE-ε4 rats had significantly elevated plasma triglyceride levels across all aging windows, in both sexes. Male APOE-ε4 rats had the highest triglyceride, ketone body and insulin levels across all groups at all ages. In APOE-ε4 females, age related decline in insulin levels while increase in ketone body levels was evident. Brain glucose uptake, as determined by FDG-PET, was significantly higher in APOE-ε4 males than APOE-ε4 females at 9-10 m and 12-13 m. APOE-ε4 females experienced a significant decline in glucose uptake when undergoing the perimenopausal transition indicative of a state of bioenergetic deficit after the perimenopausal transition. While during the same aging transition, male APOE-ε4 rats did not show any significant changes in brain glucose uptake. Therefore, the decline of glucose uptake coincident with increase in ketone body levels in females may reflect a metabolic shift from relying solely on glucose towards that utilizing both glucose and ketone bodies, which may be correlative to the increased white matter catabolism as we reported previously. Collectively, this longitudinal study will facilitate the identification of optimal intervention windows in APOE-ε4 carriers and peripheral metabolic markers predictive of neurological changes.

Abstract: Neurodegenerative diseases (NDs) - including Alzheimer's disease (AD), Parkinson's disease (PD), and spinocerebellar ataxias (SCA) - all share the common feature of intra- and extracellular protein deposits. Most NDs are sporadic, and are not inherited in a monogenic Mendelian way; only 5-10% of PD and less than 10% of AD cases are thought to have a genetic component. Still, animal models based on familial mutations are used to study idiopathic forms of NDs, as both forms are believed to be consequence of similar pathogeneses. A shared mechanism of disease in idiopathic and familial NDs is supported by almost identical clinical and pathological findings in the two forms. The field has devoted substantial resources to the study of idiopathic NDs: through the use of next generation sequencing, genome wide genetic screens in humans and in animal models of disease, and finally by attempting to identify traits of disease risk by comparing patients with controls. However, a combined quantification of the results of the different datasets has yet to be done. Here we propose an approach to combine these datasets. We use meta-analytical statistical methods to find genes showing patterns of consistent differential expression in human and mouse PD and SCA3.

Title: Small ubiquitin-like modifier (SUMO) impacts on neuronal function and neurodegeneration

Authors: *H. TAKAMURA[1,2], S. MATSUZAKI[3], K. YAMADA[1], T. KATAYAMA[1], P. E. FRASER[2,4]
[1]Osaka Univ., Osaka, Japan; [2]Tanz Ctr. for Res. in Neurodegenerative Diseases, Univ. of Toronto, Toronto, ON, Canada; [3]Dept. of Pharmacol., Wakayama Med. Univ., Wakayama, Japan; [4]Dept. of Med. Biophysics, Univ. of Toronto, Toronto, ON, Canada

Abstract: SUMOylation plays important roles in cellular events and is involved in several aspects of neuronal development and function. SUMO exists as three isoforms, SUMO1 and SUMO2/3, which display approximately 50% sequence homology. It has been reported that SUMO1 and SUMO2/3 function to regulate proteins in several ways including subcellular localization, nuclear transport, transcriptional repression, and cell cycle progression. To investigate the functional consequences of SUMOylation, we generated a SUMO1 transgenic model and identified ~100 candidate SUMO1 conjugated proteins by proteomic analysis. A number of cytoskeletal proteins, including the microtubule associate tau protein, were found to be SUMOylation targets that are involved in the development and maintenance of dendritic spines. To examine the links between tua and SUMOylation in more detail, we focused on the relationship between SUMO1 and tauopathies which are a class of neurodegenerative diseases characterized by the accumulation of abnormal hyperphosphorylated tau as neurofibrillary tangles (NFTs). Tauopathies encompass a broad range of disorders including Alzheimer's and Pick's disease, Frontotemporal Dementia with Parkinsonism (FTDP-17), corticobasal degeneration (CBD), chronic traumatic encephalopathy (CTE) and progressive supranuclear palsy (PSP). We examined the impact of SUMOylation on tau and found that the conjugation of SUMO1 modulates tau misfolding and accumulation both in vitro and in vivo. SUMO isoform-specific effect of tau aggregation was observed that was also dependent on the particular tau isoforms. These results suggest a significant contribution of SUMO1 modification to neuronal function and also have implications for the mechanisms of neurodegeneration involving tau pathology.

Title: Role of calcium release activated calcium (CRAC) channels in P2X7R-mediated cytokine production

Authors: *F. M. MUNOZ[1], X. GAO[4], J. XIA[2], J. JIANG[1], H. HU[3]
[2]Dept. of Pharmacol. & Physiol., [3]Pharmacologe and Physiol., [1]Drexel Univ. Col. of Med., Philadelphia, PA; [4]Dept. of Pharmacol. and of Chinese Materia Medica, China Pharmaceut. Univ., Nanjing, China

Abstract: Spinal astrocytes respond to peripheral inflammation by releasing cytokines, which are thought to be involved in central mechanisms underlying the maintenance and exaggeration of chronic pain. The specific molecular mechanisms that control cytokine production from reactive astrocytes remain largely unknown. Ca^{2+} signals in astrocytes mediate a remarkable variety of cellular functions, including glutamate release and cytokine production. Among the various mechanisms by which cellular Ca^{2+} signals are generated, store-operated calcium channels (SOCs) have recently emerged as a widespread pathway for regulating many Ca^{2+}-dependent functions. ATP can activate a wide variety of pathways through P2 purinoreceptors, allowing downstream effects that can lead to neuroprotection and pathology in the CNS. The P2X7 receptor (P2X7R) is a well-defined ionotropic cation channel that plays a key role in the development of chronic pain associated with nerve injury and inflammation. Recently, we have demonstrated that SOC proteins are expressed and functional in astrocytes. SOC activation increased TNF-α and IL-6 production in cultured astrocytes. Here we report that SOC activation with thapsigargin (TG) and P2X7R activation with ATP and the specific P2X7R agonist 2′(3′)-O-(4-Benzoylbenzoyl) adenosine 5′-triphosphate (BzATP) increases phosphorylation of ERK and CaMKII and subsequently stimulates production of IL-6 in cultured astrocytes. Interestingly, ATP- and BzATP-induced cytokine production was attenuated by SOC inhibitors YM58483 and 2-APB, and knockdown of SOC pore-forming subunits known as CRAC channels (Orai1, 2, 3) attenuated IL-6 production in a store-independent manner. These findings implicate a link between SOCs and P2X7R in astrocyte-mediated cytokine release.

Title: STIM1 plays a role in spinal cord synaptic transmission

Authors: *J. XIA[1], F. M. MUNOZ[2], R. JEAN-TOUSSAINT[3], H. HU[2]
[1]Dept. of Pharmacol. & Physiol., [2]Pharmacol. and Physiol., [3]Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: Increasing evidence indicates store-operated calcium channels (SOCs) in the nervous system contribute to neuronal Ca^{2+} signaling. STIM1, an ER Ca^{2+} sensor, plays a critical role in the activation of Orai channels that mediate store-operated Ca^{2+} entry (SOCE). Our recent studies suggest that SOCs are expressed and functional in spinal cord dorsal horn neurons and are involved in central sensitization. Its underlying mechanisms remain elusive. Here we found that STIM1 is mainly expressed in projection neurons and excitatory interneurons, but not in GABAergic neurons in the spinal cord dorsal horn. To determine whether STIM1 plays a role in spinal cord long term potentiation (LTP), we made conditional knockout (KO) mice in which STIM1 is deleted in vesicle glutamate transporter (VGLUT2) positive neurons and recorded field excitatory postsynaptic potentials (fEPSPs) evoked by dorsal root stimulation in the superficial dorsal horn. LTP was induced by high-frequency stimulation (HFS) of a dorsal root, which lasted for at least one hour in the spinal cord from wild type mice. However, the induction of LTP was dramatically attenuated in the spinal cord from STIM1 KO mice, suggesting STIM1 plays a role in synaptic plasticity. Furthermore, we found that AMPA-induced Ca^{2+} influx was reduced in STIM1 KO spinal cord dorsal horn neurons, but GluA1 and GluA3 protein levels were not altered in KO mice, indicating a regulatory role of STIM1 in AMPAR-mediated Ca^{2+} signaling in the spinal cord dorsal horn. Together, the results in the present study demonstrate that STIM1 plays a role in the development of spinal LTP presumably due, in part, to the regulation of AMPAR. These findings indicate an important role of STIM1 in spinal cord synaptic transmission that contributes to central sensitization.

Title: Heteromeric glycine receptors regulate the excitability of inhibitory interneurons via phasic and tonic inhibition

Authors: M. A. GRADWELL[1], D. I. HUGHES[2], *R. J. CALLISTER[3], B. A. GRAHAM[3]
[1]Biomed. Sci. and Pharmacy, Hlth. and Med., Univ. of Newcastle, Callaghan, Australia; [2]The Univ. of Glasgow, Glasgow, United Kingdom; [3]The Univ. of Newcastle, Callaghan, Australia

Abstract: The spinal cord dorsal horn contains inhibitory interneurons (INs) that release GABA and glycine. Both neurotransmitters can activate synaptic and extrasynaptic receptors to mediate phasic and tonic inhibition, respectively. In the dorsal horn and brain, GABA receptors with different subunit composition can be targeted to synaptic and/or extra-synaptic locations. Here we ask whether glycine receptors with different subunit composition can also be directed to synaptic and extrasynaptic sites in parvalbumin (PV) expressing inhibitory INs. Adult mice (P60-90, both sexes) were deeply anaesthetized with ketamine (100 mg/kg, i.p.) and decapitated. Transverse spinal cord slices (300 um thick) were prepared from the lumbar cord and whole cell recordings were obtained using a CsCl-based internal. Phasic glycinergic inhibition dominated in PVINs, because mIPSCs were bicuculline (10 uM) and picrotoxin (50 uM) resistant, and completely abolished by strychnine (1 uM). Peak scaled non-stationary noise analysis on these mIPSCs estimated mean single channel conductance at 36 ± 3 pS (n = 20). This is consistent with synaptic clustering of heteromeric beta-subunit containing glycine receptors. We also showed that PNINs are under tonic glycinergic inhibition (n=14) because holding current and baseline noise were not affected by bicuculline and picrotoxin, whereas strychnine reduced mean amplitude and baseline noise by ~100 pA and ~10 fold, respectively. Conversely, addition of glycine transporter blockers increased holding current and baseline noise. Non-stationary noise analysis, undertaken on the tonic current during the onset of strychnine block, estimated mean single-channel conductance to be 29 ± 1 pS (n = 19). These data are consistent with the tonic current being mediated by heteromeric beta subunit-containing glycine receptors. Enhancing tonic inhibition with glycine transporter blockers reduced action potential (AP) discharge frequency in PVINs (n = 23), whereas addition of strychnine had the opposite effect (n = 14). To assess whether endogenous glycine, released by synaptic activity, could also influence PVIN excitability we evoked glycine-mediated currents using an extracellular bipolar stimulating electrode. Evoked glycine currents increased holding current and baseline noise by 82 ± 46 pA and 200%, respectively (n = 10) and modulated AP discharge in a third of neurons tested. Together, these data suggest: 1) glycine subunit composition is similar at synaptic vs. extrasynaptic sites on PVINs; and 2) tonic glycine-mediated inhibition can modify the output of PVINs and alter how spinal circuits process sensory information.

Title: Regulation of spinal nociceptive processing by the Na^+ leak channel NALCN

Authors: *N. C. FORD[1], D. REN[2], M. L. BACCEI[1]
[1]Anesthesiol., Univ. of Cincinnati Dept. of Anesthesiol., Cincinnati, OH; [2]Biol., Univ. of Pennsylvania, Philadelphia, PA

Abstract: Recent work suggests that a tonic conductance mediated by the Na^+ leak channel NALCN increases the intrinsic membrane excitability of spinal lamina I projection neurons (PNs) and can be enhanced by substance P (SP) signaling. However, the degree to which NALCN is required for SP-evoked activation of spinal PNs, and its potential role in regulating pain sensitivity, remains unclear. To address this issue, NALCN was deleted in spino-parabrachial (PB) neurons via the injection of AAV1-hSyn-Cre-eGFP into the lateral parabrachial nucleus of C57BL6 $NALCN^{fl/fl}$ mice on postnatal day (P) 3. Similar injections of AAV1-hSyn-GFP were used as a control. Whole-cell patch clamp recordings were obtained from GFP-labeled spino-PB neurons using in vitro spinal cord slice preparations on P10-14. Bath application of 5 µM SP evoked significantly weaker membrane depolarization and fewer action potentials in NALCN-knockout PNs compared to PNs infected with AAV1-hSyn-GFP, suggesting that the SP-dependent output of spinal pain circuits is shaped by NALCN activity. To characterize the functional implications of NALCN expression within the spino-PB pathway for pain sensitivity, ongoing studies are comparing mechanical and thermal withdrawal thresholds in mice injected with AAV1-hSyn-Cre-eGFP or AAV1-hSyn-GFP into the PB. Spontaneous pain behaviors in response to the intraplantar injection of capsaicin will also be examined following the deletion of NALCN within spino-PB circuits. The current results suggest that NALCN channels are critical mediators of SP-induced excitation of ascending projection neurons during early life. This raises the possibility that the level of NALCN conductance in this population influences pain perception in the developing brain.

Title: The role of neuropetide-Y expressing dorsal horn inhibitory interneurons in nociceptive and pruriceptive circuits

Authors: *K. A. BOYLE, E. POLGAR, A. C. DICKIE, A. J. TODD
Inst. of Neurosci. & Psychology, Univ. of Glasgow, Glasgow, United Kingdom

Abstract: Previous work from our laboratory has identified neuropeptide Y (NPY)-expressing neurons of the dorsal horn as a subpopulation of inhibitory interneurons that are well placed to modulate spinal nociceptive circuits through connections with nociceptive projection neurons and other dorsal horn interneurons (Iwagaki et al. (2016), Pain 157:598-612). A recent study that aimed to ablate or silence dorsal horn NPY-expressing interneurons (NPY-INs) in the RH26 *NPY::Cre* mouse line reported no effects on acute mechanical or thermal nociception (Bourane et al. (2015), Science 350:550-554). However, the method employed in that study will also have captured a broader population of inhibitory interneurons that transiently express NPY. Here we demonstrate that intraspinal injection into adult RH26 mice of adeno-associated viruses (AAVs) carrying Cre-dependent constructs allows for much more specific targeting of NPY-INs. We have used this method to achieve reliable and relatively specific activation of NPY-INs through injection of an AAV construct that expresses the excitatory DREADD hM3Dq (together with the fluorescent protein mCherry) in a Cre-dependent manner. We then assessed the effects of NPY-IN activation on nociceptive circuit activity and behaviour. Following systemic administration of the hM3Dq agonist clozapine N-oxide (CNO), we were able to detect the transcription factor Fos (a marker of neuronal activation) in the vast majority of virally-infected Cre-expressing neurons in laminae I-III. However the proportion of mCherry-negative neurons in laminae I-II that expressed Fos following a noxious heat stimulus was significantly lower in CNO-treated animals compared to vehicle-treated controls, suggesting NPY-IN activation can inhibit neurons that are normally activated by noxious thermal stimuli. In agreement with this conclusion, CNO-treated mice displayed a significantly longer latency of withdrawal from a radiant heat source (Hargreaves test) compared to vehicle-treated controls, although this effect was mild. A much more robust increase in mechanical withdrawal threshold was also observed in CNO-treated mice. DREADD-mediated activation of NPY-INs also markedly reduced itch-related behaviour in mice that received an intradermal injection of the pruritic agent chloroquine. Our results

highlight NPY-INs as an important inhibitory element in dorsal horn circuits that process acute pain- and itch-related signals.

Title: Gastrin releasing peptide boosts the functional output from spinal itch-processing circuits

Authors: *M. PAGANI[1], H. JOHANNSSEN[1], H. U. ZEILHOFER[1,2]
[1]Inst. of Pharmacol. and Toxicology, Univ. of Zurich, Zuerich, Switzerland; [2]Inst. of Pharmaceut. Sci. ETH, Zuerich, Switzerland

Abstract: Gastrin-releasing peptide (GRP) and its cognate receptor (GRPR) have been identified as important components in spinal cord pruriceptive-processing. However, the functional aspects of spinal itch-processing circuits are not well understood. Here, we combined electrophysiological and optogenetic approaches to functionally characterize GRP- and GRPR-positive neurons and to study their synaptic connectivity as well as modulation by GRP. We performed whole-cell patch-clamp recordings from GRP and GRPR neurons in acute spinal cord slices to characterize their intrinsic biophysical properties and firing patterns. We found that GRP neurons constitute a rather homogenous population with 92% of cells showing initial bursting firing. GRPR neurons were more heterogeneous comprising delayed (64%) and non-delayed (36%) firing subpopulations. We also found that delayed-firing GRPR neurons had significantly hyperpolarized resting membrane potentials (RMP), lower input resistances (Ri) and higher rheobase compared to GRP neurons. These characteristics are consistent with delayed-firing GRPR cells being glutamatergic neurons involved in integrating and transmitting the spinal itch information. We then characterized the synaptic connectivity between GRP- and GRPR-positive neurons in slices prepared from GRP-ChR2_GRPR::eGFP mice and found that GRP neurons were synaptically connected to GRPR neurons. Under baseline conditions, light stimulation of ChR2-expressing GRP cells induced sub-threshold responses in GRPR neurons. Application of 300 nM GRP caused a slow depolarization of delayed-firing GRPR neurons, which often resulted in ongoing action potential firing after several minutes. Moreover, in the presence of exogenous GRP, the same light stimulation paradigm triggered action potential firing in GRPR delayed neurons. Our results represent a detailed physiological characterization of

GRP- and GRPR-cells involved in spinal pruriceptive processing and suggest that GRP acts as an essential positive modulator to enhance the output of itch-processing circuits.

Abstract: Itch, also known as pruritus, is an irritating cutaneous sensation that induces a scratch reflex. Itch has evolved to detect the presence and consequently to promote the removal of harmful agents. However, in several cutaneous and systemic diseases, itch can also become chronic, thus severely affecting the quality of life. Yet, the mechanisms that drive itch sensations are not fully understood. Previous studies have shown that spinal neurons that express gastrin-releasing peptide receptor (GRPR) are required specifically for chemically induced pruritic behaviors. Our study aims to better understand the neural circuit that provides input to GRPR neurons. To this end, we have characterized and manipulated neurons in which Cre is expressed under the control of the GRP gene, the gene that codes for the GRPR ligand. Immunohistochemical studies identified the GRP+ cells as a subset of excitatory interneurons, which are present in laminae I and II of the spinal dorsal horn. Moreover, GRP+ cells were found to receive direct synaptic contacts from MrgprA3+ neurons (a subset of primary afferent fibers associated with itch). Behavioral analysis of mice after ablating GRP+ neurons showed specifically reduced itch responses to chloroquine, histamine and serotonin. Conversely, activation of GRP+ cells showed and increased spontaneous and pruritogen-induced scratching behavior. Responses to painful thermal and mechanical stimuli were unaffected by the loss or activation of GRP+ neurons. Taken together, our results indicate a specific role of GRP+ neurons in spinal itch processing circuits.

Title: A comparison of morphology and function of gastrin-releasing peptide and substance-P expressing interneurons in the spinal dorsal horn

Authors: *A. BELL[1], A. DICKIE[1], N. IWAGAKI[1], R. KELLY[1], S. WEST[2], M. GUTIERREX-MECINAS[1], E. POLGAR[1], A. J. TODD[1]

Abstract: Numerous interneurons are present in the superficial dorsal horn of the spinal cord and these cells regulate the transmission of information perceived as touch, pain, or itch. Despite the importance of these cells, our understanding of their roles in the neuronal circuitry is limited by the difficulty in identifying functional populations. We have previously identified two non-overlapping groups of excitatory interneurons in the mouse dorsal horn defined by the expression of either gastrin-releasing peptide (GRP) or substance P. Here we aim to provide evidence that differences exist in the morphology of these cells, their synaptic inputs and their response to nociceptive and pruritic stimuli which suggest they represent two functional populations.
To allow comparison of dendritic morphology, individual cells were digitally reconstructed. Reconstructions of GRP-expressing cells were based on confocal scans of Neurobiotin filled cells from a transgenic GRP-EGFP mouse. Substance P-expressing dendritic arbours were traced from single cells revealed by Cre-dependent Brainbow viral injection in $Tac1^{Cre}$ mice. Substance P-expressing cells appear to be of predominantly radial morphology, while GRP cells are either unclassified or central. Detailed morphometric parameters were extracted from reconstructions enabling hierarchical cluster analysis. Based on this, the two cell populations can be divided into two well defined clusters demonstrating they are morphologically distinct.
GRP cells do not respond to pruritic stimulation by expressing fos or phosphorylating ERK. This is in contrast to substance P-expressing cells many of which respond to noxious thermal and mechanical stimuli and to intradermal injection of pruritogens. Further to this we show that ERK phosphorylation also seldom occurred in GRP cells following pinch, capsaicin or heat stimulation. To determine if different patterns of input underlie this differential responsiveness, we have determined the synaptic inputs to these cells via an immunofluorescence approach using the post-synaptic marker Homer. Substance P-expressing cells appear to receive a greater proportion of synapses from other excitatory interneurons than the GRP cells. GRP cells also

receive synapses from VGLUT3 expressing C-LTMR primary afferents which may have implications for their function.
Despite distinct differences between these two cell populations, their exact functional roles remain unclear. Substance P-expressing excitatory neurons are likely to be important in the transmission of pain and itch, while the situation surrounding GRP expressing cells is more uncertain.

Title: Expression of metabotropic glutamate receptors in the rat spinal cord

Authors: *M. OKUBO, H. YAMANAKA, K. KOBAYASHI, K. NOGUCHI
Hyogo Col. of Med., Nishinomiya, Japan

Abstract: Glutamate is released as a neurotransmitter by most excitatory synapses in the nervous system. It also plays a key role in the physiological excitatory circuit in the spinal cord and is involved in pathological neurotransmissions such as inflammatory and neuropathic pain conditions. The actions of glutamate are mediated by different types of receptors that are ionotropic (iGluRs, AMPA, NMDA and kainate) and metabotropic (mGluRs) ones. Although it is well-studied expression of iGluRs, that of mGluRs is not fully elucidated in the spinal cord. In this study, we examined expression of mGluRs (mGluR1-8) in the spinal cord in rats by using conventional RT-PCR and *in situ* hybridization histochemistry (ISHH). RT-PCR revealed that mGluRs mRNA, excepted for mGluR2 and 6, was detected in the spinal cord. We next examined expression pattern of mGluRs mRNA by ISHH. It showed that mGluR1 and 4 mRNAs were weakly expressed throughout the gray matter of the spinal cord. mGluR3 mRNA was expressed throughout the spinal cord and may be expressed not only in the neurons but also in the glial cells. mGluR5 and 7 mRNAs were expressed in the gray matter and were unevenly distributed to dorsal horn of the spinal cord, especially Lamina I-III. mGluR8 mRNA was relatively expressed in the gray matter of the spinal cord. mGluR2 and 6 mRNAs could not be detected in the spinal cord. These finding suggest that mGluR5 and 7, which were especially expressed in Lamina I-III of the dorsal horn, may have principal roles in the glutamate transmission that modulates pain signaling in spinal cord.

Title: Altered synaptic properties of the spinal, metabotropic GABAb receptor in female mice after neonatal injury

Authors: *C. L. BREWER[1], M. L. BACCEI[2]
[1]Anesthesiol., Univ. of Cincinnati, Cincinnati, OH; [2]Anesthesiol., Univ. of Cincinnati Dept. of Anesthesiol., Cincinnati, OH

Abstract: Early-life injury produces permanent changes in pain-transmitting neurocircuitry. However, the underlying mechanisms of how nociceptive circuits respond to and are affected by noxious stimuli remains to be elucidated. In the adult mouse spinal dorsal horn it has been shown that a reduction in fast inhibitory synaptic transmission through GABAa and glycine receptors results from neonatal hindpaw incision. However, there is a gap in knowledge regarding the effects of neonatal hindpaw incision on slow inhibitory synaptic transmission through metabotropic receptors like GABAb. The GABAb receptor is highly expressed in the superficial dorsal horn (SDH) of the spinal cord and has multi-faceted inhibitory actions at the neuronal synapse. In the presence of GABA, the receptor presynaptically inhibits calcium channels, thus reducing or preventing the release of neurotransmitter vesicles from the presynaptic cell. GABAb also activates potassium channels postsynaptically, and this causes an outward current that hyperpolarizes and prevents the cell from firing action potentials. This study focuses on two cell types in the SDH, inhibitory GABAergic interneurons that locally modulate pain circuits, and lamina I projection neurons which serve as the conduit for pain transmission from the spinal cord to the brain. Using *in vitro* patch-clamp electrophysiology in adult mouse spinal cord slices, this study has shown a larger postsynaptic outward current amplitude, evoked by the GABAb agonist baclofen, in projection neurons after neonatal hindpaw incision. Interestingly, the incision also caused a significant decay effect in the outward current, which is suggestive of increased GABAb receptor desensitization. This effect may play a role in the disinhibition involved in nociceptive processing. Incision had no effect on baclofen-induced outward current in mature GABAergic interneurons, indicating a cell type specific effect. In addition, incision did not alter the presynaptic actions of GABAb in either projection neurons or GABAergic interneurons. These results suggest that tissue damage during early life persistently alters

postsynaptic GABAb-mediated inhibitory signaling within spinal pain networks, specifically in SDH projection neurons.

Title: Differences between two well neurochemically defined excitatory interneuron populations in the mouse superficial dorsal horn

Authors: *M. GUTIÉRREZ MECINAS[1], A. DICKIE[1], N. IWAGAKI[1], M. HERAU[2], A. BELL[1], E. POLGAR[1], A. TODD[1]
[1]Spinal Cord Group, [2]Univ. of Glasgow, Glasgow, United Kingdom

Abstract: The dorsal horn of the spinal cord is important because contains the first synapse of pain and itch pathways, and is a site at which significant modulation of nociceptive and pruritoceptive transmission can occur. Interneurons, which account for the great majority of neurons in laminae I-III, are diverse in terms of their structure and function and are complexly organized. They can be divided into two main groups: inhibitory (GABAergic and/or glycinergic) and excitatory (glutamatergic) neurons. Our group has described four largely non-overlapping populations among the inhibitory interneurons have been defined in laminae I-II based on expression of neuropeptide Y, parvalbumin, nNOS or galanin/dynorphin. More recently, we have also described another four neurochemically different groups among the excitatory interneurons: those with the expression of neurotensin, neurokinin B, gastrin-releasing peptide (GRP) or substance P.
Due to their anatomical location, neurons expressing either GRP or substance P are a very interesting group to be studied further. As shown in another poster (Bell et al) these two groups are morphologically different, but differences extend beyond that. Physiologically, they show predominantly different firing patterns, which scarcely overlap. Substance P expressing cells show mainly delayed or gap firing, while the GRP show transient firing or single spikes, which is particularly interesting as these patterns are not commonly associated with excitatory interneurons. GRP expressing cells respond to MOR agonists but not 5-HT and rarely receive input from TRPV1/M8 expressing primary afferents based on electrophysiological recordings. When long propriospinal projections of these cells axons are studied using spinal injection of neuron tracer it is interesting to see that substance P expressing cells send their axons several

segments cranially while the GRP cells remains close to the cell body.
These results strongly suggest that the GRP and the substance P excitatory interneuron populations might have completely different roles in processing somatosensory information.

Title: Presynaptic facilitation of the monosynaptic reflex in humans and rats

Authors: Y. LI, A. M. LUCAS-OSMA, S. BLACK, K. K. FENRICH, M. J. STEPHENS, L. SANELLI, S. LIN, K. FOUAD, M. A. GORASSINI, *D. J. BENNETT

Abstract: The monosynaptic stretch reflex is well known to be inhibited by presynaptic GABA receptors that shunt action potentials in the sensory Ia afferent terminals on motoneurons[1], reducing local transmitter release. However, less well appreciated are the seminal works of Barron and Matthews[2] and Wall[3] that show that the action potential (AP) often fails to propagate over the entire sensory afferent terminal field (leaving silent branches), likely because of branch point failure in these highly branched and long afferents. While this branch point failure is modulated with anesthesia and injury, we have a lack of understanding of its causes. Here we explore the simple hypothesis that GABA induced primary afferent depolarization (PAD) brings the AP closer to threshold and prevents branch point failure, thus *facilitating* afferent transmission and the monosynaptic reflex, especially heteronymous reflexes where there are long afferents involved with branch points far from their motoneuron terminals. We therefore examined heteronymous and homonymous (H-reflex) monosynaptic reflexes in humans and the influence of sensory and cortical inputs known to produce PAD. In some subjects tibialis anterior (TA) muscle tendon vibration (conditioning stimulation) inhibited the homonymous soleus monosynaptic reflex when applied at a 20 - 100 ms interval prior to the reflex, consistent with the action of classic GABA-mediated PAD and presynaptic inhibition[4]. However, the same conditioning stimulation (vibration) facilitated the H-reflex in other subjects, and in all subjects more diffuse conditioning stimuli (from TA or quadriceps nerves, or motor cortex) facilitated the

H-reflex. Furthermore, the heteronymous monosynaptic reflex from the quadriceps to the soleus was consistently facilitated by diffuse sensory or cortical stimulation, over a time course consistent with PAD. Using intracellular recording from rat motoneurons we found the same facilitation of heteronymous monosynaptic reflexes during PAD evoked by heteronymous sensory afferents. Then, using neurobiotin reconstructions and intracellular recordings from afferents, we found that GABA receptors on Ia afferents facilitate AP conduction by depolarizing the afferent sufficiently to prevent AP failure. In summary, in addition to its putative role in inhibitory shunting, GABA helps prevent AP failure in afferents and thus can also produce presynaptic facilitation of reflex transmission.

Title: Identification of spinal cord neurons that presynaptically inhibit c-nociceptors

Authors: *M. MUSTAPA, A. C. DICKIE, N. IWAGAKI, A. J. TODD, D. I. HUGHES
Univ. of Glasgow, Glasgow, United Kingdom

Abstract: GABAergic interneurons account for 24-31% of cells in laminae I and II. Non-peptidergic C nociceptors central axons terminate in lamina II as a complex form known as type I synaptic glomeruli. These complex consist of GABAergic axons and dendrites, possibly arises from local inhibitory interneurons which mediated presynaptic inhibition. Calretinin (CR) is a marker that has been widely used to define excitatory interneurons in the SDH and it is also express in some inhibitory interneurons. Later studies using CR::eGFP mice showed ~10% of CR neurons populations in lamina II of the dorsal horn are inhibitory interneurons. These cells showed tonic firing and they are islet cells. Preliminary data suggests that these CR islet cells form axoaxonic synapses on C^{MrgD} nociceptors. The aim of this study was to further characterise

the anatomical and electrophysiological properties of CR islet cells, with a view to assessing their role in providing presynaptic inhibition to C fibers. We used multiple mouse lines for anatomical part of the study. First two were Nociceptin::eGFP and RORb::eGFP mice. Both of these eGFP cells labels inhibitory interneurons throughout the dorsal horn. We also used sparsely labelled $RorB^{CreERT2}$;Ai9 mice to look at the CR islet cells contact with IB4 labelled primary nociceptors and to look at the morphology. For the combined electrophysiological and morphological study, CR^{cre};Ai9 mice (in which CR cells express tdTomato) were crossed with Noc::eGFP mice, which resulted in double labelling of cells expressing both nociceptin and CR with eGFP and tdTomato. We found, CR-Noc::eGFP cells are present in 6.8% of all neurons in lamina II and 1.5-2.5% of those in laminae I and III. These cells are expressed by 25% of inhibitory interneurons in lamina II and 5-11% of those in lamina I and III. None of the four inhibitory neurochemical markers (NPY, nNOS, Galanin and Parvalbumin) are labelled with CR-Noc::eGFP neurons and ~30-40% of those expressed sst_{2A} receptor. We found 28% of sparselly labelled $Rorb^{CreERT2}$ Ai9 mice boutons contacted IB4 terminals and appear to be islet morphology. Half of excitatory synapses on Rorb cells come from IB4 boutons (51%). In the CRcre;Ai9;Noc::eGFP mice, we found cells double labelled with GFP (Noc) and tdTomato (CR). Patch clamp recordings from these CR/Noc cells showed they exhibited characteristics of inhibitory interneurons, and that the majority of cells received monosynaptic C fiber input, including input from TRPV1-lacking afferents. These results suggest that CR islet cells are a major source of presynaptic inhibition on C^{MrgD} primary afferent.

Title: Primary afferent inputs to spinal lamina III antenna cells

Authors: E. C. FERNANDES[1], I. SANTOS[1], L. L. LUZ[1], E. KOKAI[2], D. HADHAZI[2], P. SZUCS[2], *B. V. SAFRONOV[1]
[1]Neuronal Networks, IBMC, Porto, Portugal; [2]Dept. of Anat., MTA-DE-NAP B-Pain Control Res. Group, University of Debrecen, Hungary

Abstract: Dorsal horn of the spinal cord integrates and modulates primary afferent input to transmit it to supraspinal centers. Nociceptive myelinated Aδ and unmyelinated C fibers terminate in the superficial dorsal horn formed by laminae I-II, whereas thickly myelinated Aβ afferents mainly project to deeper laminae III-IV. There is in this region, however, a subset of neurons responding to both non-noxious and noxious stimuli whose role in nociceptive network is poorly understood. Here we did whole-cell patch-clamp recordings in an isolated spinal cord preparation with attached dorsal roots to characterize anatomically and electrophysiologically lamina III neurons receiving nociceptive input. Based on morphological features nine neurons in our sample have been identified as antenna cells. Their axons were located in laminae III-IV and, after crossing lamina II, also gave collateral branches in lamina I. Propriospinal collaterals in the lateral and dorsal fasciculus proprius were also present. Likewise, they had dorsal dendrites that projected as far as to lamina I (some branching extensively in the subpial white matter) and ventral dendrites distributed through laminae III-VII. These neurons showed mainly a tonic pattern of intrinsic firing (n=6). Antenna cells received monosynaptic primary afferent inputs from the low-threshold Aβ fibers (n=3), and in addition, from Aδ (n=7) and C (n=6) fibers. Thus, our results indicate that antenna cells are a specific group of lamina III neurons whose dendrites receive primary afferent input from Aβ, Aδ and C fibers, and axons relay information back to the superficial dorsal horn. Antenna cells represent an important element of the nociceptive neuron circuitry interconnecting deep and superficial dorsal horn.

Title: PV-expressing cells in the mouse spinal dorsal horn gate the transmission of innocuous tactile input to lamina I

Authors: *A. DICKIE[1], K. A. BOYLE[1], T. YASAKA[2], V. E. ABRAIRA[3], A. L. ZIMMERMAN[3], D. D. GINTY[3], M. A. GRADWELL[4], R. J. CALLISTER[4], B. A. GRAHAM[4],

D. I. HUGHES[1]
[1]Univ. of Glasgow, Glasgow, United Kingdom; [2]Dept. Immunol., Kagoshima Univ., Kagoshima, Japan; [3]Harvard Med. Sch., Boston, MA; [4]Univ. of Newcastle, Callaghan, Australia

Abstract: Chronic pain presents a major unmet clinical problem. One feature of chronic pain is the development of allodynia, where previously innocuous tactile stimuli are perceived as painful. We have shown that inhibitory spinal interneurons which express parvalbumin (PV) form axo-axonic synapses on to the central terminals of myelinated afferents, and have proposed that a loss of the inhibition they mediate could contribute to the development of allodynia following peripheral nerve injury. In this study, we aim to determine the synaptic relationship between low threshold mechanoreceptive (LTMR) afferent input and PV-cell mediated inhibition. We have used *in vitro* targeted recordings in spinal cord slices from PV^{Cre};Ai9 mice to show that stimulation of dorsal roots at Aδ strength elicits monosynaptic EPSCs in PV-expressing cells. We have used tissue from $Split^{Cre}$;Ai34 and $TrkB^{CreER}$;Ai35 mice to show that approximately 30% (mean 28.5% SD 14.9) and 35% (35.2% ± 6.3) of VGLUT1 inputs on to inhibitory PV neurons are derived from Aβ and Aδ hair afferents, respectively, and also find that central terminals of most Aβ and Aδ hair afferents receive contacts from inhibitory boutons that express PV (70.7% ± 8.1, and 80.1% ± 3.8, respectively). We also show that 27.9% (± 2.4) of VGAT boutons in contact with the dendrites of vertical cells in lamina IIi and III are derived from PV-expressing cells, and that 61.9% (± 17.2) of the VGLUT1 terminals that target these dendrites associate directly with PV/VGAT boutons. To determine whether PV cells mediate presynaptic inhibition of LTMRs and postsynaptic inhibition of vertical cells, we have also carried out *in vitro* optogenetic experiments in spinal cord slices from PV^{Cre};Ai32 mice. We find evidence of light-induced bicuculline-sensitive polysynaptic EPSCs in vertical cells, indicative of primary afferent depolarisation mediated by PV cells. We also find evidence of monosynaptic IPSCs that are sensitive to both bicuculline and strychnine, indicative of PV-cell mediated postsynaptic inhibition. Our findings provide anatomical and functional evidence that PV cells mediate both presynaptic inhibition of myelinated afferents that synapse on to vertical cells, and postsynaptic inhibition of the vertical cells themselves. We propose that decreased PV cell-mediated inhibition unmasks a circuit involving vertical cells. This enables LTMR input from lamina IIi and III to activate lamina I pain circuits, and could result in allodynia. Together, these findings identify PV interneurons as a target for therapeutic intervention to alleviate allodynic conditions.

Title: Analysis of spinothalamic tract neuron connectivity in the lumbar enlargement of the mouse spinal cord

Authors: *A. G. SKORPUT, M. S. RIEDL, C. N. HONDA, L. VULCHANOVA
Neurosci., Univ. of Minnesota, Minneapolis, MN

Abstract: Local circuitry in the dorsal horn of the spinal cord remains incompletely understood yet the plasticity of these circuits and their involvement in the development and maintenance of chronic pain states are increasingly clear. Among the remaining questions is the identity and relative abundance of interneuron subtypes that synapse onto spinothalamic tract (STT) projection neurons. As the ascending output neurons for nociceptive information flowing within intraspinal sensory circuits, the balance of synaptic inhibition verse excitation upon STT neurons is largely responsible for determining whether a given somatosensory stimulus will be perceived as noxious. Utilizing viral (AAV9) based retrograde tracing methods, we have labeled STT neurons in the lumbar enlargement with tdTomato. Application of multiphoton confocal imaging and CLARITY based tissue clearing methods has enabled visualization of STT neurons throughout the depth of the spinal cord dorsal horn along the full length of the intact lumbar enlargement. This viral tracing method labels both superficial (Layer I, IIo) and deep (Layer V) STT projection neurons, presumably representing both nociceptive specific and wide dynamic range populations. These methods are being expanded to include ΔG-Rabies based monosynaptic tracing methods to allow fluorescent labeling of interneurons with presynaptic input to STT neurons. Subsequent immunohistochemical analysis will allow identification and quantification of known dorsal horn interneuron subtypes and categorization as either inhibitory or excitatory in nature. Future experiments will examine changes to this connectivity in animal models of chronic pain. Additionally, these methods may provide a route for genetic manipulation of STT projection neurons and their presynaptic input neurons for integrated neuroanatomical and physiological analyses in naïve and chronic pain animals.

Title: Electrophysiological responses of lamina X spinal cord neurons to primary afferent stimulation

Authors: *V. KROTOV[1], A. TOKHTAMYSH[2], P. BELAN[1], N. VOITENKO[1]
[1]Bogomoletz Inst. of Physiol., Kiev, Ukraine; [2]Taras Shevchenko Natl. Univ. of Kiev, Kiev, Ukraine

Abstract: The area around the central canal (or lamina X) is the most enigmatic lamina of the spinal cord. It is established that nociception, autonomic regulation and modulation of motoneuron output are mediated by lamina X neurons. Nevertheless, their electrophysiological properties and functional connectivity are largely unknown. Using oblique LED illumination we developed a technique allowing visually guided patch clamp of lamina X cells combined with simultaneous stimulation of dorsal roots. Cell-attached recordings from the lamina X neurons of L4-L5 lumbar segments showed that 70% of these cells spontaneously generate action potentials (APs), though just 43% of these neurons generated APs in response to supramaximal (C-fiber) stimulation of L4 or L5 dorsal root. The same stimulation in the whole cell patch clamp configuration induced responses in more than 90% of neurons, indicating that in a half of lamina X neurons nociceptive stimulation results in inhibitory or subthreshold excitatory postsynaptic currents. Interestingly, the percentage of neurons responding to a low threshold A-fiber stimulation was much lower (38%), suggesting that lamina X is preferentially innervated by C-fiber primary afferents. Analysis of responses to dorsal root stimulation revealed the following. First, the responses were quite diverse, several (5-7) various types could be distinguished. The most notable one was characterized by a strong spontaneous synaptic activity superimposed on a prolonged (up to several seconds) inward current. We hypothesize that neurons exhibiting such response might serve as integrators of network activity. Second, the majority of responses had a polysynaptic component, though in at least 25% of neurons monosynaptic responses (determined by high reproducibility and low jittering) were found. Third, in 25% of lamina X neurons polysynaptic inhibitory currents were observed upon supramaximal stimulation indicating lamina X neurons are under substantial inhibitory control. Finally, low frequency (1Hz) dorsal root stimulation caused long term depression (LTD) of monosynaptic excitatory responses in 15% of tested neurons. We conclude that lamina X neurons preferentially receive inputs from C-fiber

primary afferents, stimulation of which elicits AP generation in significant proportion of these cells. A marked percentage of neurons displaying inhibitory inputs and LTD suggests that lamina X circuitry reveals the properties that might be protective during noxious C-fiber activation.

Title: Plant-derived compound-induced outward current in adult rat spinal substantia gelatinosa neurons and the chemical structure of the compound

Authors: T. YU, *T. FUJITA, C. WANG, R. SUZUKI, N. MAGORI, F. YANG, E. KUMAMOTO
Saga Med. Sch., Saga, Japan

Abstract: Many of endogenous analgesics such as opioids, nociceptin, noradrenaline, serotonin and adenosine produce a membrane hyperpolarization in spinal dorsal horn lamina II (substantia gelatinosa; SG) neurons that play a pivotal role in regulating nociceptive transmission from the periphery. Transient receptor potential ankyrin-1 (TRPA1) channels receive nociceptive cold stimuli in the peripheral terminal of dorsal root ganglion neuron while those in the central terminal of the neuron in the SG play a role in modulating nociceptive transmission. We have previously reported in a spinal cord slice that the central terminal TRPA1 channels in the SG are activated by a variety of plant-derived compounds. Among the compounds, there are allyl isothiocyanate, cinnamaldehyde, allicin, zingerone, citral, eugenol, carvacrol and thymol. The latter three compounds of them produced a membrane hyperpolarization while the others did not. It is possible that such a hyperpolarization is involved in antinociception produced by the intraperitoneal administration of the plant-derived compounds. In order to reveal what chemical structures of the plant-derived compounds are important in the production of the hyperpolarization, we examined the effects of guaiacol, vanillin, vanillic acid and *p*-cymene, all of which are similar in chemical structure to eugenol, carvacrol and thymol, on holding current and spontaneous excitatory transmission at -70 mV by applying the whole-cell patch-clamp technique to SG neurons in adult rat spinal cord slices. All of guaiacol, vanillin, vanillic acid and *p*-cymene hardly affected the frequency and amplitude of spontaneous excitatory postsynaptic current. Vanillin and *p*-cymene produced an inward and outward current, respectively, while the other compounds did not change holding currents. In all neurons tested, vanillin at 5 mM elicited

an inward current. On the other hand, *p*-cymene at 2 mM produced an outward current in 24 % of the neurons examined. Comparison of the chemical structure of eugenol with those of guaiacol, vanillin and vanillic acid indicates an importance of -$CH_2CH=CH_2$ bound to eugenol in producing the outward current. Furthermore, the observation that *p*-cymene produces an outward current having peak amplitude much smaller than those of carvacrol and thymol suggests a role of -OH bound to thymol or carvacrol in the production of the outward current. In conclusion, a membrane hyperpolarization produced in SG neurons by some of plant-derived compounds activating central terminal TRPA1 channels requires a functional group bound to the compounds, such as -$CH_2CH=CH_2$ and -OH.

Title: Effects of orexin A and orexin B on spontaneous synaptic transmission in adult rat spinal substantia gelatinosa neurons

Authors: *C. WANG, T. FUJITA, N. MAGORI, R. SUZUKI, F. YANG, E. KUMAMOTO
Saga Med. Sch., Saga, Japan

Abstract: Orexin (hypocretin) A and orexin B originating from the hypothalamus inhibit nociceptive transmission in the spinal dorsal horn. We have previously reported that orexin B produces an inward current at -70 mV and increases the frequency of spontaneous excitatory postsynaptic current (sEPSC) with no change in its amplitude in about a half of the adult rat spinal dorsal horn lamina II (substantia gelatinosa; SG) neurons examined. The SG neurons play a pivotal role in regulating nociceptive transmission from the periphery. The present study further examined the effects of orexin B and also orexin A on holding currents, sEPSCs and spontaneous inhibitory postsynaptic currents (sIPSCs; recorded at 0 mV) in SG neurons by using the whole-cell patch-clamp technique in adult rat spinal cord slices. As with orexin B, orexin A (0.05 μM) produced either inward current or increase in sEPSC frequency that was not accompanied by a change in its amplitude. These orexin A activities were concentration-dependent. The proportion of the neurons sensitive to orexin A was larger than that of orexin B. In the same neurons, the activities of orexin A were not different in extent from those of orexin B. The orexin A and orexin B activities were repeated and resistant to a voltage-gated Na^+-

channel blocker tetrodotoxin. The orexin B effects were inhibited by orexin-2 but not orexin-1 receptor antagonist (JNJ10397049 and SB334867, respectively), while the orexin A ones were inhibited by both SB334867 and JNJ10397049 albeit the latter inhibition was much smaller in extent than the former one. With respect to inhibitory transmission, orexin B (0.05 μM) increased the frequency and amplitude of glycinergic sIPSC in some 70 % of the neurons tested. This orexin B activity was repeated and sensitive to tetrodotoxin. A similar enhancement of glycinergic sIPSC was produced by orexin A (0.05 μM). These results indicate that orexin A and orexin B produce a membrane depolarization in SG neurons and increase the spontaneous release of L-glutamate onto SG neurons from nerve terminals by activating orexin-1 and orexin-2 receptors, both of which actions result in an increase of the excitability of the neurons. Such an increase in neuronal excitability produces action potentials, leading to an enhancement of glycinergic spontaneous inhibitory transmission. It is suggested that antinociception produced by orexin A and orexin B is mediated by glycinergic spontaneous inhibitory transmission enhancement occurring as a result of an increase in the excitability of SG neurons by activating orexin-1 and orexin-2 receptors.

Title: Characterization of DMT-DALDA peptide (2): Study with continuous intrathecal infusion

Authors: *S. KOKUBU[1,2], K. EDDINGER[1], S. YAMAGUCHI[2], P. W. SCHILLER[3,4], T. L. YAKSH[1]
[1]Anesthesiol., Univ. California San Diego, San Diego, CA; [2]Anesthesiol., Dokkyo Med. Univ., Tochigi, Japan; [3]Montreal Clin. Res. Inst., Montreal, QC, Canada; [4]Pharmacol. and Physiol., Univ. of Montreal, Montreal, QC

Abstract: DMT-DALDA (Dmt - 2',6'-dimethyl tyrosine) is an opioid agonist with high selective affinity for the mu-opioid receptor. Work with bolus intrathecal delivery has shown it to be extremely potent, with an efficacious intrathecal dose in the rat of 1-3 pmol as compared to 30 nmol for morphine. Further, consistent with resistance to peptidases, its peptidic structure and charge, it has duration of action that resembles hydrophilic molecules such as morphine. In the present study we characterized the efficacy and side effect profile of DMT DALDA given by

continuous intrathecal infusion to assess side effect profile, tolerance and dependence. Adult male Sprague Dawley rats were prepared with chronically implanted intrathecal catheters and osmotic mini-pumps to deliver vehicle (saline), DMT-DALDA or morphine. Hind paw thermal escape latencies were assessed using a Hargreaves-like device along with systematic assessment of motor function. In addition, effects upon intraplantar formalin-evoked flinching were examined. The following observations were made: i) Intrathecal infusion of 3-30pmol/µl/h of DMT-DALDA or 10 nmol/µL/h of morphine over 7 days resulted in a dose-dependent increase in thermal escape latency. The maximum effect was observed between 1 and 4 days after start of infusion with no motor dysfunction (preserved cornea, blink, placing and stepping, no straub tail). At 100pmol/µl/h or more, DMT-DALDA resulted in motor dysfunction. ii) In separate experiments, DMT-DALDA (20pmol/ 0.5µl/h for 14 days) displayed recovery to baseline by day 10 and below baseline by days 12-14. iii) On days 2-4 of DMT DALDA infusion, the pain antagonist naloxone, but not the delta preferring antagonist naltrendole, antagonized the analgesic action of DMT DALDA. iv) Formalin test on DMT-DALDA Infusion day 1 showed significant analgesia in phases 1 and 2. On day 6 of infusion there was minimal effect, while on day 13, there was an increase in flinching, suggesting tolerance and opioid-induced hyperalgesia. v) On days 7 and 14 of infusion Naloxone resulted in prominent withdrawal signs indicating dependence and withdrawal. These data suggest that DMT-DALDA is a potent, spinally active agonist with a propensity to produce tolerance and dependence.

Title: Multi-laminar electrophysiological recordings in the spinal dorsal horn

Authors: *C. M. GREENSPON[1], I. M. DEVONSHIRE[2], L. DONALDSON[3], V. CHAPMAN[3], G. J. HATHWAY[1]
[1]Sch. of Life Sci., [2]Biol. Support Unit, [3]Sch. of Life Sciences/Arthritis Res. UK, Univ. of Nottingham, Nottingham, United Kingdom

Abstract: Electrophysiological measurements of neuronal activity in the spinal dorsal horn (DH) have made significant contributions to our understanding of the role of the DH in peripheral sensation. The majority of studies have used single unit techniques and focused on wide dynamic

range neurons in lamina V of the DH. Recent studies have highlighted that interactions between laminae are crucial for the integration of both nocuous and innocuous sensory information, which cannot be measured with traditional recording techniques. Here we describe the use of multi-electrode arrays (MEAs) to simultaneously record activity from all laminae of the DH. MEAs were inserted into lumbar 5 of the DH in terminally anaesthetised adult Sprague-Dawley rats to record from laminae I-V. Multi-unit activity and local field potentials were recorded at each electrode. Electrical stimuli of varying intensity (0.1 - 10 mA; 2 ms), duration (5 mA; 200 μs - 20 ms), and frequency (0.1 & 0.5 Hz) were applied to the ipsilateral hindpaw and evoked spinal responses recorded. Effects of intrathecal saline and morphine (5ng/50μl) on evoked responses were recorded. Offline processing was performed using Matlab and Prism.
MEAs quantified fibre electrical thresholds as: Aβ (0.5 mA, $p < 0.0001$ - compared to sub-threshold stimulation); Aδ (1 mA, $p = 0.0054$); C-fibres (5 mA, $p < 0.0001$), post-discharge activity was evident at 5 mA stimulation ($p < 0.0001$). All fibre latencies, similarly, showed encoding of stimulus duration. Depth specific innervation profiles were detected for both C-fibre evoked and post-discharge activity in response to changing stimulus amplitude and duration. Increased firing rate in response to high frequency stimulation was significant (slope: -0.014 at 0.1 Hz, $p = 0.77$; 0.793 at 0.5 Hz, $p < 0.0001$) in the deeper laminae, but not in the superficial or intermediate laminae. Morphine caused significant inhibition in C-fibre activity in the superficial (64% reduction, $p = 0.019$) and deep (72% reduction, $p = 0.029$) laminae. Thus MEAs are an efficient and powerful tool for the study of DH activity and networks.

Title: Neural effects in lactating rats produced by suckling in a somatic reflex

Authors: *M. A. LARA GARCIA[1], Y. CRUZ[2], O. LARA GARCIA[3], P. PACHECO[4]
[1]Univ. Veracruzana, Xalapa, Mexico; [2]Univ. Autonoma Tlaxcala, Tlaxcala, Mexico; [3]Ctr. de Investigaciones Cerebrales, UV, Xalapa, Mexico; [4]Inst. de Investigaciones Biomédicas, Univ. Nacional Autonoma de México, Xalapa, Mexico

Abstract: The milk ejection involves endocrine and neural processes. The last are represented by activation of sensory receptors of the mammary glands, likewise those of the surrounding skin. During suckling, pups activate these receptors through nipple swallowing and by forelimbs movement. Piloerection presence would imply an autonomic reflex activation and probably other reflexes activation such as alert reaction. In the present study, we analyzed if the somatic reflex represented by the tail flick is also involved during suckling. Measurement of tail flick latency (TFL) was performed using lactating rats during the three thirds of lactation. TFL was obtained before, during, and after suckling period. It was observed that TFL was reduced as suckling period went on, reaching its lowest value after 30 min of suckling; moreover, this pattern is different depending on the third of lactation. Regardless presence or absence (empty gland or milk duct blockage) of milk ejection there was no difference in TFL measured 30 min after suckling had started; however, TFL had a different pattern of progressive increment after suckling. Additionally, we found that as compared to dorsum skin mechanical stimulation, mammary gland stimulation showed a significant reduction in TFL. Present results showed that during lactation, sensory input originated by the suckling stimulation produces rapid and strong neuromodulatory plastic changes in the lumbosacral spinal cord.

Title: Cortical dynamics in the mouse during a tactile-detection task

Authors: P. LE MERRE[1,3], V. ESMAEILI[1], C. C. H. PETERSEN[1], P. SALIN[3], *S. CROCHET[2,3]

Abstract: Functional coupling between cortical areas through synchronized activities in different frequency bands is thought to play an important role in various cognitive process, and is strongly affected by behavioral or mental states. In a recent study (Fernandez et al., 2016), we found that the cortical activity in the cortex of the awake mouse is dominated by long-range coherence in a low-frequency band (LF, 0.5-10 Hz), with particularly strong coherence between the medial prefrontal cortex (mPFC) and the parietal associative cortex (PtA), and between these two areas and other cortical areas. On the contrary, long-range cortical coherence dropped during slow-wave sleep in the LF band, despite a large increase in amplitude in this frequency band. In the present study, we investigated the cortical dynamics and long-range interactions in mice involved in a goal directed task requiring sustained attention. Mice were implanted with 6 chronic electrodes to record local field potential and were then trained in a whisker-based sensorimotor detection task (Sachidhanandam et al., 2013). The targeted cortical areas included sensorimotor areas directly involved in processing the whisker sensory stimulus: the whisker primary and secondary somatosensory areas (wS1 and wS2) and the whisker primary motor area (wM1). We also recorded from associative and higher-order areas: mPFC, PtA and the dorsal CA1 region of the hippocampus (dCA1). Overall, the cortical spontaneous activity in mice performing the detection task did not differ markedly from that of mice not involved in a task (spontaneous wakefulness), with periods of high-amplitude, LF activities in sensorimotor areas (wS1, wS2 and wM1) that alternated with periods of low-amplitude, high-frequency activities correlated with motor activity. Delta activity dominated in mPFC while theta activity was more prominent in PtA and dCA1. Interestingly, we observed a strong modulation of cortical activities within behavioral sessions: over single sessions, LF activity increased gradually in most cortical areas with a pronounced increase in wS2 and wM1. This change in cortical activity correlated with a change in behavioral performance with a progressive decrease in false-alarm rate and increase in reaction time, until the mice stopped performing due to lack of motivation. The increase in LF cortical activity, was accompanied by a decrease in coherence that was particularly pronounced between mPFC and PtA, and the sensorimotor areas (wS1, wS2 and wM1). Together, our results support the idea that high functional coupling between distant areas in the LF band may be a marker of high vigilance level and/or attentional states.

Title: Layer, cell-type and pathway-specific thalamocortical input to mouse primary somatosensory barrel cortex

Authors: *B. S. SERMET[1], T. B. ORAM[2], O. YIZHAR[3], C. C. PETERSEN[4]
[1]EPFL, Lausanne, Switzerland; [2]Dept. of Neurobio., Weizmann Inst. of Sci., Rehovot, Israel; [3]Weizmann Inst., Rehovot, Israel; [4]École Polytechnique Fédérale de Lausanne (EPFL), Lausanne, Switzerland

Abstract: In the mouse whisker system, sensory information is relayed to the primary somatosensory barrel cortex by two major thalamic nuclei, the ventral posterior medial nucleus (VPM) and the posterior medial nucleus (POM). While the axonal innervation pattern of these two nuclei has been studied anatomically in some detail, their synaptic input to distinct cell-types across different layers in barrel cortex is incompletely understood. We used the specificity of optogenetics to selectively stimulate axons from VPM or POM, and we measured the evoked excitatory postsynaptic potentitals *in vitro* whole-cell patch-clamp recordings. VPM or POM was infected *in vivo* with an adenoassociated virus encoding the light-gated cation channel channelrhodopsin (ChR2). Synaptic input onto individual neurons of the barrel cortex was recorded in brain slices *in vitro* by activating the ChR2-expressing thalamic axons with blue light. We first measured thalamic inputs onto excitatory neurons across all layers of the barrel cortex, finding that the biggest inputs appeared to largely colocalise with the anatomical innervation pattern. Anatomically, VPM preferantially innervates L4, deep L3 and the L5B/6A border, and, functionally, we found that the biggest input was observed in L4, followed by L2/3. Anatomically, POM innervates L5A and L1, and, functionally, we found the biggest input in L5A, followed by L2/3. In ongoing experiments, we are measuring the input from POM and VPM across cortical layers onto three distinct classes of GABAergic neurons, expressing parvalbumin, somatostatin or vasoactive instestinal peptide. Our results begin to provide a more complete understanding of the distribution of thalamic input to specific cell-types across the layers of the mouse barrel cortex.

Title: Reward-based learning drives recruitment of the medial prefrontal cortex and the dorsal hippocampus during a goal-directed sensorimotor task in the mouse

Authors: *P. F. LE MERRE[1], V. ESMAEILI[1], P. A. SALIN[2], C. C. PETERSEN[1], S. CROCHET[1]
[1]Lab. of Sensory Processing, Brain Mind Inst. Fac. of Life Sci., Ecole Polytechnique Federale De Lausanne (EPFL), Lausanne, Switzerland; [2]Forgetting and Cortical Dynamics Team, Lyon Neurosci. Res. Ctr. (CRNL), Lyon, France

Abstract: Sensory perception leading to goal-directed behavior involves multiple, spatially-distributed and inter-connected cortical areas. It has been hypothesized that sensory information flows from primary sensory areas encoding mainly the features of the stimulus, to higher-order areas encoding the valence of the stimulus. To investigate sensory signals at high time-resolution, we recorded sensory evoked potentials (SEPs) from different cortical areas in mice performing a whisker-based sensory detection task (Sachidhanandam et al., 2013). Mice were chronically implanted with 6 high-impedance local field potential (LFP) electrodes and were either trained to lick a spout immediately after a brief whisker deflection to obtain a reward (detection task), or were exposed to the same whisker stimulus not associated with reward (neutral exposition). In trained mice, whisker deflection evoked SEPs in all recorded areas with latencies increasing from primary somatosensory barrel cortex (wS1) to secondary somatosensory cortex (wS2), the whisker motor cortex (wM1), the parietal association cortex (PtA), the dorsal hippocampus (dCA1) and the medial prefrontal cortex (mPFC). The amplitude of SEPs was significantly larger in Hit trials compared to Miss trials in all areas except wS1. Pharmacological and optogenetic inactivation experiments demonstrated that activity in wS1, wS2, dCA1 and mPFC was required for task execution. The amplitude of the SEP in dCA1 or mPFC increased in correlation with behavioral performance, and whisker deflection did not evoke a SEP in dCA1 or mPFC of neutral exposition mice. Sensory responses in mPFC were acquired during reward-based sensorimotor learning and are essential for task execution. In order to further examine neuronal activity in mPFC, we performed high-density extracellular action potential recordings in mPFC of mice trained in the detection task and in mice after neutral exposition. We found that the whisker stimulus evoked an overall increase in activity of putative excitatory cells in mPFC during the detection task, with stronger evoked activity for Hit trials than for Miss trials. In agreement with LFP recordings, no sensory evoked response was observed in the spiking activity of mice during neutral exposition. Our results suggest the

hypothesis that behaviorally irrelevant stimuli evoke activity mainly limited to sensory areas (wS1, wS2 and wM1), whereas behaviorally relevant sensory stimuli additionally recruit dCA1 and mPFC that are critically involved in task execution.

Title: Optical mapping of large-scale cortical sensorimotor activity in awake head-restrained mice

Authors: M. AUFFRET, *C. C. PETERSEN
École Polytechnique Fédérale de Lausanne (EPFL), Lausanne, Switzerland

Abstract: Optical methods are beginning to provide important information about the spatiotemporal distribution and dynamics of neuronal activity in awake behaving mice. Transgenic animals allow both optical control of neuronal activity through optogenetic actuators, and optical measurement of neuronal activity through imaging genetically-encoded calcium-sensitive fluorescent probes. Those two complementary methods provide the opportunity to optically map the large-scale structure of neuronal network activity during behavior. In a previous study (Auffret et al., 2017) we investigated whisker motor maps evoked by optogenetically stimulating the dorsal sensorimotor cortex of awake mice expressing channelrhodopsin-2 in diverse brain areas. Interestingly, whisker movements were evoked by optical stimulation of multiple broadly distributed cortical regions. Here, we further investigate the organization of dorsal sensorimotor cortex through imaging of awake head-restrained transgenic mice expressing the genetically-encoded calcium-sensor GCaMP6f (Dana et al., 2014). We train mice to detect whisker stimuli and to lick a spout in order to get a reward. In ongoing experiments, we find a rapid response shortly after stimulus onset in primary somatosensory cortex for both hit and miss trials. In hit trials, we observe rapid spread of activity to frontal regions, followed by long-lasting brain-wide activity during a second phase. Our data point to a rich interaction between cortical areas that could play a key role in performing the task. Further experiments and analyses will focus on mapping distinct aspects of the neuronal activity

during different behavioral epochs involved in sensory-motor transformation and decision-making.

Title: Diverse types of interhemispheric membrane potential correlation between somatosensory cortices of awake mice

Authors: *Y. A. KATZ, K. COHEN-KASHI MALINA, I. LAMPL
Neurobio., Weizmann Inst. of Sci., Rehovot, Israel

Abstract: Synchronized neuronal activity is a major hallmark of cortical physiology and it is suggested to contribute in various cortical functions, including enhancing flow of information, coding, and plasticity. Whereas high correlation in nearby cells is expected due to common inputs, correlation among distant cells is less well understood. A particularly striking case is that of interhemispheric correlations which are suggested to arise from transcallosal projections connecting homologous areas. However, these connections cannot fully explain the positive nature of these correlations since they are known to mediate slow interhemispheric inhibition. Interhemispheric correlations were previously examined using extracellular and imaging techniques, but these methods are limited when investigating subthreshold mechanisms and cell type specificity of interhemispheric relationships. Hence greater insight into these questions can be obtained by examining the membrane potential correlations across hemispheres, which have thus far remained unknown in awake animals. Moreover, little is known about the relationships between interhemispheric correlation and brain-state. Using bilateral paired intracellular recordings from the somatosensory cortices of awake mice during ongoing activity, we found

diverse interhemispheric correlations. In the infraslow frequency range (<1 Hz) membrane potentials of some pairs were positively correlated whereas in other pairs we recorded profound negative correlations. Filtering the recordings above 1Hz revealed large diversity in the magnitude of averaged correlations, but they were always positive. Importantly, close examination of subthreshold activities in both hemispheres indicated that rapid fluctuations between Up and Down membrane potential states, thought to reflect rapid local network dynamics, were correlated across hemispheres with near millisecond precision. Moreover, in these cases spike triggered average of membrane potential across hemispheres revealed rapid common input and significant correlation in firing. Finally, slow changes in the magnitude of interhemispheric synchronization were related to physiological signals. In some pairs changes in infraslow correlation were related to pupil area and animal movements, which decreased when pupil size increased or during locomotion. The diverse types of interhemispheric subthreshold correlation suggests that interactions across hemispheres play multiple functions in behavior, and that they can be modulated by distinct behavioral states.

Title: Time-dependent population responses underlying spatial representation in the primary somatosensory cortex: The cortical body map revisited

Authors: *J. CORBO, Y. ZENNOU AZOGUI, C. A. XERRI, N. CATZ
LNIA, Aix-Marseille Univ., Marseille, France

Abstract: The sensory systems have to make sense out of ambiguous and fragmentary inputs that come from our sensors. The meaningful ‘whole’ that one perceives is made out of ‘bits’ bounded together. The rules that govern this reconstruction process may be inscribed in the computational routine of the neural networks that process sensory inputs. The illusion of tactile “saltation” suggests that successive brief tactile stimulations delivered on two different locations are felt as single object hoping linearly between the two cutaneous regions. Psychophysical exploration of this phenomenon allowed to unveil its basic rule : the distance perceived between two successive tactile stimuli is proportional to the interstimulus time interval (ISI). As the primary somatosensory cortex (SI) contains a topographically organized representation of the body cutaneous surfaces, we hypothesized that stimuli representation within this map undergoes spatial distortion dependent upon the ISI between two distant tactile stimuli. In order to test this hypothesis, we recorded the responses of about 500 SI neurons in anesthetized rats, while

delivering sequences of cutaneous stimuli on adjacent or non-adjacent digits (from digit 2 to 5), with ISI ranging from 0 to 400ms. During single-digit stimulation, S1 units displayed a "preferred" response consistent with the topographic organization. When the same stimulation was preceded by another one on a different digit, those discharges either increased or decreased as if SI neurons' selectivity changed according to their "recent stimulation history". Considered alone, the discharge of individual cells was unable to account for the time-space distortion. However, the spatial information embedded in the population response to the second stimulus was shifted toward the location of the first one, leading to a reduction in representational distance between two successive stimuli. As suggested by the "saltation" illusion, representation of space in SI is time-dependent. This dynamical change in SI population response can be thought of as a neural substrate of the perceptual time-space transformation, and challenges the classical view of the cortical cutaneous body map as a simple spatial reference frame for stimulus location.

Title: Detailed somatotopy of the rat trunk sensory cortex

Authors: *G. H. BLUMENTHAL[1], B. NANDAKUMAR[2], K. A. MOXON[3]
[1]Sch. of Biomed. Engineering, Sci. & Hlth. Systems,, [2]Sch. of Biomed. Engin. and Hlth. Sci., Drexel Univ. Sch. of Biomed. Engin. Sci. and Hlth. Systems, Philadelphia, PA; [3]Biomed. Engin., Univ. of California Davis, Davis, CA

Abstract: While there exists extensive information about the somatotopic organization of the rat forelimb and hindlimb sensory cortex, very little is known about the details of trunk sensory cortex. Knowledge of the details of somotatopic organization is important for studies of neurological injury or disease where the representation of these maps change in response to the injury and in response to therapy to restore function. The trunk cortex is especially important for studying the development of at-level pain after mid-thoracic spinal cord injury. Importantly for the trunk somatotopic organization, there is also limited knowledge about thoracic dermatomes. In this study, both the thoracic dermatomes and the somatotopic organization of the cortex in naïve rats were evaluated. Naive female Sprague Dawley rats were anesthetized with 1.5 g / kg urethane and a grid of 128 equally spaced squares were drawn on the dorsal aspect of the shaved trunk. To identify the mid-thoracic dermatomes, the mid-thoracic vertebrae and the dorsal root ganglia (DRGs) were exposed. A tungsten microelectrode was inserted into each DRG and single unit neurons were identified. Upon identification, the animal's skin was lightly stimulated with a

wooden probe and the cell's receptive field (RF) was determined in relation to the body grid. The union of the receptive fields of all cells found within a single DRG were used to define the DRG dermatome. To identify the somatotopy within the trunk sensory cortex, a craniotomy exposing the trunk representation as well as surrounding regions was performed. Dura was removed, and a tungsten microelectrode was slowly lowered through the cortex in one of several pre-defined locations. Single unit neurons and RFs of responsive neurons were identified in a similar manner as the dermatome map. In a subset of animals, local field potentials (LFPs) were recorded using electrical stimulation to the trunk. Our results identify the mid-thoracic dermatomes and support a somatotopic organization of the trunk sensory cortex in the rat, with a caudal to rostral sensory receptive field orientation over the medial to lateral cortical area, and a dorsal to ventral receptive field orientation over the caudal to rostral cortical area. LFP recordings show the cortical extent of trunk afferent information. These results provide a basis to study cortical reorganization of the trunk sensory cortex after injury or disease.

Title: Layers and columns are also present in the somatosensory avian pallium

Authors: M. FERNANDEZ, R. REYES-PINTO, C. NORAMBUENA, *J.-C. LETELIER, J. MPODOZIS
Univ. of Chile, Santiago, Chile

Abstract: One of the main components of the avian pallium corresponds to a dorsal intraventricular protrusion known as dorsal ventricular ridge (DVR). The DVR is constituted by two apposed cellular masses: the internal nidopallium (N) and the more external mesopallium (M). The internal most aspect of the N contains discrete areas receiving auditory (field L2), tectovisual (entopallium) and trigeminal (nucleus basorostralis, B) ascending projections. While the former two areas receive its sensory inputs from nuclei of the dorsal thalamus, the latter receive afferents directly from the brainstem trigeminal complex. Dorsally adjacent to each of these areas there is a nidopallial strip termed intermediate nidopallium (NI), which is limited dorsally by a portion of the ventral division of the mesopallium (MV). Previous studies have

shown that the auditory as well as the tectovisual regions of the DVR are organized according to a "laminar/columnar" arrangement, in which cells located in homotopic positions in each of these layers are reciprocally linked by an interlaminar local loop of axonal processes. Whether this type of organization extends also to the trigemino-recipient DVR is at present not known. We investigate this latter question by placing minute injections of neural tracers into selected locations of vital slices of the chicken telencephalon. After a prudent survival period, the slices were resectioned, reacted with DAB/Ni and counterstained with Giemsa. We found that neurons of the nucleus basorostralis establish reciprocal, columnar and homotopically organized projections with cells located in its overlying MV region. "Colum forming" axons originated in B and MV terminate also into the NI in a restricted manner. NI cells, in turn, send efferent projections mainly to other pallial areas. Furthermore, we found that besides of its intrapalial connectivity, B originates substantial, non-topographic projections to the underlying portion of the lateral striatum. This latter feature has been describe previously in the tectovisual, but not in the auditory, DVR. We conclude that all sensory areas of the DVR are organized according to a common neuroarchitectonic motif, which bears a striking resemblance to that of the interlaminar circuits of sensory cortices of mammals. This pattern seems to be determined by morphogenetic processes proper to the DVR, since it is not affected by the source of origin of the sensory afferents impinging upon a particular area.

Title: Neuronal processing of cross-finger motion integration in the primary somatosensory cortex

Authors: *Y.-P. CHEN[1,2], J.-J. HUANG[2], C.-I. YEH[3], Y.-C. PEI[2,1]
[1]Chang Gung Univ., Taoyuan City, Taiwan; [2]Dept. of Physical Med. and Rehabil., Chang Gung Mem. Hosp., Taoyuan, Taiwan; [3]Natl. Taiwan Univ., Taipei, Taiwan

Abstract: Dynamic object manipulation involves tactile motion perceived through multiple fingerpads. Neuronal tuning properties to direction and orientation in the primary somatosensory (S1) cortex has been delineated but the integration of tactile motion across fingers is not yet known. To this end, we used a multi-digit tactile motion stimulator with scanning balls engraved with square-wave gratings to present tactile motion to two nearby fingerpads and recorded the neuronal responses in areas 3b, 1 and 2 of anesthetized monkeys using multi-channel microelectrode arrays. Specifically, either one (one-finger condition) or both (two-finger condition) of the two fingers were presented with the stimuli, yielding a variety of combination of stimulus direction presented to the two fingers. We found that a majority of motion-sensitive neurons have two-finger receptive fields. Comparing the activities obtained in one- and two-finger conditions in motion-sensitive neurons, 26% and 45% of neurons showed enhancement or suppression of direction/orientation selectivity in the two-finger condition, respectively, while, in the remaining neurons, the responses of two-finger condition is simply a weighted sum of responses observed in the one-finger condition. Furthermore, the motion integration observed in the two-finger condition was mainly mediated by a nonlinear suppression of neuronal activities. These results indicate that motion integration across fingers is commonly observed in S1 neurons and can be accounted for by nonlinear suppressions of convergent inputs emanating from two fingers, yielding a novel non-classical receptive field property that is first reported in primate S1.

Title: Functional tract tracing with intracortical microstimulation and intrinsic optical imaging can reveal distinct intracortical neural circuits within somatosensory cortex

Authors: *R. M. FRIEDMAN[1], M. M. CHERNOV[1], D. G. ZARAZA[1], A. W. ROE[1,2]
[1]Div. of Neurosci., Oregon Hlth. & Sci. Univ. - ONPRC, Beaverton, OR; [2]Interdisciplinary Inst. of Neurosci. and Technol., Zhejiang Univ., Hangzhou, China

Abstract: Electrical microstimulation has been used to modulate behavior, study the functional organization of the brain, and drive human brain-machine interfaces. However, how local and distant neural circuits are activated by electrical microstimulation is not well understood. We

previously demonstrated that intrinsic optical imaging (IOI) can reveal cortical activity produced by intracortical microstimulation (ICMS) in primate somatosensory cortex (SI) (Brock et al. 2013, J Neurophys) and known anatomical projections between somatomotor cortical areas (Stepniewska et al. 2011 PNAS; Kudyba et al. 2013 SFN Abstr #495.21). Here, we report on the patterns of activation in finer detail. Data were obtained from rhesus and squirrel monkey SI. Following IOI mapping of digit representation in response to vibrotactile stimulation of the finger pads, an electrode was placed tangentially to the surface of cortex (20-30 degrees) and advanced in superficial layers across the digit representation in 200-300 μm steps. Trains of electrical stimulation (bipolar, 0.4 ms pulse width, 250 Hz, 250 ms, 15-100 μA) were applied and optical images were acquired. We found that small advances in the electrode position within the same cortical finger pad cortical representation could evoke different patterns of activation. These patterns are consistent with anatomical tracer studies which show clustering of anatomical connections in areas 3b and 1 (Négyessy et al. 2013 J Comp Neurol; Ashaber et al. 2014 J Comp Neurol; Negyessy et al. 2015 SFN Abstr #515.09). In summary, patterns of cortical activity evoked by ICMS are consistent with the idea that distinct modality specific intracortical networks underlie tactile feature extraction in SI.

Title: Weight perception behavior of Japanese macaque monkeys

Authors: *M. TAOKA, S. HIHARA, T. KOIKE, A. IRIKI
RIKEN Brain Sci. Inst., Wako-Shi, Japan

Abstract: Three Japanese macaque monkeys performed three weight discrimination experiments (Experiments 1,2, and 3), using objects that were different in weight but were the same in shape, size, color and texture.
Experiment 1; monkeys were trained to choose a lighter object between a pair of two (12g vs 188g for monkeys 1 and 2, and 21g vs 188g for monkey 3) with one hand. After 3-5 days, the correct choice ratios reached 95% for all three monkeys. Then, the heavier object (188g) was replaced with lighter objects (143g, 67g, etc.). All the monkeys chose the correct object in the first test session (> 10 trials) with correct choice ratios > 95% indicating that macaque monkeys are able to detect the weight difference with the hand.
Experiment 2; monkeys were tested with the same two-choice test using the other hand (naive

hand) without any training (untrained-hand test). All the monkeys showed nearly the same performance in the untrained-hand test as in the trained-hand test (correct choice ratios > 95%). This suggests that the brain center for weight judgment is shared for the two hands. In Experiments 1 and 2, the monkeys were always required to choose the same object as the lighter one (12g for the monkeys 1 and 2, and 21g for the monkey 3). There are two possible cognitive judgements to choose the correct object; lighter-heavier judgement or just choosing the same object in weight, which lead us to proceed to the next experiment (experiment 3).
Experiment 3; monkeys were trained to choose the lightest object among three objects. In the pre-test training sessions, various test-sets composed of three objects with different weights were prepared that always included a 21g object as the lightest one, so the monkeys were required to choose the 21g object in all test-sets. After correct choice ratios reached 95%, the test session started. Each test session was composed of 10 trials including one test-trial where the lightest object (21g) was replaced by a heavier one, but was still lightest among the three; for example, a session composed of 9 trials of 21g-83g-110g and one test-trial of 43g-83g-110g. All the monkeys almost always performed the task correctly (93%, 107 sessions) from the first session. In this experiment, the monkeys learned to choose the same object (21g) in the pre-test trainings but they chose the lightest one in the test trials.
These results demonstrate the establishment of lighter-heavier judgement without any specific training, further suggesting the importance of the generalized ability to detect relative differences in weight judgments.

Title: Thalamic afferents of the macaque superior parietal areas PE and PEc

Authors: D. IMPIERI[1], L. PASSARELLI[1], S. BAKOLA[1,2,3], M. GAMBERINI[1], M. G. P. ROSA[2,3], *C. GALLETTI[1]

Abstract: The dorsal surface of the superior parietal lobule in the macaque brain contains two cyto-architectonically defined areas, named PE and PEc. In area PE, the vast majority of cells responds to somatosensory stimulation, whereas area PEc contains visual, somatosensory, and bimodal cells. In area PE there is a rough topographically organized map of the body, whereas in area PEc the body representation is not topographically organized, and it is mainly focused on the limbs. The aim of this study was to describe the thalamo-cortical connections of these two parietal areas. To accomplish this, retrograde neuronal tracers were released into the cortex of six hemispheres of five male adult monkeys (*Macaca fascicularis*). Tracers were injected into the cortical thickness using a micro-syringe or placed as crystals on the exposed cortex based on visual inspection of the brain. Cyto- and myelo-architectural analysis of histological material established that in six cases tracers were delivered within the limits of area PE, and in three cases within those of area PEc. Areas PE and PEc showed a similar pattern of thalamic connections. In both cases, thalamo-cortical afferents mainly originated from Medial Pulvinar, Lateral Posterior, Ventral Posterior Lateral, and Ventral Lateral nuclei, with some differences in the strength of connections. While area PE showed a stronger input from the Medial Pulvinar and Ventral Posterior Lateral nuclei, area PEc displayed a more balanced input from the four thalamic nuclei. Minor afferents came from Ventral Anterior and Medial Dorsal nuclei for both the parietal areas, and from Central Medial/Parafascicular complex for area PE and from Central Lateral nucleus for area PEc. The Medial part of the Pulvinar nucleus is a multimodal, associative region with visual cells, that are not retinotopically organized. The Lateral Posterior nucleus is implicated in associative and somatosensory functions. In the somatotopically organized Ventral Parietal Lateral and Ventral Lateral nuclei, labelled neurons were mainly found in a region corresponding to the leg representation. All these findings corroborate the sensory-motor nature of areas PE and PEc, and particularly their involvement in the processes related to leg movements, including locomotion.

Title: Neurons in the secondary somatosensory cortex and its surrounding opercular regions discriminating bodily awareness of the self from others

Authors: M. TAOKA[1], S. HIHARA[2], *A. IRIKI[2]
[1]RIKEN Brain Sci. Inst., Wako-Shi, Japan; [2]RIKEN Brain Sci. Inst., Wako-shi, Saitama, Japan

Abstract: Previous studies reported that monkey SII (secondary somatosensory cortex) neurons exhibit more complex somatosensory response properties than the primary somatosensory cortex (SI) [e.g., attentional effects on neural activity, bilateral integration from both hemibodies, and large receptive fields (RFs) covering multiple body parts], suggesting that SII is at higher level of information processing than SI. Although the involvement of SII in tactile object recognition (Hsiao 2008) and the sensorimotor integration for manipulating objects with the hand (Taoka et al. 2013) are suggested, the functional role of SII has not been fully clarified because the existence of complete somatic maps in SII as well as the bilateral and large RFs has not been explained. Recently, we found large RFs in SII covering almost the whole body (Taoka et al. 2016) suggesting the presence of other functional roles in SII. We also reported the visual inputs in SII (Hihara et al. 2015) indicating that SII, previously thought to be a unimodal somatic area, is a multisensory area. These two findings lead us to hypothesize that SII is related to self-body consciousness.
Initially, we trained a Japanese macaque monkey to recognize the mirror image of its whole body. Then, a total of 822 unit activities were recorded from the parietal operculum including SII of both hemispheres. We found many neurons that exhibited visual response (N=124, 15%), majority of them (N=96, 77%) having visual receptive fields (v-RFs) in peri-personal space of the monkey. Most of v-RFs were in the face exclusively (N=76), whereas 20 v-RFs were found around the forelimb, trunk and/or hindlimb which the monkey could recognize only through the self-image in the mirror set in front, demonstrating the “self mirror image recognition” at the neural level. Among remaining 28 visual neurons that responded to the presentation of moving object in the monkey’s visual field, six neurons responding to the moving object around the back of the monkey which the monkey could see only through the mirror. We found other types of neural activities that might be related to self vs others discrimination; e.g., those becoming active only when the monkey touched self-body (N=7), mostly the mouth or face (N=5) by own hands. Other five neurons were active only when the monkey touched the experimenter’s body. These neural responses discriminating self and others recorded from neurons in SII and surrounding opercular regions suggest the involvement of these cortical areas in the establishment of self-consciousness of the monkey.

Title: Human tactile perception of the smoothness of parametric 3D-printed textures

Authors: *C. TYMMS[1], D. ZORIN[2], E. P. GARDNER[3]
[1]Computer Sci., [2]New York Univ., New York, NY; [3]Dept Physiology/Neuroscience, New York Univ. Sch. of Med., New York, NY

Abstract: Roughness is one of the most important qualities in haptic perception. It is a major identifier for judgments of material composition, comfort and friction, and it is tied closely to manual dexterity. Many studies on roughness perception have been conducted using various types of stimuli: Braille dots, photo-etched dot arrays, gratings, and natural textures such as sandpapers and fabrics. However, a comprehensive examination of a variety of surface textures has not been conducted, largely due to the inability to create a wide range of finely controllable surfaces. In this work, we present a set of experiments using a novel type of controllable stimulus: textures created with parametric modeling and high-resolution 3D printing. We manufactured a set of textured square plates with raised texture elements ("textons") varying in element spacing (0.625 to 1.375 mm), arrangement (isotropic and anisotropic), and diameter (0.1 to 0.5 mm). Two-alternative forced choice protocols were used to investigate the contributions of these parameters to roughness perception. Results indicated that larger spatial periods produce higher estimations of roughness (with Weber fraction 0.19). In general, subjects with smaller D2 and D3 papillary ridge spacing are better able to accurately distinguish between textures. Results also show that anisotropic textures with regularly arranged textures are perceived smoother than isotropic textures of the same wavelength, and larger texton sizes produce higher smoothness estimates at each spatial period. These types of parametric stimuli are well-suited for studying tactile sensations, and can be used in further studies on tactile roughness and smoothness perception and in related neurophysiological applications.

Title: Comparing effective responses to deep pressure and C-LTMR-optimized gentle touch

Authors: A. NECAISE[1], L. K. CASE[1], J. LILJENCRANTZ[1], *H. OLAUSSON[2], M. C. BUSHNELL[1]
[1]NCCIH, NIH, Bethesda, MD; [2]Linkoping Univ., Linkoping, Sweden

Abstract: Moderate and deep pressure touch are commonly utilized in massage therapy and have been linked to reductions in stress, depression, and pain. Yet there is no understanding of how pressure exerts these affective benefits. We propose that unmyelinated pressure-sensitive afferents identified in animals (e.g. Mense & Meyer, 1985) may exist in humans and underlie these effects. Such a mechanism would parallel the pleasantness of light stroking touch, which has been linked to the activation of C low-threshold mechanoreceptor (C-LTMR) fibers, unmyelinated sensory afferents that respond to slow gentle stroking of the skin and activate opioidergic brain regions including the insula and cingulate cortex (Gordon et al., 2013; Olausson et al., 2002). We conducted preparatory psychophysical studies to initiate this line of research. We designed a novel apparatus to administer mechanical pressure stimuli using a programmable compression sleeve. We utilized this apparatus to identify the most pleasant intensity, frequency, and location for pressure stimulation. We then compared the affective benefits of pressure to those of light stroking—an established affective touch paradigm. Participants received blocks of gentle stroking, moderate compression, and painful and non-painful heat and rated their intensity, pleasantness, wanting, liking, and mood on visual analog scales. Participants also rated qualitative touch descriptors on the Touch Perception Task (Guest et al., 2011) to further characterize their affective experience. This pressure paradigm generated significant ratings of pleasantness of a comparable magnitude to ratings of gentle stroking. Similar affective touch descriptors were endorsed for gentle brushing and moderate compression. Compression of the lower leg at a moderate compression frequency and moderate intensity was the preferred pressure stimulus. Ratings of stimulus pleasantness were correlated with mood and anxiety. These results suggest that deep pressure induces a pleasant affective response, even when delivered by a mechanical apparatus. Given its similar perceptual qualities (level of pleasantness ratings and touch descriptors), deep pressure touch might be conveyed by pathways similar to those involved in affective gentle stroking.

Title: Brain responses to natural touch recorded with intracranial stereo-EEG

Authors: *E. J. ERIKSSON[1], D. KRÝSL[2], J. NILSSON[2], K. MALMGREN[3], B. RYDENHAG[3], J. WESSBERG[1]
[1]Inst. of Neurosci. and Physiol., Sahlgrenska Academy, Univ. of Gothenburg, Gothenburg, Sweden; [2]Dept. of Clin. Neurophysiology, Sahlgrenska Univ. Hosp., Gothenburg, Sweden; [3]Inst. of Neurosci. and Physiol., Dept. of Clin. Neuroscience, Sahlgrenska Academy, Univ. of Gothenburg, Gothenburg, Sweden

Abstract: In this study we aim to investigate the brain's responses to gentle touch in patients that undergo clinical intracranial stereo-encephalography (SEEG).
The perception of touch to hairy skin is mediated by slow conducting C-tactile (CT) afferents and fast conducting Aβ afferents. CTs have low mechanical thresholds, respond strongly to caress-like stimuli, and are believed to signal pleasantness of touch. Previous studies using functional magnetic resonance imaging have shown that CT afferents project to the insula but not to primary (S1) or secondary (S2) somatosensory cortices.
The local ethical committee approved this study. Data was obtained from 3 adult patients (1 female) with focal refractory epilepsy undergoing SEEG as part of their pre-surgical evaluation. The number of electrodes, number of contacts used and placement was strictly individualized based on the medical information given by the basic evaluation of the patient. Pre-surgical MRI volumes and CT-angiograms were used to plan the implantation and a post operative CT was obtained for 3D reconstruction of the electrode placements.
All patients had electrode implantation in the left hemisphere. SEEG was recorded during soft brush stroking on the dorsolateral aspect of the forearm. Patients were seated comfortably in a hospital bed and instructed to relax and focus on the touch sensations. A trained experimenter manually delivered the stimuli with a hand held soft brush. A minimum of 100 repetitions on both the contra- and ipsilateral forearm was carried out. The brushing velocity was CT-optimal, i.e. around 3 cm/s. A fiber-optic sensor was attached alongside the bristles of the brush, marking the timing of brush contact with the skin.
In one patient with electrodes implanted in S1 and primary motor cortex (M1), contralateral

gentle touch induced event-related beta de-synchronisation (ERD) and subsequent beta rebound in these areas. S1 ERD exhibited a broader frequency range (15-30 Hz) compared to M1 (15-20 Hz), whereas the frequency range of the beta rebound was more similar between the two areas (15-30 Hz). Furthermore there was a late onset (~1000 ms) 5-10 Hz event-related synchronisation (ERS) observed in the electrodes implanted in the left precuneus to bilateral touch stimulation that may reflect the integration of Aβ and CT signaling. Further analyses will be carried out to investigate the connectivity between precuneus, S1 and the insula in the patients where electrodes were implanted in those regions.

Title: Neural correlates of orgasm intensity: An fMRI study in men

Authors: *K. ALLEN[1,2], B. KOMISARUK[2]
[1]PWP, Princeton Univ., Princeton, NJ; [2]Rutgers, The State Univ. of New Jersey, Newark, NJ

Abstract: Previous studies e.g., (J Sex Med 2011;8:2269; Hum Brain Map 2002;16:1) have identified multiple brain areas in men that are associated with arousal, intensity of arousal, and orgasm. However, those studies did not identify brain areas that may be related to the intensity of orgasm.
Using functional Magnetic Resonance Imaging (fMRI), we collected data while male participants self-stimulated to orgasm in a 3 Tesla, Siemens Trio scanner. Participants were asked to rate the intensity of orgasm on a scale of one to ten. After pre-processing with AFNI, we used a whole-brain analysis to identify areas whose activity correlated with the self-reported intensity of orgasm. During the first four seconds of orgasm, reported orgasm intensity correlated with activity levels in the left frontal medial orbital gyrus and the right anterior cingulate cortex. These areas have previously been implicated in the intensity of rewards e.g., (Biol Psychiat 2004; 55:594; Cerebral Cortex 2008;18:652) and which we found to be active during orgasm (SFN 2014;63.14). The correlation between level of fMRI activity and self-reported intensity of orgasm that we observed suggests a salient role for these regions in sexual satisfaction.
The last four seconds of orgasm did not correlate with activity in any areas of the brain,

indicating that the intensity of orgasm is identified early in orgasm, and declines as orgasm progresses.

Abstract: While the neural system that underlies action observation in the human brain is well studied, its neural dynamics is largely unknown due to the domination of fMRI studies in the field. Here, we investigated the spatiotemporal dynamics of action observation in a stereo EEG study. We recorded from 40 epileptic patients (5193 leads) implanted with intracerebral electrodes while they observed videos of three classes of actions: skin-displacing, manipulation, and interpersonal (each with four exemplars) taken from Ferri et al 2015. We marked a contact event in all the videos as the moment the actor touches the target of the action (own skin in skin-displacing, an object in manipulation, other's skin in interpersonal), and aligned the z-scored gamma (50-150 Hz) responses to this event. First, we identified the leads that were responsive after contact by the criterion that the area under curve after contact was greater than zero for any of the action classes ($p<0.05$). 43% of the leads (2256 leads) were responsive. Second, we performed a 3 (Action class) x 7 (Time bin of 100 ms) on the responses after contact on the responsive leads to identify that leads that showed action class or time specificity. 25% of the responsive leads (584 leads) showed the main effects of action class or time ($p<0.05$, corrected for multiple comparisons by FDR). Next, we characterized these leads based on their time course. First, using a home-made software, we detected the "contact" leads that responded only after the contact with an initial sharp rising response. These leads were concentrated in PFcm, PFop, OP1. When we removed the strict criterion and allowed the leads that had a rising component slightly before the contact, we additionally got responsive leads in a more distributed network of temporal, parietal, premotor, and cingulate cortex possibly reflecting the expectation of the contact event. Next, we further characterized the "contact" leads by examining their

response profile during the full course of the action exemplars. We identified two distinct types of responses: leads that responded phasically to contact events shortly for different types of target and leads that responded to contact events as well as the skin-displacing action following the contact till the end of the video. Finally, we also observed leads in the same region that did not have a phasic contact response but responded during the full course of the skin-displacing action after contact. These results highlight the importance of studying actions as temporally unfolding events using temporally resolved direct recordings to understand the spatiotemporal dynamics of action observation. Title: Modulation of tactile detection with concurrent EEG-tACS

Authors: *D. D. SLIVA[1], C. BLACK[2], U. AGRAWAL[3], M. A. LADOW[4], J. F. SANTOYO[1], P. BOWARY[5], B. D. GREENBERG[5,6], C. I. MOORE[1], S. R. JONES[1,6]

Abstract: The dynamics of rhythmic alpha-band activity (7-14 Hz) may reflect active processes engaged to diminish relay of signals from thalamus to neocortex, effectively gating sensory information. Prior work in our lab has shown that cued attention can modulate neocortical alpha oscillations in primary somatosensory cortex (SI), and that pre-stimulus alpha power in SI predicts tactile detection (Jones 2010). Furthermore, transcranial alternating current stimulation (tACS) may be capable of entraining endogenous oscillations in specific frequency bands (Zaehle et al. 2010). This study utilized concurrent EEG and tACS over SI while participants took part in a tactile detection task. Stimulation was applied at individuals' endogenous alpha frequency to assess whether augmenting ongoing rhythmic activity can reduce detection of difficult-to-perceive stimuli. Tactile detection rates were significantly reduced from baseline for

participants who received alpha, but not for participants who received sham, stimulation. Moreover, consistent with prior reports, alpha power tended to be higher on trials in which stimuli at perceptual threshold were not detected, compared to those in which stimuli were detected. However, we did not find evidence that tACS entrained alpha activity. Therefore, in our task, tACS appears to be perturbing normal dynamics in some other way to impact detection performance. This preliminary analysis supports the view that rhythmic alpha activity in SI is associated with perceptual performance, and provides proof of concept that modulation of tactile perception using non-invasive stimulation is plausible. Future work will further investigate potential neural mechanisms underlying this behavioral effect.

Title: The relationship between joint position sense and range of joint motion

Authors: *M. RADZIKOWSKI, H. TANABE, K. HAGIO, K. NAKAZAWA
Dept. of Life Sciences, Grad. Sch. of Arts and Sci., The Univ. of Tokyo, Tokyo, Japan

Abstract: INTRODUCTION: It has been known that discharge rate of joint receptor is increased at the limit of the range of joint angle in animal studies. If this can be applied to human joint position sense (JPS), proprioceptive acuity may be increased at the limit of the range of motion. Differences in JPS among individuals has been investigated at the same target angles irrespective of participants' range of joint motion, however, it could be possible that the acuity and its neural mechanism differ individually when participants are targeting a single joint angle. Thus, in this study, we investigated proprioceptive acuity using the JPS test with setting the target angle depended on the participants range of joint motions. The purpose of this study was to determine the differences in JPS relative to the individual range of joint motion.
METHOD: Healthy young subjects (N = 7) performed the ankle JPS test with an active reproduction test. We set 0% at the full dorsiflexion and 100% at the full plantar flexion, and calculated the target position (10% - 90%) for each subject. One session consists of three practices with visual feedback using a monitor indicating the target position, continued by a five time trials without visual feedback. Participants were in supine position or prone position, and each position had two start positions (rest and neutral). Participants performed the JPS test in randomized order. We obtained the ankle joint angle data from an electrogoniometer and surface

electromyographic (EMG) signal from the soleus, medial and lateral head of gastrocnemius, and tibialis anterior muscles. The EMG data was recorded while the subject holding the target position (for 1 sec.) and normalized with the maximum voluntary contraction.
Results and Discussion: The results showed that absolute errors (AE) from the target angle at 10% and 90% were significantly lower than 40%, 50%, 60% ($p < .05$), and there were no significant differences between conditions. This result was in line with the animal results showing the higher sensitivity of joint receptors at the limit of joint range of motion. It was found that when the activity of antagonist muscles increased, the AE tended to be decreased. Overall, our results indicated that the proprioceptive acuity is higher near the limit of range of joint motion and lower in the middle range of joint motion. Although the underlying neural mechanisms are not fully understood from the current results, it was suggested that not only joint receptor but proprioceptive signals from the antagonist also contribute to the observed higher acuity at the limit of joint motion range.

Title: The effect of hand position in external space on the integration of bilateral tactile stimulation in the primary somatosensory cortex

Authors: ***N. OTSURU**[1], S. KOJIMA[1], S. MIYAGUCHI[1], R. SASAKI[1], S. TSUIKI[1], Y. INUKAI[1], K. SAITO[1], M. MASAKI[1], K. YAMASHIRO[1], H. SHIROZU[2], S. KAMEYAMA[2], H. ONISHI[1]

Abstract: The primary somatosensory cortex contains a somatotopic representation of the body surfaces (Penfield and Boldrey, 1937). However, to precisely detect the stimuli location in space, we must realign tactile coordinates relative to an external frame of reference. A previous study reported that when tactile stimuli were presented to both hands, temporal order judgments were better when both hands were positioned far apart in external space (Shore et al., 2005). This indicated that the integration of bilateral tactile information in the brain is modulated by the

position of both hands in external space. However, the neural dynamics remains to be elucidated. In this study, we recorded cortical responses to tactile stimulation of the left index, right index, and both fingers using magnetoencephalography. Responses were investigated in hands-close and hands-far conditions in 12 volunteers. In the hands-close condition, index fingers were placed 1 cm apart, whereas in the hands-far condition, they were placed 30 cm apart. To elucidate the effects of hand position in external space on the integration of bilateral tactile information, we used the bilateral integration score (BIS) [(response of right index finger + response of left index finger) − response of both index fingers]. A higher BIS indicated a higher suppressive integration with stimulation of both index fingers. In the bilateral primary somatosensory cortex, BIS was lower in the hands-close condition than that in the hands-far condition. These results suggested that the integration of bilateral stimulation can be modulated by hand position in external space.

Title: Memory-based M100 component in the somatosensory cortex: An MEG study

Authors: *K. YAMASHIRO[1], D. SATO[1], H. ONISHI[1], K. SUGAWARA[1], N. OTSURU[1], S. NAKAZAWA[1], Y. YAMAZAKI[1], H. SHIROZU[2], A. MARUYAMA[1]

Abstract: A previous study showed that the ON-M100 and OFF-M100 somatosensory electrical stimulations elicited a very similar change-sensitive component, in terms of the temporal profile and the location and orientation of the source, suggesting common generation mechanisms. However, we did not record the change-sensitive component earlier than M100 using electrical stimulation. Conversely, Onishi et al. (2010) recorded very clear M50 responses using on and off stimulation generated by the application and removal of a constant mechanical pressure. In the present study, we recorded cortical activation in response to the onset and offset of tactile stimulations driven by a piezoelectric actuator using magnetoencephalography to clarify the physiological significance of the M50 and M100 somatosensory components in ten (7 males and 3 females) healthy subjects. Three inter-stimulus intervals (ISIs) (0.5, 1.5 and 3 s) were randomly presented for each event. The results showed that i) M50 and M100 somatosensory events

elicited a similar topography and temporal profile; ii) M50 and M100 components were estimated in the contralateral primary somatosensory cortex (cS1) and bilateral secondary somatosensory cortex (S2), respectively; iii) cS1 activity was independent of ISIs, whereas S2 activity as a function of the duration of the steady state preceding the change (ISI) was similar for both events, and it increased as a function of ISIs and iv) there was a significant positive correlation among the amplitudes of M100 between on and off responses across subjects. These results suggested that ON-M100 and OFF-M100 have similar generation mechanisms as well as a similar physiological significance with respect to the automatic memory-based detection of somatosensory changes. Conclusively, M50 and M100 reflect stimulus- and event-driven components that have a differential physiological significance in the somatosensory cortex.

Title: A tactile motion perception task sensitive to slowed nerve conduction in peripheral neuropathy

Authors: *S. MCINTYRE[1], G. BERGSTRÖM[2], J. CAPPER[3], C. COUGHLIN[4], I. WOODS[4], F. HENSHAW[5], R. VICKERY[6], I. BIRZNIEKS[7], P. BREEN[5]
[1]Dept. of Clin. and Exptl. Med., Linköping Univ., Linkoeping, Sweden; [2]Linköping Univ., Linköping, Sweden; [3]St George Hosp., Sydney, Australia; [4]Uniting War Mem. Hosp., Sydney, Australia; [5]Western Sydney Univ., Sydney, Australia; [6]UNSW Australia, Sydney, Australia; [7]Neurosci. Res. Australia, Sydney, Australia

Abstract: Peripheral neuropathy is associated with a decline in tactile sensation; typically measured as sensitivity to brief touch, or vibration applied to the skin. Evoked peripheral afferent activity, if relayed to the central nervous system, is sufficient to perform these simple tasks. Therefore task performance reflects mainly axonal loss caused by neuropathy. Neuropathy also causes increased temporal dispersion due to slowed conduction velocity. A more complex task affected by axonal conduction velocities may enable early detection of neuropathy and distinguishing different underlying causes. We developed an apparent motion device for use in clinical settings, in which neighbouring skin locations are successively tapped. Four tactors 20

mm apart tapped the skin on the plantar foot or lower leg. Participants judged the direction of motion, which requires them to correctly order the sequential touch events in space and time. Performance on this task is likely affected by the increased dispersion in conduction velocities associated with peripheral neuropathy. Data were collected from volunteers diagnosed with neuropathy (7 female, 8 male, aged 43 - 84) and healthy controls (8 female, 7 male, aged 53 - 87). An adaptive staircase procedure was used to determine direction discrimination performance, defined as the area under the curve (AUC), with larger values indicating slower speeds were needed to make direction judgments. On both sites tested, performance was significantly worse for the neuropathic group (foot = 130 (44), leg = 136 (39) mean (SD) AUC) than for the control group (foot = 96 (33), leg = 111 (38) mean (SD) AUC; foot: $t(52) = 3.2$, $p = 0.002$; leg: $t(50) = 2.3$, $p = 0.024$). These results indicate that the apparent motion direction judgment task has potential diagnostic value for peripheral neuropathy. It may enable early detection of neuropathy, distinguishing of different underlying causes, and characterising disease progression.

Title: Cortical processing of irrelevant somatosensory information from the leg is altered by motor attention during motor planning after stroke

Authors: *S. PETERS[1], K. E. BROWN[2], T. C. HANDY[1], S. GARLAND[3], R. STAINES[4], L. A. BOYD[5]
[2]Physical Therapy, [1]Univ. of British Columbia, Vancouver, BC, Canada; [3]Univ. of Western Ontario, London, ON, Canada; [4]Kinesiology, Univ. Waterloo, Waterloo, ON, Canada; [5]Univ. British Columbia, Vancouver, BC, Canada

Abstract: Background: The ability to actively suppress, or gate, irrelevant sensory information is needed for safe and efficient walking in sensory-rich environments. Both gating and motor attention alter somatosensory evoked potentials (SEPs) in healthy people, and after a stroke. The aim of this study was to examine to the effect of motor attention on processing of irrelevant somatosensory information during planning of plantarflexion movements after stroke. **Methods:**

Individuals with chronic stroke (5f, 5m; 70.2 ± 9.6 yrs), older (5f, 4m; 71.9 ± 7.1 yrs), and younger healthy controls (6f, 7m; 27.8 ± 4.7) participated. Tibial nerve stimulation was delivered at 2Hz while electroencephalography (EEG) recorded SEPs over the Cz electrode. Three conditions were tested in both paretic/left and non-paretic/right legs: 1) *control*, where participants were asked to remember a random 5 digit number, 2) *Attend To* the stimulated limb, and 3) *Attend Away* from the stimulated limb. In conditions 2 and 3, vibration (80 Hz) was applied over the lateral ankle to cue voluntary plantarflexion movements of the stimulated (*Attend To*) or non-stimulated leg (*Attend Away*). **Analysis**: Peak-to-peak amplitude of the N50/P50/N70 components were averaged for stimuli delivered during motor planning for each condition; change scores were calculated between each attention condition and control. A 3-way mixed-model ANOVA was performed for each SEP component with factors of Group (stroke, older, younger), Leg (paretic/left, non-paretic/right) and Condition (*Attend To*, *Attend Away*). **Results:** There was a Condition x Group interaction effect for N40 amplitude ($p = 0.021$). Post hoc tests indicated that all group means in the *Attend To* condition were different from each other ($p \leq 0.038$), with the stroke group showing the smallest difference from control. For the *Attend Away* condition, older controls and individuals with stroke were not different ($p = 0.203$), but other group comparisons were different ($p \leq 0.044$). There were no significant differences for the P50. For the N70, a main effect of Condition was found with no interaction effect ($p = 0.020$), indicating that *Attend T*o showed greater levels of gating than *Attend Away* for all groups ($p = 0.020$). **Conclusions:** Though all groups show attention-related changes to irrelevant somatosensory information from the leg during motor planning, the stroke group demonstrated the least amount of gating of irrelevant somatosensory information during motor planning. If attention alters the somatosensory stimuli from a leg movement, then directing attention may affect safe community walking.

Title: Visual deficits do not affect haptic space perception

Authors: *J. NELSON[1], I. A. KULING[1], M. GORI[2], A. POSTMA[3], E. BRENNER[1], J. B. J. SMEETS[1]

[1]Vrije Univ. Amsterdam, Amsterdam, Netherlands; [2]Inst. Italiano di Tecnologia, Genoa, Italy; [3]Univ. Utrecht, Utrecht, Netherlands

Abstract: Lack of vision affects some forms of spatial perception in blind individuals. Vision is often the best or only method to determine the size, position, and distance of objects and environmental features; blind and visually impaired people must resort to other means in order to accurately assess their surroundings. While some spatial skills are maintained or enhanced in absence of vision, others are compromised. Fewer deficits are observed in people who became blind later in life, who can be as proficient as blindfolded sighted people. Performance in various tabletop tasks such as spatial reorientation and complex shape recognition has previously been explored, and no differences have been found in performance between blind and blindfolded sighted people. Localization of one's own hand and simple length reproduction, however, have yet to be investigated. Our goal was to determine whether visual impairment affects the perception of positions and lengths in peripersonal space. We expected reduced visual experience to induce specific deformations in spatial perception, so we measured the haptically perceived location of one's own hand and the position-dependent reproduction of distance. To do so, we conducted a study in which 132 blindfolded participants with varying degrees of visual impairment used a pen to draw three lines of the same length as a reference object they had previously held in their dominant hand. The starting positions of these lines were determined by guiding participants' non-dominant hand to specified points under the table and asking them to place the pen where they thought their hand was. Two of the points lay along the body midline, one 15 cm from the edge of the table, and one 35 cm away, and the third point lay 15 cm from the edge of the table and 20 cm off the midline, on the same side of the body as their dominant hand. Participants drew a lateral line away from the midline from each of these starting points in a predetermined but random order. We found no effect of (onset age of) visual deficit on performance. All participants showed equal ability to match the starting position of the pen to the position of their non-dominant hand. Participants drew lines that were shorter than the length of the reference object, and they tended to draw slightly longer lines when starting from the more distant midline target. Furthermore, the angle of the line from the off-midline target differed from that of the lines from the midline targets in the clockwise direction. Our results indicate that visual deficits have no effect on the ability to determine the location of one's own unseen hand or reproduce lengths in peripersonal space.

Title: Frequency and duration effects in vibrotactile detection by the Pacinian psychophysical channel

Authors: *D. KILINÇ, B. GÜÇLÜ
Inst. of Biomed. Engin., Bogaziçi Univ., Istanbul, Turkey

Abstract: Our previous work based on the fast adaptive tracking procedure showed that improvement of psychophysical thresholds at longer stimulus durations (i.e. temporal summation) was independent of vibrotactile frequency in the Pacinian (P) channel. In this study, we measured psychometric functions at six frequencies (100, 150, 250, 350, 500, and 750 Hz) and five durations (10, 30, 100, 300, and 1000 ms) by the method of constant stimuli. Ten human subjects (6F, 4M; ages: 25-30) participated in the experiment. Sinusoidal bursts (rise/fall time: 10 ms) of mechanical displacements were applied on the middle fingertips of the subjects by using a cylindrical contactor (radius: 2 mm) in a two-alternative forced-choice detection task. The vibrotactile stimuli were superimposed on a 0.5-mm static indentation. Six amplitude levels were used around the threshold estimate of each subject. The amplitudes were randomized and repeated for 40 trials at each frequency-duration condition. Additionally, the order of all conditions, which were tested in different blocks, were randomized across subjects and experimental sessions. To find the psychometric functions, the probabilities of correct detection were fitted by a sigmoidal curve as a function of amplitude by nonlinear regression at each condition. The R2 values for the fits were mostly high (average: 0.88). The midpoints (i.e. thresholds) and the slopes at the midpoints were obtained from the psychometric functions. After aligned rank transform, repeated measures ANOVA was used to study the effects of frequency, duration and the interaction between them. As expected from previous work, thresholds had the characteristic U-shape of the P channel as the frequency varied ($F(5,45) = 42.50$, $p<0.001$) and duration had a significant main effect on the thresholds ($F(4,36) = 60.34$, $p<0.001$). There was an approximately 8 dB threshold improvement as the duration increased from 10 to 1000 ms, and this temporal summation effect was about constant across frequencies, i.e. no interaction ($F(1,9) = 4.84$, $p = 0.055$). Interestingly, the psychometric slopes were also influenced by frequency, somewhat like an inverted U-shape ($F(5,45) = 29.64$, $p<0.001$). The slopes increased with increasing duration ($F(4,36) = 26.58$, $p<0.001$), except at 750 Hz (frequency × duration: $F(20,180) = 3.85$, $p<0.001$). The results confirm and extend the previous findings about temporal summation in the P channel. We are working to develop a population model for predicting the effects of frequency and duration on the psychometric functions.

Title: Using MVPA-analysis to investigate the influence of prior information on the perception of vibrotactile stimuli

Authors: *P. KASSRAIAN FARD, N. WENDEROTH
Hlth. Sci. and Technol., ETH Zurich, Zuerich, Switzerland

Abstract: Bayesian inference has become a standard modeling framework applied to the sensory system that suggests perception can be biased by prior expectations. Currently, the extent to which prior information influences the neural response to vibrotactile stimuli is not well understood. Here we used Support Vector Machine (SVM) classification of functional magnetic resonance imaging (fMRI) data to investigate, first, how the brain encodes vibrotactile stimuli; and second, whether these representations are changed by prior information.
Four second epochs of vibrotactile stimulation were applied to the fingertips of human subjects. Prior to the fMRI experiment the perceptual threshold was determined for each subject individually using a staircase procedure. In the first experiment subjects received either subthreshold or suprathreshold stimuli. Classification was performed on features extracted from different somatosensory and control regions of interest (ROI), which were defined anatomically. In accordance with hierarchical models of the sensory system, which propose that sensory information is sent from thalamus to sensory cortices and is then relayed to higher order regions for further processing, decodability in different regions implies integration at different stages of sensory processing. Stimulation epochs were classified against rest using 10-fold crossvalidation and parameter optimization with a grid search. The main outcome parameter was classification accuracy. Preliminary analyses revealed that above-threshold vibrotactile stimulation of different digits can be classified with high accuracy ($> 75\%$, $p < 0.05$) in the contralateral postcentral gyrus (S1), and bilaterally in the secondary sensory cortex (S2). Moreover, we could distinguish between different stimulation intensities, even when all intensities were suprathreshold. Interestingly, differences in classification accuracy reflected proximity between stimulation intensities (although this relationship appears to be non-linear).
In the next step we will modulate the perception of near-threshold stimuli by providing prior information while keeping the physical characteristics of the stimulus constant. We will test whether prior information changes the classification accuracies of vibrotactile stimulus strength in primary or secondary somatosensory areas.

Title: Encoding of sucrose palatability and its enhancement by auditory cues in the nucleus accumbens shell

Authors: *M. A. VILLAVICENCIO CAMARILLO[1], M. G. MORENO[1], S. S. SIMON[2], R. GUTIERREZ[1]
[1]Ctr. De Investigación Y Estudios Avanzados, Mexico, Mexico; [2]Dept. of Neurobio., Duke Univ. Med. Ctr., Durham, NC

Abstract: The over consumption of sucrose is one of the main culprits of obesity. In addition of its pleasant sweet taste, the consumption of sucrose is under the control of environmental cues that enhance its palatability. Nevertheless, it is not known the neuronal correlates of this multisensory integration in the nucleus accumbens shell (NAcSh). To answer these questions, we designed three variants of a brief-access test to measure palatability responses of water and sucrose in different cross-modal behavioral contexts, and recorded single-unit activity of NAcSh neurons. The Gustatory test measures palatability only using gustatory information, whereas the Start test adds an auditory Start cue and the Start/Stop test uses two auditory cues to signal when to start and stop licking in the Reward epoch (5 s duration). Our behavioral results indicate that both auditory cues enhanced sucrose palatability but in different ways: the Start test by accelerating water rejection, whereas the Start/Stop test by increasing the first bout duration and caloric intake of sucrose. Our electrophysiological results uncovered three NAcSh populations conveying information about sucrose. One whose firing rate correlated with oromotor-palatability responses, whereas a distinct population encoded sucrose sensory information by increasing or decreasing its firing rate as the concentrations of sucrose augmented. Another population increased its synchrony with licking. Finally, in an exclusive way, NAcSh neurons that were Inactive during licking also responded with a phasic activation to the auditory cues and thus they are well posit to perform a multisensory integration to guide feeding responses. In summary, here we uncovered how the NAcSh encodes sucrose palatability and concentrations, in different cross-modal behavioral contexts and found a new code implemented by NAcSh neurons based on its synchrony with licking. Importantly, we also showed that the NAcSh Lick-Inactive

neurons (putative medium spiny D1 neurons) integrate appetitive, palatability and auditory information in order to control feeding and to modulate the expression of sucrose palatability.

Title: The representation of sweet taste intensity in the anterior/posterior insular cortex and orbitofrontal cortex in rats

Authors: *E. G. FONSECA DE LA CRUZ[1], F. ZEPEDA[2], S. A. SIMON[3], R. GUTIERREZ[4]
[1]Inst. De Fisiología Celular, UNAM, Mexico City, Mexico; [2]UPIBI, IPN, Mexico City, Mexico; [3]Neurobio., Duke Univ. Hosp., Durham, NC; [4]Pharmacol., CINVESTAV, IPN, Mexico City, Mexico

Abstract: Sweet taste signals the presence of immediate energy sources. Similar to all taste qualities, its consumption is modulated in an intensity dependent manner. Yet it is not well understood how sweet taste intensity is represented in primary and secondary gustatory cortices in freely licking animals. To address this issue, we performed single unit recording in the anterior and posterior insular (aIC and pIC) and orbitofrontal cortex (OFC) while rats classified different concentrations of sucrose as either low or high intensity. First, rats were trained in a sucrose intensity discrimination task that consisted on five epochs indicated in parenthesis: In a central spout rats licked an empty sipper and starts a lick bout (Bout Start, BS) after 2-3 dry licks they received a (Cue) 15µl drop of 3%-low or 18%-high sucrose, subsequent dry licks continued until the Bout End (Bout End, BE); then rats moved to a lateral spout (i.e., the low or high lateral port) to initiate a lick bout (BSRew), if response was correct they were rewarded by 3 drops of water, which they consumed until last lick in lateral port (BERew). Once rats learned the task, classification sessions were introduced: 80% were training trials and 20% classification trials were rats received (0,3,4.75,7.5,11.75,18%) sucrose intensities and classified them as “low” or “high” (no reward delivery). We analyzed data in all 5 epochs. All brain regions recorded contains neurons that monitors all task epochs either with an inhibition, phasic or tonic

excitations or by firing in synchrony with licking. In pIC the proportion of licking coherent neuron was higher and these neurons continued oscillating during body movement epochs (BE and BERew). Lick-coherent neurons oscillated out of phase between pIC and OFC, and some of them increased/decreased their coherence after receiving cue. We also found that sucrose intensity discrimination information increases from Cue to BSRew epochs in both pIC and OFC. Indeed, neurons in pIC and OFC monotonically increased their firing rates in an intensity dependent manner and this activity correlated with behavioral choices. Interestingly, only OFC neurons increased their firing rate before leaving the central spout and sustain this activity during body movement to the lateral spout before receiving an impending reward. This activity nearly matched subjects' behavioral decisions. We are still recording in aIC. We conclude that single unit activity in both pIC and OFC discriminates between sucrose intensities. Nonetheless, OFC sucrose selective responses were better to maintain a sweet intensity representation which might be useful for decision making and guide behavior.

Title: Role of sensory and limbic thalamic nuclei in processing taste-related information

Authors: *R. VINCIS, K. CHEN, A. FONTANINI
Dept. of Neurobio. and Behavior, Stony Brook Univ., Stony Brook, NY

Abstract: The gustatory cortex (GC) is involved in the complex integration of sensory and reward-related information associated with the experience of eating. GC achieves this level of integration by processing multiple inputs from sensory and limbic areas. The thalamus is typically viewed as the source of bottom-up, sensory signals to GC. However, our knowledge about the involvement of the thalamus in taste is based solely on studies of the first order sensory

gustatory thalamus (VPMpc). Based on anatomical evidences, other higher order limbic thalamic nuclei normally devoted to multisensory and reward processing, such as the mediodorsal thalamus (MD) can potentially interact with the gustatory system. Here, by using anatomical, electrophysiological and behavioral techniques, we investigated the role of sensory and limbic thalamic in processing gustatory information in mice.
In a first set of animals we injected the retrograde tracer CTB-555 in GC in order to map the somata of thalamic neurons that send direct afferents to GC. We found that distinct groups of thalamic neurons located in the high order limbic mediodorsal (MD) and rhomboid/reuniens (henceforth called medioventral, MV) nuclei send direct and ipsilateral projections to the portion of GC that also receive inputs from the VPMpc. Next, we investigated whether neurons in the three thalamic nuclei process different variables associated with a gustatory experience. Mice were implanted with a linear array of 16 movable electrodes in one of the three thalamic nuclei and with a head-post for head restraint. Neural activity and licking behavior were recorded while mice were engaged in multiple behavioral tasks designed to investigate chemosensory processing, active sampling and cue-taste associations. We found that while all three thalamic nuclei have neurons that are strongly modulated in anticipation of licking, they also differ in the type of taste-related information they compute. VPMpc and MD carry information about taste identity, albeit with different tuning properties. MD and MV preferentially encode for taste-outcome specific expectancy.
Overall our results show a complex involvement of the thalamus in processing taste-related information. The presence of multiple thalamic inputs to GC demonstrates the pivotal role of both sensory and limbic thalamic nuclei in driving GC activity and its potential role in modulating taste-related behaviors.

Title: Single-unit representation of flavor in gustatory cortex

Authors: *C. L. SAMUELSEN
Anatom. Sci. and Neurobio., Univ. of Louisville, Louisville, KY

Abstract: The simultaneous activation of the taste and olfactory systems during food consumption results in the multimodal integration of taste and smell, necessary for the perception of flavor. The gustatory cortex (GC) is an area of chemosensory convergence and vital in processing this multisensory information. In a previous experiment, we showed that intraoral odors and palatable tastes evoke similar responses in GC bimodal neurons (those neurons responsive to both tastes and odors). Furthermore, a brief access task showed that animals sample palatable tastes and odors similarly, while avoiding non-palatable tastes (Samuelsen and Fontanini, 2017). The results of this experiment suggested that GC bimodal neurons might represent the hedonic properties of both types of chemosensory stimuli. To test this hypothesis, we first gave rats experience with two hedonically different flavors: a pleasant taste-odor pair (0.1M sucrose - 0.01% isoamyl acetate [S-IA]) and an unpleasant pair (0.2M citric acid - 0.01% benzaldehyde [CA-B]). Rat odor preferences were then confirmed with a two-bottle access test. After flavor experience, we recorded single-unit activity in the GC of behaving rats during the intraoral delivery of tastants, odorants, and flavors. Our preliminary results suggest that the intraoral delivery of odor evokes responses in GC bimodal neurons that are similar to that of the paired taste; i.e. evoked response to isoamyl acetate is more similarly to palatable tastes and benzaldehyde evoked responses are more similar to aversive taste stimuli. These data, in concert with unimodal responses to tastes and odors after flavor experience, suggest GC to be a pivotal node for processing the quality and hedonic properties of olfactory and gustatory information after flavor experience.

Title: The neural basis of abnormal taste processing in autism spectrum disorders

Authors: *C. RIDDELL[1], J. AVERY[1], J. E. INGEHOLM[1], S. E. WOHLTJEN[2], M. A. COLLINS[1], S. MILLEVILLE[1], L. KENWORTHY[3], S. J. GOTTS[1], G. L. WALLACE[4], W. K. SIMMONS[5], A. MARTIN[1]

Syst., Washington, DC; [4]Speech and Hearing Sci., George Washington Univ., Washington, DC; [5]Laureate Inst. For Brain Res., Tulsa, OK

Abstract: Abnormal or 'picky' eating habits, including food selectivity, food refusal, and insistence on sameness while eating, are common among those with Autism Spectrum Disorders (ASD). These behaviors likely result from atypical sensory processing, including a gustatory hypersensitivity, and often lead to both significant caregiver stress, as well as an increased risk for poor health outcomes (e.g., malnutrition). Despite the prevalence of atypical eating behaviors in ASD, very little is known about the neural mechanisms that underlie abnormal taste sensitivity in autism.

We recruited both young adult and adolescent males diagnosed with ASD (n=20), and neurotypical age and gender-matched controls (n=21) to undergo functional MRI while performing a variety of tasks that examine neural responses to food stimuli. Taste sensitivity was assessed behaviorally using the Adolescent and Adult Sensory Profile. During a gustatory mapping task, subjects received sweet and neutral tastants during fMRI scanning via an MRI-compatible tastant delivery system. In a separate imaging task, subjects viewed pictures of various appetizing foods as well as pictures of non-food objects. Subjects also underwent resting scans for the examination of intrinsic functional connectivity. We performed a series of analyses to identify group differences in response to the sight and taste of food, as well as to identify how taste sensitivity interacts with the neural response to food stimuli in ASD and neurotypical individuals.

We identified a network of brain regions that exhibited a significant interaction between diagnostic category and taste sensitivity, including the bilateral superior temporal sulcus (STS), the right ventral striatum, the left fusiform gyrus, and the dorsomedial prefrontal cortex. These regions have all been previously implicated in the neuropathology of ASD. Within these regions, ASD subjects with the greatest taste sensitivity exhibited the greatest response to sweet vs. neutral tastants. Importantly, these same regions exhibited a similar interaction effect within our food pictures task, indicating that the atypical response to food stimuli within these regions extends to both the sight and taste of food. Lastly, we identified that this interaction of group and taste sensitivity was also manifested in the resting-state functional connectivity between the bilateral STS and the bilateral dorsal mid-insula. This suggests that hypersensitivity to taste in ASD results from heightened connectivity between primary taste cortex in the mid-insula and higher-order sensory association cortices, leading to abnormal processing of food-related stimuli.

Title: Taste associated with vision color in Japanese students

Authors: *S. NAGAHAMA
Human care, Teikyo Heisei Univ., Tokyo, Japan

Abstract: There may be many mechanisms about the influence of visual information on taste reception, and the complex interaction between two sensory modalities. The author reported that colors can influence a person's ability to distinguish threshold levels of basic tastes (Neuroscience 2016). Results of the threshold tests showed that red color had the effect of lowering the threshold of sweet taste, on the other hand blue color had the effect of raising the threshold of sweetness. In the case of salty taste, both red and blue color decreased the threshold of saltiness. Sour and bitter taste sensitivity were not affected by both colors. The author hypothesized that the effect of color on taste threshold is affected by cultural background and the environment. This study focused on the cross-modal correspondence between tastes and vision/colors. A total of 158 participants took part in this study (ranging from 20 to 22 years; 116 males and 42 females). The images of color patches were projected using a projector in the classroom. The images of color patches used 11 different colors, including black, blue, brown, green, gray, orange, pink, purple, red, white, and yellow. After they looked at a color patch, they chose the taste that they associated the color with, among 5 basic tastes (sweet, salty, sour, bitter and umami). Results of associations of colors with tastes showed that some colors were certainly more strongly associated with one taste than other tastes. The results revealed some cross-modal association between black with bitter, white/blue with salty, yellow with sour, pink with sweet and blown/red with umami. There wasn't much of differences between males and females. The above results of Japanese participants were similar to that had been reported for participants of many countries (Spence et al, 2014). Though lots of differences were accepted with Japan and the foreign countries by food culture and environment, it is suggested that Japanese and foreigners may be common in cross-modal correspondence between tastes and colors.

Title: The effects of amygdala input on taste-related activity in gustatory cortex

Authors: *J.-Y. LIN, N. MUKHERJEE, J. WACHUTKA, D. KATZ
Brandeis Univ., Waltham, MA

Abstract: Taste stimuli are richly laden with both chemical (taste identity, for instance sweet and salty) and behavioral/ingestion-decision related (palatability) information. Single neurons in the gustatory cortex (GC) evolve through a series of stereotypical firing 'epochs' in response to taste presentation - Following a brief, initial response to taste delivery, their firing conveys taste first identity information (Epoch 1: ~0.2-0.7s post-delivery) and then taste palatability (aka decision-related) information (Epoch 2: ~0.8s post-delivery). We hypothesize that the dynamic nature of GC taste responses is the result of the integration of temporally-restricted inputs from basolateral amygdala (BLA). Here we test this hypothesis by examining whether taste-related GC firing is altered by brief, targeted optogenetic perturbation of BLA-GC projections. We infected BLA of 4 adult female Long Evans rats with AAV-ArchT, and then implanted: 1) bilateral multi-electrode bundles with optical fibers ('optotrodes') in the GC; and 2) intra-oral cannula (IOC) for taste delivery. This preparation allows us to specifically silence BLA-GC projections while presenting a battery of taste stimuli that vary widely in their identity and palatability (0.1M NaCl, 0.3M Sucrose, 0.1M Citric Acid and 1mM Quinine-HCl). Here, we show that optogenetic inhibition of BLA-GC projections produces either an immediate or delayed suppression effect on GC taste responses. Regardless of the type of suppression, however, inhibiting BLA afferents has a larger impact on GC Epoch 2 than Epoch 1. This pattern of results is consistent with the hypothesis that, relative to other inputs, BLA primarily preferentially provides palatability information to GC. Future research will determine the impact of this brief, targeted optogenetic inactivation on taste-guided behavior, such as taste neophobia and conditioned taste aversion.

Title: Taste-related cortical population dynamics are stochastic and behaviorally-relevant

Authors: *N. MUKHERJEE, J. WACHUTKA, J.-Y. LIN, D. B. KATZ
Brandeis Univ., Waltham, MA

Abstract: Dynamic processing of sensory stimuli by broadly distributed populations of neurons has been suggested to underlie the decision making processes that lead to the generation of appropriately timed behavioral responses. The mammalian gustatory (taste) system is particularly well suited for the study of the spatiotemporal neuronal dynamics that guides precisely timed behavior: consumption decisions are easily measured and shown to occur with a wide variability of latencies; Hidden Markov Model analyses reveal a similarly sudden, similarly variable emergence of coherent decision-related firing in simultaneously-recorded ensembles of gustatory cortical (GC) neurons, and demonstrate that the behavioral and neural variability are correlated on a trial-by-trial basis—such that the latter strongly predicts the former (Sadacca, Mukherjee, et al., 2016). Our current work uses brief and precisely-timed optogenetic perturbations to test the functional significance of this correlation. Our preliminary results demonstrate that: 1) GC population firing states are temporally dissociated, such that the disruption of an earlier state does not affect later states; and 2) perturbations timed late in the taste trial is most potent in disrupting the onset of orofacial behavior. Together, these data imply that GC activity is the outcome of cross-talk between several different brain regions, an "output" region that provides direct modulation of brainstem-generated taste-reactive orofacial movements as decision-related firing emerges. All in all, these results are allowing us to unravel the role of stochasticity in the processing of taste stimuli in GC ensembles and its behavioral significance in the context of brainstem controlled ingestion-egestion orofacial behavior.

Title: Cellular and synaptic properties of BLA and GC neurons relevant to CTA

Authors: *C. LIU[1], D. LEVITAN[1], V. VALAKH[1], D. B. KATZ[2], S. B. NELSON[1]
[1]Biol., [2]Dept Psychol, Brandeis Univ., Waltham, MA

Abstract: Conditioned taste aversion (CTA) is a form of classical conditioning in which a taste is associated with gastric malaise. The learning depends on activity and protein synthesis in gustatory cortex (GC) and basolateral amygdala (BLA), suggesting that changes in GC-BLA synaptic connections and/or in the cellular properties of neurons in these regions, may contribute to memory storage. Acute slice electrophysiology was used to identify candidate plastic changes

in mice. In BLA, excitatory drive onto parvalbumin+ (PV) fast-spiking interneurons was tested by measuring miniature excitatory postsynaptic currents (mEPSCs) and did not differ between CTA trained and taste-only control animals. Intrinsic excitability of BLA projection neurons was also unchanged after CTA. In GC, no change was found in the mEPSCs recorded in PV neurons. Since mEPSCs represent input from multiple sources, BLA specific changes might be diluted. To measure BLA input to GC directly, BLA projections were stimulated optogenetically. In initial experiments, two types of pyramidal neurons with different genetic labels, firing properties and projection destinations have been identified in layer 5 of GC. Two genetically distinct subsets of L2/3 neurons have also been identified, but they do not differ in firing properties. Input to different cell types will be analyzed separately since they may have different functions during CTA. In conclusion, the fact that intrinsic properties of BLA projecting neurons don't change with CTA, suggests changes are localized to synaptic connections between BLA and GC or within GC itself. Genetic dissection of GC circuits may improve our ability to measure and manipulate GC plasticity.

Title: The profile of a range of neurochemicals in the nucleus accumbens shell differs for rewarding and aversive gustatory stimuli in rats

Authors: J. E. DOUTON[1], N. HORVATH[2], S. BALLARD[1], D. SUN[3], A. HAJNAL[5], *P. S. GRIGSON[4]
[1]Neural and Behavioral Sci., [3]Pharmacol., [4]Dept Neural/Behav Sci., [2]Pennsylvania State Univ. Col. of Med., Hershey, PA; [5]Dept Neural & Behav Sci., Penn State Univ., Hershey, PA

Abstract: The dopaminergic projection from the ventral tegmental area to the striatum, in particular to the nucleus accumbens (NAc), has been suggested to be the major substrate mediating reward. As a key structure in this pathway, the NAc is widely interconnected with other important nuclei. It is expected, then, that behaviors that are modulated by this nucleus do

not depend solely on one neurochemical, but on an interplay amongst all inputs. Of course, one of the most basic questions related to the function of the NAc is how it responds to putatively rewarding and aversive stimuli. This study addresses this fundamental question by taking advantage of the fact that rats emit different stereotypic oromotor responses (taste reactivity) to tastants of different hedonic valence when they are infused directly into their mouth. Specifically, rats emit aversive taste reactivity behavior such as gapes to unpleasant taste stimuli like quinine and mouth movements, tongue protrusions, etc. to rewarding taste stimuli such as sucrose or saccharin. Here we collected microdialysis samples during the intraoral infusion of a sweet or a bitter solution and used a new method of benzoyl chloride derivatization with ultra performance liquid chromatography and tandem mass spectrometry that allows for the detection of up to 17 neurotransmitters and metabolites. Specifically, Sprague-Dawley rats were given 15 min access to either 0.03M quinine or 0.5M sucrose for 7 days. On the 8th day, eight microdialysis samples were collected from the right NAc shell. During the fifth sample, the taste solution was intraorally delivered while the oromotor response was recorded by video. Our results show that the intraoral infusion of quinine, but not sucrose, elicited aversive reactions. In addition, distinct neurochemical profiles were observed for the rewarding and aversive stimulus. Quinine elicited an increase in the concentration of DA, GABA, Ser, Glu, Gly and Hist, while sucrose also produced an increase in DA, but a decrease in GABA, Ser, Glu, Gly Hist.

Title: Temporal coding of gustatory information in the NTS of lean and obese freely licking rats

Authors: *M. S. WEISS[1], A. HAJNAL[2], K. CZAJA[3], J. D. VICTOR[4], P. M. DI LORENZO[1]
[1]Psychology, Binghamton Univ., Binghamton, NY; [2]Dept Neural & Behav Sci., Penn State Univ., Hershey, PA; [3]VBDI, Univ. of Georgia, Athens, GA; [4]Feil Family Brain and Mind Res. Inst., Weill Cornell Med. Col., New York, NY

Abstract: Previous studies have shown that obesity changes both behavioral and brainstem electrophysiological responses to sweet tastes (e.g. Hajnal et al., *Am J Physiol Regul Integr Comp Physiol* 289:R1675-R1686, 2005). The aim of the present study was to study taste response profiles and taste-related information processing in neurons in the nucleus of the

solitary tract (NTS) of the diet-induced obese (DIO) rat. Following a minimum of 6 wks on a high fat diet (45% fat), obesity was verified via DXA body-composition scans (>18% body fat in obese rats vs. ~10% in lean rats). Rats were implanted with a chronic 16-ch drivable electrode bundle above the rostral NTS. Following recovery, rats were water deprived for ~22 hrs and placed in an operant chamber where they were allowed to lick freely. Tastants were presented in 5 consecutive lick trials interspersed with 5 licks of artificial saliva (AS) presented on a variable ratio 5 schedule. Tastants (dissolved in AS) were: NaCl (0.05 M), sucrose (0.1 M, 0.5 M), citric acid (0.016 M), caffeine (0.002 M), grape juice (0.1 M, 0.5 M), clam juice (0.025 M), heavy cream (25%), coffee (with 0.002 M caffeine), lemon juice (with 0.016 M citric acid) and AS. Results from 46 taste-responsive cells in DIO rats and 32 cells in lean rats show that the magnitude of taste responses that occur on a lick by lick basis to all stimuli are lower in obese rats ($F(1, 169) = 44.01$, $p < 0.001$). Taste-responsive neurons in obese rats were more narrowly tuned than those in lean rats ($X^2 = 5.072$, $p = 0.024$). To examine the contribution of the temporal characteristics of the response to coding taste quality, a family of metrics that quantifies the similarity of two spike trains in terms of spike count and spike timing was used (Victor & Purpura, *J Neurophysiol*, 76:1310-1326, 1996). These analyses indicate that for either 200 ms or 2 s of response, there was no difference in the amount of information about taste quality conveyed by the taste-evoked spike trains in obese (0.78 for 200 ms 0.97 bits for 2 s) vs. lean (1.0 for both 200 ms and 2 s) rats. These data suggest that taste stimuli drive NTS neurons more effectively in lean compared with obese rats. However, their ability to convey taste quality information remains intact.

Title: Optogenetic excitation of central amygdala terminals in the nucleus of the solitary tract targets responses to aversive tastes

Authors: *J. D. SAMMONS[1], C. E. BASS[2], P. M. DI LORENZO[1]
[1]Psychology, Binghamton Univ., Binghamton, NY; [2]Pharmacol. and Toxicology, Univ. At Buffalo SUNY, Buffalo, NY

Abstract: The gustatory portion of the nucleus of the solitary tract (NTS) receives information about taste directly from the periphery. It also receives centrifugal input from multiple cortical and subcortical brain structures, including the central amygdala (CeA). By integrating information from both peripheral and centrifugal input, the NTS can convey information about more than just taste quality, e.g. hedonic valence. Although no cortical or subcortical structure sends more projections to the NTS than the CeA, the functional relevance of the input from the CeA to the NTS remains poorly understood. Here, we used optogenetics to manipulate this input while recording from single cells in the NTS of awake, freely licking rats. First, an AAV2/10 viral construct encoding the gene for channelrhodopsin 2 (EF1α-ChR2-EYFP-AAV2/10) was infused into the CeA (-2.4 mm AP, ±4.0 mm ML, 7.8 DV with respect to bregma) of anesthetized rats bilaterally. After 2-4 weeks, rats were implanted with an optrode consisting of a fiber optic stub and an 8-microwire bundle of electrodes into the NTS. Following recovery, rats were presented with an array of taste stimuli under moderate water deprivation. Rats were given trials of 5 licks of a tastant (0.1 M NaCl, 0.1 M sucrose, 0.1/0.01 M MSG/IMP, 0.01 M citric acid, 0.001 M quinine, 0.1 M KCl, 0.1 M NH_4Cl, or artificial saliva) separated by 5 artificial saliva rinse licks presented on a VR5 schedule. In a random half of trials for each tastant, each lick of a taste stimulus triggered a 1 s train of laser light (25 Hz of 473 nm at 8-10 mW). Preliminary results show that excitation of CeA terminals in the NTS can selectively enhance responses to tastants with negative hedonic value, especially quinine. This suggests that the CeA may amplify the salience of tastants with negative hedonic value in the NTS. This is consistent with previous work showing that electrical stimulation of the CeA can increase aversive behaviors during tastant delivery (Riley & King, Chem. Senses 38: 705-717, 2013).

Title: Modality specific oral sensory disruption in chorda tympani and glossopharyngeal nerve responses after Hedgehog pathway inhibition in rat

Authors: A. KUMARI, Y. YOKOTA, R. M. BRADLEY, *C. MISTRETTA
Dept. of Biologic and Materials Sciences, Sch. of Dent., Univ. of Michigan, Ann Arbor, MI

Abstract: Hedgehog (HH) is a major signaling pathway that regulates maintenance of taste papillae and taste buds (TB). HH regulation of taste organs and function has been studied by

analyzing effects of pathway blockade with the HH pathway inhibitor (HPI) drug sonidegib. Sonidegib blocks the HH pathway at the SMO signaling component and is used to treat patients with basal cell carcinoma originating from PTCH1 and SMO mutations that deregulate HH signaling. We have reported previously that TB in the fungiform papillae and responses from the chorda tympani nerve are eliminated in mice after administration of the HPI drug sonidegib for 16 days. However there are no studies in other rodent species to test effects of HH pathway inhibition by HPI drugs. Although the rat is an essential animal model for human physiology and disease, there is no demonstrated role for HH regulation in the rat taste system. We used oral gavage in rats aged 5 to 7 weeks to administer the HPI drug sonidegib or a vehicle control and then study taste organs, tongue epithelium, and effects on oral taste, touch and temperature sensation. We recorded whole nerve responses from the chorda tympani nerve (innervates TB in fungiform papillae, FP) or lingual branch of the glossopharyngeal nerve (innervates TB in circumvallate papilla, CV), and then collected tongues for analysis of FP, CV and TB morphology. In initial experiments, after 16-20 days of HPI sonidegib treatment, in chorda tympani or glossopharyngeal nerve, taste responses to stimulation of the respective tongue receptive field region with a broad panel of chemicals and range of concentrations were eliminated. TB in FP and CV were lost in parallel with the neurophysiological effects. However, in both nerves, responses to cold water and tactile stimuli were sustained, the latter transmitted by a set of large amplitude action potentials. With longer periods of HPI drug treatment, after 28 days of sonidegib for chorda tympani nerve recordings the responses to cold water also were eliminated but tactile responses were retained. However even after 35 days of sonidegib treatment for glossopharyngeal nerve recordings, responses to both cold water and tactile responses were maintained. Thus HH regulatory effects on lingual sensation are modality specific, and were observed in two taste organ systems, FP and CV, that derive from different embryonic tissues and have different chemical response profiles. We have found that lingual taste organs and taste, touch and temperature sensation from FP and CV systems are selectively altered by HH pathway inhibition in rat. The results also demonstrate efficacy of another rodent model for study of HH signaling in taste homeostasis.

Title: Genetic deletion of sodium salt taste during development alters the dendritic architecture of gustatory relay neurons within the adult mouse nucleus of the solitary tract

Authors: *R. J. SKYBERG[1], D. L. HILL[2]
[1]Uva, Charlottesville, VA; [2]PSYCHOLOGY, Univ. Virginia, Charlottesville, VA

Abstract: Neural activity plays a critical role in driving the development of many sensory circuits within the mammalian brain. By genetically manipulating specific taste transduction pathways our lab has been able to examine how neural activity impacts the functional and structural development of gustatory circuits. Removal of sodium salt taste by functionally deleting the gene for the alpha subunit of the epithelial sodium channel (αENaC) within taste bud cells throughout development led to a failure to "prune" gustatory afferent terminal fields within the nucleus of the solitary tract (NST). At adulthood, the chorda tympani (CT), glossopharyngeal (IX), and greater superficial petrosal (GSP) nerve terminal fields were 1.5X-2X larger in ENaC knockout mice than in controls; suggesting that ENaC-mediated neural activity is necessary for proper development of NST circuitry (Sun et al., 2017). The present study was designed to further explore the effects of eliminating ENaC-mediated sodium taste activity on the NST circuitry. Retrograde tracers were used to visualize the dendritic fields of NST relay cells -- the cells receiving input from gustatory afferent terminal fields -- in mice lacking ENaC activity and in littermate controls. Preliminary data suggests that the dendritic fields of these relay cells are also dependent upon neural activity to develop into a mature state. The dendritic arbors of relay cells in mice lacking ENaC activity throughout life were longer and less complex than in controls. Relay cell dendritic fields also were not oriented parallel to the solitary tract like is seen in control mice. Therefore, removal of neural activity throughout development has significant effects on both the presynaptic gustatory afferent terminal fields and the postsynaptic relay cell dendritic fields in the NST. These large anatomical changes likely impact physiological changes in how taste-related information is processed, thereby influencing sensory coding of taste, and behavioral consequences related to feeding and motivated behaviors.This work is supported by NIH grant R01 DC00407.

Title: Connectomic and optogenetic analyses of a circuit modulating the rod bipolar pathway

Authors: S. J. PARK[1], E. LIEBERMAN[2], J.-B. KE[2], N. RHO[2], P. GHORBANI[2], N. JUN[1], K. L. BRIGGMAN[3], J. B. DEMB[1], *J. H. SINGER[2]

Abstract: Night vision in mammals depends on the rod bipolar (RB) cell-AII amacrine cell pathway. The RB-AII pathway receives input from rods and makes several well-established outputs to excitatory bipolar cells and to ganglion cells. But, critically, we lack an understanding of the inhibitory circuits that modulate RB-AII pathway function. Here, we identified the major inhibitory input to the AII by combining anatomical, genetic, and electrophysiological analyses in a three-step process. One, we reconstructed inhibitory synaptic inputs to AIIs in a volume of mouse retina imaged by scanning block face electron microscopy (SBEM) and found that virtually all of the inputs arose from a wide-field, multi-stratified amacrine cell (AC) with dendrites in both ON and OFF levels of the inner plexiform layer. Paradoxically, this AC received excitatory input solely from ON bipolar cells, in the OFF layers from en-passant axonal synapses and in the ON layers from more typical axon terminal synapses. Two, we evaluated published descriptions of reporter mouse lines to identify genetically-accessible ACs that had the anatomical characteristics of the cells reconstructed from SBEM images and selected the nNOS1 AC in the nNOS-creER mouse as a candidate input. And three, we used electrophysiological recordings and optogenetics-based circuit analysis of these cells to demonstrate that the nNOS1 AC provides GABAergic input to the AII. As well, the nNOS1 AC is a spiking neuron that exhibits a pure ON excitatory response, consistent with its identified bipolar cell input. Our study extends the classification of retinal neurons that receive ON input from en-passant axonal synapses made by ON bipolar cells in the OFF strata of the IPL to three: the nNOS1 AC joins the dopaminergic AC and the intrinsically-photosensitive ganglion cells in this category (citations). We conclude that the nNOS1-AC is the source of AII surround inhibition. More generally, our study demonstrates the utility of targeted, small-scale “connectomic” analysis for identification of novel neural circuits.

Abstract: The degeneration of photoreceptors in the retina is one of the major causes of adult blindness in humans. Unfortunately, no effective clinical treatments exist for the majority of retinal degenerative disorders. In this work we report on the fabrication and functional validation of a fully organic prosthesis for long-term in vivo subretinal implantation in the eye of Royal College of Surgeons rats, a widely recognized model of retinitis pigmentosa. Electrophysiological and behavioural analyses revealed a prosthesis-dependent recovery of light sensitivity and visual acuity that persists up to 6-10 months after surgery. The rescue of the visual function was accompanied by an increase in the basal metabolic activity of the primary visual cortex, as demonstrated by positron emission tomography imaging. Our results highlight the possibility of developing a new generation of fully organic, highly biocompatible and functionally autonomous photovoltaic prostheses for subretinal implants to treat degenerative blindness.

Title: UV cone photoreceptors and putative molecular mechanisms of light-dependent magnetoreception

Authors: *S. D. BALAY[1], W. T. ALLISON[1,2]
[1]Biol. Sci., [2]Med. Genet., Univ. of Alberta, Edmonton, AB, Canada

Abstract: Objective: The Earth's magnetic field serves as a navigational cue for a diverse range of organisms. This sensory information is used for animal homing, predator avoidance, prey capture, long distance migrations and more. Until recently, the literature has been dominated by behavioural evidence for magnetoreception, while the underlying mechanism for this phenomenon remains to be debated. Light-sensitive proteins called Cryptochromes (*cry*) are putative molecular candidates due to their biophysical properties: magnetic fields can alter their chemical products, they are activated by short wavelength light and are associated with retinal UV cone (*sws1*) photoreceptors in birds and the homologous blue cones in some mammals. Although *sws1* cones have been suggested to be crucial for magnetoreception, their role in *cry* expression has yet to be tested in any animal model. We sought to test if a specific *cry* isoform was expressed in retinal cone photoreceptor subtypes in zebrafish. **We hypothesized that *cry* is exclusively associated with *sws1* cones.** Loss of *sws1* cones was predicted to result in decreased expression of *cry*.
Methods: Using pharmacogenetic nitroreductase (NTR) mediated cell ablation via transgenic zebrafish, UV (*sws1*) or Blue (*sws2*) cone subtypes were selectively removed from zebrafish retina. Fluorescent in situ hybridization and RT-qPCR were used to visualize and quantify *cry* and *sws* gene expression.
Results: Zebrafish UV-cones express a *cry* isoform that appears to be non-circadian. This *cry* expression dramatically decreased by 62%±7% [$F(3, 20)= 4.90$, $p= 0.012$] when UV cones were ablated but not when blue cones were ablated [$F(3, 20)= 4.90$, $p= 0.90$] suggesting UV cone presence is required for robust *cry* expression. This study serves as the first experimental evidence that 1) cone photoreceptors are required for *cry* expression, 2) *cry* is co-localized in UV cones photoreceptors and 3) both may play a role in fish magnetoreception.

Conclusions: Zebrafish represent an excellent model for studying the proximate mechanisms of visually mediated behaviors, but have been under used in magnetoreception studies. Our lab has engineered a zebrafish line where cones can be selectively ablated from the retina, without disrupting other cells. This provides a unique opportunity to study the role of cone photoreceptors in *cry* expression and the mechanisms governing magnetoreception. Additional to our molecular work, *cry* mutants and novel behavioral paradigms are currently being designed to test the role of UV cones in zebrafish magnetoreceptive behavior.

Title: Retinal light damage in Ogg1 and Mouthy knockout mice

Authors: *A. OHIRA[1], Y. NAKABEPPU[2]
[1]Shimane Univ. Sch. of Med., Izumo, Japan; [2]Med. Inst. Bioreg Kyushu Univ., Fukuoka, Japan

Abstract: PURPOSE. To evaluate the roles of MutY homolog (MUTYH) and 8-oxoguanine DNA glycosylase (OGG1), base excision repair enzymes, in murine retinas subjected to oxidative stress.
METHODS. The left eyes of *Mutyh*- and *Ogg1*-knockout (KO) mice and C57BL/6J mice (wild-type) were exposed to light in the ultraviolet and visible region (center wavelength: 376 nm, bandwidth: 39 nm) from a xenon lamp light source with retinal radiant exposure of 75 J/cm^2. The unexposed right eyes served as controls. Seven days later, we recorded flash electroretinograms (ERGs) and measured the thickness of the outer nuclear layer (ONL). To confirm oxidative stress-induced DNA damage, we observed the accumulation of 8-oxo-7,8-dihydro-2'-deoxyguanosine (8-oxo-dG). Transmission electron microscopy showed retinal ultrastructural changes 1 and 3 days after exposure.
RESULTS. Light-induced retinal damage was suppressed partly in *Mutyh*-KO mice and not in *Ogg1*- KO mice. The ERG a- and b-wave amplitudes were decreased, and loss of the ONL was suppressed significantly in the *Mutyh*-KO mice retinas compared with wild-type mice. 8-oxo-dG expression in light-exposed retinas was suppressed compared with wild-type and *Ogg1*-KO

mice.
CONCLUSION. In *Mutyh*-KO mice, the lack of MUTYH partly suppressed the retinal damage induced by intense light exposure. Regulation of MUTYH expression or function might prevent retinal degenerative disease involved in oxidative stress.

Title: The effect of spectral input on eye growth in young chicks

Authors: *K. CHUN[1], D. WANG[2], T. LAM[1], Q. LIU[3], C. TO[1]
[1]Sch. of Optometry, The Hong Kong Polytechnic Univ., Hong Kong, Hong Kong; [2]Hainan Eye Hospital, Zhongshan Ophthalmic Ctr., [3]State Key Lab. of Ophthalmology, Zhongshan Ophthalmic Ctr., Sun Yat-sen Univ., Guangzhou, China

Abstract: Objective. To investigate the effect of different spectral compositions on the eye growth in young chicks. **Methods.** Four groups of young chicks aged 4 days (n = 8 in each group) were raised in four different lighting conditions; white light (W), combination of white and red (WR; 50:50), combination of white and blue (WB; 1:1 ratio) and combination of white, red and blue (WRB, 1:1:1) for 14 days in a 12/12-hour light/ dark diurnal cycle. Eye growth was monitored in terms of refractive errors and ocular parameters at the beginning (D0), 4 days (D4), 7 days (D7), 10 days (D10) and 14 days (D14) of exposure to specific lighting conditions. **Results.** In chicks under WB condition, a significant shortening of vitreous chamber depth (VCD) was found (-0.33 ± 0.07 mm) while the VCD of chicks under other lighting conditions increased after 4 days of exposure. A greater elongation of VCD was found in chicks under WRB condition as compare with those in W group at day 4 (WRB vs. W; 0.16 ± 0.06 mm vs. 0.07 ± 0.04 mm, $p < 0.01$, post hoc test, one-way ANOVA). After longer period of exposure, VCD of chicks in WB conditions increased but still in a smaller extent compared with other chicks at day 7, day 10 and day 14. The increase in VCD of chicks raised in WB was significantly smaller than other groups ($p < 0.001$). At day 14, chicks raised in WR had longer VCD compared to other groups (mean VCD at day 14; W vs. WB vs. WR vs. WRB; 5.98 ± 0.20

mm vs. 5.91 ± 0.16 mm vs. 6.26 ± 0.16 mm vs. 6.17 ± 0.26 mm). Chicks in WR conditions were relatively more myopic than those raised in white lighting alone at day 4 (mean change; WR vs. W; -2.19 ± 0.58 D vs. -1.19 ± 0.59 D, $p < 0.05$). At day 14, the chicks under WR were the least hyperopic while the chicks raised under WRB were the most hyperopic (mean spherical equivalent; W vs. WR vs. WB vs. WRB; +3.47 ± 0.36 D vs. +3.22 ± 0.47 D vs. +3.59 ± 0.23 D vs. 3.66 ± 0.52 D). However, the choroid did not demonstrate significant changes after the exposure. **Conclusion.** Spectral compositions of ambient lighting can significant affect eye growth in chicks. In a white light background, the addition of long-wavelength (red) light increased eye growth while short-wavelength light retarded it. The data suggested that chromaticity of the light and respective cone responses may contribute to eye growth in chicks. The white light background acts to help position the relative planes of focus of different wavelengths of light. This in turn enables differential activation of respective retinal cones and their responses to signal eye growth. Chromaticity may be an important optical cue to be decoded by the retina during eye growth.

Title: Synergistic signaling by light and acetylcholine in mouse iris sphincter muscle

Authors: *Q. WANG[1,2], W. W. S. YUE[1], Z. JIANG[1], T. XUE[3], S. H. KANG[1], D. E. BERGLES[1], K. MIKOSHIBA[4], S. OFFERMANNS[5], K.-W. YAU[1]

Sch. of Med., Baltimore, MD; [2]Dept. of Biol., Stanford Univ., Stanford, CA; [3]Sch. of Life Sci., Univ. of Sci. and Technol. of China, Hefei, Anhui, China; [4]RIKEN Brain Sci. Inst. - Wako, Saitama, Japan; [5]Max-Planck-Institute for Heart and Lung Res., Bad Nauheim, Germany

Abstract: ***Introduction:*** The size of the pupil is determined by an antagonism between the circumferential sphincter muscle and the radial dilator muscle in the iris. Upon monocular illumination, the pupils in both eyes constrict to a broadly similar extent because of the bilateral reflex pathways through the brain. Despite this widely-accepted picture, the isolated iris

sphincter muscle of nocturnal and crepuscular sub-primates is now known to be capable of light-induced contraction. In mouse, this “intrinsic” pupillary light reflex (PLR) requires the visual pigment, melanopsin, originally found in intrinsically-photosensitive retinal ganglion cells (ipRGCs). However, melanopsin’s presence and effector pathway locally in the iris remain uncertain. In this study, we provide evidence based on pharmacological, genetic-labeling, and tissue-specific gene-knockout experiments to support that the local light signal causing iris-sphincter-muscle contraction indeed originates from melanopsin in the muscle itself. ***Methods:*** The effect of pharmacological inhibition of cholinergic synaptic transmission on the local pupillary light reflex was examined by comparing the light-induced contraction of the isolated mouse iris sphincter muscle in the absence or presence of atropine or TTX. Functional presence of melanopsin in the iris was examining by tissue-specific deletion of melanopsin in smooth muscle. Phototransduction cascade of the iris sphincter muscle cells was investigated using mouse lines lacking one or more candidate genes. ***Results:*** We showed that the muscarinic receptor antagonist, atropine, eliminated the effect of acetylcholine (ACh), but not of light, on isolated mouse iris sphincter muscle. Conversely, selective genetic deletion of melanopsin in smooth muscle mostly removed the light-induced, but not the ACh-triggered, increase in isolated iris sphincter muscle’s tension, and largely suppressed the local PLR *in vivo*. We found melanopsin expression in a small subset of mouse iris sphincter muscle cells, with the light-induced contractile signal apparently spreading through gap junctions into neighboring muscle cells. Light and ACh share a common signaling pathway in iris sphincter muscle. ***Conclusion:*** In summary, our experiments have provided details of a photosignaling process in the eye occurring entirely outside the retina, as well as its integration with autonomic neural control. Thus, mouse iris sphincter muscle cells are *bona fide*, albeit unconventional, photoreceptors.
