Title: Identification of juvenility-associated long noncoding RNAs (JALNCs) as indispensable factors for the juvenile properties of the brain

Authors: *M. MORI, T. MORIMUNE, F. A. JAM, Y. KADOTA, A. TANO, Y. TANAKA, H. YUKIUE, S. AKAHANE, M. FUKUMURA
Shiga Univ. of Med. Sci., Shiga, Japan

Abstract: Inherent advantages of the young brain may be utilized for new therapeutics to combat with pediatric neurological diseases. The physiological properties of the younger brain include higher abilities for growth, learning, plasticity, regeneration and so on. Aiming at elucidating the molecular machineries for the juvenile properties of the brain, we performed transcriptome analysis with different tissues (brain, hepatocytes and cardiomyocytes) isolated from mice at different ages (postnatal days 1, 14 and 56). Thus, we identified the brain-specific transcripts that were expressed selectively at the younger ages. We call them as “juvenility-associated genes (JAGs)” of the brain. Further bioinformatics analysis revealed the brain JAGs were associated with cellular functions such as “secretion”, “glycosylation” and “extracellular matrix”, indicating an essential role of the brain JAGs for the construction of extracellular architecture during the postnatal brain development. We next sought to identify an indispensable therapeutic target for the juvenile properties. Noncoding RNAs are strong therapeutic targets because their functions are inhibited specifically via an antisense strategy using siRNA or antisense oligonucleotide (ASO). We established a pipeline for the bioinformatics analysis of the long noncoding RNAs (lncRNAs) and comprehensively identified the lncRNAs selectively highly expressed in the young brain as *j*uvenility-*a*ssociated *lnc*RNA*s* (JALNCs). Among the JALNCs, we identified Gm14230 that is evolutionary conserved and expressed highly selectively in the young brain. Gm14230 shuttles from cytosol to nucleus and is engaged in the transcriptional regulation in

cooperation with Ezh2, a histone methyltransferase. siRNA-mediated suppression of Gm14230 significantly deteriorates cell growth and perturbs the expression of genes associated with the extracellular architecture. Furthermore, loss of Gm14230 leads to the cellular senescence, indicating the juvenile-selective Gm14230 safeguards the neuronal cells from the premature senescence. Thus, our transcriptome-wide analysis leads to the identification of the factor that is indispensable for the juvenile physiology of the brain.

Title: Role of endoplasmic reticulum quality control in the adult hippocampal neurogenesis

Authors: *N. MURAO, H. NISHITOH
Dept. of Med. Sci., Miyazaki Univ., Miyazaki, Japan

Abstract: The endoplasmic reticulum (ER) has a quality control mechanism that ER resident stress sensors recognize unfolded or misfolded (malfolded) proteins and trigger the unfolded protein response (UPR). The UPR mediates the proper folding or degradation of malfolded proteins and the translational attenuation to inhibit the further production of ER proteins. A collapse of the ER quality control mechanism contributes to the onset and deterioration of several neurological disorders associated with impaired learning and memory. Adult neurogenesis is the process to generate new neurons from adult neural stem/precursor cells in restricted brain regions. Neurogenesis in the adult hippocampal dentate gyrus plays an important role in learning and memory formation, and its homeostasis is disrupted in several neurological disorders associated with memory impairment. ER quality control and adult neurogenesis are thought to be closely related to the mechanisms of learning and memory, whereas the physiological relevance among them remains to be elucidated. In the present study, we found that the disturbance of ER quality control by deletion of an ER membrane protein in the central nervous system (CNS) leads to a chronic ER stress state without cell death and impairs hippocampal neurogenesis. Our findings suggest that ER quality control mechanism in the CNS may play an important role in maintaining homeostasis of adult hippocampal neurogenesis and learning and memory.

Title: Akt drives cell cycle entry in the subventricular zone

Authors: *J. E. MARKS[1], F. LICAUSI[2], A. FOSTER[2], N. W. HARTMAN[2]
[1]Stockton Univ., Towaco, NJ; [2]Stockton Univ., Galloway, NJ

Abstract: Neural stem cells in the subventricular zone (SVZ) continually generate new daughter cells that migrate to the olfactory bulb (OB), differentiating into neurons. SVZ stem cells need to integrate extracellular signals to properly divide, differentiate and migrate. Downstream of growth factor and amino acid signaling are the Akt and mammalian target of rapamycin (mTOR) pathways. The Akt pathway is important for cellular growth, proliferation and differentiation. While there are many downstream targets of Akt, activation of this molecular cascade through mTORC1 has been proposed to increase cellular differentiation and protein translation. It is unclear whether Akt and mTOR play roles independent of each other in NSC development. Here, we show that a constitutively active form of Akt resulted in a threefold increase in the number of newly born neurons in the OB. In contrast to driving mTOR alone, Akt activation did not result in apparent aberrant migration in the SVZ or OB. Akt activation increased dendritic length and complexity; however, mTORC1 inhibition did not rescue total dendritic length. In the SVZ, inhibition of Akt decreases proliferation of stem cells. Whereas, activation of the Akt pathway drives NSCs into cell cycle progression and differentiation. Blockade of downstream mTORC1 targets inhibited differentiation, but did not alter the number of proliferative cells in the SVZ. These data suggest that Akt controls NSC differentiation via mTOR, but may exert proliferative effects on NSCs independently.

Title: TGFbeta signals regulate afferent innervation in the developing tooth

Authors: *S. PETERS, C. BARKLEY, K. NGUYEN, R. SERRA
Univ. of Alabama At Birmingham, Birmingham, AL

Abstract: Teeth require a high degree of sensory innervation to detect noxious input to protect the tooth and organism throughout their lifetime. Tooth innervation research remains in its elementary stages despite the fact that tooth decay and its associated pain responses are currently the most chronic disease in the United States. During postnatal development, sensory nerve fibers from the trigeminal nerve ganglia (TG) extend toward tooth germs and penetrate the dental pulp (DP) coincident with odontoblast differentiation and dentin deposition. Previous studies indicate the DP cells secrete neurotrophic factors to guide tooth innervation. Transforming growth factor β (TGFβ) is known to play an important role in bone and tooth development. The **objective** of this study was to investigate the role of Tgfbr2 in regulating paracrine signals from the DP guiding afferent innervation. **Methods and Results:** Our laboratory established a mouse model in which Tgfbr2 was conditionally deleted in odontoblast-producing mesenchyme using an osterix promoter driven Cre recombinase ($Tgfbr2^{cko}$). These mice survived postnatally with significant defects in bones and teeth. We performed an mRNA-Seq analysis using RNA from postnatal day 7 (P7) DP from control and mutant mice and found that neuronal pathways in development and function were highly regulated. Immunofluorescent images of neuronal marker, β3 tubulin, verified significantly reduced innervation throughout the DP and odontoblast region in P7 $Tgfbr2^{cko}$ mice. We co-cultured TG neurons in Transwell filters overlying primary $Tgfbr2^{f/f}$ DP and infected the DP with Adenovirus-Cre recombinase to knockdown Tgfbr2 in the DP. Large immunofluorescent images of entire filters were acquired with confocal microscopy and assembled with NIS-Elements 4.6 software. Pixel intensity of autothresholded images was quantified with Image J and indicated a significant reduction in neurite outgrowth when Tgfbr2 was knocked down in DP. **Conclusions:** These results suggest Tgfbr2-guided paracrine signals from the DP and/or odontoblasts of the tooth guide innervation. Research into this cross-talk is likely to provide information that will help plan preventative, therapeutic and regenerative strategies and improve the preservation of teeth.

Title: PSA-NCAM upregulation and differential expression after telencephalic lesions in turtles

Authors: *A. J. NAPOLI[1], A. S. POWERS[2]
[1]State Univ. of New York At Stony Brook, Stony Brook, NY; [2]Psychology, Stony Brook Univ., Stony Brook, NY

Abstract: Adult neurogenesis in mammals is found only in discrete regions, and this restricted localization means that it plays a limited role in CNS repair. Non-mammalian vertebrates such as reptiles, however, demonstrate adult neurogenesis throughout the telencephalon, as well as migration, maturation, differentiation, and integration of cells. These processes can be harnessed for repair and have been demonstrated to restore the cytoarchitecture and functionality of lesioned telencephalic regions in reptiles.
PSA-NCAM is a critical modulator of both developmental and reparative processes in the CNS. It facilitates the multifaceted processes of neurogenesis and circuit building and thus allows for the establishment of brain architecture as well as its reorganization after injury. We hypothesized that PSA-NCAM expression would be upregulated in the brains of lesioned animals in order to facilitate reparative processes. To determine the expression of PSA-NCAM in reptilian brains, we studied it in painted turtles, *Chrysemys picta*, with telencephalic lesions and compared them to non-lesioned controls. We observed the expression level, characteristics, and locations of PSA-NCAM expression after different survival periods ranging from 1 week to several months, using immunohistochemical labeling of PSA-NCAM along with BrdU to determine the role of new cells, and NeuN to distinguish cells as neurons.
PSA-NCAM expression is markedly upregulated in the brains of *C. picta* after lesioning, as is the generation of new neurons. Furthermore, there is differential expression over time, with early labeling found primarily on cell bodies within the ependyma and parenchyma, and most robustly in regions near the lesions. Later survival times demonstrate continued upregulation, but expression is shifted primarily to neuronal and radial glia processes throughout the tissue. Widespread generation and functional integration of new neurons in the adult telencephalon was probably a trait present in ancestral vertebrates, but was lost in mammals. Therefore, appreciation of non-mammalian vertebrates as ancestral to mammals is critically important in understanding the conservation or loss of traits that dictate neurogenesis and integration, and to the elucidation of the mechanisms that drive, or fail to drive, the process. Deficiency of

permissive signals for polysialylation of the NCAM molecule may be at the root of the limited reparative capabilities of the adult mammalian brain. This study is the first to qualify and quantify PSA-NCAM expression, and to examine its expression after lesioning of the telencephalon, in turtles.

Title: The fmrp/icam5 mrna interaction uncovers a new mechanism of modulating dendritic spine development in fragile x syndrome

Authors: *Z. YAN, Y.-P. PEI, Y.-Y. WANG, Y.-S. CHEN
Wuhan Univ. of Sci. and Technol., Hubei, China

Abstract: The absence of fragile X mental retardation protein (FMRP) results in fragile X syndrome (FXS), the most common form of inherited intellectual disability and the leading monogenic cause of autism spectrum disorders (ASD). Here, we report that FMRP regulates the synthesis of intercellular adhesion molecule 5 (ICAM5), a cell adhesion molecule that belongs to the Ig superfamily. In *Fmr1* KO mice, a preclinical model of FXS, lack of FMRP results in excessive production of ICAM5 protein, which leads to aberrant dendritic spines and abnormal behaviors. Genetic reduction of ICAM5 corrects dendritic spine abnormality in *Fmr1* KO mice, and ameliorates defective behaviors including social interaction, fear memory and anxiety. Moreover, we found that FMRP directly binds with ICAM5 mRNA, and interacts with its coding sequence that affects spine maturity through regulating ICAM5 expression. The knockdown of *Fmr1* mRNA can increase levels of ICAM5 protein expression as well as correlated impairments in dendritic spine morphology. Overexpression of FMRP decreases ICAM5, consistent with a repressive role for FMRP. Taken together, our results demonstrated that FMRP regulates synthesis of ICAM5 through direct interaction with ICAM5 mRNA, and lack of FMRP in *Fmr1* KO mice results in excessive ICAM5 production that leads to impairments in dendritic spine morphology and behaviors. To our knowledge, this is the first study to provide a functional link for ICAM5 with deficient neuronal morphology and cognitive impairment in FXS.

Title: Identification of genes regulated by short term environmental enrichment during a critical period for the survival of new neurons in the adult dentate gyrus

Authors: *C. C. CHANG, A. TASHIRO
Sch. of Biol. Sci., Nanyang Technol. Univ., Singapore, Singapore

Abstract: Environmental enrichment promotes the survival of new neurons in the adult dentate gyrus of the hippocampus. This effect is dependent on the age of new neurons, and a maximal effect has been observed on neurons during a critical period around the second week after their birth. However, the molecular mechanism underlying this experience-dependent survival during the critical period is not well understood. Here, we established a method to isolate mRNA from new neurons at a specific neuronal age in the dentate gyrus and performed microarray analysis to identify genes the expressions of which are affected by exposure to enriched environment. To label newly-generated cells at a specific age, we used a retroviral vector expressing fluorescent protein. Further, to distinguish new neurons from other types of newly-generated cells, we visually identified new neurons based on their morphology under a fluorescence microscope and selectively harvested them with laser capture microdissection. Using genetic materials obtained with this method, we performed a DNA microarray analysis for new neurons at a specific neuronal age. We exposed a group of adult female mice to enriched environment, which consisted of a large cage (W100×D100×H60 cm) with enriching materials (9 tunnels, 2 shelters and 1 running wheel) housing 10 mice per cage. We started this exposure 7 days after retroviral injection and collected the genetic materials of new neurons at 11 days after the injection. Thus, these mice were exposed to enriched environment for 4 days during the critical period for neuronal survival. We compared gene expression in these enriched mice with control mice housed always in a standard cage (W31×D16×H16 cm) housing 5 mice per cage without enriching materials. Each sample for the microarray analysis was mRNA pooled from >300 fluorescent new neurons in at least 3 mice. From this analysis, we identified 63 coding genes, 16 microRNAs and 3 ribosomal proteins that were up- or down-regulated by 4-day enrichment. Thus far, we have been able to verify the effects on some of these genes using real-time PCR. We are examining roles of these verified genes in enrichment-induced neuronal survival using retroviral vectors for overexpression or knockdown of the genes. Preliminary data indicate some

of these genes support neuronal survival. Thus, we established the method to isolate mRNA from new neurons at a specific age and identified genes regulated by 4-day enrichment during the critical period. The results from this study would provide the basis for understanding the molecular mechanism involving in experience-dependent regulation during the critical period for neuronal survival in the adult brain.

Title: Histone modifications define neural stem cells subtypes in mouse subventricular zone

Authors: *Z. ZHANG[1,2], A. MANAF[1], S. PEÑA PEREZ[1], R. SUGANTHAN[1], M. BJØRÅS[1], J. ARNE DAHL[1], A. KLUNGLAND[1,3]
[1]Dept. of Microbiology, Oslo Univ. Hosp., Oslo, Norway; [2]Inst. of Neurobio., Xi'an Jiaotong Univ. Hlth. Sci. Ctr., Xi'an, China; [3]Dept. of Mol. Med., Univ. of Oslo, Oslo, Norway

Abstract: Neural stem cells (NSCs) persist in the mammalian brain throughout life and can be activated in response to the physiological and pathophysiological stimuli. Therefore, understanding the dynamic regulation of NSCs might help develop novel therapeutic strategy for stroke and other brain diseases. Defining the epigenetic features of neural stem cells may be critical for formulating a rational strategy for the therapeutic intervention of stem cell dysfunction. Therefore, we aimed at defining different subtypes of NSCs by individual histone modifications. At first, we found high levels of Histone H3 lysine 4 trimethylation (H3K4me3), histone H3 lysine 27 trimethylation (H3K27me3) and Histone H3 lysine 36 trimethylation (H3K36me3) in neurogenesis based on their co-staining with NSCs marker SOX2 during neural development. Then, CD133 (a quiescent NSCs marker), ID1 (an active NSCs marker) and DCX (a neuroblast NSCs marker) immunostaining were used to define different subtypes of NSCs. At early development, P10, 51.7% ± 11.7% high level H3K27me3 cells expressed CD133. On the contrary, just 15.8% ± 4.1% high level H3K36me3 cells and 4.8% ± 2.2% high level H3K4me3 cells co-stained with CD133. For the active NSCs, 56.9% ± 4.8% high level H3K36me3 cells co-

stained with ID1, significantly higher than H3K27me3 (28.0% ± 11.7%) and H3K4me3 (6.6% ± 2.6%). For neuroblast NSCs, 86.1% ± 3.5% of high level of H3K4me3 co-stained with DCX, significantly higher than H3K27me3 (11.7% ± 2.7%) and H3K36me3 (21.6% ± 5.0%). These results indicated that high level of H3K27me3 could be considered a quiescent NSCs marker, high level of H3K36me3 is an active NSCs maker and high level of H3K4me3 mark neuroblasts. Our results indicate different features of histone modifications subtypes of NSCs. This research may reveal novel insight into the onset of neurodevelopment and provide an innovative epigenetic signature for discovery and characterization of key regulatory genes for neurogenesis. However, whole genome analysis need be conducted to gain insight on the role for individual histone modifications domains in neurodevelopment.

Title: Exercise increases caspase-3 expression in hippocampal astrocytes and radial glia-like cells

Authors: *M. E. STEVENSON[1], N. A. LENSMIRE[2], R. A. SWAIN[3]
[1]Psychology, Univ. of Wisconsin- Milwaukee, Milwaukee, WI; [2]Univ. of Wisconsin-Milwaukee, Milwaukee, WI; [3]Univ. of Wisconsin Milwaukee, Milwaukee, WI

Abstract: Exercise induces plasticity in the hippocampus, which includes increases in neurogenesis, the proliferation of new neurons, in the subgranular zone of the dentate gyrus (DG), and angiogenesis, the sprouting of new capillaries from preexisting blood vessels. Following exercise, astrocytes also undergo morphological changes, paralleling the events occurring in the neurovascular system. There have also been reports of increased apoptosis following aerobic exercise. In our experiment, cleaved caspase-3, a terminal protein in the apoptotic cascade, was initially used to identify apoptotic cells in the hippocampus after rats completed an acute bout of exercise. Following exercise, we found caspase-3 expression was increased in CA1 and DG. Because caspase-3 expression was elevated in DG, a region where new neurons proliferate, we wanted to identify whether newly birthed or adult neurons disproportionally expressed caspase-3 and, in turn, were undergoing apoptosis following exercise. Interestingly, caspase-3 was not highly expressed in neuronal populations, and

expression was not increased in these cells post exercise. However, caspase-3 was predominantly expressed in astrocytes. Furthermore, following exercise, caspase-3 expression was elevated in these astrocytes in DG and CA1, and in the radial glia-like cells present in the subgranular zone. To determine whether caspase-3 expression in these glial cells was associated with apoptosis, we completed a TUNEL assay as a second measure of apoptotic cell death. TUNEL staining was negligible in all groups and did not mirror the pattern of caspase-3 labeling. This suggests cleaved caspase-3 expression is non-apoptotic in these hippocampal astrocytes and radial glia-like cells. Future experiments aim to determine the non-apoptotic role of caspase-3 in these cell populations.

Title: Endogenous BDNF regulates spine development in adult-born olfactory granule cells

Authors: B. MCDOLE[1], *K. M. GUTHRIE[2]
[1]Biomed. Sci., [2]Dept Biomed Sci., Florida Atlantic Univ., Boca Raton, FL

Abstract: The olfactory bulb (OB) undergoes continuous, adaptive circuit remodeling as resident interneurons are gradually replaced by adult-born cells produced in the forebrain subventricular zone. New GABAergic granule cells (GCs) constitute the largest population. Following their migration to the OB, GCs elaborate dendrites and spines as they mature and functionally integrate. During this process, GCs receive inputs from centrifugal afferents, and on their apical dendrites, develop spine-located dendrodendritic synapses with glutamatergic bulb mitral and tufted cells. New GCs that fail to stably integrate undergo apoptosis within a few weeks of their birth. Multiple mechanisms regulate the incorporation of these new interneurons, with neural activity known to play a major role. Sensory deprivation by naris occlusion impairs spine and synapse development in adult-born GCs and increases their apoptotic loss. Brain-derived neurotrophic factor (BDNF) has a well-established role in activity-dependent spine and synapse maturation and maintenance. Using transgenic mice over-expressing BDNF in the OB, we previously showed with Golgi staining that BDNF increased overall spine density, and the prevalence of mature spines, on established populations of GCs. How increases in endogenous BDNF levels impact the maturation of adult-born GCs has not been determined. Using viral-mediated labeling of adult-born GCs in these mice, followed by neuronal reconstruction and

morphometric analyses, we followed GC maturation from 12-60 days post-infection (dpi) to test for developmental BDNF effects. While increased BDNF had no effect on dendrite growth or branching, effects on spine morphology and density were evident as early as 12 dpi. By 22 dpi, total spine density was 11% higher in transgenic mice relative to controls, and included a 28% increase in the density of headed spines. By 35 days, the latter value reached 38%, remaining stable to 60 days (42%). Despite increases in spine numbers and density, potentially indicating successful integration, numbers of surviving GCs, measured by BrdU+ cell counts, not differ from that of controls. These results establish that endogenous BDNF can shape the connectivity of adult-born GCs within dynamic olfactory circuits that process odor information.

Title: PSD-95 modulates adult-born neuron maturation in mouse hippocampus

Authors: *M. D. MARDONES[1], P. V. JORQUERA[1], A. HERRERA-SOTO[1], F. J. BUSTOS[2], B. VAN ZUNDERT[1,3], L. VARELA-NALLAR[1]

Abstract: The generation of new neurons in the dentate gyrus of adult mouse hippocampus is a process that involves proliferation of neural stem cells, neuronal fate commitment, differentiation, neuronal maturation and integration of new neurons into the hippocampal network. PSD95 is a major scaffold postsynaptic protein and has been tightly associated to synaptic development and maturation of hippocampal neurons. Here we evaluate the function of PSD95 in the different steps of adult hippocampal neurogenesis. Retroviruses (MMLV) expressing a control shRNA or an shRNA targeting PSD95, and the ZsGreen reporter protein were stereotaxically injected into 2-month-old mouse dentate gyrus. Animals were sacrificed after 2, 4 and 6 weeks post injection (wpi). Neuronal differentiation was evaluated by double immunostaining for ZsGreen and the immature neuronal marker DCX. Morphological

maturation was assessed by total dendritic length, average branch order, and total number of intersections. PSD95 knockdown did not affect differentiation of newborn cells into neurons nor migration of adult-born neurons through the granule cell layer. At 4 wpi PSD95 deficient neurons expressing the mature neuronal marker NeuN showed no changes in total dendritic length, but there was a significant increase in the total number of intersections and average branch order, suggesting that PSD95 controls dendritic development of adult-born granule neurons. Moreover, at 6 wpi mature neurons deficient in PSD95 showed a decrease in dendritic spine density indicating the relevance of this scaffold protein controlling spinogenesis in adult-born neurons.

Abstract: Stem cells in the adult mammalian brain give rise to adult-born granule cells (GCs) that help maintain an inhibitory feedback circuit within the dentate gyrus thought to be very beneficial for brain health. However, disruption of the dentate gyrus circuitry causes spontaneous recurrent seizures (SRS), which often leads to acquired epilepsy. Although adult-born (GCs) are part of an inhibitory feedback circuit within dentate gyrus critical for a range of cognitive processes, whether they are involved in SRS and epileptogenesis remains elusive. Here we

identified a critical window that excessive activity drives aberrant maturation of adult-born GCs that is sufficient to disrupt hippocampus circuitry. We found these aberrant GCs developed an abnormal morphology and migration pattern, became hyper-excitable, and resulted in spontaneous seizures. Importantly, silencing of a restricted cohort of aberrant adult-born GCs in a temporal lobe epilepsy model prevented abnormal development and SRS, thereby restoring the protective function back to the dentate gyrus. Furthermore, silencing aberrant neurogenesis prevented recurrent CA3 back-projections and restored proper cortical connections to the hippocampus circuitry. Our results demonstrate that despite their limited number, adult-born GCs have a tremendous, unlimited pathological capacity to disrupt hippocampus circuitry. Therapeutic strategies to target these few new neurons can restore normal brain function possibly in a broad spectrum of neurological disorders.

Title: Targeting aberrant neurogenesis in a clinically-relevant window leads to transient but not persistent seizure reduction

Authors: *P. VARMA[1], R. R. BRULET[2], L. ZHANG[3], J. HSIEH[4]
[1]Univ. of Texas San Antonio, San Antonio, TX; [2]Moelcular Biol., UTSW Med. Ctr., Dallas, TX; [3]UT Southwestern Med. Ctr., Dallas, TX; [4]Biol., The Univ. of Texas At San Antonio, San Antonio, TX

Abstract: Mesial temporal lobe epilepsy (mTLE), the most common form of medically refractory epilepsy in adults, emerges from the hippocampus and accounts for nearly 80% of all the temporal lobe seizures. Adult-born granule cells from the dentate gyrus born prior to an epileptic injury, for example status epilepticus (SE), contribute to epileptogenesis making them promising therapeutic targets, either genetically or pharmacologically, to prevent the formation of chronic seizures. However, current studies aiming to do so are limited in their clinical relevance as they target neural stem cell populations prior to an epileptic insult, a clinically irrelevant time period for preventing epilepsy development. Therefore, we aim to determine if

adult-born granule cells born after SE can suppress epilepsy. Using pilocarpine-induced SE model of mTLE in mice, we show for the first time that ablation of aberrant neurogenesis for eight weeks specifically after SE can reduce the formation of spontaneous recurrent seizures (SRS) by 65%. Further, we show that this effect is dependent upon the reduction of aberrant neurogenesis below a critical threshold as four weeks of blocking of seizure-induced neurogenesis was not sufficient to affect chronic SRS. However, this effect is transient and does not have a long-term impact on the reduction of seizures. These findings provide evidence that aberrant neurogenesis when targeted optimally in a clinically relevant therapeutic window, has the potential to suppress the epileptogenic process at least transiently.

Title: Olfactory perception and newborn neurons integration in a mouse with reduce number of projection neurons

Authors: *L. SANCHEZ[1], B. WANG[2], C. LOIS[2]
[2]Biol., [1]Caltech, Pasadena, CA

Abstract: The early olfactory system comprises the olfactory epithelium and the olfactory bulb (OB). Olfactory sensory neurons placed in the olfactory epithelium send their axons to the OB where they make synapses with the main projection neurons, mitral and tufted cells (M/T cells), which send their axons to cortical areas. The activity of the M/T cells in the OB is modulated by local interneurons that are incorporated into it daily. Every day, hundreds of newborn interneurons are produced in the subventricular zone and migrate rostrally to integrate into a pre-establish neuronal circuit in the OB. It is thought that projection neurons are necessary for the integration and survival of newborn interneurons, in addition, to decode the identity of the odors. Conditional cell ablation is a strategy broadly used in the brain to reveal the importance of a specific cell type during development. Here, we used a transgenic mouse line for tissue-specific genetic ablation of the main projection neurons in the olfactory bulb (OB). We induced diphtheria toxin expression in the M/T cells during development stages. Then, we analyzed how the lack of M/T cells affects the newborn interneurons integration, the olfactory bulb organization, and its operationality. We found that only 1-3 % of the main projection neurons remained in the OB while the structural organization of the OB was mostly maintained. The production of newborn interneurons was not drastically affected by the lack of M/T cells but their survival after the critical period was significantly reduced. However, the morphology of

these newborn neurons, once they are integrated into the circuit, was very similar to the interneurons of wild-type mice. Surprisingly, behavior analyses showed that mice with few M/T cells were able to detect odors as well as discriminate between two different odors. In addition, we noted that females mated and exhibited normal maternal behavior, while males were not able to mate and showed an inadequate behavior in presence of an intruder male.

Title: Characterization of adult neural stem cell potential for paracrine signaling based therapies

Authors: *J. K. DENNINGER[1], X. CHEN[2], L. WALKER[2], R. BUNDSCHUH[3], P. YAN[4], E. D. KIRBY[1]

Abstract: Stem cells are currently being studied as potential therapeutic agents for a variety neuropathologies. Although direct cell replacement is an obvious method for regeneration, using stem cells as sources of paracrine signaling factors that can modify injury outcome is an interesting alternative. In order to identify the factor(s) secreted by neural stem cells (NSCs) both at baseline and during injury, we have generated transcriptomes of NSCs in the adult mouse dentate gyrus (DG). Located in the hippocampus, the DG is an important neurogenic niche that is critical for proper cognitive function. Unfortunately, the DG is exquisitely sensitive to different types of injury such as seizures and concussions. Despite its vital function, the DG is actually a small structure, making the study of its various cell populations extremely difficult. Using a novel low-cell number RNA sequencing (lcRNASeq) protocol and Coverage-Based Limited-Cell Experiment Analysis for RNA-Sequencing (CLEAR) algorithm, we have confirmed the feasibility of accurately characterizing these NSCs on a population level from individual mice. Due to the high degree of heterogeneity between individual NSCs, the ability to obtain faithful transcriptomes from a sample of the population is key to understanding what NSCs do as a whole. For several cytokines and growth factors that are highly transcribed by NSCs according to our lcRNASeq dataset, we have confirmed synthesis and secretion of these proteins in NSC

conditioned media with a commercially available cytokine antibody array. By implementing lcRNASeq and CLEAR to obtain transcriptomic profiles of NSCs in the adult dentate gyrus at baseline and during injury, we can study changes in gene expression on a population level, allowing for the development of a comprehensive list of injury-modifying NSC-derived paracrine factors which could then be refined with further study of individual factors. Generation of such an injury-modifying NSC secretome will lead to more successful therapeutic applications of NSCs in the future.

Title: Hippocampal neural stem cells clear extracellular glutamate via excitatory amino acid transporters

Authors: *J. D. RIESKAMP, V. VALENTINI, J. P. BRUNO, E. D. KIRBY
Psychology, The Ohio State Univ., Columbus, OH

Abstract: Neural stem cells (NSCs) persist in the neurogenic niche of the rodent hippocampus throughout life. Adult NSCs contribute to hippocampal cognition by generating new granule neurons, a process that is highly sensitive to niche-derived neurotransmitter, growth factor, cytokine, and morphogen signaling. While early work focuses on NSCs as recipients of niche-derived signaling, recent studies suggest this communication is bi-directional, and NSCs influence the niche via growth factor and cytokine secretion.
Here we investigate whether NSCs have the potential to influence neighboring cells by regulating glutamate signaling via excitatory amino acid transporters (EAATs). Decades of research suggest that astrocytes and neurons use EAATs to shape neurotransmission and protect vulnerable cells from glutamate-induced excitotoxicity. However, whether NSCs similarly regulate glutamate signaling is unknown.
To address this question, we used RNA-sequencing to profile EAAT gene expression in NSCs isolated from the dentate gyrus (DG) of 2 month old mice by fluorescence activated cell sorting. We detected expression of both EAAT1 and EAAT2 mRNA. We confirmed using qPCR that NSCs *in vitro* express EAAT1 and EAAT2, with about 100-fold greater expression of EAAT1. To determine whether NSCs can clear extracellular glutamate, we exposed NSCs cultured from

the adult DG to 5 μM glutamate in the extracellular media. In the presence of NSCs, glutamate declined to 22.8% (SEM ± 3.1%, n = 3 independent replicates) of the initial concentration over 20 minutes, an effect that was completely blocked by the pan-EAAT inhibitor TFB-TBOA. Using a combination of specific EAAT inhibitors, we determined that EAAT1 is responsible for the majority of NSC glutamate transport while the contribution of EAAT2 only becomes apparent when EAAT1 is impaired.
We conclude that hippocampal NSCs exhibit the capacity to substantially alter extracellular glutamate concentrations. Furthermore, NSC glutamate transport is comparable to that reported for astrocytes *in vitro*, suggesting that NSCs could impose physiologically relevant regulation over glutamate signaling. We are currently testing this question *in vivo* using a Cre-dependent lentiviral shRNA expression vector to knock-down EAAT1 specifically in NSCs. Future work will investigate whether NSC glutamate transport has therapeutic value in the context of excitotoxic disease.

Title: Adult neural stem cells require VEGF intracrine signaling for stem cell maintenance in the dentate gyrus neurogenic niche

Authors: J. K. DENNINGER, *E. D. KIRBY
Ohio State, Columbus, OH

Abstract: Neural stem and progenitor cells (NSPCs) mediate neurogenesis in homeostasis as well as disease states. In the adult hippocampal neurogenic niche, Vascular Endothelial Growth Factor (VEGF) is highly expressed by astrocytes and newly discovered to be highly synthesized and secreted by adult NSPCs. While VEGF is a known growth factor of stem cell maintenance, proliferation, and migration in other stem cells, such as hematopoietic stem cells, how NSPC-synthesized VEGF influences stemness in adult hippocampal NSPCs is unknown. This study elucidates a novel intracrine mechanism of VEGF signaling within neural stem cells that is critical to maintaining the stem cell population. We show using cultured adult hippocampal NSPCs that blocking intracellular VEGF signaling with the chemical VEGF receptor 2 (VEGFR2) inhibitor SU5416 diminished VEGFR2 phosphorylation as well as the phosphorylation of downstream mediator Akt while antibody-mediated neutralization of

extracellular signaling did not. Functionally, intracellular inactivation of VEGF signaling with either VEGF RNA interference or SU5416 led to markedly diminished neurosphere number, indicating depletion of the stem cell population. Importantly, exogenous recombinant VEGF had no impact on phosphorylation of VEGFR2 or Akt. Immunofluorescent staining and confocal microscopy indicate that VEGFR2 activation by VEGF may occur in intracellular compartments such as endosomes, further supporting the idea that an intracrine mechanism of VEGF signaling is the primary mechanism of VEGF-mediated preservation of the stem cell compartment. Altogether, our data uncovers a novel intracrine mechanism of VEGF signaling in adult hippocampal NSPCs that is critical to preservation of stemness.

Title: Atypical excitatory-inhibitory balance in feedforward and feedback circuits in autism

Authors: *I. TRUTZER[1,2], B. ZIKOPOULOS[2]
[1]Neurosci., [2]Boston Univ., Boston, MA

Abstract: Interactions between excitatory and inhibitory elements in neural circuits are crucially altered in autism and contribute to its central symptoms. Functionally and neurochemically distinct classes of inhibitory neurons, which express the calcium-binding proteins calbindin (CB), calretinin (CR), and parvalbumin (PV), are distributed differentially between different cortical areas and cortical layers. These neurons modify the influence of the excitatory pathways, carried by myelinated axons, that project to those layers. Excitatory connections that terminate in the middle or deep cortical layers behave similarly to the feedforward pathways that are defined in sensory areas, and provide driving input to the cortex. Pathways that terminate in superficial layers behave as feedback pathways and modulate the activity of the cortex. In order to study excitatory-inhibitory balance in the human cortex we studied the distribution of the three classes of inhibitory neurons and the density of myelinated axons in post-mortem tissue from medial, cingulate, and lateral prefrontal cortices of typically developing individuals and individuals with autism. We separately studied superficial and middle/deep cortical layers in order to distinguish changes that influence feedback and feedforward pathways. Adults with autism had a significant reduction in the density of CR-expressing inhibitory neurons in both superficial and middle/deep cortical layers in lateral prefrontal cortices. There was a similar trend in medial prefrontal

cortices in adults with autism. CR-expressing inhibitory neurons in superficial cortical layers serve a disinhibitory role while those in deep layers may provide modulatory inhibition. We found no significant change in the density of PV-expressing or CB-expressing interneurons in adults with autism in these regions. In individuals with autism there was also a steeper rate of increase in the density of small myelinated axons, which are representative of short-range pathways, across layers during development. These parallel structural changes likely produce opposite functional effects: enhanced short-range feedback pathways terminate in an environment with increased inhibition, while enhanced short-range feedforward pathways terminate in an environment with reduced inhibition. Together, these changes in laminar structure may significantly affect information processing in the prefrontal cortex in autism.

Title: Balance of excitation and inhibition in orbitofrontal cortex and potential for disruption in autism

Authors: *X. LIU, J. BAUTISTA, E. LIU, B. ZIKOPOULOS
Boston Univ., Boston, MA

Abstract: The human orbitofrontal cortex (OFC) is involved in assessing the emotional significance of events and stimuli, emotion based learning, allocation of attentional resources, and social cognition. Little is known about the structure, connectivity and excitatory/inhibitory circuit interactions underlying these diverse functions in human OFC. To fill this gap we used high resolution microscopy, followed by quantitative tracing analysis, to characterize the morphology and distribution of myelinated axons across cortical layers in human OFC at the single axon level, as a proxy of excitatory pathways. In the same regions, we also examined the laminar distribution of neurochemically- and functionally-distinct inhibitory neurons that express calcium-binding proteins parvalbumin (PV), calbindin (CB), and calretinin (CR). Associations of myelinated axons with distinct inhibitory neurons changed across layers and provided a proxy for the study of the excitatory/inhibitory ratio in OFC. We found that density of myelinated axons increased consistently towards layer VI, while average axon diameter did not change significantly. Inhibitory CR-positive neurons were mostly found in layer II, the layer with the lowest density of myelinated axons. CB-positive inhibitory neurons were most dense in layer II

and upper layer III. PV-positive inhibitory neurons were mostly found in the middle/deep layers, especially lower layer III, among a dense plexus of myelinated axons, some of which also expressed PV, presumably coming from the thalamus. The balance between excitation and inhibition in OFC is at the core of OFC function. The OFC gets an overview of the sensory environment through feedforward cortical inputs and assesses the emotional significance of events, based on robust feedback input from the amygdala, in processes that are disrupted in autism spectrum disorder (ASD). We previously showed that in individuals with ASD, excitatory OFC pathways exhibit overall thinning of the myelin sheath of axons, which likely affects conduction velocity and neurotransmission. This suggests laminar-specific changes in the ratio of excitation/inhibition in OFC of individuals with ASD, and may provide the anatomic basis for disrupted transmission of signals for emotions.

Title: ASD/ID related de novo mutations in the TRIO-Rac1 pathway alter synaptic function

Authors: *C. TIAN[1,2], Y. KAY[1,2], A. SADYBEKOV[3,4], S. RAO[1,2], V. KATRITCH[3,2,5], B. HERRING[2]
[1]Neurosci. Grad. Programe, [2]Dept. of Biol., [3]Dept. of Chem., [4]Chem. Grad. Program, [5]the Bridge Inst., USC, Los Angeles, CA

Abstract: The Rho guanine nucleotide exchange factor (RhoGEF) Trio promotes actin polymerization by directly activating the small GTPase Rac1. Growing evidence suggests that disruption of the Rac1 signaling pathway at glutamatergic synapses contributes to Autism Spectrum Disorder/Intellectual disability (ASD/ID)-related behaviors seen in animal models of ASD/ID. Here, in humans, we discover a large cluster of ASD-related de novo mutations in Trio's Rac1 activating domain, GEF1. In accordance with pathological increases or decreases in glutamatergic neurotransmission observed in animal models of ASD/ID, we find that these mutations result in either reduced synaptic AMPA receptor expression or enhanced glutamatergic synaptogenesis. Rac1, activated by Trio's GEF1 domain, has recently been identified as an ID risk gene. Similar to hypofunctional ASD-related mutations in Trio, an ID-related de novo missense mutation in Rac1 results in a reduction in synaptic AMPAR expression. Additionally, this mutation prevents the induction of LTP, the cellular mechanism underlying

learning and memory formation. Together, our findings implicate both excessive and reduced Trio/Rac1 activity and the resulting synaptic dysfunction in ASD/ID-related pathogenesis, and point to the Trio-Rac1 pathway at glutamatergic synapses as a possible key point of convergence of many ASD/ID-related genes.

Title: Modifications in cytoskeletal and astrocytic proteins content in prefrontal cortex, hippocampus and cerebellum of the murine model of autism C58/J strain

Authors: *I. C. BARON-MENDOZA[1], O. GARCIA[2], A. GONZÁLEZ-ARENAS[3]
[1]Inst. De Investigaciones Biomédicas, Ciudad DE Mexico, Mexico; [2]Facultad de Psicologia, UNAM, Mexico, D.F., Mexico; [3]Inst. De Investigaciones Biomedicas, Mexico D.F., Mexico

Abstract: Autism Spectrum Disorder (ASD) is characterized by an impairment of social interaction and communication, and restricted and repetitive behaviours. Alterations in elongation of axons and dendrites, and greater spine densities in ASD patients, particularly found in brain structures as prefrontal cortex, hippocampus and cerebellum, besides a reported synaptic gene dysfunction, suggest disturbances in plasticity in the autistic brain. The cytoskeleton has a pivotal role in regulating the structure and dynamics of dendrites, spines and axons. As well astrocytes-secreted proteins are essential for synaptic connections stabilization. Hence, some modifications of cytoskeletal and astrocyte components could be involved at molecular level in neurite alterations. The objective of this research was to analyse changes in the content of cytoskeletal and astrocytic proteins in the brain of an autistic animal model corresponding to the C58/J mice strain. Prefrontal cortex (pCx), hippocampus (Hc) and cerebellum (Cer) from C58/J and C57 BL/6 (WT) mice were dissected. Samples were processed for Western Blot technique. Results were statistically analysed by one-way ANOVA test. α-tubulin content showed no change in pCx, neither Hc nor Cer between both strains. But microtubule-associated proteins as MAP2A and Tau presented differences. We observed six Tau isoforms (20-100 kDa) in pCx, Hc and Cer of WT mice strain. Four Tau isoforms disappear in autistic brain areas; 80 and 60 kDa isoforms were detected in both strains. The 80 kDa Tau isoform content in pCx, Hc and Cer of autistic mice was not different compared to the WT strain, but the 60 kDa isoform and its

phosphorylated form showed a decrease in the autistic pCx and Hc. Furthermore the MAP2A protein content was lower only in pCx of autistic mice compared to WT strain. The content of β-actin was uniform in the studied brain areas between both strains. The content of phosphorylated actin-binding protein cofilin showed a decrease in the autistic pCx and an increase in autistic Cer. Besides, synaptopodin content, another actin-binding protein enriched in dendritic spines neck, was diminished only in Hc of autistic mice. Finally, the protein content of astrocyte-secreted protein thrombospondin-1 showed a decrease in pCx and Hc of autistic mice, although the GFAP protein content was not different between both strains. Our work showed important brain structure-dependent changes in protein content of 60 kDa Tau/phospho-Tau isoform, MAP2A, phosphorylated-cofilin and synaptopodin, as well as differences in the astrocyte-secreted protein thrombospondin-1 content in pCx, Hc and Cer of autistic animals compared to WT mice.

Title: Analysis of mutant delta-catenin haploinsufficiency in altering synaptic pathology and autism-associated behavior changes

Authors: *K. NIP, H. SCOTT, T. GARVER, J. SHOU, S. KIM
Colorado State Univ., Fort Collins, CO

Abstract: δ-catenin is a neuron specific catenin with known implications in cognitive function and synaptic plasticity. The association of this protein with AMPA receptor (AMPAR)-binding protein (ABP) and the related glutamate receptor-interacting protein (GRIP) via association with PSD95 contributes to the structural integrity of the GluA2 AMPA receptor subunits within synaptic membranes. Loss of δ-catenin function is strongly associated with severly affected autism spectrum disorder (ASD) patients. Given the key links between the synaptic adhesion complex and δ-catenin, it is not surprising that δ-catenin regulates synaptic densities and architecture in neurons. Structural plasticity of spines is important for proper synapse development, maturation, and function. Alterations in spine dynamics resulting in abnormal spine morphology and density are proposed to contribute to aberrant synaptic transmission in ASD.
Many genetic disorders are caused by haploinsufficiency, in which having only one copy of the

wild-type (WT) allele is not sufficient to produce the WT phenotype when the other allele is a loss-of-function mutation or deleted. Indeed, δ-catenin haploinsufficiency induces ASD and learning disabilities in humans. δ-catenin homozygous knockout (KO) mice have not been used to determine neurobiological mechanisms underlying ASD-associated synaptic and behavioral deficits. Moreover, the precise effects of δ-catenin haploinsufficiency on pathophysiology are a major gap in our understanding in ASD. Here, we showed that δ-catenin haploinsufficiency was sufficient to impair synaptic structures and autism-related behavioral alteration. This suggests that δ-catenin heterozygous KO mice can be a useful model of δ-catenin haploinsufficiency-induced ASD.

Title: Investigation of cortical synaptic structures in microglia-specific eif4e overexpressing mouse using serial block-face sem

Authors: *G. KIM[1], Z. XU[2], S.-H. LEE[1], N. DO[1], C. LEE[1], S. KWON[3], B. XU[2], K. LEE[1]
[1]Korea Brain Res. Inst., Daegu, Korea, Republic of; [2]The Scripps Res. Inst., Jupiter, FL; [3]Catholic Univ. of Daegu, Daegu, Korea, Republic of

Abstract: Imbalance of synaptic excitation to inhibition (E/I) is thought to cause autism spectrum disorders (ASDs). The mammalian target of rapamycin (mTOR) pathway is strongly associated with ASDs by means of its upstream and downstream regulatory mechanisms. Dysregulated activity of Eukaryotic translation initiation factor 4E (eIF4E) promotes the excitatory synaptic transmission by enhancing translation of neuroligin and triggers autistic-like behavioral phenotypes including impaired social interactions and repetitive/stereotyped behaviors. However, specific cell types of eIF4E translational control and structural correlates of impaired E/I balance are poorly understood. Using serial block-face SEM and three-dimensional reconstruction of synaptic connectivity, here we show that eIF4E overexpression selectively in microglia leads to the altered ratio of excitatory and inhibitory synapses in the layer 2 pyramidal neurons of prelimbic area in the medial prefrontal cortex (mPFC). Intriguingly, the increased dendritic spines in eIF4E knock-in mice exhibited to have the reduced spine volume and PSD

surface area compared to those in wild-type animals. In contrast, the number and size of synapses in the dendritic shaft and cell soma were not different between groups. Additionally, further tracing of the presynaptic axonal segments of somatic synapses revealed that their synaptic contacts with neighboring neurons were significantly decreased in the mutant mice. Together, these results demonstrate that disrupted translational activity of eIF4E in microglia results in hyperconnectivity of excitatory synapses as well as abnormal inhibitory circuitry in layer 2 pyramidal neurons of mPFC, suggesting a structural correlates of impaired E/I balance and autistic-like behaviors.

Title: Assessment of autophagy in autism induced cell

Authors: *H. CHOI[1,2], M. JUNG[3], J. MUN[2]
[1]Eulji Univ., Gyeongido, Korea, Republic of; [2]Korea Brain Res. Inst., Daegu, Korea, Republic of; [3]Dept. of Convergence Med., Asan Med. Ctr., Seoul, Korea, Republic of

Abstract: Autophagy is highly conserved as a lysosomal degradative process which plays an important role in maintaining cytoplasmic homeostasis. As well, autophagy is involved in a cellular pathway, can lead to cell death, possibly through activating apoptosis. Despite the accumulation of evidence that autophagy is involved in cell death, there is controversy as to whether autophagy affects in cell death. Autophagy and apoptosis are interlocked in an extensive crosstalk with each other. It has recently been the focus of numerous human diseases such as neurodegeneration. Many types of neurodegenerative diseases are accompanied by the accumulation of aggregated and ubiquitinated protein. As well the inhibition of constitutive autophagy induces to the neurodegeneration in neuronal system. It is important to keep balance between autophagosome formation and autophagic degradation. Thus, the accumulation of autophagosome, disruption in the autophagic process of neurons, and decrease of autophagy is associated with neurodegenerative diseases. Until now, because there is not enough protein marker to detect every single autophagic subtypes, there is a limitation to analyzing 'autophagic flux' using light microscopy. TEM is essential to observe the specific type of autophagy because it is the most accurate method of correlating between protein degradation and the volume

fraction of autophagic vacuoles, and it is possible to do classification of autophagosome and autolysosome. It is well known that factors affecting autophagy include amino acid, insulin, and chemicals. Here we analyzed the structural changes of autophagy by several different TEM techniques to study the specific stage of autophagy that are more tightly linked with the mechanisms of autophagy dysfunction.

Center, UCLA, Los Angeles, CA; [6]West Los Angeles VA Med. Ctr., Los Angeles, CA

Abstract: Alterations in synaptic connectivity and imbalance of excitation and inhibition have long been thought to underlie autism spectrum disorder (ASD). Recessive truncating mutations in the CNTNAP2 gene, cause a syndromic form of ASD and Cntnap2 knock-out (KO) mice recapitulate core ASD deficits. However, the anatomical effects of this mutation at the cellular and ultrastructural level remain elusive. To gain a better insight into the phenotype, we used quantitative electron microscopy to determine whether the synaptic structure is modified in the prelimbic medial prefrontal cortex of CNTNAP2 knockout mice, focusing on the neuropil of layers 2/3. Mice lacking CNTNAP2 exhibited alterations in the morphology of their synapses:

we observed a decrease in dendritic spine density, a reduction of both excitatory and inhibitory synapses and multi-synaptic boutons, longer and more complex postsynaptic densities, while dendritic complexity remained unchanged. These findings suggest a profound autism-related alteration in synaptic morphology and a critical role for CNTNAP2 in establishing normal synaptic architecture in the rodent forebrain.

Title: Conditional knock-out of TSC1 in MGE-derived inhibitory interneurons upregulates mTORC1 activity, impairs hippocampal synaptic inhibition and alters contextual and spatial memory

Authors: N. HAJI[1], I. RIEBE[1], A. AGUILAR VALLES[2], J. ARTINIAN[1], I. LAPLANTE[1], *J.-C. LACAILLE[1]

Abstract: An imbalance in excitation-inhibition has been proposed as a major factor in neurodevelopmental disorders, including autism spectrum disorders (ASD). However, synaptic inhibition in ASD-linked structures involves complex local circuits composed of multiple types of interneurons and how different interneurons are affected in ASD remains largely unknown. Multiple ASD syndromes are caused by mutations in genes implicated in control of mechanistic target of rapamycin complex 1 (mTORC1) signaling pathway, including the repressor TSC1/TSC2. mTORC1 regulates cell proliferation, survival, growth, and metabolism, and in neurons is important for synaptogenesis and translation-dependent synaptic plasticity. mTORC1 hyperactivation results in impaired synaptic structure, function and plasticity, but these effects have been mainly studied in forebrain excitatory cells.
Here we asked whether inhibitory cell types in forebrain circuits are affected by TSC1 knockout to result in cell type specific synaptic or behavioral phenotypes. We investigated conditional knockout of TSC1 in MGE-derived inhibitory cells by crossing $Nkx2.1^{Cre/Cre}$ mice with $TSC1^{f/f}$ mice. We detected cell-specific increased phosphorylation of ribosomal protein S6 in

Nkx2.1$^{Cre/wt}$;TSC1$^{f/wt}$ mice, indicating upregulated mTORC1 signaling. At the behavioral level, Nkx2.1$^{Cre/wt}$;TSC1$^{f/wt}$ mice exhibited intact contextual fear memory and impaired contextual fear discrimination. Also, Nkx2.1$^{Cre/wt}$;TSC1$^{f/wt}$ displayed intact spatial learning but impaired reversal learning in the Barnes maze, indicating a deficit in spatial working memory. Whole cell voltage clamp recordings in acute hippocampal slices showed that miniature excitatory and inhibitory synaptic transmission were unaffected. Using optogenetic activation of Nkx2.1 interneurons in slices of Nkx2.1$^{Cre/wt}$;TSC1$^{f/wt}$ mice we found that synaptic inhibition of principal cells was decreased. Chronic but not acute treatment with mTORC1 inhibitor rapamycin reversed the impairment in synaptic inhibition by Nkx2.1 interneurons.
Our results indicate that TSC1 haploinsufficiency in MGE-derived inhibitory cells upregulates mTORC1 activity in these interneurons, reduces hippocampal GABAergic transmission and alters contextual fear discrimination and spatial working memory. Thus selective dysregulation of mTORC1 function in specific subtypes of inhibitory cells is sufficient to impair synaptic inhibition and contribute to hippocampus-dependent cognitive deficits in the TSC1 mouse model of ASD.

Title: Conditional loss of the tuberous sclerosis gene, Tsc1, results in altered cortical GABAergic interneuron development and physiology

Authors: *R. MALIK[1], E. L.-L. PAI[1], A. M. STAFFORD[2], J. T. NGUYEN[2], J. L. RUBENSTEIN[1], V. S. SOHAL[1], D. VOGT[2]

Abstract: Tuberous sclerosis (TS) is a multi-systemic disorder caused by mutations in *Tsc1* or *Tsc2 genes*. These genes encode proteins that form a complex, which indirectly inhibits the activity of the mammalian target of rapamycin complex 1 (mTORC1). Notably, the biology underlying the high rate of neurological symptoms in individuals with TS, including autism spectrum disorder (ASD), intellectual disability and epilepsy, is poorly understood. Moreover, accumulating evidence suggests that some ASD symptoms and associated comorbidities may be

caused due to abnormalities in cortical GABAergic interneuron (CIN) function and connectivity, which could lead to compromised neural circuitry. While the role of mTORC1 signaling and *Tsc* genes on excitatory neurons has been studied for some time, relatively little is known about their roles in CIN development and function. CINs consist of morphologically and functionally diverse subclasses of neurons that modulate cortical output, shape cortical oscillations and perform crucial roles in development of cortical circuitry. Parvalbumin (PV)-expressing and somatostatin (SST)-expressing CINs constitute two major subgroups, with substantially different morphological and physiological properties. Specifically, PV+ CINs exhibit fast-spiking firing properties and synapse onto soma/axons of excitatory neurons. By contrast, SST+ CINs have regular-spiking firing properties and target distal dendrites of excitatory neurons. Whether the development and cell-fate of these CINs is affected in TS and other syndromes with high rates of ASDs has not been examined in depth. Due to our previous findings in a *Pten* deletion model (Vogt et al., 2015. *Cell Rep*. 11:944-56), we hypothesized that aberrant signaling downstream of *Tsc1* might affect the development and function of PV and SST CINs. To test this prediction, we generated *Tsc1* conditional mutant mice where *Tsc1* was either deleted in all MGE progenitors or only in post-mitotic SST-lineage CINs. Using a combination of fluorescent imaging and *ex vivo* electrophysiological recordings, we found that *Tsc1* plays an important role in regulating the development and excitability of MGE-derived CINs. Notably, *Tsc1* deletion also resulted in unique phenotypes compared to *Pten* deletion, suggesting novel roles during CIN development. Overall, we predict that these findings may underlie symptoms in several neuropsychiatric disorders (like ASD and schizophrenia) that are linked with deficits in CIN development and function.

Title: Perineuronal nets in the hippocampus are atypical in mouse models of autism spectrum disorder

Authors: *E. C. COPE[1], A. D. ZYCH[2], N. J. KATCHUR[2], C. Y. PARK[2], S. MURTHY[2], B. A. BRIONES[2], E. GOULD[2]

Abstract: Autism spectrum disorder (ASD) is characterized by social impairments, communication deficits, and repetitive or restricted interests/behaviors. Many individuals with ASD also suffer from excessive anxiety and intellectual disabilities. Neuroimaging studies of humans with ASD have identified atypical structure in the hippocampus, a region that supports cognition, anxiety, and social behavior. Abnormalities in perineuronal nets (PNNs), a specialized extracellular matrix that enwraps certain types of neurons and limits synaptic plasticity, have been linked to other neuropsychiatric conditions, but have not been investigated in ASD. In the current work, we explored PNNs in the hippocampus in two mouse models of ASD, the BTBR idiopathic model and Cntnap2-/- transgenic model compared to C57 controls. Because the hippocampal CA2 region has been linked to spatial and contextual processing as well as social memory, we focused our analyses on this area, along with hippocampal subregions that are connected with CA2 neurons. Using Wisteria floribunda agglutinin to label PNNs, we found increased PNN+ cross sectional area in the CA2 of both BTBR and Cntnap2-/- mice compared to controls. BTBR mice also had robust increases in PNN intensity in the CA2 that coincided with increased OTX2 expression, a transcription factor associated with PNN formation. We next investigated whether PNNs in the dorsal dentate gyrus and CA3, subregions that project to CA2 neurons, differed between ASD mouse models and controls. We found decreased PNN intensity in the dorsal CA3 of both BTBR and Cntnap2-/- mice compared to controls. We also found PNN intensity changes in the dorsal and ventral CA1, brain regions that receive input from the CA2. Both mouse models showed consistent increases in PNN intensity in the dorsal CA1, whereas in the ventral CA1 BTBR mice showed an increase in PNN intensity and Cntnap2-/- mice showed a decrease in PNN intensity. While relative PNN differences between these models might reflect heterogeneity of symptoms seen with ASD, our data overall suggest that PNN abnormalities might contribute to behavioral deficits associated with ASD. Ongoing studies will determine whether changes in PNNs in the hippocampus are causally linked to ASD-related behaviors.

Title: Functional characterization of a de novo mGlu7 mutation associated with autism spectrum disorder

Authors: *J. SONG, Y. SUH
Dept. of Biomed. Sci., Seoul Natl. Univ. Col. of Med., Seoul, Korea, Republic of

Abstract: Metabotropic glutamate receptor 7 (mGlu7) is an inhibitory heterotrimeric G-protein-coupled receptor that modulates neurotransmitter release and synaptic plasticity at presynaptic terminals in the CNS. mGlu7 is also involved in a variety of neuropsychiatric disorders such as epilepsy, depression, and anxiety. Recent studies have revealed that many de novo mutations in synaptic receptors and scaffold proteins regulating development and function of synapses are associated with autism spectrum disorder (ASD). It has also been shown that exaggerated post-synaptic signaling through mGlu5 can explain the pathogenesis of Fragile X syndrome (FXS), the leading cause of inherited mental retardation and ASD. However, there is no evidence for the role of presynaptic mGlu7 in mediating ASD-related phenotypes. A recent whole exome sequencing study has identified a de novo missense mutation of mGlu7 (Arg622Gln) possibly associated with ASD. In this study, using biochemistry and confocal imaging technology, we evaluate the function of ASD-related mGlu7 Arg622Gln mutation by focusing MAPK signaling, spine morphology, localization, and surface trafficking of mGlu7 in HEK293T cells and rat cultured neurons. This approach will help to understand the etiology of ASD and to provide potential therapuetic targets.

Title: Increase aggression in ube3a transgenic model of 15q autism

Authors: *Y. NONG[1], D. STOPPEL[1], M. JOHNSON[1], J. TODOROVIC[1], X. ZHOU[1], M. NADLER[1], M. BOILLOT[1], I. NAGAKURA[1], E. KASPER[2], M. ANDERSON[1]
[1]Neurol. and Pathology, [2]Surgery, Beth Israel Deaconess Med. Ctr., Boston, MA

Abstract: Individuals with autism spectrum disorder (ASD) are prone to behavioral difficulties including excessive tantrums, irritability, and self-injurious aggressive behaviors that often require medical treatment. Maternal 15q11-13 triplication, a common and penetrant genetic cause of ASD, triples the neuron-expressed dosage of *UBE3A* that encodes an E3 ubiquitin ligase and transcriptional co-regulator. Here we report that the transgenic mouse model of maternal 15q11-13 triplication *(Ube3a2x* mice), with increased copies of the *Ube3a* gene, displays increased aggression behaviors while display impaired sociability and increased repetitive self-grooming. To map the neuronal circuits where increased UBE3A elevates aggression, we developed "*LoxTBUbe3a*" transgenic mice whereby UBE3A can be selectively increased in specific neuronal cell types and brain areas when combined with specific Cre driver mouse lines. Male mice with selective increases of UBE3A in glutamatergic neurons displayed elevated aggression (*VGluT2Cre*). In contrast, selective increases of UBE3A in GABAergic (*VGATCre*) or serotoninergic (*ePetCre*) neurons did not affect indices of aggression. Recent work has shown that glutamatergic neurons in the VMHvl can drive attack behavior in male mice. To evaluate the role of VMH neurons in UBE3A-elevated aggression, *LoxTBUbe3a-2x* (homozygous for *LoxTB-Ube3a*) alleles were combined with the *Sf1-Cre* allele (steroidogenic factor 1 [*Sf1*,*Nr5a1*], which expresses mainly in VMH). These male mice also displayed elevated aggression. We increased *Ube3a* selectively in glutamatergic neurons of the VMHvl by stereotactically injecting *AAV-hSyn-DIO-Ube3a* into VMHvl of *VGluT2-Cre* mice. These mice displayed heightened aggression compared with WT littermate male mice injected with control AAV. These results indicate that increasing UBE3A in glutamatergic neurons of VMHvl is sufficient to elevate aggression in a manner not contingent on developmental effects.

Institute, UCLA, Los Angeles, CA

Abstract: It has been reported that changes in the glutamine/glutamate ratio and imbalance between excitation and inhibition signaling could be possible neural mechanisms underlying autism spectrum disorders (ASD). An association between GABA/glutamate imbalance (affecting glutamine levels) and neuroinflammation in autistic patients has been previously postulated. Here, we used neurofibromatosis type 1 (NF1) mouse as a monogenic model to study mechanisms of autism spectrum disorders to investigate these pathological mechanisms. Using magnetic resonance spectroscopy, we observed that cortical γ-aminobutyric acid (GABA)/glutamate ratio was increased compared with wild-type animals, while we observed no differences in the hippocampus. However, both cortical and hippocampal glutamine/glutamate ratios were augmented. Since this ratio has been used as an indicator of neuronal-glial interactions, we investigated the effect of *Nf1*$^{+/-}$ mutation on glia cells. Although, our studies revealed an increase of reactive astrogliosis and glial fibrillary acidic protein (GFAP) in both regions, while microglia activation (Iba-1-positive cells) was only detected in *Nf1*$^{+/-}$ hippocampus. To investigate the known relation between glial activation and blood-brain barrier (BBB) dysfunction we investigated changes in BBB permeability. We analyzed the levels of serum albumin in the brain since this protein is undetectable or present at very low levels in the brain parenchyma under physiological conditions. Hippocampal expression of albumin was dramatically increased, while prefrontal cortex showed a slight augment of this protein. Overall, these results support the hypothesis that autism spectrum disorders are synaptic disorders showing concomitant excitation/inhibition imbalance and an abnormal neuroinflammatory response.

Title: Altered expression of mGlu5 receptor and its regulatory proteins in several autism spectrum disorders

Authors: *M. CATANIA[1], C. M. BONACCORSO[2], A. ARENA[3], J. J. ANINK[3], S. D'ANTONI[1], M. SPATUZZA[2], E. ARONICA[3]
[1]Inst. of Neurolog. Sciences, Natl. Res. Council (CNR), Catania, Italy; [2]IRCCS Oasi Maria SS, Troina (EN), Italy; [3]Dept. of (Neuro)Pathology, Academic Med. Center, Univ. of Amsterdam, Amsterdam, Netherlands

Abstract: Autism spectrum disorders (ASDs) are neurodevelopmental disorders characterized by impaired social interaction and stereotyped behaviours. Increasing evidence suggests that a convergence on signaling pathways involved in protein translation and triggered by the activation of group I metabotropic glutamate (mGlu) receptors can be common to different ASDs. A dysregulation of mGlu5 receptor-mediated signaling has been reported in different animal models of ASD, including animal models of Fragile X syndrome (FXS) and Angelman Syndrome (AS). In this context, we have found that the interaction between mGlu5 receptor and its scaffolding protein Homer is abnormal in mouse models of FXS and AS (Giuffrida et al., J. Neurosci., 2005; Pignatelli et al., J. Neurosci, 2014). Thus, we are currently investigating if mGlu5 alteration is involved in other neurodevelopmental disorders associated with intellectual disability and Autism, such as Tuberous Sclerosis Complex (TSC) and Down Syndrome (DS). To this aim, we have studied protein expression of mGlu5 receptor and its endogenous regulators of cell surface localization, intracellular trafficking and signaling, such as Homer, Preso1, Tamalin and Norbin, on brain tissue of patients affected by these different pathologies. We have found a different pattern of expression of these proteins in these different pathologies. We observed that mGlu5 receptor, Homer1bc and Tamalin levels are increased in neurons of TSC patients, whereas a reduction is detected in Preso1 and Norbin levels. No difference was observed in mGlu5 receptor expression levels of AS patients; in contrast, a reduction is shown in Homer1bc levels. In addition, our data highlighted a reduction of Homer1bc and mGlu5 receptor in neurons of DS patients. Our findings provide strong support for the hypothesis that alteration

in mGlu5 receptor expression is common to different ASDs and that a dysregulation of its regulatory proteins might have possible consequences for its activity.

Title: Understanding dysphagia through 22q11.2 deletion syndrome mediated changes in murine laryngeal motorneurons

Authors: *H. L. CAUDILL[1], D. S. MENDELOWITZ[2], A.-S. LAMANTIA[3]
[2]Pharmacol. & Phsyiology, [3]Neurosci., [1]The George Washington Univ., Washington, DC

Abstract: Pediatric dysphagia, difficulty in swallowing and feeding, is one of the most common problems associated with various developmental disorders, and is especially prevalent in patients with 22q11.2 Deletion Syndrome (22q11DS). The act of swallowing is largely regulated through vagal innervation to the larynx from laryngeal motor neuron cell bodies located within the medullar portion of the brainstem. Two laryngeal structures in particular, the vocal folds and the epiglottis, are especially important as they work to seal off the trachea during active swallowing, preventing aspiration into the lungs. Using a large deletion (LD) mouse model for 22q11DS, the objective of this work aims to establish and characterize changes in the electrophysiological properties of laryngeal motor neurons that occur in LD animals. The spontaneous firing, evoked firing, voltage-gated currents, as well as both excitatory and inhibitory synaptic neurotransmission to laryngeal motor neurons recorded from the LD animals was quantified and compared to those from wild-type (WT) littermates. Preliminary data suggests that laryngeal neurons from LD animals possess a higher spontaneous action potential (AP) firing frequency than those from WT animals. Additionally, while excitatory postsynaptic currents (EPSCs) appear to occur at the same frequency in both LD and WT laryngeal motor neurons, the spontaneous excitatory events are reduced in amplitude in the LD neurons compared to those from the WT animals. Our overall goal is to determine the different electrophysiological properties of laryngeal neurons from LD animals compared to WT littermates. This work aims to provide the foundation needed to later identify therapeutic targets and hopefully develop novel treatments to restore laryngeal activity, as well as future possible treatment strategies for pediatric dysphagia associated with 22q11DS.

Title: Exposure to alcohol alters behavioural recovery as a function of single or group housing during regeneration in planaria

Authors: *M. J. SAARI[1], L. GOODRIDGE[2], R. VERNESCU[3], A. STILLAR[4]
[2]Psychology, [3]C.H.F.S., [4]Neurosci., [1]Nipissing Univ., North Bay, ON, Canada

Abstract: Planaria, *Dugesia dorotocephala*, may be a suitable tool for the study of FASD because of their remarkable ability to grow a completely new body, including neural tissue, from even a small fraction of body tissue. This ability is mediated by the presence of totipotent somatic stem cells. In previous studies we have shown that planaria are sensitive to social isolation and we hypothesized that the social condition (isolated or group housing) may influence regeneration and possibly interact with the effects of alcohol exposure during regeneration. The purpose of this study was to explore activity and body morphology of planaria as they regenerate a new head region while exposed to two different social environments: isolated or group housed in either in an ethanol or the standard salt solution (Montjuic analog). Following removal of the head region, the planaria were placed in either individual or group housing in their respective solutions for 30 days. During the next six days all planaria were removed from their respective solution, and placed into the standard salt solution. Video of the worms was captured every 2nd day with water changes occurring on alternate days. Analyses of the videos (WormLab; MBF Bioscience) revealed significant differences in recovery between the alcohol and salt conditions and the social environment as well as behavior during and after the alcohol exposure. Significant reduction in the duration of the “scrunch reflex” (Longitudinal Body Contraction) suggests weakening of inhibitory control in planaria exposed to alcohol during regeneration. Negative phototaxis did not appear to be significantly altered by the alcohol, however. These results suggest that the effects of post-bisection head region regeneration are sensitive to the social conditions and ethanol exposure during regeneration in planaria.

Title: Neurodevelopmental and behavioral alterations after conditional deletion of type 2 cannabinoid receptors in dopamine neurons

Authors: *A. CANSECO-ALBA[1,2], M. HAMMOUDA[2], N. SCHANZ[2], Q.-R. LIU[3], E. ONAIVI[2]
[1]Pharmcobiology, CINVESTAV-IPN, Ciudad de Mexico, Mexico; [2]Biol., William Paterson Univ. of New Jersey, Wayne, NJ; [3]Lab. of Clin. Investigation, Natl. Inst. of Hlth., Baltimore, MD

Abstract: Our recent report revealed that DAT-*Cnr2* mutant mice with selective deletion of type 2 cannabinoid receptors (CB2Rs) in dopamine neurons exhibit a hyperactive phenotype characterized by hyper-locomotor activity compared to the wild type (WT) mice (Liu et al, Sci Rep. 2017 ; 7(1):17410). The endocannabinoid and dopaminergic systems play pivotal roles in a number of behavioral functions in the central nervous system such as motor control, emotion and reward. CB2Rs are expressed in the postsynaptic somatodendritic area of dopaminergic neurons and modulate midbrain dopamine neuronal activity and dopamine-related behavior in mice. In this study, we evaluated the neurodevelopmental and behavioral alterations after cell-type specific deletion of CB2Rs in dopamine neurons in DAT- *Cnr2* conditional knockout (cKO) mice. We investigated and tested the hypothesis that the DAT-*Cnr2* cKO mice may represent a model of attention deficit hyperactivity disorder (ADHD). Ultrasonic vocalizations (USVs), physical development, and reflex activities of the DAT-*Cnr2* cKO and WT male and female pups from postnatal day 1 (PND1) to the weaning day (PND21) were analyzed. Other behavioral tests including spontaneous locomotor activities and performances in the plus maze test of the animals were determined from PND 22 to 25. A separate group of DAT-*Cnr2* cKO and WT adolescent mice (PND 30±2) were treated acutely with amphetamine 2.0 mg/kg ip and their performances in the open field were accessed. We report that the DAT-*Cnr2* cKO pups started crawling and walking sooner than the WT mice. USV rates at 60-80 hertz were higher in the DAT-*Cnr2* cKO mice than in the WT mice. The DAT-*Cnr2* cKO mice gained weight more slowly than WT mice. The most important difference between the animals is that the DAT-*Cnr2* cKO mice displayed hyperactivity in the open field and plus-maze tests. When 2.0 mg/kg amphetamine was administered, it produced a significant increase in motor activity in the WT, and in contrast, a significant reduction in motor activity in the DAT-*Cnr2* cKO mice in the open

field test. Taken together, the data obtained suggests that DAT-*Cnr2* cKO mice show signs of ADHD -like phenotype, as the hyperactivity was diminished with the dose of amphetamine used. It was concluded the DAT-*Cnr2* cKO mice may be a useful model for the investigation of the components of the endocannabinoid system as possible therapeutic targets in ADHD.

Title: Effects of acute and chronic DISC1 disruption on plasticity and morphology in the prefrontal cortex

Authors: *N. R. HARDINGHAM[1], C. M. HILLDRUP[2], K. D. FOX[1]
[2]Sch. of Biosci., [1]Cardiff Univ., Cardiff, United Kingdom

Abstract: DISC1 has been identified as a schizophrenia risk factor and plays an important role in brain development. Various DISC1 models have been studied to address the role of DISC1 in neurodevelopment and brain function, but the relevance of many of the models is debatable as many have little similarity to the original DISC1 translocation. We have studied two DISC1 mouse models, one with inducible disruption of c terminus DISC1 signalling via tamoxifen injections and one with a constitutive disruption of DISC1 using the first accurate mouse model of the t(1;11) translocation (Der1, K Millar & M Didier (Sanofi)) . Transient disruption of DISC1 signalling at P7 (in the inducible model) resulted in schizotypic behaviour in the mice (Li *et al*, 2007) and a complete loss of experience dependent plasticity and LTP in adult layer 2/3 barrel cortex (Greenhill et al 2015). Schizophrenia has been strongly linked to dysfunction in the prefrontal cortex with both functional and structural prefrontal deficits implicated. We therefore set out to investigate whether following transient P7 disruption of DISC1 signalling, synaptic plasticity is occluded in the adult prefrontal cortex as it is in the barrel cortex and also to determine whether chronic disruption of DISC1 has a comparable effect to transient DISC1 disruption. We observed only a partial occlusion in prefrontal cortex LTP following transient DISC1 disruption (a 50% reduction in LTP magnitude ($p<0.01$ compared to WTs, DISC1 LTP still at significant levels), but a total blockade of LTP following chronic DISC1 disruption ($p<0.001$). This total blockade of LTP following chronic DISC1 disruption was accompanied by alterations in STP ($p<0.01$). In addition to this, we observed deficits in dendritic complexity in

adult mice following chronic DISC1 disruption (26% reduction, $p<0.001$ including a 36% reduction in basal complexity ($p<0.001$) and a 10% reduction in apical complexity (ns) but no deficit in dendritic complexity following acute DISC1 disruption (ns). In addition, after chronic DISC1 disruption we observed a reduction in spine density on basal dendrites (10%, $p<0.05$), but also an increase in spine density on apical dendrites (14%, $p<0.01$) which was via a significant increase in thin spines ($p<0.05$). The enhanced spine density on apical dendrites was also observed following acute P7 DISC disruption (24% increase, $p<0.001$). Thus, the constitutive DISC1 model exhibits more deficits, both functional and structural, than the inducible DISC1 model following disruption of DISC1 at P7. However, P7 disruption does produce some deficits suggesting possibly an extended critical period in the prefrontal cortex compared to the barrel cortex.

Title: Differing effects of hypoxia on developmental dopaminergic neurons in the developing zebrafish brain

Authors: T. M. BIELINSKI[1], J. N. MACDONALD[1], M. R. BARRETT[1], M. SEID[1], J. BONKOWSKY[3], *J.-H. SON[2]
[2]Dept. of Biol., [1]Univ. of Scranton, Scranton, PA; [3]Dept. of Pediatrics, Univ. of Utah Sch. of Med., Salt Lake City, UT

Abstract: Hypoxic injury to the developing human brain from prematurity may increase the risk of lifelong behavioral and intellectual deficits, including autism spectrum disorders, cerebral palsy, depression, bipolar disorders, epilepsy, and intellectual disabilities. However, the mechanisms of hypoxia-induced injury to the developing nervous system are poorly understood. Previously, we have demonstrated that hypoxic injury resulted in connection errors of telencephalic neurons in the vertebrate nervous system using the embryonic zebrafish (*Danio rerio*) (Stevenson et al., 2012). Here, we have studied the effects of hypoxia on the diencephalic dopaminergic (DA) neurons (1-5% of pO_2, from 24-96 hours post-fertilization (hpf)). Our results demonstrate that developmental hypoxia had differing effects on DA neurons depending on the timing and level of hypoxic exposure. Early exposure to hypoxia (24 to 48 hpf, 1% of pO_2) led to reduced DA neuron proliferation (20-30% of control normoxic group, 21% of pO2). In contrast,

later hypoxia (48 to 72 hpf, 3% of pO_2) led to an increase in developmental cell death. Interestingly, while later hypoxia exposure (72 to 96 hpf, 5% of pO_2) led to a 15-30% decrease in DA tissue content, it did not affect DA pathfinding or extension to motor neurons of the spinal cord. Our findings have important implications for understanding normal DA development and function in the vertebrate nervous system, and the pathophysiology associated with prematurity-associated hypoxia diseases.

Title: Acute effects of early seizures on hippocampal interneurons in the immature brain

Authors: T. WANG, *H. SUN
Dept. of Neurosci., Carleton Univ., Ottawa, ON, Canada

Abstract: The neonatal period is characterized by a critical period of synaptogenesis and plasticity, in part mediated by a physiological imbalance between excitation and inhibition, and this imbalance is thought to contribute to the enhanced susceptibility of the immature brain to seizures and epileptogenesis. Previous studies have shown that early life seizures induce acute enhancement of AMPAR function in hippocampal CA1 pyramidal neurons. Glutamatergic inputs from pyramidal neurons mediate Ca^{2+} influx in the interneuron dendrites and determine the functional maturation of the interneurons. However, little is known about whether early seizures will activate hippocampal interneurons. Here, we aim to investigate the acute effects of early life seizures on different interneuron populations in developing hippocampus. Early seizures were induced in c-Fos-tTA/c-Fos-GFP mice by single dose of PTZ (60mg/kg, i.p.) at P10, with saline-injected littermates used as controls. We revealed that no co-labeling of GFP and GAD65/67 following PTZ seizures (n=6), confirming that GABAergic interneurons are not activated during acute early seizures in the immature hippocampus. Using whole-cell patch-clamp recordings, CA1 interneurons were identified according to their morphology and distinctive electrophysiological properties. We found that intrinsic membrane properties were unchanged in both fast-spiking interneurons and non-fast spiking interneurons at 1h post-seizures compared with controls (n=7-11, $p>0.05$). Moreover, AMPAR-mediated sEPSC amplitude in both fast-spiking (20.8±2.0 pA, n=16) and non-fast-spiking interneurons (19.7±2.0 pA, n=14) from 1h

post-seizure mice were not different from littermate controls (fast-spiking interneurons 23.9±1.4 pA, n=18, p>0.05; non-fast-spiking interneurons 23.8±2.4 pA, n=13, p>0.05). However, AMPAR sEPSC frequency in fast-spiking interneurons from 1h post-seizure mice (0.29±0.06 Hz; n=16) was significantly lower than controls (1.27±0.19 Hz; n=18, p<0.05), while no significant changes of AMPAR sEPSC frequency were observed in non-fast-spiking interneurons from 1h post-seizure mice (1.10±0.29 Hz; n=14) compared with controls (0.69±0.14 Hz; n=13, p>0.05). Our data support that early seizures differentially regulate excitatory inputs to hippocampal pyramidal and interneurons, which may represent a potential synaptic mechanism mediating neuronal circuit reorganization in early life epilepsy.

Abstract: Schizophrenia is a complex psychiatric disorder where both genetic and environmental factors contribute to the disease development. Thus, schizophrenia risk factors include single gene mutations and copy number variations as genetic, and maternal inflammation, drug abuse and stress as environmental factors. In recent times, mouse models have been generated that recapitulate some of these risk factors. Importantly, although these mouse models show some similar phenotypic characteristics, there are also significant differences in morphological and behavioural schizophrenia-associated impairments between the models. This also resembles closely the human disorder, since schizophrenia patients have a spectrum of positive and negative symptoms that might vary from patient to patient. Substantial evidence from human studies show that the cognitive decline in schizophrenia might result from

an imbalance between excitation and inhibition in the brain due to impaired activity of interneurons. We highlight that development of interneurons is differentially affected in several genetic and environmental mouse models of schizophrenia. We show widespread vulnerability of interneurons in response to various schizophrenia-associated “hits”, affecting all stages of interneuron development - neurogenesis, migration and maturation. Looking at subtypes of interneurons derived from medial and caudal ganglionic eminence, we find higher vulnerability of specific subtypes in comparison to others. At the same time, each schizophrenia-associated risk factor has a distinct effect on interneuron development, thus affecting only a subset of interneuron subtypes while sparing the others. Such differential impairment of interneuron subtypes might explain the phenotypic differences observed in schizophrenia as well as provide novel cellular targets for interventional therapies.

Title: The role of asparagine synthetase in brain development

Authors: *X. YAO[1], D. B. GOLDSTEIN[3], Y.-H. JIANG[2]
[1]Dept. of Pediatrics, [2]Dept. of Pediatrics and Neurobio., Duke Univ. Sch. of Med., Durham, NC; [3]Inst. for Genomic Med., Columbia Univ., New York, NY

Abstract: Asparagine Synthetase Deficiency (ASNSD) is a recently identified rare autosome recessive neurological disease characterized by severe microcephaly, developmental delay, intellectual disability, cerebral atrophy and intractable seizures. ASNSD is caused by mutations in the ASNS gene encoding asparagine synthetase (ASNS). ASNS is believed to catalyze the biosynthesis of asparagine (ASN), a non-essential amino acid in humans, from aspartate and glutamine in an ATP-dependent manner. However, very few investigations have followed this lead and the exact physiological relevance related to the function of ASNS in ASN synthesis remains elusive. Remarkably, nothing is known about the pathogenesis of ASNSD and the function of ASNS in brain development and there is no treatment available. TO determine the specific role of ASNS in brain development and delineate the mechanism underlying the

neuropathogenesis of ASNSD, we generated *Asns* conventional knockout (KO) mouse and brain specific conditional KO mouse to investigate the consequence of *Asns* loss in brain development. We found that conventional Asns-KO results in perinatal lethality and significantly reduced brain mass. Brain-specific Asns-KO mice by Nestin-Cre ($Asns^{NS-/-}$) nicely recapitulate core features of ASNSD. $Asns^{NS-/-}$ mice have smaller brain mass, and display growth retardation and high penetrance for spontaneous seizures and lethality at postnatal days 15-22 (P15-22). Interestingly, the primary cultured cortical neuron from conventional Asns-KO shows significant growth defect and this defect can be rescued by supplementing extra asparagine. Our results demonstrate that ASNS plays critical roles in early brain development. Phenotypes observed in *Asns* KO mice mimics clinical features of ASNSD, suggesting that *Asns* KO mouse is a valid model to study the mechanisms underlying neurological impairment in ASNSD and to test potential strategies for clinical interventions.

Title: Rapid evaluation of ciliopathy patient-derived ZNF423 variants by genome editing in mice

Authors: *B. A. HAMILTON
Cell. & Mol. Med., UCSD Sch. Med., La Jolla, CA

Abstract: Ciliopathies are disorders that share defects in primary cilia, most often due to mutations that disrupt proteins localized to cilia. *ZNF423* encodes a transcriptional regulator with 30 zinc fingers, conserved among vertebrates, that forms alternative complexes with a variety of lineage-selective or signal-responsive transcription factors and with DNA damage response factors. Rare mutations in *ZNF423* are reported in patients with cerebellar vermis hypoplasia, Joubert Syndrome (JBTS19), or nephronophthisis (NPHP14) and other brain malformations. Patient sequencing more frequently returns variants of unknown significance, often in heterozygous state, some of which have been proposed to act dominantly. Null mutations in mouse *Zfp423* recapitulate brain malformation aspects seen in human patients, including hypoplasia or agenesis of the cerebellar vermis. To determine the impact of patient-derived variants, we used CRISPR/Cas9-mediated genome editing with synthetic components to rapidly introduce ~30 distinct mutations in *Zfp423* in mouse embryos with a uniform genetic background (FVB/NJ). Protein truncating alleles uniformly result in recessive severe ataxia with gross

malformations. Substitution alleles, even at strongly conserved sites, rarely produce strong phenotypic consequences. Surprisingly, in-frame deletions that remove or disable some zinc fingers did not produce strong effects.

Title: Beneficial impacts of minocycline administration following prenatal alcohol exposure

Authors: *T. S. BODNAR, S. SARKAR, A. CHAO, S. BAGLOT, P. HOLMAN, J. WEINBERG
Cell. and Physiological Sci., The Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Prenatal alcohol exposure (PAE) has a significant impact on immune function, resulting in an increased risk of infections, alterations in immune organ development, and disturbances to immune cell populations. We have shown previously that following PAE, cytokine levels are increased during the early postnatal period, a critical window for both brain and immune system development. Based on these findings, here it was hypothesized that administration of an anti-inflammatory agent during early-life could have a beneficial impact on the immune system following PAE.
To test this hypothesis, pregnant Sprague-Dawley rat dams were assigned to: PAE – ad libitum access to liquid ethanol diet; or Control (C) – ad libitum access to control diet. Next, offspring were administered minocycline during either lactation or during adolescence. Immune organs and brain tissue were collected following minocycline administration to assess cytokine levels. In adulthood, the response to lipopolysaccharide (LPS) challenge was assessed and, due to the modulatory role of the neuroimmune system on cognition and learning and memory, adults were tested in the Barnes Maze (spatial learning/memory task).
Results indicate that PAE males show deficits in the Barnes Maze task, specifically in the reversal phase, and that minocycline administration during lactation or adolescence appears to normalize performance. In addition, preliminary data indicate that PAE animals have a heightened cytokine response to LPS, with both sexes showing elevated levels of IL-5, along with elevated IL-13 in females and TNF-α in males. Notably, minocycline administration during lactation or adolescence also normalized the cytokine response to LPS in PAE animals.

Taken together, as altered immune function/neuroimmune signaling may underlie some of the long-term effects of PAE, findings from this ongoing study may have implications for understanding the long-lasting deficits associated with FASD and support further investment into immune-based intervention strategies.

Title: The ontogeny of cognitive, behavioral and metabolic deficits in creatine transporter deficiency

Authors: *K. C. UDOBI, N. DELCIMMUTO, A. KOKENGE, Z. ABDULLA, M. PERNA, M. SKELTON
Cincinnati Children's Res. Fndn., Cincinnati, OH

Abstract: Creatine (Cr) transporter (CrT) deficiency (CTD) is a leading cause of X-linked intellectual disability (XLID). CTD is characterized by moderate to severe intellectual disability, epilepsy, and autistic-like symptoms. On occasion CTD patients also exhibit muscular and skeletal symptoms like hypotonia, and microcephaly. Animal models of CTD exhibit cognitive and behavioral deficits, mimicking the disorder. While it is clear that Cr is essential for proper cognitive and metabolic function as evidenced by neurological and metabolic deficits resulting from the loss of cellular Cr, it is still unknown if these deficits are caused by changes in brain development due to a lack of Cr or if the loss of Cr leads to disruptions in neuronal function. To understand the role of Cr in brain development, we eliminated the Crt during two distinct life stages using mice that express a tamoxifen-inducible Cre recombinase (UBC-cre/ERT2) crossed with $Crt^{flox/y}$ mice. To understand the role of Cr in a normally developed brain, the Crt was knocked out in adult animals. The effect of Cr on brain development was examined by deletion of the Crt in neonatal mice, a period analogous to third trimester brain development in humans. Tamoxifen was administered from postnatal day (P) 5-10 in the neonatal group (P5-KO) and from P60-65 for the adult mice (P60-KO). Brain CrT transcripts were undetectable 5 days following Cre recombinase induction. Both groups of KO mice had a significant reduction in body weight compared with control (CONT) mice. Both P5-KO and P60-KO mice were hyperactive in the open-field test. Cognitive function was assessed based on deficits observed in

previous CrT knockout mice, representing three distinct types of learning to assess global cognitive function. Spatial learning was assessed in the Morris water maze (MWM). During visible platform testing, P10-KO mice had an increased latency to the platform compared with controls. The P60-KO mice show differences compared with CONT mice. In the acquisition and reversal phases, P5-KO mice had an increased in latency and path length compared with CONT. No differences were observed in P60-KO mice in the MWM. Both groups of cKO showed no deficits in object recognition or fear memory when compared with CONT mice. Both groups of cKO mice showed increases in whole-body metabolism, consistent with ubiquitous KO mice. In addition, increased brain mitochondrial respiration was observed in both groups of mice. The results of this study suggest that the loss of Cr in the adult brain is not sufficient to induce cognitive deficits, suggesting that the deficits observed are due to changes in brain development.

Title: Early postnatal alcohol exposure increases microglia density in the rat cerebellum that can be offset by voluntary exercise in adolescence

Authors: *A. Y. KLINTSOVA, J. R. JOHANSSON, Z. H. GURSKY
Psychological and Brain Sci., Univ. of Delaware, Newark, DE

Abstract: During development, precise function of brain neuroimmune system is required for maintenance of extracellular space, refinement of synapses, and clearance of apoptotic neurons. Microglia (MG), the resident immune cells of the brain, colonize the brain from the periphery in the first half of prenatal development in both humans and rodents. MG are sensitive to teratogenic effect of alcohol during brain development. The current study examines the distribution and morphology of MG in rat cerebellum following early postnatal ethanol exposure. Male and female Long Evans rats underwent one of 3 experimental postnatal treatments on postnatal days (PD) 4-9: exposure to 5.25 g/kg/day of ethanol via intragastric intubation

(alcohol-exposed, AE), intubation without any liquid (sham-intubated, SI), or undisturbed (suckle control, SC). On PD 30, animals were placed (2-3 same-sex in a cage) in one of 2 adolescent housing conditions: social housing in standard cage (socially-housed, SH), or social housing with free access to a running wheel (wheel-running, WR). On PD42, brains were fixed with 4% paraformaldehyde. Cerebelli were sectioned parasagittally at 40µm and immunohistochemically labeled for Iba-1, a MG-specific protein. Images of systematically-selected serial sections were acquired using Stereo Investigator (MBF Bioscience) for densitometry analysis of Iba-1 using ImageJ software. To assess morphology of individual MG, serial random sampling was used to acquire z-stacks within lobules (L) 1-4 and L9-10 of cerebellum, and MG morphology was analyzed using Neurolucida (MBF Bioscience).
In L1-4, there were main effects of postnatal treatment (AE>SI, AE>SC) and adolescent housing (WR<SH) on density of MG material. There was a main effect of postnatal treatment on volume (AE<SI, AE<SC), and a main effect of housing on MG material (WR<SH). In L9-10, there were main effects of postnatal treatment (AE>SI, AE>SC) and housing (WR<SH) on density of MG material, similar to the pattern observed in L1-4. WR increased the volume of L9-10 (WR>SH), suggesting that changes in volume contributed to changes in MG density. This data indicates that WR counteracts the long-term alterations in MG density following AE. In both L1-4 and L9-10, there was exclusively a main effect of adolescent housing on the average territory of individual MG (WR<SH). Reduction in cell territory is often associated with MG activation and increased cell size, which suggests that WR-induced changes in MG density in both L1-4 and L9-10 are likely driven by reductions in number of MG cells rather than altered MG morphology.

Title: A mouse model for GNAO1-associated movement disorder

Authors: *H. FENG[1], Y. YUAN[2], C. L. LARRIVEE[2], R. R. NEUBIG[2]
[2]Pharmacol. & Toxicology, [1]Michigan State Univ., East Lansing, MI

Abstract: Rationale: The heterotrimeric protein G_o, whose α subunit is encoded by *GNAO1*, regulates ion channel function, neurotransmitter release, and neurite outgrowth. Mutations in *GNAO1* have been identified in children with either epileptic encephalopathy (EIEE17) or neurodevelopment disorder with involuntary movements (NEDIM). The mechanism underlying

the complex clinical spectrum of these *GNAO1* encephalopathies is poorly understood. Previously, we discovered a genotype-phenotype correlation on patients mutations with an *in vitro* functional assay. *De novo GNAO1* mutations have both GOF and LOF biochemical function with the former associated with seizures and the latter with movement disorder. We also reported a *Gnao1* GOF knock-in mutant (*Gnao1*$^{G184S/+}$) with a mild seizure phenotype in C57Bl/6J mice. In the current study, we assessed behavioral characteristics and electrophysiology properties and morphological changes in the cerebellum of *Gnao1* mutant mouse models to explore the pathophysiology of *GNAO1*-associated movement disorders and to further validate our model associating *GNAO1* GOF mutations with movement disorder.
Methods: *Gnao1*$^{G184S/+}$ (GOF) and *Gnao1*$^{-/+}$ (HetKO) animals of both sexes (age 8 to 14 weeks) were analyzed. Spontaneous inhibitory (sIPSCs) and excitatory postsynaptic currents (sEPSCs) in Purkinje cells in cerebellar slices were measured using whole cell patch-clamp recording techniques. Morphology was assessed with Nissl staining. Motor capabilities were assessed using a battery of behavioral tests.
Results: Compared to *Gnao1* WT mice, GOF mice showed a number of behavioral abnormalities related to movement including open field, rotarod, stride length, paw angle variability, and grip strength. HetKO mice were relatively normal in motor functions. Cerebellar slices from GOF mice showed reduced sIPSC frequency but relatively normal EPSCs. Cerebella from GOF mice also had reduced lobule number but molecular layer thickness was unchanged.
Conclusions: The *Gnao1* GOF mutant mice, as with human *GNAO1* GOF patients show a pronouced movement disorder. This may be related to altered inhibitory signaling in the cerebellum.

Title: The role of interleukin-6 expression in maternal gut bacteria and the alternation of mouse offspring brain development

Authors: *V. PEÑA-GARCIA[1], A. OYETUNDE[2], B. TENG[2], D. BANNER[2]
[1]Biol., California State University, Northridge, Alhambra, CA; [2]Biol., California State University, Northridge, Northridge, CA

Abstract: There is a wealth of emerging information displaying a connection between maternal health and fetal brain development. One of the primary causes of neurodevelopmental abnormalities is mediated through an activated maternal immune system. The maternal immune system may be activated by many different environmental factors, one being exposure to a high-fat diet (HFD). Rates of maternal obesity have increased in proportion to weight increases seen in the general population. The National Vital Statistics System reported that in 2015 maternal pre-pregnancy obesity rates were greater than 25%, and rates of obesity in women aged 20-39 years is more than 34%. The mechanisms by which maternal obesity leads to neurodevelopmental disorders in the offspring remains unclear but recent research has found that changes in inflammatory cytokines may be a contributing factor. Increases in the cytokine interleukin (IL)-6 has been shown to be required for the behavioral deficits seen in offspring born to mice with an activated immune system. One of the ways that IL-6 could modulate neurodevelopment may be through the maternal microbiome. Recent evidence has shown that following maternal immune activation, neurodevelopmental disorders in offspring result from microbiome-induced increases in IL-17 that is mediated, in part, by IL-6. To address the role of IL-6 in neurodevelopmental deficits seen in maternal obesity we used IL-6 knockout (KO) mice exposed to a high-fat diet to better understand the role of IL-6 and gut microbiota in mouse fetal brain development. Preliminary results show that there is a decrease in the relative abundance of Firmicutes to Bacteroidetes for IL-6 KO mice in the pre-pregnancy and post-pregnancy stages. These decreases were not seen in the C56BL/6 mice. Analyses are ongoing, we will characterize changes to the gut microflora during pregnancy by 16S rRNA gene sequencing for bacterial identification. By comparing the gut microbiome with the absence of IL-6 and increase or decrease in other inflammatory cytokines, we will help delineate the association of maternal IL-6 and neurodevelopmental abnormalities in offspring.

Title: State of cholinergic neurons in the nucleus basalis of meynert (NBM) of adult rats following alcohol exposure during the brain growth spurt (PD 4-9)

Authors: *K. MILBOCKER, Z. H. GURSKY, A. Y. KLINTSOVA
Univ. of Delaware, Newark, DE

Abstract: Prenatal alcohol exposure is known to impact CNS development in humans and rodents, resulting in neurocognitive deficits associated with learning and memory. A period of substantial brain maturation, the brain growth spurt occurs prenatally in humans during the last trimester of pregnancy (Dobbing & Sands, 1979) and during the first two postnatal weeks in rodents (Bonthius & West, 1990). Previous studies suggest that cholinergic neurons in the forebrain-cortical circuitry could be a target in prenatal alcohol exposure leading to alterations in the innervation of the cortex and resulting in behavioral deficits in executive functioning tasks and object recognition (Robinson-Drummer et al. 2017; Kleiber et al. 2014). Our study examines the long-term effects of binge-like alcohol exposure (AE) during the brain growth spurt in a rat model of Fetal Alcohol Spectrum Disorders (FASD) on cholinergic cell number and soma volume in the NBM, as well as the overall volume of the NBM. On PD 4-9, Long-Evans rats were exposed to ethanol (5.25 g/kg/day) via intragastric intubation twice a day in milk substitute. Two control groups were sham-intubated (SI) rats that were not given any liquids and suckle-control (SC) rats. Rats were weaned and housed in same-sex groups of three at PD23. Animals were sacrificed on PD72 and forebrain tissue was collected and sectioned horizontally at 40 µm. An immunohistochemical staining of cholinergic neurons was performed on every eighth section using anti-choline acetyltransferase (ChAT) antibody. Unbiased stereology was used to estimate the total number of ChAT+ neurons in the NBM and their volumes. A one-way ANOVA was conducted to compare the effect of neonatal binge-like AE on cholinergic cell count and soma volume. A similar analysis was used to measure the effect of treatment on structural volume of the NBM. There was no significant main effect of alcohol exposure on ChAT+ cell number and NBM volume ($F(2, 9) = 0.696$, $p=0.524$ and $F(2, 9) = 0.816$, $p=0.472$; respectively). However, we did observe a main effect of treatment on the soma volume of ChAT+ neurons when comparing AE animals to SC ($F(2, 9) = 6.867$, $p=0.016$) which suggests an increase in NBM cholinergic neuronal volume following alcohol exposure during the brain growth spurt. To check the hypothesis that density of cholinergic projections from NBM to the cortex is also increased in AE animals, we are using an unbiased stereological estimate of the axonal number and length. It is shown that alcohol exposure during the brain growth spurt alters the central cholinergic system in a rat model of FASD which may result in deficits of higher order cognition.

Title: Choline alters hippocampal development: Implications for the treatment of fetal alcohol spectrum disorders

Authors: *K. R. BREIT[1], T. S. BODNAR[3], J. WEINBERG[4], J. D. THOMAS[2]
[1]Behavioral Teratology, [2]Dept Psychol, San Diego State Univ., San Diego, CA; [3]Cell. and Physiological Sci., The Univ. of British Columbia, Vancouver, BC, Canada; [4]Dept Cell. & Physiological Sci., Univ. British Columbia, Vancouver, BC, Canada

Abstract: Prenatal alcohol exposure disrupts development, leading to a variety of behavioral and cognitive problems, referred to as fetal alcohol spectrum disorders (FASD). Some behavioral problems depend on the functional integrity of the hippocampus, a brain area vulnerable to alcohol's teratogenic effects. Supplementation with the essential nutrient choline can reduce the severity of behavioral deficits associated with prenatal alcohol exposure. Specifically, choline can improve performance on tasks that depend on hippocampal function, even when administered after alcohol exposure has ceased. Consistent with behavioral improvements, we have found that early postnatal choline supplementation can alter hippocampal structure and function, including cholinergic functioning, DNA methylation and neurotrophic factors. Recently, we found that choline mitigates ethanol-related increases in ceramide, which may suggest that choline protects against neuroinflammation. In fact, the hippocampus has the highest density of cytokine receptors in the brain. The present study examined whether choline modifies immune function in the hippocampus of subjects exposed to alcohol during early development. Sprague-Dawley rats were intubated with either 5.25 g/kg/day alcohol or sham intubated from postnatal days (PD) 4-9, a brain development period equivalent to the human third trimester of pregnancy. Subjects were then injected with either 100 mg/kg/day of choline chloride or saline from PD 10-30. Thus, this study included a 2 (ethanol, sham) x 2 (choline, vehicle) x 2 (male, female) design with n's 9/group. Hippocampal tissue was dissected on PD 35 and cytokine levels measured using the Meso Scale Discovery proinflammatory panel. Choline reduced levels of the anti-inflammatory cytokines IL-4 and IL-10 in males, and IL-5 in males and females, in both alcohol-exposed and control subjects. These data suggest that choline may modify neuroimmune function in the hippocampus. Although alcohol did not alter cytokine levels, further studies are required to determine if choline protects against alcohol-related increases in cytokines during immune challenges. These data suggest that choline may protect against alcohol-related damage, in part, by altering neuroimmune function, findings that have important implications as choline is explored as a treatment for fetal alcohol spectrum disorders.

Title: A mouse model of X-linked intellectual disability protein PHF6 associated with impaired neuronal maturation

Authors: *C. CHENG[1], P.-Y. DENG[1], C. YUEDE[1], Y. IKEUCHI[2], N. RENSING[1], D. LI[1], J. HUANG[1], T. WANG[1], M. WONG[1], D. WOZNIAK[1], V. KLYACHKO[1], A. BONNI[1]
[1]Washington Univ., Saint Louis, MO; [2]The Univ. of Tokyo, Tokyo, Japan

Abstract: Mutations in PHF6 are implicated in Börjeson-Forssman-Lehmann syndrome (BFLS), an X-linked intellectual disability (XLID) characterized by mental impairment, developmental delay and seizures. However, the mechanisms by which mutations of PHF6 contribute to the pathogenesis of BFLS remain poorly understood. Here, we report a novel patient-specific PHF6 mutation mouse of BFLS. PHF6 C99F knock-in mice display deficits in memory and adaptive behaviors as well as reduced threshold to seizures. Electrophysiological studies reveal increased neuronal intrinsic excitability, providing a basis for susceptibility of BFLS mice to seizures. Transcriptomic analysis of the cerebral cortex in C99F knock-in mice and PHF6 knockout mice show that PHF6 promotes the expression of neurogenesis genes and concomitantly suppresses the expression of synaptic genes. Remarkably, PHF6-regulated genes overlap with autism spectrum genes and autism-regulated gene modules. These findings advance our understanding of BFLS pathogenesis and offer new links between BFLS and autism spectrum disorders.

Title: Long term effects of binge alcohol exposure during development on the cingulate cortex. Cell numbers and preliminary investigations using serial block face scanning electron microscopy

Authors: *R. M. NAPPER, H. KIM, P. SHOEMACK, C. JONES
Univ. of Otago, Dunedin, New Zealand

Abstract: Background: Binge drinking during pregnancy can result in permanent brain damage and brain dysfunction without external markers of damage. Animal studies have shown that the cingulate cortex (CgC), important in a range of cognitive skills, suffers acute cell death but we have little information on whether this results in long-term cell deficits or changes in synaptic interactions. This study investigated the acute and long-term effects of a single ethanol binge on total cell number in the CgC. We also undertook preliminary investigations of the morphology of synapses in the superficial CgC layers using serial block face scanning electron microscopy (SBF-SEM). Methods: Long-Evans rat pups were exposed to either alcohol (E) at a daily dose of 6.0g/kg ethanol via intubation as two feeds two hours apart, or a sham intubation (IC) on PN6. The brains were studied either 12 hours post ethanol (apoptotic cell death) or when adult (permanent cell number). Animals were perfused and brain tissue processed for light and electron microscopic studies. The optical fractionator method was used to estimate the total number of apoptotic cells (PN6) or neurons (adult) within the cingulate cortex. SBF-SEM was used to quantify aspects of synaptic connectivity. Results: On PN6, alcohol exposed animals had significantly more apoptotic cells within the CgC than controls ($P = 0.0029$): the total number of apoptotic cells in the CgC was 6,518 (±11,326) in IC (n=7) and 64,523 (±43,098) in AE (n=5) (mean±sd). There was a significant effect of location on acute cell death, with the upper CgC showing a significantly more apoptotic cells than the lower zone ($P < 0.0001$). There was a permanent deficit of neurons in the adult CgC, AE < IC ($P < 0.01$). The effect of neuronal loss on the synapses in upper cell layers of CgC was determined by 3D reconstruction of images from SBF-SEM stacks. Discussion: This study shows that the rat cingulate cortex exhibits long-term neuronal deficits following a single binge ethanol exposure and due to the complex networks within which the CgC is involved, this will impact on function. The SBF-SEM data provides an indication of how the brain synaptic connectivity is adjusted to accommodate developmental cell loss. This indicates that a single binge drinking episode during late pregnancy may result in a long-term change in brain structure and must be considered when the risks of drinking in pregnancy are assessed. It also shows that SBF-SEM is a valuable tool in understanding how cell loss contributes to brain dysfunction.

Title: Developmental cannabinoid exposure alters the effects of early alcohol exposure on behavioral development

Authors: C. RODRIGUEZ, 92120[1], K. R. BREIT[2], *J. D. THOMAS[3]
[1]Dept Psychology, [2]Behavioral Teratology, [3]Dept Psychol, San Diego State Univ., San Diego, CA

Abstract: Cannabis is the most commonly used illicit drug among pregnant women, and over half of pregnant women who report cannabis use also consume alcohol. Prenatal alcohol exposure, by itself, can lead to fetal alcohol spectrum disorders, including a variety of behavioral deficits; however, the consequences of combined prenatal alcohol and cannabis exposure on fetal development are not well understood. Using the cannabinoid receptor agonist CP-55,940 (CP), the current study examined behavioral development following exposure to CP and/or ethanol (EtOH) during postnatal days (PD) 4-9, a period of brain development equivalent to the human 3rd trimester. Sprague-Dawley rat pups received CP (0.4 mg/kg/day, i.p.) or vehicle, as well as EtOH (5.25g/kg/day) or sham intubation, utilizing a 2 (CP, Vehicle) x 2 (EtOH, Sham) x 2 (male, female) design. Peak blood alcohol concentrations (BAC) were analyzed (PD 6) to examine if CP altered blood alcohol levels during exposure. Following CP and/or EtOH exposure, all subjects performed a battery of behavioral tasks examining motor development (grip strength and hindlimb coordination, PD 12-20), motor coordination (parallel bar motor balance and coordination, PD 30-32), activity levels (open field, PD 18-21), and spatial learning (Morris water maze, PD 40-47). Developmental CP exposure exacerbated ethanol-related mortality, reductions in body growth and increased peak BAC levels. Motor development was advanced by CP exposure yet delayed by EtOH exposure, and performance of subjects exposed to the combination of CP and EtOH was intermediate. However, long-term motor coordination was not altered by developmental CP exposure, although CP exposure exacerbated long-lasting motor impairments related to EtOH exposure, specifically in females. Separately, both CP and EtOH exposure increased activity levels in the open field, but the combination produced more severe impairments in habituation than either exposure alone. Lastly, while only development EtOH exposure impaired spatial learning, both EtOH and CP independently increased thigmotaxis in the Morris water maze, with more severe increases observed following combined exposure. Thus, developmental exposure to CP or EtOH disrupted behavioral development in

unique ways, but the combination produced the most severe effects within specific behavioral domains. Importantly, these data suggest that prenatal cannabis exposure disrupts development and that effects may be more severe when combined with alcohol, which has important implications for public health policy.

Title: Modeling CDKL5 disorder in mice

Authors: *B. TERZIC, S. TANG, I.-T. WANG, K. SIZOV, Y. CUI, Z. ZHOU
Univ. of Pennsylvania, Philadelphia, PA

Abstract: Mutations in the X-linked gene encoding cyclin-dependent kinase-like 5 (CDKL5) cause the childhood epileptic encephalopathy known as CDKL5 disorder. The disease is characterized by a heterogeneous array of clinical symptoms including early-onset seizures, and severe cognitive and motor disability. There has been a steady increase in the rate of diagnoses each year, and mutations in *CDKL5* appear to be enriched in populations of patients with epilepsy or autism spectrum disorders. This suggests that the disorder may be more prominent than currently understood, and emphasizes the necessity of understanding the pathophysiology of CDKL5 in the aforementioned conditions. To determine the genetic causality of CDKL5 disorder, we generated the first *Cdkl5* knockout (KO) mouse and found that they mirror several hallmark symptoms of the human disease, including autistic-like behaviors, impaired motor control, and poor learning and memory. Given that CDKL5 is expressed in multiple tissues with the highest level in the forebrain, we next generated *Cdkl5* conditional KO mouse, ablating Cdkl5 expression predominantly from the central nervous system (Nestin-cKO). We found that these mice largely resemble *Cdkl5* constitutive KO mice, supporting the theory that CDKL5 disorder is caused by CDKL5 dysfunction within the nervous system. Our recently developed knock-in mouse modeled after a patient missense mutation, R59X, also manifests several of the phenotypes observed in *Cdkl5* KO mice, providing us with a reliable proxy to identify pathogenic mechanisms underlying CDKL5 disorder. Currently, we have expanded our genetic

approach to dissect the function of CDKL5 in different cell types in the brain, and to identify the signal transduction pathways regulated by CDKL5, particularly with regards to synapse development and function. These studies will be critical for the development of more targeted therapeutics for patients.

Title: Behavioral consequences of retinoid disruption during embryonic development in the zebrafish

Authors: *A. B. HAWKEY[1], C. L. DEAN[1], S. KULLMAN[2], E. D. LEVIN[1]
[1]Psychiatry & Behavioral Sci., Duke Univ., Durham, NC; [2]Toxicology program,, North Carolina State Univ., Raleigh, NC

Abstract: A variety of environmental contaminants are known to cause neurobehavioral toxicity after developmental exposure(s), although more work is needed to define the relevant adverse outcome pathways. Our previous work with the zebrafish model suggest the importance of retinoic acid (RA) signaling in neurodevelopment and behavioral impairment, offering one such mechanism for linking neurotoxic chemical exposures to disruptions in brain development and behavioral dysfunction. We have previously shown that embryonic excess of vitamin A (retinol) or exposure to valproic acid (VPA) which disrupts RA, alters behavioral function in larval zebrafish and into adulthood. Recent screening of TOX21 compounds has identified a number of chemicals that have the potential to transactivate the retinoic acid receptor, including select pesticides. However, additional work is needed to link their putative retinoid activity to relevant adverse behavioral outcomes. The present study measured the behavioral effects of embryonic exposure to these compounds using the larval motility assay. Zebrafish embryos were exposed to vehicle (DMSO), chlorothalonil (CTN, 10-100μM), imazalil (IMZ, 0.1-1μM) or buprofezin (BPF, 0.3-3μM) from 5-120 hours post-fertilization (hpf). Doses were selected to fall below the threshold for overt dysmorphogenesis or toxicity. Larval motility was assessed at 144hpf. This testing consisted of 10 minutes acclimation in the dark followed by two alternating light and dark phases at 10 min each. For each of the three compounds, the highest dose reduced locomotor activity. For CTN and IMZ, this pattern appeared under both lit and dark conditions. For CTN,

this pattern was limited to dark conditions. At lower doses, the pattern was more unique for each compound. The lowest dose of CTN reduced activity, but only during the dark phases, as with the highest dose. IMZ, by contrast, showed a non-monotonic dose-response function, whereby the lowest dose produced locomotor hyperactivity rather than hypoactivity under both lit and dark conditions. The present data show that compounds with retinoid activity dose-dependently alter larval activity. To complete this analysis, future tests in adulthood will assess locomotor, affective and cognitive functions following these embryonic exposures. This work was supported by the Duke University Superfund Research Center (ES010356).

Title: Glutamatergic hindbrain and motor neurons develop different patterns of network activity *in vitro*

Authors: *A. BUBNYS[1], H. KANDEL[1], G. N. REEKE[3], L.-M. KOW[1], D. W. PFAFF[3], I. TABANSKY[2]
[1]Lab. of Neurobio. and Behavior, [2]The Rockefeller Univ., New York, NY; [3]Rockefeller Univ., New York, NY

Abstract: Multielectrode arrays (MEAs) are emerging as powerful tools for studying the development and dynamics of neuronal networks noninvasively over weeks and months. One prominent feature of neurons cultured on MEAs is the development of robust network bursts that recruit many recording electrodes and may persist over many months. This kind of activity has been detected in cultures of cortical, hippocampal, and motor neurons, among others. However, the mixed excitatory/inhibitory nature of these cultures has made dissecting the neuronal components that contribute to network bursts challenging. We have developed a system to culture homogeneous populations of murine excitatory spinal motor neurons derived from a GFP reporter cell line and primary hindbrain V2a neurons developmentally expressing the transcription factor Chx10 on MEAs for up to 30 days using flow cytometry to separate the cell types of interest on the basis of fluorescent reporter expression. Both glutamatergic cell types were able to generate spontaneous bursts in the absence of inhibitory interneurons when cultured on a layer of astrocytes. However, these bursts were qualitatively different between cell types.

The motor neurons developed tonic spiking that sometimes organized itself into bursts, while the V2a hindbrain neurons developed very strong network bursts that generated signals sufficient to deflect the MEA recording channel baselines over a timescale of seconds. These results indicate that spinal motor and V2a hindbrain neurons are able to generate network bursts in the absence of inhibitory interneurons and that cell type determines network burst morphology and dynamics. The tendency of V2a hindbrain neurons to generate such robust network bursts supports their hypothesized role as the pacemaker neurons required for regulating respiratory rhythm in newborn mice.

Title: Promoter capture Hi-C reveals the genome-wide chromatin interactome and Zic1/4 cis-regulatory elements in cerebellar granule cell precursors

Authors: *K. L. RIEGMAN[1], C. GEORGE[2], R. KADO[1], C. MOHAN[1], B. J. P. HUNTLY[3], D. SIMS[2], C. OSBORNE[1], M. A. BASSON[1]
[1]King's Col. London, London, United Kingdom; [2]Univ. of Oxford, Oxford, United Kingdom; [3]Univ. of Cambridge, Cambridge, United Kingdom

Abstract: Cerebellar granule cells are the most numerous neuronal subtype. Granule cell development follows a strict temporal schedule to coordinate the development of the granule cell progenitor (GCp) pool that underlies the vast expansion and foliation of the cerebellar structure. The gene-regulatory mechanisms that control GCp development remain incompletely understood. Chromatin conformation capture techniques may provide insight into long-range gene-regulatory mechanisms as they provide information on the physical proximity of DNA sequences in the nucleus. To identify *cis*-regulatory elements that may control cerebellar growth, we performed Promoter Capture Hi-C (PCHi-C) in undifferentiated, proliferating mouse GCps. This approach identified ±80,000 promoter interacting regions (PIRs) of >18,000 gene promoters. PIRs were further characterized by a combination of ATAC-seq and ChIP-seq to identify active regulatory elements. These analyses identified approximately 19,000 PIRs as putative enhancer elements that harbour the histone modification mark H3K4me1. Of these, 4,200 appear to be ‘active’ as they were accessible, as determined by ATAC-seq, and also marked by H3K27ac. Interestingly, *Zic1/4* had several of the most statistically significant PIRs among the ±80,000 identified in our data-set. *Zic1* and *Zic4* are known to be essential for the

proliferation of GCps and also remain expressed in differentiated GCs. *Zic1/4* mutation or heterozygous deletion is responsible for Dandy-Walker malformation, a syndrome characterized by cerebellar hypoplasia. Yet, how *Zic1/4* expression is regulated in GCps is not understood. *In vitro* luciferase assays confirmed that some of these *Zic1/4* PIRs are capable of 'enhancer-like' activities. Further validation is in progress. Together, these findings provide mechanistic insights into the complex nature of *Zic1/4* gene regulation in GCps.

Title: Nr4a1 promotes maturation of striatal striosome neurons and regulates the dopamine D1 receptor signaling pathway

Authors: *M. D. CIRNARU[1], C. MELIS[1], T. FANUTZA[1], S. NAPHADE[2], B. S. MUNTEAN[3], K. MARTEMYANOV[3], L. M. ELLERBY[2], M. E. EHRLICH[1]
[1]Neurol., Icahn Sch. of Med. at Mount Sinai, New York, NY; [2]The Buck Inst. for Res. on Aging, Novato, CA; [3]Neurosci., The Scripps Res. Inst., Jupiter, FL

Abstract: The GABAergic medium-sized spiny neuron (MSN), the striatal output neuron, may be classified into striosome, i.e. patch, and matrix, based on neurochemical differences between the two compartments. The patches comprise ~15% of the striatal volume, receive limbic inputs and contain D1 and D2 dopamine receptor direct and indirect pathway MSNs. Striosome MSNs express the mu opioid receptor (*OPRM1*), substance P (SP), calretinin, and the transcription factor Nr4a1 (nuclear receptor subfamily 4, group A, member1). Activity imbalance between striosomes and matrix is hypothesized to contribute to several movement disorders, including dystonia and levodopa-induced dyskinesias, but little is known regarding the developmental regulation of the two compartments. Nr4a1 function has been studied primarily in its role as an immediate early gene. In the *Nr4a1*-null mouse, multiple aspects of the dopamine (DA) system are dysregulated, including turnover and response to DA degeneration. We sought to determine the effects of Nr4a1 genetic, constitutive overexpression and knockout in the development and function of the MSN dopaminoceptive system. Using the Nr4a1-EGFP (GENSAT) which has 2X normal *Nr4a1* mRNA and the *Nr4a1*-null (JAX Nr4a1tm1Jm1) mouse lines, and *in vitro* viral

transduction in primary striatal neurons and differentiated iPSCs, we sought to determine whether Nr4a1 is necessary and/or sufficient for striosome development. In the presence of *Nr4a1* overexpression *in vivo*, we also examined the integrity of the striatal dopaminoceptive system, MSN excitability and plasticity, and locomotor and signal transduction response to acute and chronic cocaine. In the absence of *Nr4a1*, *Oprm1* mRNA is decreased, as are the number and size of Nr4a1-identified striososmes. With *Nr4a1* overexpression, *Oprm1* mRNA increases *in vivo*, in primary striatal neurons, and in differentiated iPSCs. Locomotor response to acute cocaine (20 mg/kg, ip) is normal but induction of pERK is diminished, as is sensitization to chronic cocaine. Moreover, *Nr4a1* overexpression reduces long-term potentiation (LTP) and dysregulates multiple mRNAs of the dopaminoceptive signal transduction system. In the resting state, the adenylyl cyclase V (AC5) system is not perturbed, but the ability of AC5 to be activated by D1R and adenosine A2A receptor (A2AR) GPCR inputs in direct and indirect MSNs is diminished. **Conclusion:** Our results indicate that Nr4a1 promotes the maturation of the striatal patch medium spiny neurons and its constitutive overexpression alters the D1 receptor signaling pathway.

Title: Proper spatiotemporal formation of the striatal direct pathway is required for appropriate formation of corticofugal axon trajectories

Authors: *J. M. EHRMAN[1,2], P. MERCHAN-SALA[1], B. CHEN[3], K. CAMPBELL[1]
[1]Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH; [2]Univ. of Cincinnati, Cincinnati, OH; [3]Univ. of California Santa Cruz, Santa Cruz, CA

Abstract: The striatum is the principle output nucleus of the basal ganglia; a group of subcortical nuclei best known for their role in regulating voluntary movement. Recent studies show that they also contribute to aspects of cognitive and social behavior. Malformed or malfunctioning striatal circuitry is therefore implicated in the motor, social, and cognitive deficits characteristic of several neuropsychiatric diseases of childhood, such as obsessive-compulsive disorder, attention-deficit/hyperactivity disorder, and autism. The axons of the striatal direct pathway and descending corticofugal axonal trajectories form in close proximity to each other from mid to late gestation, suggesting that signaling between these pathways may

help to guide their outgrowth. However, the interdependence of these two axonal pathways during development remains unclear. Using murine BAC transgenic reporter lines that mark the developing striatal direct pathway (Sox8-GFP) and corticofugal pathway (Fezf2-tdTomato) we are examining the spatiotemporal relationships between these two pathways at several embryonic timepoints. Combining these reporters with genetic manipulations of these pathways allows us to interrogate their dependence upon one another for proper formation. Selective disruption of direct pathway axon outgrowth, as observed in Sox8 knockout (KO) mice, leads to mistargeting of the corticofugal pathway axons. Conversely, our preliminary findings indicate that disruption of the corticofugal pathway, as seen in Fezf2 KO mice, does not appear to disrupt striatal direct pathway formation. Thus, we hypothesize that axons of the direct pathway are required for the proper guidance of the descending corticofugal trajectories though the diencephalon and midbrain during early circuit formation. Our findings suggest an avenue by which disruptions in striatal direct pathway formation can impair the normal development of corticofugal circuitry and contribute to the motor deficits seen in childhood brain disorders.

Title: Variability of leg movements across seven days during early infancy

Authors: *W. DENG, B. A. SMITH
Div. of Biokinesiology and Physical Therapy, USC, Los Angeles, CA

Abstract: Background: Infants with or at risk of developmental disabilities tend to have different movement patterns and characteristics. Early intervention aims to provide beneficial motor experience for infants at risk and promote neuromotor development. To detect infants' typical movements patterns in the natural environment, we are using wearable sensors to measure the characteristics of leg movements infants produce across days and relate movement experience to skill development.
Purpose: To determine whether one day is sufficient to represent an infant's typical performance, or more days are needed.
Methods: We used wearable sensors to collect 7 consecutive days of full-day leg movement activity, 7-13 hours per day, from 10 infants with typical development between the ages of 1-5

months. We identified each leg movement's average acceleration, peak acceleration and duration.
Results: Absolute difference between the average of first two days and the standards (average of seven days) of average acceleration, peak acceleration and duration dropped below 5% of the standard(3.8%, 4.4% and 3.3%). Wilcoxon signed rank test shows there is no significant different between the average of first two days and standards across all measurements (p=0.51, 0.80, 0.88).
Conclusions: The variability of leg movement kinematic data across seven days is visually within a limited range in infants with typical development. The results suggest it is better to collect data for two consecutive days. Our results will inform the clinical measurement of full-day infant leg movement for neuromotor assessment and outcome measurement purposes.

Abstract: The brainstem ocular motor neurons (OMNs) mediate eye movements and are differentially affected compared with other motor neuron (MN) groups in some disorders. Specific subsets of OMNs show disrupted or aberrant innervation in congenital cranial dysinnervation disorders (CCDDs). In contrast, OMNs continue to function in Amyotrophic Lateral Sclerosis (ALS), while spinal and other brainstem MNs degenerate. We aim to define the unique developmental gene expression patterns among OMNs, and generate a toolbox of genetic

markers to help study these disorders. We first used Islet-1:GFP and Hb9:GFP mice to isolate and compare seven distinct MN pools on embryonic days E10.5 and E11.5, via microdissection and fluorescence-activated cell sorting (FACS): the three ocular motor nuclei (CN3, CN4, CN6) and the other primary MN types (CN5, CN7, and CN9/10/12 in the brainstem, and spinal cord MNs). Pooled RNA-seq analysis was performed on each with Genesifter and DESeq2. Second, we evaluated the subpopulations within CN3, CN4, and CN6 across their embryonic development time course (E9.5 to E18.5) with single cell RNA-seq and the SEURAT analysis package. Gene expression was validated with database analysis and in situ hybridization. We co-labeled for BrdU/EdU after injection on different developmental days (E8.5-E11.5) to correlate the gene expression differences with cell age. Each MN population showed unique gene expression patterns, including novel markers of OMNs, providing a genetic fingerprint of developing MNs for future studies. Spatially- and temporally-distinct subpopulations were identified within the ocular motor nuclei, including a late-born caudal CN3 population that crosses the midline and may give rise to the superior division of the oculomotor nerve, selectively affected in some CCDDs. These data uncover distinct developmental gene expression patterns and markers of the various cranial motor neurons and provide new tools to study their selective vulnerability in the CCDDs.

Title: Examination of intrinsic and extrinsic programmed cell death in the superior cervical ganglion

Authors: C. L. KAMINSKI[1], L. B. SCHMIDT[2], *B. A. PIERCHALA[1]
[1]Biologic & Materials Sci., [2]Univ. of Michigan, Ann Arbor, MI

Abstract: During development, as many as half of all neurons produced in the peripheral nervous system undergo apoptosis. It is well established that competition for neurotrophic factors secreted by targets of innervation results in the death of unnecessary neurons during defined

developmental periods of programmed cell death (PCD). An extensive amount of research on the molecular mechanisms underpinning PCD has been performed on sympathetic neurons of the superior cervical ganglion (SCG) of mice and rats. The SCG is composed of neurons that are noradrenergic, express TrkA, and require NGF for target-dependent survival. The vast majority of PCD studies in the SCG examined total cell counts as a measure of PCD, concluding that cell death occurs between embryonic day 19.5 (E19.5) to postnatal day 3 (P3) in mice. However, to what extent these total cell counts compare to direct measurements of apoptotic neurons *in vivo* has not been well characterized. In this study we intend to establish a detailed time course of PCD, as well as neurogenesis, in the SCG. In C57/bl6j mice, we are counting tyrosine hydroxylase (TH) positive cells to measure the total number of neurons in the SCG, in addition to quantifying the number of apoptotic and mitotic neurons by measuring the number of cleaved caspase-3 (CC3) and Ki67 labeled neurons, respectively. These measurements will be performed from shortly after the SCG has fully coalesced at E17.5 through adulthood. Surprisingly, there is an extensive amount of PCD embryonically before the reported decline in SCG neurons, and a significant amount of apoptosis continues to occur postnatally after what is traditionally thought of as the period of PCD. Interestingly, neurogenesis continues into postnatal ages, potentially obscuring the total neuronal cell loss that has been reported in other studies. More recent investigations of SCG developmental cell death have pointed to the role of pro-apoptotic receptor mechanisms, raising the possibility that PCD occurs via both intrinsic pathways typically thought to underlie apoptosis through loss of trophic factor support, as well as extrinsic apoptotic cascades regulated by death receptors. By examining caspase-8, caspase-9 and Bax mutant mice as described above, we are determining to what extent intrinsic and extrinsic death pathways contribute to PCD in the SCG. Taken together, by utilizing multiple strains of mutant mice with cellular markers for PCD and neurogenesis, we will define the period of PCD in SCG neurons and build an understanding of how intrinsic and extrinsic mechanisms sculpt sympathetic neural circuits.

Title: Functional divergence of sensory responses in developing sensory and motor cortex

Authors: *L. J. GOMEZ[1], J. C. DOOLEY[2], G. SOKOLOFF[2], M. S. BLUMBERG[2]
[1]Neurosci., [2]Psychological and Brain Sci., Univ. of Iowa, Iowa City, IA

Abstract: In adult rats, primary motor cortex (M1) and primary somatosensory cortex (S1) are functionally distinct cortical areas. However, M1's motor functions emerge late in development and both M1 and S1 function initially as sensory structures. Therefore, before adulthood, M1 and S1 must functionally diverge, but when and how this divergence occurs is unclear. Previous work from our lab has demonstrated that, through the first postnatal week, both M1 and S1 neurons preferentially respond to sensory feedback from myoclonic twitches generated during active (REM) sleep; in contrast, sensory feedback from wake movements is largely absent. By postnatal day (P) 12, M1 neurons preferentially respond to wake movements and fewer neurons respond to twitches. Less is known about the responses of S1 neurons to self-generated movements at P12. Given the similarity of sensory responses in M1 and S1 at P8, we hypothesized that M1 and S1 neurons will become preferentially wake responsive by P12; we further hypothesized that this transition marks the onset of functional divergence between these structures. To test these hypotheses, we conducted dual extracellular recordings at P8 and P12. We recorded multiunit activity from the forelimb representations of M1 and S1 and compared activity within and between these areas across ages. At P8, M1 and S1 neurons display similar activity profiles and respond preferentially to sensory feedback from myoclonic twitches. By P12, M1 and S1 now respond preferentially to wake movements, although a higher percentage of S1 neurons are responsive than M1 neurons. Thus, M1 and S1 begin to functionally diverge when the sensorimotor cortex transitions from being twitch responsive to wake responsive. Although the early sensory feedback from twitches plays a similar function in M1 and S1 development, differences in wake-movement responses reflect differences in the function of sensory feedback from wake movements in these two cortical areas.

Title: Optical interrogation of V2a neurons reveals role in regulating cortical activity and sleep-wake behavior

Authors: *M. M. ISAAMULLAH[1], A. KUZHANDAIVEL[2], L. HOFFMAN[1], K. SHARMA[1]
[1]Anat. and Cell Biol., UIC COM, Chicago, IL; [2]Bioengineering, Univ. of Illinois - Urbana Champaign, Champaign, IL

Abstract: In the developing mammalian neural tube, the V2a class of neurons is generated throughout the brainstem and spinal cord. Many studies have revealed that the primary function of these neurons is in patterning of motor behaviors such as breathing (Crone et al., 2012), reaching (Azim et al., 2014) and locomotion (Crone et al., 2009). In this report we show that optical stimulation of V2a neurons at the mid-hindbrain junction produces quantifiable changes in cortical oscillations. We find that brief (1min) stimulation of these neurons produces 3-7Hz oscillations in the prefrontal cortex (PFC). Similar slow oscillations in the medial PFC are known to correlate with freezing behavior (Karalis et al., 2016). Long term (8h) stimulation of the same V2a neurons promotes wakefulness that is sustained for days after stimulation. These experiments were performed in double transgenic mice (*chx10*$^{+/cre}$ *Rosa*$^{ChR2\text{-}GFP/+}$; p62-p106) expressing channelrhodopsin (ChR2) in V2a neurons with a sample size of 8 animals for each experiment. Littermate controls undergoing identical procedures and stimulation protocols but lacking ChR2 showed no cortical or behavioral response with optical stimulation at mid-hindbrain junction. This study is unique in its examination of cortical oscillations with optical stimulation of V2a at the mid-hindbrain junction. These findings suggest that V2a neurons at the mid-hindbrain junction can potentially mediate motor behaviors and wakefulness by modulating slow oscillations in the PFC.

Title: The racgap b-chimaerin is essential for cerebellar granule cell migration

Authors: *J. A. ESTEP[1], W. WONG[2], Y.-C. WONG[2], A. TAFT[2], M. RICCOMAGNO[2]
[1]Cell Biol. and Neurosci., [2]Molecular, Cell, and Systems Biol., Univ. of California Riverside, Riverside, CA

Abstract: During mammalian cerebellar development, postnatal granule cell progenitors proliferate in the outer part of the External Granule Layer (EGL). Postmitotic granule progenitors

migrate tangentially in the inner EGL before switching to migrate radially inward, past the Purkinje Cell Layer, to achieve their final position in the mature Granule Cell Layer (GCL). Here, we show that the RacGAP b-chimaerin is expressed by a small population of late arriving, pre-migratory granule cells. b-chimaerin deficiency causes these cells to become arrested in the EGL, where they differentiate and form ectopic clusters of neurons. These clusters are mainly composed of granule cells and recruit aberrantly projecting mossy fibers. Collectively, these data suggest a role for b-chimaerin as an intracellular mediator of Cerebellar Granule Cell radial migration.

Title: Characterization of cell type specific ATG14 deletion in mice reveals distinct functions of PI3KC3 activity in the nervous system via autophagy dependent and independent pathways

Authors: *K. PURTELL[1], M. PRUVOST[2], N. M. WADE[3], Z. YUE[1]
[1]Neurol., Icahn Sch. of Med. at Mount Sinai, New York, NY; [2]Advanced Sci. Res. Ctr. at the Grad. Ctr. of The City Univ. of New York, New York, NY; [3]Perelman Sch. of Med., Univ. of Pennsylvania, Philadelphia, PA

Abstract: The class III phosphatidylinositol 3-kinase (PI3KC3) is required for macroautophagy, an essential lysosome-dependent degradation process that recycles large protein complexes and organelles to maintain cellular homeostasis. The catalytic subunit, VPS34, along with the scaffolding protein, VPS15 and the regulatory subunit, Beclin1 form the core complex which associates with either autophagy-related gene 14 (ATG14) or UVRAG in a mutually exclusive manner. ATG14-containing complexes are involved in autophagosome biogenesis whereas UVRAG-containing complexes are involved in vesicular trafficking. To investigate autophagy-specific functions of PI3KC3 in the brain, we knocked out ATG14 in neurons by crossing $ATG14^{flox/flox}$ mice with mice expressing Cre recombinase under the synapsin I promoter. This ATG14 conditional knock-out (CKO) resulted in a mixed neurodevelopmental and neurodegenerative phenotype characterized by developmental delay and motor dysfunction within 1 month, followed by progressive loss of motor function, hindlimb paralysis, seizures and early morbidity by 3 months of age. Neuron-specific ATG14 CKO animals have enlarged brains

and exhibit defective myelination of the corpus callosum. This is recapitulated in oligodendrocyte-specific ATG14 CKO mice, which points to a role for ATG14 in neuron-oligodendrocyte communication. In contrast to autophagy-deficient ATG7 CKO mice, ATG14 CKOs demonstrate a unique phenotype, which indicates a role for ATG14 outside the canonical autophagy pathway.

Title: Infant leg movement activity intensity prior and post sleep throughout a week

Authors: *I. A. TRUJILLO PRIEGO[1], I. F. WERNER[4], W. DENG[2], B. A. SMITH[3]
[1]Biojinesiology and Physical Therapy, [3]Div. of Biokinesiology and Physical Therapy, [2]USC, Los Angeles, CA; [4]Dept. of Sport Sci., Univ. of Innsbruck, Innsbruck, Austria

Abstract: ***Purpose/Hypothesis***
Movement activity in infancy is important to characterize as it allows infants to explore their movement repertoire, gain strength and improve their motor abilities. Young infants tend to produce frequent short bursts of high intensity leg movement activity when they are awake, interspersed with periods of napping. We hypothesized that infant leg movement activity intensity might be lower when infants are tired just before they fall asleep, followed by higher intensity post-sleep. Our purpose here was to characterize intensity of leg movement activity of infants with typical development prior and post sleep, across days.
Materials / Methods
Wearable sensor (Opals, APDM) data were collected in home from 10 infants with typical development (1 - 4 months of age) for 8-13 hours per day for 7 continuous days. Leg movements were identified as described in Smith et al. 2015. A custom made algorithm detected sleep events from the norm of tri-axial accelerometer and angular velocity time series. Events of sleep were defined as periods of time greater than 5 min with less than 3 leg movements. Once intervals of sleep were detected, periods of 20 min prior and post sleep were identified. Next, the resultant of acceleration of each 20 min period were calculated and low-pass filtered at a cutoff frequency of 9Hz. The absolute value of the filtered signal was used to calculate the area under the curve (AUC) for each 20 min period. Hence, AUC characterized leg movement activity intensity. All periods were visually checked for artefacts and manually corrected, leading to 234 total prior events out of 250 and 224 post events out of 237 taken into consideration for analysis. The median of the AUC of each day for each infant was calculated separately for prior and post sleep

events. AUC values were tested for normality. Repeated measures ANOVA (day, post to prior) was conducted to check for AUC differences with significance set at alpha =0.05.

Results

Repeated measures ANOVA revealed a trend towards higher intensity activity prior to sleep, $F(1,7) = 3.91$, $p = 0.089$, $\eta_p^2 = 0.358$. Eight of ten infants showed this phenomenon in the majority of days. Days showed no effect and no interaction, thus this trend was consistent throughout the 7 days of recording.

Conclusions

Preliminary results did not show a significant difference in intensity of leg movement activity before and after infant sleep periods across days. The observed trend in our results showed more vigorous activity prior to sleep, which was contrary to what we hypothesized. We will continue to analyze our data, and are also interested in expanding to other measures of fluctuation in leg movement activity across days.

Title: Inactivation of Fgfr1 and Fgfr2 in cerebellar glia

Authors: *L. RUBIN[1], A. PRUITT[2], K. M. SMITH[2]
[1]Biol., [2]Univ. of Louisiana at Lafayette, Lafayette, LA

Abstract: Fibroblast growth factors (Fgfs) are a family of 22 cytokines that bind to 4 receptors, many of which play a critical role in cortical development. Fgf ligands, including Fgf2, and the Fgfr1 and Fgfr2 receptors are expressed by astrocytes and astrocytic stem cell lineages of the developing and adult CNS. Previous studies have shown that fgfrs can have compensatory effects on proliferation and development. We have inactivated Fgfr1 and Fgfr2 in postnatal astrocytes by tamoxifen inducible Cre mediated recombination using the hGFAP-CreERT2 (GCE) transgene. We targeted postnatal astrocytes by administering injections of tamoxifen from P14-17, 60 mg/kg i.p. We tested locomotor behavior of the mice for 30 minutes in an open field. Double KO mice showed hypoactivity compared to control littermates. This was not expected given previous findings with Fgfr1 single mutants. No differences in memory were observed in the 1-day morris water maze but observed mobility impairments. It was previously shown that

Fgfr1 and Fgfr2 double KO starting at E13.5 lead to multiple cerebellar abnormalities. We compared control and Fgfr1/Fgfr2 double KO mice on a hindlimb clasping test as well as a gait analysis. We found double KO mice had significantly higher scores on these test (p=.001) and a decreased number of PV+ purkinje neurons (p=.0245), indicating an impairment in motor coordination and altered cellular features. Future work will examine cerebellar morphology. We will compare the effects of Fgfr1 single and Fgfr1/Fgfr2 double mutants upon PV neuron maturation, and postnatal hippocampal proliferation.

Title: Oculomotor nerve requires an early interaction with muscle precursors for proper growth and branching pattern

Authors: *B. M. BJORKE[1], G. ROBINSON[2], K. WELLER[2], T. GOULD[3], P. J. GAGE[5], G. S. MASTICK[4]
[1]Carleton Col., Northfield, MN; [3]Dept. of Physiol. and Cell Biol., [4]Cell and Mol. Biology, Neurosci., [2]Univ. of Nevada, Reno, Reno, NV; [5]Univ. of Michigan Kellogg Eye Ctr., Ann Arbor, MI

Abstract: Muscle function is dependent upon accurate motor nerve innervation. Motor nerves are composed of motor axons that innervate distinct muscle targets, yet travel in peripheral tissue as one compact nerve. A key transition point occurs during nerve development: following navigation through peripheral tissue, the fasciculated nerve halts further growth and initiates branching to innervate distinct muscle targets. The question of what guides this transition is particularly perplexing in nerves that do not interact with an apparent guidepost that directs the location of nerve targeting prior to branching. For the oculomotor nerve, targeting the eye muscles in embryonic mice, we discovered that a mass of muscle precursors acts to coordinate the nerve transitioning between nerve growth and accurate nerve branching. We find that the oculomotor nerve grows to the eye three days prior to the appearance of any eye muscles during which time it forms a plexus with muscle precursors. This plexus persists during primary

extraocular myogenesis.
To test the functional significance of the nerve-precursor plexus, we genetically ablated muscle precursors early in nerve development, prior to nerve contact. Muscle precursor ablation resulted in oculomotor nerve fibers failing to stop to form the plexus, but instead growing past the eye. In contrast, ablating the precursor pool at later stages, after the nerve has contacted the precursor cells, results in ectopic branching around the eye. These results demonstrate that muscle precursors are required for the oculomotor nerve to transition between nerve growth and distinct stages of terminal axon branching.

Abstract: *Monodelphis domestica* is a laboratory marsupial with unique advantages for neurodevelopmental studies over traditional models. At birth, *M. domestica* are developmentally similar to a 12.5-day old mouse embryo or 6-week old human embryo. The immaturity of the neonates makes this species an exceptional animal model for investigating high-risk events during embryonic development that may increase susceptibility to neurodevelopmental disorders like schizophrenia and autism spectrum disorder. However, there is little available

documentation of early brain development for this species. To address this gap in knowledge, we obtained sequential *M. domestica* brain preparations for anatomical studies during pre- and post-natal development. Here we present high-resolution images from Nissl-stained tissue sections of *M. domestica* brains throughout the lifespan: embryonic day 13.5, postnatal day (PND) 1, PND10, PND58 (weaned), PND149 (separated from siblings), and adult. Using image analysis software, we describe the general macroscopic and cytoarchitectural characteristics of different areas of the *M. domestica* brain across different developmental time periods. These descriptive findings open the door to use *M. domestica* as a novel model for studying environmental risk factors, such as influenza virus infections, that are linked to the subsequent development of schizophrenia.

Abstract: The traditional animal models used for neurodevelopmental studies employ rodents. In contrast to rodents, opossums are born at a developmental stage equivalent to a human embryo at 6 weeks of gestation and continue developing extra-uterine, allowing for easy manipulations of the brain. In our previous studies, we characterized the behavior of normally developing pups to establish memory and motor coordination, as these are significantly affected by various

developmental pathologies. The goal of the current study is to assess the characteristic sensorimotor and memory modalities during early development in Zika-inoculated pups and to compare them with PBS-inoculated pups. We hypothesized that Zika-inoculated pups would display major deficiencies in cognitive and motor behaviors. Male and female opossums were inoculated intra-cranially with a Brazilian isolate of the Zika virus or PBS at 0 to 8post-natal days. The initial behavioral assessment was conducted at 4 weeks of age. Animals have been or will be tested using the following behavioral tests: Open Field (4-6 weeks), Object Recognition (8 weeks and 6 months), Rotarod (6 months), Barnes Maze (6 months) and Beam Balance (8 months), and behaviors are recorded and quantified using Any-maze software (Stoelting). Zika-inoculated pups did not show any gross anatomical abnormalities in head development. We have completed the Open Field test at 4 and 6 weeks of development. Exploratory behavior and locomotor activity have been measured by distance traveled, number of lines crossed, and overall time in the center of the arena. Results indicate that Zika-inoculated females have increased locomotor activity compared to Zika-inoculated males and to both sexes of PBS-inoculated pups. At 6 weeks, Zika-inoculated males and females spend, on average, half the amount of time in the center of the open field compared to PBS-inoculated males and females, suggesting increased anxiety-like behaviors. These data suggest that the virus affects different brain areas in males compared to females. The data obtained from this study will serve to examine the effects that prenatal infection with Zika virus can have on the central nervous system of infected subjects. We propose that the *M. domestica* can become a critical and unique model for assessing developmental abnormalities resulting from brain insults, such as Zika virus infection in the early stages of brain development.

Title: Monoaminergic inputs to Mushroom Body (MB) output neurons extend flight bout durations in *Drosophila melanogaster*

Authors: *S. B MANJILA[1], M. KURUVILLA[1], J.-F. FERVEUR[2], S. SANE[1], G. HASAN[1]
[1]Natl. Ctr. For Biol. Sci., Bangalore North, India; [2]Univ. Of Burgundy, Dijon, France

Abstract: Insect flight is a complex behaviour that requires the integration of multiple sensory inputs with the motor output. Flight defects can arise from either the inability to sense stimuli, from incorrect information processing in the interneurons or due to malfunctions in the motor output. Here we have studied a catecholaminergic circuit in the central brain, which helps maintain longer flight durations in *Drosophila melanogaster*. Longer flight durations are essential for reaching fresh sources of food, finding a mate and identifying suitable places for depositing eggs in the fly's natural environment. Independent studies previously have shown that *Drosophila* flight can be modulated by monoamines like octopamine, dopamine and serotonin as well as several neuropeptides. Both dopamine and octopamine (analogous to vertebrate norepinephrine) act as a neuromodulator as well as a neurotransmitter in invertebrates. Earlier we had shown that maintenance of flight for long durations requires the Protocerebral Anterior Medial (PAM) cluster of central dopaminergic neurons which project to MB[1]. Based on the contextual cues, dopaminergic inputs can modify MB output[2]. In this study, we try to understand the major octopaminergic and dopaminergic neurons that finally feed in to the MB and alter MB output to maintain long durations of flight. Using genetic tools to perturb neuronal activity, we identified subsets of central brain monoaminergic neurons required for flight. Acute perturbation of activity in MB output neurons, which receive inputs from specific dopaminergic neurons also resulted in decreased flight bout durations. Our data support a model where this octopaminergic-dopaminergic circuit feeding into the MB, help generate a contextually relevant flight motor output. In vertebrates, basal ganglia (BG) act as an action selection centre based on the inputs received from different regions of the brain, mainly the cortex[3]. Our studies suggest that MB can also act as a context dependent action selection centre like BG in addition to its role in learning and memory, which results in a contextually relevant motor output like longer flight durations.

Abstract: BACKGROUND AND PURPOSE:
The rapid emergence of synthetic cannabinoids (SCs) as drugs of abuse poses a significant challenge to health care systems and policymakers worldwide. The morbidity and mortality associated with SC use highlights the need for a deeper understanding of the mechanisms underlying their toxicity. We have used a novel approach to determine the efficacy of SCs at CB1 receptors by using receptor depletion with the irreversible CB1 antagonist AM6544 and the Black and Leff operational model to calculate values of relative efficacy.
EXPERIMENTAL APPROACH:
Studies were carried out in mouse AtT20 neuroblastoma cells stably expressing human CB1. Receptor depletion was achieved following pre-treatment of cells with AM6544 (10 μM, 60 mins). We used membrane potential dye to measure CB1-mediated hyperpolarisation produced by activation of native G protein-gated K channels in the AtT20 cells. From the operational model, the efficacy (tau, or inverse of receptor occupancy needed to produce 50% of the maximal effect) and affinity (K_A) parameters were obtained for each drug.
RESULTS:
Pretreatment with AM6544 had no effect on the potency or maximal effect of native somatostatin receptor-induced hyperpolarization as compared to untreated cells (Control, pEC_{50} 9.13 ± 0.05, E_{max} 38 ± 1%; AM6544 treated pEC_{50} 9.18 ± 0.04, E_{max} 39 ± 0.7%). Pretreatment with AM6544 reduced the maximal response of the reference CB1 agonist CP 55,940 (6.43), which represents a loss of 94% of the receptors. In undepleted cells, CP55940 has a tau of 91, in comparison, the tau for THC was 1.33. The highest efficacy SC tested, 5F-MDMB-PICA, had a tau of 314. Interestingly, most of the SCs tested (JWH018, AM2201, WIN55,212, PB-22, 5F-PB-22, UR144, XLR11, AB-CHMINACA, AB-PINACA and 4 cyano-CUMYL-BUTINACA) had approximately 50 % of the efficacy of CP 55,940. However, there was no correlation between the affinity of SCs and their efficacy ($r^2 = 0.06$, $P > 0.05$), the SCs with highest affinity, 4 cyano-CUMYL-BUTINACA (pK_A 7.61) and AB-CHMINACA (pK_A 7.60) had tau of 45 and 42 respectively.
CONCLUSION AND IMPLICATIONS:
This study is the first to calculate the efficacy of wide range of SCs using Black and Leff operational model. We found that AM6544 did not interfere with SRIF receptors or their shared signalling pathways with CB1 reinforcing the idea that AM6544 is a specific, irreversible antagonist of CB1 receptor. There was no correlation between efficacy and affinity, or efficacy

and the emergence of SCs on the market. There was no obvious relationship between efficacy and reported toxicity of SCs, so toxicity could arise from yet unappreciated biased signalling or non-CB1 mediated effects.

Title: Impairments in behavior and hippocampal synaptic function in the trace amine-associated receptor 2 knockout mouse

Authors: *A. G. ALMONTE[1], A. L. DEAL[2], J. K. KONSTANTOPOULOS[2], J. L. WEINER[1], E. A. BUDYGIN[2]

Abstract: Trace amine-associated receptor 2 (TAAR2) is a member of a family of G-protein coupled receptors that are activated by a class of biogenic amines called trace amines, which are present at nanomolar concentrations in the brain and periphery. While previous work suggests that TAAR2 is expressed in olfactory sensory neurons and may function as a chemosensory receptor, little is known about TAAR2 expression and function in other brain areas. Here, we characterize a TAAR2 knockout mouse line in which the TAAR2 gene is deleted and replaced with a lacZ reporter. We show reporter expression in various brain regions, in particular the hippocampus. We also assessed a battery of behaviors and performed a screen of hippocampal neurophysiological function. We show that TAAR2 KO mice have increased locomotor activity in the open field arena, impaired performance in the novel object recognition task, and increased immobility time in the tail suspension task. Extracellular field potential recordings at hippocampal Schaffer collateral-CA1 synapses reveal differential effects of TAAR2 deletion along the dorsoventral axis. In the dorsal hippocampus, TAAR2 KO mice show normal baseline synaptic transmission, but impaired induction of long-term potentiation (LTP). In the ventral

hippocampus, however, TAAR2 KO mice show decreased baseline synaptic transmission and normal LTP induction. Notably, our observations of deficits in the novel object recognition task and in LTP induction in the dorsal hippocampus are consistent with the known roles of this region in encoding this type of declarative memory. Together, these behavioral and neurophysiological phenotypes suggest novel roles for TAAR2 function in modulating behavioral output, synaptic function, and the induction of synaptic plasticity.

Abstract: Dopamine input to the dorsal and ventral striatum originates from separate populations of midbrain neurons. Despite differences in afferent inputs and behavioral output, little is known about how dopamine release is encoded by dopamine receptors on medium spiny neurons (MSNs) across striatal subregions. Here we examined the activation of D2 receptors following the synaptic release of dopamine in the dorsal striatum (DStr) and nucleus accumbens (NAc) shell using viral overexpression of a G-protein coupled inward rectifier potassium (GIRK)

channel. We found that D2 receptor-mediated synaptic currents were slower in the NAc and this difference occurred at the level of D2-receptor signaling. D2 receptors on MSNs demonstrated higher sensitivity for dopamine in the NAc. Deletion of two regulators of G-protein signaling (RGS7/9) slowed D2-receptor mediated signaling to a similar extent in both regions, but had no effect on dopamine sensitivity. We found that the regional difference in sensitivity of D2 receptors for dopamine was due to preferential coupling to Gαo in the NAc. These results identify differences in the sensitivity and timing of D2-receptor signaling across the striatum that influence how nigrostriatal and mesolimbic signals are encoded across these circuits.

Title: Beta-arrestins regulate mglu7 function by Nedd4-mediated ubiquitination

Authors: S. LEE, S. PARK, H. LEE, *Y. SUH
Dept. of Biomed. Sci., Seoul Natl. Univ. Col. of Med., Seoul, Korea, Republic of

Abstract: Metabotropic glutamate receptors (mGlu receptors) are G protein-coupled receptors (GPCRs) that regulate synaptic transmission and neuronal excitability via downstream signaling cascades. Because abnormal regulation of mGlu receptor function is implicated in a number of neurological and psychiatric disorders, mGlu receptors are emerging as therapeutic targets in neuroscience field. Previously, we reported that SUMOylation at Lys889 on mGlu7, a member of Group III mGlu receptors regulates mGlu7 trafficking in neurons. In this study, we have further investigated the regulatory mechanism by ubiquitin-mediated modification on mGlu7, as there are several potential residues that can be modified by ubiquitination at the intracellular loops and the C-terminus of mGlu7. We found that mGlu7 is ubiquitinated via beta-arrestin 1-mediated Nedd4 recruitment in an activity-dependent manner. Ubiquitination regulates mGlu7 function not only by facilitating receptor endocytosis and degradation, but also by regulating mGlu7-mediated MAP kinase signaling. Given the importance of in-depth knowledge of the

precise mechanisms of receptor function for more elaborate therapeutic approaches, our findings will contribute to the improvement of therapeutic targets of mGlu7.

Title: Characterization of N-linked glycosylation of metabotropic glutamate receptor 7

Authors: *D.-H. PARK, Y. SUH
Dept. of Biomed. Sci., Seoul Natl. Univ. Col. of Med., Seoul, Korea, Republic of

Abstract: Metabotropic glutamate receptor 7 (mGlu7) has been shown to mediate excitatory synaptic neurotransmitter signaling and plasticity in the mammalian brain and is implicated in multiple neuropsychiatric disorders. Therefore, it is important to understand trafficking mechanism of mGlu7 from the ER to presynaptic terminal. A series of studies have reported that extracellular N-linked glycosylation modulates receptor surface expression and receptor-protein interactions in the central nervous system. Using biochemistry and confocal imaging technology, we have investigated the pattern and effects of N-glycosylation of mGlu7 in HEK 293T cells and rat cultured neurons. We identified that mGlu7 has four N-linked glycosylation residues in its extracellular domain, all of which tend to be glycosylated at similar levels. We found that mutations in the N-glycosylation sites of mGlu7 lead to a marked reduction of receptor surface expression, retention of receptors in the ER, and degradation of mGlu7 via the lysosomal degradation pathway. We also explore the possibility that N-linked glycosylation may regulate the proper localization of mGlu7 in the presynaptic active zones. Taken together, these data support that N-linked glycosylation of mGlu7 contributes to receptor trafficking, stability, and synaptic localization of mGlu7 in neurons.

Title: Inhibitory elements in the promoter region of mouse lysophosphatidic acid receptor gene Lpar1

Authors: H. PARK, N.-H. KIM, *A. SADRA, S.-O. HUH
Pharmacol., Hallym Univ., Chuncheon, Korea, Republic of

Abstract: Lysophosphatidic acid (LPA) is a prominent endogenous lysophospholipid with signaling properties outside the cell. It signals through specific G protein-coupled receptors, known as LPA1-6. For one of its receptors LPA1 (gene name Lpar1), details on the cis-acting elements for transcriptional control have not been defined. Using 5'RACE analysis, we report the identification of an alternative transcription start site of mouse Lpar1. We also characterized approximately 3,500bp of non-coding flanking sequence 5' of mouse Lpar1 gene. In mouse neocortical neuroblasts with constructs from the 5' regions of mouse Lpar1, it is revealed that the region between -248 to +225 serves as the basal promoter for Lpar1. We also found that the 5' proximal promoter region lacked a TATA box. The region between -761 to -248 contains a negative regulatory element affecting the basal expression of Lpar1. This region possesses three E-box sequences. Mutagenesis of these E-boxes and transient expression demonstrated that two of the E-boxes are negative modulators of Lpar1. One of these binds the HeLa E-box binding protein (HEB), and modulation of HEB levels in transfected cells regulates the transcription of the reporter gene. Based on our data, we propose that HEB may be required for a proper regulation of Lpar1 expression in the model cells as to affect its functions in both normal brain development and disease settings.
Significance statement
Regulation of the expression of Lpar1, the major receptor for the bioactive lipid LPA, is characterized in this research by defining the cis-acting negative regulatory elements. LPA/Lpar1 axis is required for normal brain development and the role of HEB E-box protein is explored here.

Title: NECAB1 and NECAB2 are the two major calcium-binding proteins of the CB_1 cannabinoid receptor-positive GABAergic interneuron population in the neocortex, hippocampus and the basolateral amygdala

Authors: *J. R. GLAVINICS[1,2], V. MICZÁN[1,2], K. KELEMEN[1,3], Z. LÁSZLÓ[1,4], I. KATONA[1]
[1]Inst. of Exptl. Medicine, HAS, Budapest, Hungary; [2]Fac. of Information Technol. and Bionics, Pazmany Peter Catholic Univ., Budapest, Hungary; [3]Univ. of Med. and Pharm. of Tirgu Mures, Tirgu Mures, Romania; [4]Sch. of PhD Studies, Semmelweis Univ., Budapest, Hungary

Abstract: Most GABAergic interneuron types can be distinguished based on their calcium-binding protein expression profiles. However, surprisingly, to date no specific EF-hand calcium-binding proteins have been described in CB_1 cannabinoid receptor-positive interneurons, which represent a major population of GABAergic cells throughout the forebrain. Since calcium buffering has a fundamental role in shaping various neuronal functions, we investigated whether this interneuron family expresses yet undetected calcium-binding proteins. *In silico* analysis of a publicly available single-cell RNA-sequencing database (Zeisel et al., 2015, Science, 347:1138-42), in situ hybridization, immunofluorescence staining and confocal microscopy were used to identify the EF-hand calcium-binding proteins expressed by the CB_1-positive interneurons. *In silico* analysis uncovered high mRNA expression levels of the N-terminal EF-hand calcium binding proteins 1 and 2 (NECAB1 and NECAB2) in the CB_1-positive hippocampal interneuron population. We confirmed that the majority of CB_1-positive cells indeed expressed NECAB1 and NECAB2 mRNA at high levels by using RNAScope multiplex fluorescent in-situ hybridization assay in hippocampal mouse brain slices. To verify these findings at the protein level, we performed CB_1 and NECAB1 or NECAB2 double fluorescent immunostainings, which revealed high abundance of these calcium binding proteins in CB_1-positive interneurons throughout the neocortex, hippocampus and the basolateral amygdala. Finally, after biocytin-labeling and morphological characterization of perisomatic and dendritic CB_1-positive interneurons in the CA1 subfield of the hippocampus, we found that NECAB1 tends to be present primarily in the somatodendritic compartment, whereas NECAB2 has a higher density in the axon terminals.

Taken together, the present observations demonstrate that NECAB1 and NECAB2, two previously uncharacterized calcium-binding proteins are highly expressed by CB_1-positive interneurons in the hippocampus, neocortex and basolateral amygdala. Moreover, the results also support the possibility that the different calcium-binding protein profiles of the major interneuron types play specific roles in controlling the distinct physiological properties of these GABAergic interneurons.

Title: Receptor density and distribution of 5-HT_2 receptors in the cingulate cortex and fusiform gyrus in autism: A multiple concentration saturation binding study in children and adults

Authors: *C. BRANDENBURG[1], G. J. BLATT[1], D. SIDIBE[2]
[1]Hussman Inst. For Autism, Baltimore, MD; [2]Hussman Inst. for Autism, Baltimore, MD

Abstract: Background: Although SSRIs are among the most commonly prescribed medications in autism, several studies show variable efficacy during SSRI use. Some of this variability may be a result of differential expression of serotonin (5-HT) receptors across individuals. A previous single concentration autoradiographic study from our laboratory showed decreased 5-HT_2 receptor binding in postmortem sections in the superficial layers of the posterior cingulate cortex (PCC) and the fusiform gyrus (FG) in autism and control cases. 5-HT_2 receptors are G-protein coupled receptors that are located mostly postsynaptically in limbic regions such as the anterior cingulate cortex (ACC) and PCC as well as in some neocortical areas including the FG. In autism cases, all three cortical areas were also shown to have decreased GABA-ARs and GABA-BRs in previous studies. Objective: Determine differences in 5-HT_2 receptor density and affinity between autism and neurotypical individuals through a saturation binding assay. Methods: Utilizing a large cohort of postmortem brain tissue, a saturation binding assay was conducted on 20µm sections from the ACC, PCC and FG (n=16-19 autism, n=18-19 controls) by incubation

with ^{3}H ketanserin (Perkin Elmer) at concentrations of 120, 90, 30, 9, 3, 1.5 and 0.5 nM then loaded into X-ray cassettes with tritium standards and tritium-sensitive hyperfilm. Non-specific binding was determined with a competitive displacer (Ritanserin 100µM). After exposure, films were developed and digitized to quantify ligand binding in femtomoles per milligram of tissue in superficial and deep layers of each region. A Welch's t-test was utilized for statistical analysis. Results: $5HT_2$ receptor density and affinity in the ACC, PCC and FG did not have statistically significant binding density differences between total autism and control cases. However, when the cases were grouped into children (≤16) (n=8-9) and adults (>16) (n=9) the superficial and deep layers of the adult ACC showed a significantly lower B_{max} in the autism cases (p=0.040 and p=0.050). No differences were seen in the PCC or FG. Conclusion: A Cochrane review concluded that SSRI use has variable efficacy in autism, with adverse effects infrequent in adults but significant in children. Our cohort of data is consistent with this finding, in that children in the autism group did not show differences in receptor number or affinity, but adults with autism had lower mean levels of binding suggesting that SSRIs may be useful in such cases. Comparison of $5HT_2$ expression to other potentially altered 5HT receptors in these cases will provide useful insight into how the 5HT system may be differentially impacted.

Abstract: It´s generally accepted that pallidal neurons does not express CB1 receptors, whereas recent evidence indicates CB2 receptors in Globus pallidus (GPe) in primates. Here we explore the existence of mRNA of CB1 and CB2 receptors in pallidal neurons of the mouse, their expression and function in pallido-pallidal terminals. We made RT-PCR experiments in slices and primary neural cultures of globus pallidus from 12-14 days old mouse. Typical bands corresponding to CB1 and CB2 receptors were found. Immunochemical studies shown an intense mark corresponding to CB1 and CB2 receptors in the same neurons. To evaluate the presence in terminals we decided to perform functional tests through electrophysiological recordings in C57

mouse GPe slices using patch-clamp whole-cell recordings with pharmacology. Recording evoked inhibitory postsynaptic currents (eIPSC) using a stimulus train protocol (5 pulses at 20 Hz) for test intranuclear axon collaterals (GPe-GPe), we evaluate the function of these receptors in the modulation of GABA release. GPe-GPe synapses were characterized by activity-dependent depression. Once the synaptic terminal was characterized, we recorded the basal current for 5 minutes, then, for 15 minutes, we administered agonists of CB1 (ACEA 100 nM) and CB2 receptors (GW833972A 100 nM) observing a decrease in the amplitude of the eIPSCs by almost 40% for CB1 (n = 26 neurons) and 20% for CB2 (n = 16 neurons) associated with a presynaptic effect since the ratio (pulse rate x/pulse1) changed significantly. Selective CB1 and CB2 AM 251 and AM 630 blocked respectively the effects indicating a receptor mediated effect. These data indicate the presence and functionality of CB1 and CB2 receptor on pallido-pallidal terminals.

Title: Interaction between type-2 corticotropin releasing factor and D1 dopaminergic receptors in the amygdala-prefrontal cortex transmission

Authors: *H. E. YARUR, I. M. VEGA-QUIROGA, K. GYSLING
Pontificia Univ. Catolica de Chile, Santiago, Chile

Abstract: The prefrontal cortex (PFC) is a brain area involved in working memory, attention and goal directed behavior. Stressful events could modify the animal behavior, affecting the performance of working and/or emotional memories. Neuronal activity in PFC is reduced when stressful events occur (García et al, 1999). One of the brain areas which projects heavily to the ventral region of the PFC and that has been implicated in sending crucial information about emotional stimuli to the PFC, is the basolateral amygdala (BLA) (LeDoux 2000). Maroun and Richter-Levin (2003), showed that acute stressful stimuli can block the induction of plasticity between the BLA and the PFC. Corticotrophin releasing factor (CRF) is a central regulator of endocrine and behavioral responses to stressors. We have observed that type-2 CRF receptor (CRF2) modulates the transmission of BLA to PFC. There is also evidence showing that D1 and D2 dopamine receptors (D1R and D2R) modulate neuronal transmission in BLA-PFC synapsis

(Floresco and Tse 2007). Furthermore, it has been shown that CRF and dopamine act synergistically to regulate the BLA to PFC synapsis (Orozco-Cabal et al, 2008). Thus, we decided to further study whether CRF2 and D1R regulate synaptic transmission between BLA and PFC. To this end, we performed *in vivo* microdialysis experiments in anesthetized rats in which the BLA was stimulated by a depolarizing solution and PFC extracellular levels of glutamate and dopamine were analyzed, in the presence or absence of pharmacological antagonists for CRF2 and dopamine receptors. The results show that CRF2 antagonist increased the extracellular levels of glutamate and decreased the dopamine levels in PFC induced by BLA stimulation. The CRF1 antagonist did not modify glutamate levels but increased significantly dopamine levels in the PFC after BLA stimulation. The combination of D1R and CRF2 antagonists blunted the increase of PFC glutamate levels induced by BLA stimulation. The results suggest that CRF2 exerts control of the BLA transmission over PFC and that modulates the dopaminergic component in the BLA-PFC transmission.

Title: D3/D3nf isoform expression determines the functional response to D3 receptor activation on cAMP formation and [^{3}H] GABA release in the striatum

Authors: *B. CAMPOS[1], J. AVALOS-FUENTES[2], C. PIÑA LEYVA[3], F. PAZ-BERMÚDEZ[2], D. ERLIJ[4], G. B. FLORAN[5]

Ctr. Col. of Med., Brooklyn, NY; [5]CINVESTAV IPN, Mexico DF, Mexico

Abstract: The functional response to the activation of dopamine D3Rs can be mediated by two different signaling pathways: In one, designated as "typical", the receptors couple with Gi proteins and inhibit the activity of adenylyl cyclase and the formation of cAMP. In the other, the "atypical", the receptors stimulate Gs mediated responses when D1Rs are co-activated, further increasing adenylyl cyclase activity. It has been suggested that the abundance of the non-functional isoform of the D3R called D3nf, determines the density of D3Rs in the plasma membrane. In the substance nigra pars reticulata, the signaling of the D3R normally is "atypical" but becomes "typical" during experimental Parkinson. In this study we determined whether the two modalities of signaling are correlated with the relative expression of the D3R and D3nf

isoforms during experimental Parkinson.
We induced hemiparkinsonism in adult Wistar male rats by the unilateral administration of 6-OHDA in the middle forebrain bundle. Using Real-Time qRT-PCR, we found a decrease in D3nf isoform mRNA expression in the lesioned striatum. Western Blot determinations showed that D3nf protein levels were also decreased in the lesioned side. This decrease in the relative expression of the D3nf isoform was accompanied by a change in the functional response to D3R activation. In the control hemisphere, activation of D3Rs potentiated the formation of cAMP and [^{3}H] GABA release induced by activation of D1Rs depolarized with high K^+, i.e., it induced an "atypical" response. In contrast, in the denervated hemisphere the activation of D3Rs inhibited the formation of cAMP and [^{3}H] GABA release stimulated by D1R activation. These data indicate that the relative expression of D3Rs and D3nf isoform correlates with the functional response produced by activating D3Rs. This response is probably mediated by changes in the number of receptors located in the membrane.

Title: The role of PAR-1 activation in sharp wave ripple event frequency

Authors: *P. BOZZELLI[1], P. LI[3], S. VILLAPOL[2], J.-Y. WU[1], K. CONANT[1]
[1]Neurosci., [2]Departament of Neurosci., Georgetown Univ., Washington, DC; [3]Pediatrics, Sun Yat-Sen Mem. Hospital,Sun Yat-Sen Univ., Guangdong, China

Abstract: Protease-activated receptor 1 (PAR-1) is unique amongst G-protein-coupled receptors in that it is activated through proteolytic cleavage of its N-terminus by various extracellular enzymes. Previous work has shown that PAR-1 is critical for NMDA-receptor-mediated long term potentiation (LTP) and hippocampal-dependent memory. Through in situ hybridization, we observe that PAR-1 is prominently expressed in the CA2 region of the hippocampus. PAR-1's involvement in hippocampal-dependent memory tasks has been well established; however, given that CA2 and its associated circuitry are involved in sociability and anxiety, we seek to evaluate these behaviors in WT and PAR-1 knock-out mice. Both CA1 and CA2 are involved in

triggering sharp-wave ripples (SWRs), which are highly synchronous neuronal population events; therefore, we have sought to determine whether PAR-1 activation, through distinct activating enzymes, is involved in SWR event frequency. PAR-1 is canonically activated by the serine protease thrombin; however, a subset of the matrix metalloproteinase (MMP) class of enzymes, MMPs -1, -3, and -13, are also able to activate the receptor through cleavage of the N-terminus at non-canonical sites. Through local field potential recordings, we are able to evaluate whether PAR-1 activation, by canonical and non-canonical peptide agonists, results in a disruption to SWR event frequency. Preliminary data reveals that both MMP- and thrombin-generated peptide agonists alter SWR event frequency. This work has clinical implications in that the PAR-1-activating proteases are upregulated in diseases/injuries such as neuroHIV infection and stroke, and that aberrant activation of PAR-1 may underlie certain brain dysfunctions.

Title: Role of serotonin in the neuromodulation of layer 5 neurons in rat prefrontal cortex

Authors: *R. RAMA
Inst. of Neurosci. and Med. 2 And10, Jülich, Germany

Abstract: Serotonin (5HT) is a key neurotransmitter that can modulate both excitatory and inhibitory synaptic neurotransmission through differential activation of its receptor subtypes. Neuronal activity within prefrontal cortex (PFC) is modulated by the activation of specific 5HT receptors, 1A and 2A ($5HT_{1A}R$, $5HT_{2A}R$), which are coupled to $G_{i/o}$ and G_q proteins, respectively. Activation of 1A reduces the excitability by inducing hyperpolarisation (HP) whereas, activation of 2A enhances excitability by inducing depolarisation (DP). A correct balance between excitation (E) and inhibition (I) is important for brain function. Disruption in the E/I balance is thought to be involved in several neuropsychiatric disorders including autism and schizophrenia. Results: Here, we have investigated role of 5HT in layer 5 (L5) of PFC using whole-cell patch-clamp recordings with simultaneous biocytin fillings. Based on the neuronal morphology and action potential firing pattern, we identified two major types of pyramidal cells (PCs): 1) broad tufted PCs with apical dendrites with many terminal branches and 2) slender

tufted PCs with only few tuft dendrites. As individual PCs express both $5HT_{1A}R$ and $5HT_{2A}R$, we hypothesized that 5HT has the ability to modulate E/I balance in PFC. A majority (80%) of PCs showed DP (4.0 ± 1.9, n=22) while a minority (20%) showed HP (1.6 ± 0.2, n=5) with 5HT application. Notably, the extent of DP significantly different between broad (3.0 ± 1.2, n=9) and slender (6.2 ± 2.3, n=12) tufted PCs. $5HT_{1A}R$ agonists in presence of a $5HT_{2A}R$ antagonist induced a HP in DP neurons. Similarly, $5HT_{2A}R$ agonists in presence of $5HT_{1A}R$ antagonists induced a DP in HP neurons. Discussion: 5HT facilitates DP in one set and HP in another set of PCs. The overall 5HT response results from an interaction between inhibition and excitation mediated by $5HT_{1A}R$ and $5HT_{2A}R$ respectively. The net DP response in one set is due to a dominant $5HT_{2A}R$ activity while the net HP in the other set of PCs is a result of predominant $5HT_{1A}R$ activity. Its already known that $5HT_{1A}R$ and $5HT_{2A}R$ largely (80%) co-localise in rat and mice PFC and our data further confirm these findings at a single cell level. Further, slender tufted PCs showed a greater DP 5 HT response than broad-tufted PCs. This differential response may be related to their distinct projections to cortical and subcortical structures. However, additional studies will be required to characterize the neuronal connectivity between PCs and these brain structures.

Title: Additive effects of allosteric ligands acting at distinct sites on muscarinic acetylcholine receptors: Signal shaping

Authors: *J. ELLIS, G. ELMSLIE
Psychiatry and Pharmacol., Penn State Univ., Hershey, PA

Abstract: It is known that muscarinic acetylcholine receptors possess multiple distinct allosteric sites (Lazareno et al, 2000, Mol Pharmacol 58:194). We have recently reported that amiodarone and dronedarone interact with their own novel allosteric site on these receptors (Stahl et al, 2011, Mol Pharmacol 80:378; Jayasuriya et al, 2017, Pharmacol 99:128). Interestingly, the major effect of amiodarone is to enhance the maximal degree of response elicited by acetylcholine and other agonists, without significantly altering the potency of the agonist. Most muscarinic positive allosteric modulators (PAMs) act by enhancing the potency of agonists without affecting the maximal effect evoked. Dronedarone displays mixed effects on muscarinic responses. The

orthogonality of the effects elicited (i.e., changes in maximal response on the y-axis vs changes in potency on the x-axis) allows a clear demonstration of the simultaneous binding of different allosteric modulators to their distinct sites. For example, the negative modulator tacrine shifts the dose-response curve for acetylcholine to the right; pairing appropriate concentrations of tacrine and amiodarone leads to the enhancement of response at high concentrations of acetylcholine at the same time that responses to low concentrations are inhibited. Pairing of different ligands produces the opposite effect. Because of this ability to differentially modify the low and high ends of the concentration-response curve, we have named this modulation "*signal shaping*". It is likely that neurotransmitter levels differ at different locations in the synapse. For example, it is known that transmitter spillover exerts effects at relatively distant sites, but the concentration at those sites will necessarily be significantly lower than at the post-synaptic receptors within the original synapse. Similarly, presynaptic autoreceptors and postsynaptic receptors may be exposed to different concentrations of transmitter. The effect of signal shaping, as described above, occurs in the sense that responses above a certain magnitude are enhanced, while responses below that magnitude are reduced, or vice versa. We speculate that signal shaping may provide a novel means to regulate the ratio of extra-synaptic (spillover) to intra-synaptic signaling, or of presynaptic to post-synaptic signaling.

Title: D2 receptor upregulation in accumbens cholinergic interneurons: Effects on pause duration and associative conditioning

Authors: *E. F. GALLO[1], E. TEBOUL[2], B. AKDOGAN[3], N. ZARRELLI[3], B. COTTEN[5], P. D. BALSAM[6], J. A. JAVITCH[4], C. KELLENDONK[3]
[1]Psychiatry, Columbia University/NYSPI, New York, NY; [2]New York State Psychiatric Inst., New York, NY; [4]Psychiatry and Pharmacol., [3]Columbia Univ., New York, NY; [5]Barnard Col., New York, NY; [6]Barnard Coll Columbia Univ., New York, NY

Abstract: Alterations in striatal dopamine D2 receptor (D2R) availability are associated with several neuropsychiatric disorders that feature motivational dysfunction. Cholinergic interneurons (CINs), which express D2Rs, account for 2-3% of the striatal cell population, but

exert widespread control over striatal circuit function. *In vivo*, CINs exhibit a dopamine-dependent pause in firing activity in response to reward-related stimuli that is deemed critical for cue-reward associations. *In vitro* studies have implicated the D2R in mediating the dopamine-dependent pause recorded in CINs. However, conventional pharmacological tools are limited in their ability to disentangle the specific contribution of CIN D2Rs to the pause and to associative learning given that other cell types that operate within striatum to process reward also express D2Rs. Because reward-related cues are known to evoke increases in phasic dopamine release in the NAc, we sought to determine whether increased D2R expression in CINs alters their response to dopamine release. To this end, we expressed D2Rs or EGFP in CINs of the NAc while expressing ChR2 in midbrain dopamine neurons using a ChAT-Cre x DAT-Cre mouse line. Using acute slices, we measured the duration of the pause in CIN firing evoked by 20 Hz optogenetic stimulation of dopamine afferents. CINs overexpressing D2Rs showed a significant pause elongation compared to EGFP-expressing CINs (D2R: 2.18 ± 0.28 s, n = 22; EGFP: 0.77 ± 0.11 s; $p < 0.005$, n = 20), without altering the average interspike interval. Blocking D2Rs with sulpiride abolished the pause in both conditions, indicating that D2Rs are necessary for the light-evoked pause in CINs. We then tested whether D2R upregulation in CINs leads to alterations in associative learning using a Pavlovian conditioning task in which animals are presented a brief 8-s conditioned stimulus (CS) that predicts reward. We found that both EGFP and D2-expressing mice increased their rates of responding to the CS (head entries/s) similarly over 16 days, suggesting that associative learning is unaltered. However, analysis of the response patterns during the 8-s CS, revealed that, unlike controls which increased responding in the later phases of the 8-s cue (i.e. closer to reward delivery), D2R overexpressing mice showed sustained responding across the duration of the cue, reflecting an alteration in temporal control over conditioned responding. These results indicate that D2Rs expressed in CINs of the NAc are important regulators of pause duration, and raise the possibility that the D2R-dependent pause elongation leads to alterations in appropriate responding to reward-related cues.

Title: Muscarinic receptor isoforms differentially regulate pyramidal neuron excitability within layer VI of the mouse medial prefrontal cortex

Authors: A. V. PATEL, *C. D. BAILEY
Dept. of Biomed. Sci., Univ. of Guelph, Guelph, ON, Canada

Abstract: Pyramidal neurons located within layer VI of the rodent medial prefrontal cortex (mPFC) play an important modulatory role in prefrontal cognitive networks. This role is facilitated by acetylcholine activation of nicotinic receptors (nAChRs) and muscarinic receptors (mAChRs), which both act to regulate the excitability of mPFC layer VI neurons. Although the function of nAChRs has been extensively characterized, the function of mAChRs on mPFC layer VI neurons is not fully understood. Activation of mAChRs induces a complex response in neighboring mPFC layer V neurons, where the Gq-coupled M1 isoform mediates a transient inhibition followed by a prolonged excitation. The objective of this current study was to determine the role of mAChR isoforms toward the overall muscarinic response in layer VI neurons. Of particular interest was the relatively-rare Gq-coupled M3 isoform that is selectively expressed in layer VI. Whole-cell current-clamp electrophysiological recordings were made in active mPFC layer VI neurons sampled from male and female mice during young postnatal life (postnatal day (P) 15-20) and in adulthood (P60-100). Responses to bath-applied ACh (1 mM for 30 s) were measured in the continuous presence of nAChR antagonists. The majority of sampled neurons exhibited an early, transient inhibition followed by a prolonged excitation. The proportion of neurons exhibiting the inhibition response, and the duration of this response, were significantly greater in young mice than in adult mice. In contrast, the magnitude of the excitatory response did not change with age. Neither measure was affected by sex. Pharmacological experiments using isoform-selective antagonists demonstrated that both the M1 and M3 isoforms were required for the inhibition response in all groups tested, whereas the M2 isoform contributed to this response in male mice only. The M1 isoform contributed to the excitatory response in all groups tested, whereas the M2 and M3 isoforms contributed to this response in adult mice only. Ongoing experiments aim to confirm the expression of mAChR M1, M2, and M3 isoforms within recorded neurons, and to determine whether the function of these mAChR isoforms relates with the morphology of recorded neurons. Collectively, our findings suggest that mAChR regulation of mPFC layer VI neuron excitability is mediated via distinct contributions of M1, M2, and M3 receptor isoforms, and that these contributions vary across sex and age.

Title: Extracellular cyclic AMP-adenosine pathway: A potential target for treating skeletal muscle atrophy

Authors: *F. RODRIGUES ELOI, T. CHIAVEGATTI, A. ANDRADE-LOPES, R. OLIVEIRA GODINHO
Pharmacol., Univ. Federal de São Pauola, São Pauola, Brazil

Abstract: Introduction: The GsPCR/ adenylyl cyclase / intracellular cAMP pathway is an interesting therapeutic target for treating skeletal muscle atrophy since it is involved in attenuation of muscle proteolysis. Assuming that the intracellular cAMP suffers efflux, is degraded into adenosine extracellularly, and that the skeletal muscle cells express all 4 adenosine receptor subtypes, herein we evaluate the possible modulatory effects of the "extracellular cAMP-adenosine pathway" on skeletal muscle proteolysis. Material and Methods: L6 rat cell line ($3x10^5$ cells/ mL) were grown in DMEM plus 10% fetal calf serum on 35 mm dishes. Myogenic differentiation was induced with DMEM plus 5% horse serum. Activation of GPCR was evaluated using the functional [^{35}S]GTPγS binding assay. Briefly, membrane fractions from L6 myotubes (n=4-5) were incubated with 0.1 nM [^{35}S]GTPγS and 50 μM GDP, in the absence or presence of cAMP or adenosine. Nonspecific binding was determined in the presence of 50 μM unlabeled GTPγS. The effect of cAMP, adenosine, CGS-15943 (non-selective adenosine receptor antagonist) and DMPX (selective A_2 receptor antagonist) on L6 myotubes proteolysis was evaluated by measuring the rate of tyrosine release into the incubation medium using a fluorometric method (at 485/590 nm). Results and Conclusion: cAMP increased by up to 150% the basal binding of [^{35}S]GTPγS to L6 myotube membranes. This effect was mimicked by adenosine or its analog NECA. Treatment of cultures for 4 h with cAMP reduced by up to 18% the basal rate of tyrosine release. The anticatabolic effect of cAMP was sustained for up 5 h and mimicked by incubation of cells with adenosine, which reduced by up to 28% the basal rate of tyrosine released. Interestingly, pre-treatment of cells with CGS-15943 or DMPX completely abolished the antiproteolytic effects of either cAMP or adenosine. This data shows that extracellular cAMP can modulate the skeletal muscle proteolysis through activation of adenosine receptor coupled to stimulatory G protein, becoming a target for developing pharmacological strategies for treating skeletal muscle atrophy. Title: An effort to build an *in vitro* high-throughput screening for seizure liability based on calcium oscillation of human ipsc-derived neurons

Authors: *Y. WANG[1], S. DU[1], S. HISADA[2]
[1]Hamamatsu Corp., Bridgewater, NJ; [2]Hamamatsu Photonics K.K., Hamamatsu City, Japan

Abstract: Drug-induced seizure liabilities are typically tested in expensive and low throughput ex vivo rat hippocampal brain slices. An in vitro model based on micro-electrode arrays using human iPSC derived neurons has been suggested (https://doi.org/10.1093/toxsci/kfy029). There is a surge of interest in higher throughput methods, one of them being fluorescence measurement of calcium oscillations in neuronal cultures. However, progress has been limited by the long imaging acquisition time for an entire 96- or 384-well plate, and also by the heterogeneity of neurons derived from human iPSCs. With the advent of new camera technologies as well as availability of highly enriched, functionally mature human neurons derived from iPSCs, these limitations can now be overcome. Here we attempt to build a model to compare human iPSC derived neurons, with and without astrocyte, with rat primary cells upon treatment of reference and control compounds.

Abstract: Highly selective positive allosteric modulators (PAMs) of the M1 subtype of muscarinic acetylcholine receptor have emerged as an exciting new approach for the potential improvement of cognitive function in patients suffering from Alzheimer's disease and schizophrenia. To date, M1 PAM discovery programs have produced a structurally diverse range of M1 PAMs with distinct pharmacological properties, including different levels of agonist activity and differences in signal bias. Previously, we have shown that intrinsic agonist activity is detrimental to M1 PAM efficacy in our preclinical animal models. However, little is known about the impact of signal bias on M1 PAM efficacy *ex vivo* and *in vivo*. Canonical M1 signaling induces activation of phospholipase C (PLC) and it was assumed that activation of PLC is a key mechanism by which M1 activation induces multiple CNS effects. However, our lab has shown that M1 activation can also lead to activation of phospholipase D (PLD), independent of PLC activation. Therefore, to characterize the role of PLD downstream of M1 in the CNS, we set out to characterize the role of PLD in three different M1-dependent electrophysiological assays in *ex vivo* brain slices. Using selective PLD inhibitors, we report that PLD does not play a role in cholinergic agonist-induced increases in medium spiny neuron excitability in the striatum nor agonist-induced increases in spontaneous excitatory post synaptic currents in layer V medial prefrontal cortex (mPFC) pyramidal neurons, both of which are M1-dependent. Interestingly, we find that inhibition of PLD, specifically the PLD1, blocks cholinergic agonist-induced long-term depression (LTD) of layer V field excitatory post synaptic potentials electrically stimulated in layer II/III of the mPFC. Importantly, loss of LTD at this mPFC synapse is known to correlate with behavioral deficits in *in vivo* rodent cognition assays. Recently, we have published that some M1 PAMs display a signal bias in which they potentiate signaling through PLC but not through PLD. Therefore, using the same brain slice electrophysiology paradigms, we set out to compare the nonbiased M1 PAM, VU0453595, with two biased M1 PAMs, VU0405652 and VU0405645, that potentiate signaling through PLC but not PLD. Interestingly, we find that biased M1 PAMs fail to potentiate M1 LTD in the mPFC and that a biased M1 PAM can actually block a robust LTD induced by a high concentration of cholinergic agonist, suggesting true signal bias. These finding suggest that PLD plays a critical role in the ability of M1 PAMs to

modulate some CNS functions and that screening for signal bias is essential to fully understand and evaluate M1 PAM clinical candidates.

Title: Selective antagonists of the M_4 muscarinic acetylcholine receptor relieve parkinsonian motor deficit

Authors: *M. S. MOEHLE[1], J. M. ROOK[2], D. J. FOSTER[2], S. E. YOHN[2], C. M. NISWENDER[2], C. LINDSLEY[2], C. K. JONES[2], P. CONN[2]

Abstract: Anti-muscarinic therapy that broadly targeted each of the 5 muscarinic acetylcholine receptors was the first approved therapy for Parkinson's Disease (PD), and has efficacy in reducing the primary motor symptoms of other movement disorders as well. However, the clinical utility of these compounds is greatly limited by severe central and peripheral side effects. Recently, our lab has made major breakthroughs in the development of selective antagonists and allosteric modulators of individual muscarinic subtypes. Using these compounds we have identified the M_4 subtype as a major regulator of dopaminergic signaling, release, and related motor behaviors. These data have highly implicated that selective antagonists of the M_4 receptor may yield robust anti-parkinsonian efficacy without the severe central and peripheral side effects observed with non-selective muscarinic antagonists, yet there has been little evidence or tools available to directly test this hypothesis. Here, we report the development and characterization of the first selective M_4 antagonist that possess at least 100 fold selectivity over other muscarinic subtypes. Using this novel antagonist, we performed a series of electrophysiological and behavioral experiments to directly test the hypothesis that selective antagonists of M_4 will have robust anti-parkinsonian motor efficacy. We found that selective inhibition of M_4 was able to relieve motor deficits in several animal models that have predictive validity of anti-parkinsonian

efficacy such as haloperidol induced catalepsy and forelimb asymmetry. Additionally, we found that this antagonist can reverse M_4 activation induced suppression of dopamine release in the striatum and M_4 activation induced suppression of D_1 dopamine receptor signaling in the substantia nigra pars reticulata. These initial studies provide compelling evidence that M_4 selective antagonists will have broad efficacy in removing parkinsonian motor disability, and provide critical pre-clinical rationale for larger drug discovery efforts.

Title: M_1 muscarinic receptors modulate discrete glutamatergic inputs to the prefrontal cortex: Implications for novel treatments of posttraumatic stress disorder

Authors: *J. T. MAKSYMETZ[1,2], M. E. JOFFE[1,2], S. P. MORAN[1,2], J. E. ZACHRY[1,2], B. J. STANSLEY[1,2], K. J. TEMPLE[2], D. W. ENGERS[2], C. W. LINDSLEY[2,1], P. J. CONN[1,2]

Abstract: The medial prefrontal cortex (mPFC) integrates a diverse array of cortical and subcortical inputs to mediate higher order cognition and the neuromodulator acetylcholine is highly implicated in these functions. We previously reported a form of muscarinic long-term

depression (mLTD) of synaptic transmission in the mouse mPFC, however, it is unknown if this mLTD occurs at distinct subcortical inputs. Using an optogenetic approach in *ex vivo* layer V mPFC brain slices, we found that muscarinic activation with the non-selective agonist oxotremorine-M induces mLTD at inputs from the ventral hippocampus (vHipp) and basolateral amygdala (BLA) but not the mediodorsal nucleus of the thalamus. Similar to mLTD observed with electrical stimulation, the mLTD at the vHipp and BLA inputs is blocked by an M_1 antagonist, and M_1 activation with a selective atypical M_1 agonist is sufficient to induce mLTD at these inputs. We also found that vHipp-mPFC mLTD is lost in pyramidal neurons in which M_1 has been selectively deleted using viral-mediated expression of Cre recombinase. Taken together, these data indicate that M_1 is poised to regulate synaptic transmission at two long-range limbic inputs to the mPFC, whose activity is necessary for the extinction of learned fear. Based on this, we tested the hypothesis that M_1 activity can bidirectionally modulate fear extinction. First, we found that systemic administration of the M_1 antagonist VU0255035 impaired contextual fear extinction. We then proceeded to test whether enhancing M_1 receptor activity could rescue deficits in a model in which contextual fear extinction is impaired. To this end, we used the extensively validated stress-enhanced fear learning (SEFL) model of posttraumatic stress disorder (PTSD). We found that mice subjected to SEFL exhibited enhanced contextual fear compared to control animals and exhibited impaired extinction to the conditioning context. Excitingly, treatment with the M_1 positive allosteric modulator (PAM) VU0453595 before extinction enhanced contextual fear extinction in SEFL conditioned mice. Altogether, these data suggest that the M_1 muscarinic receptor dynamically modulates the strength of fear-related inputs into the mPFC. Through these actions, M_1 PAMs may provide a novel treatment strategy to facilitate exposure therapy in the clinic for the treatment of PTSD.

Title: Reduced axonal surface expression and PIP_2 sensitivity in K_v7 channels disrupts their function to inhibit neuronal excitability in Kcnq2 epileptic encephalopathy

Authors: *E. KIM, J. ZHANG
Dept. of Mol. and Integrative Physiol., Univ. of Illinois At Urbana-Champaign, Urbana, IL

Abstract: Neuronal Kv7/KCNQ channels are voltage-gated potassium channels composed of Kv7.2/KCNQ2 and Kv7.3/KCNQ3 subunits. Enriched at the axonal membrane, they potently suppress neuronal excitability. *De novo* and inherited dominant mutations in Kv7.2 cause early onset epileptic encephalopathy characterized by drug resistant seizures and profound psychomotor retardation. However, their precise pathogenic mechanisms remain elusive. Here, we investigated select epileptic encephalopathy mutations in calmodulin (CaM)-binding helices A and B of Kv7.2. We discovered that R333W, K526N, and R532W mutations located peripheral to CaM contact sites decreased axonal surface expression of heteromeric channels although only R333W mutation reduced CaM binding to Kv7.2. These mutations also altered gating modulation by phosphatidylinositol 4,5- bisphosphate (PIP2), revealing novel PIP2 binding residues. While these mutations disrupted Kv7 function to suppress excitability, hyperexcitability was observed in neurons expressing Kv7.2-R532W that displayed severe impairment in voltage-dependent activation. The M518V mutation at the CaM contact site in helix B caused most defects in Kv7 channels by severely reducing their CaM binding, K+ currents, and axonal surface expression. Interestingly, the M518V mutation induced ubiquitination and accelerated proteasome-dependent degradation of Kv7.2, whereas the presence of Kv7.3 blocked this degradation. Furthermore, expression of Kv7.2-M518V increased neuronal death. Together, our results demonstrate that epileptic encephalopathy mutations in helices A and B of Kv7.2 cause abnormal Kv7 expression and function by disrupting Kv7.2 binding to CaM and/or modulation by PIP2. We propose that such multiple Kv7 channel defects could exert more severe impacts on neuronal excitability and health, and thus serve as pathogenic mechanisms underlying Kcnq2 epileptic ncephalopathy

Title: Nonuniform changes in h channel expression along the dorsoventral axis of the hippocampus in a rat model of temporal lobe epilepsy

Authors: *E. C. ARNOLD[1], R. A. GRAY[2], D. JOHNSTON[2]
[1]Inst. for Neurosci., [2]Ctr. for Learning and Memory, The Univ. of Texas At Austin, Austin, TX

Abstract: The CDC estimates one percent of adults in the United States have epilepsy. Temporal Lobe Epilepsy (TLE), which affects the hippocampus and surrounding cortices, is the most common form of focal epilepsy. In animal models of TLE, CA1 neurons have been shown to be susceptible to selective changes in ion channel expression, called acquired channelopathies, which increase the excitability of a neuron. In addition, several recent studies in normal rodents find differences in ion channel expression along the dorsoventral axis of CA1. We hypothesized that the presence of these acquired channelopathies in an animal model of epilepsy might depend on the dorsoventral region of CA1. To test this, we modeled TLE in the rat by inducing status epilepticus (SE) with kainic acid. We found spontaneous seizures occurred in the first month post-SE. For all experiments, slices of the dorsal and ventral hippocampus were prepared from rats 1-2 months post-SE. In acute slices, we used current clamp recordings to compare the intrinsic membrane properties post-SE to control. We expected that neurons along the dorsoventral axis might show a uniform increase in excitability superimposed on the gradient described in normal rats. Our data, however, suggests otherwise – the firing of dorsal and ventral neurons does not appear to be uniformly regulated. Neurons in the dorsal, but not the ventral, CA1 are more excitable post-SE firing more action potentials and possessing an elevated input resistance. We then hypothesized the increase in firing of dorsal CA1 neurons was due, in part, to a reduction in the presence or activity of ion channels open at subthreshold voltages. Targeting the subunits of two ion channel classes, HCN and GIRK, we used immunohistochemistry to assess the localization of these proteins. While the expression of GIRK channels did not appear to have changed in dorsal or ventral hippocampus post-SE, we found a reduction in HCN1 immunostaining in the dorsal dendrites, which corresponded to our physiological findings. Next, we tested the physiological contribution of h channels to membrane properties via whole cell recordings at the apical dendrites of dorsal CA1 neurons. We found a dramatic reduction in electrophysiological markers associated with h channels post-SE including peak resonance frequency and sensitivity to the channel blocker, ZD7288. In this study, we have provided evidence that post-SE neurons in the dorsal CA1 modify their intrinsic properties by reducing h channel expression, and this acquired channelopathy does not occur in ventral CA1 neurons.

Title: Using zebrafish as a tool to model patient mutations of KCNB1 and its role in epilepsy

Authors: *A. COLON-RODRIGUEZ[1,2], K. F. BURBACH[2], E. FERINO[2], M. BADER[2], P. J. LEIN[3], L.-E. JAO[4], M. Y. DENNIS[2]

Abstract: Genetic factors responsible for complex neurological disorders, including epilepsy, are poorly understood. De novo mutations in KCNB1 encoding $K_v2.1$ voltage-gated potassium channel have been identified in patients with sporadic infantile epilepsy. Nearly all variants identified are missense making their pathogenicity uncertain. Knock out (KO) *Kcnb1* mice exhibit neuronal hyperexcitability, sensitivity to convulsant-induced seizures, defects in spatial learning and motor activity, and anxiety-like behavior. A recent study examining *kcnb1* KO in zebrafish resulted in a reduced ventricular system and gain of function caused hydrocephalus; however, additional phenotypic and neuronal alterations were not examined. The focus of this study is to recapitulate neurological phenotypes in zebrafish observed in patients and mouse models and characterize them molecularly and phenotypically. Using zebrafish as a model allows us the potential to conduct more robust, higher throughput experiments. This mainly due to the ability of zebrafish to reproduce robustly and their rapid development. To create our mutants, we used CRISPR gene editing to generate novel KO alleles for *kcnb1* in zebrafish. Zebrafish were then characterized by Illumina sequencing identifying a 23-bp deletion allele. To quantify molecular impacts on the resulting mutant *kcnb1* transcripts and protein, we performed quantitative real-time PCR and western blot, respectively, of 10 days post fertilization (dpf) larvae. Subsequent morphological and behavioral analyses were performed on 5 dpf zebrafish. Our results show no significant differences between mutant zebrafish carrying one (heterozygote) or two (homozygous) copies of KO alleles compared to wildtype fish in body size or head size. However, there was a significant increase in activity (distance moved) between heterozygous and homozygous fish in the presence of PTZ, a $GABA_A$ antagonist, recapitulating phenotypes observed previously in *Kcnb1* KO mice. Ongoing studies include characterizations of synaptic alterations in *kcnb1* mutants via electroencephalograms, immunohistochemistry, and RNA-seq. Additionally, efforts are ongoing to introduce evolutionarily conserved missense patient mutations in zebrafish using gene editing. The results of this study will lay the groundwork to (1) identify neurodevelopmental alterations of *kcnb1* mutations in zebrafish, and (2) develop tools that we will continue to use as we move forward to characterize unknown disease-related mutations in a higher-throughput manner.

Title: Epileptogenic seizures and increased excitability promote upregulation of KCNQ M-type K+ channels in the hippocampus

Authors: *S. D. HASTINGS, C. CARVER, M. S. SHAPIRO
Cell. and Integrative Physiol., Univ. of Texas Hlth. San Antonio, San Antonio, TX

Abstract: M-type (KCNQ2/3) K+ channels play a key role in the excitability of neurons, however, their role in acquired epileptogenesis is not well understood. Previous studies by our group found that KCNQ2 and KCNQ3 mRNA was upregulated in the hippocampus in response to chemoconvuslant seizure activity. Using transgenic mice with a GFP reporter to detect expression of KCQN2 mRNA (GENSAT KCNQ2-EGFP/FW221Gsat/Mmucd, 015412-UCD), we are able to visualize seizure-dependent effects on KCNQ2 expression in the subregions of the hippocampus.
KCNQ2-GFP reporter mice were administered either the muscarinic agonist pilocarpine or the GABAA receptor antagonist pentylenetetrazol to induce clonic seizures in adult, 2-month old mice. Alternatively, a subset of animals were given 280 mg/kg pilocarpine to induce status epilepticus (SE). Brains were removed either 48 hours or 7 days after seizure induction and fixed in 4% PFA for immunohistochemistry. Dorsal hippocampus sections were immunostained with anti-GFP and anti-MAP2 antibodies and secondary fluorescent labels. GFP/MAP2 fluorescence was quantified for dentate gyrus (DG), CA1, and CA3 pyramidal regions.
Chemoconvulsant seizures induced increase of KCNQ2 mRNA in CA1 and CA3 subregions at the 48 hr timepoint, but no signficant increase was observed in the DG. CA1 and CA3 levels of KCNQ2 mRNA increased in response to both pilocarpine or pentylentetrazol, signifying that KCNQ2 upregulation occurs independent of the mechanism of convulsant activity. Total KCNQ2 protein levels were also increased in the whole hippocampus. In hippocampi examined 7 days after seizure, levels of KCNQ2 mRNA were reduced in all regions below that of control. In a subset of mice experiencing SE, there was a significant increase in KCNQ2-expressing DG granule cells, but excitoxicity induced widespread neuronal death in CA1 and CA3 pyramidal neurons.
Brain-slice electrophysiology recordings of M-current were taken from CA1 and DG neurons in comparison of naive and pilocarpine seizure animals. CA1 demonstrated increased M-current after seizure challenge, however there were no significant changes in M-current between control

and seizure DG granule cells.
We demonstrate that a single seizure promotes KCNQ2 upregulation in the hippocampus in a region-specific manner and in a limited window after seizure. Such novel ion channel plasticity may serve as a compensatory mechanism after a hyperexcitable event. The upregulation we describe could be potentially leveraged in anticonvulsant enhancement of KCNQ2 channels as therapeutic target for preventing epileptogenic seizures.

Abstract: The mammalian KCNQ (Kv7) gene family encodes M-currents, carried by subthreshold voltage-gated K^+ channels strongly modulated by diverse Gq-coupled GPCRs such as muscarinic receptors. The importance of this subclass of K^+ channels is highlighted by human mutations in all 5 members of this gene family (KCNQ1-5) associated with genetic channelopathies affecting cardiac, brain and auditory function, with mutations in KCNQ5 being most recently reported. We report here functional characterization of 6 new human KCNQ5 *de novo* mutations comprising 4 missense and 2 nonsense mutations identified by whole exome

sequencing in patients with epilepsy and intellectual disability, non-overlapping with mutations previously reported. Surprisingly, all missense mutations resulted in gain-of-function channels shifted in voltage-dependence of activation towards hyperpolarized potentials, demonstrated by heterologous expression and patch-clamp recordings in HEK293 cells. By contrast, both nonsense mutations conceptually truncate the channel protein prematurely, likely resulting in loss-of-function. Loss-of-function was confirmed for one nonsense allele that preserved all membrane-spanning domains S1-S6. This allele failed to express functional currents, nor traffic properly to the plasma membrane. To validate linkage of these *de novo* mutations to *in vivo* channelopathies, we generated 2 independent mKCNQ5 KO mouse lines, using Cas9/sgRNA to target exon 5 which encodes the turret domain immediately preceding the K^+ selectivity filter. Selective mKCNQ5 loss-of-function in both KO lines was confirmed by genomic sequencing, qRT-PCR and western blot analysis, without compensatory misregulation of mKCNQ1-4. Homozygous mKCNQ5 KO mice from both lines exhibited spontaneous tonic clonic convulsions and absence-type seizures during routine cage handling, with late adult onsets (>P150) and moderate penetrance (~25% of observed animals). Cortical EEG recordings from both KO lines during resting/sleep revealed abnormally higher activity in alpha (8-12 Hz) and beta bands (12-30 Hz) compared to WT, and a higher propensity for interictal spikes, poly-spikes and generalized synchronous oscillations. Similar to SCN1A mouse models of Dravet Syndrome, KCNQ5 KO mice exhibited abnormal thermal-induced seizures, with a temperature threshold of 40.5 ºC at which 50% of animals seized. Taken together, these results identify both gain-of-function and loss-of-function molecular phenotypes due to human KCNQ5 mutations linked to epilepsy and intellectual disability, and provide *in vivo* validation for the epileptogenic potential of KCNQ5 loss-of function.

Title: ERG3 potassium channel-mediated suppression of neuronal intrinsic excitability and prevention of seizure generation in mice

Authors: *Z. HUANG[1], X. KUO[2], S. Z. MING[2], F. M. HUA[2]
[1]Mol. and Cell. Pharmacol., Peking Univ., Beijing, China; [2]Dept. of Mol. and Cell. Pharmacol., Peking Univ. Hlth. Sci. Ctr., Beijing, China

Abstract: The input-output relationship of neuronal networks depends heavily on the intrinsic properties of their neuronal elements. Profound changes in intrinsic properties have been observed in various physiological and pathological processes, such as learning, memory and epilepsy. However, the cellular and molecular mechanisms underlying acquired changes in intrinsic excitability are still not fully understood. Here, we demonstrate that ERG3 channels are critically involved in the regulation of intrinsic excitability in hippocampal CA1 pyramidal neurons and DG granule cells. Knock-down of ERG3 channels significantly increases neuronal intrinsic excitability, which is mainly caused by decreased fast afterhyperpolarization (AHP), delayed time to the generation of an action potential (AP) and enhanced summation of somatic excitatory post-synaptic potentials (EPSPs). Interestingly, the expression level of ERG3 protein is significantly reduced in human and mouse brain tissues with temporal lobe epilepsy. Moreover, ERG3 channel knock-down in hippocampus significantly enhanced seizure susceptibility, while mice treated with ERG3 channel activator NS1643 were less prone to epileptogenesis. Taken together, our results suggest ERG3 channels play an important role in determining the excitability of hippocampal neurons and dysregulation of these channels may be involved in the generation of epilepsy. ERG3 channels may thus be a novel therapeutic target for the prevention of epilepsy.

Title: MicroRNA-mediated regulation of hippocampal A-type currents is associated with reduced seizure frequency in a mouse model of epilepsy

Authors: D. TIWARI[1], D. H. BRAGER[2], N. EL-SAYED[1], J. KRZESKI[1], J. RYMER[1], L. SCHROEDER[1], S. DANZER[1], *C. GROSS[1]

Abstract: Epilepsy is characterized by changes in neuronal excitability and is often associated with altered expression or function of ion channels. One example of such a channelopathy observed in genetic and acquired epilepsy is the reduction of hyperpolarizing A-type potassium currents in the hippocampal CA1 region. These A-type currents are mainly mediated by the voltage-gated potassium channel Kv4.2, and here we confirm that Kv4.2 protein and mRNA are reduced in the pilocarpine mouse model of epilepsy. Emerging evidence suggests that microRNAs (miRNAs), small non-coding RNAs that regulate post-transcriptional expression of protein-coding mRNAs, are crucial regulators of genes involved in epilepsy. In line with this hypothesis, we have shown previously that expression of Kv4.2 is regulated by microRNA-induced silencing. Here, we show that antisense-mediated inhibition of the Kv4.2-targeting microRNA miR-324-5p in mice selectively increases A-type potassium currents in pyramidal neurons of the CA1, while leaving membrane potential, channel properties and other potassium currents unaltered. Using a pilocarpine mouse model of acquired epilepsy we found that inhibition of microRNA-induced silencing of Kv4.2 by intracerebroventricular injection of an antagomir (miRNA inhibitor) specific to miR-324-5p caused a reduction in seizure frequency. Our results suggest that miR-324-5p selectively regulates A-type potassium currents and that its manipulation can reduce seizures in epilepsy. Ongoing studies are assessing if reduced RNA-induced silencing of Kv4.2 underlies the observed reduction in seizure frequency.

Abstract: Developmental and epileptic encephalopathies (DEEs) are a heterogeneous group of severe early onset diseases of childhood characterized by developmental delay, intellectual disability, pharmacoresistant epileptic seizures and often other neuropsychiatric deficits. DEEs are commonly caused by *de novo* mutations which often affect voltage-gated ion channels. With mutations in Na^+ and K^+ channels at the focus of research on DEEs and other infantile epilepsy syndromes, knowledge about disease causing mutations in Ca^{2+} channels is emerging more slowly. Here, we present a functional characterization of missense mutations in *CACNA1E*, which we recently identified in patients with a form of West syndrome. This widely expressed gene encodes the voltage gated $Ca_V2.3$ (R-type) presynaptic Ca^{2+} channel. Mutations in this gene have so far not been identified as a causative factor in human epilepsy. To characterize the gating defects of mutant channels, we performed whole cell patch clamp recordings of tsA201 cells that were transiently transfected with the pore forming wild type (wt) or mutant α_{1E}-subunit and the β_{2d}-subunit. Functional effects of three mutations identified in patients with DEE, all located in the S6 segment of the second domain of $Ca_V2.3$, revealed clear gain of function effects with a significant hyperpolarizing shift of the voltage dependence of activation and a slowing of the inactivation time course. Our findings establish *CACNA1E* as a new 'epilepsy gene' and provide novel insights in the mechanisms causing the various forms of DEE.

Title: Efficacy of sodium channel inhibitors as anticonvulsants in the mouse maximal electroshock seizure assay is predictive of the therapeutic plasma concentration in humans

Authors: *P. KARIMI TARI[1], K. NELKENBRECHER[1], M. WALDBROOK[1], G. DE BOER[2], R. KWAN[2], C. M. DUBE[1], T. FOCKEN[3], C. DEHNHARDT[3], N. SHUART[4], S. GOODCHILD[4], L. SOJO[2], J. EMPFIELD[5], C. J. COHEN[5], J. JOHNSON[5]

Abstract: The Maximal Electroshock Seizure (MES) assay has been widely used to characterize the efficacy of antiepileptic drugs. This assay involves induction of epileptic-like event in rodents and measures the ability of test compounds to inhibit seizures. Efficacy in this assay has often been considered a requirement for development of new therapeutic agents. In particular, clinically effective inhibitors of voltage-gated sodium channels (Na_V's) are all active in the MES assay. Although the dose-dependence of activity has been well defined, the relationship between plasma and brain concentration and efficacy is not often assessed. Here, we report the plasma and brain EC_{50}'s in the mouse MES assay and compare them with plasma concentrations observed to be effective at reducing epilepsy symptoms in patients. For the Na_V channel inhibitors phenytoin, carbamazepine and lacosamide, the plasma concentration needed for clinical efficacy is 1-5 times the plasma EC_{50} in the mouse MES assay. In other words, for efficacy in humans one needs to achieve plasma levels that are equivalent to or greater than the EC_{50} for protection in the mouse MES assay. We find that plasma levels associated with adverse effects in mice are similar to those associated with adverse events in the clinic. Thus the ratio between the mouse MES EC_{50} and toxicity in mice may serve as a predictor of clinical therapeutic safety index.

We find that a very high therapeutic index in mice can be achieved with Na_V inhibitors that selectively block $Na_V1.6$, with >100 fold selectivity against all other Na_V isoforms. We present an exemplar compound that safely achieves >90% suppression in the MES assay. We anticipate that this new class of selective Na_V inhibitors will achieve greater seizure suppression in humans with a significantly improved tolerability than is currently possible with available, non-selective Na_V inhibitors. The first exemplar of this class, XEN901, is currently in Phase I clinical trials.

Title: Distinct functional alterations in SCN8A epilepsy mutant channels

Authors: *Y. PAN[1], T. R. CUMMINS[2]
[1]Indiana Univ. Sch. of Med., Indianapolis, IN; [2]Dept Biol., Indiana University-Purdue Univ. Indianapolis, Indianapolis, IN

Abstract: More than 60 epilepsy-related mutations have been identified in *SCN8A*, the gene that encodes voltage-gated sodium channel isoform 1.6. However, effective treatments to temper the highly active network in such patients are often lacking, in part due to the functional heterogeneity of *SCN8A* mutations. Here we characterized a novel epilepsy mutation, R850Q, in the human Nav1.6 and compared its aberrant functional alterations with three other SCN8A epilepsy mutants previously characterized in rodent Nav1.6 constructs. We discovered that R850Q conducted higher level of persistent current, with no increase in resurgent current amplitude. R850Q also had slightly hyperpolarized voltage-dependence of activation, which increased its window current. We observed that the human Nav1.6 channel bearing the T767I mutation also displayed increased persistent current and hyperpolarized voltage-dependence of activation. In contrast, R1617Q showed a slower rate of inactivation, faster recovery from inactivation, increased persistent current, and an increased resurgent current amplitude. R1872Q had an increased current density, a slower rate of inactivation, a hyperpolarizing shift in voltage-dependence of activation, and a depolarizing shift in voltage-dependence of inactivation. Interestingly, all the mutant channels exhibited distinctive resurgent current kinetics compared to the wild-type channel. We propose that these changes, including the kinetic changes in resurgent currents, are likely to contribute to aberrant neuronal excitability.

Title: Dyshomeostatic mechanisms of KCNQ2-related epileptic encephalopathy in patient-specific iPSC-derived excitatory neurons

Authors: *D. SIMKIN[1,2], T. J. SEARL[1], J. J. MILLICHAP[3], B. N. PIYEVSKY[2], G. L. ROBERTSON[2], M. FORREST[4], P. PENZES[4], A. L. GEORGE, Jr.[1], E. KISKINIS[2]
[1]Pharmacol., [2]Neurol., [3]Epilepsy Ctr. and Div. of Neurology, Departments of Pediatrics and Neurology, Ann & Robert H., [4]Physiol., Northwestern University, Feinberg Sch. of Med., Chicago, IL

Abstract: Mutations in *KCNQ2*, which encodes a pore-forming K^+ channel subunit responsible for neuronal M-current, have been associated with neonatal epileptic encephalopathy (NEE), a complex disorder that manifests as severe early-onset seizures and impaired neurodevelopment due to an imbalance in neuronal circuit activity in the brain. While the effects of *KCNQ2* mutations have been studied extensively in heterologous expression systems, their effects on the inherent properties of human neurons have not. Specifically, what remains unclear is how the likely defects in M-current affect the electrophysiological properties of human neurons during a critical period of neuronal maturation. Here we use KCNQ2-NEE patient-specific and isogenic control iPSC-derived excitatory neurons to elucidate the dynamic functional effects of a *KCNQ2* mutation.
Our data indicate that neurons from a NEE patient carrying a KCNQ2 loss-of-function mutation (T274M) develop hyperexcitability progressively over time in culture but are no different from isogenic control neurons in terms of network or intrinsic excitability at early time points of maturation (using multi-electrode arrays and current-clamp electrophysiology, respectively). However, M-current amplitude is ~60% smaller in KCNQ2-NEE neurons as compared to isogenic and healthy control neurons at early and later time points in maturation. This suggests a dissociation between loss of M-current and hyperexcitability. We demonstrated that suppression of M-current in isogenic control neurons by acute inhibition of KCNQ2/3 channels with XE991 evokes hyperexcitability by slowing action potential (AP) repolarization and reducing the post-burst afterhyperpolarization (AHP). However, KCNQ2-NEE neurons exhibit faster repolarization and enhanced AHPs indicating an ability to generate more APs per burst. Moreover, we found that we were able to recapitulate the defects of KCNQ2-NEE neurons, only when we treated isogenic control neurons chronically but not acutely with XE991. Thus, mere

loss of M-current does not account fully for hyperexcitability exhibited by KCNQ2-NEE neurons. We conclude that neuronal hyperexcitability in KCNQ2-NEE neurons is a result of dyshomeostatic changes initiated by dysfunctional KCNQ2 channels.

Title: Effects on neuronal excitability of SCN3A mutations causing early infantile epileptic encephalopathy

Authors: *E. M. GOLDBERG[1,2,3], N. P. SOTUYO[2], T. ZAMAN[1]
[1]Neurol., The Children's Hosp. of Philadelphia, Philadelphia, PA; [2]Neurosci., [3]Neurol., The Perelman Sch. of Med. at The Univ. of Pennsylvania, Philadelphia, PA

Abstract: Epilepsy is a severe neurological disease defined by recurrent seizures and associated with comorbid developmental delay and intellectual disability. The most severe type of epilepsy, the early infantile epileptic encephalopathies, are largely due to mutation in genes important for brain development and function. Voltage gated Na+ channels underlie action potential generation and propagation in excitable cells, and mutation in genes encoding voltage-gated sodium (Na+) channel α subunits are well-known causes of disease including childhood epilepsy. We recently showed that heterozygous *de novo* variants in *SCN3A* encoding the Na+ channel subunit Nav1.3 is a cause of very early onset epileptic encephalopathy; such mutations produce increased slowly-inactivating/persistent current and a left-shift in the voltage dependence of activation to more hyperpolarized potentials, suggesting a gain of channel function as the underlying pathogenic mechanism. However, the effect of such mutations on native neuronal function is not known. Here, to assess the impact of epilepsy-associated Nav1.3 variants on neuronal excitability, we express wild-type and mutant human Nav1.3 (Nav1.3-WT, Nav1.3-Ile875Thr, and Nav1.3-Val1769Ala) in cultured rat hippocampal pyramidal neurons via transient transfection, and in layer 2/3 pyramidal neurons in mouse neocortex using *in utero* electroporation. Current clamp recordings revealed spontaneous bursting from resting membrane potential with transition to depolarization block in cells expressing mutant hNav1.3, but not in

cells overexpressing hNav1.3-WT or in untransfected cultured neurons or in neighboring non-electroporated cells in brain slices. Such results further support the pathogenic nature of the identified epilepsy-associated Nav1.3 variants yet indicate that the effects of such variants on neuronal excitability may be complex.

Title: Alterations in oscillatory activity of CeM neurons in mice lacking $Ca_V3.1$ isoform of T-channels during isoflurane-induced unconsciousness

Authors: *T. TIMIC STAMENIC, S. FESEHA, S. TODOROVIC
Anesthesiol., Univ. of Colorado Denver, Anschutz Med. Ca, Aurora, CO

Abstract: Previous studies established that $Ca_V3.1$ T-channels in the thalamus are inhibited by prototypical volatile anesthetic isoflurane (ISO) at clinically relevant concentrations. However, the specific mechanisms underlying the role of $Ca_V3.1$ channels in thalamocortical oscillations *in vivo* during general anesthesia with volatile anesthetics are largely unknown.
We recorded *in vivo* local field potentials (LFPs) from adult wild type (WT) and $Ca_V3.1$ knockout ($Ca_V3.1$ KO) mice under ISO anesthesia. Additionally we recorded changes in LFPs 30 minutes after injection of pan-selective T-channel blocker TTA-P2 (3,5-dichloro-N-[1-(2,2-dimethyl-tetrahydro-pyran-4-ylmethyl)-4-fluoro-piperidin-4-ylmethyl]-benzamide, 60 mg/kg i.p.) in WT and $Ca_V3.1$ KO mice. The LFPs are recorded from Barrel cortex and central medial nucleus of thalamus (CeM), part of intralaminar complex that is heavily implicated in control of arousal.
Baseline relative power revealed decreased delta (two-way RM ANOVA, $p<0.001$) and increased alpha oscillations ($p<0.01$) in $Ca_V3.1$ KO vs. WT mice in CeM, but not in the cortical leads.
Under 1% ISO anesthesia, relative power of delta oscillations in $Ca_V3.1$ KO mice was diminished (24.2%, 10 animals), when compared to WT mice (40.9%, 6 animals) in CeM (two-way RM ANOVA, $p<0.001$). Moreover, the change of relative delta power from awake state during 1% ISO revealed different level of delta rise: 12.0% in WT and 5.7% in $Ca_V3.1$ KO (t-test, $p<0.01$) in CeM. These changes were not detected in cortex. During 2% ISO anesthesia the same trend was observed. Importantly, suppression-to-burst ratio was higher during 1.4% ISO

administration in $Ca_V3.1$ KO (0.38) than in WT (0.10) mice ($p<0.05$), indicating greater suppression of thalamocortical information transfer in $Ca_V3.1$ KO mice.
In WT animals we observed that TTA-P2 increased relative power of delta oscillations to 50.7% (7 animals), while in $Ca_V3.1$ KO mice its effect was much smaller (29.9%, 10 animals, $p<0.001$) in CeM. On the other hand, relative power for alpha and beta oscillations were two-fold higher in $Ca_V3.1$ KO mice when compared to WT mice ($p<0.001$ and $p<0.01$, respectively). The same was detected in cortex. Consistent with this notion, the change of relative delta power from awake state after TTA-P2 administration revealed different level of delta increase: 26.5% in WT and 13.6% in $Ca_V3.1$ KO mice (t-test, $p<0.001$) in CeM, and 32.6% in WT and 15.3% in $Ca_V3.1$ KO mice (t-test, $p<0.001$) in cortex.
Our results demonstrate for the first time the importance of thalamic $Ca_V3.1$ T-channels in thalamocortical oscillations that underlie clinically important effects of volatile anesthetics.

Title: Effect of conditional ryanodine receptor 2 knockout on neuronal activity in the hippocampus and learning

Authors: *M. MITTAG[1], L. WISCHHOF[2], F. BERTAN[3], L. SOSULINA[4], D. DALÜGGE[4], S. REMY[4], D. BANO[2], P. NICOTERA[3], M. FUHRMANN[1]
[1]Neuroimmunology and Imaging, [2]Aging and Neurodegeneration, [3]Synaptic Connectivity and Neurodegeneration, [4]Neuronal Networks, DZNE German Ctr. for Neurodegenerative Dis., Bonn, Germany

Abstract: Ca^{2+} signaling, mediated by entry of Ca^{2+} through the plasma membrane or release from the endoplasmic reticulum (ER), plays an important role in neuronal function. Elevation of intracellular Ca^{2+} triggers release of neurotransmitters at the synapse, contributes to dendritic spikes, induces activity-dependent changes in gene expression and regulates synaptic plasticity. Although much of the entry of Ca^{2+} into neurons occurs through plasma membrane channels, the ER is the major dynamic pool for intracellular Ca^{2+}. We hypothesize that ryanodine receptor 2 (RyR2), a receptor that is situated at the ER mediating the release of Ca^{2+} from the ER into the cell, is involved in spatial information processing in the hippocampus. To address this hypothesis, we locally restricted the conditional knockout of RyR2 to CA1 neurons and recorded

Ca^{2+}-transients of CA1 neurons in anaesthetized and awake head-fixed mice during spatial navigation. Furthermore, we tested whether conditional RyR2 knockout affected spatial learning. We observed that the conditional RyR2 knockout resulted in a changed Ca^{2+}-event frequency in the awake, resting animal. Furthermore we observed a decreased fraction of place cells as well as a decreased firing probability of place cells within their respective place field. In addition RyR2 knockout mice exhibited impaired learning in the radial arm maze after conditional knockout. These findings indicate a major role of RyR2 in spatial learning in the hippocampus.

Title: Development of a high-throughput screening assay for l-type calcium channels in neurons

Authors: Y.-L. ZHANG[1], E. NACU[1,2], M. E. FITZPATRICK[1], W. CROTTY[1,2], E. M. SCOLNICK[1], K. EGGAN[1,2], *J. R. COTTRELL[1]
[1]Stanley Ctr. for Psychiatric Res., Broad Inst. of MIT and Harvard, Cambridge, MA; [2]Dept. of Stem Cell and Regenerative Biol., Harvard Univ., Cambridge, MA

Abstract: Genetic analysis of psychiatric disease has implicated *CACNA1C* and *CACNA1D* as important schizophrenia and bipolar susceptibility genes. These risk genes encode the α1 subunits of the two major L-type calcium channels (LTCC), $Ca_V1.2$ and $Ca_V1.3$, expressed in the brain. However, LTCC modulators have potential for significant on-target cardiac liability, and no brain selective LTCC antagonists are currently available. As individual LTCC genes are expressed as multiple isoforms due to alternative splicing or proteolytic processing, some of these isoforms show markedly higher expression in human brain than in human heart. In addition, there may be brain-specific mechanisms for modulating LTCC function that can only be identified through their analysis in a neuronal context. Here, we report a high throughput calcium influx assay for identifying positive and negative modulators of LTCCs directly in primary rat hippocampal neurons and iPSC-derived human neurons. We validated this assay using LTCC pharmacological tools and performed a pilot screen of 4,551 compounds from the Broad Institute's repurposing library. From the screen, we were able to identify known LTCC blockers and activators in both type of neurons. More importantly, we discovered novel LTCC modulators in both rat hippocampal and Ngn2-induced human neurons, pointing to potential novel approaches for modulating LTCC function directly or indirectly. In summary, our assay

could prove a powerful approach for identifying neuron-specific modulators of LTCCs that avoid cardiac liabilities for the potential treatment of multiple psychiatric disorders.

Title: A mutation in CaV2.1 linked to ataxia, hypotonia and developmental delay profoundly impairs channel voltage-sensitivity

Authors: *S. TYAGI[1], T. R. BENDRICK[1], D. FILIPOVA[2], S. PAPADOPOULOS[2], R. A. BANNISTER, 80045[1]
[1]Med., Univ. of Colorado SOM, Aurora, CO; [2]Vegetative Physiol., Univ. of Cologne, Cologne, Germany

Abstract: Ca^{2+} flux into axon terminals via P/Q-type $Ca_V2.1$ channels is the trigger for neurotransmitter vesicle release at neuromuscular junctions and many central synapses. Recently, an arginine to proline substitution (R1673P) in the S4 voltage-sensing helix of the fourth membrane-bound Repeat of $Ca_V2.1$ was linked to a severe neurological disorder characterized by hypotonia, ataxia, cerebellar atrophy and global developmental delay. Since the R1673P substitution occurs at a position that is likely to be critical for sensing membrane potential, we investigated its effect on channel gating. To do so, we fused Venus fluorescent protein to the amino-termini of wild-type rat $Ca_V2.1$ and rat $Ca_V2.1$ carrying the equivalent of the human R1673P mutation (R1624P). These constructs were then expressed in tsA-201 cells for use in whole-cell patch-clamp experiments. With 2 mM Ca^{2+} serving as the charge carrier, we observed a profound depolarizing shift in activation of V-$Ca_V2.1$ R1624P relative to V-$Ca_V2.1$ ($V_{1/2act}$ = 16.8 ± 1.8 mV, n = 17 *vs*. -3.4 ± 1.7 mV, n = 16, respectively; $p < 0.001$). A similar shift was observed when 2 mM Ba^{2+} was used as the charge carrier ($V_{1/2act}$ = 11.5 ± 4.8 mV, n = 4 *vs*. -4.6 ± 3.6 mV, n = 6, respectively; $p < 0.05$). Application of roscovitine (12.5 μM), a compound previously shown to stabilize the open state of wild-type $Ca_V2.1$ channels, increased Ca^{2+} flux via R1624P at test potentials corresponding to peak activation of wild-type $Ca_V2.1$ (~3-fold at +10 mV, n = 9; $p < 0.005$) and slowed deactivation following repolarization from +10 mV to -40

mV (τ_{deact} = 0.62 ± 0.05 *vs*. 1.07 ± 0.14 ms before and during roscovitine application, respectively; $p < 0.01$). Taken together, our results indicate that the $Ca_V2.1$ R1673P mutation almost certainly causes a profound impairment of channel voltage-sensitivity *in vivo*, thereby increasing the probability of synaptic failure at both neuromuscular junctions and central synapses. In addition, our data raise the possibility that therapeutic agents that increase $Ca_V2.1$ open probability or prolong action potential duration may be effective in combatting this and other related disorders.

Title: Cognitive and affective behavioral phenotype of $Ca_V3.1$ knock-out mice: The importance of subicular circuitry

Authors: *S. M. JOKSIMOVIC[1], N. BUSQUET[2], R. VALDEZ[3], S. M. TODOROVIC[1]
[1]Anesthesiol., [2]Dept. of Neurol., [3]Dept. of Pediatrics, Div. of Neurol., Univ. of Colorado, Anschutz Med. Campus, Aurora, CO

Abstract: Low-voltage activated T-type calcium channels (T-channels) are important regulators of neuronal excitability and oscillatory activity. Thus far, only mice lacking the $Ca_V3.2$ isoform of T-channels have been studied in experimental protocols assessing hippocampal activity, with limited data on the role of the $Ca_V3.1$ isoform, which has been mainly associated with aberrant sleep patterns. We have recently shown that $Ca_V3.1$ T-channels regulate burst firing and synaptic plasticity in the subiculum, the main output structure of the hippocampal formation. However, the role of T-channels, particularly the $Ca_V3.1$ isoform, in cognitive processing, as well as affective behavior, remain largely unexplored.
First, we recorded local field potentials (LFPs) from the dorsal subiculum (dSub) and cortical EEG activity of freely-moving adult male WT and $Ca_V3.1$ knock-out (KO) mice using bilateral depth electrodes (in mm from bregma; AP: -2.8, ML: ±1.0, DV: 1.9) and cortical screws (AP: -

1.0, ML: ±3.0), respectively. Then, we performed behavioral characterization of KO mice using an extensive behavioral battery aimed to assess learning and memory [Y-maze, radial arm water maze (RAWM), novel object recognition test (NORT), and contextual fear conditioning (CFC)] or anxiety-related behavior (open field and elevated zero maze).
In vivo LFP recordings revealed a profound decrease in high-frequency oscillations in dSub of KO mice, without significantly affecting lower frequency bands, as compared to WT mice. For example, both absolute and relative gamma power (30-50 Hz) were decreased for about 50% in left dSub of KO animals ($p=0.010$ and $p=0.043$, respectively). Interestingly, we did not detect significant changes in the cortical oscillatory activity. In behavioral testing, mice lacking $Ca_V3.1$ isoform showed impaired spatial navigation in RAWM, as well as diminished recognition memory in NORT, as compared to the WT group. These cognitive deficits in KO animals were accompanied by alterations in emotional processing, as assessed by the behavior in the open field test and elevated zero maze, as well as by the magnitude of the freezing response to fear conditioning.
Our findings provide the first evidence that high-frequency oscillations in the dorsal subiculum heavily rely on $Ca_V3.1$ T-channel activity. We recently showed a vital role of these channels in synaptic plasticity of the subiculum, but not CA1 region. Based on these two important observations, we propose that specific changes in subicular activity observed in mice lacking $Ca_V3.1$ T-channels may be accountable for a variety of behavioral deficits associated with cognitive and affective processing.

Title: Neuronal voltage gated calcium channel genes produce secondary nuclear proteins that are subcellularly regulated in an activity-dependent manner

Authors: *E. RAO[1], D. P. HEJAZI[2], X. DU[3], J. GODFREY[3], C. M. GOMEZ[4]
[1]Neurobio., [3]Neurol., [4]Dept Neurol., [2]Univ. of Chicago, Chicago, IL

Abstract: Voltage-gated calcium channels (VGCCs) play crucial roles in the central nervous system, including regulating fast and slow neurotransmitter release, altering gene expression through a myriad of signaling pathways, and inducing post-synaptic responses such as long-term

potentiation and long-term depression. Our lab has shown previously that the P/Q-type VGCC gene *CACNA1A* is bicistronic, meaning that it encodes two structurally unrelated proteins with distinct functions from the same mRNA. The *CACNA1A* gene encodes the CaV2.1 VGCC subunit through canonical, cap-dependent translation, and additionally encodes a transcription factor, α1ACT, through a cryptic Internal Ribosomal Entry Site (IRES) within the open reading frame. We propose that this bicistronic expression mechanism is conserved throughout the larger VGCC superfamily, and to this end we have shown that the L-type VGCC gene *CACNA1C* and the T-type VGCC gene *CACNA1H* also produce secondary proteins that localize to the nucleus in cultured cells and endogenous neuronal tissue. These secondary proteins produced by *CACNA1C* and *CACNA1H*, termed CCAT and α1HCT respectively, translocate to the nucleus under control of cellular ionic milieu where they act as nuclear regulatory units, affecting expression of a wide array of genes. We hypothesize that these secondary proteins function as activity coupled transcription factors that regulate an ensemble of genes coincident with calcium channel activity. Furthermore we propose that dysfunction or dysregulation of these novel secondary proteins could contribute to the complex phenotypes observed in neuropsychiatric diseases related to mutations in *CACNA1C* and *CACNA1H*, and could therefore potentially be attractive therapeutic targets. The findings of this project may have vast implications for a wide variety of neurological disorders affecting *CACNA1C* and *CACNA1H*, and could provide novel therapeutic targets for the treatment of such disorders.

Title: Non-linear Ca^{2+} events along apical obliques of layer 5 cortical pyramidal neurons

Authors: M. L. CASTANARES, H. MA, *V. DARIA
The Australian Natl. Univ., Canberra, Australia

Abstract: Apical obliques are thin branches that are densely expressed in CA1 pyramidal neurons and sparsely in Layer5 (L5) pyramidal neurons. While the number of apical obliques is less (~ 4-10 branches along the trunk) in L5 neurons, they bifurcate from the apical trunk at Layer 4 making them synaptic targets of projections from the thalamus. In addition, forward-propagating impulses from the tuft dendrites to the soma (e.g. synaptic inputs or dendritic Ca^{2+}

spikes) and back-propagating action potentials (bAPs) traverse a section along the apical trunk where these obliques start to bifurcate. What is the role of these obliques in the propagation of these impulses? Objective: We aim to understand whether these oblique dendrites act as passive leaky segments that attenuate the signals or if they are capable of generating regenerative dendritic events that can potentially boost forward- or backward- propagating signals. Method: Using a multi-compartmental model of a L5 pyramidal neuron [Shai, *et al*, 2015], we describe a condition where there is a non-linear rise in the membrane potential following a train of two bAPs. Within 4 to 40 Hz of the bAP train, a critical frequency of about 20 to 30 Hz, sets a non-linear Ca^{2+} influx. The non-linear rise in the Ca^{2+} response is observed after the second bAP and are concentrated at apical obliques situated about 100microns from the soma. On the other hand, these non-linear responses are not found at proximal (~50 microns) and distal (>150microns from the soma) obliques where they exhibited a linear increase in Ca^{2+} transients. Unlike the Ca^{2+} spikes generated at the nexus (an event which requires a train of 4-6 bAPs at 80-100Hz), the Ca^{2+} spikes at the obliques occurs at a more physiologically lower frequency of 20-30Hz. This suggests that oblique dendrites can potentially function as active sub-integration sites at a slower somatic activity way before Ca^{2+} spikes at the nexus are generated.

Title: Regulation of NMDA receptor phosphorylation *in vivo* by administration of voltage gated calcium channel agonist, BayK8644

Authors: *R. V. OMKUMAR, M. JOHN, M. KUMAR, M. MADHAVAN
Rajiv Gandhi Ctr. for Biotech., Thiruvananthapuram, India

Abstract: Calcium influx through N-methyl-D-aspartate receptors (NMDAR) and voltage gated calcium channels (VGCC) plays major roles in postsynaptic signaling mechanisms. Eventhough multiple calcium signaling pathways converge at the level of free calcium release in the cytosol,

they maintain specificity towards their respective targets that are further downstream. NMDAR subunit GluN2B is phosphorylated at Ser^{1303} (*J Biol Chem. 1996, 271, 31670-8*). Phosphoryation at this site is a prominent event in cell culture systems as well as *in vivo* (*Int. J. Neuropsychopharmacol., 2010, 13, 1255-1260*). and influences the conductance of NMDAR channel (*Cell 2010, 140, 222-234*). Level of phosphorylation of GluN2B-Ser^{1303} is likely to be sensitive to calcium signaling since the calcium sensitive kinases, CaMKII (*J Biol Chem. 1996, 271, 31670-8*) and PKC (*Mol. Pharmacol., 2001, 59, 960*) are known to phosphorylate this site. Protein phosphatase 1 dephosphorylates this site (*Neurochem. Int. 2012, 61, 961-5; PLoS One, 2012, 7, e34047*). Despite the available data, the functional significance of phosphorylation at this site is not completely understood. In this study, we explored the effect of calcium signaling through VGCC on phosphorylation status of GluN2B-Ser^{1303} in the rat *in vivo* model. VGCC was activated by intraperitoneal (IP) injection of the VGCC activator, BayK8644. Subsequently, the levels of phospho-GluN2B-Ser^{1303} in the cortex and in the hippocampus were monitored by western blotting. We find that phosphorylation at this site increases in response to activation of VGCC by BayK8644 treatment. However the level of GluN2B remains largely unchanged indicating that the effect is brought about by kinases or phosphatases. The effect could be prevented by prior intracerebroventricular (ICV) administration of the specific blocker of VGCC, nifidipine. The effect was also blocked by pretreatment of the animals with ICV administration of KN-93 indicating that it is mediated through CaM kinase. The levels of various other proteins involved in cell survival and cell death are also being studied. We conclude that under *in vivo* conditions, calcium influx through VGCC activates CaM kinase. This in turn phosphorylates GluN2B-Ser^{1303}.

Title: The development and characterization of a new, conditional mouse model over-expressing $Ca_v1.2$

Authors: *R. PARENT[1], L. J. OUILLETTE[2], H. BURNS[2], A. SMARSH[2], V. A. CAZARES[3], G. G. MURPHY[4]
[1]Mol. and Behavioral Neurosciences Inst., [3]Mol. and Behavioral Neurosci. Inst., [4]MBNI/Physiology, [2]Univ. of Michigan, Ann Arbor, MI

Abstract: L-type voltage gated Ca^{2+} channels (LVGCC) are integral membrane proteins that modulate the influx of Ca^{2+} into excitable cells in response to membrane depolarization. In the brain, $Ca_v1.2$ is the most abundant LVGCC and accounts for ~89% of LVGCCs. $Ca_v1.2$ has been shown to couple Ca^{2+} currents to transcriptional regulation, playing an important role in dendritic development, synaptic plasticity, neuronal survival and learning and memory. The $Ca_v1.2$ protein complex is an assemblage of three different subunits, with the main pore forming subunit, α1C, being encoded for by *CACNA1C*. Functional mutations within exon 8 cause Timothy Syndrome, which is characterized by heart defects and autism spectrum symptoms, likely resulting from a gain of function mutation. Additionally, GWAS studies have linked several SNPs within *CACNA1C*, most of which are found in intron 3, to bipolar disorder, schizophrenia and major depression disorder. It is not clear how polymorphisms in *CACNA1C* function to modulate psychiatric disease, but it is likely the result of alterations in transcriptional regulation, with evidence suggesting that genetic variation at SNP rs1006737 results in an increase in expression levels of *CACNA1C*.
Changes in expression of $Ca_v1.2$ have also been linked to Alzheimer's disease (AD). It is a well-supported hypothesis that calcium dysregulation contributes to the pathology of AD, with amyloid proteins being able to induce Ca^{2+} influx into neurons. It has also been shown that APP interacts directly with $Ca_v1.2$, and complete loss of APP results in a substantial increase in $Ca_v1.2$ in GABAergic neurons, and a comparable increase in Ca^{2+} currents.
It is clear that changes in the *CACNA1C* sequence and $Ca_v1.2$ expression are associated with several different disease states. There has been a significant amount of work demonstrating the loss of $Ca_v1.2$ in mice produces a number of behavioral and affective phenotypes, but surprisingly little effort has been made to understand the impact of increased expression. Therefore, we have created a novel line of transgenic mice that over express $Ca_v1.2$, which contains an HA tag allowing us to detect the exogenous protein expression. Expression of the full length transgene is driven by the CAG promoter, and contains a Lox-Stop-Lox cassette upstream of the cDNA sequence, allowing us to control its expression using cre-recombinase. We have achieved germline transmission of the transgene in six different founder lines, with expression of the HA tag in at least two of them when crossed with synapsinI cre driver mice. Additional characterization is ongoing.

Title: Determining the molecular identity of the mitochondrial Na^+/Ca^{2+} exchanger in neurons

Authors: *G. C. WALTERS[1], J. E. RYSTED[1], Z. LIN[2], A. GNANASEKARAN[2], R. A. MERRILL[2], S. STRACK[2], Y. M. USACHEV[2]
[1]Neurosci., [2]Pharmacol., Univ. of Iowa, Iowa City, IA

Abstract: In neurons, mitochondria efficiently buffer Ca^{2+} influx during excitation, and then release Ca^{2+} back into the cytosol, which helps shape $[Ca^{2+}]_i$ transients and regulates many Ca^{2+}-dependent neuronal functions. The putative identity of the uniporter required for mitochondrial Ca^{2+} efflux was previously reported as the $Na^+/Ca^{2+}/Li^+$ exchanger known as NCLX (*SLC8B1*). However, our findings showed that NCLX did not localize to mitochondria in neurons. Therefore, we further explored the role of NCLX in neurons by simultaneously monitoring Ca^{2+} concentration in the cytosol ($[Ca^{2+}]_{cyt}$) and mitochondria ($[Ca^{2+}]_{mt}$) of cultured DRG neurons obtained from wild type (WT) and NCLX knockout (KO; Jackson Lab, C57BL/6J background) mice. In these experiments, $[Ca^{2+}]_{cyt}$ and $[Ca^{2+}]_{mt}$ elevations were elicited by trains of action potentials (5-8 Hz, 4-8 s) using extracellular field stimulation. Surprisingly, NCLX deletion did not significantly affect either $[Ca^{2+}]_{mt}$ elevation or the rate of Ca^{2+} extrusion from mitochondria. Similarly, NCLX deletion had no significant effect on the rate of Ca^{2+} extrusion from mitochondria in hippocampal neurons. As prior studies examined the role of NCLX in HeLa cells rather than neurons, we next used simultaneous measurements of $[Ca^{2+}]_{cyt}$ and $[Ca^{2+}]_{mt}$ in HeLa cells. In these experiments, we found that there was no effect of shRNA knockdown of NCLX in either $[Ca^{2+}]_{cyt}$ or $[Ca^{2+}]_{mt}$ amplitude or response duration to histamine, arguing against the role of NCLX in this process. To identify other genes involved in mitochondrial Ca^{2+} regulation we compared gene arrays from mice deficient in mitochondrial Ca^{2+} influx (MCU KO) to WT and identified the $Na^+/Ca^{2+}/K^+$ exchanger 2 (NCKX2/*SLC24a2*) as a putative target. In neurons, we found that NCKX2 was primarily localized to the mitochondria, suggesting a possible role of NCKX2 in mitochondrial Ca^{2+} extrusion. In Hela cells, we found that NCLX localized primarily to the ER whereas NCKX2 was localized to the mitochondria or Golgi. Overall, these data suggest that NCLX is not the main regulator of mitochondrial Ca^{2+} extrusion in neurons and possibly non-neuronal cells.

Title: Axonal wiring and postsynaptic $GABA_A$-receptor abundance are regulated by the presynaptic calcium channel $\alpha_2\delta$-2 subunit via a trans-synaptic mechanism

Authors: S. GEISLER[1], C. L. SCHÖPF[1], R. I. STANIKA[1], M. KALB[1], M. CAMPIGLIO[1], D. REPETTO[2], L. TRAXLER[1], M. MISSLER[2], *G. J. OBERMAIR[1]
[1]Med. Univ. Innsbruck, Innsbruck, Austria; [2]Westfaelische Wilhelms Univ. of Muenster, Muenster, Germany

Abstract: Auxiliary $\alpha_2\delta$ subunits modulate current properties and membrane trafficking of voltage-gated calcium channels and have been implicated in synapse formation. Indeed, we could recently demonstrate that excitatory synapse formation failed in a cellular $\alpha_2\delta$ triple knockout model (Schöpf et al., *submitted*). Thus $\alpha_2\delta$ subunits are redundant key regulators of glutamatergic synaptogenesis, however, their role in inhibitory synapses is still elusive. Here we show that the specific expression of a single isoform, $\alpha_2\delta$-2, in presynaptic glutamatergic terminals induces a mismatched localization of postsynaptic $GABA_A$-receptors ($GABA_A$Rs). In theory this puzzling observation can be explained by (1) a compensatory upregulation of postsynaptic $GABA_A$Rs in response to $\alpha_2\delta$-mediated enhanced excitatory activity, (2) an active participation of presynaptic $\alpha_2\delta$-2 in the trans-synaptic anchoring of postsynaptic $GABA_A$Rs, and (3) aberrant axonal wiring induced by presynaptic expression of $\alpha_2\delta$-2. In order to distinguish between these hypotheses we analyzed the consequences of presynaptic $\alpha_2\delta$-2 expression on glutamatergic and GABAergic synapse composition and synaptic transmission. Using high-resolution immunofluorescence analysis we show that presynaptic $\alpha_2\delta$-2 increases postsynaptic $GABA_A$Rs both in glutamatergic and GABAergic synapses. The synaptic cell adhesion molecules α-neurexins have previously been shown to regulate presynaptic calcium channels by acting together with $\alpha_2\delta$ subunits. Here we show that $\alpha_2\delta$-2-induced clustering of mismatched postsynaptic $GABA_A$Rs is further upregulated in hippocampal neurons lacking all three α-neurexins. Thus, α-neurexins can modulate the effect of presynaptic $\alpha_2\delta$-2; however, they are not required for recruiting $GABA_A$Rs by presynaptic $\alpha_2\delta$-2. Most importantly, by employing high-

and super-resolution (gSTED) microscopy we demonstrate that presynaptic expression of $\alpha_2\delta$-2 induces an aberrant wiring of glutamatergic axons to GABAergic postsynaptic positions. Electrophysiological recordings in cultures of paired neurons revealed that the aberrant wiring resulted in reduced synaptic transmission (EPSC) and increased paired-pulse facilitation. Finally, using structure homology modeling and immunofluorescence analyses we identify a single splice region in $\alpha_2\delta$-2 responsible for mediating the trans-synaptic effect on $GABA_ARs$. Taken together, our findings provide novel insights into trans-synaptic mechanisms and are particularly interesting considering neuropsychiatric diseases such as autism spectrum disorders, which are associated with axonal wiring defects.

Title: L-type calcium channels modulate the firing pattern of the basolateral amygdala principal neurons

Authors: *Y. ZHANG, E. GARCIA, L. YANG, R. GOPAUL, T. SNUTCH
Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Calcium influx via neuronal L-type calcium channels (LTCCs) has been implicated in regulating neurotransmitter release, neuronal excitability, synaptogenesis, and dendritic growth. However to date, the functional role of LTCCs in regulating neuronal excitability and homeostasis during early developmental stages of the brain has not yet been thoroughly explored. LTCCs are highly expressed in the basolateral amygdala (BLA), an integrative center of the brain for emotional behaviors, where they are known to play a role in fear extinction. Here, we utilized whole-cell patch clamp techniques on acute brain slices from Sprague Dawley rats to examine the contributions of LTCCs to the excitability of BLA principal neurons during critical developmental periods. Results show that acute application of the LTCC agonist (S)-Bay K8644 increased excitability of BLA principal neurons from both immature post-natal day 7 (P7) and juvenile post-natal day 21 (P21) stages. The suprathreshold steady-state firing frequency (sSSFF) increased from 9.02±0.44 Hz to 13.89±3.68 Hz at P7 and from 6.58±0.57 Hz to 14.46±3.98 Hz at P21. In the presence of neurotransmission blockers, increased intrinsic

excitability was evident at P7 (sSSFF: 6.47±0.85 Hz to 11.38±1.64 Hz) but not in P21 neurons. The acute local injection of (S)-Bay K8644 (50 µg/kg) into the BLA of P10 animals produced subsequent changes in the firing pattern at P21: ~83% of P21 neurons displayed burst-firing compared to ~56% in control animals; further, firing adaptation during stimulation was fully abolished in slices from (S)-Bay K8644-treated but not control animals. We hypothesize that these effects may be related to LTCC-mediated modification to the calcium-activated potassium channel-related afterhyperpolarization. Dysfunction of the BLA has been implicated in the etiology of psychiatric disorders including anxiety, depression, and autism spectrum disorders. Our findings suggest that functional increases in LTCC activity during neurodevelopment could potentially underlie alterations of neuronal circuitry and contribute to neurodevelopmental disorders.

Title: CRAC channels contribute to TRPV1-mediated calcium entry in dorsal root ganglion neurons

Authors: *Y. MEI, D. WEI, H. HU
Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: TRPV1 (transient receptor potential vanilloid 1) is a member of the transient receptor potential (TRP) superfamily of cation channels. TRPV1 acts as a transducer and molecular integrator of noxious stimuli in the periphery. It is well-known that TRPV1 is expressed not only on the plasma membrane, but also on the ER membrane. However, the functional significance of $TRPV1_{ER}$ remains exclusive. Previous reports have shown that activation of TRPV1 by agonist capsaicin causes Ca^{2+} release from the intracellular Ca^{2+} stores in rodent dorsal root ganglia (DRG) neurons. We have demonstrated that store-operated calcium channels (SOCs) are mainly expressed in nociceptors including TRPV1 positive neurons. These findings prompted us to ask whether capsaicin-induced Ca^{2+} release can trigger store-operated calcium entry (SOCE). To answer this question, we performed immunofluorescence staining using specific antibodies. We observed that TRPV1 was co-expressed with STIM1, a major component of the SOC family, in

DRG neurons. Live-cell imaging results showed that activation of TRPV1 with capsaicin triggered a translocation of STIM1 from the ER towards to the plasma membrane. TRPV1-mediated Ca^{2+} entry was also attenuated by CRAC inhibitors, YM-58483 and Synta66. Knockout of Orai1 or knockdown of Orai2 or Orai3 significantly decreases capsaicin-induced Ca^{2+} entry, indicating that CRAC channels contribute to TRPV1-mediated Ca^{2+} entry. We then attempted to identify the ER Ca^{2+} stores that are involved in TRPV1-mediated Ca^{2+} release. Ryrodine receptors (RyRs) are known to be expressed in nociceptors. We found that depletion of ryanodine sensitive Ca^{2+} pools by caffeine caused SOCE. Interestingly, caffeine attenuated/abolished TRPV1-mediated Ca^{2+} release in the majority of TRPV1 positive neurons, suggesting that TRPV1-mediated Ca^{2+} release may be from caffeine-sensitive stores, at least partially. In addition, our *in vivo* studies indicated that Orai1 or STIM1 deficient mice showed a decrease in TRPV1-mediated nociception. Collectively, our findings reveal that$TRPV1_{ER}$ activation triggers CRAC channel activation and SOCE. This study provides a novel mechanism underlying TRPV1-mediated nociception.

Title: The role of the Mitochondrial Ca^{2+} Uniporter (MCU) in the pathogenesis of Alzheimer's disease

Authors: *B. D'ORSI[1], L. GALLO[1], E. GREOTTI[1], D. DE STEFANI[1], T. POZZAN[1], R. RIZZUTO[2]
[1]Dept. of Biomed. Sci., Univ. of Padua, Padova, Italy; [2]Dept. of Biomed. Sci., Univ. of Padua, Padua, Italy

Abstract: Ca^{2+} homeostasis impairment and mitochondrial dysfunction are crucial events associated with several neurological conditions, including Alzheimer's disease (AD), ultimately leading to neurodegeneration. In recent years, the role of the Mitochondrial Calcium Uniporter (MCU), a 40 kDa protein of the inner mitochondrial membrane, has been extensively studied. MCU is responsible for Ca^{2+} uptake into the matrix and is modulated by several regulatory subunits. However, the authentic connection between mitochondrial Ca^{2+} overload, through the MCU, and AD has never been directly addressed. The composition of the MCU complex in neurons is unique, indicating a specific and specialized role of mitochondrial Ca^{2+} uptake in the

CNS. In particular, MICU3, whose expression is mainly restricted to neurons, is a highly potent MCU stimulator. Using genetic approaches in combination with improved variants of organelle-targeted Ca^{2+} indicators, biochemical and imaging techniques, we determined that silencing of designated MCU regulators drastically increased (MICU2) or decreased (MICU3) cytosolic and mitochondrial Ca^{2+} uptake in response to 4-Aminopyridine/Bicuculline in wild-type (WT) cortical neurons. As the homozygous deletion of *MCU* mostly results in embryonic lethality, while $MCU^{+/-}$ mice are viable and fertile, with no evident phenotype, we also examined mitochondrial Ca^{2+} uptake in post-natal cortical neurons derived from $MCU^{+/-}$ mice. Notably, deletion of *MCU* diminished mitochondrial Ca^{2+} transients in response to NMDA-induced excitotoxicity. Moreover, WT and transgenic mice carrying the FAD-linked PS2-N141I mutation in the presence of the APP Swedish mutation APPswe were employed to investigate whether and how MCU complex components (MCU, MCUb, EMRE, MICU1, MICU1.1, MICU2 and MICU3) are altered during AD disease progression *in vivo*. In summary, we are not only providing direct evidence of the contribution of each MCU in promoting mitochondrial Ca^{2+} uptake following AD-related toxic stimuli *in vitro*, but also elucidate the physiological and pathophysiological role of MCU *in vivo*. Our results may provide the necessary mechanistic detail to be exploited in the drug discovery process towards the treatment of AD.

Title: TRPM2 deficiency modulates neural plasticity in the mouse hippocampus

Authors: *S. KO[1], S. WANG[1], S. LEE[1], M. PARK[1], S. JUNG[1,2], H. SON[1,3]
[1]Grad. Sch. of Biomed. Sci. and Engineering, Hanyang Biomed. Resear, [2]Dept. of Physiology, Col. of Med., [3]Dept. of Biochem. and Mol. Biology, Col. of Med., Hanyang Univ., Seoul, Korea, Republic of

Abstract: Transient receptor potential melastatin type 2 (TRPM2) is an oxidative stress-sensing calcium-permeable channel that is abundantly expressed in the CNS. Recent studies have reported that TRPM2 contributes to the calcium dysregulation associated with neurodegenerative diseases. However, it remains unclear whether TRPM2 affects neurogenesis and synaptic

plasticity which can lead to a variety of neurological disorders. Here we show that the genetic ablation of TRPM2 resulted in increased neurogenesis in adult mouse hippocampus. In addition, TRPM2 ablation induced expression of synaptic molecules, such as Synapsin 1 (Syn1), NMDA receptor subunit 1 (NR1), and AMPA receptor subunit 2 (GluR2). As both impaired neurogenesis and synaptic plasticity in hippocampus have been implicated in major depressive disorder (MDD), our findings suggest that TRPM2 might play a central role in MDD.

Title: Investigating the role of STIM1 and store-operated calcium entry in mouse purkinje neurons

Authors: *S. K. DHANYA, SR[1,2], G. HASAN[1]
[1]Lab. of intracellular calcium signalling, Natl. Ctr. For Biol. Sciences,Tata Insti, Bangalore, India; [2]Sch. of Chem. and Biotech., SASTRA Univ., Thanjavur, India

Abstract: Calcium plays a significant role in different aspects of neuronal signaling and function. Apart from various modes of calcium entry through ligand and voltage-gated calcium channels in neurons, it is known that Store-operated channels (SOCs) which consists of the pore-forming Orai proteins and the Endoplasmic Reticulum (ER) calcium sensor Stromal Interaction Molecule (STIM) also exist in neurons. Store-Operated Calcium Entry (SOCE) is based on the interaction of STIM proteins with Orai which opens in response to depletion of ER calcium. Previous studies have proposed that SOCE is required for the maintenance of neuronal calcium homeostasis that in turn can influence synaptic transmission and plasticity in the mature brain. However, the importance of SOCE and its relevance to mammalian neuron function is not very well studied. Studies have proposed that deranged calcium signaling in cerebellar Purkinje neurons might leads to neuronal degeneration and Spinocerebellar Ataxia (SCA). It has been found that mGluR1-dependent synaptic potentials and IP3R-dependent calcium signals are strongly attenuated in the absence of STIM1 in Purkinje neurons, but the molecular mechanisms explaining the deficits is not well understood. We have used Mouse Purkinje neurons as a

mammalian model system to understand how STIM1 modulates neuronal function and how altered function of STIM1 leads to neurodegeneration. We generated STIM1 knock out mice that lack STIM1 selectively in Purkinje neurons using the Cre-lox system. Immunostaining of cerebellar sections revealed that STIM1 protein was abolished in Purkinje neurons from 12 week old mice whereas levels of the Calbindin protein remained unaltered. STIM1 knock out mice exhibit impaired motor learning from 17 weeks onwards when subjected to the accelerating rotarod assay. To understand if knockout of STIM1 followed by loss of SOCE affects the global gene expression profile of Purkinje neurons we carried out an RNAseq experiment comparing micro-dissected 1year old STIM1 KO Purkinje neurons with control Purkinje neurons. Preliminary analysis suggests that pathways down regulated through STIM1 knockout were related to nervous system development and cation transmembrane transport. These data suggest that RNAseq experiments could help in identifying potential therapeutic targets for SCA and other neurodegenerative disorders.

[1]Neuro- and Sensory Physiol., [2]Dept. of Neuro- & Sensory Physiol., Univ. Med. Ctr. Göttingen, Goettingen, Germany; [3]IMPRS Mol. Biol., Goettingen, Germany; [4]Univ. Med. Ctr. Goettingen, Goettingen, Germany; [5]Univ. Central Del Caribe, Bayamon, PR

Abstract: ‘Form follows function’ is one of the underlying principles in the organization of biological structures. Conversely, if we know the form and organization of a given structure, we can draw conclusions on its function. Following this credo, we are investigating postsynaptic function by elucidating its nanoscale architecture. To do so, we employ a wide range of techniques, ranging from super-resolution microscopy, over electron microscopy to quantitative biochemistry with the goal to generate a 3D model of a dendritic spine, the main postsynaptic compartment of glutamatergic synapses.
Using STED microscopy, we resolved the precise localization of over 100 proteins in dendritic

spines, including, for example, all SNARE proteins. Finally, we also followed the relocalization of several proteins during homeostatic plasticity, analyzing, for example, the redistribution of SNAP47 during different activity states.
We determined the absolute copy numbers of ~5000 proteins in a neuron, using quantitative mass spectrometry. We were able to break down these numbers to dendritic copy numbers with imaging techniques. This yields the first comprehensive description of a dendritic spine in absolute quantitative terms, and will also enable us to infer protein complex stoichiometry, further augmenting our model and our understanding of structures such as the scaffold organization in the post-synaptic density.
Finally, we are using serial-sectioning electron microscopy to determine the morphology of the spines in culture, which will serve as the backbone for the 3D model.
In total, this data will not only reveal the intricate architecture of dendritic spines and enable us to simulate physiological processes such as depolarization in dendritic spines, but it will also serve as a tool for other researchers in the neuronal cell biology field.
The final model will comprise a large databank on the proteome of the neuron in general, and even more detailed analysis in the postsynaptic compartment, which colleagues can use to develop and test novel hypothesis.

Title: Synapse size predicts EPSP amplitude in mouse barrel cortex

Authors: *G. F. SCHUHKNECHT, S. HOLLER-RICKAUER, G. KÖSTINGER, K. A. C. MARTIN
Inst. of Neuroinformatics, Univ. of Zurich, ETH Zurich, Zurich, Switzerland

Abstract: The field of connectomics is currently subject to great attention and immense research efforts. One of its central promises holds that acquiring the complete wiring diagram of all the neurons and their synaptic connections in a block of the brain using an electron microscope (EM) will ultimately lead to a deep understanding of the embedded neuronal circuits. A serious difficulty is that we do not yet understand how the anatomical features of even a single cortical synapse seen in the EM correlate with its physiological strength. To bridge this gap, we studied the physiology and ultrastructure of the same synapses. First, we recorded pairs of synaptically connected layer 2/3 pyramidal neurons in mouse barrel cortex (at postnatal days 21 to 30) *in vitro* and measured the mean amplitude and variance of the excitatory postsynaptic potentials (EPSPs). The synapses in this study (n = 8 connected pairs) had mean EPSP amplitudes varying between 0.4mV and 2.3mV and further analyses indicated that multiple release sites were present. The pre- and postsynaptic neurons were filled with biocytin, which allowed us to identify all putative synaptic contacts between the axon of the presynaptic neuron and the dendrites of the postsynaptic neuron in the light microscope (LM; average of 4.1 contacts per pair). Finally, we performed correlated LM-EM on all contacts seen in LM to test whether these contacts formed synapses. Surprisingly, of the 8 pairs, 6 were connected by only a single anatomical synapse. Two pairs (both of which also had the largest EPSPs) were connected by 2 synapses, each. Significantly, in all cases, the number of physiological release sites exceeded the number of anatomical synapses found in EM. This implies that individual cortical synapses contain multiple transmitter release sites and that release of a single vesicle does not saturate all the postsynaptic receptors. Most previous correlative studies relied on LM and likely overestimated the number of synapses, and so concluded that each synapse contains only a single release site. Importantly for the interpretation of structural connectomes, we found that a synapse's postsynaptic density (PSD) size was strongly correlated with its average evoked EPSP (r = 0.9). This relation could be a key step in giving functional attributes to the structural connectomes of neocortex.

Title: Physiological effects of a direct interaction between postsynaptic proteins Shank3 and CaMKII

Authors: *T. L. PERFITT[1], C. R. MARKS[2], X. WANG[3], T. NAKAGAWA[2], D. A. JACOBSON[2], R. J. COLBRAN[4]
[1]Mol. Physiol. & Biophysics, [2]Mol. Physiol. and Biophysics, [3]Vanderbilt Brain Inst., Vanderbilt Univ., Nashville, TN; [4]Molec Physiol & Biophysics, Vanderbilt Univ. Sch. Med., Nashville, TN

Abstract: Shank3 is a postsynaptic scaffolding protein that is important for organizing neurotransmitter receptor signaling complexes at excitatory synapses. Mutations or deletions in the SHANK3 gene are associated with neuropsychiatric disorders, such as autism spectrum disorder (ASD) and schizophrenia. Shank3 contains several protein-protein interaction domains that link postsynaptic receptors and channels, such as $Ca_V1.3$ L-type calcium channels, to downstream signaling molecules and the actin cytoskeleton Calcium/calmodulin-dependent protein kinase II (CaMKII) is a signaling protein that is activated by calcium influx through these postsynaptic receptors. Recent proteomics data from our lab found that Shank3 is highly abundant in CaMKII complexes isolated from mouse brain synaptic fractions. Therefore, we hypothesized that CaMKII can directly bind to Shank3.
Here, we confirm that complexes containing Shank3 and CaMKII can be co-immunoprecipitated from mouse forebrain and co-transfected HEK293T cells. Using GST-pulldown and purified CaMKII, we have identified a minimal CaMKII-binding domain in Shank3. This *in vitro* direct interaction requires pre-activation of CaMKII by Thr286 autophosphorylation. We used site-directed mutagenesis to identify residues in Shank3 that are critical for the direct Shank3-CaMKII interaction *in vitro*, as well as for co-immunoprecipitation from transfected HEK293T cells, but not for Shank3 binding to other proteins, such as $Ca_V1.3$. These residues are also critical for co-localization of transfected CaMKII and Shank3 in HEK293 cells and immortalized striatal Q7 cells. Moreover, co-immunoprecipitation from transfected HEK293 cells is essentially abrogated by mutation of the Thr286 autophosphorylation site to phospho-null Alanine. Knockdown of Shank3 in primary hippocampal neurons significantly reduces CaMKII-

dependent LTCC-CREB signaling to the nucleus.
Ongoing studies are testing the physiological effects of disrupting the Shank3-CaMKII interaction on Shank3/CaMKII localization, neuronal morphology, and calcium signaling.

Title: Drebrin depletion affects accumulation of NMDAR subunits and causes less immunoreactivity of MAP2

Authors: *N. KOGANEZAWA, H. YAMAZAKI, T. SHIRAO
Gunma Univ. Grad. Sch. of Med., Gunma, Japan

Abstract: Dynamic microtubules have an important role in the maintenance of dendritic spines. Inhibition of microtubule growth or depletion of EB3, one of the microtubule plus-end binding proteins, affects spine morphology. Drebrin, an actin binding protein, is known to regulate actin dynamics and has critical roles in neuronal development, neuronal migration and synaptic plasticity. Although the presence of microtubules in dendritic spines was disputed, it is now generally believed. However, the small number of spines containing microtubules suggests a dynamic and transient entering of microtubules into spines. Microtubules entry into spines is known to occur in response to $Ca2^{+}$ influx through synaptic NMDA receptors (NMDARs). Drebrin directly binds to EB3 and regulates this entry. These facts suggest that microtubule dynamics couple with actin dynamics that is regulated by drebrin. Here, to investigate if drebrin regulates microtubules dynamics in dendrites, we used primary hippocampal cultured neurons derived from drebrin knockout (DXKO) mice. Microtubule-associated protein 2 (MAP2) binds to microtubules and modulates microtubule stability. As MAP2 and EB3 binds directly, we first observed MAP2 immunoreactivity using wild-type (WT) neurons and DXKO neurons. We detected less MAP2 positive neurons in DXKO neurons than in WT neurons. Because the close relationship between glutamate activation and MAP2 alterations are well known, we then applied AP-5, an NMDAR antagonist, to both neurons. Interestingly, we found that WT neurons treated by AP-5 showed less immunoreactivity of MAP2 whereas there was no change in DXKO neurons. This result suggests low functionality of NMDARs in DXKO neurons. We therefore examined the accumulation of NMDAR subunits immunocytochemically and found that DXKO

neurons had different pattern of their accumulation compared to WT neurons. Taken together, drebrin depletion alters NMDAR function and affects MAP2 immunoreactivity which might affect stability of microtubules.

Title: The epilepsy gene tbc1d24 encodes a novel synaptic protein that is required for the maintenance of excitatory synapses in hippocampal neuron

Authors: *L. LIN, Q. LYU, X. SHEN, J. ZHAO, A. CHAI, K.-O. LAI
Sch. of Biomed. Sci., The Univ. of Hong Kong, Hong Kong, Hong Kong

Abstract: Many inherited neurodevelopmental disorders are resulted from mutations that disrupt synapse development and function. Numerous mutations have been identified in the human *tbc1d24* gene associated with epilepsy and intellectual disability, but the physiological role of TBC1D24 in the brain is not well defined. Here we investigate the potential function of TBC1D24 at excitatory synapse of hippocampal neurons. Using super-resolution structured illumination microscopy (SR-SIM), we found that TBC1D24 co-localized with the postsynaptic scaffold protein PSD-95 in dissociated hippocampal neurons. Short-hairpin RNA (shRNA)-mediated depletion of TBC1D24 in mature hippocampal neurons *in vitro* led to reduction of dendritic spine density, number of excitatory synapses and the frequency of miniature excitatory postsynaptic current (mEPSC). Knockdown of TBC1D24 in adult mouse hippocampus further demonstrated the essential role of TBC1D24 in the maintenance of dendritic spines *in vivo*. Our findings therefore suggest that synaptic dysfunction might contribute to the pathophysiology of epilepsy and intellectual disability in individuals harboring the *tbc1d24* gene mutations.

Abstract: Glutamate is the major excitatory neurotransmitter in the brain mediating fast neurotransmission. Among postsynaptic ionotropic glutamate receptors, NMDA receptors (NMDAR) play an important role in plastic changes in synaptic strength, often through changes in synaptic AMPA receptors (AMPAR) content and spine structure. We have previously discovered an input-side dependent left-right asymmetry of spine structure and synaptic glutamate receptor content at the CA3-CA1 connection in the hippocampus: Synapses in CA1 *stratum radiatum* made by inputs from the right hemisphere have, on average, 50% larger size of postsynaptic density (PSD) and twice higher ratio of perforated synapses, higher density of the AMPAR subunit GluA1 and lower density of the NMDAR subunit GluN2B than synapses with inputs from the left. Interestingly, left-input synapses have been reported to produce stronger long-term potentiation, which correlates with a specific role of left CA3 in forming associative spatial long-term memory. The ratio of GluN2A/GluN2B affects synaptic plasticity, and insertion of GluA1 induces enlargement of PSD. We also found that PSD size correlates positively with GluA1 density but negatively with GluN2B density. No such correlation exists for the densities of other AMPAR (GluA2, GluA3) or NMDAR (GluN1, GluN2A) subunits. These findings prompted us to assess the roles of GluA1 and GluN2B in formation of the input-side dependent asymmetry, by assessing PSD size asymmetry with electron microscopy in CA1-selective GluA1 and GluN2B knock-out mice, and GluN2B-2A swap mice, in which the carboxyl-terminal domain of GluN2B was changed to that of GluN2A. We found that CA1-selective GluA1 knock-out mice lack asymmetry of PSD size, with similar size and ratio of

perforated synapses as left-input synapses in wild-type mice. CA1-selective GluN2B knock-out mice also lack the asymmetry, but with similar structural properties to wild-type right-input synapses. Interestingly, PSD size correlates negatively with GluN2B density in GluA1 KO similarly to wild-type mice but not in GluN2B-2A swap mice, suggesting that the asymmetrical allocation of GluN2B occurs upstream of that of GluA1. Altogether our data indicate that both GluA1 and GluN2B are necessary for formation of the input-side dependent asymmetry, but in different manners. GluA1 is necessary for development of the right-input phenotype with larger PSD. GluN2B, on the other hand, is necessary for formation of the left-input phenotype, depending on its carboxyl-terminal domain. Our results are consistent with an idea that GluN2B allocation serves as the most upstream asymmetry, followed by that of GluA1 and PSD size.

Title: Distinct neurodevelopmental and neuropsychiatric-like phenotypes in Shank2 gene-targeted mice

Authors: *A. ELTOKHI[1,2,3], G. A. RAPPOLD[1], R. SPRENGEL[2,3]
[1]Inst. of Human Genet., Heidelberg, Germany; [2]Max Planck Inst. for Med. Res., Heidelberg, Germany; [3]Inst. of Anat. and Cell Biol., Heidelberg, Germany

Abstract: The *SHANK2* gene, also known as *ProSAP1*, is a member of the *SHANK* gene family encoding postsynaptic scaffold proteins. At excitatory synapses in the mammalian brain, the SHANK proteins link the ionotropic and metabotropic glutamate receptor via other receptor-associated proteins to the actin cytoskeleton and intracellular signaling pathways. Damaging variants in *SHANK* genes are frequently associated with diverse neuropsychiatric disorders including autism and schizophrenia. However, due to the limitations of *in vitro* systems and ethical limitations of studies involving humans, the causal relation between *SHANK* variants and the underlying molecular mechanisms for the neurodevelopmental and neuropsychiatric disorders need to be unraveled in animal models. In our review, we focused on the differences in the *Shank2* gene manipulations in mice and the different experimental designs and conclusions of the different studies. By comparing ten different conventional and conditional *Shank2* knockout mouse models, we were able to demonstrate that they all had very distinct molecular,

electrophysiological and behavioral phenotypes i.e. autistic-like and mania-like phenotypes. This indicates that different mutations within *Shank2* gene lead to different outcomes. To this end, we present our view as to why a spectrum of phenotypes can arise from different *SHANK2* variants and which neuronal circuits are affected by the different mutations in mouse models.

Title: Regulation of trans-synaptic nanoalignment by the actin cytoskeleton

Authors: *A. D. LEVY, A.-H. TANG, T. A. BLANPIED
Physiol., Univ. of Maryland, Baltimore, Baltimore, MD

Abstract: Each side of the synapse contains underlying architecture critical for neurotransmission. On the presynaptic side, the axonal bouton organizes neurotransmitter-containing vesicles and the associated vesicle release machinery in a region called the active zone (AZ). On the postsynaptic side, the dendritic spine organizes neurotransmitter receptors and associated signaling proteins in the postsynaptic density (PSD). The AZ and PSD are further organized at the nanoscale: AZ proteins are distributed heterogeneously within the AZ and form nanoscale clusters that preferentially guide where vesicle fusion occurs, and PSD proteins form clusters that concentrate neurotransmitter receptors and their scaffolds. The organization and function of both the AZ and PSD depends on the specialized underlying structure of the actin cytoskeleton. At the AZ, actin interacts with vesicular proteins, and actin depolymerization regulates vesicle release and recycling. At the PSD, actin is heavily enriched in spines, and its remodeling acutely destabilizes PSD internal structure.
We recently discovered that vesicles fuse in the AZ preferentially at RIM nanoclusters, and these clusters align trans-synaptically with postsynaptic nanoclusters of scaffolds and receptors. This trans-synaptic “nanocolumn” positions receptor densities at the highest concentration of neurotransmitter, and therefore enables fast, strong, and tunable responses. However, the molecular mechanism of the establishment and maintenance of the nanocolumn is still unknown. We hypothesize that the actin cytoskeleton controls synaptic nanoalignment.
We find that treatment of mature dissociated hippocampal cultures with the actin depolymerizing drug latrunculin A disrupts nanoalignment of RIM and PSD95 nanoclusters within minutes, without destroying nanoclusters themselves. This result suggests that normal actin dynamics are

required for proper alignment of the nanocolumn. To test whether actin dynamics on only one or on both sides of the synapse are required for nanoalignment, we have developed new methods for acute, optical, cell-specific regulation of actin polymerization. In concert with post-hoc super-resolution imaging, these tools allow us to address the cell- and synapse-specific roles of actin dynamics in controlling the structure of the nanocolumn.

Title: Regulation of NMDA receptor activation following spontaneous glutamate release

Authors: *S. RANSOM METZBOWER[1], T. A. BLANPIED[2]
[1]Physiol., Univ. of Maryland Baltimore, Baltimore, MD; [2]Dept. of Physiol., Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract: NMDA receptor (NMDAR) activation due to spontaneous release of neurotransmitter plays a critical role in both maintenance and modification of synaptic strength. Because Ca^{2+} influx through NMDA receptors gates multiple signaling cascades at the postsynaptic density (PSD), the mechanisms that regulate receptor activation are important to delineate. However, the sources of variability between synapses in NMDAR activation by spontaneous release are not clear. Here, we asked what NMDAR subtype mediates the majority of response to spontaneous neurotransmitter release, and whether structural aspects of the synapse contribute to inter-synaptic variability.
To isolate NMDA receptor-mediated Ca^{2+} influx, we imaged GCaMP6f in cultured hippocampal neurons (21 to 35 DIV) in the presence of TTX, 0 Mg^{2+}, ryanodine, DNQX, and thapsigargin, allowing detection of miniature spontaneous Ca^{2+} transients (mSCaTs) in single spines. The GCaMP6f response reflected the total NMDAR-mediated Ca^{2+} influx, since mSCaT amplitude was modulated bidirectionally by altering extracellular [Mg^{2+}] or [Ca^{2+}]. Amplitude and frequency of mSCaTs were remarkably variable between and within synapses. A low concentration of the high-affinity antagonist CPP strongly decreased event frequency, but prompted a much smaller reduction in amplitude. Importantly, in essentially all synapses, responses were at least partially blocked by the GluN2B-specific antagonist ifenprodil, and in many, mSCaTs were eliminated. Thus, in these cells, very few NMDARs are activated by spontaneous release, and the majority of these contain GluN2B.

We next asked whether synapse size or subcellular position contribute to the magnitude of NMDAR activation. We measured spine area, and in order to obtain a highly resolved measurement of PSD area, we performed live or post hoc correlative super-resolution imaging of PSDs following Ca^{2+} imaging of the same synapses. Neither spine area nor PSD area correlated with NMDAR activation, revealing that NMDAR activation is independent of synapse size. Additionally, we found no evidence that NMDAR activation was affected by synapse distance or number of branch points from the soma.
These data suggest that following spontaneous glutamate release, the magnitude of spine Ca^{2+} elevation is highly variable despite the low number of NMDA receptors activated per release event. This variance may arise principally from the stochastic properties of channel opening rather than the many other factors that contribute to the number of activated receptors. Additionally, this reveals a novel role of GluN2B-NMDARs in responding to spontaneous release at individual hippocampal synapses.

Title: Autism-associated variants of syntaxin binding protein 5 (STXBP5) disrupt dendritic morphology via the regulation of rho signaling

Authors: *W. SHEN, M. KILANDER, Y.-C. LIN
Hussman Inst. for Autism, Baltimore, MD

Abstract: Autism is a neurological condition characterized by marked qualitative differences in communication and social interaction. Genetic studies have implicated numerous genes, which encode proteins important for synaptic development and function, and may contribute to autism phenotypic diversity. Deletion and mutations of syntaxin binding protein 5 (STXBP5, also known as tomosyn) have been identified in a small number of individuals with autism. STXBP5/tomosyn is a syntaxin binding protein that negatively regulates neurotransmitter release. STXBP5/tomosyn contains an N-terminal WD40 domain and a C-terminal SNARE motif. STXBP5/tomosyn has also been shown to regulate neurite outgrowth in immature neurons via the interaction with ROCK, downstream effector of RhoA. Here we examined the mechanism regulated by STXBP5/tomosyn to control dendritic structures in mature neurons and also tested the hypothesis that the autism-associated variants in STXBP5/tomosyn disrupts

dendritic morphology by altering the Rho signaling pathway.
We first used shRNA knockdown approach to examine dendritic complexity in cultured hippocampal neurons. Tomosyn knockdown neurons exhibited compromised dendrite arborization and reduced dendritic spine density. These neurons also showed increased Rho activity measured by Rho biosensor. Inhibiting Rho activity with dominant negative RhoA or C3 transferase was sufficient to restore complete dendritic morphology. However, inhibition of ROCK rescued dendrite complexity but not dendritic spine density. The shRNA-resistant wildtype tomosyn, but not autism-associated variants, rescued the dendritic phenotype in tomosyn knockdown neurons. In addition to binding to syntaxin-1, tomosyn also bound to syntaxin-4, which plays a role in the trafficking of AMPA receptors. The tomosyn knockdown neurons exhibited fewer surface-expressed AMPA receptors, suggesting a role of tomosyn in regulating receptor trafficking. Interestingly, the autism-associated tomosyn variants displayed altered binding to syntaxin-4, suggesting a potential disruption of AMPA receptor trafficking. In conclusion, we showed that STXBP5/tomosyn controls dendritic morphology via regulation of Rho signaling. *STXBP5* variants found in individuals with autism may disrupt this process, resulting in altered dendritic structures and receptor trafficking, thereby impacting normal circuitry and function.

Title: InSyn1 regulates GABAergic synaptic transmission and cognitive behaviors

Authors: *A. UEZU[1], T. W. BRADSHAW[2], P. DEVLIN[2], E. SPENCE[3], Y. GAO[4], I. KIM[5], R. RODRIGUIZ[6], S. H. SODERLING[1]
[2]Cell Biol. and Neurobio., [3]Cell Biol., [4]Dept. of Cell Biol., [5]Psychiatry and Behavioral Sci., [6]Mouse Behavioral and Neuroendocrine Analysis Core Facility, [1]Duke Univ., Durham, NC

Abstract: Previously we have developed an *in vivo* chemico-genetic approach for the discovery of local proteomes of neuronal substructures. Using this technique, termed *in vivo* BioID or iBioID, we uncovered the molecular framework of the inhibitory postsynaptic complex (iPSD), with over 140 novel trafficking, transmembrane, and signaling proteins enriched at this structure. We also found several previously uncharacterized proteins, one of which we named Inhibitory

Synaptic protein 1 (InSyn1) that was tightly associated with the iPSD. We report here InSyn1 is a novel regulator of the dystroglycan complex (DGC) in neurons. DGC is composed of several proteins and we found InSyn1 interacts with one of these to target it to inhibitory synapses. Furthermore, CRISPR-based depletion further confirmed dystroglycan is critical for InSyn1 iPSD localization. To better understand the physiological relevance of InSyn1 in the nervous system, we generated InSyn1 KO mice. Interestingly, InSyn1 null hippocampal neurons show defects in the spatial distribution of the DGC, which was further supported by electrophysiological recordings. Because genetic mutations in the DGC not only display severe muscular dystrophy but also exhibit cognitive dysfunctions, we performed a battery of hippocampal-dependent behavioral tests and found InSyn1 null mice exhibit complex cognitive abnormalities. These data indicate that InSyn1 is critical for the function of a distinct subset of inhibitory synapses and is important for cognitive behaviors.

Title: Regional variations of excitatory vs. inhibitory input to cortical pyramidal neurons *in vivo*

Authors: *W. WENG, D. B. ARNOLD
Dept. of Biol. Sci., USC, Los Angeles, CA

Abstract: Although excitatory/inhibitory balance in cortical neurons has been studied in the context of whole cells using electrophysiology, less is known about the spatial distribution of excitatory and inhibitory inputs within the dendrites of individual neurons. To examine the distributions of synaptic inputs we expressed FingRs (Fibronectin intrabodies generated with mRNA display) that recognize PSD-95 and gephyrin in mouse cortical neurons in vivo using in utero electroporation. At 3 weeks of age we added cranial windows to these mice and subsequently imaged the distributions of endogenous PSD-95 and Gephyrin using two photon microscopy. Examination of FingR expression in pyramidal neurons revealed that PSD-95 puncta are distributed in a dense and uniform manner, whereas gephyrin puncta are sparse and unevenly distributed. The density of gephyrin puncta varies dramatically between dendritic branches of the same neuron and is increased towards the proximal end of dendritic branches. In addition, gephyrin puncta tend to occur in small clusters, despite their overall sparse distribution.

Given the overall uniform distribution of PSD-95 puncta, these results indicate that excitatory/inhibitory balance varies dramatically between different sub-compartments within dendrites of cortical pyramidal neurons.

Abstract: A theory of cognitive function proposes that inputs to the distal dendrites of neocortical pyramidal neurons contribute to binding external and internal information into a global perceptual concept (Larkum, 2013). The cell-sparse, dendrite-rich neocortical layer (L) 1 of somatosensory cortex is a central locus of those dynamic interactions between feedback inputs that include M1 and S1 and feedforward inputs that drive action potentials in the cell body. L1 is the site of many disparate converging information streams, including afferent input from paralemniscal thalamus, and including a large number of local afferent inputs. These inputs to L1 are in position to target the apical tufts of both the intratelencephalic (IT) and pyramidal tract (PT) neurons.
Here, we used a rabies retrograde tracing approach in L5-Cre lines (PT, Sim-Cre; IT, TLX3-Cre) in conjunction with fast blue application in L1 to compare how inputs to these classes of pyramidal neurons differ, and whether the input to L1 arises from the same brain areas and layers as input to the L5 pyramidal neurons. We show that 1) within S1, IT and PT neurons connect extensively to L2/3 and L5, to some extent to L4, and to some bipolar neurons in L6b; 2) A subset of neurons that are presynaptic to IT and PT neurons and double-labeled with rabies virus also connect to L1; 3) More presynaptic connections are found in the ventro-basal thalamus in PT neurons than in IT neurons, some of which are also connected to L1; 4) Other regions are presynaptically connected to somatosensory IT and PT neurons, including somatosensory cortex S2, motor cortex M1 and M2, and midline and paralemniscal (POm) thalamic neurons; 5) While there is overlap between presynaptic neurons to L1 and the Cre-lines tested, there are clusters of neurons that only project to IT or PT neurons, or to L1.
Taken together, our results suggest that presynaptic inputs to the distinct classes of L5 neurons

are different locally within S1, and for long-range projections from a variety of other brain regions. There is a mix of convergent and divergent input to L1 and to each type of pyramidal neurons.

Title: Tropomyosin isoforms Tpm3.1 and Tpm4.2 modulate synaptic function

Authors: *C. CHAICHIM, H. STEFEN, M. BRETTLE, P. W. GUNNING, E. C. HARDEMAN, T. FATH, J. M. POWER

Abstract: The neuronal actin cytoskeleton is crucial for forming, maintaining, and modulating synapses. Actin filament dynamics are regulated by many actin-associated proteins. An important family of proteins are the actin-associated tropomyosins, which control access of other actin-associated proteins to actin filaments. Two isoforms of tropomyosin are known to be enriched in the postsynaptic compartment and associated with the postsynaptic density: Tpm3.1 and Tpm4.2. Both prevent binding of actin depolymerizing factor, therefore having an actin stabilising action. We hypothesised that enhancing actin stability will augment mature dendritic spine formation and increase synaptic function.
Whole-cell patch clamp recordings of mEPSCs in cultured hippocampal neurons prepared from transgenic mice overexpressing Tpm3.1 and wild-type (WT) control embryos revealed no difference in amplitude or frequency between WT and Tpm3.1 overexpressing cells. Morphometric analysis showed that dendritic spine density was decreased in Tpm3.1 overexpressing cells ($p = 0.02$; unpaired t-test, Tpm3.1 Tg $n = 33$, WT $n = 28$), but the proportions of spine types was unaltered.
Hippocampal field excitatory postsynaptic potentials (fEPSPs) were recorded in acute brain slices prepared from male transgenic mice and littermate controls. Synaptic potentiation induced by high frequency stimulation (100 Hz 1s) was greater ($p = 0.04$; RM-ANOVA) in Tpm3.1 transgenic mice ($n = 16$) than controls ($n = 15$), suggesting that Tpm3.1 overexpression improves synaptic plasticity.

Hippocampal cultures prepared from Tpm4.2 knockout mice had reduced mEPSC amplitude ($p = 0.001$) and frequency ($p = 0.002$) compared to WT controls (unpaired t-test, Tpm4.2 n = 16, WT n = 17). This shows that Tpm4.2 is critical for normal baseline synaptic transmission.
Our results highlight the importance of these tropomyosin isoforms and the actin cytoskeleton in synaptic function.

Title: Expression of the GABA-A receptor α4 subunit is selective for specific spine types in female mouse hippocampus at puberty

Authors: *J. PARATO[1], S. S. SMITH[2]
[1]SUNY Downstate, Brooklyn, NY; [2]Dept Physiol Pharmacol, SUNY Downstate Med. Ctr., Brooklyn, NY

Abstract: Adolescent synaptic pruning occurs in multiple brain regions and is thought to be necessary for normal post-pubertal brain function. We have previously shown that extrasynaptic GABA-A receptors containing the α4 subunit trigger pubertal pruning in the CA1 and CA3 hippocampus (Afroz and Parato et al., 2016), when the density of the mushroom ("memory") and stubby spines decreases by half. These α4βδ receptors increase tonic inhibition, which prevents NMDA receptor activation leading to decreased expression of kalirin-7, a spine protein which is necessary for spine maintenance (Ma et al., 2003). In the absence of pruning, behavioral flexibility in a spatial learning task is impaired, likely due to the abundance of the mushroom spines (Afroz and Parato et al., 2016), emphasizing the importance of pubertal pruning of the mushroom spines. Although α4 has been localized to the dendritic spine at puberty (Shen et al., 2010), it is not yet known whether pubertal α4 expression is selective for certain spine types. Therefore, for this study we tested the hypothesis that α4 expression at puberty is more prevalent on mushroom and stubby spines than on thin spines in the female mouse hippocampus. To this end, we employed a novel Golgi-immunohistochemistry protocol (Sebastian et al., 2013) that allows for visualization of spine types and co-localization of α4 staining (Santa Cruz sc7355). Puberty was identified by vaginal opening (~PND 35). Z-stack images (0.1 um) were taken of pyramidal cells from CA1 and CA3 hippocampus on an Olympus FluoView TM FV1000

confocal inverted microscope. Reconstruction of the Golgi-stained dendrite and 3D colocalization of α4 to spine volumes was performed with Imaris software. In comparing the number of spines of each type which express α4 per 10um segment, there were significantly more mushroom spines which express α4 compared to the thin spines (2.8+/-1.4, mushroom vs 1.4+/-1.3, thin, P<0.002) in CA1 hippocampus as well as in CA3 hippocampus (3+/-1.2, mushroom vs. 1.2+/-1.1, thin, P<0.02). There were also more stubby spines expressing α4 compared to the thin spines (3.4+/-1.9, stubby vs. 1.4+/-1.3, thin, P<0.002, CA1; 3.2+/-1.7, stubby, vs. 1.2+/-1.1, thin, P<0.003, CA3). Thus, α4 localization to the mushroom spines at puberty may explain how these receptors trigger pruning of this spine type which is essential for normal learning flexibility in adulthood.

Title: Resolving the functional organization of postsynaptic glutamate receptors

Authors: *N. SCHEEFHALS, H. D. MACGILLAVRY
Utrecht Univ., Utrecht, Netherlands

Abstract: The spatial organization of neurotransmitter receptors at neuronal synapses critically determines the efficiency of synaptic transmission. At excitatory synapses, ionotropic AMPA-type glutamate receptors (AMPARs) mediate the majority of fast synaptic transmission, while metabotropic glutamate receptors (mGluRs), including the group I mGluRs (mGluR1/5), modulate synaptic efficacy on much slower time scales. Interestingly, while AMPARs concentrate in the core of the postsynaptic density (PSD) that directly opposes the presynaptic vesicle release site, mGluRs are enriched in the perisynaptic domain surrounding the PSD. The spatial segregation of these functionally distinct receptor types is thus predicted to allow for precise temporal control of synaptic transmission and plasticity, yet we know little about the mechanisms that underlie the subsynaptic organization of different glutamate receptor types. Here, we used complementary super-resolution imaging approaches to resolve the dynamic

distribution of AMPARs and mGluRs in dissociated hippocampal neurons. Using STED imaging and single-molecule localization microscopy we confirmed early EM studies showing that mGluRs and AMPARs are spatially segregated in subsynaptic domains. We found that while AMPARs are enriched in the PSD, mGluR5 is almost completely excluded from the synapse, but rather accumulates in nanoscale domains at perisynaptic sites. Moreover, using single-molecule tracking we found that compared to the synaptic pool of AMPARs, which is largely immobile, mGluR5 is relatively mobile and is only transiently confined at perisynaptic sites. To start understanding how mGluR5 is attracted and trapped at perisynaptic sites, but remains excluded from the core of the synapse, we set out to delineate whether specific protein-protein interactions control this particular distribution of mGluR5 at synapses. Surprisingly, the distribution of mutated versions of mGluR5 suggest that the intracellular tail of mGluR5 is not required for the observed perisynaptic distribution, but rather prevents the accumulation of receptors in the core of the synapse. Based on these findings we propose that at excitatory synapses functionally distinct glutamate receptor types are spatially segregated in subsynaptic domains, in part via intracellular interactions that can either promote or hinder the entry of receptors into the PSD. These findings suggest novel mechanisms by which synaptic receptor complexes are spatially segregated to efficiently modulate synaptic transmission and plasticity.

Title: Targeting histone deacetylation for recovery of maternal deprivation-induced changes in BDNF and AKAP150 expression in the VTA

Authors: *F. S. NUGENT[1], S. GOUTY[2], B. M. COX[3], H. KASSIS[1], A. BERENJI[2], W. ZHU[2], R. HAMMACK[2], R. D. SHEPARD[1]

Abstract: Severe early life stressors increase the probability of developing psychiatric disorders later in life through modifications in neuronal circuits controlling brain monoaminergic signaling. Our previous work demonstrated that 24hr maternal deprivation (MD) in Sprauge Dawley rats modifies dopamine (DA) signaling from the ventral tegmental area (VTA) through changes at GABAergic synapses in the VTA that were reversible by in vitro histone deacetylase (HDAC) inhibition through restoration of the scaffold A-kinase anchoring protein (AKAP150)

signaling (Authement et al., 2015). Using this model in male rats with in situ hybridization, Western blots and immunohistochemistry we confirmed that MD-induced epigenetic modifications at the level of histone acetylation was associated with an upregulation of HDAC2. MD also increased Akap5 mRNA levels in the VTA. Western blot analysis of AKAP150 protein expression showed an increase in synaptic levels of AKAP150 protein in the VTA with accompanying decreases in synaptic levels of protein kinase A (PKA). Moreover, the levels of mature brain-derived neurotrophic factor (BDNF) protein of VTA tissues from MD rats were significantly lower than in control groups. In vivo systemic injection with a selective class I HDAC inhibitor was sufficient to reverse MD-induced histone hypoacetylation in the VTA for 24hr after the injection. Furthermore, HDAC inhibition normalized the levels of mBDNF and AKAP150 proteins at 24hr. Our data suggest that HDAC-mediated targeting of BDNF and AKAP-dependent local signaling within VTA could provide novel therapeutics for prevention of later-life psychopathology.

Title: Dynamic control of synaptic substructure and function by adhesion molecules

Authors: *A. M. RAMSEY[1], A.-H. TANG[2], T. BIEDERER[4], T. A. BLANPIED[3]
[1]Dept. of Physiol., Univ. of Maryland, Baltimore, Baltimore, MD; [2]Physiol., [3]Dept. of Physiol., Univ. of Maryland Sch. of Med., Baltimore, MD; [4]Dpt. of Neurosci., Tufts Univ. Sch. of Med., Boston, MA

Abstract: The complex neural processes of information encoding, storage, and retrieval are enabled by precise and efficient regulation of synaptic strength. Recent work indicates that one critical factor likely to control synaptic strength is the nanoscale organization of proteins within the synapse. Our lab discovered that a protein called Rab3 Interacting Molecule (RIM), which is essential for neurotransmitter release, is clustered into ~100 nm subdomains within the active zone, and that vesicle exocytosis preferentially occurs where there is a higher subsynaptic density of RIM. Furthermore, these presynaptic sites of neurotransmitter exocytosis are aligned

with postsynaptic nanoclusters of receptors, which has major implications for the regulation of receptor activation and synaptic efficacy through the subsynaptic positioning of receptors. Though many mechanisms may contribute to the trans-synaptic alignment of receptors to sites of release, a particularly attractive model is that synaptic cell adhesion molecules mediate alignment through high-affinity trans-synaptic protein binding. Leucine Rich Repeat Transmembrane neuronal (LRRTM2) participates in trans-synaptic protein binding with PSD-95 and several neurexin isoforms. Using multicolor 3D dSTORM, we found that LRRTM2 is tightly enriched within PSD-95 nanoclusters and across from RIM1/2 nanoclusters. In order to test the ongoing role of LRRTM2 in established synapses, we engineered a mutant version of LRRTM2 that contains a thrombin-cleavable target sequence at an extracellular, juxtamembrane site. Using a knockdown and replacement strategy, we performed 3D multicolor dSTORM and found that acute cleavage of LRRTM2 results in rapid reduction in the nanoscale alignment of proteins at synapses. Furthermore, we performed whole-cell patch clamp of cultured hippocampal neurons to test how acute disruption of the LRRTM2 extracellular binding interaction impacts synaptic transmission. We find that acute cleavage of LRRTM2 results in a substantial decrease in the evoked AMPAR-mediated EPSC amplitude but only a slight alteration in probability of release. Together, these findings provide experimental support for the idea that trans-synaptic nanoscale organization plays an important role in maintaining synaptic strength. A structural role played by one or more specific cleft proteins provides further evidence for a molecularly guided "nanocolumn" architecture within the synapse. More broadly, these results also indicate that synaptic cell adhesion molecules can play specific and unexpected roles in regulating function at established synapses well after synaptogenesis.

Title: α4βδ GABA-A receptors trigger pruning of mushroom spines in primary motor cortex during adolescence

Authors: M. TEKIN, H. SHEN, *S. S. SMITH
Dept Physiol Pharmacol, SUNY Downstate Med. Ctr., Brooklyn, NY

Abstract: Pubertal synaptic pruning is thought to play a role in refining memories. Proper neurodevelopment of the primary motor cortex (M1) is essential for motor learning and

coordination yet synaptic pruning of basilar dendrites in layer 5 (L5) of M1 has not been studied. Previous research has shown that α4βδ $GABA_A$ receptors (GABARs) trigger pubertal synaptic pruning in the CA1 hippocampus (Afroz et al., 2016). Autism Spectrum Disorder has been linked to abnormalities in the α4 GABAR subunit (Collins et al., 2006) and motor deficits (Geschwind 2009). Thus, the following experiments were used to test the hypothesis that adolescent pruning of L5 pyramidal cells in M1 is regulated by α4βδ GABARs. Golgi staining was used to assess spine density and spine types in each group from z-stack projection (0.3 µm) photomicrographs taken with a Nikon DS-U3 camera mounted on a Nikon Eclipse Ci-L microscope using a 100x oil objective. Spine density across the basilar dendrites (proximal, medial and distal segments) of pubertal vs. post-pubertal mice was compared using either wild-type (P35WT vs. P56WT) or α4 knockout mice (P35α4KO vs. P56α4KO). Using an analysis of variance followed by a post-hoc Tukey's test, we found no significant difference in total spine density between P35WT and P56WT but observed a significant decrease in proximal mushroom spines (P35WT, spine density = 0.057±0.006 spines/µm, P56WT, spine density = 0.026±0.005 spines/µm, $P<0.05$), and an increase in long thin spines (P35WT, spine density = 0.053±0.008 spines/µm, P56WT, spine density = 0.101±0.014 spines/µm, $P<0.05$) in L5. These changes were not observed in L5 when comparing P35α4KO and P56α4KO mice. The functional expression of α4βδ GABARs in L5 M1 pyramidal cells in pre-pubertal wild-type (P28WT) mice and pubertal (~P35WT, identified by vaginal opening) was assessed by performing whole cell patch clamp analysis of pyramidal cell responses to 100nM gaboxadol (selective for α4βδ GABARs). The results demonstrate an 150% increase in gaboxadol response at puberty compared to pre-puberty (P28WT, 18.24±2.4 pA, P35WT, 45.12±3.9 pA, $t(8) = 5.9$, $P=0.00019$) reflecting a significant increase in α4βδ GABAR expression at puberty. These results suggest that selective pruning of mushroom spines in the proximal region of M1 L5 pyramidal cells occurs during puberty, and that α4βδ GABARs are responsible for this pruning.

Title: FAM81A protein, a component of the postsynaptic density in adult brain

Authors: *A. DOSEMECI[1], H. K. LOO[1], C. A. WINTERS[1], T. S. REESE[1], J.-H. TAO-CHENG[2]
[1]NINDS, Lab. Neurobio., [2]NINDS EM Facility, NIH, Bethesda, MD

Abstract: Proteomic analysis of affinity-purified PSD-95 complexes had previously identified a 'hypothetical protein', product of the gene FAM81A (Dosemeci et al 2007). Recent data mining reveals that FAM81A mRNA and protein expression are highest in brain tissue (Human Protein Atlas). Here we show that FAM81A protein in brain is expressed late in development, with a post-natal gradual increase in levels that parallels the expression of PSD-95. Comparison of subcellular fractions from adult brain show that the distribution of FAM81A is similar to PSD-95, with a drastic enrichment in the postsynaptic density fraction. Immuno-electron microscopy of adult brain tissue reveal specific immunogold labeling for FAM81A at a subpopulation of postsynaptic densities. The label for FAM81A is concentrated at the outer edge of the postsynaptic density core, within 30-40 nm from the postsynaptic membrane. While nuclear localization of FAM81A has been reported for certain cell lines (Human Protein Atlas) immuno-electron microscopy studies on adult brain tissue are so far inconclusive. On the other hand, size and sequence considerations indicate that the protein can potentially localize to the nucleus, as well as the cytoplasm, and NCBI Conserved Domain search reveals a sequence similar to the SMC_N (N-terminus of Structural Maintenance of Chromosomes) domain. Further studies are focused on testing the presence of FAM81A at the neuronal nuclei, which may point to a potential function in communication between synapse and nucleus.

Title: Rapid modulation of transsynaptically aligned glutamate receptor nanocluster rings during homeostatic plasticity

Authors: P. FREI, *M. MUELLER
Univ. of Zurich, Zurich, Switzerland

Abstract: Subtle changes in the organization of synaptic proteins may have profound effects on synaptic transmission and animal behavior. The *Drosophila* neuromuscular junction (NMJ) has emerged as a powerful model system to explore the 'sub-synaptic' molecular architecture of presynaptic active zones using super-resolution light microscopy approaches. However, little is known about a corresponding postsynaptic organization and its relationship to presynaptic architecture. Using dual-color super-resolution stimulated emission depletion (STED)

microscopy, we here uncovered that postsynaptic glutamate receptors are arranged in distinct, sub-diffraction 'nanoclusters' at the *Drosophila* NMJ. Interestingly, around six of these clusters form rings with an average diameter of ~200 nm. Moreover, these receptor rings precisely align with rings formed by the C-termini of the presynaptic cytomatrix protein Bruchpilot (Brp), suggesting transsynaptic co-alignment. While postsynaptic *neto* RNAi expression results in more pronounced receptor rings due to predominant loss of 'extrasynaptic' receptors, postsynaptic knock down of *ankyrin* leads to diffuse receptor-cluster organization and larger Brp rings. Finally, preliminary data suggest a rapid expansion of these transsynaptic ring modules on the minute time scale during presynaptic homeostatic plasticity. These findings provide evidence for ring-like, transsynaptic nanomodules that undergo rapid changes during synaptic plasticity.

Title: Multiprotein complexes containing synapse-associated proteins are differentially sensitive to lysis buffer detergent

Authors: *S. E. SMITH, J. LAUTZ, E. A. BROWN, E. P. GNIFFKE
Ctr. for Integrative Brain Res., Seattle Childrens Res. Inst., Seattle, WA

Abstract: Proteins do not act in isolation, but assemble into large multi-protein complexes to perform diverse cellular functions. In response to neuronal stimulation with KCl, glutamate, or agonists, multiprotein complexes containing proteins typically associated with the post-synaptic density rapidly change their composition. These activity-dependent dynamics may be a mechanism by which the cell responds to activity, both by activating intracellular signal transduction cascades and by changing the composition of the postsynaptic membrane (Lautz et al, 2018). However, the study of synaptic multiprotein complexes is complicated by the need to solubilize complexes when preparing cell lysates for co-immunoprecipitation. Typical preparations of the "postsynaptic density" involve solubilizing synaptic fractions in TritonX100, then recovering the insoluble portion and solubilizing it in a high-pH buffer containing the harsh detergent deoxycholate. This treatment would be expected to destroy many protein-protein interactions that may exist at the native synapse. However, it is unclear if, or to what extent, less harsh detergent conditions will solubilize protein complexes associated with the electron-dense

post synaptic density. In this study, we used immunoprecipitation-flow cytometry (IP-FCM) to examine the solubility of several synaptic proteins, as well complexes containing multiple proteins; targets included Homer1, Shank1 and 3, PSD95, SynGAP, and representative members of the GRIA, GRIN and mGluRs receptor families. We find that protein solubility and complexes are greatly affected by detergents. For example, SynGAP and PSD95 show much greater solubility in deoxycholate, and lower solubility in Triton and NP40-contianing buffers. Detection of a protein complex containing PSD95 and SynGAP by IP-FCM follows the same pattern. In contrast, Homer1 shows similar solubility in all detergents, but a shared complex containing Homer and mGluR5 is detected only in NP-40 or Triton-containing buffers. Homer in complex with Shank proteins (detected by a pan-Shank antibody) follows a similar pattern. Thus, it seems that Shank and Homer interactions are disrupted by deoxycholate buffers; in fact, SynGAP and Shank3 are detected in a shared complex only in Triton lysis buffer, despite SynGAP detection being several-fold higher in deoxycholate. We therefore conclude that, for the study of many activity-dependent interactions, non-traditional solubilization protocols can result in the detection of a greater number of proteins in shared complexes that respond to synaptic activity.

Title: Spontaneous and evoked neurotransmission are partially segregated at inhibitory synapses

Authors: *P. M. HORVATH[1], L. M. MONTEGGIA[2], E. T. KAVALALI[2]
[2]Neurosci., [1]UT Southwestern Med. Ctr., Dallas, TX

Abstract: Neurotransmission can be classified into two broad types: spontaneous and evoked. Much of the work examining these types of neurotransmission and their properties has been done in excitatory synapses. Previous work has shown a segregation of AMPA receptors which respond to spontaneous and evoked neurotransmission at excitatory synapses in both the central nervous system as well as the drosophila neuromuscular junction. Additionally, central nervous system NMDA receptors also show a near complete segregation of spontaneous and evoked neurotransmission. Although inhibitory synapses also transmit both spontaneous and evoked neurotransmission, they differ from excitatory synapses in both structure and function. Therefore, it has been unclear if the same principle of segregation holds true at inhibitory

synapses. Addressing this question previously had been inhibited by a lack of well-characterized use-dependent $GABA_A$ receptor blockers. Here, we evaluated picrotoxin's ability to function as a use-dependent $GABA_A$ receptor blocker in dissociated hippocampal cultures. Indeed, picrotoxin is able to block both spontaneous and evoked neurotransmission in a use-dependent manner. By making use of this tool, we show that there is partial, but not full, segregation of spontaneous and evoked neurotransmission at inhibitory synapses. These data indicate that while the principle of segregation of spontaneous and evoked neurotransmission still applies at inhibitory synapses, it is not as complete as at excitatory synapses.

Title: Functional differences of neuroligins: 4x vs. 4y

Authors: *T. A. NGUYEN, M. A. BEMBEN, Y. LI, K. W. ROCHE
NINDS, Bethesda, MD

Abstract: Autism Spectrum Disorders (ASDs) are a diverse set of cognitive developmental disorders that result in a wide range of behavioral deficits. Interestingly, ASDs have long been reported to affect many more males than females. This sex bias in ASDs has been a puzzle in the field. Neuroligins (NLs) are postsynaptic cell adhesion molecules involved in synapse formation and modulation. There are five NLs (NLGN1, NLGN2, NLGN3, NLGN4X, NLGN4Y) encoded in the human genome, whereas in rodent there are four (NLGN1, NLGN2, NLGN3, NLGN4-like). NLGN4X and NLGN4Y are of particular interest because they are sex-linked genes located on the X and Y chromosome, respectively. In addition, multiple mutations in both the extracellular domain (ECD) and the intracellular domain (ICD) of NLGN4X have been shown to associate with ASDs. NLGN4X and NLGN4Y are highly conserved with only fourteen amino acid differences in the ECD and five in the ICD. Here, we show that while having approximately 97% sequence similarity, NLGN4Y does not have the same functions as NLGN4X. Overexpressing NLGN4Y in heterologous cells or in neurons shows that NLGN4Y does not traffic well to the surface, and due to this deficiency in trafficking, NLGN4Y cannot induce synaptogenesis. Chimeras of NLGN4X and NLGN4Y demonstrate the lack of surface expression is due to the ECD of NLGN4Y. Swapping NLGN4Y ECD with NLGN4X rescues NLGN4Y surface expression and synapse formation. Aside from forming synapses, the strength of

synapses can be modified through protein phosphorylation. NLGN4X has been shown to be phosphorylated by protein kinase C (PKC) at threonine 707 (T707) with a profound impact on the synaptogenic properties of NLGN4X. Surprisingly, I observed that PKC cannot robustly phosphorylate NLGN4Y. To screen for new phosphorylation residues specific to NLGN4X or NLGN4Y, I used in vitro kinase assays in conjunction with mass spectrometry. I found that NLGN4X can be phosphorylated by protein kinase A (PKA) but not at the analogous residue on NLGN4Y. Interestingly, a single amino acid difference between NLGN4X and NLGN4Y is responsible for the lack of phosphorylation in NLGN4Y. Using differentiated human neurons from induced pluripotent stem cells, I show that endogenous NLGN4X is phosphorylated by PKC and PKA. Therefore, using a variety of assays, I've identified important functional divergence between NLGN 4X vs 4Y. Taken together, my data indicate that functional deficits in NLGN4Y may contribute to the ASD gender-bias, because NLGN4X mutations will have a dominant effect in males.

Title: Proteomic analysis of trio and kalirin interactomes

Authors: *J. PASKUS, M. BEMBEN, Y. LI, K. W. ROCHE
Natl. Inst. of Hlth., Bethesda, MD

Abstract: Rho family GTPases regulate many synaptic processes including, but not limited to, actin cytoskeleton and spine remodeling. Guanine nucleotide exchange factors (GEFs) are crucial regulators of Rho protein signaling through catalyzing the exchange of GDP for GTP. Kalirin and Trio are essential RhoGEFs of the postsynaptic density, regulating local spine dynamics, synaptic transmission, and plasticity. Intriguingly, Kalirin and Trio are paralog proteins, sharing ~60% total homology, with ~90% conservation of their respective GEF1 domains. Consequently, it has been suggested that Kalirin and Trio may be effectively redundant. However, total and brain-specific deletions of Trio are largely fatal in mice, whereas Kalirin knockout animals are viable. Moreover, recent whole-exome sequencing data have implicated Trio, but not Kalirin, as an ASD-associated gene, together suggesting potential divergence in their developmental and synaptic function. It is not known whether these proteins share discrete or intersecting protein-protein interaction networks, and defining unique or common interactors may aid in elucidating their respective synaptic roles. To establish the interactomes of Kalirin and Trio, we first generated antibodies to Kalirin-7, the major brain-

specific isoform, and Trio using non-conserved epitopes to eliminate cross-reactivity between these paralog proteins. We next immunoprecipitated endogenous Kalirin-7 and Trio from crude synaptic fractions of mouse brain and used liquid chromatography-tandem mass spectrometry to screen for Kalirin-7 and Trio interactors. Comparative analysis of these GEF interactomes revealed distinct and intersecting protein-protein interactions between Kalirin-7 and Trio involving synapse-adhesion, excitatory neurotransmission, and GTPase signaling. Of potential convergent interactors, members of the Neuroligin (NLGN) family of cell adhesion proteins were of particular interest given their overlapping phenotype with Kalirin-7 and Trio, namely their ability to regulate spinogenesis and excitatory transmission. We further validated these interactions *in vitro* and *in vivo*, demonstrating that Trio and Kalirin-7 indeed interact with neuroligin isoforms. Our findings establish interactome networks for two important GEFs of the postsynaptic density, revealing distinct, yet overlapping, interaction networks. We further establish neuroligins as common interactors, which has implications for both the basic biology of synaptic transmission, and in neurodevelopmental and degenerative disorders.

Title: PKA phosphorylation of NLGN1 regulates trafficking and PSD-95 binding

Authors: *J. JEONG, M. A. BEMBEN, Y. LI, K. W. ROCHE
NINDS, BUILDING 35, Bethesda, MD

Abstract: The NLGN gene family encodes single-pass transmembrane postsynaptic cell adhesion molecules that are important for synapse assembly and function. Five NLGN genes (NLGN1, 2, 3, 4X, and 4Y) are identified in humans and four genes (Nlgn1 to Nlgn4) in mice. While all isoforms show high similarity in amino acid sequence, each of the NLGN isoforms displays distinct expression patterns and subcellular localization. NLGN1 is mostly localized to glutamatergic excitatory synapses and is critical for excitatory synapse assembly and function. The large extracellular domain of NLGN1 is responsible for transsynaptic binding with neurexin, a presynaptic cell adhesion molecule. The short cytoplasmic tail of NLGN1 is exposed to a variety of intracellular regulation.
Importantly, NLGN1 binds to PSD-95 via the PDZ ligand. PSD-95 is a scaffolding protein at excitatory synapses and interacts with a large number of channels, receptors, and membrane proteins to organize glutamatergic postsynaptic signaling. PSD-95 and NLGN1 have been investigated together in many studies for their physiological roles in the glutamatergic signaling

pathway. Several studies have shown a functional correlation between NLGN1 and PSD-95. However, PDZ ligand-dependent and -independent NLGN1 function has also been investigated. All these studies suggest an important physiological interplay between NLGN1 and PSD-95. In this study, we found protein kinase A (PKA) phosphorylates NLGN1 on S839, near the PDZ ligand. Interestingly, a phosphomimetic mutation of NLGN1, S839E, significantly reduced the interaction between NLGN1 and PSD-95 in vitro and in situ. Also, when the NLGN1 and PSD-95 interaction was disrupted, surface expression of NLGN1 was reduced in cultured neurons. We further observed that impaired NLGN1 and PSD-95 interactions reduced synaptic NLGN1 expression and NLGN1-dependent synaptic enhancement, as well as reduced increases in spine density. Our results establish a molecular mechanism that regulates NLGN1 and PSD-95 binding in a phosphorylation-dependent manner, which provides novel insights into excitatory synapse development and function.

Title: Quantification of the input-output relationship in an interneuron of *C. elegans* under natural noise

Authors: *K. ASHIDA[1], K. HOTTA[1], K. OKA[2]
[1]Dept. of Biosci. & Informatics, Keio Univ., Yokohama-Shi, Japan; [2]Keio Univ., Yokohama, Kanagawa, Japan

Abstract: A dendrite receives variable and separate inputs from presynaptic neurons, and neurons show sporadic neuronal activity even under natural states on the different neuronal sub-compartments, neurite. To investigate the effects of fluctuating neurotransmitter-release on postsynaptic neuronal activity is crucial in vivo. Here, we focused on AIY interneurons in a nematode, *Caenorhabditis elegans*. They receive sensory information as glutamate inputs throughout the neurite, and integrate environmental information. Moreover, AIY shows a sporadic Ca^{2+} response with and without stimulation; on the other hand, sensory neurons show responses in a deterministic manner. For identification the relationship between input and output in natural state, the simultaneous imaging of glutamate inputs and Ca^{2+} responses in AIY was performed. Furthermore, the relationship between the regional specificity of inputs and neuronal responses were also investigated. For further analysis, we employed Shannon's information theory, which allows measuring the amount of information transfer between sender and receiver and quantifying the reliability of signal transduction in biological systems. Finally, we measured

the Ca^{2+} and membrane potential simultaneously to investigate their relationship. From these results, we showed that input fluctuations are necessary and sufficient to explain Ca^{2+} response fluctuations in AIY regardless of odor stimulation to worms. Furthermore, we found that odor modulates the regional specificity of the information transfer by Shannon's information theory. Finally, we found that Ca^{2+} spikes directly correspond to the depolarization of the membrane potential. As far as we know, this is the first report identifying the region-specific relationship of fluctuations between input and output in vivo under natural environmental noise.

Title: Coincidence detection within the excitable olfactory bulb granule cell spines

Authors: S. AGHVAMI[1], M. MÜLLER[2], *M. LUKAS[3], H. SEYED-ALLAEI[4], B. N. ARAABI[1], V. EGGER[2]
[1]Computat. Modeling and Machine Learing, Sch. of Electrical and Computer Engin., Univ. of Tehran, Tehran, Iran, Islamic Republic of; [2]Neurophysiology, Inst. of Zoology, [3]Univ. of Regensburg, Regensburg, Germany; [4]Inst. for Res. in Fundamental Sci. (IPM), Tehran, Iran, Islamic Republic of

Abstract: In the mammalian olfactory bulb, the inhibitory axonless granule cells (GCs) feature reciprocal synapses that interconnect them with the principal neurons of the bulb, mitral and tufted cells. These synapses are located within large excitable spines that can generate local action potentials (AP) upon synaptic input. Moreover, GCs are capable of firing global APs that propagate throughout the entire dendrite. Strikingly, local postsynaptic Ca^{2+} entry was shown to summate linearly or even supralinearly with Ca^{2+} entry triggered by coincident global APs, even though the underlying conductances would be expected to overlap. We investigated this phenomenon by constructing a compartmental GC model to simulate the spine membrane potential, the ionic currents and the intracellular dynamics of Ca^{2+} in response to coincident local and global signals as a function of their temporal separation Δt. These simulations yielded strongly sublinear summation of spine Ca^{2+} entry for the case of perfect coincidence $\Delta t = 0$ ms. Summation efficiency sharply rose for both positive and negative pairing intervals Δt. The increase was more pronounced and eventually supralinear for positive Δt, and less pronounced

for negative Δt, i.e. when the global AP preceded the synaptic input. This dip was dependent on the presence of voltage-gated sodium channels in the spine head while NMDA receptors or either T-type or high-voltage activated Ca^{2+} channels were not essential. We tested these predictions experimentally by pairing two-photon uncaging of glutamate at spines and somatically evoked APs at Δt = -10 ms, 0 ms, +10 ms (n = 9 spines). The respective spine Ca^{2+} signals were recorded with two-photon imaging and showed significant differences in summation efficiency, with sublinear summation around 0 ms (nonlinearity NL = 0.76 ± 0.15), slightly sublinear summation at -10 ms (NL = 0.86 ± 0.27) and supralinear summation at +10 ms (NL = 1.13 ± 0.28, P < 0.01 vs 0 ms), in close overlap with the simulations. Finally, analysis of response latencies of synaptically evoked global APs yielded a mean Δt = 9.6 ± 8.4 ms (n = 20), explaining the earlier finding of roughly linear summation of synaptic local and global signals. We conclude that these simulations and experiments provide another proof for the existence of the GC "spine spike". In the wake of a synaptic global AP the substantial summation of Ca^{2+} entry within a previously activated reciprocal spine might contribute to an increase in release probability. Such a coincidence mechanism might foster the synchronization of principal neuron and GC network activity within gamma and beta oscillation cycles.

Title: Lateral inhibition and rhythmic gating by the dendrodendritic microcircuit in the olfactory bulb

Authors: *M. MIGLIORE[1,2], M. L. HINES[2], C. GREER[2], G. M. SHEPHERD[2]
[1]Natl. Res. Council, Palermo, Italy; [2]Neurosci., Yale Univ., New Haven, CT

Abstract: A model for dendrodendritic interactions between mitral and granule cells in the olfactory bulb has been hypothesized to generate both lateral inhibition and rhythmic potentials in olfactory processing (Rall and Shepherd, 1968). Over the past 50 years, the model has been subjected to many tests and confirmed on anatomical, physiological and pharmacological grounds. Current questions are whether the model can account for the long distances required for lateral inhibition implied by non-topographical distributions of activated olfactory glomeruli, as

well as for rhythmic potentials. We review here the evidence that the model accounts for both these critical features.
The original model hypothesized that depolarization to activate the mitral-to-granule synapses could occur by either passive or active means. Active properties of the lateral dendrites were demonstrated by Xiong and Chen, 2002. They showed that action potential propagation occurs through the mitral cell lateral dendrites, and furthermore that direct activation of granule cells can inhibit propagation at arbitrary distances from the origin of the action potential at the mitral cell soma.
On this basis, our labs have carried out a series of anatomical studies of the dendrodendritic synapses and computational studies of the model with active dendritic properties. The propagating action potential enables the lateral dendrite to activate the mitral-to-granule cell excitatory synapses at arbitrary distances from the soma, as in the experiments. The lateral dendrites are known to spread up to 1.5 cm around the circumference of the external plexiform layer, covering virtually all the territory of the medial or lateral olfactory bulbs containing the non-topographically activated glomeruli.
With regard to rhythmic potentials, recent studies (cf. Osinski and Kay, 2016) have provided evidence that the dendrodendritic synaptic interactions are involved in generation of either beta or gamma waves, depending on the balance of excitatory drive between sensory input and centrifugal modulation.
In summary, after 50 years the original model with active properties continues to apply. We review these studies and discuss how the dendrodendritic synaptic interactions are coordinated with microcircuits at the input level to the glomeruli and the output level to the olfactory cortex to play a key role in the neural basis of olfactory perception.

Title: Glutamate and gaba co-transmission: Cell-types, distribution, synaptic and vesicular mechanisms

Authors: *D. H. ROOT, S. ZHANG, D. J. BARKER, J. A. MIRANDA-BARRIENTOS, B. LIU, H.-L. WANG, M. F. MORALES
Integrative Neurosci. Res. Br., Natl. Inst. on Drug Abuse, Baltimore, MD

Abstract: Glutamate-GABA neurons within the ventral tegmental area (VTA) are capable of synaptically releasing both glutamate and GABA in the adult mouse. We aimed to identify populations of glutamate-GABA neurons outside VTA and determine the synaptic and vesicular mechanisms that underlie glutamate and GABA co-transmission.
We performed dual *in situ* hybridization for the detection of neurons co-expressing VGluT2 mRNA and GAD mRNA in rats. We found six brain structures containing concentrated populations of neurons co-expressing VGluT2 mRNA and GAD mRNA: the VTA, entopeduncular nucleus (EPN), supramammillary nucleus (SUM), lateral habenula (LHb), posterodorsal tegmental nucleus (PDTg), and caudal pontine reticular nucleus (PNC). By triple *in situ* hybridization for the detection of neurons co-expressing VGluT2 mRNA, GAD mRNA, and VGaT mRNA we found that only the VTA, EPN, and SUM contained neurons co-expressing VGluT2, GAD, and VGaT mRNAs. In contrast, VGluT2 neurons co-expressing GAD mRNA in LHb, PDTg, and PNC lacked VGaT. Thus, neurons belonging to the VTA, EPN, and SUM contain the molecular machinery to synthesize and vesicularly package both glutamate and GABA. However, neurons belonging to the LHb, PDTg, and PNC are capable of vesicularly packaging glutamate and synthesizing GABA, but are incapable of canonical vesicular packaging of GABA by VGaT.
By viral labeling of projections from VTA to LHb, EPN to LHb, and SUM to dentate gyrus in rats, we found that glutamate-GABA neurons establish a common synaptic architecture involving distinct asymmetric (putative excitatory) and symmetric synapses (putative inhibitory) from single axon terminals. These data suggest that glutamate-GABA neurons co-transmit glutamate and GABA from separate synaptic vesicles. We explored this possibility within rat LHb, which receives co-transmitted glutamate and GABA from VTA or EPN in mice. Consistent with results from mice, we found that both VTA and EPN pathways to LHb co-transmitted glutamate and GABA in GAD::Cre rats. To determine if glutamate and GABA are co-transmitted from the same or different synaptic vesicles, we purified synaptic vesicles from LHb. By co-immunoprecipitation and co-immunolabeling of LHb purified synaptic vesicles, we found that VGluT2 and VGaT are distributed on separate synaptic vesicles. We conclude that 1) neurons co-transmitting glutamate and GABA by their expression of VGluT2, VGaT, and GAD, are found in VTA, EPN, and SUM; and 2) VTA, EPN, and SUM axon terminals co-transmit glutamate and GABA via distinct synaptic vesicles at independent synapses within single axon terminals.

Title: Mapping somatodendritic circuits of midbrain dopamine neurons

Authors: *S. ZYCH, C. P. FORD
Univ. of Colorado Anschutz Med. Campus, Denver, CO

Abstract: Midbrain dopamine (DA) neurons in the substantia nigra pars compacta (SNc) and ventral tegmental area (VTA) largely innervate a single terminal region, such that DA neuron populations are distinct and non-overlapping. In addition to terminal dopamine release, these cells locally modulate the excitability of neighboring DA neurons via somatodendritic dopamine release. This leads to activation of D2 autoreceptors (D2R) located on the soma and dendrites of DA neurons, evoking an inhibitory postsynaptic current (D2-IPSC) mediated by G-protein coupled inward rectifying potassium channels. However, the local somatodendritic circuitry between midbrain DA neuron populations has yet to be elucidated. It remains unclear whether DA neurons that project to distinct terminal sites provide somatodendritic inhibition to differentially-projecting DA populations. Using electrical or optogenetic stimulation of midbrain DA neurons to evoke dendritic DA release, we performed whole cell recordings in *ex vivo* brain slices to measure D2R-mediated inhibition between DA cell populations. We found that electrical stimulation and non-selective photoactivation of DA neurons in the VTA and SNc resulted in a post-synaptic D2-IPSC, which was abolished by sulpiride (200nM), confirming that electrical and optogenetic stimulation both cause sufficient DA release to evoke a D2-IPSC. To examine local midbrain circuitry, we injected a retrograde virus encoding channelrhodopsin (ChR2) into the nucleus accumbens (NAc) and the dorsal striatum (DStr). Thus, ChR2 expression in midbrain DA neurons labelled these target-specific populations. We observed that photoactivation of the DStr-projecting population evoked a D2-IPSC in half of recorded SNc DA cells, indicating that the local circuitry of the SNc enables somatodendritic modulation of neighboring neurons. We are further investigating preferential regulation within the SNc between DA populations that project to the medial versus lateral subdivisions of the DStr. We observed that photoactivation of the NAc-projecting population in the VTA resulted in no detectable D2-IPSC in both NAc-projecting and non-projecting DA cells. We are examining whether the activity of another DA population or multiple populations is necessary to evoke D2 IPSCs and mediate local regulation in the VTA.

Title: Depolarization-induced sensitization and synaptic properties of layer 2/3 pyramidal cells in mouse granule retrosplenial cortex

Authors: *M. GAO, Y. IKEGAYA
Grad. Sch. of Pharmaceut. Sci., The Univ. of Tokyo, Tokyo, Japan

Abstract: The retrosplenial cortex (RSC) is a cognitive hub that is involved in a variety of cognitive functions, including spatial memories, head direction, and context fear memories with interval delays. Consistent with this fact, the RSC has reciprocal synaptic connections with various brain regions, including the visual cortex, the hippocampus, the medial entorhinal cortex, and the subiculum. Thus, the RSC is likely to conduct synaptic integrations in different levels of neural information. However, there is only limited knowledge concerning about the basic properties of individual RSC neurons. A previous study has demonstrated that small pyramidal cells in the layer 2/3 of the rat RSC exhibit late-spiking properties through activity of a series of Kv channel subtypes (Kurotani et al, Brain Struct Funct, 2013), but it remains unclear how RSC neurons react to diverse synaptic inputs or how these features influence the computational properties of RSC neurons. Here, we used whole-cell patch-clamp recordings to examine the spiking properties of RSC layer 2/3 neurons and found that RSC layer 2/3 late-spiking neurons tend to produce spikes with shorter latencies after current injection-induced depolarization, and this tendency was more evident when the prior current injection had longer durations, larger depolarizations, or shorter intervals between the current injection and spike-evoking stimulation. These properties were in the opposite direction to that observed for RSC layer 5/6 neurons, anterior cingulate layer 2/3 neurons, and hippocampal CA1 neurons. Optogenetic stimulation of excitatory afferents projected from the subiculum reproduced similar results. We will further examine the synaptic properties of RSC layer 2/3 neurons to reveal a possible role of RSC in the integration of information flow.

Title: Voltage imaging reveals gap junction enhancement of inhibitory interneuron synchrony in layer II/III of mouse cortex

Authors: *K. S. SCHEUER[1], P. O. BAYGUINOV[2], M. B. JACKSON[1]
[1]Neurosci., Univ. of Wisconsin-Madison, Madison, WI; [2]Washington Univ., St Louis, MO

Abstract: Neurons fire action potentials when the summation of excitatory inputs exceeds a threshold. The time window within which input can be integrated has a strong impact on the temporal fidelity of neural firing; over longer time spans, neurons are able to sum more excitatory inputs and consequently exhibit reduced selectivity and lower temporal resolution. When the time window is narrower, however, inputs must be tightly synchronized to trigger an action potential. Under these conditions, neurons can act as coincidence detectors and transmit information at a temporal resolution of 2 msec or less with sub-millisecond variability. Inhibitory interneurons (INs) are critical for narrowing this summation time window; in rat hippocampal pyramidal cells, $GABA_AR$ antagonists increase the integration window nearly 10-fold and nearly triple the variability in spike timing. To investigate the factors which influence IN activity and thereby gain insight into spike timing in local cortical circuits, we used hybrid voltage optical sensors (hVOS) to measure voltage changes in murine LII/III INs. This technique allowed us to study ten or more INs simultaneously in an area of approximately 500-1000 μM with a time resolution of 0.5 msec. We used Cre-lox recombination to target a genetically-encoded hVOS probe either generally to GABAergic INs with a glutamic acid decarboxylase 2 Cre driver, or specifically to parvalbumin (PV) INs with a PV-Cre driver. Cortical slices prepared from the offspring of these crosses contained many hVOS probe-labeled INs, most of which responded with optically-reported voltage changes to electrical stimulation. Responses to electrical stimulation were visible in a single trial, and revealed significant trial-to-trial variations in latency of 1-2 msec. However, in many pairs of INs, these latencies were highly correlated and varied in concert. To test the role of gap junctions in this correlation, we used quinine or mefloquine to block the primary neuronal connexin (Cx36) and two additional connexins present in PV+ IN gap junctions (Cx32 and Cx43). Most of the IN pairs previously identified as correlated in response latency became uncorrelated following the addition of connexin blockers. This study indicates that the gap junctions known to couple INs serve to synchronize their

responses and give IN circuits greater temporal power in controlling the timing and integration windows of local cortical circuits.

Title: Localization of inhibitory interneurons integrating central amygdaloid inputs to locus coeruleus neurons using virus mediated cell type specific wheat germ agglutinin tracing method

Authors: *J.-C. HSIEH[1], M.-Y. MIN[2], C.-C. CHEN[3], H.-W. YANG[4]
[1]department of life science, [2]Natl. Taiwan Univ., Taipei, Taiwan; [3]Academia Sinica, Taipei, Taiwan; [4]Chung Shan Med. Univ., Taichung, Taiwan

Abstract: It has been reported that neurons in the central amygdala (CeA) and locus coeruleus (LC) increase their activity when predictive relationships between events are first noticed or altered, and electrical stimulation of CeA causes phasic response in LC neurons. Nevertheless, the underlying mechanism remains unknown. Given the majority of projecting neurons in CeA outputs are GABAergic, we hypothesize that CeA inputs might trigger LC phasic response through with inhibition of local GABAergic interneuron synapsing on LC neurons. To test this hypothesis, we first examined local GABAergic interneuron by producing a serotype 2 adeno-associative virus (AAV2), carrying floxed stop codon followed by sequence encoding wheat germ agglutinin (WGA), a commonly used transneuronal tracer. Second, we choosed AAV-Syn-ChrimsonR-tdT (addgene, plasmid#59171) as a marker to examine the input from CeA. After injecting AAV2-CMV-floxed stop-WGA into LC and AAV-Syn-ChrimsonR-tdT into CeA of cross bred transgenetic mouse line of tyrosine hydroxylase-cre(TH-cre) and glutamic acid decarboxylase-green fluorescent protein (GAD-GFP). This resulted in localization of a population that is WGA-immunoreactive (WGA-ir) within LC and the surrounding peri-LC areas. We further observed that, while most of these WGA-ir neurons are also TH-ir, a few of them are not. We reason that these WGA-ir but non-TH-ir neurons represented WGA transneuronal transportation from TH-ir neurons basing on two arguments. First, there are no catecholamine neurons other than LC NAergic neurons in the dorsal potine area; second, we have validated that there is no leak-out cre expression in LC of TH-cre mice, as cre-dependent expression of eYFP was only found in TH-ir neurons in TH-cre mouse injected AAV2-floxed-eYFP in LC. Basing on analysis from 2 animals with precise injection, about 20% of WGA-ir but non-TH-ir neurons also expressed GFP, showing they are GABAergic neurons. Furthermore, we have observed in one case that a WGA-ir, non-TH-ir and GFP^+ neuron received tdT labeled

fiber. The above observations support our hypothesis that disinhibiting of local GABAergic neurons is involved in trigger of phasic activation of LC neurons by CeA inputs.

Abstract: Neurogenesis in the adulthood continuously provides the dentate gyrus (DG) of the mouse hippocampus with pools of granule cells (GC) that integrate into the preexisting network. We have previously showed that immature GC have lower thresholds of activation than the rest of the mature GC, are less selective in their responses to afferent inputs and respond to a wider range of frequencies of afferent activity. The differences in the activation profile of immature and mature neurons are dictated by the inhibitory circuits. These results suggest that mature and immature granule cells could then represent two different codes coexisting in the same structure: A sparse-code of mature neurons with low firing rates and high selectivity, and a dense-code of immature neurons in which most neurons are active at any moment and information is encoded by variations in firing rate. In this work we wanted to evaluate how neuromodulators, in particular acetylcholine, affects processing of inputs in both mature and immature GC. Using both pharmacologic and optogenetic tools combined with electrophysiological recordings, we observed that in presence of cholinergic activation, mature neurons increase their spiking response to stimulation of medial perforant path (mPP) inputs, whereas no significant changes were seen for immature 4 week old neurons. Then we recorded from individual neurons in a whole cell configuration, isolating the evoked excitatory and inhibitory currents (EPSCs and IPSCs) in response to mPP stimulation. We observed that Ach induced a reduction in the inhibitory component of the response, which was more prominent for mature neurons. This produced an increase in the excitation to inhibition balance that explained the differential spiking response. In addition, we observed that activating mPP at high frequency, normally insufficient to produce long term potentiation (LTP) in control conditions, produce LTP when paired with

optogenetic activation of cholinergic axons. We conclude that acetylcholine can provide a temporal window in which the information processing and plasticity rules of granule cells change, possibly allowing this brain region to adapt the encoding to the behavioral demands.

Title: The modulation of responses characteristics depending on the input frequency in hippocampal granule cells

Authors: N. NAKAJIMA, T. OINUMA, H. HAYAKAWA, E. SUGISAKI, *T. AIHARA
Tamagawa Univ., Tokyo, Japan

Abstract: The hippocampal dentate gyrus is a gate for memory association among cortexes. It was reported that the granule cells (GCs) in the dentate gyrus receives individual inputs by two different pathways from entorhinal cortex. One is spatial (place) information which is propagated through the medial perforant path to the medial dendrite (MD, at the middle molecular layer). The other is non-spatial (e.g. odor) information which is propagated through the lateral perforant path to the distal dendrite (DD, at the outer molecular layer). In addition, 4-8Hz (theta) and 20-40Hz (gamma) oscillations were observed in entorhinal cortex, an origin of pathways to MD and DD, in the rat brain during the odor discrimination task, respectively. However, the response-characteristics and the associative-interaction of two inputs on dendrites of GCs, depending on the input frequency, is still unclear. In this study, to investigate the integration of two input information propagated to hippocampal GCs, electrical regular-stimuli consisting 5 pulses were applied at 10 Hz - 40 Hz to two pathways projected to dendrites, MD and DD, of granule cells in a rat hippocampal slices and magnitudes of field excitatory-post-synaptic-potentiation (fEPSP) were measured. In our experiments, NMDA receptor and GABAergic receptor as post-synaptic factors were controlled by application of D-APV and picrotoxin, respectively, and thereby response characteristics for two inputs were analyzed paying attention to pre- and post-synaptic mechanism in the presence and absence inhibitory interneurons. As the result, magnitudes of successive fEPSP for regular electrical-stimulus to DD and MD showed transient and sustained responses, respectively. Especially, sustained responses for stimulus to DD were significantly influenced by temporal interaction between the NMDA current and the IPSP induced by inhibitory interneurons, depending on the input frequency. In addition, our previous report showed successive inputs to DD facilitated the temporal-pattern discrimination for MD input in

GCs. These results suggest that modulation of the sustained response at DD by interaction between NMDA receptors and GABAergic receptor depending on the input frequency are crucial role for the integration of two inputs in GCs.

Title: Changes in synaptic transmission in NTS of rats in response to acute hypoxia are not affected by previous exposure to sustained hypoxia or chronic intermittent hypoxia

Authors: *D. ACCORSI-MENDONCA[1], L. G. H. BONAGAMBA[2], B. H. MACHADO[3]
[1]Univ. São Paulo, Ribeirão Preto, Brazil; [2]Univ. of Sao Paulo, Ribeirao Preto, Brazil; [3]Sch. Med. Ribeirao Preto, USP, Ribeirao Preto, Brazil

Abstract: Peripheral chemoreflex is activated under hypoxia and produces cardiovascular and respiratory changes to keep the oxygen level in the physiological range. Neurons are highly sensitive to sustained hypoxia (SH) as well to chronic intermittent hypoxia (CIH), with implications on the synaptic transmission. Here, we evaluated the effect of previous short-term SH (FiO_2 0.1, 24 hours) or CIH (10 days, FiO_2 0.06, 8 hours/day) on changes induced by acute hypoxia (5 min) on the electrophysiological profile of NTS neurons. For this purpose, we used whole-cell patch clamp technique and brainstem slices from Wistar rats (P30). Normoxia condition was obtained by bubbling bath solution with 95% O_2 and 5% CO_2 and for the acute hypoxia the bath solution was bubbled with 95% N_2 and 5% CO_2. We observed that acute hypoxia induced a hyperpolarization (-63 ± 3.4 mV vs -73 ± 4.6 mV, n=8) and blocked the spontaneous firing frequency in NTS neurons from control rats. Acute hypoxia also decreased the RMP in neurons from CIH animals (-68 ± 3.2 mV vs -78 ± 4.7 mV, n=5) as well in SH rats (-62 ± 2.3 mV vs -68 ± 4.0 mV, n=12) and reduced the firing frequency in both groups. Acute hypoxia did not affect the R_{input} in NTS neurons from any group [(control: 1.03 ± 0.11GΩ vs 1.20 ± 0.28 GΩ, n=11)(SH: 1.15 ± 0.18 GΩ vs 0.93 ± 0.23 GΩ, n=8)(CIH: 0.95 ± 0.16 GΩ vs 0.75 ± 0.13 GΩ, n=6)]. With respect to the excitatory transmission, acute hypoxia reduced the amplitude of glutamatergic post-synaptic currents in neurons from all groups [(control: 142 ± 25 pA vs 91 ± 27 pA, n=14)(SH: 319 ± 73 pA vs 232 ± 68 pA, n=12)(CIH: 81 ± 12 pA vs 66 ± 7

pA, n=7). The data are showing that preconditioning to SH or CIH does not prevent the changes induced by acute hypoxia on the excitatory transmission and passive properties of neurons in the NTS of rats.

Title: NMDA spikes in human neocortex

Authors: *G. TESTA-SILVA[1], S. HONNURAIAH[1], C. FRENCH[2], J. KING[4], K. DRUMMOND[4], L. M. PALMER[3], G. J. STUART[1]

Abstract: Since the days of Golgi and Cajal, dendrites have been recognised as neuronal structures of potential relevance to information processing and storage in the brain. Yet, despite their potential significance, what we know about dendritic physiology stems, almost exclusively, from rodent research. Over the past decade, however, there has been increased interest in research on human neurons, obtained primarily from epilepsy and tumour surgeries in adult patients. In the present study, we build on this body of work to investigate whether local dendritic NMDA-dependent regenerative plateau potentials (NMDA spikes), which have been shown to play a critical role in information processing in rodent neurons, also occur in human neurons, and if so, describe their kinetics and the experimental conditions required for their generation. To address this, we recorded from supragranular tufted pyramidal cells in neocortical human slices from both epilepsy and tumour patients. Using glutamate iontophoresis, we probed excitation of basal dendrites, with our preliminary efforts illustrating linear integration in the majority of basal dendritic locations (from 50 up 250 um from the soma). In contrast, glutamate iontophoresis onto oblique dendrites routinely evoked supra-linear regenerative responses, which were abolished in the presence of APV, illustrating that human dendrites can generate NMDA spikes. To understand why these supra-linear voltage events were preferentially evoked in the oblique dendrites of human pyramidal neurons, we explored the underlying biophysical mechanisms in a morphologically realistic, active compartmental model. These results show that the dendrites of human cortical pyramidal neurons can generate NMDA spikes, as previously illustrated in rodent pyramidal neurons. Taken together, our findings suggest that human cortical

pyramidal neurons contain distinct dendritic domains, which respond differently to synaptic input.

Title: Functional autapses in neocortical pyramidal cells

Authors: W. KE[1], L. YIN[1], R. ZHENG[1], Q. HE[1], Y. ZHANG[1], J. LI[1], B. WANG[1], Z. MI[1], M. RASCH[1], T. LI[2], G. LUAN[2], *Y. SHU[1]

Abstract: Autapses are special synapses formed in a single neuron, from the axon onto its own somatodendritic compartments. Autapses are abundant in neurons in culture systems, they have been considered as aberrant and redundant neuronal structures. However, autaptic contacts are found massive in certain types of GABAergic interneurons in the neocortex and play critical roles in regulating spike precision and network activity. In this study, we sought to determine whether neocortical pyramidal cells (PCs) form functional autapses. In acute mouse neocortical slices (postnatal 14-21 days, either sex, sex differences were not assessed), we performed simultaneous soma-axon patch clamp recording combined with axotomy or treated the preparation with $SrCl_2$ to isolate autaptic currents. We found that autapses are mainly formed by subcortically projecting layer-V PCs but rarely in cortico-cortical PCs and those in layer II/III. Autapses are not just transient structures in the developing brain. PCs in adult mouse (2 months) and human (male, 30-40 years, with intractable epilepsy) cortical tissue also show autaptic connections. Surprisingly, autapses produce giant postsynaptic responses (n=62 cells), five-fold greater than PC-PC recurrent synapses (n=10 pairs). In addition, autaptic responses are exclusively mediated by AMPA receptors. Further experiments showed that the activation of PC autapses enhances burst firing, neuronal responsiveness and coincidence detection of self-activity and incoming synaptic inputs. Together, our findings indicate that PC autapses are not aberrant structures, they are functional instead and represent an important circuit element in the neocortex.

Title: Impact of layer 6 corticothalamic neurons in the prefrontal cortex

Authors: *D. COLLINS, A. G. CARTER
Ctr. for Neural Sci., New York Univ., New York, NY

Abstract: The cerebral cortex sends two distinct output streams to the thalamus, originating in deep layers five (L5) and six (L6). In the prefrontal cortex (PFC), both L5 and L6 corticothalamic neurons send axons to the same PFC-projecting thalamic nuclei. However, the relative contributions of these corticothalamic circuits in the PFC remain largely unexplored. Here we use transgenic mice along with optogenetics and whole-cell physiology to investigate the role of L6 in PFC-thalamus communication. We first study connections from the PFC to the thalamus to understand how the PFC shapes excitatory drive. We next explore the role of L6 inputs to the reticular thalamus in driving inhibition of thalamic nuclei. Finally, we examine L6 activity within the local circuit of the PFC. Together, our findings reveal new ways in which L6 neurons mediate PFC-thalamus communication.

Title: Ventral hippocampal inputs preferentially drive cortico-cortical neurons in the infralimbic prefrontal cortex

Authors: *X. LIU, A. G. CARTER
Med. Sch., New York Univ., New York, NY

Abstract: Inputs from the ventral hippocampus (vHPC) to the prefrontal cortex (PFC) play a key role in working memory and emotional control. However, little is known about how excitatory inputs from the vHPC engage different populations of neurons in the PFC. Here we use optogenetics and whole-cell recordings to study the cell-type specificity of synaptic connections in acute slices from mouse PFC. We first show that vHPC inputs target pyramidal neurons in superficial and deep layers of infralimbic (IL) PFC, but only deep layers of prelimbic (PL) PFC. We then compare connections onto different classes of projection neurons located in these layers and sub-regions of PFC. We establish vHPC inputs similarly contact cortico-cortical (CC) and cortico-amygdala (CA) neurons in layer 2/3 (L2/3) of IL, but preferentially target CC neurons over cortico-pontine (CP) neurons in layer 5 (L5) of both IL and PL. Of all these neurons, we determine that vHPC inputs are most effective at driving action potential (AP) firing of CC neurons in L5 of IL. We also show this connection exhibits frequency-dependent facilitation, with repetitive activity enhancing AP firing of IL L5 CC neurons, even with intact inhibition. Together, our findings reveal how vHPC inputs engage defined populations of projection neurons within the PFC, allowing them to preferentially activate the intra-cortical network.

Title: Target cell-specific asynchronous glutamate release from neocortical pyramidal cells

Authors: S. DENG[1], J. LI[1], J. ZHU[2], Q. HE[1], Z. MI[1], *M. ZHANG[1], Y. SHU[1]
[1]Beijing Normal Univ., Beijing, China; [2]Yale Univ., New Haven, CT

Abstract: The arrival of action potential (AP) at presynaptic terminal usually causes immediate synchronous release (SR) of neurotransmitter within a time window of 1-2 ms. Prolonged asynchronous release (AR) that is not tightly coupled to presynaptic AP also occurs at output synapses of certain types of GABAergic interneurons in the hippocampus and neocortex upon high-intensity stimulation. Asynchronous GABA release provides long-lasting inhibition in

target cells and desynchronizes their activities. However, it remains unclear whether AR occurs at output glutamatergic synapses of pyramidal cells (PCs). We performed dual recordings from cortical PCs and neighboring inhibitory interneurons including the fast-spiking (FS) cell and the low-threshold spiking (LTS) cell in rodent cortical slices (postnatal 15-20 days, either sex, sex differences were not assessed). We found surprisingly that, in response to AP bursts in the presynaptic PC, AR occurs at its output synapses in a target cell-specific manner. In comparison with PC synapses onto FS (n=10 pairs) and neighbor PCs (n=7), those onto LTS (n=10) show the strongest AR and cause prolonged depolarization and firing in the postsynaptic cell. Intracellular application of EGTA (n=9) could abolish the occurrence of AR, indicating a dependence on residual Ca^{2+}, and Ca^{2+} influx at PC-LTS synapses is mainly mediated by P/Q-type Ca^{2+} channels. Further experiments revealed an important role of Ca^{2+} sensor synaptotagmin-7 (Syt7) in the occurrence of AR. Knocking out Syt7 (n=19) reduced both the number of AR events and the AR-induced basal currents, leading to a reduction of lateral inhibition between PCs. In conclusion, our results demonstrate that asynchronous glutamate release occurs at PC output synapses and its strength is target cell specific. The robust AR in PC-LTS synapses could induce prolonged activities in LTS cells, which may subsequently provide long-lasting inhibition and regulate dendritic integration in neocortical PCs.

Title: Non-reciprocal open-loop interactions in thalamo-thalamicreticular network

Authors: *K. PAUL[1], J. W. BROWN[2], A. TAHERI[4], R. V. KENYON[4], T. Y. BERGER-WOLF[4], D. A. LLANO[3]
[1]Beckman Inst., [2]Col. of Med., [3]Beckman Institute, Mol. and Integrative Physiol., Univ. of Illinois at Urbana-Champaign, Urbana, IL; [4]Dept. of Computer Sci., Univ. of Illinois at Chicago, Chicago, IL

Abstract: The thalamic reticular nucleus (TRN) has well-established closed loop reciprocal connectivity with the thalamus. However, there is growing evidence of additional non-reciprocal or open loop connectivity between them, in which thalamic neurons are not reciprocally inihibited by the TRN neuron that they excite. Such an arrangement may provide a basis for the

transmission of neuronal information between thalamic nuclei, both intramodal and crossmodal. In this study, we employ experimental and computational approaches to show that information transmission may occur along the thalamus via non-reciprocal, open-loop thalamus-TRN interconnectivity. Whole-cell patch-clamp recordings were performed in colliculo-thalamocortical and somatosensory slice preparations from mice (P12-24). Recordings were obtained using standard extracellular solution and Cs based intracellular solution in the voltage clamp mode. The holding potential was kept at 0 mV or +10 mV to maximize amplitudes of the photostimulation evoked inhibitory postsynaptic potentials. MNI-caged glutamate (Tocris) was added to recirculating ACSF and stimulated using a pulsed UV laser (355 nm, DPSS) over a grid of points encompassing the TRN and several thalamic nuclei (MGB, VB, dLGN) and focal photolysis was accomplished by non-neighbor stimulation of points within the grid. Current responses were obtained in the voltage clamp configuration with the outward current amplitude representing the strength of the disynaptic connection. Pharmacological investigations showed that monosynaptic and disynaptic TRN-thalamus inhibitory maps are attenuated by local application of excitatory synaptic blockers in the TRN but not by inhibitory blockers. This suggests that open-loop interactions occur via the TRN-thalamus AMPA connectivity. We further investigated contributions of TRN-TRN electrical synapses in the non-reciprocal transmission using gap junction blockers as well as in Connexin 36 KO mice. The experimental findings were complemented with a computational model of the thalamo-reticular-cortical network to show that propagation of oscillatory activity was best supported in networks with strong closed and open loop reticulothalamic connectivity, with minimal contribution of intrareticular chemical or electrical synapses.

Abstract: Experimental observations have shown that glutamatergic inputs to the basal dendrites of cortical pyramidal neurons activate AMPA and NMDA receptors, which can bring the dendrites into a long-lasting depolarized state: a dendritic plateau potential. These sustained depolarizations push the cell body towards spike threshold and reduce the membrane time constant. In such a "*Prepared*" state, the pyramidal cells can respond to other sparse synaptic inputs more quickly and easily, facilitating synchronization of firing. During the plateau depolarization, a neuron can tune into ongoing network activity and synchronize spiking with other neurons to provide a coordinated "*Active*" state (robust firing of somatic action potentials), which would permit "binding" of signals through coordination of neural activity across a population. Under this scenario, *Active* cells are recruited from cells in the *Prepared* state, and therefore the transient *Active* ensemble is embedded in the longer-lasting *Prepared* ensemble of neurons. We hypothesize that "embedded ensemble encoding" may be an important organizing principle in networks of neurons, explaining how electrical signaling endows central nervous system with capacity to form large number of neural ensembles. We have developed a morphologically-detailed model reconstructed from a cortical Layer 5 prefrontal pyramidal cell in the NEURON simulator. Both synaptic AMPA/NMDA and extrasynaptic NMDA receptors are placed on basal dendrites to model the induction of plateau potentials. The active properties of the cell are tuned to match the amplitude and duration of plateau potentials recorded by voltage-sensitive dye imaging in dendrites and whole-cell patch measurements in soma. Then, the effects of input location, receptor conductance, calcium-activated potassium channels and voltage-activated calcium channels were explored in the model. These findings help us to better understand the implications of dendritic plateaus at the cellular and network level. In the future, this detailed individual cell model can be used to develop cortical meso-scale network models for exploring the hypotheses pertaining to the recruitment of neurons into neural ensembles.

Abstract: Applying glutamate near basal dendrites of cortical pyramidal neurons has been shown experimentally to activate AMPA and NMDA receptors, which can result in dendritic plateau potentials: long-lasting depolarizations in the dendrites which spread into the soma, bringing the cell closer to the spiking threshold and reducing the membrane time constant. When in such a "*Prepared*" state, pyramidal cells can more quickly and easily respond to synaptic inputs, facilitating synchronization of firing in this subset of cells. These "*Active*" cells thus represent another neuronal ensemble which is embedded in the ensemble of Prepared cells. We hypothesize that "embedded ensemble encoding" may be an important organizing principle in networks of neurons. Starting with a morphologically-detailed model reconstructed from a cortical Layer 5 prefrontal pyramidal cell, synaptic AMPA/NMDA and extrasynaptic NMDA receptor models were placed on basal dendrites to induce plateau potentials. The active properties of the cell were tuned to match plateau potentials recorded by voltage-sensitive dye imaging in dendrites and whole-cell patch measurements in soma (see companion poster). We then methodically simplified the model while maintaining the general behavior of the cell as well as its response to glutamate stimulation. Using the simplified pyramidal neuron model, along with a previously-published inhibitory interneuron model, we created network models to explore the behavior of subpopulations of neurons in *Prepared* and *Active* states. The network model simulations showed increased synchrony during the dendritic plateau in the subsets with AMPA/NMDA receptor activation in the basal dendrite. Dendritic plateaus induced by strong basilar dendrite stimulation can increase population synchrony produced by weak coherent stimulation in apical dendrites. These findings may help to understand the implications of dendritic plateaus at the cellular and network level, and may lead to a better understanding of ensemble synchronization and multimodal cortical information processing.

Abstract: Dendritic plateau potentials are supralinear synaptic integration events and are crucial for single-neuron computations. Plateau potentials could be initiated at the distal branches by activation of spatially clustered and temporally synchronized excitatory inputs in the striatal spiny projection neurons (SPNs). However, it is largely unknown how following excitatory and inhibitory synaptic activities shape the plateau potentials. Here, by using detailed SPN computational simulation, we show that plateau potentials broadened the spatiotemporal window for integrating excitatory inputs and promote spiking. By further combining two-photon imaging, optogenetics, and dual-color uncaging of glutamate and GABA, we directly tested the spatiotemporal interaction between the plateau potential and the GABAergic inhibitions. We demonstrated the temporal window of spiking was differentially tuned by GABAergic inhibition in a cell-type-specific manner. This delicate inhibitory control of the spike output is most efficient at the dendritic branch where the plateau potentials are initiated and relies on the reestablishment of NMDA receptor Mg^{2+} block. These findings provide a new insight into how spatiotemporal window of SPN spike output can be finely shaped by branch-specific dendritic inhibition.

Title: Coincidence and sequence detection by electrically-coupled interneurons

Authors: *P. ALCAMI
Eberhard-Gwinner-Strasse, Starnberg, Germany

Abstract: Electrical synapses are ubiquitous in interneuron networks. They form intercellular pathways, allowing electrical currents to leak between coupled interneurons. I explored the impact of electrical coupling on the integration of excitatory signals and on the coincidence detection abilities of electrically-coupled cerebellar basket cells in juvenile mice and rats. Simultaneously-injected current pulses in coupled cells increased their firing rate and their probability of recruitment and they reduced the latency of action potential generation. Furthermore, action potential probability was increased and action potential latency was shortened in response to synaptic stimulations in mice lacking the protein that forms gap junctions between basket cells, connexin36, relative to wild-type controls. These results suggest that electrical synapses between basket cells decrease the probability and increase the latency of stimulus-triggered action potentials, both effects being reverted upon simultaneous excitation of coupled cells. Varying the delay at which coupled cells are stimulated revealed that the probability of action potential generation is also increased when a basket cell is stimulated shortly after a coupled cell. These findings suggest that electrically-coupled interneurons behave as coincidence and sequence detectors that dynamically regulate the impact of inhibition onto postsynaptic targets depending on the degree of input synchrony in the coupled interneuron network.

Title: Binge alcohol drinking alters computing of executive and emotional information in nucleus accumbens medium spiny neurons

Authors: *G. E. MARTIN[1], J. KOLPAKOVA[2]
[2]Neurobio., [1]Univ. of Massachusetts Med. Sch., Worcester, MA

Abstract: Drug addiction is a devastating neuropsychiatric disorder that affects millions of individual in the US and worldwide. Decades of research support the idea that addiction is a chronic illness of the brain caused by impaired neuronal communication. More specifically, one theory posits that uncontrolled drug use results in part from the inability of neurons in specific brain regions (e.g. hippocampus, prefrontal cortex, amygdala and nucleus accumbens) to correctly integrate and prioritize distinct (e.g. cognitive, contextual and emotional) information. Yet, despite decades of research, the experimental validation of this idea remains elusive, in great part due to technical obstacles that have precluded testing this hypothesis directly. To address the central question of neuronal computing in naïve and binge alcohol drinking mice, we have developed innovative technology that permits us, for the first time, to directly test how the nucleus accumbens computes information from distinct circuits, and how binge drinking influences this process. To do this, we recorded light-driven excitatory postsynaptic potentials in nucleus accumbens medium spiny neurons (MSNs) in fresh mouse brain slices, and used a novel optogenetic approach that we recently developed to selectively and independently activate specific neuronal populations that originate from the prefrontal cortex and the basolateral amygdala regions, and which converge onto MSNs in the nucleus accumbens. These candidate populations are responsible for processing executive and emotional information, respectively, but their role in drug and alcohol addiction is not fully understood. We show that **i)**executive and emotional information converging onto the same accumbens spiny neurons mutually control each other's strength, **ii)**binge alcohol drinking profoundly upsets this reciprocal control in male mice by favoring the processing of emotional information at the expense of cognitive ones. Importantly, we also showed that this phenomenon is sex-specific as it appears to follow different rules in females vs. males. These data offer the tantalizing hint that restoring the transmission of information between the prefrontal cortex to the accumbens may help limit alcohol consumption, a possible strategy for treating alcohol abuse in humans.

Title: Form follows function: Synaptic design to account for short term plasticity at mossy fiber boutons

Authors: *N. SINGH[1], S. NADKARNI[2]
[1]Biol., Indian Inst. of Sci. Educ. and Res., Pune, India; [2]Biol., Indian Inst. of Sci. Educ. and Res. Pune, Pune, India

Abstract: Mossy fibers (MF) provides the first entry of neuronal signals to the hippocampus and make synapses with CA3 pyramidal neurons. In contrast to other well studied synapse in the hippocampus, the CA3-CA1 synapse, the MF bouton has a large size (~8 μm^3) and hundreds of docked vesicles. Each MF bouton has an elaborate arrangement of active zones that span multiple dendritic protrusions of the CA3 neuron and operate at low vesicle release probability (Pr ~ 0.2). In response to a high frequency stimulus, fast and long-lasting increase in Pr and generation of a postsynaptic AP is seen (conditional detonation). This postsynaptic AP generation is more sensitive to the number (~6) of stimuli and not the rate of stimulus between 10-100 Hz (AP counting). Additionally these boutons are capable of an extensive range of short time plasticity profile. We investigate the causal relationship of the presynaptic components of synaptic transmission and its specialized spatial arrangement in the MF bouton to the characteristic plasticity displayed.
Our strategy here is to build a physiologically realistic computational model of the MF bouton and populate it with basic components underlying synaptic transmission with biophysical realism (concentrations, numbers, diffusion constants, reaction rates and spatial arrangement etc.). We compute calcium signals in the bouton, at the active zones, and measure activity dependent changes in vesicle release rates. We establish a relationship between presynaptic release rate and the probability of generating a postsynaptic AP at the MF-CA3 synapse. Various factors in MF boutons have been shown to individually participate in orchestrating and modulating short term plasticity. Our model elucidates the implication of elaborate active zone arrangement at this synapse and its spatial relationship to the calcium channels in altering STP. We propose an minimal synaptic design that can account for the typical plasticity attributes observed at this synapse.
MF-CA3 synapses are said to be specialized for pattern separation and make use of plasticity to differentiate between similarly encoded patterns, consequently retaining distinct memories

effectively. A clear understanding of contributions of the synaptic signaling at the MF would provide insights into changes in synaptic strength and its precise relationship to higher order computation.

Abstract: The increase in the complexity of brains in evolution is accompanied by a surprisingly small number of new synaptic proteins. However, a few vertebrate-specific synaptic proteins arose. One of these vertebrate-specific proteins, Mover, is strongly upregulated in schizophrenia.Mover is a synaptic vesicle-attached phosphoprotein, regulated by activity, and binds the conserved Calmodulin and the vertebrate-specific protein Bassoon. Mover is differentially expressed at subsets of synapses. Knockdown of Mover in the calyx of Held leads to an increased calcium sensitivity of release.In this study, we used a Mover knockout mouse line to investigate the role of Mover in the hippocampus and its behavioral phenotype. While Schaffer collateral synapses were unchanged by the knockout, the mossy fibers showed strongly increased facilitation. The effect of Mover knockout in facilitation was both calcium- and age-dependent, having a stronger effect at higher calcium concentrations and in younger animals. Increasing cAMP levels by forskolin potentiated equally both wildtype and knockout mossy fiber synapses. However, forskolin-potentiation and Kainate receptor blockade independently occluded most of the increased facilitation observed in the knockout.Mover knockout mice show unimpaired memory but display increased willingness to persist in open arms in an elevated plus maze and spend more time in the center of open field tests. These results suggest an anxiolytic effect caused by the absence of Mover.These discoveries suggest that Mover a) has distinct roles at different synapses; b) generally acts to dampen the extent of presynaptic events; c) acts as a brake that can be released during low activity; d) promotes anxiety-like effects. We suggest a model in which Mover inhibits the Kainate receptor/cAMP pathway, which explains the

observed electrophysiological results and supports the proposed role of Mover dynamically buffering synaptic strength.

Title: Mover promotes activity-dependent superpriming of synaptic vesicles at the Calyx of Held

Authors: *H. POFANTIS[1], T. DRESBACH[2]
[1]Univ. of Goettingen, Goettingen, Germany; [2]Dept. of Anat. and Embryology, Univ. Med. Ctr. Göttingen, Goettingen, Germany

Abstract: Mover is a vertebrate-specific presynaptic protein that is attached to synaptic vesicles. It is an interaction partner with calmodulin and Bassoon, another vertebrate-specific active zone protein. The expression levels of Mover are variable throughout the brain; in some subsets of synapses it is highly expressed whereas in others it is below detection limit, indicating a modulatory function at the operation of the synapses. Additionally, Mover is highly upregulated in the brains of schizophrenic patients, specifically in the anterior cingulate cortex.
In this study we aimed to elucidate Mover's function in synaptic transmission and short-term plasticity in a central glutamatergic synapse, the calyx of Held, by using a Mover knockout (KO) mouse line. For that purpose, we stimulated bushy cell axons, which give rise to the axo-somatic calyx of Held terminal, placing a parallel bipolar electrode close to the brainstem midline. We recorded evoked excitatory postsynaptic currents (eEPSCs) from postsynaptic principal cells of the medial nucleus of the trapezoid body using a whole-cell patch clamp configuration.
We found that in Mover knockout mice the steady-state EPSC at the end of a stimulus train is increased. Moreover, the linear relationship of the initial EPSC amplitude to the steady state EPSC amplitude was enhanced in the KO, indicating a weaker short-term depression of the superprimed component of the EPSCs. By subtracting the normally-primed component of the EPSCs we calculated a significantly lower release probability of the superprimed synaptic vesicles in the knockout mice. These data suggest an activity-dependent effect of Mover on the synaptic vesicle pool and especially on the superprimed synaptic vesicles.

Title: Intrinsic plasticity associated with barrage firing episodes in rodent and human neurogliaform cells culminates in short-term potentiation of dendritic EPSP-spike coupling

Authors: *R. CHITTAJALLU[1], K. AUVILLE[1], D. CALVIGIONI[1], C. FANG[1], X. Q. YUAN[1], K. A. PELKEY[1], K. ZAGHLOUL[2], C. J. MCBAIN[1]

Abstract: The capacity for neuronal communication within circuits to undergo dynamic modifications has been intensely studied and is mediated by a bewildering array of synaptic/cellular mechanisms. Here, we demonstrate that injections of brief supra-threshold current steps or synaptic induced action potentials (8 Hz, 30 Hz, 100Hz and theta-burst stimulation) in mouse cortico-hippocampal neurogliaform cells (NGFCs) culminates in a period of continued firing that occurs in the absence of any further input. Such slow neural integration has been described in a variety GABAergic interneuron (IN) subtypes and is termed persistent or retroaxonal barrage firing (RaBF). In our hands, RaBF in NGFCs is induced after 547 ± 27 action potentials and each RaBF episode lasted 2.6 ± 0.9 seconds (n = 128). The RaBF observed in the current study is, in general, shorter in duration than previously described and therefore the paradigms/experimental conditions employed likely constitute the minimum requirement to induce this firing mode. Interestingly, following these brief excursions into RaBF, NGFCs enter a state of augmented excitability that manifests as an increased action potential output in response to somatic depolarizing current/voltage injections. From a more physiological standpoint, subthreshold EPSPs elicited by electrical stimulation of afferent fibers are subsequently able to trigger action potentials in NGFCs after RaBF demonstrating a potentiation of dendritic EPSP-spike (E-S) coupling. RaBF can be repeatedly induced in a given NGFC and although RaBF duration is relatively consistent upon successive induction protocols, the time span of the subsequent potentiation in this intrinsic excitability is enhanced (63 ± 10 vs. 240 ± 160 seconds after 1st and 4th RaBF episode, respectively; n=39, 11), suggesting an ability to prime the circuit for this form of plasticity. In a parallel set of experiments, we recorded from layer I human cortical INs (hINs) where reelin-positive putative NGFCs reside. RaBF could also be induced in hINs possessing NGFC morphology resulting in a potentiation of intrinsic

excitability similar to that observed in rodent. Taken together these data demonstrate an activity-dependent neural plasticity mechanism that enhances NGFC recruitment potentially resulting in a temporal window of increased dendritic inhibition of pyramidal cells that is conserved across rodent and human cortical circuits.

Title: Noradrenergic modulation of hippocampal CA3 and CA1 networks

Authors: *T. J. BACON[1,2], L. Y. PRINCE[3], K. TSANEVA-ATANASOVA[4], A. E. PICKERING[1,2], J. R. MELLOR[1,2]
[1]Physiology, Pharmacol. & Neurosci., [2]Sch. of Physiology, Pharmacol. and Neurosci., [3]Physiology, Pharmacology, and Neurosci., Univ. of Bristol, Bristol, United Kingdom; [4]Dept. of Mathematics and Living Systems Inst., Univ. of Exeter, Exeter, United Kingdom

Abstract: The hippocampus encodes new memories by strengthening synaptic coupling to create ensembles of principle neurons. Release of neuromodulators within the hippocampus regulates this process and is therefore predicted to determine which memories are encoded. The locus coeruleus (LC) is a brainstem nucleus that projects diffusely throughout the cortex, releasing noradrenaline (NA) to co-ordinate multiple brain areas and mediate a variety of cognitive processes, including learning, memory, vigilance, and sleep (Kety, 1972; Sara *et al., 1994*). Within the hippocampus NA release acts as a novelty signal, with the LC switching from tonic firing in familiar spaces to burst firing when an animal enters a novel environment (Vankov *et al.,* 1995). The effects of such a switch on synaptic dynamics, ensemble recruitment and memory formation are still poorly understood.
Well-documented hippocampal effects of NA are its potentiation of LTP and inhibition of the slow afterhyperpolarisation (sAHP) current, a Ca^{2+}-activated K^+ current that plays an important role in synaptic integration. To explore the relatively understudied modulatory effects of NA on various hippocampal synaptic inputs and post-synaptic firing properties we have used a

combination of whole-cell patch-clamp recording in *ex vivo* hippocampal slices, opto- and chemogenetic manipulations and computational modelling.
At Schaffer Collateral-CA1 (SC-CA1) synapses bath-applied NA attenuated both excitatory and feedforward inhibitory responses resulting in little change in Excitatory-Inhibitory (E-I) ratio whereas at mossy fibre-CA3 (MF-CA3) synapses NA augmented excitatory whilst decreasing feedforward inhibitory inputs thereby increasing the E-I ratio. NA also caused a small depolarisation of CA1 & CA3 neurons and a minor increase in input resistance. These results suggest that at SC-CA1 synapses, NA does not alter CA1 hippocampal output through a change in synaptic input, but through changes in post-synaptic excitability. Within the CA3, the effect of NA on naturalistic granule cell firing patterns was modelled using a Tsodyks-Markram model of the MF-CA3 synapse, which suggested that an increase in baseline mossy fibre release probability underlies the enhanced MF-CA3 EPSCs. Thus, an increase in CA3 output is predicted to result from a combination of increased E-I ratio and post-synaptic excitability.

Title: Corticosterone and BDNF as possible contributors to the post-exercise priming of rat motor cortex and hippocampus

Authors: *J. S. THACKER[1], W. STAINES[1], J. G. MIELKE[2]
[1]Kinesiology, [2]Sch. of Publ. Hlth. and Hlth. Systems, Univ. of Waterloo, Waterloo, ON, Canada

Abstract: The priming of motor cortex to facilitate plasticity is an approach that may improve motor rehabilitation following injury. Emerging evidence supports the possibility that aerobic exercise may offer one means to achieve priming, however, the mechanisms whereby priming may occur following an acute bout of aerobic exercise are currently debated. One molecular mechanism may be related to the migration of receptors towards synaptic densities, which is a process shown to play a key role in the induction of long-term potentiation. Previous work from our lab suggested that a single event of moderately intense (20 m/min for 20 minutes) exercise significantly augments the phosphorylation of AMPA receptor (GluA1 & GluA2) and NMDA receptor (GluN2A & GluN2B) subunits. In a follow up study this phosphorylation was related to changes in the cellular distribution of these receptors within synaptic densities, which we argue signifies a novel molecular mechanism to explain the priming of motor cortex following single session aerobic exercise. However, based on these findings, the identity of the molecular

pathway that could be responsible for the priming phenomenon remains unclear. In our previous investigations we noted that aerobic exercise was a potent stimulus for the release of peripheral corticosterone (CORT) and central brain-derived neurotrophic factor (BDNF). As a result, we aimed to investigate the relative contributions that these molecules may have on the priming of motor cortex for plasticity. Specifically, we hypothesized that BDNF and CORT alone would be insufficient to mimic exercise induced priming, but that the combination of CORT-BDNF would induce similar effects to those seen following single-session exercise. Young, male Sprague-Dawley rats (n = 18) on a reverse light cycle (12h/12h) were sacrificed and tissue slices prepared from both the motor cortex and hippocampus. Slices were provided 1 hour to recover from surgery under standard conditions, before being exposed to either 30 minutes of CORT (200 nM), BDNF (20 ng/mL), or CORT-BDNF. Immediately following treatment, surface proteins were labelled by incubating slices in biotin. After homogenization, synaptoneurosomes were prepared (to enrich pre/post-synaptic terminals), and then proteins at the synaptic membrane were isolated by incubation with neutravidin beads. Next, we plan to probe surface synaptic fractions for proteins of interest by Western blotting analysis. The work in progress aims to establish that combined effects of CORT-BDNF following a single session of aerobic exercise is, in part, responsible for the "primed" state within motor cortex.

Title: Synapse-specific regulation revealed at single synapses is concealed when recording multiple synapses

Authors: *J. W. LINES[1], A. COVELO[2], R. GOMEZ[3], L. LIU[2], A. ARAQUE[4]
[1]Neurosci., [2]Univ. of Minnesota, Minneapolis, MN; [3]La Laguna, Santa Cruz de Tenerife, Spain; [4]Neurosci., Univ. of Minnesota Twin Cities, Minneapolis, MN

Abstract: Synaptic transmission and its activity-dependent changes are fundamental processes in nervous system function. Neurons may receive thousands of synaptic contacts, but synaptic regulation may occur only at individual or discrete subsets of synapses. While there exist several electrophysiological methods to assess synaptic transmission at distinct scales of observation,

e.g., through local field potential and individual whole-cell recordings, their experimental limitations to detect synapse-specific modulation is poorly defined. We have investigated the ability of electrophysiological recordings at different levels of analysis to detect synapse-specific short-term plasticity changes induced by endocannabinoids, which are known to regulate specific synapses (Navarrete and Araque, 2010). Using hippocampal slices, we combined local field potential and whole-cell recordings of CA3-CA1 synaptic activity evoked by Schaffer collateral stimulation of either multiple or single synapses, to test their ability to detect endocannabinoid-mediated short-term synaptic regulation. Additionally, we developed a mathematical model to perform Monte Carlo simulations assuming a bimodal distribution of regulated and unregulated synapses to simulate the experimental requirements of the different recording methods to detect discrete changes in subsets of synapses. Our results show that endocannabinoid-induced depolarization-induced suppression of excitation (DSE) and astrocyte-mediated synaptic potentiation can be observed when monitoring single or few synapses, but are statistically concealed when using gross recordings of multiple synapses. These results indicate that the electrophysiological methodology is critical to properly assess synaptic changes occurring in subsets of synapses, and that relevant synapse-specific regulatory phenomena may be experimentally undetected but nonetheless have important implications in the spatial extension of synaptic plasticity.

Title: Conformational states of kainate receptors shapes short-term plasticity by controlling receptor lateral mobility at glutamatergic synapses

Authors: *A. I. POLENGHI[1], S. GUAZZI[1], P. GOROSTIZA[2], A. BARBERIS[1]
[1]Fondazione Inst. Italiano Di Tecnologia, Genova, Italy; [2]Inst. for Bioengineering of Catalonia, Barcelona, Spain

Abstract: Kainate receptors (KARs) mediate slow postsynaptic currents that significantly impact on synaptic integration and spike transmission. However, the molecular determinants responsible for the postsynaptic stabilization of KARs are poorly understood. In particular, the interactions

between scaffold proteins of the glutamatergic postsynaptic density and the different KARs conformational states have never been investigated. Here, we combine optogenetic and Quantum-Dots based single particle tracking approaches to study the role of KARs conformational states on KARs lateral mobility at synapses. For this purpose, we use engineered ionotropic kainate receptors - light-gated GluK2 receptors (LiGluK2Rs) - that can be switched in the desensitized or closed state by illumination with UV or blue light, respectively, in a precise and reliable way. We report that desensitized KARs are reversibly trapped at glutamatergic synapses through the interaction between LiGluK2-C-terminus (in particular the residues 892-908, a non-PDZ domain) and the β-catenin/N-Cadherin complex. Coimmunoprecipitation experiments revealed that desensitization of KARs increased the receptor interaction with the β-catenin/N-Cadherin complex. By using the glutamate uncaging technique we demonstrate that the immobilization of desensitized KARs at synapses leads to an increased current desensitization during repetitive glutamate uncaging applications. In AMPA/KARs mixed responses, such effect favors the fast AMPA component while lowers the slow kainate component, thus reducing the temporal window of signals integration. Finally, we demonstrate that mutants disrupting the interaction between LiGluK2 and β-catenin/N-Cadherin complex (LiGluK2Δ16 and N-CadherinΔE) abolish the trapping of desensitized KARs at synapses thus leading to a decreased current desensitization during repetitive stimulation with respect to control conditions. Overall, we show that the modulation of synaptic KARs lateral mobility by the receptor conformational states regulates the short-term plasticity of glutamatergic currents.

Title: Interplay of entorhinal cortical input and local inhibitory network at the origin of slow inhibition in hippocampal granule cells

Authors: *Y. MIRCHEVA, M. R. PERALTA, III, K. TOTH
Laval Univ., Quebec City, QC, Canada

Abstract: The perforant path (PP) conveys information between enthorhinal cortex (EC II) and the hippocampus. Cortical cells project to the molecular layer (ML) of the DG where excitatory signals initiate an interplay with local inhibition in order to achieve proper information transfer. Nearly simultaneous signalling to both glutamatergic and local GABA-ergic cells engages network interactions that will modulate input integration and firing pattern in dentate granule cells (DGCs). Fast and slow inhibitory mechanisms are major players in the selection of active

cells and precision of spike timing. We describe a slow inhibition mechanism in DGCs mediated by GABA receptors (GABA-R) and mGluRs. It results in long lasting hyperpolarization (LLH) of the membrane potential following a PP stimulation. LLH is preferentially induced by short bursts in the lower gamma frequencies (20-50 Hz) in young and adult mice, but not in juvenile pups. We demonstrate that synaptic neurotransmitter release from PP terminals is sufficient to induce LLH through feedforward inhibition in ML. We further address the functional consequences of LLH in DGCs and show that it significantly alters their firing properties during membrane depolarization induced AP firing. To investigate how LLH would affect firing in response to synaptic activity, we used single or double PP input stimulation. Stimulation protocol is based on reports of correlated theta/gamma oscillations coupling in EC II and DG. Single input 5 Hz trains (NoLLH, 3s) were applied alone or in combination with nested 50 Hz bursts (LLH) from the same input or from another input. We used an AP frequency distribution analysis in order to compare between NoLLH and LLH. NoLLH trains (0.05 ± 0.002) in combination with LLH bursts from the same input resulted in a global AP frequency decrease (0.03 ± 0.003; $p = 0.0024$). Similarly LLH induced by a second input decreased significantly AP frequency distribution in response to 5 Hz NoLLH (0.09 ± 0.01 to 0.04 ± 0.006, $p < 0.0001$). LLH created a restrained neuronal discharge in favor of shorter firing time window (2.07 ± 1.17 s). These results suggest that short bursts in the gamma frequency can significantly impact the integration of signals arriving close in time. Thus LLH represents temporal reference for upcoming signals. Moreover, stimulation of a specific PP terminal induced LLH only in a subset of DGCs. Thus LLH might also contribute to selective activation of cells in the DG.

Title: Inhibition of astroglial glutamine synthetase decreases leucine transport across the blood brain barrier

Authors: *S. E. GRUENBAUM[1], R. DHAHER[2], K. BEHAR[3], H. ZAVERI[4], M. ERFE[2], T. EID[2]

[1]Dept. of Anesthesiol., [2]Dept. of Lab. Med., [3]Magnetic Resonance Res. Ctr., [4]Dept. of Neurol., Yale Univ. Sch. of Med., New Haven, CT

Abstract: Introduction: Astroglial glutamine synthetase (GS), which metabolizes glutamate and ammonia to glutamine, is critical several brain processes. Perturbations in the expression and activity of GS are thought to play a causative role in the pathogenesis of several conditions of abnormal neurotransmission. Although the long-term consequences of GS inhibition on amino acid homeostasis in the brain are unknown, it is thought that amino acid influx in the brain is tightly coupled with glutamine efflux via the L-type amino acid transporter (LAT_1). The objective of this study was to determine the effects of chronic GS inhibition with methionine sulfoximine (MSO) on glutamine and leucine homeostasis in the brain. **Methods:** Twelve rats were surgically implanted with microdialysis guide cannulas in the bilateral dentate gyrus. Rats were randomly divided for surgical implantation of either a MSO (n=6) or phosphate buffer saline (PBS; n=6) pump in the right dentate gyrus. After 7 days, bilateral microdialysis probes were placed under brief isoflurane anesthesia, and microdialysis flow was established and dialysate samples were collected every 30 minutes. A 113 mM ^{15}N-Leucine (3.6 mL per hour) and 2 M 2-^{13}C-sodium acetate (0.0633 μL/g/min for t = 0-5 minutes, 0.0316 μL/g/min for t = 5-10 minutes, and 0.0253 μL/g/min for t > 10 minutes) solution was infused intravenously for 300 minutes. The EZ:Faast Free Amino Acid analysis kit and ultra-performance liquid chromatography/ tandem mass spectrometry was used for quantification of amino acids in the dialysate fluid. **Results:** At baseline (t = 0h), the concentrations of glutamine were significantly lower in MSO-treated rats ($p < 0.001$) in the ipsilateral (GS-inhibited) hippocampus. There were no differences in glutamine concentrations between MSO and PBS-treated rats in the contralateral hippocampus. In PBS-treated rats, there was a significant increase in ^{15}N-leucine between t = 0h and t = 5h in the contralateral ($p < 0.05$) and ipsilateral ($p < 0.05$) hippocampus. In MSO-treated rats, there was a significant increase in ^{15}N-leucine between t = 0h and t = 5h in the contralateral ($p < 0.05$) hippocampus, but not in the ipsilateral hippocampus (p = n.s.). **Conclusions:** This study demonstrated for the first time that basal glutamine concentrations are low in areas of the brain where GS is acutely inhibited, and that leucine uptake in these brain areas are markedly decreased. Perturbations in glutamine and leucine homeostasis have been implicated in several disease processes, and the glutamine-dependent leucine influx in the brain may be a novel and important therapeutic target to treat these conditions.

Title: Identification of LTP-associated CCK signal transduction pathways in a primary hippocampal cell culture

Authors: *R. JESKY[1], D. K. Y. SHUM[2], J. HE[1]
[1]City Univ. of Hong Kong, Hong Kong, Hong Kong; [2]Univ. of Hong Kong (HKU), Hong Kong, Hong Kong

Abstract: Keywords: Cholecystokinin; Hippocampus; Signal transduction; MAPK; CREB
Within the CNS, cholecystokinin, one of the most ubiquitous neuropeptides in the brain, facilitates an array of fundamental functions. Studies have demonstrated that cholecystokinin (CCK) is involved in everything from pain modulation, anxiety, hunger, satiation, and the brain's reward systems to neuropsychiatric disorders, and learning and memory. Early studies investigating the mechanisms of cholecystokinin (CCK) revealed that CCK was mediated by two variant G protein-coupled receptors - CCK1R and CCK2R - and further uncovered that it signaled through various pathways, but the current understanding of the mechanisms under which CCK modulates such an extensive range of functions within the CNS are limited. Research in our lab (Prof. Jufang, He's) has shown that CCK is a cardinal component of neocortical plasticity and plays a significant role in memory consolidation. In addition, evidence suggests it is requisite for long-term potentiation (LTP). This implies that it is integral to synaptic plasticity, and thus modulates plastic changes in the brain from the synapse to neuronal circuitry. As a principle correlate of learning and memory, LTP has been thoroughly investigated with results evincing that various kinases (i.e., CaMKII/IV, DAG, PKC, cAMP, PKA, MAPK, and CREB) are involved. The mechanisms by which CCK facilitates LTP are not yet fully understood, but to elicit LTP CCK must activate a coordinated array of signal transduction via second messenger phosphorylation within known canonical cellular cascades. Preliminary results show that in hippocampal neurons CCK triggers phosphorylation of c-Raf and its substrates such as MEK2 along with the downstream phosphorylation of CREB, which suggests that CCK-8s activation of CCK receptors is mediated through the MAPK pathway. With the cardinal functions of MAPK in dendritic morphogenesis and their pertinence to LTP formation, initial results suggest that CCK may act in concert with requisite growth factors or solely initiate the MAPK cascade leading to LTP formation. Further electrophysiological studies will be required to additionally clarify the full capacity of CCK-induced signaling cascades.

Title: Low chloride transporter expression in vasopressin neurons as a substrate for excitatory GABA signaling

Authors: *M. O. FISHER, JR[1], J. G. TASKER[2]
[2]Cell and Mol. Biol., [1]Tulane Univ., New Orleans, LA

Abstract: The excitability of a neuron is dependent upon the intracellular and extracellular ionic concentrations. Several proteins function as ion pumps/transporters that work to maintain the relative ionic concentrations necessary for neuronal signaling. The potassium-chloride co-transporter two (KCC2) is a symporter that works to actively pump K^+ and Cl^- out of the cell in order to maintain a low intracellular [Cl^-], while the sodium-potassium-chloride cotransporters one and two (NKCC1/NKCC2) are symporters that actively pump Na^+, K^+, and Cl^- into the cell, opposing the actions of KCC2 on Cl^- transport. In the adult, high KCC2 expression leads to low intracellular [Cl^-], which causes $GABA_A$ receptor Cl- channels to flux Cl^- into the neuron, causing a hyperpolarization of the neuron. Early in development however, low KCC2 expression reverses the Cl^- gradient and causes $GABA_A$ receptors to flux Cl^- out of the neuron, leading to depolarization and excitation of the developing neuron. The change in the polarity of GABA signaling during development is, in part, due to a shift in KCC2 expression from low to high with maturation of synaptic circuits. Previous studies have demonstrated an excitatory $GABA_A$ receptor-mediated response due to a GABA equilibrium potential (E_{GABA}) that is shifted positive, like that seen early in development, in adult vasopressin (VP)-secreting neurons of the rat hypothalamus. In the current study, we used immunohistochemistry to compare expression levels of the main C^{l-} transporters, KCC2, NKCC1, and NKCC2, between vasopressin- and oxytocin-secreting neurons. We found that, in adult male Wistar rats, expression of all three transporters is uniformly lower in VP neurons than in adjacent oxytocin (OT)-secreting neurons within the hypothalamus. To further build on these findings, we are utilizing a Cre-dependent virus system in order to express a light-activatable chloride-fluxing channel conditionally in vasopressin-secreting neurons.

Title: The effect of vasopressin receptor activation on mouse locus coeruleus neuronal activity

Authors: *E. CAMPOS-LIRA[1], L. KELLY[2], V. S. HERNANDEZ[1], L. ZHANG[1], J. SWINNY[2]
[1]Physiol., Sch. of Medicine, Natl. Autonomus Univ., Ciudad DE México, Mexico; [2]Sch. of Pharm. and Biomed. Sci., Univ. of Portsmouth, Portsmouth, United Kingdom

Abstract: The locus coeruleus (LC) nucleus is the main source of noradrenaline (NA) throughout and modulate a range of functions such as arousal, cognition and the stress response. Neurochemically diverse inputs, from a myriad of brain regions regulate the level of LC neuronal activity, in a behaviour dependent manner. One such afferent input contains the neuro-hormone arginine-vasopressin (AVP). The overall aim of the project was to characterise the effects specific AVP receptor subtypes on the spontaneous firing rates (FRs) of the mouse LC, using AVP receptor agonists and antagonist together with a patch clamp electrophysiology in acute brain slices of mouse.
A total of 50 cell were recorded from 15 animals. Application of the V1b and V2 agonist desmopressin (200 µM) had contrasting effects on LC spontaneous FR (n = 20) with 45% of cells showing an increased FR (1.7 to 2.8 Hz) and 55 % showing a significant decrease (1.4 to 0.8 Hz), also presenting significant changes in Tau values of the AHP in both scenarios. The application of a V1a antagonist ((d(CH2)51, Tyr(Me)2, Arg8)-Vasopressin, 30 nM) (n=16) also had contrasting effects on LC FR with 62 % of cells exhibiting an increase (1.6 to 2.1 Hz) whilst 38 % showed a decrease (2 to 1.4 Hz). For the V1b receptor antagonist (TASP 039325, 20 nM) (n = 14), 57 % responded with an increased FR (2.2 to 3.2 Hz) whilst the remaining 43% showed a decrease in activity (1.7 to 1.4 Hz). These diverse responses to LC-AVP receptor modulation suggest that different population of LC neurons express different AVP receptor profiles.

Title: AMP-activated protein kinase activation reduces rundown of dopamine-induced current in rat substantia nigra compacta neurons

Authors: *S. W. JOHNSON[1], A. C. MUNHALL[1], K.-Z. SHEN[2], W. YANG[2]
[1]Dept Neurol, Portland VA Med. Ctr., Portland, OR; [2]Neurol., Oregon Hlth. Sci. Univ., Portland, OR

Abstract: Recent work has shown that AMP kinase influences the cellular expression of many ion channels and receptors. We examined effects of AMPK activators and inhibitors on whole-cell current evoked by D2 dopamine receptors in SNC neurons in slices of rat brain. During patch-clamp recordings, slices were superfused for 25 min with a high concentration of dopamine (100 μM) that was chosen to produce receptor desensitization. Sulpiride (1 μM) was added to the superfusate during the last 5 min of dopamine superfusion in order to measure the magnitude of residual dopamine D2 receptor-mediated current. Under control conditions, dopamine-induced outward current reached an average of 57 pA two min after beginning superfusion. This outward current then decayed in amplitude, typically diminishing to baseline levels within 10 min, and sulpiride revealed no residual D2-mediated current. When recording with pipettes that contained the AMPK activator A769662, peak dopamine-induced current was not significantly different from the control value. However, the rate of rundown of dopamine-induced current was significantly slowed by A769662 ($P<0.0005$, linear mixed model analysis). Moreover, the addition of sulpiride after 20 min of dopamine superfusion caused a significant inward current (16 pA). Using pipettes containing the AMPK activator ZLN024, rundown of dopamine-induced current was significantly slowed compared to rundown of the dopamine control current. Moreover, the addition of sulpiride caused a significant inward current in the presence of ZLN024 (19 pA). The AMPK inhibitors compound C and STO609 prevented the ability of A769662 to reduce rundown of dopamine-induced current. Finally, we recorded current produced by quinpirole (30 μM), which is a D2 agonist without D1 activity and not a substrate for the dopamine transporter. Quinpirole produced an average peak outward current of 59 pA two min after starting superfusion. As with dopamine, quinpirole-induced current decayed to zero over the 20 min superfusion, and sulpiride revealed no residual D2-mediated current. But unlike dopamine, A769662 produced no change in rundown of quinpirole-induced current. These

results suggest that D2 receptor stimulation alone is not sufficient to observe prolongation of current by AMPK.

Title: UHPLC ALEXYS neurotransmitter analyzer for sensitive detection of gaba & glutamate, histamine, LNAAs and other amino acids

Authors: *H.-J. BROUWER[1], L. M. VAN HEERWAARDEN[1], M. EYSBERG[2], N. J. REINHOUD[1]
[1]Antec Scientific, Zoeterwoude, Netherlands; [2]Antec Scientific (USA), Boston, MA

Abstract: Ultra-High Performance Liquid Chromatography (UHPLC) is a rapidly growing separation technique based on the application of LC columns with sub-2 μm particles operating at higher linear velocities and high back pressures. UHPLC offers advantages in chromatographic resolution, analysis speed, and sensitivity over conventional HPLC systems. The combination of Electrochemical Detection (ECD) with UHPLC can be a powerful solution to increase the sample throughput and sensitivity of neurotransmitter analysis in microdialysates, brain homogenates and other sample matrices. A new versatile UHPLC ALEXYS Neurotransmitter Analyzer based on the DECADE Elite detector with SenCell has been developed. This analyzer is based on a flexible and scalable approach to offer an analysis solution for multiple different neurotransmitter applications (Biogenic amines and acidic metabolites, amino acid neurotransmitters and Acetylcholine).
A fast and sensitive method is presented for the analysis of the amino acid neurotransmitters GABA and Glutamate in microdialysates based on the new ALEXYS neurotransmitter analyzer (see figure 1). Separation and detection is achieved using a single sub-2 μm particle column and automated pre-column derivatization with o-phthaldialdehyde (OPA), respectively. A step-gradient is used for clean-up of late eluting amino acid neurotransmitters present in microdialysate samples at the end of the run. With this approach excellent detection sensitivity can be achieved with minimal sample consumption. Other Amino Acids e.g. Histamine, and Large Neutral Amino Acids (LNAAs: Tyr, Val, Met, Orn, Leu, Ile, Phe, Lys, Trp) can be analyzed too using this method.
Method features:
• Automated odorless in-needle OPA-sulphite derivatization.
• Small sample use per analysis: 5 uL only (injection volume 1.5 μL)

• Fast and efficient separation using sub-2 μm particle column
• Post separation step-gradient to eliminate late eluting components
With this approach, a high sample throughput and low detection limit of around 10 nmol/L (15 fmol, 6 pg on column) for GABA is achievable.

Title: Chromatin structure of neurons and glia

Authors: *R. D. FIELDS, P. R. LEE, S. C. CLARK, R. V. CHEREJI, D. J. CLARK
NICHD, NIH, Bethesda, MD

Abstract: In eukaryotes, nucleosomes are the basic DNA packing units whose positions affect all DNA-related processes within the cell. Modification of chromatin through epigenomic events

is fundamental to the function of the genome. Most environmental signals in the nervous system converge onto chromatin to control gene activation and repression. Therefore, chromatin structure and control of gene expression are tightly linked. Here we determine the basic chromatin structure, characterized by nucleosomal spacing in neurons and glia and correlate the nucleosomal maps of each cell type with gene expression data. We have obtained genome-wide nucleosome maps of cultured dorsal root ganglion (DRG) neurons, astrocytes and oligodendrocyte progenitor cells (OPCs) using micrococcal nuclease (MNase) digestion of chromatin, followed by paired-end sequencing of nucleosome core particles. Correlation of gene expression and nucleosome mapping data was carried out by sorting genes according to expression level and analyzed for nucleosome phasing relative to transcription start sites. We have determined that DRG neurons have a significantly shorter (165 base pairs) nucleosome spacing ($N=9$, $p<0.001$) across the entire genome, compared to astrocytes (182 base pairs) and OPCs (183 base pairs). However, when nucleosome distributions on transcriptionally active genes were analyzed, we observed that DRG neurons, astrocytes and OPCs have very similar nucleosomal spacing at the 5' ends of expressed genes (184, 187 and 184 base pairs, respectively). Our findings demonstrate a significant difference in genome-wide chromatin structure between neurons and glia with implications for the regulation of global gene expression and neuron-glia communication.

Title: The chromatin remodeling protein, Kismet, regulates presynaptic vesicle endocytosis at glutamatergic synapses

Authors: *F. L. LIEBL, K. LANE, K. BERNARD
Southern Illinois Univ. Edwardsville, Edwardsville, IL

Abstract: Glutamatergic synaptic transmission is important for a number of behaviors including learning and memory, movement, and visual perception. This neurotransmission relies on the proper localization of cell adhesion molecules and recycling of presynaptic vesicles. We have previously shown that the chromodomain helicase DNA (CHD) binding protein, Kismet (Kis),

positively regulates the synaptic localization of glutamate receptors, neurotransmission, and the apposition between glutamate receptors and presynaptic active zones at the *Drosophila* neuromuscular junction. As a transcriptional regulator, Kis likely broadly affects glutamatergic synaptic development. Indeed, we found endocytosis of presynaptic vesicles is deficient at *kis* mutant synapses. We hypothesize that Kis regulates both activity-dependent bulk endocytosis and clathrin-mediated endocytosis as there is a significant reduction in presynaptic transcript levels of *endophilin B* and *AP180* in *kis* mutants. Further, kis mutants cannot sustain evoked amplitude responses to high frequency stimulation. Surprisingly, our knock down and rescue experiments suggest that Kis is required in postsynaptic muscles for proper presynaptic endocytosis. We are currently investigating whether Kis affects synaptic function by suppressing Polycomb Group repression.

Title: CRC regulates presynaptic neurotransmitter release at the *Drosophila* neuromuscular junction

Authors: *L. GRAY, G. KAUWE, P. HAGHIGHI
Buck Inst. for Res. on Aging, Novato, CA

Abstract: The highly conserved integrated cellular stress response depends on a cellular program that regulates translation through the phosphorylation of eif2a by stress-sensing kinases. While general translation is dampened through this pathway, a small subset of stress-responsive genes is upregulated. Among these genes, perhaps the most prominent is activating transcription factor 4 (ATF4), a critical regulator of the cellular stress response that facilitates an array of functions, from cellular repair to apoptosis. In addition to the stress response, ATF4 is also implicated in long term memory formation via regulation of CREB; however, details of the underlying mechanisms remain unclear. We have begun an investigation of the role of ATF4 in the regulation of neurotransmitter release, using a combination of genetics and electrophysiology at the Drosophila neuromuscular junction (NMJ). Our preliminary findings suggest that CRC, the Drosophila homologue of ATF4, plays a critical role in the regulation of neurotransmitter release at the NMJ. Furthermore, we are conducting bioinformatics analysis of candidate transcriptional

targets of CRC in motorneurons to understand the cellular programs under the control of ATF4 at the presynaptic level. Results of our experiments will be presented.

Title: Identification and characterization of the promoter and of regulatory elements on the cerebral sodium/calcium exchanger isoform 2, NCX2, gene in rat pheochromocytoma cells

Authors: A. SERANI[1], P. MOLINARO[2], N. GUIDA[4], S. NATALE[2], L. FORMISANO[2], G. DI RENZO[2], *L. ANNUNZIATO[3]
[1]Neurosci., Federico II Univ. Naples, Napoli, Italy; [2]Neurosci., Federico II Univ. Naples, Naples, Italy; [3]Federico II Univ. Naples, 80131 Naples, Italy; [4]IRCSS SDN Naples, Naples, Italy

Abstract: The isoform 2 of sodium-calcium exchanger (NCX2) is selectively expressed in CNS, where it participates in the regulation of Na^+ and Ca^{2+} homoeostasis. Under physiological conditions, NCX2 increase neuronal Ca^{2+} clearance after spike potentials, and its knock-out increases spatial-learning and memory performance. In addition, under some pathophysiological conditions, such as stroke, NCX2 exerts a neuroprotective effect. Although the relevance of the regulatory mechanisms involved in the expression of this antiporter under physiological and pathophysiological conditions is easily conceivable, no studies have been reported on the characterization of its promoter and on the identification of the transcription factors (TFs) involved in its regulation.We identified, in PC12 cells, a region of 1200 bp named S3 and located upstream the slc8a2 gene, encoding for NCX2, containing several conserved TF binding sites. Interestingly, many of these sequences are target of regulatory proteins that are expressed in CNS and participate to synaptic plasticity. The identified putative promoter S3 induced the transcription of a luciferase reporter gene in two different neuronal cell lines, PC12 and SHSY, expressing the endogenous NCX2 gene. Interestingly, S3 failed to induce luciferase activity in BHK and U87 cell lines that do not express NCX2 under control conditions. Moreover, among the putative TFs involved in NCX2 transcriptional regulation, the overexpression of Sp1, Sp4 or CREB exerted a stimulatory effect, whereas SREBP1 exerted an inhibitory action, on both endogenous NCX2 transcription and luciferase activity of S3. These results reinforced the hypothesis that the identified S3 region contains the promoter of NCX2 gene and share the same mechanisms of transcriptional regulation. In addition, by using site-directed mutagenesis and

ChIP assay, we identified the regulatory binding sites of Sp1, Sp4, CREB and SREBP1 on the S3 region. Notably, these TFs and NCX2 expression, regulate synaptic plasticity and neurotransmission, thus, it is conceivable to hypothesize that the antiporter might represent one of their downstream effectors.In addition, we found that in U87 cells, not expressing NCX2 under control conditions: (a) Sp1, Sp4, or CREB failed to increase the expression of the endogenous NCX2 gene and the luciferase activity of the identified S3 promoter, and (b) 5 nM of 5'-azacytidine for 72h, by impairing DNA methylation, restored NCX2 expression and its transcriptional regulation by the above-mentioned TFs. These results suggested the presence of an additional regulation of NCX2 expression by DNA methylation as it occurs in glioblastoma cells.

Title: A SUV39H1selective inhibitor enhances synaptic plasticity by prolonging ERK activation

Authors: *L.-Q. TONG[1], A. IONESCU[1], C. BUTLER[1], S. SNIGDHA[1], K. TSEUNG[2], L. OVERMAN[1], C. W. COTMAN[1]
[1]UC Irvine, Irvine, CA; [2]Scripps Col., Claremont, CA

Abstract: Epigenetic regulation of genes and proteins is fundamental to the aging process and the associated decline in learning and memory. We reported previously that pharmacological inhibition of SUV39H1 using ETP69, a novel and selective inhibitor of SUV39h1, decreased levels of H3K9me3 (a repressive mark) in the hippocampus of aged mice, promoted spine formation, and improved memory performance (Snigdha et al., 2016, J Neurosci, 36(12): 3611-3622). However, the mechanism underlying the beneficial effects of ETP69 on neuronal function remains an unexplored area of research. In the present study, we evaluated the effects of ETP69 on signal transduction pathway associated with neuronal activity-dependent synaptic plasticity. ETP69 treatment induced a prolonged (24 h) increase in the phosphorylation of ERK1/2, which plays an important role in memory consolidation, in primary cultures of hippocampal neurons. The effects of ETP69 racemic enantiomers on ERK1/2 phosphorylation were also examined.

Both L-1721 and L-1722 increased ERK1/2 phosphorylation. Further, the ETP69-induced PSD-95 expression was blocked by PD98059, an inhibitor of ERK. These data suggest that SUV39H1 inhibition-mediated downregulation of H3K9me3 acts through enhancement of synaptic function by ERK activation.

Title: Synaptic conditioning frequency, temporal pattern and plasticity outcome effect gene expression in visual cortex

Authors: *Q. S. FISCHER[1], M. CHAUDHRY[2], D. KALIKULOV[1], M. A. FOX[1], M. J. FRIEDLANDER[1]
[1]Virginia Tech. Carilion Res. Inst., Roanoke, VA; [2]Virginia Tech. Carilion Sch. of Med., Roanoke, VA

Abstract: Deep brain stimulation studies have shown a variety of stimulation parameters, including frequency and patterning of conditioning stimulation, influence the efficacy of treatment. However, little is known about the changes in gene expression produced by varying these parameters. We examined whether frequency, temporal pattern, or plasticity outcome of synaptic conditioning influence gene expression. Acute visual cortical slices were prepared from 10-13 week-old male LE rats. For recording, slices were perfused with artificial cerebrospinal fluid at 32-34^{o}C. A stimulating rake electrode was placed in layer 4, and a field potential recording electrode was placed in layer 2/3. All recordings had: 15 mins pre-conditioning, 15 mins conditioning, and 15 mins post-conditioning. Pre- and post-conditioning had 0.1Hz stimulation. Conditioning was either: 1) 10 Hz discontinuous stimulation (9 epochs of 100 stimuli each, divided by 8 equal rest periods) with regular (equal) interstimulus intervals (ISIs), 2) 10 Hz discontinuous stimulation with irregular ISIs (described by a Poisson distribution), 3) 100 Hz discontinuous regular stimulation, or 4) no stimulation. Groups 1-3 were subdivided based on plasticity outcome (i.e. those showing long term potentiation - LTP, verses long term depression - LTD). Three hrs after the recording experiments, layer 2/3 above the stimulation electrode was isolated. RNA was extracted using a Bio-Rad Aurum Total RNA kit. At least 5 samples from each treatment group were processed with RNAseq. Sequences were aligned via

Tophat2 and counted via HTSeq. Relative expression of mRNA was tested for significance using the Benjamini-Hochberg corrected Wald Test in DESeq2. We identified 18,377 genes, 298 of which showed a significant change in expression across treatments. Subsequently, we selected the 12 genes with a greater than 1.5 fold change in expression, and known relevance to synaptic structure/function (e.g. cell adhesion, receptor expression/clustering, ion channel coding, or second messenger signaling). In slices exhibiting LTD verses those with no stimulation, Ak8, Htr2c and Rasa4 were downregulated, while Kcnj10 was upregulated. In contrast, for slices showing LTP verses those with no stimulation, Nyap2 and Slc9a9 were upregulated. In slices exhibiting LTP verses those showing LTD, Ak8, Gpr84, Hspa8, Nid2 and Nptx1 were upregulated, while Htr2c and Snx1 were downregulated. Finally, in slices with regular conditioning verses those with Poisson conditioning, Nid2 was upregulated, while Gpr84 and Pcp4 were downregulated. These results suggest stimulation pattern and plasticity outcome influence gene expression.

Title: A role for REST in adult ocular dominance plasticity

Authors: *C. G. ELEFTHERIOU[1], E. CARMINATI[1], F. CESCA[1], L. MARAGLIANO[1], F. BENFENATI[1,2], J. MAYA-VETENCOURT[1]

Abstract: The repressor element 1 (RE-1) silencing transcription factor (REST) is considered to be a master regulator of neural development and has recently been demonstrated to play crucial roles in the adult brain under both physiological and pathological conditions. So far, however, the role of REST in adult ocular dominance (OD) plasticity remains to be explored. We addressed this issue by using the monocular deprivation (MD) paradigm. This widely used model of plasticity demonstrates a shift of OD following brief MD (≤3 days) only during early life but not in adulthood. We infected the binocular primary visual cortex of adult mice with a constitutive construct either meant to block the binding of REST to the RE-1 DNA sequence (active) or not to block this binding (sham). Following 6 weeks of infection, the

electrophysiological assessment of OD plasticity was performed after 3 days of MD of the contralateral eye, using visually evoked potentials (VEPs) recorded with 16 micro-wires chronically implanted in the infected hemisphere. Contralateral over Ipsilateral (C/I) VEP ratios were calculated on days 1 and 3 using full-field white flashes in freely moving animals. Adult mice infected with the active construct displayed a significant shift of ocular dominance after 3 days of MD whilst uninfected mice and mice infected with the sham construct did not. Moreover, we observed a significant increase in the expression of two plasticity genes (BDNF and NPAS4) in the visual cortex of mice infected with the active construct but not in control animals. These two factors have previously been implicated in the physiological processes underlying experience-dependent plasticity in adult life. Together, our data suggest that a decrease of REST activity enhances juvenile-like plasticity in the adult visual cortex.

Title: Communication of pathway-specific circuit activity to the genome by the immediate early gene Npas4

Authors: *S. BRIGIDI[1], M. HAYES[2], P.-A. LIN[3], A. HARTZELL[3], S. HEINZ[2], B. L. BLOODGOOD[1]
[1]Div. of Biol. Sciences, Neurobio. Section, Univ. of California San Diego, LA Jolla, CA; [2]Med., [3]Neurosci. Grad. Program, Univ. of California San Diego, La Jolla, CA

Abstract: Mechanisms that govern plasticity are executed over many time scales and the most enduring forms of plasticity require regulation of the genome. Inducible transcription factors (ITFs) are a subset of immediate-early genes that support learning by linking transient molecular signals with long-lasting changes in cellular function through activity-dependent changes in gene expression. Npas4, a bHLH-PAS domain ITF, is undetectable in quiescent neurons but is rapidly induced in response to membrane depolarization *in vitro* and learning-related sensory experiences *in vivo*. Experience-dependent Npas4 expression dramatically reorganizes inhibitory

synapses along the somato-dendritic axis of CA1 pyramidal neurons (PNs), increasing somatic and decreasing dendritic inhibition. This suggests that Npas4 regulates neuronal functions immediately linked to excitation by recalibrating inhibition in discrete domains of the PN. However, the nature of excitatory signals that lead to Npas4 induction, and whether the genome is capable of differentiating between excitatory signals that originate from distinct regions of the PN remains unknown.
Here we identify two independent pathways that lead to Npas4 expression in PNs within the CA1 microcircuit that have distinct kinetics and functional consequences. Action potentials (APs) lead to the accumulation of Npas4 in the nucleus through a signaling pathway that requires Ca^{2+} influx through L-type voltage-gated Ca^{2+} channels, transcription, and translation. However, sub-threshold transmission at Schaeffer Collateral synapses triggers rapid local translation of a pool of Npas4 mRNA localized to PN apical dendrites, requires NMDA receptor signaling, and results in the protein trafficking to the nucleus to regulate gene expression. Using CRISPR to manipulate Npas4, we identified regions of the 3' and 5' UTR of Npas4 mRNA that control dendritic trafficking and activity-dependent translation, respectively. Surprisingly, Npas4 forms distinct heterodimers with other bHLH-PAS transcription factors in response to APs or synapse activation. As activity recruits each heterodimer to preferred sites along chromatin genome-wide, we predict stimulus-specific heterodimers facilitate communication of pathway-specific information to the nucleus in order to regulate unique aspects of Npas4's cellular phenotype. Together, our findings suggest that Npas4 communicates the activity history of the cell to its genome by executing an excitation-to-inhibition transfer function that distinguishes APs from input-specific synaptic activity.

Title: Real-time imaging of endogenous mRNA in the live mouse brain

Authors: *J. SHIM, B. LEE, H. MOON, H. PARK
Dept. of Physics and Astronomy, Seoul Natl. Univ., Seoul, Korea, Republic of

Abstract: A memory is represented by the simultaneous activation of an ensemble of neurons referred to as 'engram.' The storage of long-term memory is mediated by the enduring changes in the engram cells and their connections, which requires activity-dependent transcription and local protein synthesis. However, the spatio-temporal regulation of gene expression during memory encoding, storage, and retrieval processes in the live brain are poorly understood. To investigate the dynamics of transcription in the hippocampus and the cortex of a live animal, we implemented real-time imaging of mRNA in the mouse brain using two-photon microscopy. We used our transgenic mice in which the endogenous β-actin or Arc mRNAs are fluorescently labeled by the MS2 or PP7 system. We performed glass-covered cranial window surgery to make optical access, which enabled us to find transcription sites in the hippocampus and the visual cortex of a live mouse. For the next step, we are conducting contextual fear conditioning experiments to investigate the transcriptional dynamics of Arc mRNA in the hippocampus during fear memory formation and retrieval. This study will contribute to understanding the dynamics of gene expression in the engram cells and their roles in learning and memory *in vivo*.

Title: The effect of CPEB3 ribozyme self-scission on mRNA maturation in the mouse hippocampus

Authors: *C. CHEN[1], T. J. HEMSTEDT[2], C.-K. LAU[1], M. A. WOOD[2], A. LUPTAK[3]
[2]Neurobio. and Behavior, [1]Univ. of California Irvine, Irvine, CA; [3]Pharmaceut. Sci., Univ. of California, Irvine, Irvine, CA

Abstract: Synaptic strengthening is a prominent feature of memory formation and reconsolidation. Oligomerization of a translation regulator, cytoplasmic polyadenylation element-binding protein 3 (CPEB3), has been shown to occur during stable long-term memory formation in the hippocampus. The aggregation of this functional prion-like CPEB3 regulates polyadenylation-induced mRNA translation and synaptic protein synthesis, which is crucial for persistence of memory. Given that a single nucleotide polymorphism (SNP) in the human

CPEB3 ribozyme has been suggested to increase ribozyme self-scission rate and to impact human episodic memory, the ribozyme self-scission likely mediates pre-mRNA processing and consequently translational control. Intronic ribozymes have previously been shown to modulate the levels of spliced mRNAs in *cis* and the case of the CPEB3 ribozyme provides a unique opportunity for control of the CPEB3 mRNA production through modulation of the ribozyme activity. To study the mechanism by which the self-cleaving CPEB3 ribozyme affects the mRNA's processing, we inhibited the CPEB3 ribozyme *in vivo* using antisense oligonucleotides (ASOs). ASOs against CPEB3 ribozyme were injected bilaterally into the CA1 region of the dorsal hippocampus of C57/BL6J mice. Results suggested that ASOs inhibited CPEB3 ribozyme activity, which led to an increase in CPEB3 mRNA expression. Together, this work provides new insights into the role of CPEB3 ribozyme activity and downstream gene expression regulation in memory formation.

Title: Real-time imaging of transcription and transport of labeled-endogenous Arc mRNA in live neurons

Authors: *H. MOON[1], S. DAS[2], R. H. SINGER[2,3], H. PARK[1]
[1]Seoul Natl. Univ., Seoul, Korea, Republic of; [2]Anat. & Structural Biol., Albert Einstein Col. of Med., Bronx, NY; [3]Janelia Res. Campus, Ashburn, VA

Abstract: Orchestration of synaptic plasticity encodes memories. An immediate early gene Arc is known to be deeply involved in the modulation of synaptic plasticity. Arc mRNAs are transcribed in response to neuronal activity and transported to the desired destinations including distal parts of dendrites for local translation. We have developed Arc-PBS KI mouse for single mRNA imaging in live cells by knocking in 24 tandem arrays of PP7 binding site (PBS) in the 3′ untranslated region (3′ UTR) of the Arc gene. Using the Arc-PBS KI mouse, we investigated the dynamics of transcription and the transport of Arc mRNAs in live primary neuron cultures. First, we simultaneously imaged somatic Ca^{2+} activity and Arc mRNA transcription after stimulation

by bicuculline. Whereas synchronized bursts of Ca^{2+} activity was induced in all neurons, Arc transcription was induced only in a subpopulation of neurons during 30 min of observation after stimulation. To determine the factor governing this selection of Arc transcribing neurons, we performed immunostaining of Ser-133 residue phosphorylated CREB and single molecule FISH of Arc mRNA together. We found that neurons with higher level of CREB phosphorylation (Ser-133) had higher probability of Arc transcription. Next, we investigated transport of Arc mRNAs along the dendrites after stimulation. Most of the Arc mRNAs were in the rest phase (~77%) during one-minute observation time, and even the directed motions of Arc mRNAs were frequently interrupted by rests, similar to the previously reported behavior of β-actin mRNAs. The active movements of Arc mRNAs were bidirectional with almost equivalent occurrence of anterograde and retrograde steps and with a speed of ~1.5 μm/s in both directions. We also assessed the effect of neuronal activity on Arc mRNA transport dynamics by inhibiting global neuronal activities with pharmacological reagents. However, no significant differences were observed on Arc mRNA movement with global silencing of neuronal activity. In summary, this study presents new perspectives about the dynamics of transcription and transport of endogenous Arc mRNA, which plays important roles in synaptic plasticity at the molecular level.

Title: Upf1-dependent decay of Arc transcripts studied by live-cell imaging

Authors: *M. R. VIEIRA[1], Y. PARK[2], Y. KIM[2], H. PARK[1]
[1]Dept. of Physics & Astronomy, Seoul Natl. Univ., Gwanak-gu, Seoul, Korea, Republic of; [2]Div. of Life Sci., Korea Univ., Seoul, Korea, Republic of

Abstract: The Arc gene is crucial in regulation and consolidation of long-term memory and its expression is tightly related to synaptic plasticity. The impact of Arc expression in memory may depend on its molecular mechanisms of mRNA metabolism that are now beginning to be elucidated. Nonsense-mediated mRNA decay (NMD) is a surveillance mechanism by which mRNAs with premature termination codons are degraded. Arc mRNA is thought to be a natural target of NMD process due to the two conserved introns in the 3' untranslated region (3'UTR). We aim to characterize the Arc gene NMD process in fibroblasts as well as in neurons to

understand the impact of Arc mRNA decay in synaptic plasticity. To visualize the endogenous Arc mRNA in live cells, we utilize the Arc-PBS knock-in mouse model in which 24 repeats of PP7 binding sites (PBS) are inserted between the stop codon and the first intron in the 3'UTR of the Arc gene. Mouse embryonic fibroblasts (MEFs) were isolated from the Arc-PBS mouse and immortalized by SV40 T antigen. In the Arc-PBS MEF cell line, we expressed PP7 coat protein (PCP) fused with green fluorescent protein (PCP-GFP) using lentiviral transfection. Live-cell imaging revealed transcriptional burst of Arc gene in MEFs upon serum induction. The amount of Arc mRNA increased to 30-fold at 30 minutes after induction and decreased back to only 10-fold at 1 hour compared to the Arc mRNA level in the steady state. Then we knocked down Upf1, which is a key NMD factor, using short-hairpin RNAs (shRNA) targeting the coding sequence (CDS) and 3'UTR of Upf1. Knocking down of Upf1 in MEFs resulted in the accumulation of Arc mRNA to a 50-fold increase at 1 hour after serum induction. Our results suggest that Upf1 has a role in regulation and degradation of Arc transcripts. Our future studies involve understanding Arc NMD process and its role in synaptic plasticity in neurons.

Title: Arc is a master regulator of gene transcription: Relevance for Alzheimer's disease

Authors: *A. VANDONGEN, H. VANDONGEN, H.-W. LEUNG, N. OEY, Y. JIANG, J. YIN, G. FOO
Duke-NUS Med. Sch., Singapore, Singapore

Abstract: Alzheimer’s Disease (AD) is a devastating neurodegenerative disorder characterized by the progressive loss of both synaptic function and long-term memory formation. There is currently no therapy that prevents, stabilizes or reverses the progression of this disease, which is projected take on epidemic proportions as the world population ages. Arc is a master regulator of synaptic plasticity and is required for memory (re)consolidation. One of Arc’s functions is homeostatic regulation of synaptic strength, a process that is dysregulated in AD. Several previous studies have revealed an association between Arc and AD. A landmark study published in 2011 showed that Arc protein is required for the formation of Amyloid-beta (Aβ) plaques, the pathological hallmark of AD, which appears long before patients’ symptoms begin to show. Moreover, Arc protein levels are aberrantly regulated in the hippocampus of AD patients, and are

locally upregulated around amyloid plaques, whereas a polymorphism in the Arc gene confers a decreased likelihood of developing AD. Most recently, it has been shown that spatial memory impairment is associated with dysfunctional Arc expression in the hippocampus of an AD mouse model. The precise role that Arc plays in AD pathogenesis is still, however, unclear. Recently published data from our laboratory indicate that Arc associates with the histone-acetyltransferase Tip60 and epigenetically regulates H4K12Ac, a memory-associated histone mark which declines with age, suggesting a role for Arc in mediating age-related memory deterioration. We will present deep sequencing data of Arc knockdown experiments that establish a novel function for Arc in the nucleus, where it epigenetically regulates the transcription of many activity-dependent genes involved in a wide range of neuronal functions. The genes affected by Arc knockdown include several AD susceptibility genes, suggesting that Arc may contribute to the pathogenesis of AD. This hypothesis is being tested using a triple-transgenic AD mouse model, as well as cerebral organoids derived from Induced Pluripotent Stem Cells (IPSCs) from familial AD patients and controls.

Title: CPEB3 knockout mice are susceptible to develop PTSD-like behavior

Authors: *Y.-S. HUANG, H.-W. CHAO, W.-H. LU, P.-Y. LIN, M.-F. WU
Academia Sinica/Institute of Biomed. Sci., Taipei, Taiwan

Abstract: Cytoplasmic polyadenylation element binding protein 3 (CPEB3) regulates target RNA translation in neurons. Our previous study found that CPEB3-knockout (KO) mice exhibited enhanced consolidation of spatial memory in the Morris water maze, but their ability to rapidly acquire new spatial information during the reversal learning when the platform was relocated to a new position was obviously impaired (Chao et al 2013, *J Neurosci* 33:17008-17022). Moreover, CPEB3-KO neurons have increased spine rigidity and reduced synaptic flexibility as evidenced by slow morphological and biochemical responses to the c-LTD condition and defective depotentiation in the hippocampal SC-CA1 synapses (Huang et al 2014, *Front Cell Neurosci* 8: e367). Because of aberrant synaptic plasticity observed in CPEB3-

depleted neurons, we examined whether CPEB3-KO mice are prone to develop post-traumatic stress disorder (PTSD)-like symptoms using a context-dependent fear conditioning and extinction paradigm. CPEB3-KO mice with normal renewal fear response in the conditioning context showed increased spontaneous recovery fear in the extinction context compared to their wild-type littermates. The molecular and cellular changes accounted for the PTSD-like behavior in CPEB3-KO mice are currently investigated.

Title: Hippocampal synaptic plasticity in FKBP5-deficient mice

Authors: *S. ZHANG, M. CHEON, C. CHUNG
Konkuk Univ., Seoul, Korea, Republic of

Abstract: FK506 binding protein51 (FKBP5) is a prolyl isomerase which serves as a co-chaperone of heat shock protein 90 (hsp90). Previous studies have shown that during glucocorticoid receptor (GR) activation, FKBP5 expression increases in various brain regions including the hippocampus, the amygdala and the prefrontal cortex. FKBP5 regulates the sensitivity of GR by inhibiting translocation of activated GR. FKBP5-knockout (KO) mice are reported to be resilient to stress exposure compared to wild-type (WT). However, it is unknown what are the consequences of FKBP5-deficiency in synaptic functions. We found that FKBP5 KO mice exhibited a decreased level of basal synaptic transmission and a reduced synaptic efficacy in the hippocampus. Interestingly, when we examined the synaptic plasticity of the Schaffer collateral pathway, we observed successful LTP but completely impaired LTD in FKBP5 KO mice. Our observations suggest that basal synaptic transmission has been reduced upon FKBP5 deficiency although the reduction was not enough to alter the induction of LTP. Further studies are required to reveal the role of FKBP5 in the LTD and the implication of LTD impairment in the absence of FKBP5 in stress resiliency of this mice.

Title: Investigating translational machinery and regulation of local translation in healthy and pathologic hIPSC-derived neurons

Authors: *J. J. LANGILLE[1], W. S. SOSSIN[2]
[2]Dept Neurobiol, [1]McGill Univ., Montreal, QC, Canada

Abstract: The ability to spatiotemporally regulate the production of proteins, termed translational control, is crucial for normal neuronal function (homeostasis, memory) and its aberration is the basis of pathology (Fragile X, Tubular Sclerosis). Polysomes, stalled post-initiation by ribonucleic acid (RNA) binding proteins— dissociable by downstream effectors of synaptic plasticity inducing stimuli— confer the space-time regulation of protein synthesis. Our exploratory research investigates the translational machinery and regulation of local translation in healthy and pathologic hIPSC-derived neurons. Specifically, we sought to assess whether hIPSC-derived neurons possess stalled polysomes, whether these stalled polysomes are regulated by stimuli implicated in synaptic plasticity, and their aberration in human disease models. Elucidation of the mechanistic basis for aberrant translation seen in pathologies such as Fragile X would provide novel avenues for therapeutic intervention. Ribopuromycylation was used to visualize aforementioned stalled polysomes and was combined with metabotropic glutamate receptor (mGluR)-agonism via dihydroxyphenylglycine (DHPG) to assess regulation by plasticity (mGluR long-term depression (LTD)) associated signaling cascades. hIPSC-derived neurons showed dendritically localized, initiation inhibitor (homoharringtonine) resistant, puromycin puncta. Interestingly, our findings suggest puromycylated polysomes may exist in two distinct populations which differ in their inclusion of ribosomal protein S6. We are investigating whether these populations are differentially regulated by plasticity (long-term potentiation vs LTD); we will also investigate if increased translation following DHPG application, shown here, derives from the reactivation of stalled polysomes as would be evidenced by a decrease in puromycylated polysome number after DHPG treatment. In sum, these findings suggest hIPSC-derived neurons contain stalled polysomes regulated by plasticity implicated stimulation. We can now see whether this process is perturbed in hIPSC neurons derived from patients with neurodevelopmental disorders such as Fragile X. These findings have been corroborated in rodent hippocampal neurons using the aforementioned techniques as well as sun-tagging live imaging (Graber et al, PNAS. 2013 Oct 1; 110(40):6205-16210). Experiments

sampled ~ 10 - 250 neurites per condition across multiple cultures; all appropriate controls were included. Age and sex differences were not quantified.

Title: Ribosome profiling reveals excitation of neuronally differentiated sh-sy5y cells induces distinct programs of mrna translation and post-transcriptional regulation

Authors: *D. J. KILTSCHEWSKIJ[1,2], M. J. CAIRNS[1,2,3]
[1]Mol. Neurobio., The Univ. of Newcastle, Callaghan, Australia; [2]Priority Ctr. for Brain and Mental Hlth. Research, Hunter Med. Res. Inst., Newcastle, Australia; [3]Schizophrenia Res. Inst., Sydney, Australia

Abstract: Modifications to neuronal structure and function in response to excitatory stimuli are driven by a cascade of transcriptional, translational and post-translational events. A major dimension of this system is mRNA translation, which is thought to exhibit distinct and swift changes following neuronal activity. Despite this, profiles of translation, the identity of mRNAs involved and the degree of post-transcriptional regulation in this system are still poorly understood, particularly in short time-frames following neuronal excitation. In the current study, we consequently sought to profile and explore immediate and early (1 and 2 hours post stimulus) patterns of mRNA translation on a global scale by conducting ribosome profiling (Illumina) on neuronally differentiated SH-SY5Y cells subjected to 4 successive cycles membrane excitation (K+, 100mM). The extent of post-transcriptional regulation was concurrently investigated by analysing mRNA and microRNA expression using conventional RNAseq and small RNAseq, respectively (Illumina). Differential expression analysis of ribosome profiling data identified a total of 1813, 269 and 568 differentially translated genes at all 3 respective time-points after application of statistical (fdr < 0.05) and fold change (fc > 1.5) thresholds, revealing an extensive remodelling of translational profiles following membrane excitation. Gene-set enrichment analysis of these groups uncovered enrichment of gene ontologies relating to neuronal activity and extra cellular matrix interaction immediately after excitation. By contrast, later time-points were overrepresented for genes associated with transcriptional regulation, suggesting a spatiotemporal partition exists between immediate and early programs of excitation-induced

translation. Integrative analysis of mRNA translational status and abundance (RNAseq) revealed a fascinating time-based lag between these factors, wherein correlation was initially weak (r = -0.042), yet progressively strengthened (1hr: r = 0.224, 2hrs: r = 0.419), implying a layer of post-transcriptional regulation. Supporting this finding, a number of mRNAs subjected to downregulation at the translational level at all 3 stages were enriched for binding sites of upregulated neuronal microRNA, particularly miR-1271-5p and miR-125b-5p. Together, these results suggest unique programs of mRNA translation are induced in immediate and early time-points following neuronal excitation. We additionally suspect a key role for post-transcriptional regulation, particularly by microRNA, in the remodelling of mRNA translational status during these time-periods.

Title: Ubiquitination of m6A-demethylase FTO regulates its protein stability and localization

Authors: *J. WIDAGDO[1,2], T. ZHU[1,2], X. L. H. YONG[1,2], V. ANGGONO[2,1]
[1]Queensland Brain Inst., St Lucia, Australia; [2]The Univ. of Queensland, Brisbane, Australia

Abstract: As the most prevalent internal modification on eukaryotic RNA, methylation of adenosine residue or N^6-methyladenosine (m6A), affects various aspects of RNA metabolism. m6A is catalyzed by a multi-protein complex of m6A-methyltransferase and reversed by the m6A demethylating enzymes. Dynamic regulation of m6A plays important role during development and learning and memory. Our recent study demonstrates that in the medial prefrontal cortex, upregulation of m6A was induced by a fear conditioning paradigm. The activity-dependent regulation of m6A highlights the dynamic nature of m6A-enzymes. However, little is known of how these proteins are regulated. Here, we report that the m6A-demethylase, fat mass and obesity-associated (FTO) undergoes post-translational ubiquitination on Lys-216. Knock-in HeLa cells harboring the ubiquitin-deficient K216R mutation displayed a slower rate of FTO turnover, resulting in an increase in the level of FTO as well as enhanced phosphorylation of the ribosomal S6 kinase. Given the strong association of FTO and energy metabolism, we showed that amino acid starvation induced nuclear translocation of FTO, but

markedly affected in the K216R mutant. Collectively, our results reveal the functional importance of ubiquitination in controlling FTO expression and localization, which may be crucial for determining body mass and composition, as well as synaptic plasticity, learning and memory.

Abstract: New roles for the proteasome in the nervous system are emerging, especially the roles that the proteasome plays in regulating neuronal activity. Recent studies in mouse neuronal cultures show that uncapped 20S core subunits of proteasomes specifically bind to the neuronal plasma membrane and modulate neuronal activity (Ramachandran and Margolis, 2017). The in vivo significance of these neuronal membrane-specific proteasomes (NMPs) is unknown. Here, we showed that the core proteasome subunits (α1-7) are abundantly expressed in Xenopus laevis tadpole brain, and are associated with membrane preparations, giving us an opportunity to investigate the functional role of NMPs in a powerful in vivo system. Biotin-Epoxomicin (Bio-Epox) is a membrane-impermeable proteasome inhibitor that covalently inhibits the activity of NMPs. After injection of tadpole brains with Bio-Epox, biotinylated 20S catalytic subunits were only recovered in the membrane preparation. Western blots of subcellular preparations showed that Bio-Epox remained in the membrane preparation for up to 6 hours with no detection in the cytosol, validating the use of Bio-Epox as a NMP-specific inhibitor in vivo. We then used in vivo calcium imaging in the optic tectum of tadpoles to study the role of NMPs in regulating spontaneous neuronal activity. Interestingly, blocking NMPs in tectal neurons with Bio-Epox

significantly increased spontaneous neuronal activity in a dose-dependent manner. The increase in spontaneous activity was observed as soon as 5 min post-injection and lasted for at least 30 min. In the presence of BMI (bicuculline methiodide), when spontaneous neuronal activity was already heightened, blocking NMPs further increased neuronal activity. Based on unpublished data showing that NMP targets intracellular substrates that are being newly synthesized, we used bio-orthogonal metabolic labeling (BONCAT) to label newly synthesized proteins (NSP) and studied the function of NMPs in tadpole brains. In BONCAT, azidohomoalanine (AHA) is incorporated into NSPs and then tagged with biotin alkyne by click chemistry to allow specific detection of NSPs (Liu et al., 2018). Using BONCAT, we found that BMI increases NSPs and that blocking NMPs with Bio-Epox in the presence of BMI further increased NSPs. Bio-Epox alone did not increase NSPs, suggesting that NMPs actively degrade NSPs in response to increased neuronal activity. Taken together these data are consistent with findings observed in cultured mouse neurons. Our findings presented here are the first to demonstrate NMPs actively modulate neuronal activity in vivo and may function in part by regulating expression of activity-induced NSPs.

Title: The neuronal protein Arc acts as a repurposed viral Gag protein that mediates cell-to-cell communication

Authors: *E. D. PASTUZYN, R. B. KEARNS, J. N. EINSTEIN, J. D. SHEPHERD
Neurobio. and Anat., Univ. of Utah, Salt Lake City, UT

Abstract: The neuronal gene Arc is crucial for consolidation of long-term memories, and Arc knockout (KO) mice are deficient in multiple forms of synaptic plasticity. Arc mediates synaptic plasticity via trafficking of AMPA receptors to and from the postsynaptic membrane. However, the molecular biology of Arc is not well-characterized. Recently, Arc was discovered to have structural homology to Gag, a critical component of retroviruses like HIV that is sufficient to form an infectious particle. This suggested that Arc may exhibit viral-like properties: the ability to self-assemble into proteinaceous shells or capsids, interaction with lipid membranes, encapsulation of nucleic acids, and release from cells. We found that Arc performs all of these

key functions associated with viral Gag. Electron microscopy shows that purified Arc protein forms capsids similar to HIV. Immunoprecipitation of Arc protein from brain tissue pulls down *Arc* mRNA, suggesting the two are directly interacting or forming a complex. Neurons release extracellular vesicles, which contain RNA and are thought to be important in cell-to-cell communication or transfer of material. The extracellular vesicle fraction from cultured cortical neurons contains both Arc protein and *Arc* mRNA. Incubation of cultured Arc KO neurons with either the extracellular vesicle fraction from wildtype (WT) neurons, or purified Arc protein alone, results in transfer of both Arc protein and *Arc* mRNA into KO neurons. Furthermore, transferred *Arc* mRNA is available in the cytoplasm for activity-induced translation into new Arc protein. Extracellular vesicles are a heterogeneous population that can be differentiated by membrane surface markers, such as receptors, as well as potentially by their cargo. We purified Arc vesicles using differential ultracentrifugation and density gradients to determine which subpopulation of extracellular vesicles Arc is associated with. We then performed proteomic and deep RNA sequencing of purified Arc vesicles to determine the composition of cargo, which will provide insight into the function of this form cell-to-cell communication. These studies show that Arc serves as a novel intercellular messenger in neuronal networks and can regulate neuronal function in a non-cell autonomous manner.

Title: Functional presynaptic ribosomes in the mammalian brain, and presynaptic effects of inhibiting protein synthesis

Authors: *K. G. PARADISO[1], M. S. SCARNATI[2], R. KATARIA[1], M. BISWAS[1]
[1]Cell Biol. and Neurosci., Rutgers Univ., Piscataway, NJ; [2]Dept. of Neurosci. and Cell Biol., Rutgers-Robert Wood Johnson Med. Sch., New Brunswick, NJ

Abstract: To determine if ribosomes are present and functional in presynaptic terminals in the mammalian brain, we used the SUrface SEnsing of Translation (SUnSET) technique to detect the location of active ribosomes in mouse brain slices. In this assay, puromycin becomes incorporated into nascent polypeptide chains, and is detected by antibody labelling. We find clear evidence of ribosomal activity in calyx of Held presynaptic terminals, based on

colocalization of puromycin with the vesicular glutamate transporter VGLUT1 which specifically labels the calyx nerve terminal. Addition of anisomycin to inhibit translation completely blocks the presynaptic and postsynaptic puromycin signal, demonstrating the specificity of this assay. In separate immunocytochemistry experiments, we find 5.8s ribosomal RNA, a major component of ribosomes, is also present in the presynaptic terminal. These results demonstrate that calyx of Held presynaptic terminals in the mammalian brain contain functional presynaptic ribosomes capable of presynaptic protein synthesis. This suggests that active presynaptic translation could affect presynaptic activity. In separate experiments, we inhibited translation and examined the effects on synaptic transmission. We find an increase in spontaneous release frequency, demonstrating that presynaptic vesicular release is affected by ongoing protein synthesis. In contrast, the amplitude and shape of spontaneous release events were not affected by inhibiting protein synthesis, demonstrating that postsynaptic activity is not affected. In response to evoked stimulation after inhibiting protein synthesis for ~1 hour, we find a decrease in the initial probability of release with increased levels of release during sustained stimulation at 100 Hz and 200 Hz. This is accompanied by an increased level of vesicle recycling at 100Hz and 200 Hz when protein synthesis is inhibited. These results indicate that ongoing protein synthesis is necessary to maintain specific levels of vesicular release. Overall levels of release are increased when protein synthesis is inhibited. Given that normal levels of release are sufficient to produce an adequate postsynaptic response, this indicates that ongoing protein synthesis acts to limit excess neurotransmitter release. Ongoing protein synthesis therefore acts to limit excess energy consumption that is required for vesicle recycling. This suggests that ongoing protein synthesis increases the efficiency of the presynaptic terminal by limiting excess vesicle release.

Title: Imaging transcription dynamics of neuronal activity-regulated genes in hippocampal neurons

Authors: *S. DAS, R. H. SINGER
Albert Einstein Col. of Med., Bronx, NY

Abstract: Spatio-temporal control of gene expression in a neuronal network is an essential element of memory formation. However, it has not been possible to follow the dynamics of memory-associated mRNAs in living neurons in response to neuronal activity in real time. We generated transgenic mouse models where the endogenous Arc (Arg 3.1) and β-actin genes are tagged in their 3'UTR with stem loops that bind different fluorescent coat proteins, allowing simultaneous visualization of two different mRNAs in the same neuron in real time. The physiological response of the tagged genes to neuronal activity is identical to the endogenous wild-type and faithfully captures the true dynamics of the mRNAs. Real time transcription dynamics of immediate early gene Arc reveals: i) a robust transcriptional burst with a prolonged ON-state after stimulation, and ii) reactivation of transcription at the same allele even after the initial stimulation is removed. This is quite distinct from how β-actin responds to neuronal activity with more stochastic bursting. The tagging and imaging of endogenous genes, one inducible and other constitutive, provide an important tool to investigate how individual neurons transduce activity into regulation of gene expression with unprecedented temporal resolution.

Title: Direct administration of osteocalcin into the dentate gyrus affects contextual fear memory via a CPEB3 mediated mechanism

Authors: *S. KOSMIDIS, L. HARVEY, E. KANDEL
Neurosci., Columbia Univ., New York, NY

Abstract: Recent studies highlight the contribution of several sites in the aging process, illustrating the importance of blood-derived factors in memory. One such humoral factor is the bone-derived hormone Osteocalcin (OCN). Injection of OCN into the dentate gyrus enhances discrimination memory via the GPR158 protein. Subsequent RNA seq analysis upon direct administration of OCN in the dentate gyrus after fear memory recall, demonstrated that OCN enhances translation of several memory-related genes. We therefore hypothesized that the cytoplasmic poly-adenylation element binding protein 3 (CPEB3) could be involved in the translational regulation of OCN signaling. Here we demonstrate that OCN signaling via GPR158 leads to phosphorylation of CPEB3, which in turn exerts control over translation. Using RNA-immuno-precipitation coupled with deep sequencing, we further found that CPEB3 binds to

several mRNAs involved in the recall of fear memory. Finally we find that overexpression of CPEB3 phosphorylation mutants in the dentate gyrus differentially affects fear memory.

Title: Characterization of the mTORC1 effector PDCD4 in activity dependent translation

Authors: *I. KATS[1], E. KLANN[2]
[1]New York Univ., New York, NY; [2]Ctr. for Neural Sci., New York Univ. Ctr. for Neural Sci., New York, NY

Abstract: Translation initiation, regulated by mechanistic target of rapamycin 1 (mTORC1) and its effectors eIF4E and p70 S6 kinase 1 (S6K1), is relevant to both normal memory function and disease. Either increased expression of eukaryotic initiation factor 4E (eIF4E) or deletion of its repressor eukaryotic factor 4E binding protein 2 (4E-BP2) causes autistic endophenotypes in mice. Moreover deletion of S6K1 can cause deficits in various types of memory. Inhibitors of either the interaction of eIF4E with eukaryotic initiation factor 4G (eIF4G) or the eukaryotic initiation factor 4A (eIF4A) have also been shown to affect protein synthesis in brain slices and to disrupt long-term potentiation. eIF4A1, the DEAD box helicase in the cap-dependent translation initiation complex, has proven to be important for translation in cancer cells where it is often upregulated. The inhibitor of eIF4A1, PDCD4 is phosphorylated and broken down by the proteasome pathway in cancer cells to permit protein synthesis and cell growth. Our preliminary data show that PDCD4 is down regulated by neuronal stimulation and that the pathway responsible for this regulation is S6K1- and proteasome-dependent. Moreover, in contract to non-neuronal cell types, PDCD4 is present in the cell body as well as dendrites and its overexpression in neurons causes a decrease in dendrite complexity. The localization and regulation of PDCD4 implicates the importance of PDCD4 and eIF4A1 as mTORC1 effectors in not only activity-dependent translation but also synaptic plasticity and memory function. To test this idea we have begun to examine synaptic function and memory processes in PDCD4

knockout mice. In summary, our findings indicate that PDCD4 acts as a downstream effector of mTORC1 in neurons, and thus, is an important regulator of activity-dependent translation.

Title: Investigating non-canonical protein synthesis in neurons

Authors: *H. WONG[1], J. LEVENGA[1], C. HOEFFER[1,2]
[1]Inst. for Behavioral Genet., [2]Integrative Physiol., Univ. of Colorado Boulder, Boulder, CO

Abstract: Protein synthesis is required for persistent forms of synaptic plasticity such as long-term potentiation and long-term depression, which are thought to be cellular substrates of memory. The primary pathway for protein synthesis is canonical translation, which initiates with binding of the small ribosomal subunit and associated translation initiation factors to the 5' cap of eukaryotic mRNAs. While this pathway is well-studied and known to support synaptic plasticity and memory, protein synthesis can also occur to a lesser extent through non-canonical pathways. In one mode of non-canonical translation, protein synthesis initiates from an internal ribosome entry site (IRES) in the mRNA transcript. An IRES is an element within the mRNA that recruits the ribosome by various mechanisms different from canonical initiation. Very little is known about the contribution of this IRES-mediated mode of translation to neural function. However, a few proteins associated with synaptic plasticity have been reported to contain an IRES in their mRNA. We hypothesized that IRES-mediated translation may play a role in the protein synthesis supporting persistent forms of synaptic plasticity. To explore this idea, we have developed bicistronic translation reporters to measure cap- and IRES-mediated protein synthesis in neurons. Using these reporters in addition to complementary approaches, we are examining translational activity in hippocampal neurons following different stimulation and treatment conditions. These studies may provide new insight into the translation mechanisms underlying synaptic plasticity and how their dysfunction could be involved in memory disorders.

Title: Detection of native RNAs dynamics in living neurons by fluorescence correlation spectroscopy

Authors: *H. FUJITA[1], S. KAMIZONO[1], R. OIKAWA[2], M. HAYAKAWA[2], F. TOMOIKE[2], S. TSUNEDA[1], H. ABE[2], T. INOUE[1]

Abstract: Peripheral localization of transcripts mediates many neuronal processes, the dynamics of which are the key to understanding development, cellular signaling and synaptic plasticity. While several techniques have been used to visualize mRNAs in live cells, dynamics of endogenous and non-engineered mRNAs in living neurons have been difficult. We developed a method to analyze the behavior of native mRNAs without modifying their sequences in living neurons. In order to fluorescently label native RNAs, we used reduction-triggered fluorescence (RETF) probes, of which fluorescence emission was chemically activated after a pair of probes hybridize to the target RNA side by side. We chose activity-regulated cytoskeleton-associated (Arc) and inositol 1,4,5-trisphosphate receptor type 1 (IP3R1) mRNAs as targets.Fluorescence signal deriving from the RETF probe increased and spread over the cytosol after loading to cultured hippocampal neurons by a whole cell patch clamp method. Fluorescence correlation spectroscopy (FCS) was applied to discriminate bound and unbound probes by the difference in diffusion coefficients. The slower diffusing component reflected RNA-bound probes and the faster one reflected unbound probes presumably due to RNA degradation. The balance between the faster and slower diffusion components was different when IP3R1 mRNA probes were used, suggesting a difference in the turnover rates between Arc and IP3R1 mRNAs. Neuronal activation drastically increased concentrations of the both diffusion populations within 40 min, which was interpreted as the production and degradation of Arc mRNA. Simulation of diffusive RNA within the dendritic space using the obtained diffusion coefficient of Arc mRNA (1.0 $\mu m^2/s$) showed that RNA does not reach distal dendrites by diffusion within reasonable time, supporting the notion that the active transport mechanism is necessary to deliver mRNA to the distal dendrite.

Title: Machine learning tech for neural omics

Authors: *B. R. MONK[1], A. RAJKOVIC[3], R. MALINOW[2]
[1]Cog Neuro IDP, [2]UCSD, San Diego, CA; [3]Informatics, Univ. of London, London, United Kingdom

Abstract: We have developed a computational framework for informing neural disease-related diagnostics. This framework integrates and leverages powerful machine learning libraries (e.g. Google Tensorflow) to perform regression based and artificial neural network based computations that can, for example, inform dementia diagnoses. In one use-case our platform could correctly diagnose Alzheimer's Disease patients with 75-80% accuracy, after training a neural net classifier on whole exome sequences from 5k patients and 5k controls. This prediction accuracy generalized to individuals never seen by the machine classifier. The platform can also output a confidence level for each prediction; for individuals returning highly confident predictions the classifier can reach upwards of 85% accuracy. Our data also suggests there remain substantial gains to be had in prediction accuracy (and precisely how these can be achieved). We think such a platform could be adapted for use in both a clinical setting and for aiding primary research, and we are interested in collaborating with other parties in further developing this tech. Title: A multi-omic analysis of the pre-histopathological and sex-biased molecular pathology in the hippocampus of the 5XFAD mouse model of Alzheimer's disease

Authors: *R. S. NOWAKOWSKI[1], J. L. BUNDY[2], C. M. VIED[3]
[1]Biomed. Sci., FSU Col. of Med., Tallahassee, FL; [2]Duke Mol. Physiol. Inst., Duke Univ., Durham, NC; [3]Translational Sci. Lab., Florida State University, Col. of Med., Tallahassee, FL

Abstract: Alzheimer’s disease is a progressive neurodegenerative disorder and is the most common form of dementia. Like many neurological disorders, Alzheimer’s disease has a sex-biased epidemiological profile, affecting approximately twice as many women as men. To

identify the molecular mechanism of this sex bias at its earliest onset, we investigated the molecular changes in females and males using the 5XFAD genetic mouse model of Alzheimer's disease at 3 different ages. The 5XFAD model contains two mutated human transgenes (*APP* and *PSEN1*) associated with familial Alzheimer's disease co-inserted into the mouse genome. We profiled the transcriptome, the miRNAome and proteome of the mouse hippocampus during early stages of disease development (one, two, and four months of age). At one month, only the transgenes are differentially expressed. At two months of age, which is prior to observable plaque deposition, our analysis reveals 42 genes that are differentially expressed between transgenic and control animals In four month old animals, we detect 1316 differentially expressed genes between transgenic and control mice, many of which are associated with immune function. Additionally, we find that some of these transcriptional differences are correlated with altered protein levels in four month old transgenic animals. Importantly, our data indicate that female 5XFAD mice exhibit more profound molecular pathology than their male counterparts as measured by differences in gene expression. In addition to the transcriptome and proteome analyses, we will present miRNA expression data generated from the same RNA used to produce the transcriptomic data. The three omics datasets will be correlated and the pathways containing the significantly changed genes analyzed to produce a comprehensive profile of the molecular changes that occur due to Alzheimer's disease in the 5XFAD mouse model.

Title: Early apoptosis in Alzheimer's disease 5XFAD mouse model is induced through multiple pathways: A comparative transcriptomics study on *in vivo* neuron-microglia interaction phase

Authors: *F. XUE, Q. WANG, H. CHEN, Z. XUAN, L. GUO, H. DU
Biol. Sci., The Univ. of Texas at Dallas, Richardson, TX

Abstract: Alzheimer's disease (AD) is a devastating neurodegenerative disorder, characterized by progressive cognitive decline. Neuronal death and neuroinflammation are featured AD brain pathology closely associated with the toxicity of a key AD mediator, Amyloid beta (Aβ). Microglia has both neuron protection and neuroinflammation functions, and may play different roles at early or later stage of amyloidopathy. Therefore, the examination on neurons and microglia separated from AD-sensitive brain tissues has paramount importance to address the "cause and effect" question. In this study we used an AD mouse model (5xFAD) overproducing human form Aβ. Experiments were conducted on young 5xFAD mice, which mimic mild brain

amyloidopathy, neuronal injury and cognitive deficits in early AD. Experimentally, we modified brain tissue dissociation, fluorescence-activated cell sorting (FACS), high integrity RNA purification, and moderate depth RNAseq methods, and revealed the steady transcriptomic changes in neuron and microglia from 5xFAD mice in comparison with those from the age- and gender-matched wildtype littermates. The robust gene upregulations in MAPK, Toll-like receptor, JAK-STAT, and Insulin signaling pathways in neurons sorted from 5xFAD mouse cortex and hippocampal tissue indicated that the initiation of apoptosis was induced through multiple pathways. However, the downregulation of several key actors in apoptosis pathways as well as the activation of several anti-apoptosis pathways (eg. Focal adhesion, Wnt) seem to suggest a balance between pro- and anti-apoptosis in neuron population. Surprisingly, the CD11b+ microglia from 4 months old 5xFAD mice did not exhibit significant inflammatory response, which is different from previous inflammation activation results. Such discrepancy may be explained by a more rigorous sample preparation that we used in current study. In addition, our RNAseq data also verified recently reported single-cell RNAseq markers of disease-associated microglia (DAM), which suggests a potential protective effect of microglia on neurons against Aβ in young 5xFAD mice. In summary, our results suggest that the early neuron apoptosis in Alzheimer's Disease (AD) 5XFAD mouse model was induced through multiple pathways, but not through inflammatory response in microglia.

Title: Decoding competing endogenous RNA regulations in Alzheimer's disease

Authors: ***Y. CAI**[1], Z. SUN[2], H. JIA[2], J. WAN[2,3]
[1]SZ-PKU-HKUST Med. Ctr., Peking Univ., Beijing, China; [2]SZ-PKU-HKUST Med. Ctr., Shenzhen, China; [3]Hong Kong Univ. of Sci. and Technol., Hong Kong, China

Abstract: Leverging the fast developing sequencing technology, large amount of non-coding RNA (ncRNA) have been discovered involving in diseases and health. Alzheimer's disease (AD) is a heterogeneous neurodegenerative disease. Recent studies have identified ncRNAs influentially involved in AD pathogenesis. Competing endogenous RNA (ceRNA) regulation is one of the most important mechanism. Briefly, ceRNAs can compete with other endogenous RNAs by microRNA response elements (MREs) and manipulate biological processes, such as tumorigenesis. Abundant of studies have reported miRNAs in AD pathogenesis, as well as ceRNA regulations and networks in tumorigenesis. Although few, the studies of ceRNAs in AD pathogenesis is growing.
In the first session of this study, we constructed the first ceRNA network based on APPswe/PS1ΔE9 transgenic mice model, leveraging whole transcriptome sequencing and miRNA-seq of cortex samples from AD and wild type mice. Differentially expressed lncRNAs were identified, then input into bioinformatics batabases, such as LncBase, TarBase, DIANA web server v.5, mining for ceRNA interactions. In this network, 1091 nodes and 1171 edges were constructed. Four hub lncRNAs (C030034L19Rik, Rpph1, A830012C17Rik, and Gm15477) and five hub miRNAs (miR-182-5p, miR-330-5p, miR-326-3p, miR-132-3p, and miR-484) are enriched in nine AD-associated pathways and an AD-related gene pool.
In the second part of this study, one of the ceRNA pathway Rpph1-miR330-5p-Cdc42 were studied with molecule biology verification and cell biology functional assays. The underlying ceRNA interactions were validated using molecular biology approaches, such as Dual Luciferase Reporter Assay, quantitative RT-PCR and Western blotting; cell biology approaches, such as primary neuronal culture for dendritic spine and neurites morphological examination. Long non-coding RNA Ribonuclease P RNA component H1 (Rpph1) is upregulated in the cortex of APPswe/PS1ΔE9 mice compared to wild type controls. Rpph1 binds to miR326-3p/miR-330-5p and causes the release of their downstream target Cdc42, which leads to CDC42 upregulation. This effect was disrupted upon mutation of the MRE on Rpph1. Moreover, overexpression of Rpph1 increased dendritic spine density in primary cultured hippocampal pyramidal neurons, whereas knocking down of Rpph1 had the reverse effect. This pathway may represent a compensatory mechanism in the early stage of the AD pathogenesis.
In the third part of this study, we focus on the advanced strategies in ceRNA regulations based on evidence in neurodegenerative disorders, mainly summarized five miRNA and ceRNA hierarchies in cross regulations.

Abstract: Alzheimer's disease (AD), a progressive and debilitating neurodegenerative disorder, stands alone as one of the ten leading causes of death in the United States that cannot be prevented, slowed, or cured. However, research suggests that the brain changes associated with AD often begin 20 or more years before symptoms appear, which makes this a critical time window for possible preventative treatments. Therefore, it is essential to discover early biomarkers in those at risk for AD. Because aging is the greatest risk factor for the development of AD, it is also important to examine age-related changes in the brain and age-related cognitive decline (ARCD). Metabolomics represents one of the best omics platforms for the diagnosis and prognosis of neurodegenerative diseases, as the metabolome is a reflection of genetics, protein profiles, and environmental influences. Furthermore, metabolic decline is one of the earliest symptoms detected in patients with mild cognitive impairment (MCI). Here in, we used metabolomics to define system-level alterations following cognitive decline in aged and APP/PS1 mice. At 6, 12, and 24 months of age, both AD and aged-match control (Ctrl) mice were tested for cognitive impairment in a 3-shock contextual fear conditioning (CFC) paradigm. Brain tissue (i.e, hippocampus, hypothalamus, PFC, and cerebellum) and biofluid (i.e., plasma) metabolomic analysis was performed. By examining behavior across ages in these animals, we aimed to determine if early metabolomic changes could associate with cognitive decline observed following natural aging and AD development. Furthermore, since metabolomics pathways are largely conserved between species, these results could improve the translation of preclinical research. Our results confirmed that AD mice exhibit memory deficits in the CFC paradigm compared to controls at 6, 12, and 24 months of age. However, aged-match Ctrl mice also exhibited cognitive decline across ages. These memory impairments were correlated with metabolome changes in both the left and right hemispheres of the hippocampus. Specifically, in AD mice, metabolome changes were left lateralized, meaning there were greater changes in the left hemisphere of the hippocampus compared to the right. These data support human literature showing greater grey-matter atrophy in the left hippocampus of Alzheimer's patients. Ctrl mice exhibited equal metabolome changes in both hemispheres, which highlights the differences in ARCD and AD progression. Our future directions are to further analyze other brain regions and to determine the role of peripheral organs through metabolic signaling.

Abstract: Background: The systemic failure to develop successful treatments for Alzheimer's Disease (AD) is in part driven by an incomplete understanding of the multi-factorial and heterogeneous biological processes that underlie this disease. To address this challenge, the AMP-AD Target Discovery Project has identified transcriptional endophenotypes that characterize AD-altered processes in the postmortem brain and, using these, evaluated common sources of heterogeneity in their manifestation across 2114 samples collected from 3 studies and 7 brain regions. **Methods:** To identify AD transcriptomic endophenotypes that are robustly observed across data sets and methodologies, we apply five distinct network methodologies (MEGENa, metanetwork, WINA, SpeakEasy, and rWGCNA) to learn coexpression modules within each tissue type and combine these modules with a meta-analysis of differential expression signatures of AD to produce consensus modules for each tissue via a graph clustering algorithm. **Results:** Thirty disease-associated transcriptomic networks were consistently observed across brain regions and independent of analytical method. Many of the conserved AD-altered transcriptional networks show strong enrichment for known AD pathway signatures including evidence of neuroinflammation and synaptic dysfunction. Others represent potentially new insights into AD biology and may suggest sex specificity of transcriptional endophenotypes.

For example, there is strong evidence of female specific neuronal, vascular, and myelination dysfunction and male specific changes in DNA damage repair and response to unfolded proteins. **Conclusions:** These results, which require further replication, may suggest sex-specific disease pathways or rates of AD pathophysiology progression. In women cell type specific transcriptional dysregulation appears to be more prominent, whereas in men, failure of various proteostatic pathways may be more instrumental in pathophysiology. Neuroinflammatory pathways reveal transcriptional changes in both sexes. Furthermore, these observations provide a set of AD transcriptional endophenotypes that can be used to identify causal factors that modulate changes in biological processes that lead to or propagate AD pathophysiology. Some of these transcripts and their protein products are being evaluated as potential drug targets.

Abstract: Background: Amyloid plaques in the human brain are a pathological hallmark of Alzheimer’s disease (AD). The last three decades as seen the etiology of AD increasingly linked to chronic, low-grade, asymptomatic microbial brain infections. We recently reported Abeta is an innate immune protein and the peptide’s expression protects against fungal and bacterial infections in animal and cell culture models, doubling host survival in some cases. However,

fibrilization pathways mediate Abeta antimicrobial activities. Thus, infection can dramatically accelerate beta-amyloid deposition. Here we report on a study to determine microbes normally residing in aging human brain and how this population may change in AD. **Methods:**Human frontal cortex brain samples from different age groups were screened for microbial signal by Whole Genome Metagenomics Sequencing (WGMS) using next generation technique (NGS). Screening aimed to identify non-human nucleic acid sequences. Additional established methods were also used to confirm findings.**Results:**Initial sequencing data confirmed the presence of microbial populations in aging and AD human brain samples, with bacterial organisms being more abundant (40-60 % of total microbial populations). Organisms identified included fungi, viruses and protozoa. Bacterial genera identified include *Acinetobacter, Pseudomonas, Escherichia*,*Bacteroidetes*, as well as symbiotic bacteria, including *Eubacterium, Bifidobacterium*, *Roseburia*and *Akkermansia*. Eukaryotic microorganisms, were also present, including species from the *Plasmodium*genus. Most significantly, data suggest AD brain may have altered microbial populations compared to age-matched non-demented controls. Conclusions:Preliminary data suggest the existence of a microbial population in human brain samples whose composition changes across age and disease. Findings are consistent with a link between enhanced β-amyloid deposition in AD and a shift in the population of microorganisms in brain.

Title: Comparative cell and nuclear isolation strategies for transcriptomic analysis of neurons, microglia and astrocytes

Authors: *F. LETRONNE[1], J. MILOSEVIC[2], K. NAM[2], B. PLAYSO[2], N. F. FITZ[2], C. WOLFE[1], I. M. LEFTEROV[2], R. KOLDAMOVA[3]

Abstract: While multiple methods have already been developed for isolation of neurons or astrocytes from frozen human brain tissue for transcriptomic analysis, microglia isolation from frozen tissue is still a challenge. Here we compare standard protocols applied for cellular and nuclear isolation from fresh and frozen mouse brain tissue to our new protocol for simultaneous isolation of neuronal, astrocytic and microglial nuclei from frozen human brain. Cellular populations or nuclei from mouse brain, can be isolated and sorted by FACS to perform RNA-seq and analysis of transcriptomes. However, most of the methods for isolation of cells or nuclei from fresh or frozen mouse brain involve mechanical stress that increases cellular damage, and/or protease treatment at 37°C (as trypsin or papain) that may induce alterations in RNA and possibly sequencing data. In our method, Accutase allow an efficient cell dissociation at 4°C. Because of longer postmortem intervals or extended storage of human brains at −80°C, brain cells are more fragile or damaged and the use of standard isolation protocols results in a significant decrease of the number of cells/nuclei and therefore the quantity of RNA, and sequencing libraries impacting subsequent transcriptomic analysis. Therefore, in our protocol, the gentle manual trituration of the brain tissue with modified Pasteur pipettes that varied in tip diameter, slow centrifugations at 4°C, using cold buffers and keeping the samples on ice contribute to diminish cell damages and increase cell yield. After trituration, half of the single-cell suspension is exposed to anti-Cd11b-microbeads and processed into columns for magnetic separation. Then, the enriched microglia cell suspension and the leftover single cell suspension are fixed and permeabilized with Ethanol to extract the nuclei. Finally, the nuclei are labelled with DAPI, anti-NeuN, anti-GFAP and anti-SPI1. Using flow cytometry to estimate the percentage of each cell population in the samples, we were able to see a higher yield of nuclei obtained with our new protocol. Moreover, unlike the standard cell isolation methods, we were able to use down to 3000 neuronal, astrocytic and microglial nuclei sorted by FACS to perform RNA isolation and RNA-sequencing. This new protocol has been optimized to ensure a high quality of RNA for transcriptomic analysis purpose, the possibility to study simultaneously the transcriptome of neuronal, astrocytic and microglial nuclei from the same tissue and to reduce the amount of initial frozen material. This method for human frozen brain should facilitate and optimized the use of frozen tissue for Human brain transcriptomic research.

Abstract: Background Standard approaches to understand gene expression and regulation in the brain include identification of differentially and co-expressed genes. The Accelerating Medicines Partnership Alzheimer's Disease (AMP-AD) consortium has produced multiple, large RNA-seq datasets from several postmortem brain regions. The ENCODE project has produced DNAse Hypersensitivity (DHS) samples for various brain regions. We have integrated these large datasets into transcriptional regulatory networks (TRN), providing a directional and mechanistic list of putative transcription factors for nearly all expressed genes in the brain. **Methods** We reprocessed all ENCODE brain DHS samples at scale, generating footprints—signatures of occupancy by DNA binding proteins—using the Wellington and HINT algorithms. We assembled motifs from JASPAR2016, HOCOMOCO, UniPROBE, and SwissRegulon, removing redundant motifs with Tomtom and intersecting our footprints with all possible overlapping motifs. This resulted in a total of 1,530 motifs mapping to 1,515 different transcription factors. We developed and utilized Transcriptional Regulatory Network Analysis (TReNA), available as an R Bioconductor package. Gene regulatory regions in our model were obtained through Genehancer, enabling inclusion of all known enhancer regions. TReNA utilizes an ensemble of machine learning techniques, including lassopv, square root lasso (flare) and randomForest to prioritize transcription factors based on the expression levels in RNA-seq for each target gene. All resulting scores are scaled and normalized into a composite score, ranking transcription factors for each target gene. **Results** Our TRNs contain a prioritized list of putative transcription factor regulators for all genes. The footprints (and their genomic locations) allow us to integrate genetic information from GWAS or eQTL analysis to generate testable hypotheses around the functional annotation of variants. We have done this for all primary AD-associated loci from identified in GWAS. We have also identified putative targets for the AD-associated transcription factor MEF2C. We have identified multiple microglia-enriched transcription factors that regulate many differentially and co-expressed genes in AD, in particular, the AD-associated transcription

factor SPI1. **Conclusions** These resulting models can be applied to other datasets that generate lists of differentially or co-expressed genes as well as provide testable hypotheses for non-coding variants of interest. We are actively engaged in testing several hypotheses through experimental means and have made these TRNs publically available.

Title: A multi-omic analysis of preclinical late-onset Alzheimer's disease: Integrating metabolomic, proteomic, and transcriptomic biomarkers from human peripheral blood

Authors: T. J. GROSS[1], M. S. FIANDACA[2], F. MACCIARDI[3], H. J. FEDEROFF[2], *M. MAPSTONE[2]
[1]Anat. and Neurobio., [2]Neurol., [3]Pyschiatry and Human Behavior, Univ. of California, Irvine, Irvine, CA

Abstract: Late-onset Alzheimer’s disease (LOAD) is an age-related neurodegenerative disorder associated with progressive dysfunction of learning and memory. There are currently no validated clinical laboratory tests that prospectively assess risk of developing LOAD. Although specific biomarkers have been proposed, few discovery efforts have explicitly leveraged a systems biology, multi-omic approach to discovery and validation. Here, we report such an analysis of peripheral blood, contrasting cognitively healthy controls (Control = 50) with initially cognitively healthy individuals who developed memory impairment over a five-year observational study period (Converter = 26). We collected peripheral venous blood at entry to the study and analyzed blood plasma fractions for protein and small metabolite content using proteomic aptamer microarrays and targeted metabolomic mass spectrometry, respectively. We sequenced RNA obtained from buffy coat leukocytes. We modelled disease state (Converter vs. Control) as a function of the quantified biomolecules using the mixOmics DIABLO algorithm. Phosphatidylcholines (PCs) were depleted in the plasma of Converter samples compared to

controls, as previously reported from this cohort. Depletion of PCs correlated with altered transcripts that survived thresholding at the $r = .70$ level. Specifically, we found negative correlations between PC levels and two differentially expressed transcripts in Converter and Control samples. Considered individually, each -omics module submitted to analysis demonstrated highly favorable performance in its ability to distinguish Controls from Converters (ROC $AUC_{Protein} = 0.88$, ROC $AUC_{RNA} = 0.97$, ROC $AUC_{Metabolites} = 0.97$). These results expand upon our previous findings from this cohort in which we reported alteration of PC metabolism in preclinical AD. Here, we find that changes in the plasma metabolome are accompanied by relatively robust, disease-associated alterations in the blood transcriptome and proteome. Integration of these -omic levels may reveal biologically cohesive pathways underlying the pathobiology of preclinical LOAD. Further work is necessary to identify and validate causative factors driving these relationships.

Title: BDNF and TrkB hippocampal gene expression predict neurofibrillary tangle and neuritic plaque pathology during the progression of dementia

Authors: *S. D. GINSBERG[1,2,3,4], M. H. MALEK-AHMADI[6], M. J. ALLDRED[1,2], Y. CHEN[6], K. CHEN[6], M. V. CHAO[2,4,5], S. E. COUNTS[7,8], E. J. MUFSON[9]

Inst., Phoenix, AZ

Abstract: The neurotrophin brain-derived neurotrophic factor (BDNF) and its cognate neurotrophin receptor, TrkB, regulate several key brain functions involved in neuronal survival, neuroplasticity, and learning and memory. Defects in the expression of BDNF or activity of TrkB are found in several neurodegenerative disorders including mild cognitive impairment (MCI) and Alzheimer's disease (AD). Specifically, downregulation of BDNF and TrkB have been observed during the progression of dementia. However, whether alterations in BDNF and/or TrkB interact with AD pathological lesions, including neurofibrillary tangles (NFTs), neuritic plaques (NPs), and diffuse plaques (DPs) remains unknown. To determine the relationships between changes in Bdnf and TrkB mRNA with AD lesions, gene expression data was accrued from hippocampal CA1 pyramidal neurons and regional hippocampal and entorhinal cortex dissections from participants in the Rush Religious Orders study (RROS) who died with a premortem clinical diagnosis of no cognitive impairment (NCI), MCI, or AD. Negative binomial (NB) regression analysis revealed that downregulation of Bdnf was independently associated with increased hippocampal CA1 NFTs, whereas TrkB downregulation was independently associated with increased entorhinal cortex NFTs during the progression of dementia. A significant interaction was found between Bdnf and APOE e4 status with NPs indicating that e4 carriers with greater NFT pathology had lower Bdnf expression. DPs did not correlate with cognitive decline, consistent with the Bdnf and TrkB findings. Taken together, these results indicate that BDNF and TrkB dysregulation may be upstream of hallmark AD neuropathology, most notably hippocampal and entorhinal cortex NFTs. This study provides proof-of-concept that individual transcripts within a functional gene ontology group (e.g., neurotrophins and neurotrophin receptors) can be used to predict (or be the outcome measure) associated with AD neuropathology. The significance of the possible temporal sequence of BDNF/TrkB deficits preceding neuropathological accumulation lies in its therapeutic potential. Several research laboratories, including our group, hypothesize that BDNF signaling deficits lead to selective vulnerability of specific neuronal populations, including hippocampal CA1 pyramidal neurons and cholinergic basal forebrain neurons within nucleus basalis subfields. These data suggest attenuating BDNF/TrkB signaling deficits either at the level of BDNF, TrkB, or downstream of TrkB signaling may potentially abrogate NFTs and/or NPs.

Title: Quantitative assessment of endosomal characteristics within basal forebrain cholinergic neurons (BFCNs) in trisomic mice following maternal choline supplementation (MCS)

Authors: *M. K. GAUTIER[1,2], M. J. ALLDRED[1,3], H. M. CHAO[1,3], A. SALTZMAN[1], S. D. GINSBERG[1,3,4,5]

Abstract: Down syndrome (DS) is the most common non-lethal chromosomal disorder in humans. By early middle age most DS individuals develop the pathological hallmarks of Alzheimer's disease (AD). These include the formation of amyloid-beta plaques, neurofibrillary tangles, and the presence of abnormally enlarged early endosomes. The Ts65Dn mouse model of DS/AD recapitulates key aspects of DS and AD pathology, including cognitive deficits in learning and memory, aberrations within the endosomal-lysosomal system, and degeneration of basal forebrain cholinergic neurons (BFCNs). We hypothesize that BFCN degeneration is due to deficient neurotrophic support within the septohippocampal circuit. We have previously reported that maternal choline supplementation (MCS) was able to improve neuronal size, shape, and density of septohippocampal neurons in young and aged Ts65Dn mice, as well as attenuate the overexpression of several genes involved in endosomal-lysosomal pathways. We therefore postulate that MCS will improve the efficiency of septohippocampal endosomal transport. To determine whether MCS treatment can significantly improve endosomal defects in BFCNs, we are conducting unbiased regional surveys of early endosomes in Ts65Dn mice and their normal disomic (2N) littermates at two time-points: 3-4 months of age and 10-12 months of age. BFCNs within the medial septal nucleus (MSN) and the vertical limb of the diagonal band (VDB) are dual labeled with antibodies directed against choline acetyltransferase (ChAT) and rab5, a cholinergic marker and an early endosomal marker, respectively. To determine whether MCS has an effect on early endosome pathology, quantitative analysis of vesicular attributes such as rab5-immunoractive endosomal area and cellular localization are performed in three-dimensional (3D) space using Imaris 9.1 software (Bitplane). Morphometric analysis of BFCN size and shape, as well as unbiased neuronal counts and density measurements will be performed using 3D reconstruction of z-stacks encompassing the entire soma of ChAT-immunoreactive MSN/VDB BFCNs to assess the impact of MCS treatment on the structure and function of the septohippocampal circuit. Preliminary results support the use of this quantitative scheme for accurate assessment of endosomal counts and volume within these vulnerable neurons that may respond to the nontoxic, well tolerated nutrient choline. MCS treatment may prove useful as an intervention for cognitive deficits and neuropathological alterations within the septohippocampal circuit associated with DS and AD, and we posit that this benefit is due in part to normalizing early endosome abnormalities.

Title: Differential expression signature in cortical p-tau-containing pyramidal neurons between demented and non-demented Down syndrome subjects

Authors: *E. J. MUFSON[1], B. HE[1], J. C. MIGUEL[1], M. N. SABBAGH[1], M. J. ALLDRED[3], S. D. GINSBERG[3], I. T. LOTT[4], E. DORAN[4], S. E. PEREZ[2]
[1]Neurobio., [2]Dept Neurobio., Barrow Neurolog. Inst., Phoenix, AZ; [3]Ctr. for Dementia Res., Nathan Kline Inst., Orangeburg, NY; [4]Pediatrics, UC Irvine Med. Ctr., Orange, CA

Abstract: Down syndrome (DS) is a genetic disorder characterized by intellectual disability and accompanied by phosphorylated tau protein (p-tau) containing neurofibrillary tangles (NFTs) and amyloid-beta (Aβ) plaques by the third decade of life. But not all middle-aged to aged individuals with DS will develop Alzheimer's disease (AD) type dementia. Recently, we found that DS subjects with dementia displayed a significant increase in the phosphorylated NFT burden in frontal cortex compared to those without dementia, while Aβ plaque load was similar in both groups, suggesting that p-tau plays a pivotal role in the onset of dementia in DS. However, molecular mechanisms underlying cortical NFT formation and its association with dementia in DS remain unknown. Here, we assessed the genetic signature of frontal cortex glutamatergic pyramidal neurons containing the p-tau pre-tangle maker pS422 in layers V-VI obtained from DS subjects with AD-like dementia (DS-AD; n=10) and without dementia (DS; n=5) using a combination of laser capture microdissection and custom-designed microarray analysis. Quantitative analysis revealed that the DS-AD group showed significantly lower transcript expression of genes related to APP/Aβ/tau metabolism [β-secretase (*Bace1*), γ-secretase (*Ncstn, Psenen, Aph1a*), α-secretase (*Adam10*)] and tau (*Mapt5*) than DS without dementia. Glutamatergic gene transcripts encoding several subtypes and subunits of glutamate receptors [glutamate receptors (*Grm1, Grm5*), NMDA receptors (*Grin2b, Grin2d*), ionotropic receptors (*Grik2, Gria3*), glutamate receptor interacting proteins (*Grip1, Grip2*)] and mRNAs

related to cholinergic neurotransmission [acetylcholinesterase (*Ache)*, butyryl cholinesterase (*Bche*), muscarinic (*Chrm2, Chmr4*) and nicotinic receptors (*Chrna2, Chrna3, Chrna4, Chrna7*)] were downregulated in DS-AD compared to DS without dementia. In addition, gene related to cell death [TNF-1 (*Tradd*), tumor protein p53 (*Tp53*), caspase 6 (*Casp6*), BCL2-associated X (*Bax*), several cell cycle proteins (*Ccnb1, Ccnd1, Ccnd2*)], G-protein signaling (*Rgs2, Rgs3, Rgs4, Rgs9, Rgs10*), adenylate cyclase (*Adcy1, Adcy6*), homeobox 2 (*Emx2*), autophagy protein 5 (*Atg5*), proto-oncogene c-fos, *Jun* and factor EB (*Tfeb*) transcripts were downregulated in DS-AD compared to DS. Conversely, expression of the epigenetic gene *Sirt6* in DS-AD was greater than in DS. These data suggest that cortical pyramidal p-tau containing projection neurons display different genetic signatures between age-matched demented and non-demented DS, where glutamatergic, cholinergic and APP/Aβ/tau metabolism are critically compromised in demented individuals with DS.

Title: Single population RNA sequencing (RNA-seq) analysis of basal forebrain cholinergic neurons (BFCNs) within the medial septal nucleus in the Ts65Dn mouse model of Down syndrome and Alzheimer’s disease identifies unique transcriptional mosaics following maternal choline supplementation (MCS)

Authors: *M. J. ALLDRED[1,2], H. M. CHAO[1,2], T. LHAKHANG[3], A. HEGUY[3], S. D. GINSBERG[1,2,4,5]

Abstract: Individuals with Down syndrome (DS) develop basal forebrain cholinergic neuron (BFCN) and hippocampal CA1 pyramidal neurodegeneration along with synaptic loss, neurofibrillary tangles, and amyloid plaques similar to Alzheimer’s disease (AD) by the third

decade of life. Both AD and DS patients exhibit selective vulnerability of septohippocampal neurons during disease progression. Unfortunately, therapeutic intervention has thus far failed, likely due to the number of pathways affected and the information gap underlying the mechanism(s) driving this selective vulnerability. The Ts65Dn mouse model recapitulates cognitive and morphological deficits of DS and AD, including BFCN degeneration. Perinatal maternal choline supplementation (MCS) delivers increased choline to disomic (2N) and trisomic offspring through the dam during the entire brain development period. MCS improves behavioral phenotypes associated with DS/AD and protects BFCNs from neurodegeneration in the Ts65Dn model. However, changes in gene/encoded protein expression due to MCS within vulnerable septohippocampal neurons have not been characterized. We utilized high-throughput, single population RNA sequencing (RNA-seq) to assess expression level changes due to MCS treatment in BFCNs from the medial septal nucleus (MSN). Expression profiles from MSN BFCNs were generated by laser capture microdissection (LCM) to isolate ~500 choline acetyltransferase (ChAT)-immunoreactive neurons in adult Ts65Dn and 2N littermates from choline normal and choline supplemented dams. Successful cDNA library construction from this small input RNA source enabled RNA-seq on individual populations for downstream transcriptional analysis. This procedure allowed for quantitative analysis of mRNAs and noncoding RNAs (ncRNAs) to help understand mechanism(s) underlying neurodegeneration, and link these expression level changes to established pathological hallmarks and cognitive decline for therapeutic development in human DS and AD. Results showed that ~500 BFCNs is sufficient for cDNA library preparation for RNA-seq and we identified unique transcriptomic profiles for MCS and choline normal animals independent of genotype. We demonstrate expression level changes in several relevant gene ontology (GO) pathways within single populations of LCM-captured MSN BFCNs in the Ts65Dn model of DS and AD in conjunction with a noninvasive, nontoxic treatment, MCS. We will utilize these profiles to further understand the molecular and cellular underpinnings of selective vulnerability and resilience with the goal of preserving the septohippocampal circuit in DS and AD.

Abstract: Genomic mosaicism (GM) in human brains has been revealed in different forms including aneuploidy, DNA-content variation (DCV), copy-number variation (CNV), and single-nucleotide variation (SNV). The function of these somatic DNA variations is still largely unknown. Alzheimer’s disease (AD) is a devastating neurodegenerative disease leading to memory loss and cognitive decline. Inheritable mutations and gene dosage of amyloid precursor protein gene (*APP*) have been shown to cause familial AD (FAD). However, the etiology of sporadic AD (SAD), representing the vast majority of AD cases, is not fully understood. Previously, we reported somatic neuronal DCV and specifically, APP CNV increases in SAD frontal cortices. In this study, we further identified novel APP genomic structural alterations in AD frontal cortical neurons by a range of PCR-based and targeted genomic DNA pull-down methodologies. Enriched mosaic presence of *APP* structural variants in both SAD and FAD, compared to age-matched non-diseased brains, was explicitly demonstrated by genomic DNA *in situ* hybridization. These data indicate APP genomic structural alteration, a novel form of GM, is associated with SAD, and raise the possibility that GM may also play a functional role in FAD.

Title: Cortical regional specific telomere length reduction during the progression of AD

Authors: *B. HE[1], S. E. PEREZ[1], M. MALEK-AHMADI[2], M. NADEEM[1], E. J. MUFSON[1]
[1]Dept Neurobio., Barrow Neurolog. Inst., Phoenix, AZ; [2]Banner Alzheimer's Dis. Inst., Phoenix, AZ

Abstract: Telomeres are a special protective cap located at the terminal end of a chromosome, their DNA is highly conserved cross species and prevents chromosomal fusion, recombination and degradation. In humans, telomeres which contain a series of DNA repeats (5'-TTAGGG-3') are considered as a potential biomarker of aging. Several studies reported shorter telomere length in peripheral blood mononuclear cells, T-cells and leukocytes in Alzheimer's disease (AD) compared to normal controls. Reports indicate that telomere length differ between brain region in AD. For example, telomere length is longer in the hippocampus but not change in the cerebellum in AD compared to normal controls. To explore alterations in telomere length, we examined frozen tissue from forty-eight precuneus cases with a premortem clinical diagnosis of no cognitive impairment (NCI) (n=23, M/F=12/11, age: 86.69 ± 5.64), mild cognitive impairment (MCI) (n=13, M/F=4/9, age: 88.96 ± 4.22) and AD (n=12, M/F=5/7, age: 89.84 ± 6.05) and forty-three visual cortex samples (NCI: n=16, M/F=6/10, age: 87.2 ± 5.76 ; MCI: n=13, M/F=3/10, age: 89.96 ± 3.93 ; AD: n=14, M/F=4/10, age: 90.63 ± 4.61) to measure telomere (T reaction) and 36B4 (S reaction) by quantitative polymerase chain reaction (qPCR). T/S ratio was used to estimate the telomere length. The results showed that precuneus telomere length was shorter in MCI ($p<0.001$) and AD ($p=0.001$) compared to NCI. Telomere length did not change between the MCI and AD cases ($p=0.6$).Telomere length showed no significant group differences when compared with Consortium to Establish a Registry for Alzheimer's Disease diagnosis (CERAD) ($p = 0.48$) and Braak stage ($r= -0.20$, $p =0.16$). Telomere length was correlated with Mini-Mental State Examination (MMSE) ($r=0.48$, $p<0.001$), Global Cognitive Score (GCS) ($r=0.47$, $p<0.001$), Episodic Memory ($r=0.41$, $p=0.004$), Working Memory ($r=0.34$, $p=0.02$) and Perceptual Speed ($r=0.41$, $p=0.004$). By contrast, visual cortex telomere length did not differ significantly between NCI, MCI and AD groups ($p=0.25$) or by CERAD diagnoses ($p=0.11$). Visual cortex telomere length did not correlate with any cognitive test score or Braak stage. The present findings reveals that telomere length was shorter in MCI and AD compared to NCI in precuneus but not in the sensory visual cortex and the former was related to cognitive decline during the progression of Alzheimer's disease.

Abstract: Alzheimer's disease (AD) neuropathologic patterns of neurofibrillary tangles are used to classify AD subtypes, which we termed hippocampal sparing (HpSp), typical, and limbic predominant. Utilizing a translational neuropathologic approach, we assessed the genetic contribution to selective vulnerability of the hippocampus in AD. The HpSp and limbic predominant AD cases were assessed as extreme phenotypes, which was complemented by comparison of controls and typical AD cases as enhanced phenotypes. RNA-sequencing was used to uncover gene expression changes associated with phenotype differences. We validated our findings in a larger cohort using NanoString and examined relevance to hippocampal neuropathology. RNA-sequencing was performed in 40 autopsy-confirmed AD subtypes and 15 controls. Validation with NanoString and quantification with digital pathology were performed in 158 AD cases and 32 controls. To prioritize genes, we employed bioinformatics methods to examine differential expression, enrichment of cellular process networks, and known AD target genes. We prioritized 52 genes from our RNA-sequencing studies to be validated using NanoString. We quantified digital pathology measures of early tangles (CP13), mature tangles (Ab39), amyloid-β burden (33.1.1), neuronal loss (H&E) and markers for microglia (CD68), endothelia (CD34), and astroglia (GFAP).Using a translational neuropathologic approach combined with deep learning based prediction models; the *SLC38A2* gene was nominated in the top gene using a multi-way importance model. The *SLC38A2* gene was originally prioritized in our RNA-sequencing data as it was found to be enriched in the sodium transport network and found differentially expressed between controls and typical AD (FDR=0.002, $p<0.00001$). RNA-seq gene expression measures validated well with NanoString for *SLC38A2* ($R=0.982$, $p<0.001$). Regression analysis was used to examine the contribution of demographics, tau and amyloid burden, neuronal loss and glial pathology. Early tau (Estimate=0.35, p=0.03) and late tau measures (Estimate=0.02, p=0.009) significantly predicted gene expression, but not amyloid measures or neuronal loss. Microgliosis approached significance (Estimate=0.35, p=0.03), but with no contribution from endothelial cell burden or astrogliosis. Age approached significance as a predictor of SLC38A2 gene expression (Estimate=-0.11, p=0.06), but not sex (Estimate=0.03, p=0.81) or *APOE* ε4 (Estimate=0.17, p=0.13). Our data supports consideration of intra-disease

divergence with regard to case stratification and may reveal genes previously masked by heterogeneity of cohorts.

Title: PICALM variant rs3851179^{A} has a protective role in neurons against Aβ toxicity

Authors: *Z. DAI[1], E. LAWSON[1], A. SAGARE[1], Z. ZHAO[1], R. TANZI[2], B. ZLOKOVIC[1]
[1]Zilkha Neurogenetic Inst., Los Angeles, CA; [2]Genet. and Aging Res. Unit, MassGeneral Inst. for Neurodegenerative Disease, Massachusetts Gen. Hospital, Harvard Med. Sch., Charlestown, MA

Abstract: Increasing Genome wide associational studies (GWAS) have proposed phosphatidylinositol-binding clathrin assembly protein (PICALM) highly associates with late-onset Alzheimer’s disease (AD). PICALM can bind to clathrin and lipoprotein receptor-related protein 1 (LRP1). Therefore, PICALM plays a very important role in clathrin-mediated endocytosis and participate the internalization and intracellular trafficking of cell surface receptors. We have previously reported that endothelial cells derived from human iPSCs carrying homozygous *rs3851179^{A}* alleles exhibited increased PICALM expression and improved transvascular clearance of Aβ across human blood-brain barrier (BBB) *in vitro,* when compared with isogenic cells from iPSCs carrying homozygous risk *rs3851179^{G}* alleles. In order to investigate *rs3851179^{A}* allele functions in neurons in Aβ toxicity and AD, we established direct differentiation protocol to generate human cortical neurons from iPSCs carrying different *rs3851179* alleles. Interestingly, Western blot analysis showed higher PICALM expression in iPSC-derived neurons carrying protective *rs3851179^{A}* allele compared to those carrying non-protective *rs3851179^{G}* allele. Then, we treated iPSC-derived neurons with Aβ oligomers. While Aβ treatment resulted in dramatical cell death and dendritic spine loss in homozygous *rs3851179^{G}* (GG) neurons, *rs3851179^{A}* (AA) neurons displayed a strong resistance to Aβ

toxicity. Currently, our data indicate that *rs3851179*^{A} (AA) provides PICALM with a protective role in neurons against Aβ toxicity. Next, we will confirm the function of *rs3851179*^{A} (AA) in Aβ toxicity and AD and address its molecular mechanism.

Ctr., New York, NY

Abstract: Background: To date, hundreds of risk loci have been associated with neurodevelopmental, neuropsychiatric and neurodegenerative diseases. When risks are mediated through gene expression, eQTL can implicate the specific genes involved through colocalizing algorithms or global tests of case-control differences in the predicted gene expression. In each

case, eQTL from the relevant tissue are necessary to understand the specific expression patterns contributing to disease, which may not be captured in readily available tissue such as blood. Recently, several large initiatives, including the CommonMind Consortium (CMC), the Accelerating Medicines Partnership for Alzheimer's Disease (AMP-AD) and GTEx, have made high-quality data available from the RNA-sequencing and genotyping of post-mortem brain collections.
Methods: Here we generate the best-powered brain eQTL resource to date which spans multiple brain regions and diseases. In total, we have collected 5 cohorts from CMC and AMP-AD, comprised of tissue from approximately 2300 individuals and representing 4 brain regions, the largest collection of which is from dorsolateral prefrontal cortex comprised of 1800 samples. A common analysis pipeline was applied to each cohort. Samples were imputed to the Haplotype Reference Consortium panel. RNA-seq data was aligned and quantitated in a manner appropriate to sequencing protocol; and quantified expression was normalized, adjusting for available known clinical and technical covariates, and hidden confounders, prior to applying a linear model to detect eQTL, adjusting for inferred genetic structure and diagnosis. Meta-analysis across cohorts was then performed. The eQTL were then used to identify candidate genes underlying GWAS peaks for Alzheimer's Disease in the IGAP cohort.
Results: We identify more than 4.2 million proximal (distance ≤ 1 Mb) eQTL at FDR ≤ 5%, for more than 18,000 genes/lncRNAs. While the replication of GTEx eQTL is high (96.5%), we identify 4 million eQTL, for 15,500 genes, not identified in GTEx. Preliminary analysis identifies potential colocalizations underlying 9 GWAS peaks.
Conclusion: We have generated a well powered eQTL brain resource which is valuable for identifying genes contributing to the risk for neurodegenerative and neuropsychiatric disease.

Title: Systems biology-based method to identify and prioritize Alzheimer's disease candidate driver genes

Authors: *S. MUKHERJEE[1], T. M. PERUMAL[2], K. DAILY[2], S. SIEBERTS[2], L. OMBERG[2], C. PREUSS[3], G. CARTER[3], L. MANGRAVITE[2], B. LOGSDON[2]
[1]Neurodegenerative Dis. Res., [2]Sage Bionetworks, Seattle, WA; [3]The Jackson Lab., Bar Harbor, ME

Abstract: Background:Late onset Alzheimer's disease (LOAD) is a debilitating illness with no known disease modifying treatment. Identification of new AD biology will be key to finding effective treatments. To better prioritize experimental evaluation of AD drivers, we present a data driven approach to rank genes based on their probability that they drive a molecular state associated with LOAD using transcriptional data collected from postmortem brain tissue.
Methods:We developed a machine learning model that uses analytic summaries of transcriptional data collected from postmortem brain tissue across three studies (ROSMAP, Mayo RNAseq, MSBB) in AMP-AD to prioritize driver genes. The model used: 1) differentially expressed gene sets, 2) global network topological features, and 3) module specific network topological features for 42 co-expression modules. First, we learned the unique characteristics of 27 previously known drivers of AD identified from published LOAD GWAS studies. Next, we used the model to predict a new list of high confidence driver genes and re-trained the model to account for the many unknown driver genes. Then, the model was retrained in an iterative manner until we converged on a set of high confidence genes. Finally, the predicted probability of a gene being a driver and the p-value of its most significant AD specific variant (using IGAP stage 1+2) was used to create a score.
Results:This analysis identified a set of 283 high confidence driver genes. This set of new candidate AD driver genes was significantly enriched for genes containing SNPs that were marginally associated with LOAD in the IGAP GWAS (p-value: 0.05). Further, many of the top scoring predicted genes (FAT4, HLA-DPA1, MTHFD2L, RBPMS and GDA) contain known SNPs with p-values lower than 0.0001 in the IGAP study.
Conclusions:Here, we provide a generalizable framework for integration of diverse systems biology outputs to rank and identify new transcriptomic and genetic drivers of Alzheimer's disease. This provides evidence that integration of multiple systems biology resources can provide insights into new Alzheimer's disease loci, which can help researchers prioritize future experimental studies focusing on specific genes and pathways that are driving disease etiology.

Abstract: Mitochondrial dysfunction is a fundamental characteristic of neurodegenerative diseases, including Alzheimer's disease. While the origin and underlying cause of mitochondrial dysfunction in AD has not been identified, it has been linked to specific genetic polymorphisms, including the TOMM (Translocase of the Outer Membrane) genotype. Specific TOMM40-APOE haplotypes have been associated with cognitive decline, including memory and executive decision making. However, the neural substrates underlying this selective deficit is currently unknown. We sought to address this problem by examining cognitive performance and whole-brain grey matter density (GMD) in cognitively normal individuals who were either homozygous for the VL- or L-poly T, homozygous for the short TOMM40 poly-T allele, or heterozygous individuals (controlling for APOE e3/e3 and e3/e4, age, and education). We found decreased executive function (as indexed by Trails B) in homozygous long TOMM40 individuals. GMD followed expected trends (S/S > S/L > L/L) in expected regions (e.g., PCC); surprisingly, L/L individuals showed greater GMD in a number of regions, including right prefrontal cortex (PFC). Critically, brain-behavior relationships were moderated by TOMM40 subtype, such that only L/L individuals showed a relationship between GMD and executive function. These results help to link brain-behavior relationships to specific polymorphisms to be dysfunctional in models of AD.

Title: Effect of epigenetics and gender differences in mice expressing neuronal or glial aromatase

Authors: *G. AIT-GHEZALA[1], J. CUI[2], Y. SHEN[3], R. LI[2]
[2]Ctr. for Hormone Advanced Sci. and Educ. (CHASE), [1]Roskamp Inst., Sarasota, FL; [3]Roskamp Inatitute, Sarasota, FL

Abstract: Memory dysfunction is characteristic of aging, neurodegenerative diseases such as Alzheimer’s disease, the most common dementia in elderly, is more prevalent in women than in men, Indeed, a sharp reduction of estrogen and progestins at menopause significantly increases the risk of memory decline and Alzheimer’s disease in middle-aged women relative to men. One of the risk factors is related to the in aged women. It is unknown whether epigenetics has any role in altering risk of AD in females, such as altering cognitive function. For instance, it has been shown that hippocampal memory formation is highly regulated by post-translational histone modifications and DNA methylation. In addition, Both aging and Alzheimer’s disease are illustrated by hypermethylation at specific CpG islands in the hippocampus and neocortex. However, gender differences never been established and how these epigenetic sequences affect modulatory influences, such sex hormones, on hippocampal memory never been fully investigated.
In addition, limited human studies of early pregnancy and motherhood showed alteration of cognitive functions in later life, however, researches on rodents showed a persistent improvement of learning and memory performance in females with history of giving birth compared to virgin controls. Thus, in the current study we investigated the effect of epigenetics and gender differences in mice expressing neuronal or glial Aromatase in comparison to age matched wild type mice. Our data provide valuable insight into how sex hormones employ

Title: Nference target identification for Alzheimer’s disease

Authors: *T. WAGNER[1], S. EBRAHIM[2]
[1]Nference, Inc., Cambridge, MA; [2]Harvard Med. Sch., Cambridge, MA

Abstract: Objective: Effectively treating Alzheimer’s Disease (AD) will necessitate understanding and targeting multiple distinct phenotypes. The nference Biomedical Knowledge Synthesis Platform (nferX) uses a proprietary neural network to identify significant associations between concepts in literature. nferX can be leveraged target discovery engine for such complex diseases because it can connect concepts at a large scale. Rather than looking at a single gene or pathway as a target for AD treatment, nferX can simultaneously assess all genes and all pathways. Additionally, nferX can make novel connections between concepts that may have never been explicitly linked together in literature.
Approach: A modular approach using the nferX platform identified genes significantly associated with AD phenotypes and disease terms, split into categories termed modules. A semantic score was calculated for each gene, based on the percentage of significant associations a gene had within each module. Biological datasets (i.e. gene expression studies, microarrays, and SNPs) were layered on top of these semantic results to provide additional evidence supporting potential AD targets. We applied thresholds for a significant level of association and signal within these datasets to reduce the list of targets. Clustering approaches were employed to group targets into classes. Additional filters, such as the number of articles in the literature (i.e. novelty), or alternative weights for each semantic module can be applied to prioritize other aspects of the gene-disease association. While our approach can be used to rank curated lists of targets, the primary value of nferX is providing highly actionable targets and illuminating “blind spots” in the current pre-clinical and clinical landscape. Thus, we compared the pathways enriched in our targets to those currently in clinical trials for AD.
Conclusions: we have used nferX to couple literature associations and molecular signals to arrive at a list of AD targets comprised of both known and novel genes. We have used this list to rank current clinical AD targets and identify novel targets of interest. Finally, we have identified blind spots in current AD landscape, as well as drugs that could potentially address these needs.

Title: Profiling microRNA form brain by microarray in a transgenic mouse model of Alzheimer's diease

Authors: *L. WANG[1], R. LIU[1], H. JIANG[1], J. ZHANG[1], S. GUO[2], L. MIN[2], Q. GUO[2]
[1]Inst. of Medicinal Biotech. Chinese Acade, Beijing City, China; [2]Dept. of Gastroenterology, Beijing Friendship Hospital, Capital Med. University; Natl. Clin. Res. Ctr. for Digestive Disease; Beijing Key Lab. for Precancerous Lesion of Digestive Dis., Beijing, China

Abstract: MicroRNAs (miRNAs) are small non-coding RNAs, which regulate numerous cell functions by targeting mRNA for cleavage or translational repression, and have been found to play an important role in Alzheimer’s disease (AD). Our study aimed to identify differentially expressed miRNAs in AD brain as a reference of potential therapeutic miRNAs or biomarkers for this disease. We used amyloid precursor protein (APP) and presenilin 1 (PS1) double transgenic mice and age-matched wide-type (WT) littermates to determine the expression of miRNAs in the brain. MiRNAs were profiled by microarray, and differentially expressed miRNAs underwent target prediction and enrichment analysis.
Microarray analysis revealed 58 differentially expressed miRNAs in AD mouse brain, which involved 39 miRNAs that were significantly up-regulated and 19 that were down-regulated at different ages. Among those miRNAs, a total of 11 miRNAs, including miR-342-3p, miR-342-5p, miR-376c-3p, and miR-301b-3p, was not only conserved in human, but also predicted to have targets and signaling pathways closely related to the pathology of AD.
To explore the potential functions of the 11 selected miRNAs, GO and KEGG pathway analyses were performed to elucidate the biological function. GO terms covered 3 domains: molecular function, biological process, and cellular component. Nervous system development was significantly enriched GO terms at molecular function domain. Moreover, the 10 most significantly enriched pathways mapped with KEGG pathway analysis including MAPK signaling pathway, endocytosis, TGF-beta signaling pathway, and the Wnt signaling pathway are closely connected with AD.
In conclusion, in this study, differentially expressed miRNAs were identified in AD brain, and proposed as biomarkers, which may have the potential to indicate AD progression. Although

preliminary, these results may aid in investigating pathological hallmarks and identify effective therapeutic targets.

Title: Genetically diverse AD model identifies dipeptidyl peptidase 7 as a novel modifier of cognitive function

Authors: *S. M. NEUNER[1,4], J.-G. ZHANG[1], V. M. PHILIP[2], M. J. HUENTELMAN[5], C. C. KACZOROWSKI[3]

Abstract: Recent studies of familial AD cases suggest genetic modifiers may delay the onset and progression of AD symptoms by decades. However, specific genetic modifiers and mechanisms involved in providing protection against high-risk AD mutations remain largely unknown. Unfortunately, resilience to AD has generally been difficult to study in human populations, as the number of patients with causal mutations is relatively small and unaffected individuals rarely enter the clinic. As genetic factors promoting resilience may provide key targets for prevention of AD, our lab has recently developed a novel panel of genetically diverse mice harboring five causal human FAD mutations in *APP* and *PSEN1* to address this significant question. We have evaluated cognitive function across this panel (termed the AD-BXDs), and corresponding non-transgenic littermate controls (Ntg-BXDs), throughout the lifespan using a battery of memory tests, and have found that the genetic background of each individual strain has a profound effect on the penetrance of FAD mutations. Using genetic mapping, a significant quantitative trait loci (QTL) containing gene variants that modify severity of contextual fear memory (CFM) deficits across both AD- and Ntg-BXD mice at 6 and 14 months of age was identified, using sex, age, and genotype as covariates in the model. Dipeptidyl peptidase 7 (*Dpp7*) was identified as the

most likely positional candidate involved in modifying cognitive function due to strong correlation with CFM ($r = -0.4$, $p < 0.001$), presence of local variants affecting expression (cis-eQTL, LOD = 7.7, $p < 0.05$), and upregulated expression in AD mice relative to Ntg mice ($log_2FC = 0.4$, adj. $p < 0.001$). To test the hypothesis that *Dpp7* is causally involved in regulating CFM, adeno-associated viral serotype 9 (AAV9) vectors encoding either cDNA for *Dpp7* or an eGFP control were delivered into the hippocampus of adult (4m) 5XFAD mice. Eight weeks later, mice were trained on contextual fear conditioning and we found that overexpression of *Dpp7* significantly enhanced CFM [$t(1,15) = 2.6$, $p = 0.02$, n = 7-10/grp], suggesting that *Dpp7* may promote cognitive resilience in AD. Ongoing work in the lab will investigate the mechanism of this enhancement, assess the utility of *Dpp7* as a therapeutic target to prevent or delay the cognitive decline typically observed in AD, and evaluate the effect of *Dpp7* overexpression in Ntg mice. Overall, work presented here demonstrates the utility of incorporating genetic diversity into animal models of disease in order to identify novel gene variants that are causally involved in modifying susceptibility to cognitive deficits.

Title: Cell-type specific transcriptomics using viral TRAP to identify neuron-glial relationships in neurodegeneration

Authors: *Y. KOMURO, M. MACHNICKI, S. CARMICHAEL, J. D. HINMAN
Neurol., UCLA, Los Angeles, CA

Abstract: The inciting pathogenic events in Alzheimer’s disease remain unknown, and increasing evidence suggests that multicellular interactions may be antecedent to classic pathology. One possible approach for identifying relevant and novel pathways for multicellular interactions in Alzheimer’s disease is to study variance in spatial and temporal gene expression patterns within and between cell types. Transcriptomics allows increasing power to quantify and analyze these patterns and can provide an unbiased entry point for identifying disease-relevant genes and pathways. Single-cell and whole tissue post-hoc gene expression approaches are insightful but limit the sequencing depth or spatiotemporal accuracy of transcriptional profiling. In this study, we characterize novel viruses that utilize translating ribosome affinity purification

(TRAP) in a cell-type specific manner for rapid collection of cell-type specific RNA transcripts and subsequent sequencing. The engineered lentiviruses and adeno-associated viruses express an HA-tagged ribosomal protein (Rpl10a-HA) driven by a cell-type specific promoter (CamKII, GFAP, or PDGFRa). We demonstrate the utility of the viruses for targeting specific cell types under particular spatiotemporal conditions and the ability to sequence the transcripts at high depth. Following injection into an in vivo mouse model, RNA sequencing indicated that the viruses were expressed with high specificity in the target cell types. Furthermore, quality control measures showed that the rapidly-isolated RNA was robust in both quantity and quality, allowing for a high sequencing depth. These results establish viral TRAP as a promising tool for cell-type specific transcriptomics. In this manner, viral TRAP methodology may increase the utility of transcriptomics for novel pathway identification in multicellular transcriptional profiling of neurodegenerative processes.

Title: Central nervous system-mediated sensorimotor decline in a novel transgenic mouse model of Alzheimer’s disease

Authors: *G. G. ACOSTA[1], S. M. NEUNER[1,2], A. R. OUELLETTE[1], N. BACHELDER[1], K. M. S. O’CONNELL[1], C. C. KACZOROWSKI[1]

Abstract: Alzheimer’s disease (AD) often presents with multiple non-cognitive comorbidities including sensorimotor deficits, significantly impacting the quality of life for patients and caregivers. Mechanisms underlying these multifactorial symptoms are poorly understood, yet their identification will be critical to find and develop effective therapeutic targets. We recently developed a novel panel of genetically diverse mice harboring five causal human familial AD mutations (AD-BXDs) and have previously demonstrated differential susceptibility to cognitive symptoms of AD. Here, we assessed effects of aging and AD mutations on a battery of sensorimotor tasks. Both aging non-transgenic and AD mice showed overall sensorimotor impairment relative to young mice, suggesting aging alone worsens motor function. However,

AD-BXD mice showed an exacerbated decline in motor coordination tasks requiring CNS involvement (negative geotaxis, narrow beam), but not grip strength. Additionally, AD-BXD females showed worsened negative geotaxis compared to males. Interestingly, motor deficits did not correlate with cognitive deficits, suggesting that these deficits may be regulated by distinct mechanisms. This is the first study examining effects of aging and AD mutations on sensorimotor performance in a large panel of genetically diverse mice (n=25 strains, 833 mice) that better model human genetic diversity. Our results parallel motor deficits reported in human AD and in previous transgenic AD mouse models. Ongoing genetic mapping studies will identify modifiers of motor deficits in our mouse panel and evaluate their utility as potential therapeutic targets. Results here provide insight into mechanisms of non-cognitive deficits associated with AD and provide a more complete understanding of AD pathophysiology.

Title: Gene-by-diet interactions modify symptoms of Alzheimer's disease

Authors: *A. DUNN[1], A. R. OUELLETTE[1], S. M. NEUNER[2,1], K. M. S. O'CONNELL[1], C. C. KACZOROWSKI[1]
[1]The Jackson Lab., Bar Harbor, ME; [2]Univ. of Tennessee Hlth. Sci. Ctr., Memphis, TN

Abstract: Alzheimer's disease (AD) is complex, with both genetic (G) and environmental (E) factors regulating disease progression. Identification of gene-by-environment interactions that modulate AD pathogenesis is critical to developing novel and personalized treatments. However, extracting GxE effects is challenging in humans due to human genome complexity and difficulty controlling environmental factors, such as diet. To overcome these barriers, we developed a panel of genetically diverse mice carrying the 5XFAD transgene which contains five human familial AD mutations (AD-BXDs). Because the AD-BXDs model some of the genetic heterogeneity of humans, they are ideally suited to investigate translationally-relevant GxE

interactions. Here, we used AD-BXDs to determine how genetics and diet interact to modify AD-related pathogenesis. To determine the effect of genetic background, diet, and gene-by-diet interactions in AD-related metabolic and cognitive traits, we fed a high fat diet (HFD; 45% fat by calorie) to 10 strains of AD-BXDs for eight weeks and monitored metabolic and cognitive function before and after HFD. Control groups included AD-BXDs on chow, and nontransgenic BXDs on chow and HFD. We observed accelerated working memory decline in AD-BXDs on HFD compared to controls after eight weeks on HFD. However, this was dependent on genetic background and genetic risk for AD, with some AD-BXD strains maintaining cognitive function on HFD. Subsequent analyses indicated gene-by-diet interactions accounted for 18% of individual variation in memory decline in transgenic AD-BXDs on 8 weeks of HFD. Higher body weight and adiposity were protective against working memory decline in nontransgenic BXDs, but not in AD-BXDs. Our results suggest that diet and genetic background interact to mediate vulnerability to AD pathogenesis, and that metabolic factors (e.g., obesity, body composition, glucose metabolism) may contribute to cognitive decline differentially in normal aging versus AD. Ongoing work is examining the effects of longer-term HFD on cognitive and metabolic function in the AD-BXDs, as well as differences in hippocampal gene expression that may contribute to differential cognitive effects of HFD. The sizable contribution of gene x diet effects on cognitive decline in the AD-BXDs suggests that the mechanisms underlying cognitive decline in response to HFD are ripe for discovery. Future analyses will build upon these data to identify genetic and molecular targets contributing to AD pathogenesis sensitized by a HFD that may be exploited to delay, prevent or treat AD.

Title: Systems genetics reveals microglia involvement in resilience to Alzheimer’s disease

Authors: *S. E. HEUER, S. M. NEUNER[1,2], M. J. HUENTELMAN[3], K. M. S. O'CONNELL[1], C. C. KACZOROWSKI[1]

[1]The Jackson Lab., Bar Harbor, ME; [2]The Neurosci. Inst., Univ. of Tennessee Hlth. Sci. Ctr., Memphis, TN; [3]Neurogenomics, The Translational Genomics Res. Inst., Phoenix, AZ

Abstract: In Alzheimer's disease (AD), the age of symptom onset is highly variable, with some patients exhibiting cognitive symptoms several decades later than predicted based on family history and genetic status. This variability cannot be explained by simple clinical or environmental factors, suggesting that additional genetic factors modify disease onset. The identification of modifier genes that confer resilience in high-risk patient populations would reveal new mechanisms and thus therapeutic strategies to delay disease onset. Disease-relevant genetic variants are difficult to identify in human populations, primarily because asymptomatic individuals rarely enter the clinic. Mouse models represent an ideal complement to human studies, as they present many advantages, such as defined genotypes, early access to brain tissue, and precise environmental control. However, the traditional mouse models of AD have failed to translate into successful treatments that improve cognition in humans. Here, we employ a novel AD mouse genetic reference panel, designed to overcome some of the barriers presented by current AD models. Analyses of whole-genome RNA expression from the hippocampus using a variety of bioinformatics approaches including differential expression, gene set enrichment, principal component, and Pearson's correlations revealed a strong negative association between microglia transcriptional signatures and cognitive resilience to AD, when assessed using a variety of memory tasks. Overall, work here introduces a humanized mouse population as an innovative and reproducible resource for the study of AD and identifies a core set of microglial genes as novel therapeutic targets to promote cognitive resilience to AD.

Title: Hypothalamic dysfunction in the etiology of Alzheimer's disease

Authors: *K. O'CONNELL[1], T. MCMURPHY[1], A. DUNN[1], S. NEUNER[2], C. C. KACZOROWSKI[1]
[1]The Jackson Lab., Bar Harbor, ME; [2]Univ. of Tennessee Hlth. Sci. Ctr., Memphis, TN

Abstract: For a patient diagnosed with Alzheimer's disease (AD), there exist no treatments to prevent, slow, or halt disease progression. Memory loss and cognitive decline are hallmarks of AD, thus current research is focused on CNS regions relevant to learning and memory, such as the hippocampus. However, one of the most consistently reported non-cognitive symptoms in AD patients is weight loss, which may precede the onset of dementia by up to 17 years. Thus, dysfunction in CNS regions regulating metabolism and energy balance, such as the hypothalamus, may represent some of the earliest causative changes associated with AD. Here, we used our novel mouse model of genetic diversity in AD (AD-BXDs), which combines high-risk familial AD mutations with a well-established background of genetic diversity, to investigate complex interactions between genetic background, age, and energy homeostasis. To determine the relationship between body weight and cognitive decline, we measured body weight and working memory in 25 strains of female AD-BXDs and their non-transgenic littermate controls (Ntg-BXDs) and 17 strains of male AD/Ntg-BXDs across the lifespan. Working memory was assessed using Y-maze task; the age at which performance dropped below 50% was designated the age of onset for cognitive decline. At 2 months of age, AD and Ntg-BXDs exhibit similar body weights, but by 6 months, the AD-BXD mice begin to significantly diverge from the Ntg-BXDs, preceding cognitive decline by 3 months. Further, in AD-BXDs (but not Ntg), body weight at 6 months was significantly correlated with long-term memory at 14 months, suggesting this is specific to AD and not a general feature of aging. We also found that there is amyloid deposition in the hypothalamus that is closely associated with Iba-1^{+}microglia, therefore on-going experiments are testing a specific role for the hypothalamus in AD pathogenesis using a mouse model that expresses Aβ exclusively in the hypothalamus to determine the impact of hypothalamic dysfunction in both cognitive and non-cognitive symptoms of AD. The hypothalamus is understudied in the context of AD; the present work is well-poised to directly test the causality of hypothalamic dysfunction in AD using well-controlled model systems with high translational relevance.

Title: Novel models of late-onset Alzheimer's disease

Authors: *M. SASNER[1], H. WILLIAMS[1], A. OBLAK[2], C. PREUSS[1], B. LOGSDON[4], K. NHO[3], A. J. SAYKIN[3], S. J. SUKOFF RIZZO[1], P. R. TERRITO[3], B. T. LAMB[5], G. CARTER[1], G. HOWELL[1]
[1]The Jackson Lab., Bar Harbor, ME; [2]STARK Neurosci. Res. Inst., [3]Radiology and Imaging Sci., Indiana Univ. Sch. of Med., Indianapolis, IN; [4]Sage Bionetworks, Seattle, WA; [5]Stark Neurosciences Res. Inst., Indianapolis, IN

Abstract: The Alzheimer's Disease (AD) patient population consists almost entirely (~98%) of the late-onset form of AD (LOAD); however, most animal models currently used to develop therapies for AD are based on familial AD (fAD) mutations in *APP*, *PSEN1* or *PSEN2*. This may contribute to the lack of translation to the clinic for therapeutic agents being evaluated in preclinical studies. The Model Organism Development and Evaluation for Late-onset AD (MODEL-AD) Center was created to develop, characterize, and distribute more precise preclinical models for LOAD. Our approach is to engineer mouse models to express combinations of genetic variants identified in human LOAD patient populations. This strategy integrates human and mouse data, with the purpose of creating new AD models with a high degree of preclinical translatability for novel therapeutic targets.
Since the *APOE4* allele and variants at the *TREM2* locus are among the strongest genetic risk factors for LOAD, we first created a homozygous model expressing humanized *APOE4* and the R47H allele of the *Trem2* gene. This model exhibits altered metabolic phenotypes and neurovascular deficits. We then generated a humanized *APP* model on this background by altering the three amino acids that differ between human and mouse Abeta42, as the human protein may be more prone to aggregate.
Additional genetic variants have been prioritized in loci previously identified by GWAS using data from the ADNI and ADSP projects. These variants have been engineered into the APOE4/Trem2*R47H model to increase the risk of developing AD-like phenotypes. We have created mouse models expressing SNPs corresponding to risk variants in *ABCA7, MTHFR and PLCG2*, knockouts of mouse *Il1rap* and *Ceacam1* and a knock-in model expressing human *CR1*. In addition, we have generated *APOE3* and *APOE2* variants to serve as controls.
The new models are aging for phenotypic studies. We will present validation data including transcriptomics, pathology, and functional assays, with new models being compared to both fAD models and clinical samples.
All new models will be made available for both academic and for-profit use from The Jackson Laboratory, and all validation data will be shared via the AMP-AD knowledge portal (www.synapse.org/alzheimers). We seek input and collaborations from the basic research and pharma/biotech communities. For more information see www.model-ad.org .

Title: hAb-KI: A knock-in mouse model for sporadic Alzheimer's disease

Authors: *S. FORNER[1], D. BAGLIETTO-VARGAS[1], L. TRUJILLO-ESTRADA[1], A. CADETE MARTINI[1], E. A. KRAMAR[2], S. JIANG[3], D. MATHEOS[2], C. DA CUNHA[1], K. C. GREEN[1], M. A. WOOD[2], A. MORTAZAVI[3], G. R. MACGREGOR[3], A. J. TENNER[1], F. M. LAFERLA[1]
[1]UCI MIND, [2]Neurobio. and Behavior, [3]Developmental and Cell Biol., Univ. of California Irvine, Irvine, CA

Abstract: The majority of Alzheimer’s disease (AD) cases are sporadic, which means that the disease originates spontaneously without any known cause. To date, no lab has succeeded in developing a model for sporadic AD, which represents one of the consequential hurdles remaining in the field. Thus, it is critical to study and elucidate factors and conditions that trigger the disease in the 98% of patients that lack the known mutations that cause familial AD (FAD). Here, we introduce a novel animal model of sporadic AD (hAß-KI), in which the mouse Aβ encoding DNA sequence was replaced with the human Aβ sequence (which is known to more readily aggregate than the mouse Aß). We used a combination of genetic, biochemical, histological and behavioral approaches to generate and characterize this innovative AD model. DNA sequence analysis demonstrated that hAβ-KI express humanized Aβ and that expression of amyloid precursor protein (APP) was similar between wild type and hAβ-KI mice. hAβ-KI present with diffuse Aβ aggregates from 18 months of age and no Congophilic or ThioS aggregates were observed. Cognitive deficits begin at 10 months in hAβ-KI and long-term potentiation (LTP) deficits is observed at 18 months of age. A highly innovative aspect of this study is that we generated the first Knock-in mouse that express human non-mutated Aβ in the fully natural context of the endogenous mouse App gene and without the addition of any FAD

mutations or overexpression of APP or its metabolites. This mouse model should enable a more physiologically relevant understanding of the underlying mechanisms driving AD pathology, by more closely recapitulating the pathological cascade of events that occurs in the majority of human AD patients.

Abstract: Alzheimer’s disease (AD) is an irreversible, progressive brain disorder that slowly destroys memory and cognition, and eventually the ability to carry out the simplest tasks. In most people with Alzheimer’s, symptoms first appear in their mid-60s. Estimates vary, but data suggest that more than 5 million Americans may have AD. Most of diagnosed cases (>95%) are late-onset AD (LOAD). One of the obstacles to developing compounds to treat AD may be that models currently used for preclinical testing are based on familial mutations, which account for less than 5% of all AD cases. The Model Organism Development and Evaluation for Late-onset AD (MODEL-AD) Center has been established as a consortium consisting of Indiana University, The Jackson Laboratory, University of California-Irvine and Sage Bionetworks with the purpose

of creating animal models of LOAD that can be used to develop therapeutics to prevent AD. Therefore, MODEL-AD aims to: identify and prioritize novel genetic variants, genes and biomarkers from AD patient data; generate and validate new animal models based on LOAD variants; and utilize these novel models in a preclinical testing paradigm. The consortium consists of multiple cores at each site. The Bioinformatics and Data Management Core (BDMC) prioritize novel sequence variants, create analytical pipelines for human-mouse phenotype comparisons, and analyze phenotypic data. The Disease Modeling Project (DMP) creates new mouse models based on variants identified by the BDMC, and validates them by comparing to quantitative measures (e.g. transcriptomics) to clinical data. The Preclinical Testing Core (PTC) evaluates novel compounds in new models with an AD-like phenotype based on a tertiary screening pipeline with predetermined go/no go criteria. These criteria include exposure levels in target tissues, target engagement, disease modifying effect, and *in vivo* functional activity and therapeutic index. The *APOE4/Trem2* model as well as a humanized Aß mouse will serve as standard backgrounds as additional LOAD genetic variants are introduced at IU/JAX/ UCI. Data from these models include: functional assays, neuropathology, amyloid and tau pathology, transcriptional and metabolic profiling, and *in vivo* imaging. All data will be made available through the Sage-Synapse portal. Conclusions: All models, protocols, and data sets will be made widely available. For more information see www.model-ad.org.

Abstract: The preclinical testing core (PTC) of the Model Organism Development for Late Onset Alzheimer's Disease (MODEL-AD) consortium has established a streamlined preclinical strategy with go/no-go decision points that allow critical and unbiased assessments of potential therapeutic agents. The PTC strategy includes a primary screen to determine: 1) drug formulation; 2) drug stability; and 3) in vivo pharmacokinetics and target tissue concentrations in models at disease-relevant ages. A secondary screen evaluates target engagement and disease modifying activity utilizing non-invasive PET/MRI as a pharmacodynamic (PD) readout matched to known disease pathology in the model. Compounds demonstrating positive PD effects in the secondary screen are further interrogated via a tertiary screen of functional assays that assess the compounds ability to normalize a disease-related phenotype in cognition and neurophysiological tests. For the present studies, we selected the anti-epileptic drug levetiracetam (LEV), a compound currently in clinical trials for the treatment of cognitive impairment associated with AD, for testing in the 5XFAD mouse model of early onset AD. Serial plasma and terminal brain tissue samples following acute oral administration (10, 30, and 100 mg/kg, n=3/sex/dose) revealed brain concentrations were linearly related with plasma concentrations over a broad range. Using a non-compartmental analysis (NCA), the terminal elimination half-life (T1/2, 2.7±0.56 hr), time to maximum concentration (Tmax, 0.86±29 h), volume of distribution (Vd/F, 2.54±0.68 L/kg), and plasma clearance (Cl/F, 0.59±0.33 L/h/kg) were independent of dose level. As expected there were dose-dependent changes in oral maximum plasma concentration (Cmax) and drug exposure (AUC0-inf). Interestingly Cmax revealed a statistically significant effect of sex ($p<0.05$). Using NCA rate constants and a one-compartment model, PK/PD simulations revealed a requirement of twice daily (BID) dosing for pharmacodynamic studies which enabled a 3 month prophylactic treatment trial of 5XFAD mice. In these studies, the effects of BID LEV (10, 30, and 56 mg/kg PO) dosing on 18F-FDG and 18F-AV45 PET/MRI, EEG, cognitive and locomotor effects are currently being evaluated.

Sch. of Med., Indianapolis, IN; [5]Sage Bionetworks, Seattle, WA; [6]Jackson Lab., Bar Harbor, ME; [7]Stark Neurosciences Res. Inst., Indianapolis, IN

Abstract: The abundance of genetic associations and genomic characterizations are motivating the creation and assessment of new animal models for late-onset Alzheimer's disease (LOAD). To complement existing models, the MODEL-AD consortium is creating new mouse models based on specific genetic variants prioritized from genome-wide association studies. Detailed phenotyping of these models will provide the necessary information for further basic research and preclinical use.
We have developed bioinformatics pipelines to: (1) identify key genetic variants that confer risk of AD from genome-wide association studies; (2) translate candidate variants into mouse models; (3) align human disease and animal model phenotypes to specify the optimal research use of each animal and characterize the effects of multiple genetic variants; and (4) broadly disseminate all data and preclinical research protocols for community use. Here we present our analysis to date and future plans.
Drawing from multiple large-scale genetic resources, including IGAP, ADNI, and ADSP, we have identified candidate variants in *APOE*, *TREM2*, *ABCA7*, *MTHFR*, and *PLGC2* for engineering in mouse models. We additionally identified *IL1RAP* and *CEACAM1* as candidate genes for deletion. Mouse models have been created to incorporate these variants, and we will present analysis of transcriptomic data from some of these models. Transcriptome clustering methods were used to identify sets of genes with differential expression driven by one or more

variants, and these sets were compared to human LOAD transcriptomes from the Accelerating Medicine's Partnership for Alzheimer's Disease (AMP-AD). This analysis identified specific molecular modules that are altered by the genetic variants in a similar manner as observed in the human postmortem brain tissues.
All data are broadly shared data via the AMP-AD Knowledge Portal hosted by Sage Bionetworks. Future work will expand all of these findings and resources, and additionally integrate data and protocols from preclinical studies that use the animal models. These resources will be part of a broad knowledgebase to serve the creation and study of multiple animal models to effectively model late-onset Alzheimer's disease *in vivo*.

Abstract: To date, Alzheimer's disease (AD) is the most common form of dementia that has no effective treatment. Over the past 20 years researchers have used animal models to further understand the etiology of AD, and determine the pathways involved in this neurogenerative disease. While these animal models have proved fruitful in the understanding of some of the hallmark features associated with AD, they have not demonstrated predictive translatability for AD. The Model Organism Development and Evaluation of Late-onset Alzheimer's Disease

(MODEL-AD) Center was established to develop, validate, and distribute novel mouse models for LOAD, with the aim to aid in the development of novel therapeutics for AD. MODEL-AD is a consortium involving Indiana University, The Jackson Laboratory, University California-Irvine, and Sage Bionetworks. To validate our characterization paradigm and preclinical pipeline for new models, we have utilized familial AD (fAD) models. Our phenotyping pipeline includes functional assays, *in vivo* MRI and PET imaging, transcriptomics, biochemistry, and neuropathology. Mice were assessed using a battery of functional assays and *in vivo* imaging performed at a variety of ages ranging from 4 mos to 14 mos (the timeframe when the majority of reported phenotypes occur in these strains). Tissue was then harvested and transcriptional profiling and neuropathology of the brain assessed in both male and female mice as follows. One brain hemisphere was frozen, and the other hemisphere fixed. Transcriptional profiling was performed on the frozen portion, while biochemical and neuropathological analysis was carried out on the fixed hemisphere. To assess AD relevant changes, we used antibodies against the following proteins: 22C11 (APP); 6E10, 4G8 (Aβ); Tau-46 (pan-tau); CP13, PHF1 (phospho-tau); NeuN, NFL, MBP, SYN and PSD-95 (neurons); GFAP, COL4 (astrocytes); IBA1, CD68, TREM2 (microglia, monocytes); PDGFRB (pericytes); and Fibrin, Albumin (vascular integrity). Transcriptional profiling was used to stage the progression of AD in fAD models and to compare the differentially expressed genes/pathways to those observed in human AD. This allows us to directly determine human relevance in each of these models. MODEL-AD is making all mouse models, protocols, and data sets widely available through a variety of resources including JAX mice, clnical and research services and the AMP-AD knowledge portal (Synapse). We welcome input and collaboration from the scientific community. For more information see www.model-ad.org.

Title: Comparative effects of ethanolic extracts of bacopa floribunda and angraecum eichlerianum on amyloid beta model of male wistar rats

Authors: *M. OYELEKE OMOTOLA[1,2], O. L. AROKOYO[1], H. T. ONI[1], B. V. OWOYELE[2]
[1]Afe Babalola Univ., Ado Ekiti, Nigeria; [2]Physiol. Dept., Univ. of Ilorin, Ilorin, Nigeria

Abstract: This study investigated the effects of crude extracts obtained from *Bacopa floribunda* and *Angraecum eicherianum*. A total number of 48 (n=6) male wistar rats were used for this study. *Angraecum eichlerianum* (AE) and *Bacopa floribunda* (BF) extracts were given at a dose of 200mg/kg/day and Alzheimer's disease was induced by a single bi-lateral intra-cerebroventricular injection of Amyloid beta protein (4µg/µl/site) using a stereotaxic apparatus. A pre-treatment and post-treatment model with BF and AE was employed for 21 days. Rats were grouped as follows; Group 1 (Normal saline), Group 2 (Amyloid beta without treatment), Group 3 (BF alone), Group 4 (AE alone), Group 5 (group pre-treated with BF), Group 6 (group Pre-treated with AE), Group 7 (group post-treated with BF) and Group 8 (group Pre-treated with AE). Morris water maze task and Y maze was carried out on different days during the course of the study. Twenty-four hours after the last administration, rats were sacrificed and brain tissues excised. The hippocampus was removed and assayed for the levels of glutamate, acetylcholinesterase, Na^+ - k^+ ATPase activities and Amyloid beta deposition using ELISA kits. Data were analyzed using One-way ANOVA followed by a post-hoc test and expressed as Mean ± SEM.

A significant ($p < 0.05$) increase was observed in the activities of acetylcholinesterase in group 6 when compared with every other group, likewise, a significant ($p < 0.05$) decrease was observed between groups 5 and 7 when compared with groups 1, 2, 3, 4 and 8. Results also showed that group 3 alone had the highest level of significance ($p < 0.05$) of Na^+- k^+ ATPase activities when compared with every other group. Groups 6, 7 and 8 also showed some levels of significance when compared with groups 1, 2, 4 and 5. Neurobehavioural scores (Y maze and Morris Water maze) were observed to be better in BF and AE groups compared to untreated and normal saline groups.

In conclusion, BF elicited its protective action by increasing the levels of Na^+ - k^+ ATPase while the mechanism of action of AE was by reducing the activities of acetylcholinesterase in Amyloid beta induced Alzhiemer's disease.

Title: Aav9 and crispr cas9 based epigenetic manipulations to study antipsychotic drugs induced side effects in aged mice

Authors: *S. CHAKRABORTY[1], G. RODRIGUEZ[2], H. DONG[2]
[1]Dept. of Psychiatry and Behavioral Sci., Northwestern Med. Chicago, North Aurora, IL; [2]Dept Psychiatry and Behavioral Sci., Northwestern Univ. Feinberg Sch. of Med., Chicago, IL

Abstract: Alzheimer's disease (AD) is a progressive cognitive decline and over 90 % patients also develop behavioral and psychological symptoms of dementia (BPSD) that increase disease progression, causing great distress to caregivers, and lead to institutionalization. However, there is currently no FDA approved treatment for AD patients with BPSD. Antipsychotics are still common prescribed drug for BPSD at increased risk for developing side-effects. Previously, we have shown that the changes histone markers at gene promoters such as dopamine receptor 2 (Drd2) and serotonin receptor 2A (5HT-2A) leading to decreased receptor expression and functionality in aged mice, suggesting epigenetic mechanisms may regulate antipsychotic action during aging. In this study, we will further confirm our hypothesis that age-related histone modification is one of the key mechanisms underlying increased sensitivity to the side effects induced by antipsychotic in aged mice by using gene editing tools with AAV9 and CRISPR Cas9 system intervention.
Young C57BL/6 mice (3 months old) were microinjected bilaterally into the frontal cortex and striatum with AAV9-HDAC1-GFP (Vectorbio labs) containing hSYN1, a neuron-specific promotor. After 4-6 weeks of microinjection, haloperidol (HAL) induced drug response was measure by several behavioral tests. HDAC1 expression was confirmed by western blot and immunohistochemistry.
In the groups of the prefrontal injection with AAV9-HDAC1-GFP, the behavioral tests did not show any changes between vehicle and drug groups. However, in the striatum injected groups in Catalepsy behavioral tests, animals with AAV9-HDAC1-GFP microinjection show significant increase in duration of cataleptic episodes and in Rotor rod behavioral tests shorter latency to fall (Sec) as compared to vehicle control group , suggesting motor function impaired due to HDAC1 overexpression by AAV9-HDAC1-GFP virus injection. Currently we are looking at how AAV9-HDAC1-GFP in combination with HAL effect young animals in cataleptic and memory function behaviors. We will also determine whether decreasing HDAC1 by AAV9-CRISPR-Cas9-GFP (Applied Biological Material Inc) into brain regions similar to the regions in the AAV9-HDAC1-GFP overexpression experiments in aged mice can reverse D2R and 5-HTR repression and mitigate sensitivity to the side effects induced by HAL.

Title: Neuronal deletion of the mitochondrial protein prohibitin leads to neurodegeneration in mice

Authors: D. A. LANE[1], L. QIAN[1], A. KAHL[1], C. ANDERSON[1], G. MANFREDI[1], C. IADECOLA[1], *P. ZHOU[2]
[1]Feil Family Brain and Mind Res. Inst., [2]Brain and Mind Res. Inst., Weill Cornell Med., New York, NY

Abstract: Prohibitin (PHB) is an inner mitochondrial membrane protein that is critical for normal mitochondrial function. PHB is also profoundly neuroprotective against several stress/injury paradigms including cerebral ischemia (J. Neurosci., 32:583, 2012, Stroke 45:1131, 2014, JCBFM 2017). However, it is unknown if PHB loss is in itself damaging to the brain. To answer this question, we utilized conditional deletion of neuronal PHB by crossing $PHB^{flox/flox}$ mice with mice expressing Cre under the control of the CamKIIα promoter ($PHB^{fl/fl/cre+}$) to achieve postnatal selective neuronal ablation of PHB. $PHB^{fl/fl/cre-}$ littermates were used as controls. $PHB^{fl/fl/cre+}$ mice were born and developed normally. Western blots of brain tissue lysates showed that PHB deletion starts at 14 weeks of age in the cortex, hippocampus, striatum, but not in cerebellum, as expected from the pattern of CamKIIα directed Cre expression. $PHB^{fl/fl/cre+}$ mice exhibited progressive brain atrophy, starting at 6 months of age (35% loss at 12 months of age, $p<0.05$, n=8-12/group), associated with synaptosome loss (48% at 10 months of age), indicative of neurodegeneration. The brain atrophy was also associated with a progressive body weight loss, starting also at 6 months of age. In brain, the most severe changes were observed in the cortex and hippocampus, while the cerebellum was unaffected. Histologically, we found evidence of neuronal and white matter damage with a significant decrease in the g-ratio (axon diameter/axon+myelin diameter) in the corpus callosum. There was neuronal and astrocytic accumulation of lysosomes, that was especially evident near cortical blood vessels. Biochemical analyses revealed accumulation of ubiquitinated protein aggregates in brains of $PHB^{fl/fl/cre+}$ mice starting at four months of age. These pathological changes resulted in abnormalities in behavior and memory. $PHB^{fl/fl/cre+}$ mice showed increased anxiety starting earlier in female than in male mice (4 vs. 6 months of age). Furthermore, Barnes maze testing

revealed deficits in spatial memory that affected $PHB^{fl/fl/cre+}$ female mice earlier than male mice (6 vs. 8 months of age). In summary, conditional deletion of PHB in neurons results in a progressive neurodegenerative phenotype and behavioral/cognitive changes reminiscent of alterations seen in neurodegenerative diseases, such as brain atrophy and memory loss in Alzheimer's disease. The data unveil an absolute requirement for PHB in neuronal health and in maintaining the structural and functional integrity of the brain. This mouse model may serve as a useful tool to understand neurodegenerative processes initiated by mitochondrial dysfunction.

Abstract: Alzheimer's disease (AD) is the most common form of dementia found in elderly. AD is caused by the accumulation of toxic proteins including amyloid-β (Aβ). At the present, none of the approved medications for AD can stop the progression of the disease or reverse brain function. The purpose of this study was to investigate the effect of the extracts of *Jatropha multifida, Aegle marmelos, Nelumbo nucifera* and the mixture of three extracts against Aβ toxicity in *Caenorhabditis elegans* (*C. elegans*). The mixture of three extracts is a traditional Thai herb formula used in fatigue patients recovering from illness such as fever and diarrhea. We used a transgenic *C. elegans* strain CL4176 which expresses the human $A\beta_{42}$ to investigate the effects and the mechanisms of action of these extracts against Aβ toxicity *in vivo*. The extract of *A. marmelos, N. nucifera*, and the mixture extracts significantly delayed Aβ-induced paralysis. Using RNAi method, we found that *A. marmelos* lost the ability to delay Aβ-induced paralysis in worms fed with *daf-16* RNAi bacteria, but not in worms fed with *hsf-1* and *skin-1* RNAi bacteria. These results indicated that *daf-16* transcription factor was required for *A. marmelos*-mediated delayed paralysis. On the other hand, both *N. nucifera* and the mixture extracts did not require

daf-16, *hsf-1*, and *skin-1* in order to reduce Aβ toxicity. Using real-time PCR, we found that *A. marmelos* also enhanced the level of *daf-16* gene. Taken together, these results indicated that *A. marmelos* reduced Aβ toxicity via DAF-16-mediated cell signaling pathway. Furthermore, we also found that *A. marmelos* and the mixture extracts significantly extended lifespan and displayed anti-oxidative effect against paraquat-induced oxidative stress in wild type *C. elegans*.

Abstract: Stress is a risk factor for various neuropsychiatric disorders and neurodegenerative diseases. For example, individuals who develop post-traumatic stress disorder (PTSD) have an higher risk of Alzheimer’s disease (AD). Exposure to stress in rodent models confers increased AD-related neuropathology, as measured by increased production of amyloid-beta (Aβ) and hyperphosphorylated tau (p-tau). The stress-mediating peptide, corticotropin-releasing factor (CRF), has been demonstrated to be mechanistically linked to these pathological hallmarks through CRF receptor 1 (CRFR1) signaling, yet the mechanism(s) underlying the CRF-AD link is currently unknown. Elucidation of the signaling intermediates involved in this relationship could provide novel therapeutic targets, uncovering additional routes that could alleviate the burden of AD. Small molecule CRFR1 antagonists, such as R121919, are an underexplored class of potential therapeutic drugs that can may be efficacious in preventing and/or treating AD in Veteran populations. This study explored the therapeutic potential of R121919 on disease pathology and behavioral deficits at various endpoints in an AD mouse model (PSAPP). R121919 significantly reduces Aβ in the cortex and hippocampus of PSAPP mice. CRFR1 antagonism also impacted changes in the inflammatory tone, as evidenced by change in microglial activation patterns surrounding plaques. Additionally, treatment with R121919

prevented the onset of hippocampal dependent memory deficits normally seen in PSAPP mice. These data support the therapeutic potential of small molecule CRFR1 antagonists on AD pathogenesis.

Title: Brain-specific estrogen improves cognitive functions

Authors: *D. BI[1,2,3], W. JIANG[1,2,3], R. LI[4], Y. SHEN[1,2,3,4]
[1]Neurodegenerative Disorder Res. Ctr. (NDRC), Sch. of Life Sci., Univ. of Sci. and Technol. of China, Anhui, China; [2]Inst. on Aging and Brain Disorders, Univ. of Sci. and Technol. of China, Hefei, China; [3]Material Sci. at Microscale Natl. Lab., Hefei, China; [4]Roskamp Inst., Sarasota, FL

Abstract: Estrogen decline has been implicated in a higher risk of Alzheimer’s disease (AD) for post - menopausal women, due to the role of estrogen in learning and memory. Although estrogen replacement therapy improves cognitive functions and delays the onset of AD, it may cause severe side effects, including breast, endometrial and ovarian cancer. Therefore, development of brain-specific estrogen reagents would be critical for potential therapies of neurological disorders. In the brain, both neurons and astrocytes produce estrogen. To investigate whether increasing estrogen specifically in neurons and in astrocytes would enhance learning and memory, we have generated Thy1-Ar and hGFAP-Ar mice in which aromatase, the estrogen synthetase, is specifically overexpressed in neurons and astrocytes, respectively. In the barns maze tests, which are commonly used to examine mouse spatial and reference memory, we found that Thy1-Ar and hGFAP-Ar mice of both sex spent significantly less time to find the target hole compared with the age- and sex-matched wild type mice, suggesting that brain-specific estrogen significantly improved cognitive functions. To investigate neural mechanisms underlying the cognitive enhancement, we recorded the electrophysiological properties of pyramidal neurons of the hippocampus in Thy1-Ar and hGFAP mice. In both female and male hGFAP-Ar mice, the amplitude of excitatory postsynaptic current (mEPSC) was significantly enhanced, whereas the inhibitory postsynaptic current (mIPSC) was unaltered compared to wild

type mice. In contrast, neither mEPSC nor mIPSC of Thy1-Ar mice changed, except for a significant increase of the frequency of mEPSC in male Thy1-Ar mice. These results suggest that the estrogen produced by both neurons and astrocytes could enhance learning and memory. Astrocyte-derived estrogen functions by enhancing the excitatory synaptic transmission, whereas, neuron-derived does probably in a different mechanisms. This observation demonstrates that brain-specific estrogen reagents could be an advanced intervention for cognitive impairment of post - menopausal women.

Title: 5alpha-reduced metabolites of testosterone offer protection against the development of AD neuropathology in 3xTg Alzheimer's disease male mice

Authors: *H. A. WILSON[1], A. L. MENDELL[1], S. D. CREIGHTON[2], B. D. WINTERS[2], N. J. MACLUSKY[1]
[1]Biomed. Sciences, Ontario Vet. Col., [2]Psychology, Univ. of Guelph, Guelph, ON, Canada

Abstract: The gonadal steroid hormone, testosterone, may protect against the development of Alzheimer’s disease (AD). The gradual reduction of testosterone in aging males is linked to an increased risk of AD, while gonadectomy and testosterone replacement in male mice alter pathophysiological markers of AD, such as amyloid β (Aβ) deposition and hyperphosphorylation of tau. In the brain, testosterone is metabolized via 5α-reductase (5α-R) to other neuroactive steroids. Levels of these metabolites are also altered in male triple transgenic AD (3xTg) mice, and may contribute to the protection conferred by testosterone. In this study, we explored whether inhibition of 5α-R might impact pathophysiological markers of AD in male 3xTg mice. Male wild type (WT; C57bl/6/129S) and 3xTg mice were given daily injections of finasteride (5α-R inhibitor; 50mg/kg i.p) or vehicle (18% β-cyclodextrin) for 20 days. Female WT and 3xTg mice were included, receiving vehicle injections only, to evaluate potential sex differences. Western blots were conducted to characterize total tau expression, phosphorylation of tau at AD-related residues, and Aβ expression in the hippocampus (n=5-6/group). Results demonstrated increased tau hyperphosphorylation at Serine-202 in 3xTg females and finasteride-treated 3xTg

males, but not vehicle-treated 3xTg males. Changes in tau hyperphosphorylation at Serine-202 were not accompanied by any significant differences in total tau, or by changes in phosphorylation at Serine-396. Small oligomeric -Aβ expression was detected in the hippocampus in all 3xTg animals, with a trend toward higher expression in females. Immunohistochemistry (IHC) was then conducted to examine region-specific differences in Aβ (n=4-5/group). Female 3xTg mice had stronger Aβ staining compared to all 3xTg males in dorsal cornu ammonis (CA) 1, the dorsal subiculum in the anterior ventral hippocampus (VHC), CA1 of the anterior VHC, and layer V of the primary somatosensory cortex. No significant effects of finasteride treatment were observed for Aβ IHC. However, female 3xTg mice had stronger Aβ staining in CA3 of the posterior VHC compared to vehicle-treated, but not finasteride-treated 3xTg males. Strong positive staining for Aβ was also observed in the anterior basolateral amygdala, with no significant sex differences. Together, these results suggest that the relative protection of testosterone in the development of AD in males may be partially dependent on metabolites of testosterone, which reduce site-specific tau hyperphosphorylation in the hippocampus and may impact Aβ levels in a region-specific manner.

Title: Effects of cannabidiol and tetrahydrocannabinol treatment on memory function, neuron loss and molecular signature in a mouse model of Alzheimer’s disease

Authors: M. E. SICHLER[1], J. WILTFANG[2], M. J. LÖW[1], C. BOUTER[3], T. A. BAYER[1], *Y. BOUTER[1]

Abstract: Introduction: Limited therapeutic effects of current Alzheimer (AD) treatments highlight the need for new research approaches. Thereby drugs that target different aspects of AD pathology simultaneously could provide therapeutic benefits compared to more traditional interventions. Targeting the endocannabinoid system is such an approach. Endocannabinoid signaling has been demonstrated to be involved in numerous processes, including brain

development, memory formation, motor control, neuroinflammation, excitotoxicity and oxidative stress. Furthermore, several in vitro studies showed that cannabinoids reduce Aβ-induced neurotoxicity as well as cell death and facilitate neurogenesis. It could also be demonstrated that cannabinoids stimulate the removal of intraneuronal Aβ in vitro. The aim of the study was to investigate the multi-faceted therapeutic potential of Tetrahydrocannabinol (THC) and Cannabidiol in a mouse model for Alzheimer's disease.
Material & Methods: Tg4-42 mice express Abeta4-42 and develop severe hippocampal neuron loss as well as memory deficits starting at 4 months of age. Tg4-42 Alzheimer mice were treated daily with Cannabidiol and Tetrahydrocannabinol, respectively. Treatment started presymptomatically at 3 months and continued for six weeks. Behavior tests were performed to access motor and memory functions as well as anxiety. Design-based Stereology was used to analyze neuron loss in the hippocampus of Tg4-42. Deep sequencing will be performed to identify differentially expressed genes.
Results and Conclusion: THC- and Cannabidiol-treatment improved spatial reference memory in an dose-dependent manner. Treatment with cannabinoids did not alter the anxiety behavior or motor performance of Tg4-42 mice. In addition, the effects of THC and Cannabidiol on the molecular signature will be presented as well as the effects on neuron loss in the dentate gyrus and CA1 of the hippocampus. Cannabinoid-treatment in Tg4-42 mice show the potential of the endocannabinoid system as a therapeutic target in Alzheimer's disease influencing the molecular signature and improving memory deficits. Our findings reinforce a cannabis-based medicine as a potential AD therapy.

Title: Benefits of exercise on cognition and white matter pathology in a mouse model of vascular cognitive impairment and dementia

Authors: *L. J. TRIGIANI[1], M. LACALLE-AURIOLES[1], M. BOUROUROU[1], L. LI[2], A. D. GREENHALGH[3], J. G. ZARRUK[3], S. DAVID[3], M. G. FEHLINGS[2], E. HAMEL[1]
[1]Lab. of Cerebrovascular Res., Montreal Neurolog. Institute, McGill Univ., Montreal, QC, Canada; [2]Krembil Res. Inst., Toronto, ON, Canada; [3]McGill Univ., Montreal, QC, Canada

Abstract: Rationale: White matter (WM) pathology is a clinically predictive feature of vascular cognitive impairment and dementia (VCID). Here, we investigated WM changes in a VCID mouse model and determined whether physical exercise (PE) could be protective based on evidence pointing to its ability to delay dementia onset. Transgenic mice overexpressing transforming growth factor-β1 (TGF mice) with an underlying cerebrovascular pathology were fed a high cholesterol diet (HCD) to trigger cognitive deficits. We investigated WM pathology and the mechanisms underlying the benefits of PE.
Methods: Six groups of equally distributed male and female mice (*n* = 20-24/group, 3-4 months old) were used and all *in vivo* experiments were performed blind to the identity of the mice. Groups consisted of wild-type (WT) and TGF mice fed standard lab chow, WT and TGF mice fed a 2% HCD, and WT and TGF mice fed the HCD and given access to running wheels. After 3 months of treatments, behavioural tests were performed: Morris water maze, novel objection recognition, and Y-maze. Fluorescent-activated cell sorting was used to investigate peripheral immune cell infiltration. Cerebral blood flow (CBF) responses evoked by whisker stimulation were measured by Laser Doppler flowmetry, whereas baseline CBF was measured in WM areas with [14C]-iodoantipyrine autoradiography. WM functionality was measured in micro-dissected corpus callosum using *in vitro* electrophysiology to record compound action potentials. Mice were intracardially perfused for immunohistochemistry analysis.
Results: The HCD had a significant effect in WT and TGF mice that was prevented by PE on the novel object recognition task, the same was observed but only in TGF mice for the Y-maze. Both baseline WM CBF and sensory-evoked CBF increases were reduced in VCID mice, deficits that were countered by PE. VCID mice displayed focal WM functional deficits characterized by lower compound action potential amplitude, which were not found in PE groups. In addition, markers of WM pathology in VCID mice such as increased number of collapsing capillaries, microglial activation associated with WM damage, and reduced number of oligodendrocytes, were all prevented by PE.
Conclusion: Our findings suggest that targeting WM pathology in VCID may be key to improving cognitive symptoms and that regular aerobic PE is an effective preventative treatment. It is possible that reduced CBF in conjunction with increased WM inflammation and reduced number of oligodendrocytes resulted in memory impairments. Increased CBF and oligodendrocyte maturation, and reduced WM-associated inflammation by PE may have helped overcome cognitive deficits induced by HCD.

Title: Memory impairments and synaptic failure in APP/PS1 AD model mice are alleviated by eEF2K inhibitor NH125

Authors: *N. KASICA, W. YANG, X. ZHOU, T. MA
Howard Hughes Med. Inst. - Wake Forest Univ., Winston Salem, NC

Abstract: Mounting evidence indicates synaptic failure as an early and key event in Alzheimer's Disease (AD) pathophysiology. Maintenance of long-term memory and synaptic plasticity requires *de novo* protein synthesis. Phosphorylation of mRNA translation factor eukaryotic elongation factor 2 (eEF2) by its kinase eEF2K results in inhibition of general protein synthesis. Previous studies have shown elevated levels of eEF2 phosphorylation in *post mortem* AD human brain tissue and in AD mouse models. Here we investigated whether suppression of eEF2 phosphorylation via eEF2K inhibitor NH125 can alleviated AD-associated synaptic failure and memory impairments. Aged APP/PS1 mice (12-16 months) and age-matched controls were injected intraperitoneally with NH125 or vehicle following a previously established dosing protocol over two weeks. The mice then underwent cognitive assessment via the Novel Object Recognition (NOR) and Morris Water Maze (MWM) tasks. We found that cognitive impairments displayed in aged APP/PS1 mice were alleviated with treatment of NH125. Furthermore, electrophysiology experiments demonstrated that AD-associated defects in hippocampal long-term potentiation (LTP) were rescued by NH125. Additionally, results from Surface sensing of translation (SUnSET) assay revealed that impaired *de novo* protein synthesis in hippocampus of AD model mice was improved by NH125. Taken together, our results suggest that treatment with a eEF2K inhibitor, NH125, alleviates cognitive impairments and restores translational capacity in a mouse model of AD.

Title: Upregulation of endothelial Picalm using an FDA approved drug enhances amyloid-β clearance from murine brain

Authors: *K. KISLER, A. P. SAGARE, S. BAZZI, C.-J. HSU, D. LAZIC, E. J. LAWSON, A. R. NELSON, Z. ZHAO, B. V. ZLOKOVIC
Dept. of Physiol. and Neuroscience, Zilkha Neurogenetic Inst., Keck Sch. of Med. of the Univ. of Southern California, Los Angeles, CA

Abstract: PICALM, phosphatidylinositol binding clathrin assembly protein, is a known genetic risk factor for Alzheimer's disease (AD). In healthy mice and humans, PICALM is highly expressed in brain endothelial cells, involved in clathrin-mediated endocytosis and trafficking, and clearance of amyloid-β (Aβ) from the brain across the blood-brain barrier. However, in AD PICALM brain endothelial levels are reduced. We have previously shown that PICALM reduction leads to reduced Aβ clearance from brain and exacerbation of Aβ pathology, which could be reversed by increased endothelial-specific expression of PICALM after viral transfection. Thus, therapeutic strategies that upregulate *Picalm* expression in the vasculature could lead to novel advancements in AD treatment. Using a drug screening approach, we have identified an FDA-approved drug capable of upregulating endothelial *Picalm in vivo*. To mimic features of AD, we used 5XFAD mice carrying a single copy of the *Picalm* gene ($Picalm^{+/-}$; 5XFAD) and treated them with the drug for two months, beginning at 3 months of age. Drug-induced *Picalm* upregulation in these animals reduced brain Aβ load by 40-60% in the cortex and hippocampus, significantly improved performance in hippocampal-dependent behavioral tests, and improved cerebral blood flow response to stimulus, indicating cognitive and cerebrovascular improvements compared to vehicle treated animals. Together this data indicates that *Picalm* upregulation could be a promising new therapeutic target for AD.

Title: Comprehensive touchscreen cognitive characterisation of APP/PS1 mouse model of Alzheimer's disease reveals subtle and progressive impairments

Authors: *A. SHEPHERD[1], T. ZHANG[1], J. K. H. LIM[2], V. H. Y. WONG[2], C. T. O. NGUYEN[2], B. V. BUI[2], A. J. HANNAN[1], E. L. BURROWS[1]

Abstract: Mouse models expressing human gene mutations provide powerful tools to investigate mechanisms underlying cognitive decline in Alzheimer's disease (AD). Touchscreen technology facilitates the assessment of cognitive domains directly relevant to impairments described in AD patients. We examined cognition in male mice expressing familial AD mutations in amyloid precursor protein (APPswe) and presenilin-1 (PS1ΔE9) and littermate controls using touchscreen technology, as well as vision using electroretinography and ocular coherence tomography (n=8-12, 4 cohorts), with researchers blinded to genotype. Mice were initially trained to nose-poke a visual stimulus on a touch-sensitive computer screen for a reward. Mice were food restricted to 75% throughout the testing period to facilitate motivation and tested for 1 hour, 6-7 days a week. Tasks were scaled in complexity to test cognitive domains relevant to those impaired in human AD and analysed using regression models, analogous to clinical methods. APP/PS1 mice show subtle behavioural inflexibility impairments at 12 months of age, that progressively worsen to severe at 24 months of age. Working and associative memory were assessed in APP/PS1 mice at 8-15 months and, unexpectedly, showed no impairments. Mice were assessed in two equivalent maze-based tests at comparable time-points for bench-marking with published findings. Conflicting with published results, neither cognitive impairments nor retinal changes were uncovered in these mice. The absence of impairment is speculated to be due to several experimental factors known to improve memory, including daily cognitive stimulation, increased physical exercise and chronic food restriction. This is the first exploratory cognitive characterisation of APP/PS1 mice using touchscreens, and informs the validity of this mouse model of AD. Furthermore, our findings validate this approach of utilising clinically relevant modes of assessment to facilitate translation from pre-clinical models to the clinic.

Title: Potential therapeutic role of niacin in Alzheimer's disease

Authors: M. MOUTINHO, V. E. VON SAUCKEN, *G. E. LANDRETH
Stark Neurosci. Res. Institute, NB214C, Indiana Univ. Sch. of Med., Indianapolis, IN

Abstract: The niacin receptor (HCAR2 or GPR109A) is expressed in immune cells, and its activation by specific agonists results in decreased inflammation. The expression of HCAR2 is stimulated by an inflammatory environment, suggesting that this receptor is part of a natural compensatory response to control inflammation. Alzheimer’s disease (AD) has a prominent inflammatory component, however it remains unknown if HCAR2 plays a direct role in AD pathology. Interestingly, dietary intake of niacin, a HCAR2 agonist, has been suggested to be protective against AD and age related cognitive decline. Therefore, we hypothesized that HCAR2 activation by niacin could have a therapeutic role in AD. Our results indicate that HCAR2 expression increases with disease progression in the brains of the 5xFAD mouse model of AD. These findings suggest that this pathway is already primed in the AD brain due to the robust inflammatory environment, which supports the idea of HCAR2 as a promising therapeutic target for disease modification. We treated a cohort of 5-month old 5xFAD mice with a commercially available formulation of niacin (Niaspan®) daily by oral gavage for 30 days, with the dosages of 0, 50 and 100 mg niacin/kg. The 5xFAD mice treated with 50 and 100 mg/kg of niacin exhibited a significant reduction in amyloid-β burden as assessed by 6E10 staining. Immunohistochemical analysis revealed a small reduction in the number of compact, thioflavin S-positive plaques in the subiculum of mice treated with niacin 100 mg/kg. Importantly, niacin exerts a neuroprotective effect as evidenced by reduced neuronal loss in the subiculum of Niaspan® treated mice. These preliminary data suggest that niacin treatment could have beneficial effects in AD, including neuroprotection, even after the onset of severe amyloid pathology. Niaspan® is a FDA approved drug, thus there is translational potential of this strategy into clinical practice, supporting further study of this therapeutic approach.

Title: G protein-biased beta1-adrenergic receptor partial agonists for the treatment of Alzheimer's disease

Authors: *B. YI, A. JAHANGIR, A. K. EVANS, J. ERNEST, M. GREEN, M. SHAMLOO
Dept. of Neurosurg., Stanford Univ. Sch. of Med., Palo Alto, CA

Abstract: Beta1-adrenergic receptor (ADRB1) is a therapeutically attractive target for Alzheimer's disease that can provide symptomatic relief and disease-modifying effects. Here, we report our effort to develop novel ADRB1 agonists with high CNS penetration. Xamoterol is a partial agonist of ADRB1 that selectively activates the cAMP cascade. In two independent mouse models of Alzheimer's disease, xamoterol was shown to be effective in rescuing memory deficits and attenuating pathology associated with the disease, suggesting that this class of compounds may have the unique potential to provide comprehensive therapeutic benefits for the treatment of Alzheimer's disease. While xamoterol is the best tool compound available, use of xamoterol for CNS indications is limited by its poor oral bioavailability and low CNS penetration. Based on these findings, we sought to develop a novel ADRB1 partial agonist with pharmacological properties similar to xamoterol, but with improved bioavailability and enhanced CNS penetration. Our medicinal chemistry effort exploring the structure-activity relationship of xamoterol derivatives led to the discovery of a series of compounds. These compounds produce partial agonistic activity on G-protein signaling with EC_{50} values in the low nanomolar range. Similar to xamoterol, these compounds are functionally biased and selectively activate G-protein coupled signaling with very little activity on the beta-arrestin pathway compared to the unbiased agonist isoproterenol. The compounds also produce strong anti-inflammatory effects both *in vitro* and *in vivo*, and show high brain penetration. The newly identified, functionally selective partial agonists of ADRB1 are invaluable research tools to investigate the adrenergic system in Alzheimer's disease pathology and potential novel lead compounds for restoring cognitive deficits and altering the progression of Alzheimer's disease.

Title: Finasteride differentially impacts dendritic morphology of hippocampal neurons and impairs object recognition memory in male 3xTg-AD mice

Authors: *A. L. MENDELL[1], S. D. CREIGHTON[2], H. WILSON[1], L. ISAACS[1], B. D. WINTERS[2], N. J. MACLUSKY[1]
[1]Biomed. Sci. - Ontario Vet. Col., [2]Psychology, Univ. of Guelph, Guelph, ON, Canada

Abstract: Alzheimer's disease (AD) is characterized by amyloid beta deposition and neurofibrillary tangle formation. Development of pathophysiology in AD has been shown to lead to alterations in neuronal structure, which have been proposed to contribute to functional memory impairments. The incidence of AD is higher in women compared to men, and several studies have demonstrated that the severity of neuronal dysfunction and cognitive decline are worse in females. These sex differences may be associated with loss of protection due to the menopausal decline of circulating ovarian steroids, while the age-related decline in testosterone levels in men is more gradual. Work by our group and others has shown that 3alpha-hydroxy, 5alpha-reduced metabolites of testosterone may contribute to neuroprotection conferred by androgens, as well as to sex differences in the incidence of AD. In this study, we explored the impact of inhibiting synthesis of testosterone-derived neurosteroids on object recognition memory (ORM; n=9-11/group) and dendritic morphology (n=5-6/group) in the CA1 and CA3 hippocampal subfields in male triple transgenic AD mice (3xTg-AD), with females included to evaluate sex differences. Male 6-month old wild-type (WT) and 3xTg-AD mice received daily injections of finasteride (5alpha-reductase inhibitor; 50mg/kg i.p) or vehicle (18% beta-cyclodextrin, 1% v/b.w.) for 20 days. Female WT and 3xTg-AD mice only received vehicle injections. Finasteride treatment in males differentially impaired ORM after short-term (5min; 3xTg-AD only) or long-term (3h; 3xTg-AD and WT) retention delays, while vehicle-treated 3xTg-AD males and females were only impaired after the long-term delay. Dendritic spine density (DSD), dendritic branching, and total dendritic length of pyramidal neurons in the CA3 subfield were reduced in 3xTg-AD females, but not males. Both DSD and dendritic branching were significantly reduced by finasteride in 3xTg-AD males, abolishing the sex difference in CA3. In the CA1 subfield, DSD and dendritic branching were reduced in all 3xTg-AD mice,

with no significant effects of finasteride. These results highlight subfield-specific sex differences in dendritic structure of hippocampal neurons in 3xTg-AD mice, and suggest that these differences are at least partially attributable to 5alpha-reduced neurosteroids. Memory impairments were exacerbated by finasteride in 3xTg-AD males, indicating that the changes in neuronal structure were associated with altered cognitive function. Overall, these findings suggest that 5alpha-reduced neurosteroids may contribute to sex differences in the development and severity of AD.

Title: Cognitive effects of intermittent deep brain stimulation of the Nucleus basalis of Meynert in a transgenic rat model for Alzheimer’s disease

Authors: P. KOULOUSAKIS, V. VISSER-VANDEWALLE, *T. SESIA
Dept. of Stereotactic and Functional Neurosurg., Univ. Hosp. of Cologne, Koeln, Germany

Abstract: Alzheimer’s disease (AD) is a fatal progressive neurodegenerative disease and the most prevalent form of dementia. Degeneration of cholinergic neurons in the basal forebrain has been shown to be one of the earlier hallmarks of the disorder. Associated acetylcholine deficiency has been positively correlated with cognitive impairment in AD. The nucleus basalis of Meynert (NBM) has a high density of cholinergic efferent neurons projecting to the entire cortical mantle. Deep brain stimulation (DBS) is a neurosurgical procedure in which electrodes are implanted into specific areas to be electrically stimulated. Lately, NBM DBS has been proven safe and successful in AD patients, who are stimulated continuously. A recent study in healthy aged monkey suggests that an intermittent pattern of stimulation (20 s ON/ 40 s OFF) boost performance in a cognitive test. We aim at testing this new pattern of electric stimulation in an animal rat model for AD. For this study, we use the transgenic rat line Tgf344-AD due to its robust validity in modeling AD. We use three behavioral tests adapted from the characterization study of the Tgf344-AD rat line in combination with three patterns of stimulation. Tests include open field maze (OFM), object recognition task (ORT), and modified Barnes maze (BM). Rats were stimulated at 200 µA either intermittently at 20 Hz (new

paradigm) or continuously at 60 Hz (current clinical standard). Post-mortem tissue analysis confirms electrode localization. Performances under stimulation conditions are compared to baseline performances acquired prior any stimulation. We use one group of 8 rats from 12-18 months old of age and another group of 8 rats of 18-26 months old of age. Older rats retrieved the escape hole faster, even under the longest retention period condition, when stimulated intermittently. Under this new pattern of stimulation, their performances also exceeded those of the younger group. Intermittent bilateral stimulation of the NBM shows the best improvement cognitive performance in older (18 months) rats. These preliminary results suggest that intermittent stimulation is a promising new pattern of stimulation to be tested in the clinic to further optimize NBM DBS in AD patients.

Title: Repeated acoustic stimulation improved sleep-wake behavior and electroencephalographic markers in a mouse model of Alzheimer's disease

Authors: *V. J. DREW, M. PARK, J. LEE, S. RYU, T. KIM
Gwangju Inst. of Sci. and Technol., Gwangju, Korea, Republic of

Abstract: Background: Alzheimer’s disease (AD), a neurodegenerative disease associated with memory loss, accounts for the majority of dementia patients. Pathophysiology of AD is not fully understood, but amyloid beta (Aβ) accumulation and tauopathy have been implicated as the major biomarkers and, possibly, pathogenic factors. Recently it has been known that gamma frequency entrainment reduced Aβ in the brain (Iaccarino, et al., 2016) and a growing body of evidence supports the relationship between sleep and dementia. However, careful investigation of sleep-wake behavior in the animal model of AD is still lacking. Therefore, we sought to examine the characteristics of sleep-wake control in an AD model and their changes caused by acoustic stimulation at 40 Hz. Methods: We used 5XFAD transgenic mice as an AD models of Aβ overproduction. At the age of six months, two-hour daily acoustic stimulation of click sound at 40 Hz were given for 14 days at the beginning of dark period. We also performed the 24-hour

electroencephalographic (EEG) recordings for the sleep-wake analyses at the stimulations days 1, 7 and 14. Aβ load was measured with immunohistochemistry and ELISA of the pre- and infra-limbic cortices and hippocampus and EEG data were analyzed for the gamma oscillations and brain connectivity. We analyzed the 24-hour sleep-wake profiles, bout length and frequency, and the power spectrums. The sleep data were analyzed using Sirenia Sleep software. Results: We found that the number of Aβ plaque, as well as Aβ40 and Aβ 42, decreased in the brain after 14-day acoustic stimulation. Sleep analysis revealed that the amounts of sleep and wake were not different among the three consecutive EEG recordings. However, there were trends toward shortened and less frequent sleep and wake bouts over the stimulation period. Power spectrum of wake epochs showed abnormally increased delta power and reduced stepwise at days 7 and 14. Conclusion: Repeated acoustic stimulation resulted in decrease levels of amyloid beta and wake delta power in EEG and more consolidated sleep and wake stages. These changes may reflect improved amyloid pathology could also ameliorate the continuity of wakefulness and sleep. We speculate that a better quality of wakefulness and cognition might be heralded by decreased wake delta power, but this should be confirmed with behavioral tests. Consequently, we suggest that non-invasive acoustic stimulations at 40 Hz might have therapeutic effect on a mouse model of Alzheimer's disease.

Title: Pharmacological PKR inhibition rescues deficits in synaptic plasticity and memory in Alzheimer's disease mouse models

Authors: K.-D. HWANG, M. BAK, S. KIM, *Y.-S. LEE
Dept. of Physiol., Seoul Natl. Univ. Col. of Med., Seoul, Korea, Republic of

Abstract: Alzheimer's disease (AD) is a neurodegenerative disorder associated with memory loss and deficits in synaptic plasticity. Although amyloid β (Aβ) and hyper-phosphorylation of tau are considered as major causes, AD can be caused by a large number of different genetic mutations and other unknown factors. Considering such a heterogeneous nature of AD, it would

be desirable to develop treatment strategies that can improve memory irrespective of the individual causes. In this study, as a proof-of-concept, we targeted the phosphorylation of eukaryotic translation initiation factor 2α (eIF2α) as a memory-enhancing strategy. Previously, reducing the phosphorylation of eIF2α was reported to enhance long-term memory and synaptic plasticity in mice. Moreover, hyper-phosphorylation of eIF2α is observed in the brains of postmortem AD patients. In this study, we examined whether PKR inhibition can rescue synaptic and learning deficits in two different AD mouse models; 5XFAD transgenic and $A\beta_{1-42}$-injected mice. We found that the acute treatment of PKR inhibitor (PKRi) can restore the deficits in long-term memory and long-term potentiation (LTP) in both mouse models without affecting the Aβ load in the hippocampus. Our results prove the principle that targeting memory enhancing mechanisms can be a valid strategy for developing treatments for memory deficit associated with AD.

Title: Neurochemical and behavioral effects of intranasal insulin administration in young and aged rats

Authors: *J. M. ERICHSEN[1], C. B. CALVA[1], C. A. GRILLO[1,2], L. P. REAGAN[1,2], J. R. FADEL[1]
[1]Dept. of Pharmacology, Physiology, and Neurosci., Univ. of South Carolina, Columbia, SC; [2]WJB Dorn VA Med. Ctr., Columbia, SC

Abstract: Alzheimer’s Disease (AD) is the most common form of dementia that affects ~10% of individuals over 65. Recently, insulin administration has been suggested as a potential therapy for AD patients, as individuals with insulin resistance and type 2 diabetes have demonstrated impaired memory and cognitive function. Peripheral administration of insulin can induce side

effects like hypoglycemia, but intranasal (IN) administration allows direct access to the brain without affecting systemic insulin or glucose levels, is non-invasive, and easy to administer. Additionally, IN insulin enhances memory in rodents, healthy individuals, and those with AD, although the mechanistic basis for these pro-cognitive changes has yet to be elucidated. To address these questions, a subset of young (3 months) F344xBN F1 rats were administered 250 ug biotin-labeled IN insulin and brain sections were prepared to examine the neuroanatomical pattern of IN insulin distribution and binding. Staining appeared in the medial septum, diagonal band of Broca, medial forebrain bundles, islands of Calleja, piriform cortex, and spinal trigeminal tract, indicating that the IN method effectively delivers insulin to the brain. Additional young and aged (26-28 months) rats were administered IN insulin or IN saline to examine effects on feeding behavior and neurochemistry. Food intake was assessed for 18 hours after IN administration of 250 ug insulin or saline in both young and aged rats. IN insulin significantly suppressed food intake in both groups but the effect in aged rats was delayed relative to young animals, suggestive of insulin resistance in the aged cohort. Finally, brain neurochemistry was assessed with *in vivo* microdialysis. Differences in acetylcholine and glutamate levels in the six hours after IN administration of insulin vs. saline were observed, indicating that changes occur at the neurotransmitter level. More studies are needed to fully understand the molecular and behavioral changes following IN insulin administration, but these data demonstrate the capacity for IN insulin to rapidly target the brain and influence neurotransmission and feeding behavior.

Title: Cortical control of the stomach and its potential relevance to Alzheimer’s disease

Authors: *D. J. LEVINTHAL, R. P. DUM[1], P. L. STRICK[2]
[1]Neurobiology, Ctr. for Neural Basis of Cognition, Systems Neurosci. Ctr., Univ. Pittsburgh,

Pittsburgh, PA; [2]Neurobiology, Systems Neurosci. Ctr., Brain Inst., Univ. Pittsburgh Sch. Med., Pittsburgh, PA

Abstract: We injected rabies virus (RV) into the stomach wall of several macaques. The site we injected was innervated solely by the vagus nerve, a major output of the parasympathetic nervous system. The injections of RV resulted in retrograde transport to first-order neurons in the dorsal motor nucleus of the vagus and the ambiguus complex, followed by retrograde transneuronal transport to second-order neurons in the medulla, and then third-order neurons in the rostral insula. These results suggest that the insula functions as a "parasympathetic motor cortex" for central command signals that influence stomach function. The rostral insula has been regarded as a cortical site for monitoring our internal state (for references and review see Craig, '09). Our results indicate that descending command signals from the rostral insula have the potential to create or at least influence our internal state.

We next allowed virus transport to proceed beyond the rostral insula. This led to the surprising result of dense labeling in the entorhinal cortex (EC). This observation is especially noteworthy because EC is known to be one of the first sites of tau accumulation in Alzheimer's disease. Indeed, Braak and Braak ('91) designated tau accumulation in EC as Stage 1 of the disease. Our results raise the possibility of a link between the stomach's microbiome and tau deposition in EC. For example, a toxic substance could originate in the stomach and use retrograde transneuronal transport through the vagus nerve and a chain of as few as five interconnected neurons to gain access to EC. The presence of this material in EC neurons could then trigger a pathological process that results in the abnormal deposition of tau, and thus, the onset of the earliest stages of Alzheimer's disease.

In another animal, we allowed transport to proceed to one stage beyond EC and observed dense labeling in the hippocampus. Tau accumulation at this site is considered to be Stage 2 of Alzheimer's. There has been a growing awareness in the Alzheimer's field that the orderly progression of tau from its initial site in EC to other sites may be mediated by neural connections. If our results can be confirmed and extended, they indicate that retrograde transneuronal transport through specific neural connections may mediate the progression of tau in Alzheimer's disease. If these conclusions are correct, then one potential approach to impede the progression of Alzheimer's, and prevent cognitive impairment and memory dysfunction, would be to inhibit retrograde transport in these circuits.

Title: G protein-biased beta1-adrenergic receptor partial agonists for the treatment of Alzheimer's disease

Authors: *P. MEMAR ARDESTANI, B. YI, A. K. EVANS, M. SHAMLOO
Dept. of Neurosurg., Stanford Univ. Sch. of Med., Palo Alto, CA

Abstract: Alzheimer's disease (AD) is the most common neurodegenerative disease, directly affecting about 24 million people worldwide. Currently, there is no effective treatment for AD to prevent, cure, or slow its progression, emphasizing the need for a novel therapeutic strategy. The lack of effective AD therapies can be attributed to the complex array of factors involved in its development and progression. Given the complex nature of AD, therapeutic agents that simultaneously modulate different key target points of AD pathology would represent the most ideal and comprehensive therapy. Beta1-adrenergic receptor (ADRB1), which is involved in multiple key aspects of AD, is a unique and therapeutically attractive target for AD that could enable a comprehensive strategy for the treatment and management of the disease. Here, we demonstrate that specific activation of G-protein signaling of ADRB1 leads to beneficial effects on impaired cognitive function and pathology associated with the disease in two independent mouse models of AD. In 2 different transgenic models in which mice either express 5 mutations related to Familial Alzheimer's Disease, [5XFAD; 3 mutations in the amyloid precursor protein and 2 in presenilin 1] or 2 mutations in amyloid precursor protein (T41B), transgenic and wildtype male mice were chronically dosed with vehicle or with the G-protein biased ADRB1 partial agonist, xamoterol (5XFAD, 6 mg/kg daily oral gavage or 3 mg/kg subcutaneous pump; T41B, 0.3-1.0 mg/kg daily subcutaneous injection). When chronically dosed, the G-protein biased ADRB1 partial agonist improved novel object recognition and spatial learning in 5XFAD mice, and reduced hyperactivity and improved contextual fear conditioning in T41B mice. Chronic dosing with xamoterol also decreased amyloid beta and modulated indices of neuroimmune activation in both models. Reduction in tau pathology was also observed with chronic dosing with xamoterol in 5XFDA mice. Together, our findings suggest that activation of the ADRB1 G-protein signaling pathway may be a therapeutic approach for AD.

Title: Combination of memantine and 6-chlortacrine leads to promising dual inhibitor of acetylcholinesterase and NMDA receptor; a novel multi-target compound against Alzheimer’s disease

Authors: *O. SOUKUP[1], J. KORABECNY[2], E. NEPOVIMOVA[1], K. VALES[3], K. SKRENKOVA[4], L. KLETECKOVA[3], M. HORAK[5]
[1]Univ. Hosp. Hradec Kralove, Hradec Kralove, Czech Republic; [2]Biomed. Res. Ctr., Univ. Hosp., Hradec Kralove, Czech Republic; [3]Natl. Inst. of Mental Hlth., Klecany, Czech Republic; [4]Inst. of Physiol. CAS, Praha, Czech Republic; [5]Inst. of Physiol. AS CR, Praha-4, Czech Republic

Abstract: Alzheimer’s disease (AD) is the most common form of dementia in elderly. Current treatment is based on these cholinergic and glutamatergic, theory. It involves acetylcholinesterase inhibitors donepezil, galantamine and rivastigmine, and NMDAR antagonist memantine. However, treatment is only symptomatological and temporary and it seems that cure needs to be complex due to a multifactorial nature of the disease. In this context, so called “multi-targeting approach” has been established almost two decade ago in order to successfully address not only the disease symptoms but also disease progression. This work provides design, synthesis in vitro and in vivo characterization of novel drug candidate amalgamating tacrine scaffold, namely 6-chlortacrine with memantine into one molecule. By using patch clamp, we have shown that novel hybrid is a potent open channel blocker of the NMDARs which acts by “trapping“ mechanism. Fuerthermore, the affinity to AChE (IC50=9nM) investigated by Ellman´s method is similar to donepezil and therefore the compounds possesses both requested properties, i.e. it is an anticholinesterase and anti-NMDA agent. We have also investigated the effect of the compound in vivo using NMDA-induced lession of the hippocompus and we have observed significant reduction of the lession, in comparison to both control and memantine treatment. Thus, the novel hybrid compound effectivelly combines both currently established approaches in the treatment of AD, capable to prevent from excitotoxicity in vivo.

Title: Effects of tetrahydrocannabinol treatment on brain metabolism and inflammation in a mouse model of sporadic Alzheimer’s disease

Authors: *C. BOUTER[1], M. E. SICHLER[2], I. KOSTUL[2], T. A. BAYER[2], Y. BOUTER[2]
[1]Nuclear Med., [2]Mol. Psychiatry, Univ. Med. Ctr. Goettingen, Goettingen, Germany

Abstract: Limited therapeutic effects of current Alzheimer treatments highlight the need for new research approaches. The endocannabinoid system plays a role in neuroinflammation and memory formation and therefore addresses major pathological hallmarks of Alzheimer’s disease. The aim of this study was the evaluation of the therapeutic potential of Tetrahydrocannabinol (THC) on neuron loss and neuroinflammation in a mouse model of sporadic Alzheimer’s disease. Tg4-42 mice develop severe neuron loss in the hippocampus in correlation to intra-neuronal Aβ expression starting at 4 months of age. Furthermore, Tg4-42 mice display increased astrogliosis in the hippocampus. Tg4-42 mice were treated with high dose THC daily for 6 weeks starting at 5 months. GFAP and IBA1 markers were used to examine the impacts of THC treatment on inflammation in Tg4-42 mice. Unbiased stereology was applied in order to quantify neurons in the dentate gyrus and CA1 region of the hippocampus. Tg4-42 mice were characterized by autoradiography using the TSPO ligand ^{18}F-GE180. Furthermore, ^{18}F-FDG-PET/CT was used to study therapeutic effects in vivo at 3 and 6 months. While GFAP staining of reactive astrocytes did not show a significant difference between THC-treated mice and untreated controls, IBA1 detected significantly reduced microgliosis in the dentate gyrus of THC-treated Tg4-42 mice. Stereological analysis revealed that THC-treated animals displayed a significant increase in the number of neurons in comparison to controls. Autoradiography and ^{18}F-FDG-PET/CT results will be also presented.
First results on THC-treatment in Tg4-42 mice show the potential of the endocannabinoid system as a therapeutic target in Alzheimer’s disease influencing neuroinflammation and neuron loss.

Title: Long-term treatment of 7,8-dihydroxyflavone protects against cortical amyloid-beta accumulation and activates hippocampal BDNF-TrkB signaling in a mouse model of Alzheimer’s disease

Authors: *C. M. TOGNONI[1,2], A. R. SCIAUDONE[1,3], I. CARRERAS[1,3], J. K. BLUSZTAJN[2], A. DEDEOGLU[1,3]

Abstract: Brain-derived neurotrophic factor (BDNF) signaling through the tropomyosin receptor kinase B (TrkB) is a candidate for targeted therapies to treat Alzheimer’s disease (AD). Recently, our lab demonstrated early protective effects of the TrkB agonist, 7,8-dihydroxyflavone (DHF), on AD-related pathology and dendritic arborization in the 5xFAD mouse model of AD when treated (5 mg/kg i.p., 3 days/week) from 1 to 3 months of age (Aytan et al. Eur J Pharmacol. 2018 Jun 5;828:9-17). In this study, we examined the effects of a longer-term and late-stage treatment with DHF in 5xFAD female mice from 1 to 8 months of age. Concentrations of Aβ proteins were measured via enzyme-linked immunosorbent assay (ELISA), which revealed that DHF treatment had significantly decreased soluble Aβ42 protein levels in the frontal cortex. We did not detect differences between untreated and treated mice in the densitometry of Aβ plaques in the hippocampus by immunohistochemistry (IHC) of Aβ42. By IHC with anti-phospho-TrkB (Tyr816) antibody, we found increased phosphorylated TrkB in the hippocampus and amygdala of DHF-treated compared to untreated 5xFAD mice, suggesting DHF enhanced activation of the receptor and its downstream signaling cascades that mediate synaptic plasticity and the maintenance and growth of dendrites and dendritic spines. Together, these preclinical results indicate that long-term treatment of DHF in the 5xFAD mouse model of AD protects against cortical Aβ accumulation and activates hippocampal BDNF-TrkB signaling, which is known to have protective effects on neuroplasticity and memory.

Title: Intravenous mesenchymal stem cells administration as a neuroprotective therapy in a rat model of sporadic alzheimer's disease

Authors: *M. ZAPPA VILLAR[1], J. LOPEZ HANOTTE[1], J. PARDO[1], G. MOREL[1], M. GARCÍA[2], P. REGGIANI[1]
[1]INIBIOLP, Sch. of Medicine, Natl. Univ. La Plata, La Plata, Argentina; [2]Gene Therapy Lab, Sch. of Biomed. Sciences, Austral Univ., Pilar, Buenos Aires, Argentina

Abstract: Alzheimer's disease (AD) is the most prevalent neurodegenerative pathology with no efficient therapy. The signaling pathways that become defective, altering the normal protein homoeostasis of amyloid β-peptide (Aβ) and tau protein, and thus initiating a series of pathophysiological responses ultimately causing synaptic loss and cognitive decline, are unclear and much sought after.
Our objective is to develop therapeutic strategies that allow preventing and/or overcoming the degenerative changes in the brain with experimental AD. In this context, cell therapy emerges as a promising therapeutic approach. We set up a model of sporadic AD by the intracerebroventricular (icv) injection of streptozotocin (STZ) in rats.
In a first study, we evaluated behavior and gliosis in the dorsal hippocampus of STZ-injected rats after 24 days. We assessed learning and spatial memory by the Barnes Maze (BM) and anxiety-related behavior by the Marble Burying (MB) test. STZ-treated rats exhibited impairments in these tests as compared with control counterparts. Furthermore, STZ rats displayed Stratum Radiatum (SR) volume reduction and a decreased NeuN immunoreactivity (neuron loss) in the hippocampal CA1 region, together with an increased immunoreactivity for the microglial (Iba1) and astroglial (GFAP) markers (neuroinflammation).
In another experimental approach, we assessed the effect of intravenous administration (as a non-invasive route) of Human Umbilical Cord Mesenchymal Stem Cells (HUC-MSC) on cognitive performance in the AD rat model. Three experimental groups were used: Sham, STZ, and STZ+MSC. After 24-day STZ injection, when the damage was already established, animals received every 18 days, a suspension of $1x10^6$ HUC-MSC in a tail vein. During the last two weeks until the end of the study we performed Open Field, BM, and MB tests to estimate memory, depression-like, and anxiety-like behaviors. STZ treated rats were deficient in all

behavioral tests and morphological assessment. STZ+MSC group increased exploratory frequency in the Open Field test. Moreover, these animals showed an improvement in their spatial memory performance in the BM. Anxiety-like behavior in the MB test was also attenuated by exposure to MSC. Interestingly, MSC therapy restored hippocampal atrophy in the SR region and ameliorated neuron loss. Additionally, decreased microgliosis and astrogliosis was observed in the MSC-treated rats.
We conclude that MSCs therapy is a suitable biological tool in neurodegenerative disorders, restoring the progression of cognitive impairment and neuroinflammation when systemically administered for more than two months.

Title: Activation of endogenous neurogenesis is a potential therapeutic approach for Alzheimer's disease

Authors: *M.-Y. KIM, S. HAN
Shinebiopharma Inc., Seoul, Korea, Republic of

Abstract: Alzheimer’s disease(AD) is thought to be caused by damage of neural networks due to damage or loss of neurons in the hippocampus and cerebral cortex through the deposition of amyloid-beta plaques. Even though amyloid-beta was thought to be the target for AD treatment, no successful drug treatment has yet been established. This is because although the amyloid-beta aggregates were removed, it was not possible to induce the repair of the damaged neurons or nervous tissue. In this study, we evaluated whether the induction of endogenous neurogenesis could be a potential therapeutic approach in Alzheimer’s disease.
First, we established an assay system for screening drug candidates which simultaneously induce neuronal differentiation of neural stem cells (NSCs) and provide protection against cell death from Aβ oligomers. We identified SNR1611 which induced neuronal differentiation of NSCs and provided cell death protection to neurons in the presence of Aβ oligomers *in vitro*. SNR1611 also induced neurogenesis in the dentate gyrus of the hippocampus of 12-month old 5XFAD mice, an Alzheimer’s disease mouse model, when observed one month after its oral administration. SNR1611 not only activated neurogenesis in the dentate gyrus but also increased the number of neuronal cells in the cortex of 12-month old 5XFAD mice, characterized by the

many plaques and damaged neurons in the cortex. In addition, SNR1611 treated 5XFAD mice showed a tendency of recovery in recognition memory.
These results suggest that SNR1611 can be a potential drug for Alzheimer's disease by inducing endogenous neurogenesis and the strategy of inducing endogenous neurogenesis can be a novel target for treatment of Alzheimer's disease.

Title: Effects of Danggui-Shaoyao-San decoction on hippocampal expression profiles of non-coding RNAs in a mouse model of Alzheimer's disease

Authors: ***S. CHENG**, Z. SONG, F. YIN, F. LI
Col. of Integrated Traditional Chinese and Western Med., Hunan Univ. of Chinese Med., Hunan Province, China

Abstract: Danggui-Shaoyao-San (DSS) is a well-known herbal formula that has been clinically applicable for treating neurological disorders. It is reported that it could improve the function of the dopaminergic, adrenergic, and serotonergic nervous systems. Interestingly, DSS can alleviate cognitive dysfunction of Alzheimer's disease (AD) patients. Accumulating evidence indicates that non-coding RNAs are strongly implicated in AD-associated pathophysiology. Whether the ameliorative functions of DSS is associated with ncRNAs remains largely unknown. In the present study, we used microarray analysis technology to characterize the expression patterns of circular RNAs (circRNAs), long-non-code RNA (lncRNA), microRNAs (miRNAs), and mRNAs in hippocampal tissue from APPswe/PS1ΔE9 (APP/PS1) mice treated with DSS, to integrate interaction data and thus provide novel insights into the mechanisms of DSS. A total of 287 circRNAs, 118 lncRNA, 156 miRNAs and 382 mRNAs were identified to be significantly dysregulated (fold-change ≥ 2.0 and p-value < 0.05) in the hippocampus of DSS treated AD mice. Quantitative real-time polymerase chain reaction (qRT-PCR) was then used to validate the expression of randomly-selected circRNAs, lncRNA, miRNAs and mRNAs. Next, GO and

KEGG pathway analyses were performed to further investigate ncRNAs biological functions and potential mechanisms. Our results suggest the ncRNA regulated by DSS involves in the neurodevelopment, intercellular communication, action potential regulation of neurons, development and differentiation of oligodendrocytes, neurotransmitters and regeneration of neurons in APP/PS1 mice

Title: Amelioration of learning and memory deficits in aged and 3xtg-ad mice by mild level of stress

Authors: L. CHAN[1], G. PARK[2], *J.-H. JANG[1]
[1]Dept. of Pharmacol., Sch. of Medicine, Keimyung Univ., Daegu, Korea, Republic of; [2]Col. of Pharm., Kyungpook Natl. Univ., Daegu, Korea, Republic of

Abstract: Stress is regarded as one of the critical risk factors for neurodegeneration leading to learning and memory deficits. Although several researchers have reported that mild level of stress could enhance cognitive functions, its underlying molecular mechanisms are not clearly verified. In this study we have investigated the effect of mild restraint stress (MRS) against the learning and memory dysfunction in aged mice as well as triple transgenic mice of Alzheimer's disease (3xTg-AD) by conducting diverse behavior tests and molecular analyses. MRS improved mean escape latency, the time taken to find the platform during training trials in Morris water-maze test. In addition, the neuropathological markers for AD such as accumulation of beta-amyloid peptide and hyperphosphorylation of tau protein were mitigated by MRS. MRS effectively decreased ratio of pro-apoptotic Bax to anti-apoptotic Bcl-2, the representative proteins involved in apoptosis. To elucidate the neuroprotective mechanism of MRS, we have examined the molecules involved in the oxidative stress and inflammation. MRS attenuated the lipid peroxidation and protein oxidation through up-regulation of antioxidant enzymes via modulating redox-sensitive proteins such as NF-E2-related factor 2. MRS also attenuated the pro-inflammatory responses by suppressing expression of cytokines in aged mice. Moreover, MRS increased the levels of brain-derived neurotrophic factor by phosphorylation of cAMP

response element-binding protein in 3xTg-AD mice. Taken together, these findings suggest that MRS may have beneficial effects for the learning and memory impairments during neurodegenerative process by decreasing neuropathological markers of AD and oxidative stress as well as inflammatory responses, and increasing neurotrophic factors involved in neuroregeneration.

Title: Risk-Factor induced memory dysfunction and Aβ oligomer pathology in a non-transgenic model of sporadic Alzheimer’s disease

Authors: *C. WEISS[1], K. L. VIOLA[2], M. A. BICCA[2], W. L. KLEIN[2], J. F. DISTERHOFT[1]
[1]Dept Physiol., Northwestern Univ. Med. Sch., Chicago, IL; [2]Dept Neurobio., Northwestern Univ., Evanston, IL

Abstract: The purpose of this study is to develop a non-transgenic animal model of sporadic Alzheimer’s Disease (AD) in rabbit because its amino acid sequence for amyloid is nearly identical to the human sequence, and its lipid metabolism is very similar to human lipid metabolism. This suggests that the rabbit is a good species to examine diabetes and high cholesterol as risk factors for sporadic AD. We used aging female rabbits to compare the effects of diets enriched with either 2% cholesterol or 10% sucrose (vs standard chow) on cognition and neuronal pathology. Cognition was assessed with the novel object and novel location recognition tests to assess cortical and hippocampal function, respectively. A discrimination index was calculated based on the time investigating novel or familiar objects or locations. Scores ranged between 0 and 1.0 with 1.0 representing exclusive investigation of the novel object/place, and 0 representing equal exploration. Pathology was assessed by staining brain sections containing hippocampus and frontal cortex with NU4, an antibody specific for amyloid oligomers. Diabetes was assessed by an iv glucose tolerance test. Cognition was tested after 20 weeks of the

designated diet. High cholesterol diet impaired both object location and object recognition tests (mean scores of 0.06 and 0.10, respectively) relative to rabbits on standard diet (mean score of 0.70). High sucrose diet impaired object recognition (0.19 vs 0.44 control diet), but not the object location test (0.72 vs 0.70). Blood glucose levels (BGL) and insulin levels revealed a large spike in insulin release for rabbits on sucrose diet, and those rabbits exhibited BGL that returned to baseline more quickly than the BGL of the other two groups. This suggests a state of prediabetes and maybe insulin resistance in the brain, i.e., Type 3 diabetes (de la Monte and Wands, 2008). Analysis of immunoreactivity to amyloid oligomers with the NU4 antibody revealed a 20- and 35- fold increase respectively in hippocampus and frontal cortex relative to sections from control rabbits. Experiments are in progress to determine the basis for the differential impact of the diets on hippocampal-dependent memory dysfunction. **Conclusions:** Diets that promote high cholesterol or diabetes impair neuronal metabolism, increase AD-like pathology, and decrease cognitive functions. These diets in the rabbit provide model systems to understand mechanisms related to the onset and progression of sporadic AD.

Title: Neurochemical effects of intranasal orexin-A and [Ala^{11},D-Leu^{15}]-orexin-B administration in rats

Authors: *C. B. CALVA, J. R. FADEL
Pharmacology, Physiology, Neurosci., Univ. of South Carolina Sch. of Med., Columbia, SC

Abstract: Cognitive dysfunction is well described in numerous psychiatric and neurological disorders. The hypothalamic orexin (hypocretin) system, a central integrator of physiological function, also plays an important role in coordinating proper cognition. Prior work from our lab has shown an age-related reduction of orexin (OX) neurons in rats, suggesting that orexins play a role in the cognitive and homeostatic dysfunctions observed during aging. While clinical investigations of OX antagonist-based pharmacotherapies are ongoing, the paucity of OX agonists has limited the ability to research their therapeutic potential. To circumvent this hurdle,

intranasal OX administration has been suggested as a means of directly targeting the brain while avoiding the side effects or limited brain penetration that occur with systemic administration. Preliminary behavioral evidence suggests that intranasal orexin-A (OxA) may enhance cognition and wakefulness; however, the receptor activation mechanisms underlying these effects remain largely unknown. We have previously demonstrated that intranasal OxA activates cortical and basal forebrain regions involved in attention and learning, and increases cortical acetylcholine release in both young and aged rats. Because OxA binds the orexin-1 and orexin-2 receptor with equal affinity, our observations could not be attributed to a specific receptor. Accordingly, we utilized intranasal administration of the selective orexin-2 receptor agonist, [Ala^{11},D-Leu^{15}]-orexin-B (OxB), to compare the patterns of neuronal activation in young and aged animals that result from intranasal administration of OxA or [Ala^{11},D-Leu^{15}]-OxB. Here, young (3-4 months) and aged (26-28 months) male Fisher344/Brown Norway rats received intranasal administration of saline, OxA, or [Ala^{11},D-Leu^{15}]-OxB (25 μL of a 100 μM solution) into each naris after 7 days of habituation to vehicle administration. Two hours post-treatment, animals were sacrificed and their brains were processed for immunohistochemical detection of the neuronal activity marker, c-Fos, and phenotypic markers of specific neuronal populations. In young rats, intranasal OxA significantly increased c-Fos expression in a larger number of cortical and basal forebrain regions compared to intranasal [Ala^{11},D-Leu^{15}]-OxB. Additionally, intranasal OxA administration resulted in significantly higher c-Fos expression in basal forebrain cholinergic neurons of aged animals versus young animals. In total, these data indicate that intranasal OX administration, largely via the orexin-1 receptor, activates brain regions and neurotransmitter systems that decline with age.

Title: TgF344-AD rats exhibit alterations in locomotion and acoustic startle response prior to cognitive function impairment

Authors: *B. ZOU[1], K. XIAO[1], C. PASCUAL[1], W. S. CAO[1], F. MA[2], D. HUA[2], I. MAEZAWA[3], L. W. JIN[3], X. X. XIE[1]

Abstract: Alzheimer's disease (AD) is becoming an increasingly widespread detriment in society with the growing aged population and lack of effective treatments. Establishing novel animal models that objectively identify early phenotypes, monitor disease progress, and evaluate responses can provide a powerful approach to the discovery of new interventions. To this end, we characterized the neurobehavior of a transgenic rat model (TgF344-AD) expressing mutant human amyloid precursor protein (APPsw) and presenilin 1 (PS1ΔE9) genes; each independently cause early-onset familial AD. The memory phenotype of TgF344-AD rats (10 - 11 months old) was evaluated using contextual and tone-fear condition (automated assessment by the SmartCage system) and novel object recognition tests. TgF344-AD rats exhibited memory similar to age-matched non-transgenic (nonTg) rats, but displayed increases in homecage spontaneous activity (active time and total infrared beam break counts), locomotion (travel distance, but not speed) and rearing compared to non-Tg rats monitored by the SmartCage for 8 days under a normal light/dark condition. Furthermore, evaluation of startle response and pre-pulse inhibition (PPI) with acoustic stimulation revealed that the PPI was significantly impaired at 80 and 90db of pre-pulse stimulation, while there was a trend of enhancement in startle response of TgF344-AD compared to nonTg rats. These preliminary results indicate that homecage activity, particularly locomotion and startle PPI assessments, along with learning and memory tests can be used to evaluate TgF344-AD rat behavioral phenotypes and treatment responses. Our novel tricyclic pyrone compounds (especially CP2), which have been shown to reduce Aβ accumulation, Aβ plaque formation, and *Tau* pathology, are currently under evaluation via chronic treatment using this rat AD model and behavioral phenotypic analysis.

Title: The recombinant C-terminal fragment of the tetanus toxin protects the acetylcholinesterase activity and spatial memory by intraseptal injection of amyloid-β peptide (25-35)

Authors: *I. LIMON PEREZ DE LEON[1], A. PATRICIO-MARTÍNEZ[2], L. SÁNCHEZ-ABDÓN[3], F. LUNA-MORALES[4], J. AGUILERA[5], G. MORALES-FLORES[3]
[1]Benemerita Univ. Autonoma de Puebla FCQ Lab. Neurofarma, Puebla, Mexico; [2]Facultad de

Ciencias Biológicas-BUAP, Puebla, Mexico; [3]Lab. de Neurofarmacología FCQ-BUAP, Puebla, Mexico; [4]Lab. de Neuroendocrinología FCQ-BUAP, Puebla, Mexico; [5]Univ. Autònoma de Barcelona, Barcelona, Mexico

Abstract: The C-terminal fragment of tetanus toxin (Hc-TeTx) is a non-toxic peptide of tetanus toxin with neuroprotective effects. Hc-TeTx has the ability to bind to nerve cells and be retrogradely transported through synapse. It has been shown that the administration of the peptide Amyloid-β (25-35) ($A\beta_{25-35}$) in the *Septum Medial* (SM) decreases the expression of (AChE, an enzyme that degrades acetylcholine). The administration of Hc-TeTx in SM protects the expresion of AChE of cholinotoxic effect of $A\beta_{25-35}$, however there is no evidence of the protective effect of Hc-TeTx administered peripherally. The aim of this work was to evaluate the effect of intramuscular administration of the Hc-TeTx fragment on the activity of AChE and spatial memory by intraseptal injection of $A\beta_{25-35}$ in rats. Male Wistar rats were used approximately 250-350g, Hc-TeTx or SSI was administered intramuscularly, Twenty four hours later SSI, $A\beta_{35-25}$ and $A\beta_{25-35}$ were administered by stereotactic surgery in SM (AP: +0.6, L: 0.0, P: -5.2, according to Paxinos). The experimental groups were: Intact, SS+SSI (2μL), SSI+$A\beta_{35-25}$ (2μg/2μL), Hc-TeTx+SSI (20μg/kg), SSI+$A\beta_{25-35}$ (2μg/2μL) and Hc-TeTx+$A\beta_{25-35}$. Fifteen days post-injury the spatial learning was evaluated and twenty nine days post-injury the memory was evaluated in the Morris water maze (MWM). The next day, the groups were euthanized for the dissection and extraction of the SM and dorsal hippocampus to evaluate the activity of the AChE by the Ellman test. The experimental groups showed no impair the spatial learning, but the SSI+$A\beta_{25-35}$ group significant decrease of 50% the memory compared to the intact group. The Hc-TeTx+$A\beta_{25-35}$ group performance in 73% of the animals in the memory compared with the SSI+$A\beta_{25-35}$ group. The experimental groups did not exhibit changes in the activity of the AChE in the hippocampus, while the peptide $A\beta_{25-35}$ group decreased about 43% the activity of AChE in SM compared with the intact group, the other experimental groups did not present a statistically significant difference. On the other hand, the group Hc-TeTx+$A\beta_{25-35}$ maintained the activity of the AChE in SM by 43% compared with the intact group; the findings of this study suggest that Hc-TeTx has a protective effect on the cholinergic system. In conclusion, the intramuscular administration of Hc-TeTx in injured rats causes the survival of SM neurons and prevents damage to memory by improving septo-hippocampal communication.

Title: Sirtuin 2 inhibition: A new therapeutic approach for age-related cognitive decline

Authors: *T. DÍAZ PERDIGÓN[1], B. BELLOCH PEREZ[2], R. TORDERA BAVIERA[2], E. PUERTA RUIZ DE AZUA[2]
[1]Univ. De Navarra, Pamplona/Iruna, Spain; [2]Univ. de Navarra, Pamplona, Spain

Abstract: Background: Aging is considered to be a major risk factor for neurodegenerative diseases including Alzheimer Disease (AD). Epigenetic changes are currently recognized as part of the aging process and have been implicated in many age-related diseases. In agreement with this hypothesis, a recent study has shown an age-dependent accumulation of SIRT2 in the mouse brain and spinal cord. Since excess SIRT2 might be deleterious to neurons, SIRT2 inhibition has been proposed as a novel therapeutic strategy for age-related cognitive decline.
Methods: A novel and potent SIRT2-selective inhibitor, the compound 33i (5mg/kg i.p., 4 weeks) or vehicle was administered to 5-month-old (preventive treatment) and 8-month-old SAMP8 (therapeutic treatment) and aged matched control SAMR1 mice. The SAMP8 mouse model, based on aging, has been considered to represent more closely the multifactorial nature of AD. Behavioral and biochemical tests were performed to study the effects of SIRT2 inhibition.
Results and conclusions: 33i significantly reversed the learning and memory impairments shown by 6 month-old SAMP8 mice in the Morris Water Maze. Although 33i did not reverse tau-hyperphosphorylation or Aβ accumulation, its beneficial effects as a preventive treatment could be due to an increase in GluN2A, GluN2B and GluA1 protein expression seen in both SAMR1 and SAMP8 mice treated with 33i. Furthermore, a decrease in neuroinflammation was seen in 6-month-old SAMP8 mice treated with 33i evidenced by a reduction of GFAP, IL1, IL6 and TNFα expression.
As a therapeutic treatment, SIRT2 inhibition slightly improved the performance of the 9 month-old SAMP8 in the MWM. GluN2A, GluN2B and GluA1 protein expression were also increased in both 9-month-old SAMR1 and SAMP8 treated with 33i. However, this compound didn't decrease the neuroinflammation shown by the SAMP8 at this age, suggesting that, once the pathology is established, SIRT2 inhibition could be proposed as an adjuvant treatment to improve memory in combination with other drugs.
Altogether, the results of this study indicate that SIRT2 inhibitors may be an ideal novel target to prevent or treat age-related cognitive decline, AD and other neurodegenerative diseases.

Title: Inhibition of neutral sphingomyelinase 2 with MS882 for the treatment of Alzheimer's disease

Authors: *K. RAHN[1,2], M. SALA[3], A. THOMAS[2], R. P. DASH[2], C. TALLON[2], L. LOVELL[2], Y. WU[2], R. RAIS[2], R. NENCKA[3], C. ROJAS[2], B. SLUSHER[2]
[1]Baltimore, MD; [2]Johns Hopkins Univ., Baltimore, MD; [3]Inst. of Organic Chem. and Biochem., Prague, Czech Republic

Abstract: The enzyme neutral sphingomyelinase 2 (nSMase2) catalyzes the hydrolysis of sphingomyelin to phosphorylcholine and ceramide. This reaction is a major source of ceramide, a bioactive lipid critical for the cellular secretion of exosomes. Exosomes are lipid vesicles that play a critical role in standard intercellular cargo transport and communication. Over the last decade, it has become apparent that toxic intracellular tau aggregations travel within the brain in a manner reminiscent of a "prion-like" disease, potentially via exosomes. Recent studies have demonstrated that blocking nSMase2 activity, either genetically or pharmacologically using the prototype nSMase inhibitor GW4869, improves cognition, reduces histopathological signs of disease including tau propagation, and decreases brain exosome and ceramide levels in rodent models of AD. The current armamentarium of nSMase2 inhibitors, however, are not clinically viable, as they have low potency (uM IC_{50}s), poor solubility, and limited brain penetration. Our laboratory recently carried out a human nSMase2 inhibitor high throughput screening (HTS) campaign of over 350,000 compounds. Our chemistry hit optimization efforts led to a nanomolar potent, orally available, brain-penetrant (AUC_{brain}/AUC_{plasma}=0.6) inhibitor termed MS882, that was found to dose-dependently inhibit exosome release from glial cells both *in vitro* and *in vivo*, while a structurally similar but inactive analog had no effect. Using this compound, we performed efficacy studies using the 5XFAD mouse model of AD. Male and female wild type (WT) and 5XFAD mice were administered daily intraperitoneal injections of vehicle or 10mg/kg MS882 from 12 - 35 weeks of age (n=13-16/group). This dose was determined to provide MS882 levels in the brain sufficient to inhibit nSMase enzymatic activity for >10 hours post dose. Fear conditioning tests conducted at 34 weeks revealed a significant deficit in contextual memory in 5XFAD+Vehicle mice versus WT+Vehicle mice ($P<0.001$). This deficit was

significantly restored in 5XFAD mice treated with daily MS882 (P<0.01 vs 5XFAD+Vehicle). Post-mortem analyses including exosome, ceramide, and nSMase levels as well as histological endpoints are underway. Taken together, these data support the regulation of exosome release via nSMase2 inhibition as a novel treatment for AD.

Title: Effects ofDCP-LA on learning and memory in an *in vivo* Alzheimer's disease model with ovariectomized rats

Authors: P. A. SUTTER, R. B. KNOWLES, *C. R. MCKITTRICK
Biol., Drew Univ., Madison, NJ

Abstract: Alzheimer disease (AD) is the sixth leading cause of death in the United States and affects females disproportionately more than males for reasons unknown. Several promising studies have shown that the PKC-epsilon activator 8-[2-(2-pentyl-cyclopropylmethyl)-cyclopropyl]-octanoic acid (DCP-LA) reverses the effects of AD in *in vivo* models. Because these studies have been limited to either male transgenic mice or male rats, this study explores the effects of DCP-LA in a pharmacological AD model in female rats. The ferrous-amyloid-buthionine (FAB) model was used to induce AD pathologies. This model infuses a combination of ferrous sulfate, amyloid beta fragments, and buthionine sulfoximine into the lateral ventricle of rats over a four-week period. The FAB model mirrors both behavioral and molecular pathologies of AD and models the role of oxidative stress in AD. In the present study, half of the females also received ovariectomies (OVX) to model postmenopausal conditions, since the female population over 65 is the most susceptible to AD. Osmotic minipumps containing either FAB or saline were implanted into 48 three-month-old female Sprague-Dawley rats with infusion cannulae targeted to the cerebral ventricle; at the same time, animals received either

OVX or sham surgery. Four weeks postsurgery, the rats received a single intraperitoneal injection of DCP-LA (1 mg/kg in 5% DMSO) or vehicle 24h prior to exposure to the Morris Water Maze (MWM). Spatial learning was assessed over 5 days of training, and memory was assessed 48 h after the last training session. Immunohistochemistry for NeuN and synaptophysin is currently being conducted to determine neuronal and synaptic density differences between treatment groups.FAB-treated animals showed significant deficits in both learning and memory as compared to controls. OVX did not affect learning but did lead to memory deficits as compared to controls, with FAB + OVX rats performing worse than all other treatment groups in the memory task. DCP-LA administration effectively restored learning and memory performance back to control levels in the FAB-treated animals but did not fully restore memory deficits in OVX animals, suggesting that FAB and OVX impair memory through different mechanisms.These data suggest that the loss of sex hormones in females may lead to cognitive deficits and these deficits can be exacerbated by oxidative stress conditions similar to those implicated in AD. Furthermore, these results suggest that DCP-LA may have therapeutic potential for treatment of AD, as it has now been shown to reverse the of FAB in both male and femalerats.

Title: Plasminogen Activator Inhibitor-1 Antagonist TM5A15 reduce neuropathology and memory deficits in APP/PS1 mice

Authors: *G. RODRIGUEZ[1], S. DOMINGUEZ[1], D. E. VAUGHAN[2], T. MIYATA[3], H. DONG[4]
[1]Psychiatry and Behavioral Sci., [2]Dept. of Med., Northwestern Univ., Chicago, IL; [3]Dept. of Mol. Med. and Therapy, Tohoku Univ. Grad. Sch. of Med., Sendai, Japan; [4]Dept Psychiatry and Behavioral Sci., Northwestern Univ. Feinberg Sch. of Med., Chicago, IL

Abstract: The pathological hallmark of Alzheimer’s disease (AD) is the aggregation of amyloid beta peptides in the brain which causes a varying degree of cognitive deficits. Amyloid beta peptides are metabolized through biosynthesis and degradation and it is a crucial equilibrium that is needed in order to prevent neuropathologies of AD. Plasmin, a serine protease, plays an

important role in the degradation of Aβ. Several previous studies have shown that there is an increase level of plasminogen activator inhibitors present in the plasma of AD mice models as well as in AD patients. However, whether reversing the increased plasminogen activator inhibitor could prevent neuropathgenesis of AD has not been well investigated. In this study, we test whether a novel plasminogen activator inhibitor-1 (PAI-1) antagonist, TM5A15, can ameliorate cognitive deficits and decrease the Aβ plaques deposition in APP/PS1 mice, an animal model of Alzheimer's disease. We administered 3 month old APP/PS1 mice with TM5A15 for up 6 months via chow diet. Mice underwent behavior testing of locomotor activity, novel object recognition, Morris water maze, and spontaneous alternation after 3 months of treatment and 6 months of treatment to assess the mice learning and memory performance. Blood serum was collected from all groups and mice were then sacrificed to collect brain tissue for biochemical and immunohistochemistry analysis. Behavioral tests showed there was no significant affect after 3 months treatment with TM5A15, when APP/PS1 mice were 6 months. However, after 6 months of treatment, the APP/PS1 mice displayed significant improvement in spontaneous alteration ($p<0.01$), novel object recognition ($p<0.01$), and Morris water maze ($p<0.05$) when they were 9 months of age. Biochemical results indicated a decrease of amyloid plaque deposition in the whole brain for APP/PS1 treated animal samples compared to those APP/PS1 mice that did not receive treatment. In addition, western blot analysis showed higher protein expression of BDNF ($p<0.05$) in APP/PS1 animals that were treated compared to those that were not. These data suggests that increased PAI-1 activity contributes to Aβ aggregation and TM5A15 could prevent the formation of Aβ plaques in APP/PS1 mice.

Title: ABCA1 activation in the CNS as a therapeutic target for APOE4-induced Alzheimer's disease risk

Authors: *A. C. VALENCIA[1], T. MCNALLY[1], D. BALU[1], N. FAULK[1], Y. SALEH[1], A. HANSEN[1], D. PHAM[1], N. ALLABABIDI[1], J. YORK[1], J. JOHANSSON[2], J. BIELICKI[3], M. LADU[1]

[1]Anat. and Cell Biol., Univ. of Illinois at Chicago, Chicago, IL; [2]Artery Therapeutic's Inc, San Ramon, CA; [3]Lawrence Berkeley Natl. Laboratory,, Univ. of California, Berkeley, CA

Abstract: *APOE4,* which encodes the apolipoprotein E4, (apoE) is the greatest genetic risk factor for Alzheimer's disease (AD), increasing risk up to 15-fold compared to *APOE3*. However, there is a critical lack of therapeutics targeting mechanistic pathways for this *APOE4*-induced AD risk. While the mechanism underlying *APOE*-modulated AD risk remains unclear, *APOE4* is associated with accelerated amyloid-beta (Aβ) accumulation, both as amyloid plaque and soluble oligomeric forms of Aβ (oAβ), the latter considered a proximal neurotoxin. In addition, apoE4 levels in the brains of humans, and transgenic mice (Tg) expressing human *APOE,* are lower than apoE3. Thus, our therapeutic target for *APOE4* carriers is increasing apoE levels and decreasing Aβ levels. We used the EFAD-Tg mice, which specifically overexpress Aβ42 and express human *APOE4* (E4FAD) or human *APOE3* (E3FAD). ABCA1 is the major transporter of lipid to apoE-containing lipoproteins in the CNS. Thus, ABCA1 is a promising therapeutic target for increasing apoE levels by increasing its stability via an increase in lipidation. Artery Therapeutics, Inc. developed novel ABCA1 agonists, including CS6253 (Cs), for the treatment of peripheral cardiovascular disease. Cs demonstrates high selectivity and potency for ABCA1-mediated cholesterol efflux in a process where ABCA1 protein is stabilized. Both male and female E4FAD and E3FAD mice were treated with Cs using a prevention (4-8 months) paradigm. To establish dose, an *in-vitro* screen and PK analysis was done. In vitro, Cs increased apoE levels by 10-20-fold and the lipoprotein cholesterol efflux capacity in primary astrocytes expressing apoE3 or apoE4. *In-vivo,* Cs is brain penetrant, reaching higher concentrations than that needed for *in vitro* efficacy. Cs increased ABCA1 levels and reduced both soluble and insoluble Aβ as well as amyloid deposition in brains of male E3FAD and E4FAD mice. In male E3FAD mice, Cs increased learning in Morris Water Maze, synaptic viability, and reduced Aβ deposition and astrogliosis. There were no significant effects in female E3FAD or E4FAD mice except for an increase in ABCA1 levels. In summary, activation of ABCA1 by Cs was effective in male EFAD mice (E3FAD > E4FAD) in preventing synaptic loss, neuroinflammation, Aβ deposition, and reduction in soluble Aβ levels. Further investigation is needed to understand the mechanisms underlying sex differences with regard to ABCA1 activators, and to design optimal treatment paradigms for Cs-based ABCA1 agonism as a therapeutic for AD.

Title: Modulation of circadian activity in pathological and non pathological aging

Authors: S. SUNDARAM, *D. GULICK
Univ. of South Florida, Tampa, FL

Abstract: Patients with Alzheimer's disease (AD) often suffer a disruption of circadian clock function, resulting in a constellation of abnormal behavior patterns in the evening hours, termed Sundown Syndrome (SS). Recent studies suggest modulators of the endogenous clock, particularly casein kinase 1 (CK1) isoforms ε and δ, as possible therapeutic targets for the alleviation of SS-related symptoms. CK1 is a serine/threonine kinase responsible for the phosphorylation and subsequent turnover of the Period (PER) protein, which is an essential component of the negative arm of the molecular circadian clock. We have hypothesized that PF-670462, a selective inhibitor of the CK1 ε/δ isoforms, will reduce SS-like behaviors in models of both pathological (AD) and non pathological aging. We have studied this in 7-10 month-old APP/PS1 transgenic mice as a model of β amyloid neuropathology commonly seen in AD, and in 18 22 month-old C57BL/6J mice as a model of normal aging. Changes in cognitive capacity and histopathology were studied among the following cohorts: 1) APP/PS1 + PF-670462, 2) APP/PS1 + vehicle (VEH), 3) C57BL/6J + PF-670462, and 4) C57BL/6J + VEH. We assessed changes in behavior between the cohorts on a variety of behavior measures, including anxiety (open field test), spatial memory (Y maze test), depression (forced swim test), and learning (fear conditioning). Brain tissue was collected following behavioral testing, and immunohistochemistry was performed to assess changes in levels of β-amyloid, PER1, and BMAL1 (a circadian positive arm transcription factor) in each condition. PF-670462 rescues both cognitive and behavioral deficits in these models when compared to controls, and these improvements are associated with decreases in β amyloid aggregation and reduced longer peak in the expression of PER1 across the circadian day. Thus, therapeutic targeting of endogenous modulators of the circadian clock presents a unique, yet efficacious method of symptom reduction for SS in AD.

Title: Testosterone improves memory and strength in diabetic mice

Authors: *S. A. FARR[1], M. L. NIEHOFF[2], K. A. ROBERTS[2], D. A. ROBY[2], J. E. MORLEY[2]
[1]St Louis Univ/VA Med. Ctr., Saint Louis, MO; [2]Intrnl. Medicine/Geriatrics, St. Louis Univ. Sch. of Med., St. Louis, MO

Abstract: Background: Diabetes is a costly, multidimensional disease that can lead to significantly increased risks for patients, including those associated with a loss of cognition and physical strength, as well as a decreased level of testosterone in male patients. The goal of this study was to determine whether testosterone treatment would be effective in improving memory and muscle strength in diabetic mice. **Methods:** The subjects were 36 male CD-1 mice. Twenty-five were intravenously injected with streptozotocin, 150mg/kg, to induce a diabetic state. Once the appropriate mice were confirmed to have diabetes, time-release testosterone pellets were implanted (11 nondiabetic mice and 13 diabetic mice received placebos and 12 diabetic mice received testosterone). Four weeks later the mice were tested for memory (novel object recognition and T-maze), activity (open field) and strength (string hang, cage hang, rod, and grip strength meter tests). Following the completion of cognitive and strength testing brain and muscle tissue samples were collected for biochemical analysis. **Results:** In the novel object recognition test, the placebo-treated diabetic mice spent significantly less time investigating the novel object compared to both the diabetic mice that received testosterone treatment and the nondiabetic controls ($p<0.01$). In T-Maze retention, placebo-treated diabetic mice took a greater number of trials to reach criterion compared to the testosterone-treated diabetic mice and the nondiabetic mice. Grip strength test indicated diabetic mice that received a placebo performed significantly worse than the diabetic mice that received testosterone ($p<0.05$) and the nondiabetic mice ($p<0.0001$). In the rod test, placebo-treated diabetic mice spent significantly less time balanced on the rod than nondiabetic mice ($p<0.01$), there was no difference between the testosterone-treated diabetic mice and the placebo-treated nondiabetic mice. During the activity test, the placebo-treated diabetic mice traveled significantly less distance than both the nondiabetic mice and the testosterone-treated diabetic mice ($p<0.05$). **Conclusion**: Testosterone improved memory and strength, in the testosterone-treated diabetic mice compared to the placebo-treated diabetic mice in T-maze and novel object recognition, grip strength, and rod test. The current results suggest testosterone could be a treatment for the memory- and strength-related problems associated with diabetes.

Title: Distribution of insulin in brain after intranasal administration

Authors: *J. J. LOCHHEAD[1], P. RONALDSON[2], T. P. DAVIS, 85716[2]
[1]Pharmacol., [2]Univ. of Arizona, Tucson, AZ

Abstract: In the brain, insulin acts as a growth factor, regulates energy homeostasis, and is involved in learning and memory acquisition. Many central nervous system (CNS) diseases have deficits in insulin signaling. Pre-clinical studies have shown intranasal insulin is neuroprotective in models of Alzheiemer's disease, Parkinson's disease, and traumatic brain injury. Clinical trials have shown intranasal insulin elicits beneficial cognitive effects in patients with Alzheimer's disease. Previous studies have shown insulin can be detected within the CNS within minutes following intranasal administration. The anatomical pathways which insulin utilizes to reach the CNS and the cellular targets within the CNS after intranasal administration, however, are not fully understood. In the current study, we intranasally administered fluorescently labeled insulin and imaged its localization within the brain and trigeminal nerves. Our data indicates intranasal insulin is able to reach cellular targets within the CNS along extracellular components of the trigeminal nerve. Upon CNS entry, we found FITC-insulin colocalized with the insulin receptor. These findings suggest the intranasal route of administration is able to rapidly deliver insulin to the CNS and subsequently activate neuroprotective insulin signaling pathways.

Title: Effect of mesenchymal stem cell-derived exosomes on neurogenesis of Alzheimer's disease mouse model

Authors: *E. E. REZA-ZALDIVAR[1], Y. K. GUTIERREZ-MERCADO[2], S. SANDOVAL-AVILA[2], M. A. HERNANDEZ-SAPIENS[2], A. L. MARQUEZ-AGUIRRE[2,3], A. A. CANALES-AGUIRRE[2]

Abstract: Alzheimer disease (AD) is the most common type of dementia that affects regions of the central nervous system, which are synaptically plastic and are involved in higher functions such as the acquisition of new information as learning and memory. Currently, an effective cure for AD is not available. Therefore, cell therapy has emerged as an alternative for the treatment of AD. The use of adult stem cells, as neural stem cells and mesenchymal stem cells (MSC) of bone marrow and adipose tissue, has the potential to decrease cognitive deficits, possibly by reducing neuronal loss through blocking apoptosis, increasing neurogenesis, synaptogenesis and angiogenesis. These processes are mediated primarily by secretion of many growth factors, anti-inflammatory proteins, membrane receptors and microRNAs, mainly released into exosomes. These nanovesicles could be used as part of strategy to promote neuroplasticity, improving cognitive impairment and neural replacement in AD due its capacity to encapsulate and transfer several functional factors like proteins, lipids and regulatory RNA. The aim of this study was evaluated effects of MSC-derived exosomes in neurogenesis and cognitive capacity of AD mouse model. The MSC-derived exosomes were obtained from conditioned media using ultracentrifugation and subsequently identified by western blot for CD81 expression. For model establishing, 48 C57BL/6 mice of 6-8 old week were used. The AD model was carried out administering 10 ng/ μL of beta amyloid (βA) in Dentate Gyrus (DG) bilaterally. Morris Water Maze (MWM) and Novel Object Recognition (NOR) tests was performed to evaluate cognitive deficits past 15 days administration. Afterwards, the different treatments were administrated (10 ug/μL exosomes, PBS and $1x10^6$ MSCs) in DG. 14 and 28 days post treatments administration, MWM and NOR were carried out to evaluate cognitive capacity, then, brains were collected, fixed and sliced to determine neurogenesis by immunofluorescence using Nestina, Doublecortina, PSA-NCAM, Tuj-1, and NeuN antibodies. Here, we found that exosomes

administration stimulates neurogenesis in the SVZ, besides of reduce cognitive impairment produced by βA administration, these effects are similar to those shown in the MSC. This may allow the development of cell-free therapeutic strategies for AD. Despite these results, is import understand the molecular signaling in these events of neuroplasticity and how the cognitive improvement is performed.

Title: Automated cognitive testing in mouse models relevant to Alzheimer’s disease

Authors: *M. LOOS[1], C. M. HELDRING[2], B. KOOPMANS[1], E. REMMELINK[1], M. VERHAGE[3], R. E. VAN KESTEREN[2], A. B. SMIT[2]

Abstract: Alzheimer’s disease (AD) is characterized by progressive decline in cognitive function. For preclinical testing of novel interventions, for instance against the effects of Aβ or Tau, it is key to develop robust tests in mice that assess cognitive functions relevant to AD. We previously described an automated one-night CognitionWall discrimination learning task that can be used longitudinally. In this automated home-cage (PhenoTyper)-based task, mice obtain a food reward every fifth time they pass through one of three entrances in a wall placed in front of a reward dispenser (CognitionWall). The task likely engages the hippocampus, since it requires short-term and/or working memory as well as pattern separation, which are cognitive functions relevant to AD. A systemic injection of a low dose of MK-801, a non-competitive antagonist of NMDA receptors that attenuates LTP, impaired discrimination learning in wild type mice, as demonstrated by a significantly increased number of entrances to reach the learning criterion (80% through the correct entrance). We investigated whether a phosphodiesterase (PDE9) inhibitor was able to revert this cognitive deficit. We observed that transgenic APP/PS1 mice were significantly slower at reaching the learning criterion, not only around the age at which amyloid plaques start to be visible (26 - 30 weeks of age), but also before plaque formation at 16 weeks of age. We investigated the potential beneficial effect of BACE1 inhibition as well as other proof-of-concept interventions in this task. Characterization of cognitive performance of

Tau models in this task such as the P301S and htau is ongoing. Taken together, this series of studies confirms the idea that this automated cognitive task is instrumental in preclinical testing of interventions targeting AD.

Title: Granisetron, a selective 5-HT3 receptor antagonist, alleviates AD pathology in TgSwDI mouse model through CREB pathway

Authors: *S. B. RIHANI, A. KADDOUMI
Drug Discovery and Develop., Auburn Univ., Auburn, AL

Abstract: Alzheimer's disease (AD), the most common form of dementia, is a progressive neurodegenerative disorder with no available disease-modifying treatment to slow or reverse its progression. Several studies in aging and AD demonstrated a compromised blood-brain barrier (BBB) and disrupted brain intracellular Ca^{2+} homeostasis in patient's brains. Therefore, enhancing the BBB integrity in addition to normalizing intracellular Ca2+ homeostasis could be an effective strategy to treat AD. Recently, we developed a high throughput-screening assay to screen compounds that enhance BBB integrity, which identified multiple hit compounds. Among these hits, granisetron emerged as a potent drug. Granisetron is an FDA approved selective serotonin 5-HT3 receptor antagonist widely used for clinical treatment of chemotherapy-induced nausea and vomiting. The aim of this study was to evaluate granisetron potential as a therapeutic molecule against AD. To study this aim, granisetron was tested in C57Bl/6J young and aged (n=7/group) wild type mice for its effect on BBB tightness, and in TgSwDI mice (n=5/group) as a model for AD. Findings from immunostaining, western blot and ELISA demonstrated the one-

month treatment with granisetron to enhance the BBB integrity in both aged and AD mice. This effect was associated with an overall reduction in Aβ load and neuroinflammation in the brains of TgSwDI mice. Supported by proteomics analysis and findings from in vitro mechanistic studies, granisetron rectified Aβ-induced Ca^{2+} dyshomeostasis by restoring CaMKII/CREB and PKA/CREB pathways in TgSwDI mice brains, which was associated with a significant improvement in the cognitive function. These results support granisetron repurposing as a potential drug to hold, slow and/or treat AD.

Title: Effects of antioxidant in mouse model for Alzheimer's: A behavioral phenotyping and microdialysis study

Authors: *M. MONBUREAU[1], A. F. MALIK[2], P. J. NORTHEY[2], J. ROESER[2], E. HOLLAND[2], C. CIARDIELLO[2], N. MORISOT[2], C. ZHU[2], M. G. VAN DER HART[2], H. B. JANSSENS[2], A. RASSOULPOUR[2]
[1]Discovery, [2]Charles River Labs, South San Francisco, CA

Abstract: There is a good amount of evidence that a good antioxidant status may be protective against cognitive decline (Mecocci et al. 2018). However, evidence both supporting and refuting the benefits of antioxidants on Alzheimer's disease and cognitive performance is abundant, leading to uncertainty in the field. In rodents, treatment with Sulforaphane inhibited Aβ oligomer production, reduced tau hyperphosphorylation, oxidative stress, and neuroinflammation and prevented decline in spatial learning and memory in a mouse model for AD and had similar effects in AD-like lesions in a diabetic mouse model (Hou et al., 2018, Pu et al., 2018). On the other hand, exercise, but not antioxidants reversed ApoE4 associated impairments in ApoE mice (Chaudhari et al., 2016). Evidence is not more conclusive in humans. Epidemiology studies suggest diets rich in antioxidants reduce risk of AD (Morris, 2009), while clinical studies showed AD patients treated with antioxidants showed some functional improvement, but no cognitive benefits were observed (Sano et al., 1997, Petersen et al., 2005). A randomized, double blind, placebo-controlled clinical trial in mild to moderate AD patients showed that antioxidant treatment did not influence CSF biomarkers related to amyloid or tau pathology, but the treatment did reach its target, as it lowered CSF F2-isoprostane levels in the brain, a biomarker for oxidative stress. However, the treatment may have caused faster cognitive decline (Galasko

et al., 2012). In the current study, we attempted to elucidate whether an antioxidant could reduce oxidative stress in the brain and whether this has an impact on AD biomarkers and cognitive performance in the Tg2576 mouse model for Alzheimer's disease. To this aim, we treated 12-week-old female Tg2576 mice with Saffron (50 mg/kg daily dose 5-7 days weekly for 8 weeks). Saffron, a potent antioxidant, has been shown to improve learning and memory in an aged mouse model (Papandreou et al., 2011), and the neuroprotective and antioxidant effects of saffron have been previously reported (Papandreou et al., 2011, Linardaki et al., 2012). After 8 weeks of treatment, behavioral phenotype was evaluated in the Y-maze, NOR, open field, EPM, L/D box, and Fear conditioning. Then, microdialysis was conducted in freely moving animals, along with terminal CSF and plasma. In dialysates, Aβ 41, 42, and 38, and Tau along with Ach, 5-HT, NE, DA, GABA, Glu were measured. Further, F2-isoprostane levels were measured in CSF, dialysates, and brain. We found that behavioral deficits and Aβ levels were higher in Tg2576 mice compared to WT, but 8-weeks of treatment with Saffron did not reverse this phenotype.

Title: A novel, small-molecule activator of glutamate transporter EAAT2 translation delays disease progression in a tauopathy model of Alzheimer's disease

Authors: J. B. FOSTER[1], F. ZHAO[1], R. LASHLEY[1], K. J. HODGETTS[2], *C.-L. G. LIN[1]
[1]Dept Neurosci, Ohio State Univ., Columbus, OH; [2]Brigham and Women's Hosp. and Harvard Med. Sch., Cambridge, MA

Abstract: Current therapeutics for Alzheimer's disease (AD) are limited in efficacy as they only provide temporary, palliative care, but do not significantly modify disease progression or outcomes. Therefore, there is need to develop novel therapeutics that can stop, slow, or even reverse disease progression. Glutamatergic transmission is essential for numerous neuronal

processes but is elevated in AD patients and can lead to increased tau phosphorylation and excitotoxicity. Excitatory amino acid transporter 2 (EAAT2) is responsible for clearing glutamate from the synaptic cleft and preventing excitotoxicity. We have developed a small-molecule compound series that is capable of increasing EAAT2 expression through a translational induction mechanism and previously showed that it has profound efficacy in an amyloid-β (J20) AD model. Here, we evaluated the efficacy of an advanced compound in rTg4510 mice - an aggressive model that exclusively exhibit tau-related pathology, including increased glutamate release. We hypothesized that long-term compound treatment will delay disease progression, improve synaptic integrity, and restore normal behavior. rTg4510 mice were treated with LDN/OSU-215111 (10 mg/kg P.O. via voluntary consumption) beginning at an early-symptomatic time-point (p60) and were treated to p120 or p240. At a moderate stage of disease, p120 compound-treated rTg4510 mice performed significantly better in cognitive tasks (novel object recognition/T-maze), a working memory test (Y-maze), and showed significantly reduced hyper-exploratory behavior. Even at a late stage (p240), where disease pathology is severe, treated rTg4510 mice still performed better in the novel object recognition task, as well as the Barnes Maze, and display normalized exploratory behavior. Consistent with 8-month behavioral data, hippocampal CA3-CA1 long-term potentiation (LTP) in compound-treated rTg4510 mice was normalized. At both time points, compound treatment partially normalized EAAT2 protein levels and preserved synaptic integrity. It was also determined that compound treatment delayed the deposition of toxic tau-species, provided neuroprotection, and reduced neuroinflammation. Importantly, when treatment was ceased at p240, LTP and behavior remained significantly improved relative to vehicle-treated mice 30d later. We are currently working to better define the mechanism by which this compound-series provides protection in AD. This study suggests that LDN/OSU-215111 may be a viable, clinically-relevant, and disease-modifying treatment for the many facets of AD.

Title: Neuroprotective effects of the novel nmda channel blocker, rl-208, in samp8 mice model

Authors: *C. G. FERRE[1], J. COMANYS-ALEMANY, Jr[1], A. LARISA TURCU, Jr[2], R. LEIVA[2], S. VÁZQUEZ CRUZ[2], M. PALLÀS[1]

Abstract: Alzheimer's disease (AD) is the main cause of dementia, a group of brain disorders with behavioral abnormalities and memory loss. Currently, there is no effective therapy able to cure or reduce the AD progression. Memantine, a non-competitive NMDA receptor antagonist improved in cognition and molecular alterations after preclinical treatments. Nevertheless, such neuroprotective effects of memantine in preclinical studies do not translate into clinical results. For this reason, our research group has synthesized a new NMDA channel blocker, RL-208 bearing an amine polycyclic scaffold. The present work evaluated the *in vivo* efficacy of the RL-208 in cognition and cellular pathways in SAMR1 and SAMP8. Males, 5 months-old, were divided into four groups: two control groups, SAMR1 and SAMP8, and two mice treated groups with both strains. RL-208 administered in drinking water, 5 mg/Kg per day during 4 weeks. Behavioral tests (Elevated Plus Maze (EPM), Open Field (OF), Novel Object Recognition Test (NORT) and Object Location Test (OLT)) were applied and molecular analysis was performed through Western blot, RT-PCR and Fluorimetric Assay in hippocampus tissue. After the treatment, behavioral changes in both treated-mice groups were found. Furthermore, better cognitive performance was found in SAMP8 treated with RL-208, whereas SAMR1 maintained cognitive functions. Consistent with behavioral results, RL-208 treated-mice groups significantly reduced protein levels of a neuropathological marker such as Tau hyperphosphorylation (Ser396 and Ser404) and increased gene expression of *Adam10.* Remarkably, the RL-208 increased gene expression of *Neprilysin* contributing to β-amyloid degradation in the brain. Moreover, it was observed increased gene expression of antioxidant protective enzymes *Hmox1 and* GPx1 protein levels as well as the reduction of hydrogen peroxide levels in both treated groups. Taken together, these results demonstrate the neuroprotectant role of RL-208 through specific biological pathways related to aging and neurodegenerative diseases, having a potential therapeutic role in brain disorders.

Title: HCE01 prevents memory impairments induced by heat stress in mice

Authors: *E. HUH, W. LEE, M. OH
Kyung Hee Univ., Seoul, Korea, Republic of

Abstract: Under heat stress conditions, prolonged heat stress causes neuroinflammation and neuronal damage, which are well-known causative factors for memory loss in animals' brain. HCE01 has been used for many years as an important traditional medicinal herb for treating fever. However, the effects of HCE01 on hyperthermia-induced memory impairments have not been investigated. In the present study, we investigated the effects of HCE01 on neuropathological changes induced by high temperature. To conduct this study, we treated mice with heat stress (43°C) for 15 min per day, repeated with 3 days. The administration of HCE01 significantly reduced the elevation of mouse body temperatures induced heat stress. Additionally, HCE01 attenuated heat stimuli-mediated stress responses via inhibiting the release of cortisol and upregulation of HSP70 and c-Fos in mice. In the mouse hippocampal CA3 region, HCE01 inhibited thermal stress-triggered gliosis, activation of astrocytes and neuronal loss. HCE01 also reduced the hyperthermia-induced expression of NF-κB, TNF-α and IL- 1β in the hippocampus of mice. For the underlying mechanisms, we found that HCE01 significantly decreased pro-inflammatory mediators such as IL-9 and IL-13 in the hypothalamus of mice. Furthermore, we observed that HCE01 attenuated the cognitive functions impaired by thermal stress. These results indicate that HCE01 improves the heat stress-mediated memory dysfunction and brain damage via reduction of hyperthermia and neuroinflammation in mice. Based on the study, fever-reducing medicinal herb might attenuate heat stress-induced neural damage.

Title: Quantification of low abundant neurodegenerative biomarkers in blood using Milliplex and SMC high sensitivity immunoassays

Authors: *J. HWANG, L. CHEN, A. SAPORITA, Q. XIAO
R&D, Milliporesigma, Saint Louis, MO

Abstract: Neurodegenerative disorders such as Alzheimer's Disease (AD) have become more prevalent worldwide as population ages. Quantification of protein biomarkers in patients with AD and PD is important for monitoring progression. Monitoring neurodegenerative biomarkers in cerebrospinal fluid (CSF) has led to much of our current understanding of AD. However, due to the invasive nature of collecting CSF samples, new blood biomarkers are needed. Here we report our results from screening biomarkers most commonly associated with neurodegenerative diseases using both Milliplex® multiplex immunoassays for CSF screening and Single Molecule Counting (SMC™) high sensitivity immunoassays for serum and plasma screening. CSF samples from normal versus AD patients displayed significant differences in Aβ40, Aβ42, phosphorylated Tau, GFAP, NSE, UCHL1, PRNP and NRGN levels. However, many of these neurodegenerative disease biomarkers are not detectable in some blood samples due to low abundance and thus require higher sensitivity immunoassays. For example, our Milliplex assays for Aβ42 detect these peptides in CSF, but lack the sensitivity for measurement in blood. To this end, we developed SMC™ Aβ40 and Aβ42 immunoassay kits that can accurately quantitate Aβ40 and Aβ42 levels in human, mouse, and rat blood samples. The limits of detection (LOD) of Aβ40 and Aβ42 in these novel assay kits are 0.67pg/mL and 1.68 pg/mL, respectively. Using this high sensitivity technology, Aβ40, but not Aβ42, was shown to have significant correlation to AD plasma samples. In summary, SMC high sensitivity immunoassay kits can provide a powerful non-invasive biomarker tool in studying the pathogenesis of neurodegenerative diseases such as Alzheimer's disease.

Title: Novel molecular structures that detect amyloid β associated with Alzheimer's disease

Authors: *S. RASOOL[1,2], L. RANDOLPH[1], J. NGOLAB[2], R. D. SOUZA[1], J. YANG[1], S. SARRAF[1], R. A. RISSMAN[3]
[1]Amydis, San Diego, CA; [2]Dept. of Neurosciences, [3]Neurosci, UCSD Sch. Med., La Jolla, CA

Abstract: The accumulation and deposition of amyloid deposits in the brain is the hallmark of many neurodegenerative diseases including Alzheimer's (AD). To date, late-stage diagnosis of AD is achieved using functional memory and behavioral tests; however, early stage asymptomatic diagnosis remains a challenge. Amydis has synthesized a new family of novel fluorescent molecules and evaluated their capability to bind with amyloid β (Aβ), which is involved in the pathogenesis of AD. Amydis novel probes bind to aggregated Aβ and fluorescently stained amyloid deposits in human brain tissues from patients with AD. Amydis has focused on two key areas: (a) the diagnostic utility of these molecular probes in AD, CAA and other amyloid associated neurodegenerative diseases and (b) the use of amyloid-binding agents to understand pathophysiological mechanism of the disease. These fluorescent amyloid-binding probes display a significant increase in fluorescence emission upon binding with aggregates of Aβ40 and Aβ42 as compared to the emission of the free probe in solution. To assess whether these novel molecular probes can stain amyloid deposits in brain tissue, free floating sections of the hippocampal region of a patient with familial Alzheimer's disease (FAD) were stained with an Aβ sequence specific (6E10) antibody along with our probes followed by fluorescence microscopy. The binding of these probes colocalized with the immunoreactivity of 6E10 dense core plaques. Additionally, we confirmed that our lead compounds were able to stain amyloid deposits from post-mortem CAA patients. Sections of the median frontal cortex and hippocampus from human CAA brain were stained with a fibril specific (OC) antibody along with these new probes. Fluorescence microscopy revealed that these compounds not only bind to amyloid dense core plaques but also to vascular amyloid β present in cerebral vessels, complementing our results from FAD brain tissue. Moreover, positive staining of these probes completely colocalized with OC positive staining in CAA-laden plaques and Aβ in cerebral vessels. In conclusion, these novel fluorescent compounds can be used not only to detect Aβ associated with AD and CAA, but also have a potential for detecting amyloid biomarkers in other neurodegenerative diseases.

Title: Using an amyloid-PET defined cohort to optimize volumetric-based diagnosis of dementia

Authors: *L. N. KOENIG[1], S. KEEFE[1], L. MARPLE[1], B. A. GORDON[1], J. C. MORRIS[1,2], M. MILLER-THOMAS[1], G. S. DAY[1], J. SHIMONY[1], T. L. S. BENZINGER[1]
[1]Washington Univ. In St. Louis, Saint Louis, MO; [2]Knight Alzheimer Dis. Res. Ctr., Saint Louis, MO

Abstract: Background: While hippocampal atrophy is a well-known biomarker of Alzheimer Disease (AD), its use in a clinical setting is limited because atrophy begins years before clinical onset. This preclinical (amyloid positive) stage of AD is undetectable without amyloid biomarkers and is present in over a third of older populations, making it difficult to separate the atrophy of normal aging from AD. Separating atrophy of other dementia types from AD is similarly difficult as the affected regions overlap, though AD-specific patterns of atrophy have been reported. We aim to create atrophy-based biomarkers from structural Magnetic Resonance Images (MRI) that can best distinguish patients with various dementia types. Methods: A cognitively normal (CN) cohort, sourced from the Open Access Series of Imaging Studies (OASIS), was used to determine age-specific norms. Only β-amyloid negative individuals (PiB-PET mean cortical SUVR < 1.42 or AV45-PET < 1.19) who remain CN (CDR=0) for >2 years after neuroimaging were included. Volumes and cortical thicknesses were extracted using the open-source software Freesurfer. After normalizing volumes to intracranial volume, measures were plotted by age and smoothed using a weighted LOESS regression. We next will use an unbiased approach to determine a weighted combination of measures that can best predict clinical diagnoses in symptomatic dementia patients. Results: 184 OASIS subjects age 42 to 84 fit criteria to form the CN cohort. Right and left hippocampal volumes declined an average of 27.15 and 25.90 mm^3 per year, with average volumes of 3897 (535.4) and 3794 (517.8) mm^3. The clinical data from dementia patients is in the process of being extracted. Conclusion: While a single test should not be used for medical diagnoses, structural neuroimaging is routinely obtained in patients with dementia. By increasing the amount of diagnostic information obtained from a structural MRI, our open-source tool will benefit patients and clinicians alike.

Title: Circulating GDF11 is associated with cortical thickness, amyloid burden, and cognitive performance

Authors: *M. J. SCHAFER, A. M. V. WENNBERG, E. J. ATKINSON, P. M. VANDERBOOM, H. R. BERGEN, III, R. C. PETERSEN, M. M. MIELKE, N. K. LEBRASSEUR
Mayo Clin., Rochester, MN

Abstract: Circulating factors that influence neuropathology can be leveraged as clinically useful diagnostic and prognostic biomarkers. Growth differentiation factor 11 (GDF11) is a hypothesized pro-rejuvenative protein that may impart neuroprotective effects through TGF-β signaling. Whether changes in circulating GDF11 levels are associated with cognitive decline

across the Alzheimer's disease (AD) dementia clinical spectrum or are associated with neuroimaging biomarkers of AD, including amyloid PET, cortical thickness on MRI, and hypometabolism measured by FDG-PET, is unknown. Using a highly precise liquid chromatography with tandem mass spectrometry (LC-MS/MS) assay, we explored cross-sectional associations between plasma GDF11 levels and AD imaging biomarkers and cognitive performance among cognitively unimpaired (CU) and mild cognitively impaired (MCI) older adults enrolled in the Mayo Clinic Study on Aging (MCSA). We show that higher GDF11 levels are associated with lower amyloid PET SUVR, as well as greater cortical thickness and brain metabolic activity in AD signature brain regions. Correspondingly, we demonstrate that higher plasma GDF11 levels are associated with better performance in language and memory tests. Our results suggest that circulating GDF11 levels are a potential biomarker of AD-related cognitive aging and early-stage dementia.

Abstract: Alzheimer's disease (AD) is known as a progressive disease that affects a gradual decline in brain function such as cognitive function, memory capability, and language processing. Recently, many researchers have been tried to early diagnose AD before clinical

symptoms emerge using amyloid-tracer PET and CSF. The biomarkers showed that presymptomatic AD (clinically normal but risk of developing AD) and normal aging can be distinguished. However, these imaging techniques are either very costly or painful due to highly invasive, thus they are difficult to utilize for longitudinal monitoring of disease progression. Electroencephalography (EEG) is a non-invasive neuroimaging technique that can be relatively easy and simple to measure the brain activity changes. In this study, we investigated EEG features and behavior performance according to disease progression from normal controls (NC), presymptomatic AD, prodromal AD to AD. Forty NC (aged 72.4±5.8), twenty patients with presymptomatic AD (aged 75.1±3.8), thirty patients with prodromal AD (aged 76.1±3.5), and eight patients with AD (aged 76.5±3.3) have been recruited in the experiment. All subjects performed three experimental paradigms-visual oddball, 1-back working memory, and verbal fluency task-in a consecutive order during 32-channel wireless EEG with dry electrodes (g.tec, Austria) recording at a sampling rate of 500 Hz. The behavior performances of the oddball and 1-back task were estimated using correct button response. Event-related (de-)synchronization (ERD/ERS) were used as EEG features. In the oddball task, behavior accuracy showed a weak decrease in presymptomatic AD ($p = 0.101$), prodromal AD ($p = 0.082$), and AD ($p = 0.061$) compared to NC. The 1-back performance (both accuracy and reaction time) showed significant decline in AD ($p < 0.05$) compared to the other groups. In addition, reduced beta ERS in centro-parietal area was observed in both prodromal AD and AD compared to NC ($p < 0.1$) during 1-back task. The beta ERS was also decreased in presymptomatic AD, but there was no significant difference compared to NC. We found that there were some differences among NC, prodromal AD, and AD, however, neurophysiological difference between NC and patients with presymptomatic AD was unclear. It may seem to be trivial because we cannot clinically distinguish presymptomatic AD from normal ageing. In further analysis, we will investigate EEG features for each task (cognitive, working memory, and verbal processing) and integrate them into a new biomarker. We expect that integrated features may be helpful for diagnosis of presymptomatic AD, as well as for longitudinal monitoring of disease progression.

Title: Mass spectrometry imaging technique reveals a novel visualized metabolism map in the brain of Alzheimer's disease's mouse model

Authors: ***F. GAO**[1], X. WANG[2], X. YANG[2], G. HUANG[2], Y. SHEN[3]
[1]Sch. of Life Sci., Univ. of Sicence and Technol. of China, AnHui Province, China;
[3]Neurodegenerative Dis. Res. Ctr. (NDRC), [2]Univ. of Sci. and Technol. of China, Hefei, China

Abstract: The current therapies for Alzheimer's disease (AD) in clinic are based on neurotransmitters as therapeutic targets. However, using traditional mass spectrometry (MS) coupled to HPLC techniques to analysis the small molecular metabolites in tissue homogenate, it is still not possible to visualize how those neurotransmitters, are generated and metabolized in the whole brain simultaneously during the aging process and AD disease progress. Fully characterization of the disrupted metabolic pathways in aging as well as in the AD brain may provide new diagnostic biomarkers and therapeutic targets for AD. In the present study, we have modified an ambient mass spectrometry imaging (MSI) method based on desorption electrospray ionization (DESI) and we are now able to detect hundreds of small molecular metabolites in situ of whole mouse brain, including the spatial distribution and the relative abundance of metabolites in the brain. We analyzed the alteration of the metabolites in process of ageing and pathogenesis of AD. We observed that more than 100 small molecule metabolites, including neurotransmitter metabolites, i.e. glutamine-glutamate/GABA cycle, were altered at the very early stage in AD model mice (APP23), suggesting the metabolism was disrupted before deposition of Aβ plaques in the brain. Thus, our study reveals metabolic alterations at spatiotemporal resolution that implicated in AD pathogenesis, which may benefit for early diagnosis and drug development for AD.

Title: Effect of probiotic treatment on metabolic profile of serum and brain prostaglandin and bile acids in a transgenic mouse model of Alzheimer's disease

Authors: *H. KAUR[1], M. Y. GOLOVKO[2], C. K. COMBS[3]
[1]Dept. of Biomed. Sci., [2]Dept of Biomed. Sci., Univ. of North Dakota, Grand Forks, ND; [3]Dept of Biomed. Sci., Univ. of North Dakota Sch. of Med., Grand Forks, ND

Abstract: Increasing evidence suggests the involvement of intestinal dysbiosis and associated metabolic changes in the pathogenesis of various brain disorders. Clinical studies have demonstrated the effectiveness of probiotics for treatment of intestine and brain related diseases. However, the mechanisms by which intestinal microbiota modulate brain functions are unclear. In this study we examined eicosanoids including prostaglandins as well as primary and microbiota-derived bile acids in a mouse model of Alzheimer's disease. Wild type (WT) control C57BL/6 mice were compared to a mouse line that has the human Aβ sequence knocked in to the mouse APP gene along with three disease causing mutations (APP NL-G-F). The animals at 7 months of age were randomly divided into two groups and orally treated with vehicle or probiotic (VSL#3) for 8 weeks. Microbiome analysis was performed to study the effect of probiotic supplementation on intestinal microbiota. Eicosanoids and bile acids were also analyzed in serum and brain using UPLC-MS/MS. The microbiome results showed a significant decrease in the ratio of Firmicutes/Bacteroidetes in vehicle treated AD mice compared to wild type controls suggesting intestinal dysbiosis. VSL#3 supplementation resulted in a dramatic change in microbiota composition in both WT and APP NL-G-F treated lines. Multiple significant decreases in serum and brain bile acids were observed in vehicle treated APP NL-G-F mice as compared to WT controls. Interestingly, VSL#3 feeding significantly altered serum and brain bile acid levels in WT but not APP NL-G-F mice. Various serum eicosanoids were significantly increased in vehicle treated APP-NL-G-F mice as compared to WT controls. However, brain eicosanoids were mostly decreased in vehicle treated APP NL-G-F mice compared to WT controls. Probiotic supplementation had an ability to decrease levels of several serum eicosanoids in APP NL-G-F mice. However, probiotics decreased levels of brain eicosanoids only in WT animals with no effect on APP NL-G-F mice. Our study demonstrates an altered eicosanoid (including prostaglandin) and bile acid metabolome profile associated with intestinal dysbiosis in Alzheimer's disease mice. Moreover, it suggests that probiotic intervention may exert a beneficial effect in AD mice by altering eicosanoid levels in the brain.

Title: Aging, brain white matter hyperintensities, and structural brain network efficiency in 2257 participants of the framingham heart study

Authors: *S. SEILER[1], E. FLETCHER[1], A. BEISER[2], J. J. HIMALI[2], C. L. SATIZABAL[2], S. SESHADRI[2], P. MAILLARD[1], C. DECARLI[1]

Abstract: Objective There is evidence that aging and vascular damage affect the structural brain network. Data from large datasets on healthy individuals are scarce. We therefore explored the effects of aging and white matter hyperintensities (WMH) on the structural brain network of 2257 healthy participants of the cross-sectional Framingham Heart Study over a wide age range. Methods We computed the structural brain network of 2257 healthy participants of the Framingham Heart Study (mean age: 54 (13) years, range: 26 to 91 years; 53% female) from diffusion tensor imaging (DTI) probabilistic fiber tractography using the FSL program PROBTRACKX. A connectivity matrix was constructed for 64 automatically segmented gray matter regions, covering the whole cortex. WMH were segmented automatically using published protocols. We calculated global efficiencies for the whole network and nodal efficiencies for 64 individual nodes using the freely available R code “brainGraph”. “brainGraph” is based on published and widely used network analysis protocols. We assessed the relationships between global and nodal efficiencies, age, and WMH volumes using multiple linear regression analyses. To assess regional differences, we computed the structural core of the network using s-core decomposition. All analyses were computed using R and adjusted for age as appropriate, gender, and total cranial volume. Results Lower global efficiency correlated significantly with higher age (β=-0.18, p=9.59x10^{-9}) and higher WMH volume (β-0.14, p=5.11x10^{-7}). Node-wise analysis and s-core decomposition revealed that this relationship was different for nodes belonging to the structural core as compared to more peripheral nodes. Efficiency of core nodes correlated positively with age (β=0.18, p=2.73x10^{-9}), while peripheral nodes showed a negative relationship (β=-0.21, p=2.51x10^{-12}). An age-independent negative effect of WMH volume on efficiency was present in the peripheral network only (β=-0.11, p=5.05x10^{-5}). Conclusion Higher age and larger WMH volumes correlated with lower efficiency of the peripheral network, while the central network shows an opposite relationship. If the age-resistance of the central network expresses the brains scaffolding or a compensatory mechanism in response to age-related changes remains to be determined.

Abstract: Translational research in Alzheimer’s disease (AD) pathology provides evidence that accumulation of amyloid-β and hyperphosphorylated tau, neuropathological hallmarks of AD, is associated with complex disturbances in synaptic and neuronal function leading to oscillatory abnormalities in the neuronal networks that support memory and cognition. Accordingly, our recent study on transgenic TgF344-AD rats modeling AD, showed an age-dependent reduction of stimulation-induced oscillations in the hippocampus, and disrupted long range connectivity together with enhanced neuronal excitability in the cortex, reflected in greatly increased expression of high-voltage spindles (HVS), an epileptic absence seizure-like activity (Stoiljkovic et al., 2017). To better understand the translational value of observed oscillatory abnormalities in these rats, we examine here the effects of donepezil, an acetylcholine esterase inhibitor clinically approved for AD treatment. Nucleus pontis oralis (nPO) stimulation-induced hippocampal oscillations were recorded under urethane anesthesia in adult (6-months old, n=6) and aged (12-months old, n=5) TgF344-AD and wild-type (WT) rats. Spontaneous cortical activity was monitored in a cohort of freely-behaving aged rats (n=5, for each genotype) implanted with frontal and occipital cortical EEG electrodes. Subcutaneous administration of donepezil significantly augmented stimulation-induced hippocampal theta oscillation in aged WT rats and both adult and aged TgF344-AD rats, which had been previously shown to have diminished response to nPO stimulation. Moreover, in TgF344-AD rats donepezil also significantly increased theta phase-gamma amplitude coupling in the hippocampus during stimulation. However, neither of these effects were significantly changed in adult WT rats. In freely-behaving condition, donepezil treatment had opposite effect on cortical oscillatory connectivity in TgF344-AD and WT rats, and it reduced the occurrence of HVS activity in TgF344-AD rats. Together, these results imply that pharmacologically enhancing cholinergic tone with donepezil could

partially reverse oscillatory abnormalities in TgF344-AD rats, which is in line with its clinical effectiveness in AD patients. Therefore, our study suggests good translational opportunities for these neurophysiological signals recorded in TgF344-AD rats, and their application could be considered in drug discovery efforts for developing therapies with disease-modifying potential.

Abstract: Abstract:
Vascular dysfunction is increasingly recognized in the pathophysiology of Alzheimer’s disease (AD), and measures of vascular dysfunction can be evaluated using cerebrospinal fluid (CSF) and imaging-based biomarker approaches. A clinical need exists to identify reliable biomarkers for early AD diagnosis, early intervention, and evaluating the efficacy of clinical trials. Here, we quantified novel CSF biomarkers of responses and injury to the neurovascular unit (NVU) – comprising vascular cells, glia, and neurons – using antibody-based single/multiplex assays. CSF was obtained from human subjects of the University of Southern California Alzheimer’s Disease

Research Center (ADRC), Huntington Medical Research Institutes, and the Washington University Knight ADRC. CSF biomarkers of the NVU were analyzed in relation to subjects' cognitive status [no cognitive impairment (NCI) vs. mild cognitive impairment (MCI)] and AD genetic risk factor apolipoprotein E-ε4 (*APOE4*) [carriers vs. non-carriers]. We found that CSF-based biomarkers of the blood-brain barrier/vascular injury are altered in *APOE4* carriers versus non-carriers with NCI and these markers are further altered in *APOE4* carriers versus non-carriers with MCI. Furthermore, preclinical changes in the mural cell vascular injury marker, soluble platelet-derived growth factor receptor-β (sPDGFRβ), is related to early cognitive impairments, independent of CSF amyloid-β $(Aβ)_{42}$ and phosphorylated tau levels, and predict longitudinal decline in cognitive function. These data suggest that CSF biomarkers of cerebrovascular dysfunction are altered early in cognitive impairment and accelerated in *APOE4* carriers. Moreover, vascular biomarkers (e.g., CSF sPDGFRβ) may be a useful predictor of subtle cognitive dysfunction. Altogether these data importantly elucidate the detectable changes in CSF of neurovascular injury across the preclinical-MCI-AD spectrum.

Title: Neuropsychological decline improves prediction of dementia beyond ad biomarker and mci diagnoses

Authors: *D. A. NATION[1], J. K. HO[1], S. DUTT[2]
[2]Psychology, [1]USC, Los Angeles, CA

Abstract: Introduction: Cognitive diagnosis in older adults is traditionally based on a single exam, but serial testing is required to detect cognitive changes in preclinical Alzheimer's disease when cognitive performance is within normal range. We evaluated the prognostic utility of longitudinal diagnosis of cognitive decline in older adults with and without preclinical

Alzheimer's disease. Methods: Regression models quantified 12-month neuropsychological decline relative to normative expectations among dementia-free older adults (N=1074). Progression to Alzheimer's dementia over follow-up (18-120 months) was diagnosed using independent modes of assessment. Baseline brain volumes were compared between older adults with and without longitudinal decline using voxel-based morphometry. Results: In Cox regression models controlling for age, sex, education, apolipoprotein E4, and baseline cognitive diagnosis, neuropsychological decline predicted increased dementia risk,X^2=69.810, p<.001, odds ratio=2.903, even after correction for cerebral spinal fluid biomarkers (amyloid-beta, phosphorylated tau, total tau), X^2=28.202,p<.001, odds ratio=2.364. Voxel-based morphometry analysis indicated smaller hippocampal and medial temporal volume in participants with neuropsychological decline. Discussion: Preclinical decline was detectable and highly predictive of future dementia. Patients showing longitudinal decline exhibited greater evidence of hippocampal and medial temporal lobe atrophy. Assessment of neuropsychological trajectory would improve patient selection and randomization for clinical trials.

Title: Oligomeric abeta as a mechanistic biomarker for alzheimer's disease in human plasma

Authors: *M. LADU[1], N. COLLINS[2], D. BALU[1], C. ESTRADA[1], J. GEORGE[1], L. J. VAN ELDIK[3], A. C. VALENCIA-OLVERA[1]
[1]Anat. and Cell Biol., Univ. of Illinois, Chicago, Chicago, IL; [2]Genet. Counseling,, Indiana StateUniversity, Terre Haute, IN; [3]Univ. of Kentucky, Lexington, KY

Abstract: *APOE4* is the greatest genetic risk factor for Alzheimer’s disease (AD), increasing risk up to 15-fold compared to the more common *APOE3*. Autosomal dominant mutations that increase the peptide amyloid-β (Aβ42) cause the rare familial form of AD. Aβ42 aggregate to form amyloid plaques and soluble oligomeric Aβ (oAβ), the latter considered a proximal neurotoxin. Among *APOE4* carriers, females have an increased AD risk, rate of cognitive loss and accumulation of Aβ42 compared to males. Thus, our hypothesis is that oAβ is a mechanistic biomarker that can track AD progression based on *APOE* genotype and sex. Many current AD biomarkers for are not predictive, reliably diagnostic or easily measured. To test the value of oAβ as a biomarker, we developed a unique monoclonal antibody, MOAB-2, that enabled

development of an ELISA that detects 1pg/ml oAβ. In addition, we developed the EFAD mice, a novel preclinical transgenic mouse that overexpresses human Aβ42 and expresses the human *APOE* genotypes. In EFAD mouse brains, Aβ42 levels correlate with *APOE*-modulated AD pathology, while oAβ levels correlate with *APOE* and sex-modulated AD pathology, as well as and disease progression. Therefore, we measured oAβ levels in brain and plasma from healthy controls and AD patients with *APOE3* or *APOE4* genotypes (n=50-72, from the Alzheimer's Disease Center of the University of Kentucky). In brain and plasma, oAβ levels were higher in AD vs. control. In brain, stratification by genotype and sex within the AD cohort, reveal oAβ levels higher only in *APOE4/4* females. In plasma, stratification of the AD cohort by sex and *APOE* reveal significantly greater oAβ levels in *APOE4* vs. *APOE3* and females vs. males. Importantly, when the data is further stratified by sex within genotype, oAβ levels are higher in female *APOE4/4* vs. male *APOE4/4* and in male *APOE4/4* vs. male *APOE3/4*. These results support our hypothesis that changes in oAβ levels underlie the *APOE4* and female-induced risk for AD. Furthermore, oAβ changes driven by *APOE4* and female sex are detected with higher sensitivity in plasma vs. brain indicating a promising non-invasive novel mechanistic biomarker. Future longitudinal studies will determine thresholds and establish the predictive value of oAβ in plasma as a mechanistic biomarker. Such a mechanistic biomarker is critical for effective prediction of AD and will enable clinical studies to determine the efficacy of predictive therapeutics.

Title: The lesion analysis of amyloid plaques in the three-dimensional level of whole brain

Authors: *B. LONG, J. ZHANG, X. LI, H. GONG
Wuhan Natl. Lab. for Optoelectronics, Hubei, China

Abstract: Amyloidosis of the central nervous system has been widely proved to be one of the main hallmarks in Alzheimer's disease (AD). According to the amyloid cascade hypothesis, the accumulation of neurotoxic amyloid plaques in the brain is intrinsic and fundamental for disease

onset, however the spatiotemporal origins of the lesions remain unknown. Here, we explored an easy-handling staining method to label whole brain amyloid plaques and imaged with fluorescence micro-optical sectioning tomography system (fMOST). We performed brain-wide comprehensive study of progressive amyloid plaques between the 5XFAD mice and C57BL/6J control mice at different age. The three-dimensional datasets showed that the lateral septum, subiculum and hippocampus were the primary susceptibility to Aβ accumulation in 5XFAD mouse model. Therefore, the combination of the present whole-brain staining method and fMOST technology provided detailed overview of the amyloid plaques in the whole mouse brain, which will contribute to the study of Alzheimer's disease.

Title: CMP^3: A CSF multiple pathophysiology panel for clinical trials in Alzheimer's disease

Authors: *B. A. TROMBETTA, B. C. CARLYLE, S. E. ARNOLD
Neurol., Massachusetts Gen. Hosp., Charlestown, MA

Abstract: Background
Alzheimer's disease (AD) is a complex disease driven by cycles of protein misfolding, inflammation, and neurovascular and metabolic dysfunction. Although tau and amyloid-β levels in cerebrospinal fluid (CSF) are strong indicators of AD pathology, they are inadequate for measuring disease progression or drug response. To diagnose the disease earlier and expand opportunities for intervention, it is critical to develop more sensitive and diverse biomarkers of AD. Measurement of proteins in pathways that drive AD may provide better biomarkers of disease susceptibility, progression, and therapeutic effects. We investigated a collection of 30 CSF biomarkers that represent diverse pathways active in AD. These analytes will be used to derive a CSF multi-pathophysiology panel ("CMP3") of biomarkers for the diagnosis, staging, and pathophysiological profiling of AD.
Methods
MesoScale Discovery and Quanterix multiplex assays were used to quantify a targeted selection

of CSF protein biomarkers relevant to neurodegeneration, metabolism, oxidative stress, vascular injury, and neuroinflammation. Analyte concentrations were determined in a well-characterized cohort (n=85) of AD cases with mild-stage dementia and well-matched cognitively unimpaired aged controls. CSF samples were collected by the Penn Memory Center and MassGeneral Institute for Neurodegenerative Disease (MIND) Tissue Bank. The cohort was comprised of 40 men and 45 women, predominantly Caucasian (81/85), with a mean age of 67.6 (11.8) years.

Results

Statistical modeling of disease severity correlation, hierarchical clustering of analytes, and analysis of confounding variables were performed. From this preliminary evaluation, we identified several analytes that correlated significantly with core AD biomarkers. We found that creating pathophysiological profiles incorporating these analytes increased the diagnostic accuracy of CSF biomarkers to differentiate between cognitively unimpaired individuals and AD.

Conclusions

Development of a CSF panel that encompasses multiple key pathways in AD could transform CSF outcome measures included in AD clinical research studies. These findings may help clarify the diverse and interrelated changes among various mechanistic pathways of AD onset and progression, with the potential for individual stratification and enabling personalization of treatment approaches. Larger studies are warranted to test the utility of the panel for measuring AD severity across the spectrum of pre-clinical AD, MCI, and late-stage dementia, and compared to other neurodegenerative diseases.

Title: TOMM40 & APOE gene expression & cognitive decline in Japanese Alzheimer’s disease subjects

Authors: *J. IGA, A. MISE, Y. YOSHINO, K. YAMAZAKI, Y. OZAKI, T. SAO, T. YOSHIDA, T. MORI, Y. MORI, S. OCHI, S.-I. UENO
Neuropsychiatry, Ehime Univ., Toon, Japan

Abstract: Background: *TOMM40* is located on chromosome 19, is in linkage disequilibrium with *apolipoprotein E* (*APOE*), and is reported in several genome-wide association studies to be associated with Alzheimer's disease (AD).
Objective: Assess *APOE* and *TOM40* and mitochondrial genes as blood biomarkers for AD.
Methods: We examined *TOMM40, PTEN-induced putative kinase 1* (*PINK1*), *Parkin RBR E3 ubiquitin protein ligase* (*PARK2*), and *APOE* mRNA expression in relation to the methylation rates of CpG sites in the upstream region of *TOMM40* exon 1 in peripheral leukocytes and *TOMM40* 523 polyT genotypes in 60 AD and age- and sex-matched control subjects.
Results: *TOMM40* mRNA expression was significantly lower in AD subjects (0.87 ± 0.18 vs. 1.0 ± 0.23, p = 0.005), and *PINK1* mRNA expression was higher in AD subjects (1.5 ± 0.61 vs. 1.0 ± 0.52, p < 0.001). *TOMM40* mRNA expression was significantly correlated with the Mini-Mental State Examination total score (r = 0.290, p = 0.027). There was no expressional change in peripheral *APOE* mRNA in either AD or control subjects (p = 0.32). Methylation rates in the upstream region of *TOMM40* exon 1 were not different between AD and control subjects (average rate: 1.37 ± 0.99 vs. 1.39 ± 1.20, p = 0.885), and *TOMM40* 523 polyT genotypes were also not different between AD and control subjects (p = 0.67).
Conclusion: *TOMM40* mRNA expression was lower in AD subjects and was correlated with cognitive decline. Significant changes in both *TOMM40* and *PINK1* mRNA may be related to mitochondrial dysfunction.

Title: ApoE-å4 suppresses age-dependent increases in plasma Aâ42 levels

Authors: T. NAKAMURA, *T. KAWARABAYASHI, Y. SEINO, M. HIROHATA, S. MIKIO
Hirosaki Univ. Grad. Sch. of Med., Hirosaki, Japan

Abstract: Background: There is a great need for biomarkers that could predict onset of cognitive impairment and diagnose early stage of Alzheimer's disease (AD). Some recent publications have been describing the usefulness of plasma Aβ as a biomarker of CNS amyloidosis, but a unified view has not been proposed yet. **Methods**: Plasma Aß40, Aß42 levels are measured by ELISA in 1,109 participants in the first year of the Iwaki Health Promotion (IHP) Project, and plasma Aβ levels are measured every 1 year in 554 out of 1,109 participants

for 4 years. Basic profiles of health of 600 items include height, weight, body fat percentage, ability of exercise, MMSE score, WMS-R, ADL, blood chemistry, whole genome analysis including the ε4 genotype of apolipoprotein E (ApoE). We analyzed whether these items affect levels of plasma Aβ. **Results**: (1) In First year, a significant linear increase with age was observed for Aß40 levels ($Y=0.4724X+79.65$, $r^2=0.2208$, $p<0.0001$), Aß42 levels ($Y=0.02466X+10.04$, $r^2=0.04898$, $p<0.0001$), and the Aß40/42 ratio ($Y=0.02234X+8.113$, $r^2=0.09725$, $p<0.0001$). (2) These linear lines were affected by presence of ApoE-ε4. Age-dependent plasma Aβ42 increases were suppressed by ApoE-ε4 ($p<0.0001$), and plasma Aβ40/42 ratios increases were enhanced by ApoE-ε4 ($p<0.0001$). (3) The same trends were observed for each year follow-up. **Conclusions**: Adjustment for aging and ApoE-ε4 allele are needed to measure plasma Aβ as a biomarker of CNS amyloidosis in the future research.

Title: Aerosol delivery of thioflavin for retinal amyloid-beta plaque detection in Alzheimer's disease mouse model

Authors: *S. BARTON[1], V. A. JANVE[2], E. TO[4], J. MATSUBARA[4], W. PHAM[3]
[2]Biomed. Engin., [3]Radiology and Radiological Sci., [1]Vanderbilt Univ., Nashville, TN; [4]Ophthalmology & Visual Sci., Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Alzheimer's disease (AD) is a neurodegenerative disorder characterized by memory loss and executive dysfunction. There are currently no disease modifying therapeutics available and major clinical trials have been unsuccessful. One reason for failure of these trials is at the time of treatment, significant and irreversible neurodegenerative changes have already occurred such that a therapeutic benefit cannot be achieved. Therapeutic efficacy could potentially be improved if initiated in presymptomatic stages of disease. However, techniques to detect AD pathology are expensive or invasive and cannot be readily used in an asymptomatic population. Recent studies have shown β-amyloid (Aβ) plaques, a pathologic feature of AD, are found in the retinas of AD patients and preclinical mouse models. It is hypothesized that retinal plaques could serve as a surrogate biomarker for total plaque burden in the brain and early detection could

identify patients with AD prior to symptomatic onset. As such, we are developing a noninvasive method of retinal plaque detection using thioflavin, a fluorescent Aβ-binding molecule that could be visualized when bound. Thioflavin has poor blood brain barrier permeability and thus limited penetration across the blood-retinal barrier. However, we have shown that delivery of thioflavin via nebulization significantly improves delivery to bind Aβ in the brain. Our current study is to investigate aerosol delivery for detecting Aβ plaques in the retina.
Wild-type (WT) and 5xFAD mice, a transgenic model of AD, were treated with aerosolized thioflavin. Retinal tissue whole-mounts and transverse sections were prepared and analyzed using confocal microscopy. Thioflavin fluorescence was closely associated with ganglion cell bodies in the same retinal layer where Aβ plaques were found in non-treated 5xFAD retinas stained with anti-Aβ antibodies. Importantly, thioflavin was not detected in treated WT retinas. These findings demonstrate that thioflavin retention is plaque-dependent. In future work, retinas from treated 5xFAD mice will be co-stained for Aβ to confirm thioflavin is bound to plaques. Treated 5xFAD mice will also be imaged *in vivo*, using a retinal imaging microscope to determine if thioflavin fluorescence can be detected noninvasively. If successful, aerosolized thioflavin could be used to evaluate retinal Aβ plaques as a predictive biomarker for development of AD and facilitate early intervention to improve therapeutic outcomes.

Title: Determining the fatty acid/lipid profiles of 3xTg-AD mice in plasma and in red blood cell membranes

Authors: S. HOULE[1], B. GENOVESE[2], R. A. QUINLAN[2], L. S. WEBB[2], *D. A. MITRANO[2]
[1]Neurosci. Program, [2]Mol. Biol. & Chem., Christopher Newport Univ., Newport News, VA

Abstract: Alzheimer's disease (AD) is the most common form of dementia, accounting for anywhere between 60 to 80 percent of all dementia cases in the United States. The disease is progressive and has no cure, making it the sixth most common cause of death in the United States. While the disease is progressive, those who suffer may have AD for several years before

they begin to notice its hallmark symptoms. With only two FDA- approved treatments available, early diagnosis is paramount in the effort to improve the quality of life for those with AD. Recently, several studies have identified 10 lipid biomarkers found in the blood that can be used to predict (with 90% accuracy) a shift from normal cognitive function to mild cognitive impairment. These biomarkers (particularly phosphatidylcholine) are predictive of a downturn in cognition due to their nature as a component of lipoproteins. For this reason these molecules interact with ApoE; of which the ApoEε4 allele is known to be a genetic risk factor for familial Alzheimer's disease. This study, therefore, ultimately seeks to further validate the 3xTg-AD mouse model for human Alzheimer's by creating blood lipid profiles through establishing and analyzing standard curves from high pressure liquid chromatography and mass spectrometry (HPLC-MS) of the plasma and red blood cell membranes of the 3xTg-AD mice to one day aid in the development of a blood biomarker that can be used to diagnose AD in humans.

Title: Young to middle-aged dogs with high Abeta-levels show higher pTau levels in CSF

Authors: *H. BORGHYS, B. VAN BROECK, C. THEUNIS, F. TEKLE, D. DHUYVETTER
Janssen Res. & Develop., Beerse, Belgium

Abstract: Understanding the relevance of changes in Alzheimer's disease biomarkers that occur before the pathology becomes evident, can contribute to the development of a treatment for Alzheimer's disease. A longitudinal follow-up of an animal species with a similar amyloid pathology in the brains as in humans may contribute to this research. Amyloid plaque formation is one of the two main neuropathological hallmarks of Alzheimer's disease in humans. Dogs are similar to man with respect to amyloid precursor protein (APP)-processing and age-related amyloid plaque deposition. Dogs also are used as a natural model of age-dependent cognitive dysfunction. In our colony of beagle dogs Aβ-concentrations in cerebrospinal fluid (CSF), sampled in awake animals from the lateral ventricle, were regularly measured over a period of years. We identified dogs showing low or high Aβ42 levels and formed two groups of eight animals each. The age of the animals, which ranged from 2-6 years, was comparable between both groups. Since dogs normally start to develop amyloid plaques from an age of 9-10 years onwards, these dogs are assumed to have no or minimal amyloid plaque formation.To assess baseline pTau levels in these animals, four CSF samples were taken within a period of 8 days. In

the same samples Aβ 1-37/1-38/1-40 and 1-42 were measured. We have found that the dogs with high Aβ levels in CSF also show high pTau levels.

Abstract: Since there is no single established causative factor in over 95% of Alzheimer’s cases, understanding the roles of various Alzheimer’s disease (AD) risk factors will be essential in reducing the prevalence of AD and developing therapeutic treatments. The occurrence of non-fatal traumatic brain injury (TBI) in military personnel has increased with the widespread use of improvised explosive devices in recent wars. TBI has been identified as a risk factor for developing dementia later in life, but the molecular mechanisms underlying associations between TBI history and AD risk remains to be elucidated. In this study, we perform a retrospective analysis on TBI history and clinical Alzheimer’s diagnosis data from a sample of 1.1 million veterans from VA healthcare systems nationwide through the VA Informatics and Computing Infrastructure (VINCI). Patient’s history of TBI and AD status were determined by ICD-9 and ICD-10 diagnosis codes. We found 160,581 patients with at least 1 diagnosis of TBI and 60,704 of these patients were over the age of 50 with at least 2 confirmed TBI diagnoses. Additionally, we analyzed TBI history, Alzheimer’s status and plasma amyloid β protein (Aβ) levels in a group of 75 veteran AD and older control patients. No statistically significant association was identified between the plasma Aβ42 levels within either the AD or control group based on TBI

history. In conclusion, we demonstrate that a notable fraction of the veteran population with a history of TBI has a diagnosis of AD, suggesting that TBI and AD are closely associated. Further research, including further testing of other AD biomarkers in plasma, is needed to fully explore the contribution of TBI history to AD risk. This study was supported by the Veterans Affairs Office of Research and Development (WX), NIH (LM), and the Cure Alzheimer's Fund (WX).

Title: Abnormal inhibitory attention in patients with idiopathic REM sleep behavior disorder reflected in theta- and beta-band activities

Authors: *S. HEO[1], D. YEO[1], K. CHA[1], P. SEO[1], H. KIM[1], S. CHOI[1], J. CHOI[1], K.-Y. JUNG[2], K. KIM[1]

Abstract: Idiopathic rapid-eye movement (REM) sleep behavior disorder (IRBD) is a sleep disorder characterized by dream enactment behavior and the loss of muscle atonia during REM sleep. IRBD patients are known to be associated with high risk of developing neurodegenerative diseases, such as Parkinson's disease, multiple system atrophy, and dementia with Lewy bodies. Visuospatial abilities, attentional and executive functions have also been reported to be impaired in IRBD. We investigated the dysfunctional visuospatial attention of IRBD patients, focusing on the inhibition of return (IOR), based on event-related electroencephalograms (EEGs) and their cortical current sources in frequency domain. Sixteen drug-naïve idiopathic RBD patients (age: 64.9±6.9 years, F: 3, M: 13) and nineteen healthy controls (age: 63.4±7.3 years, F: 5, M: 14) performed Posner's cueing task while sixty-channel EEGs were recorded. When the target is presented in cued location, the condition is "valid". If the target appears on the contralateral side

of the cue, the condition is “invalid”. Cortical source current densities were estimated using weighted minimum norm estimate method, and then, time-frequency analysis were performed to obtain event-related spectral perturbation (ERSP). To investigate IOR effect, ERSP was compared between validity using mass univariate analysis method.The IOR effect in behavior was found in controls but not in the IRBD group. The IOR effects in theta-band and beta-band ERSP were found only for the control subjects, in visual cortex at 100-300 ms, and in motor regions at 200-500 ms, respectively. The theta- and beta-band activities seems to reflect visual perception and motor processes, which are essential for the attention-mediated target processing. The lack of IOR effects in ERSP may indicate cortical dysfunction for attentional inhibition associated with IRBD.

Title: Proteomic profiles of plasma and post-mortem brain tissues from Alzheimer’s patients

Authors: M. CHEN[1], G. SURPRIS[2], T. D. STEIN[3], *W. XIA[4]
[1]Bedford VA Hospital, Harvard TH Chan Sch. of Publ. Hlth., Bedford, MA; [2]Bedford VA Hosp., Bedford, MA; [3]Boston VA Med. Ctr., Boston, MA; [4]GRECC, Pharmacol. & Exptl. Therapeut., Bedford VA Hospital, Boston Univ., Bedford, MA

Abstract: Alzheimer’s disease (AD) is one of the most common neurodegenerative disorders in US. Inflammation has been shown to be a major factor in late onset Alzheimer’s disease (LOAD). Increased inflammatory profile of blood lymphocytes, and the inflammation mediated diseases such as AD converge on vulnerabilities caused by an aging immune system. The current biomarkers for AD in cerebrospinal fluid (CSF) are limited by the relatively invasive nature of CSF sampling. Studies in human plasma have been conducted in searching for reliable biomarkers of AD. The purpose of this study is to use mass spectrometry (MS)-based analysis to find the connection between the peripheral and central nervous system, and to explore proteins associated with neuroinflammation in AD pathogenesis. To accomplish this, we collected blood and at autopsy, post-mortem brain tissue (from superior frontal cortex, inferior cortex and

cerebellum area) from five Alzheimer's disease (AD) patients and five healthy controls. Liquid chromatography/MS was used to analyze plasma proteins and proteins in brain tissues labeled with isobaric mass tags (TMT) for relative protein quantification and differentially expressed proteins were identified. We also examined protein-protein interaction networks associated with the mechanism of AD through a bioinformatics approach. Our study revealed a group of differentially expressed plasma proteins that are associated with AD, including those proteins involved in inflammation, lipid metabolism and disturbed metal homeostasis. Comparative analysis between the plasma proteins and brain tissue proteomics from the same AD patients revealed the top enriched common pathways related to neuroinflammation. In AD brain tissue, oligodendrocyte proteins such as PLP1 and CNPase, and astrocyte proteins GFAP and S100B, proteins associated with increased glial differentiation and activation, were up-regulated, while MAP2, a protein associated with neural dendrites, was reduced. This specifies a change in the proteomic signature of the AD brain that underlies the pathology of reactive gliosis and the loss of synaptic integrity. In conclusion, a group of dysregulated proteins associated with AD was identified in plasma and three brain regions from AD. Our comparative proteomic analysis between plasma and brain regions of the same subjects shows the relevance between peripheral compartment and central nervous system.

Title: A subset of gene expression profiles in human post-mortem brain aging and Alzheimer's disease are robust, concordant, and show exaggerated changes in female Alzheimer's disease subjects

Authors: *K. HARGIS-STAGGS[1], E. S. JOHNSON[2], N. M. PORTER[3], O. THIBAULT[4], E. M. BLALOCK[5]
[2]Dept. of Pharmacol. and Nutritional Sci., [3]Pharmacol. and Nutritional Sci., [1]Univ. of Kentucky, Lexington, KY; [4]Dept. of Pharmacol. and Nutritional Sci., Univ. Kentucky Med. Ctr., Lexington, KY; [5]Dept Pharmacol, Univ. Kentucky Coll Med., Lexington, KY

Abstract: Sporadic Alzheimer's disease (AD) is increasing in parallel to the aging population, with the majority (~2/3) of AD cases affecting women. AD is a complex disease characterized by amyloid beta and neurofibrillary tangle pathologies, and risk factors include head injury, high blood pressure, high cholesterol, and inheritance of certain gene variants (e.g., ABCA1, APOEe4, APOEe2, etc.). Despite the vast amount of research, successful therapies that modify the disease have yet to be developed. One reason could be that some unmodifiable risk factors, such as aging and sex, contribute to vulnerability and progression in AD as well, but their molecular roles have not been robustly assessed. We hypothesize that a subset of age-related transcriptional changes precede, and are exaggerated by, AD, and further that female AD sufferers will have exaggerated expression compared to males for this restricted subset of robustly identified genes. To address this, we looked at transcriptional profiles of normal human aging (8 profiles) and AD (9 profiles) to test for a statistically significant agreement for Aging or AD changes across independent samples from different labs. We further tested for a statistically significant relationship between robust aging and AD-related changes. We found 85 genes that were significantly changed with age, worsened in AD, and exaggerated in female vs male subjects These genes also showed very strong directional and magnitude-of-change agreement between normal aging and AD. Taken together, this panel of genes likely contains key candidate molecules for intervention testing and rationale therapeutic development.

Title: The role of vesicle trafficking in Alzheimer's disease: Development of exosome biomarkers

Authors: *V. EKUTA, G. LIAN, V. SHEEN
Neurol., Beth Israel Deaconess Med. Ctr., Boston, MA

Abstract: Background Alzheimer's disease (AD) is a progressive neurodegenerative disorder that causes dementia in the elderly. Recent evidence suggests that early AD detection is instrumental for designing appropriate therapeutics. Thus, developing a sensitive and predictive biomarker that detects disease onset is imperative. Our current understanding of AD

development is based on the amyloid hypothesis, which suggests that amyloid-beta fibril formation and aggregation leads to progressive neuronal cell death. Previous research implicates dysfunctional vesicle trafficking and lysosomal clearance in neurodegenerative disease. These observations suggest that vesicular trafficking impairments should precede amyloid-beta aggregation and AD clinical manifestations. Hence, our overall project goal is to determine whether vesicle trafficking-related protein changes may serve as a predictive AD biomarker. **Objective** 1. To determine vesicle trafficking protein serum and exosome composition differences among 4 patients that developed AD, 4 age-matched patients with mild cognitive impairment (MCI), and 4 healthy age-matched controls. 2. To identify putative vesicle trafficking candidate proteins and protein networks that discriminate between AD and healthy controls. **Methods** 1. Western blot analysis of serum samples to examine the expression of trafficking proteins in healthy controls, MCI, and individuals that later developed AD. 2. Western blot analysis of plasma exosome derived vesicle trafficking proteins in the populations noted above. 3. SOMAscan Proteomics to identify vesicle trafficking candidate proteins and novel protein markers in the populations noted above. **Results** 1. Western blot studies showed significantly increased LAMP-1 serum levels in patients that developed AD, relative to age-matched controls and MCI. 2. Western blot studies showed a trend (albeit not statistically significant) for increasing exosome LAMP-1 expression in patients that developed AD compared to healthy controls. 3. SOMAscan Proteomics Platform identified several candidate target proteins involved in lipid processing and vesicle trafficking with potential links to caveolin and filamin A. **Discussion** Our preliminary work suggests several trafficking proteins may be implicated in AD pathogenesis. Furthermore, serum changes in these proteins may be accompanied by exosome protein expression changes. A better mechanistic understanding will facilitate the development of a predictive AD serum biomarker.

Title: Development and Validation of an *in vitro* system for Alzheimer’s disease studies

Authors: W. LUO[1], J. LEE[2], L. MORIARTY[2], *E. JORDAN[2]
[1]Bio-Rad Labs. Canada Ltd., Mississauga, ON, Canada; [2]Bio-Rad Labs., Hercules, CA

Abstract: Alzheimer’s disease (AD) is one of the most common neurodegenerative diseases, which accounts for over 80% of dementia cases in people over 65 years old. The rapid increase in AD cases not only has a significant impact on the economy, but also imposes huge burdens on

families and society due to the disease rendering patients dependent upon others for their health and safety. Many disease models have been established to study AD, including animal models, primary cultures, stem cells models, and cancer cell models. While these models provide good opportunities for exploring and understanding AD development, they are still far from being ideal and are very limited, either due to high expense, difficult maintenance, or low correlation to real life situations. In our study, we developed a model system using easily-maintained human neuroblastoma cells (SH-SY5Y) which can be differentiated into mature neuron-like cells and further induced into AD-like cells. We validated the model system by checking the expression of key neural biomarkers, including AD markers, and demonstrated that this system can be used for AD drug screening tests. Additionally, we screened lncRNA panels to identify lncRNAs that are differentially expressed during the transition of these cells from neuroblastoma to the AD model system. This model system provides a great potential to mimic real AD development models and drug treatment. Based on its ease of establishment and flexibility to incorporate various techniques, it has the ability to be extremely beneficial for a range of biological and pharmaceutical applications.

Title: Retinal structural and functional changes in mouse models of Alzheimer’s and Parkinson’s disease

Authors: *C. T. NGUYEN[1], J. K. H. LIM[1], V. H. Y. WONG[1], A. J. VINGRYS[1], J. MULLEN[2], D. I. FINKELSTEIN[3], B. V. BUI[1]

Abstract: The retina is an accessible outpouching of the central nervous system and may reflect cortical changes that occur with Alzheimer’s and Parkinson’s disease. As retinal assessments such as electroretinography (function) and optical coherence tomography (structure) are simple and inexpensive to conduct they may prove useful as biomarkers of cortical disease that can be used to streamline drug discovery from animal to human studies. This work aims to examine

whether retinal function and structure are altered in animal models of Alzheimer's and Parkinson's disease across a range of timepoints. A transgenic mouse model of familial Alzheimer's Disease (5xFAD) and their wild-type (WT) littermates were studied at 6, 12 and 17 months of age (n = 10 - 17 / group). A toxin model of Parkinson's disease was induced in C57BL6/J mice using MPTP (1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine, 4x i.p. injections, 20mg/kg) and vehicle control and examined at day 21 and 45 post-induction. Another MPTP group was administered L-DOPA (0.2 mg/ml) or vehicle in their drinking water and assessed at day 45 (n = 12 - 15 / group). All structure and function assessments were conducted under ketamine:xylazine (80:10 mg/kg).

5xFAD mice revealed early changes to retinal ganglion cell function compared to WT (6 & 12 m.o., positive scotopic threshold response, $p < 0.05$). At the oldest age there was also deeper retinal dysfunction of the bipolar and photoreceptoral cells (17 m.o., positive scotopic threshold response, b-wave, a-wave, $p < 0.05$). These early functional changes paralleled structural thinning of retinal ganglion cell axons (retinal nerve fibre layer; 6, 12, 17 m.o. $p < 0.05$) whilst other retinal layers remained intact. In contrast, MPTP mice exhibit a different retinal phenotype. At 21 days no retinal changes were found. At 45 days slower amacrine (oscillatory potential, $p < 0.05$) and bipolar cell responses were found (b-wave, $p< 0.05$) whereas other retinal components were preserved. These functional changes were reversed with L-DOPA treatment ($p< 0.05$). No significant structural changes were found in MPTP mice.

This is the first exploratory study to examine the time course of retinal structure and function in the 5xFAD Alzheimer's disease and MPTP Parkinson's disease model. That these animal models recapitulate key changes which have been reported in human Alzheimer's and Parkinson's disease pave the way for their utility as useful translational biomarkers. Moreover, reversal with therapeutics (L-DOPA) also indicate for their use as a preclinical screening tools in drug development. This important step will enable better and faster development of treatments for these diseases.

Title: Non-canonical structural variants of sphingosine 1-phosphate are altered in the plasma of patients with vascular dementia, but not with Alzheimer’s disease

Authors: *D. R. HERR, W. S. CHEW, M. K. P. LAI, 117600
Pharmacol., Natl. Univ. of Singapore, Singapore, Singapore

Abstract: Sphingosine-1-phosphate (S1P) has been shown to regulate a variety of processes in central nervous system cells, such as differentiation, survival, and excitability of neurons, activation of astrocytes, and processing of amyloid precursor protein. Therefore, it is plausible that S1P signaling is dysregulated in individuals suffering from dementia, leading to measurable, quantitative changes in circulating S1P levels. To test this hypothesis, we obtained plasma from 384 individuals that had normal cognition, mild cognitive impairment, or dementia; and were subclassified by the presence or absence of cerebrovascular disease. Each sample was evaluated by mass spectrometry for the concentrations of the four most abundant S1P isoforms: d16:1, d17:1, d18:0, and d18:1. We found that S1P was significantly reduced in dementia patients, but only with respect to d16:1 S1P and not with any other isoform. When dementia was stratified into Alzheimer’s disease (AD) vs. vascular dementia (VaD), only VaD was negatively correlated with d16:1 S1P. To understand how a reduction of d16:1 S1P may contribute to the pathology of VaD, we evaluated the effects of d16:1 S1P on S1P receptors and on astrocytic cells *in vitro*. The potency of d16:1 S1P in activating $S1P_{1\text{-}3}$ was comparable to that of d18:1 S1P, but d16:1 S1P displayed a possible reduction in efficacy toward some receptor subtypes. Although both isoforms caused an increase in the expression of pro-inflammatory cytokines, the effect of d16:1 S1P was significantly less than that of d18:1 S1P. Importantly, we demonstrate that the presence of d16:1 S1P can attenuate the effect of d18:1 S1P. This suggests that d16:1 S1P can act as an immunomodulatory compound by “fine tuning” the pro-inflammatory effect of d18:1 S1P. Therefore, the reduction of d16:1 S1P in vascular dementia patients may dis-inhibit S1P-mediated astrogliosis and exacerbate neuroinflammatory cognitive decline.

Title: EEG biomarkers for frontotemporal dementia

Authors: S. WANINGER[1], M. BENESH[1], *C. BERKA[1], E. RATTI[2], P. VON ROSENSTIEL[2], M. MENDEZ[3], A. VERMA[4]
[1]Advanced Brain Monitoring, Carlsbad, CA; [2]Biogen, Cambridge, MA; [3]Univ. of California, Los Angeles, CA; [4]Biogen Idec, Cambridge, MA

Abstract: Objective: There is a critical unmet need for reliable, cost effective and noninvasive biomarkers to detect and monitor disease progression of frontotemporal dementia (FTD). Neurophysiological metrics including quantitative EEG may provide sensitive metrics for tracking disease progression and assessing efficacy of novel interventions for dementia as well as assist in differential diagnosis of FTD versus Alzheimer's disease (AD).
Methods: Resting state EEG data was acquired from 8 behavioral variant (bvFTD) participants (average age 66, 50% female), 10 AD participants (average age 77, 52% female), and 10 healthy control (HC) (average age 65, 50% female) for 5 minutes for eyes open (EO) and 5 minutes for eyes closed (EC). Power spectral density (PSD) and low resolution brain electromagnetic tomography (LORETA) analysis were performed using Neuroguide software. Statistical analysis for PSDs and LORETA was performed by independent t-test. Discriminant function analysis (DFA) classifiers were used to fit a multivariate normal density to bvFTD, HC, and AD classes with a pooled estimate of covariance. The trained model was evaluated using leave-one-participant-out cross-validation to evaluate the model's generalization capabilities.
Results: Compared to HC, bvFTD participants showed significant increases in delta and theta PSD bands during EO, particularly over the frontal region. LORETA revealed significant increases for the bvFTD in the delta band for the medial and superior frontal gyrus and anterior cingulate during EC and increases in delta and theta in temporal, frontal, parahippacampal gyrus and anterior cingulate during EO. Significant differences between bvFTD and AD were also observed, particularly in alpha and beta in the superior frontal region and anterior cingulate during EC. The DFA model correctly classified all but one bvFTD versus healthy participants with 94 % accuracy/87 % specificity and all of the FTD versus AD participants with 100 % accuracy/specificity.
Conclusions: The data suggest that EEG may provide a powerful tool for assessing FTD, have

potential as a sensitive and robust biomarker for tracking disease progression, and provide an adjunct diagnostic tool for differentiation from AD.

Title: Nucleolin degrades alpha synuclein via the autophagy-lysosome pathway

Authors: *D.-H. HO, S. JEONG, D. NAM, W. SEOL, I. SON
Inam Neurosci. Res. Ctr., Gunpo-City, Gyeonggi-Do, Korea, Republic of

Abstract: Alpha-synuclein (aSyn) is a major component of Lewy body (LB), which is known as a pathogenic marker of Parkinson’s disease (PD). The accumulation of aSyn is caused by dysfunction of protein degradation machinery, including ubiquitin-proteasome system (UPS), Chaperone-mediated autophagy (CMA) and lysosome activity. Misfolded aSyn or chemically modified aSyn would have a resistance to the degradation and is responsible for the generation of oligomeric aSyn in cytosol or vesicles, such as late endosome, autophagosome or lysosome. Proteins, which could enhance degradation of aSyn, are a potential therapeutic target, in as much as accumulated aSyn is the culprit of the pathogenesis of PD. Nucleolin (NCL) is one of the major components of a nucleolar structure. NCL is correlated with oxidative stress-mediated induction of heat shock proteins (Hsp), especially Hsp70, a chaperone for aSyn via CMA. A hexanucleotide repeat expansion in *C9orf72* (*C9orf72*-HRE) is a critical cause of amyotrophic lateral sclerosis (ALS), and increased nucleolar stress via disruption of NCL by the *C9orf72*-HRE in ALS-patients’ cells. A previous study demonstrated that NCL was reduced in PD brain, and overexpression of NCL alleviated rotenone-induced neural toxic effects; knock-down of NCL vice versa. These results suggest that malfunctioning of NCL would exacerbate ALS or PD

pathology. Thus, we hypothesized that artificial expression of ectopic NCL could rescue the synucleinopathy in PD. Overexpression of Flag-aSyn was decreased by co-expression of GFP-NCL in mouse embryonic fibroblast (MEF) compared to GFP protein but co-expressed p21 was not decreased by GFP- NCL. Not only co-transfection of Flag-aSyn and GFP-NCL but also serial transfection of GFP-NCL after Flag-aSyn degraded Flag-aSyn in Triton X-100-soluble and -insoluble fraction. Induction of GFP-NCL increased LC3B mRNA levels significantly and LAMP2, HSP70, and Cathepsin D mRNA levels. Cathepsin D activity also increased in GFP-NCL transfection. Interestingly, bafilomycin A1, the blocker of docking between autophagosome and lysosome, eliminated degradation of Flag-aSyn by GFP-NCL. NH_4Cl showed a similar result to the bafilomycin A1 treatment. However, MG132 treatment showed enhanced degradation of both Flag-aSyn and GFP-NCL. These results support that ectopic expression of NCL degrades aSyn via autophagy-lysosome pathways. We are confirming results of rat primary neuron and validating the Nucleolin-mediated degradation of aSyn fibril form exogenously added.

Abstract: The protein α-synuclein (α-syn) is a key component in both familiar and sporadic Parkinson’s disease (PD) pathophysiology. Point mutations in the α-synuclein gene (*SNCA*) and multiplication of wildtype *SNCA* cause familiar parkinsonian syndromes and the overall *SNCA* levels were shown to directly correlate with the severity of the symptoms. Thus, α-syn dyshomeostasis can be considered as key process to contribute to the susceptibility to PD. Given the strong effects of increased α-syn protein expression on PD severity observed in patients with

multiplications of wildtype *SNCA*, decreasing α-syn could be an important therapeutic improvement. Therefore, the pivotal aim of this study was to establish and perform a novel automated screening assay for the reliable detection of modulators of α-syn expression.
To that end we generated stable human neuroblastoma SH-SY5Y *SNCA*-full-length knock-in GFP/firefly luciferase fusion protein cell lines using CRISPR/Cas9-mediated gene editing. This model system enables us to quantify endogenous α-syn expression by measuring luciferase signal intensity in cell lysates. A second cell line with a randomly integrated luciferase construct served as a specificity control. As a proof of concept experiment Valproic acid (VPA), which is known to induce a parkinsonian like phenotype in patients, was used as lead compound and revealed a 3-fold induction of luciferase activity and the respective increase of α-syn at protein level.
Next, we tested 1.650 bioactive (FDA approved) compounds in a fully automated, robust screening assay (intra-assay variability <10 %, inter-assay variability <10-15 %) in a 96-well plate format and after statistical and candidate definition we obtained a list of 153 potential *SNCA* expression inhibitors and 164 potential *SNCA* expression activators. These compounds were tested for their potential to induce cell death and/or proliferation and dose-response experiments were performed. All compounds inducing either cell death or proliferation or not displaying a dose-response were ruled out. In total 16 *SNCA* expression activators and 5 inhibitors remained.
Direct translational benefit can be drawn from this project, since the identification of compounds that increase or reduce intracellular α-syn protein levels allows the direct re-assessment of PD patients' overall medication and the substitution of risk-bearing drugs.

Abstract: Traumatic brain injury (TBI) is defined as damage to the brain that consequently disrupts normal function. One of the hallmarks of TBI is neuronal death, but has also been related with the development of neurodegenerative disorders, including Parkinson's disease (PD), where loss of dopaminergic neurons and dopaminergic dysfunction are observed. To date, no *in vitro* model exists in which the dopaminergic damage observed in TBI is replicated. In the present study, we evaluated the effects of *in vitro* simulated TBI on human dopaminergic neurons. To simulate TBI, neurons were subjected to 0%, 10%, 15%, 25% and 50% deformation. Twenty-four hours after injury, cell viability and apoptosis were determined by lactate dehydrogenase (LDH) release and DNA fragmentation as well as ethidium homodimer and caspase 3/7 staining. Dopamine (DA) levels were determined by ELISA. Only 50% stretch increased LDH release and ethidium homodimer staining, suggesting the induction of necrosis. On the contrary, 25% and 50% stretch increased DNA fragmentation while 15%, 25% and 50% increased caspase 3/7 staining, suggesting that moderate and severe TBI promote neuronal apoptosis. Finally, levels of intracellular DA decreased in a stretch-dependent manner with 15%, 25% and 50% stretch, while extracellular levels were increased only at 50%. These data support the use of stretch as a model to simulate TBI *in vitro* in dopaminergic neurons, replicating the acute effects of TBI in the dopaminergic system. This method can be used to study the long-term consequences of TBI, including PD and other neurodegenerative disorders.

Title: Investigating an alpha-synuclein binding aptamer as a potential treatment avenue to prevent protein fibril formation in Parkinson's disease

Authors: *K. VENTURA[1], E. MCCONNELL[2], J. CALLAHAN[2], V. HUNT[2], A. KOUDRINA[2], M. C. DEROSA[2], M. R. HOLAHAN[1]
[1]Neurosci., [2]Chem., Carleton Univ., Ottawa, ON, Canada

Abstract: A key component of the neurodegenerative processes underlying Parkinson's Disease (PD) is the aggregation of alpha-synuclein (α-Syn). One current hypothesis is that misfolded native or mutant α-Syn protein dimers become oligomers and can form insoluble fibrils

eventually leading to aggregation into inclusions. These fibrils and inclusions have been found to trigger apoptotic and other toxic signals leading to neuron death. The ability to prevent this aggregation during the disease process would have enormous potential for slowing the neurodegenerative cascade in PD.
Using bionanotechnology strategies, we have sought to determine whether a DNA aptamer, targeted to bind to alpha-synuclein monomers, can inhibit protein aggregation and reduce Parkinson's-related neurodegeneration. Specifically, we have identified a DNA aptamer that can recognize, bind, and block the aggregation of α-Syn protein. Our DNA aptamer selectively bound to the α-Syn monomer and prevented α-Syn fibril formation in vitro. Next, we assessed the ability of the α-Syn binding aptamer in vivo in transgenic mice expressing the human A53T variant of α-Syn. We examined the colocalization of the anti-alpha-synuclein (phosphor S129) antibody and Cy3.5 labelled α-Syn aptamer on ex vivo tissue slices using fluorescent microscopy. Our results suggest that we have been successful at targeting and binding to α-Syn both in vitro and in vivo. The ability to inhibit protein aggregation with an exogenous treatment during aging would be a key strategy in studying and potentially slowing the neurodegenerative process in PD.

Title: Downregulation of SNCA expression by targeted editing of DNA-methylation: A potential strategy for precision therapy in PD

Authors: *B. KANTOR[1], L. TAGLIAFIERRO[2], J. GU[2], M. E. ZAMORA[2], E. ILICH[3], C. GRENIER[4], Z. Y. HUANG[4], S. MURPHY[4], O. CHIBA-FALEK[2]
[1]Duke U, Chapel Hill, NC; [2]Neurol., [3]Neurobio., [4]Div. of Gynecologic Oncology, Dept. of Obstetrics and Gynecology, Duke Univ., Durham, NC

Abstract: *SNCA* gene has been associated with Parkinson’s disease (PD) and accumulating evidence suggest that elevated levels of wild-type *SNCA* are pathogenic. On the other hand, robust reduction of *SNCA* level showed neurotoxicity, demonstrating that normal physiological levels of *SNCA* are needed to maintain neuronal function. Thus, there is an unmet need to develop new therapeutic strategies targeting the regulation of *SNCA* expression. DNA

methylation at *SNCA* intron 1 contributes to the regulation of *SNCA* transcription, and differential methylation levels at *SNCA* intron 1 were found between PD and controls. These evidences established DNA-methylation at *SNCA* intron 1 as an attractive therapeutic target mediated by manipulation of *SNCA* levels. In this study, we developed a system that comprises of an all-in-one lentiviral vector for targeted editing the methylation in the CpG islands along the *SNCA* intron 1. The system is based on CRISPR/deactivated-Cas9 nuclease (dCas9) fused with the catalytic domain of the DNA methyltransferase 3A (DNMT3A). Applying the system to human induced pluripotent stem cells (hiPSC)-derived dopaminergic neurons from a PD-patient with the triplication of *SNCA* locus, resulted in targeted DNA-methylation of *SNCA* intron 1 that enabled fine-tuned downregulation of *SNCA*-mRNA and protein. Furthermore, we showed that the reduction in *SNCA*-mRNA levels by the gRNA-dCas9-DMNT3A system rescued cellular disease related phenotypes characteristics of the *SNCA*-triplication hiPSC-derived dopaminergic neurons, *e.g.* mitochondrial ROS production and cellular viability. Our findings established that DNA hypermethylation at particular CpG islands within *SNCA* intron 1 allows an effective and sufficient tight-downregulation of *SNCA* expression levels, suggesting the potential of this target sequence combined with the CRISPR/dCas9 technology as a novel epigenetic-based therapeutic approach for PD.

Title: Nicotine protects against manganese and iron-induced toxicity in SH-SY5Y cells: Implication for Parkinson's disease

Authors: B. GETACHEW[1], A. B. CSOKA[2], K. N. MCPIKE[2], M. ASCHNER[3], *Y. TIZABI[1]

Abstract: Manganese and iron are trace elements that are needed in minute quantities for proper growth and physiological functions, as both play critical roles in a variety of enzymatic reactions.

At high concentrations, however,they can be toxic and cause neurodegenerative disorders, particularly Parkinson-like diseases. Nicotine, on the other hand, has been shown to have neuroprotective effects against various endogenous or exogenous toxins that selectively damage dopaminergic cells. For example, we have previously reported that exposure of neuroblastoma-derived SH-SY5Y cells (used as a cellular model of central dopaminergic neurons) to salsolinol, an endogenous dopaminergic selective toxicant, results in significant cell loss and that pre-treatment with nicotine can protect against this toxicity. In this study, we sought to determine whether nicotine might also protect against manganese or iron induced toxicity in these cells. Exposure of SH-SY5Y cells for 24 hours to manganese (10 µM) and iron (10 µM) resulted in approximately 55% and 50% toxicity, respectively. Pretreatment with nicotine (1 µM) reduced the toxicity for both manganese and iron by approximately 35%. Though the mechanism(s) of neuroprotective effects of nicotine against manganese and iron are under investigation the current findings further support the utility of nicotine in Parkinson-like neurodegenerative disorders. Title: Neuroprotective effect of a novel dopamine agonist, D-512 in a rotenone model of Parkinson's disease

Authors: *D. YEDLAPUDI, P. RAVIPATI, L. XU, A. K. DUTTA
Pharmaceut. sciences, Wayne State Univ., Detroit, MI

Abstract: Parkinson’s disease (PD) is the second most common neurodegenerative disorder after Alzheimer’s disease affecting nearly 1% of the population over the age of 60. Neuropathologically, it is defined by death of dopaminergic neurons and the presence of intracellular inclusion bodies called Lewy bodies. In this study, we explored the effect of a multifunctional novel potent dopamine D2/D3 receptors agonist, D-512 in a rotenone model of PD *in vitro*. In this regard, we have previously shown that D-512 has potential in symptomatic and neuroprotective treatment of PD as it exhibited protection from neurotoxins like 6-OH DA and MPTP both *in vitro* and *in vivo* models of PD (1).

However, since rotenone based models have been known to recapitulate multiple symptoms of PD like dopaminergic neuronal death, alpha synuclein aggregation and Lewy body formation (2), we wanted to check if D-512 was able to reduce the toxicity caused by Rotenone in MN9D and PC12 cells.
Pre-treatment with D-512 showed a reduction in the toxicity caused by Rotenone in both MN9D and PC12 cells. Neuroprotection was found to coincide with a decrease in ROS levels, caspase-3 cleavage and activation of phospho-tyrosine hydroxylase levels in MN9D cells. D-512 was also able to inhibit the activation of ERK and restore the mitochondrial membrane potential caused by treatment of rotenone in PC12 cells. These observations suggest that D-512 might constitute a novel therapy for PD. This work is supported by a grant from NINDS (NS 047198, AKD).

Title: Development of a novel therapeutic for treatment of synucleinopathies

Authors: *J. DELA CRUZ
InTouch BioSolutions LLC, Moreno Valley, CA

Abstract: Using a human pigmented cell line as an in vitro model of neuromelanin-containing neurons, we uncovered a pathway that results in the accumulation of alpha-synuclein and subsequent neurodegeneration providing a target for novel therapeutic approaches. We have identified a peptide with functions in pigment modulation, inflammation and energy homeostasis. It is produced and released by activated microglia and is elevated in the cerebrospinal fluid of patients with Parkinson's disease (and multiple system atrophy). Injection of this peptide within the rat midbrain dopaminergic neurons results in significant decreases in striatal dopamine. Indeed, treatment with a similar peptide exacerbated symptoms in PD patients. Although, pharmacologic reduction of the peptide improved symptoms, it did not halt the progression of disease. We found that upon exposure to the peptide, the pigmented cell line

displayed the cardinal features of synuclein pathology: a) accumulation of intracellular alpha-synuclein, b) decreased melanin production and c) increased cell death by apoptosis. We conclude that the peptide disables cellular autophagy. Mice impaired in neuronal cell autophagy invariably develop neurodegenerative disease and we observed progressive motor deficits in mice administered the peptide by intranasal route. Collectively, these observations point to the peptide as the likely culprit in synucleinopathies making it a very compelling therapeutic target. We have now shown that the biologic inhibitor of the peptide is able to block and more importantly reverse the effects of the peptide in vitro. The biologic inhibited the accumulation of intracellular alpha-synuclein and restored cellular autophagy, melanin production and preserved cell viability. As a therapeutic, the inhibitor may reverse the adverse effects of the peptide in synucleinopathy and promote an environment ideal for recovery and cell restoration therapies. Our current goals are to prepare a brain targetable biologic, demonstrate delivery of the inhibitor to the brain of monkeys and evaluate efficacy in melanin-containing parkinsonian monkeys.

Title: Closed-loop deep brain stimulation using local field potential features in a computational model of the cortico-basal ganglia network

Authors: *J. E. FLEMING, E. DUNN, M. LOWERY
Sch. of Electrical & Electronic Engin., Univ. Col. Dublin, Dublin, Ireland

Abstract: Deep Brain stimulation (DBS) is an established surgical treatment for Parkinson’s disease (PD) when medication is no longer effective. Setting stimulation parameters is a difficult and time-consuming process, requiring a skilled clinician to find optimal stimulation parameters over several parameter tuning sessions. Closed-loop DBS has been suggested as a solution to this, where disease biomarkers are monitored and utilized to set stimulation parameters. Local Field Potential (LFP) recordings from the basal ganglia have shown increased power in the beta frequency band (10-30 Hz) during PD. This increase correlates with motor impairment during the disease, and its suppression, by levodopa or during DBS, with improved motor function and has been suggested as a possible biomarker for PD. Computational modelling allows the simulation and investigation of this complex behaviour and testing of alternative DBS strategies which are not yet suitable for clinical testing. The objective of this study was to investigate the

effectiveness of different LFP features for use in closed-loop DBS strategies using a computational model of the cortico-basal ganglia (CBG) network.
The CBG network was modelled using single-compartment Hodgkin-Huxley type neuron models. Cortical neurons were modelled with multiple compartments, with cortical soma, axon and collateral segments. Local field potentials were simulated for the cortex and subthalamic nucleus (STN). The DBS extracellular field was modelled and applied directly to cortical collateral segments to simulate antidromic cortical stimulation through the hyperdirect pathway. Model parameters were set so the network displayed bursting in the beta band corresponding to a dopamine depleted state, as observed clinically. Four features were estimated for use in a closed-loop DBS strategy. From the STN LFP, the beta band average rectified value (ARV) and sample entropy were estimated. The vector strength and magnitude of beta band coherence between the cortical and STN LFPs was also estimated. These features were utilized by a proportional-integral-derivative controller to modulate the DBS amplitude and drive each feature to a predefined target value.
An approximately linear relationship between feature values and the DBS amplitude was observed for currents between 1 mA – 2 mA. The controller was capable of modulating the proportional error of the features within this region. The controller performance was affected by the measurement window length. Beta ARV modulation performed well for window lengths of 100 milliseconds, while the other features required longer window lengths to accurately estimate their value.

Abstract: Carbon monoxide (CO) was regarded as toxic gas in the past. Recently, it has been reported that low concentration of CO exerts therapeutic actions under various pathological conditions such as liver failure, heart failure, gastric cancer, and cardiac arrest. However, the

effect of CO in neuronal diseases like Parkinson's disease (PD) has remained to be elucidated. To test whether CO could have neuroprotective effect against oxidative cell death in PD, we examined the effect of CO-releasing molecule (CORM)-2 on 6-hydroxydopamine (6-OHDA)-induced cell death in C6 glioma cells. Treatment of CORM-2 significantly attenuated 6-OHDA-induced apoptotic cell death in a dose-dependent manner. CORM-2 treatment decreased Bax/Bcl2 ratio and caspase-3 activity, which had been increased by 6-OHDA. CORM increased phosphorylation of NF-E2-related factor 2 (Nrf2) which is a transcription factor regulating antioxidant proteins. Subsequently, CORM-2 also increased the expression of heme oxygenase-1 and superoxide dismutases, which were antioxidant enzymes regulated by Nrf2. Taken together, it is suggested that CO released by CORM-2 treatment may have protective effects against oxidative cell death in PD through the potentiation of cellular adaptive survival responses via activation of Nrf2 and upregulation of heme oxygenase-1, leading to increasing antioxidant defense capacity.

Title: Development of a novel FRET-based cellular biosensor to monitor alpha-synuclein protein-protein interactions

Authors: *A. R. BRAUN[1], D. D. THOMAS[2], J. N. SACHS[1]
[1]Biomed. Engin., [2]Biochemistry, Mol. Biology, and Biophysics, Univ. of Minnesota TC, Minneapolis, MN

Abstract: We have developed a pair of cellular, fluorescence-lifetime (FLT) FRET-based biosensors capable of monitoring early-stage oligomeric aSyn-aSyn interactions. Misfolded alpha-Synuclein (aSyn) is the pathological hallmark for numerous alpha-synucleinopathies (e.g. Parkinson's Disease-PD, Dementia with Lewy-bodies-DLB, and Multiple-systems atrophy-MSA). Native aSyn is an intrinsically disordered protein, predominantly localized to synaptic terminals. Under disease-associated conditions, misfolded aSyn assembles into kinetically metastable "on-" or "off-pathway" oligomers, ultimately forming fibrillar aSyn deposits (i.e., Lewy bodies and Lewy Neurites). Increasing evidence suggests that the oligomeric forms of aSyn are the toxic species responsible for neurodegeneration associated with PD, DLB, and MSA.

Due to their kinetically unstable nature, aSyn oligomers pose significant challenges to isolate and characterize their biophysical properties and mechanism of action. Developing a cellular biosensor to monitor aSyn-aSyn interactions provides a novel tool to target this important, pathological protein-protein interaction, and establishes a platform for future therapeutic discovery.
Using GFP- and RFP-aSyn fusion proteins expressed in HEK293 and SH-SY5Y cells, we have developed two classes of aSyn biosensors sensitive to either inter-molecular or intra-molecular FRET signals. Our FLT-based biosensor affords a 30-fold increase in sensitivity relative to conventional intensity-based FRET measurements. Pilot high-throughput screens of small-molecule libraries have identified a series of tool compounds that demonstrate sensitive FRET dose response and rescue cytotoxicity induced by aSyn-overexpression. These compounds will be used to develop a deeper understanding of the mechanism of aSyn oligomer-induced cytotoxicity.

Title: Development and validation of a high content-based assay to measure Tom20 loss in dopaminergic human neurons differentiated *in vitro*

Authors: *F. VERKAAR[1], R. DE WIT[1], M. WATSON[2], P. THOMPSON[2], S. DIJKSTRA[1]
[1]Charles River Labs., Leiden, Netherlands; [2]Mission Therapeut., Cambridge, United Kingdom

Abstract: Parkinson’s disease (PD) pathogenesis has been linked to mitochondrial dysfunction through several lines of research, starting with the finding that the mitochondrial complex I inhibitor rotenone induces parkinsonism. In addition, mutations in genes encoding proteins involved in the selective clearance of mitochondria (mitophagy), such as PARK2 and PINK1, are present in the majority of autosomal recessive cases of PD. Phenotypic readouts to measure mitochondrial (dys)function in disease-relevant cellular backgrounds are therefore thought to represent powerful predictive tools to probe PD pathobiology and identify potential therapeutics. Here, we describe the development of a high content-based assay to measure loss of the mitochondrial marker TOMM20 (Tom20) in differentiated ReNcell VM cells, which represent a replenishable source of human dopaminergic neurons. Using immunocytochemical detection coupled to high-throughput image acquisition with an IN Cell 6000 plate-based imager,

concentration-dependent reductions in mitochondrial Tom20 content were observed following treatment with a range of mitochondrial stressors, such as CCCP, oligomycin/antimycin (O/A) and valinomycin. Specificity of the readout for mitochondria was validated by co-staining with MitoTracker mitochondrial dye, and the assay was successfully miniaturized to 96-well format. Loss of Tom20 with mitochondrial damaging agents most likely represents mitophagy. The assay is expected to facilitate hit-to-lead- or target validation programs in the PD space by enabling compound profiling in a human neuronal background.

Abstract: Parkinson's disease (PD) is characterized by the loss of dopaminergic neurons of the *substantia nigra pars compacta* (SNc), and by the formation of Lewy bodies composed chiefly

of alpha -Synuclein (*SNCA*). Importantly, duplications and triplications of the *SNCA* locus cause familial forms of PD, single nucleotide polymorphisms in *SNCA* are major risk factors for PD, and correlate with higher *SNCA* transcript levels. Additionally, beta-adrenergic receptor agonists reduce alpha-Synuclein levels and PD risk. Thus, increased alpha -Synuclein levels are intrinsically tied to PD pathogenesis, this underscores the importance of identifying the factors that regulate its levels. To find these factors, we conducted a pooled RNAi screen of a collection of 7,787 druggable genes which identified 351 putative modifiers of alpha-Synuclein levels. Of these, we validated 60 candidates and selected 10 for further testing. Using a cross-species approach, we identified six strong modulators of alpha -Synuclein levels and toxicity in cell lines, Drosophila, human neurons and mouse brain. More broadly, the strategy employed here can be used for other diseases caused by dosage sensitive proteins.

Abstract: Deep brain stimulation (DBS) of the subthalamic nucleus (STN) is widely used to treat Parkinson’s disease (PD). This procedure does not cure the disease but radically alleviates motor symptoms and leads to a significant reduction of dopamine medication and severe

associated adverse effects such as dyskinesia, improving the quality of life of PD patients. The cellular and molecular mechanisms of DBS as well as its long-term effects on cerebral tissue are still poorly understood. Through this case report, we aim to describe fine neuroanatomical and neurochemical alterations of stimulated brain parenchyma and associate these changes to clinical outcomes of STN DBS. Our case report deals with the detailed post-mortem investigation of a PD patient's brain treated with DBS for 11 years, the longest STN stimulation period ever reported. Clinical data indicates significant positive outcomes of STN DBS on physical functioning with a score going from 48 to 11 on UPDRS III, along with a 70% daily reduction of dopamine medication. A 3D reconstruction of patient's brain indicates that the active contacts were placed in the dorsolateral region of the STN, corresponding to its sensorimotor functional territory. This 3D virtual environment was then used to model current spreading throughout the tissue. As expected, we observed a 300 µm-width gliosis around the electrode leads showing high immunoreactivity for GFAP (specific marker of astrocytes), for the proliferating cell nuclear antigen (PCNA) and for the neurotrophic factor GDNF. We also identified astrocytes endowed with highly varicose processes, exclusively in the STN stimulated area. A significant reduction of the number of Iba1+ microglia was also observed near the active contacts, the vast majority being immunoreactive for CD68, supporting the hypothesis of altered neuroinflammation induced by DBS. We also found a 23% increase of the length of GLUT1+ capillaries in the STN stimulated area compared to non-stimulated STN regions. Immunoreactivity for the vascular endothelial growth factor (VEGF) was low in this STN stimulated region, indicating that angiogenesis occurred rather early following the surgery, but stabilized with time. Moreover, the subventricular zone in this particular DBS implanted brain was thicker than in non-implanted PD brains and similar to non-pathological brains, suggesting that DBS may restore normal neural cell proliferation in PD. Interestingly, we also noted a significant reorientation of serotonin (SERT+) axons near the active contacts. We hope that this case report will provide new insights for a better understanding of the long-term effects of DBS, including its mechanisms of action.

Title: Inhibiting phosphoinositide 3-kinase/mammalian target of rapamycin signaling reduces cellular phosphorylation of protein kinase B to increase macro- and chaperone-mediated autophagy and mitigate alpha synuclein-induced neurotoxicity

Authors: *J. K. BOWDEN-VERHOEK[1], E. STOCKING[1], J. L. WONG[1], E. ARIAS-PEREZ[2], N. FUSSI[3], M. HÖLLERHAGE[3], G. HOEGLINGER[3], A. M. CUERVO[2], W. WRASIDLO[1], D. PRICE[1], M. GILL[1], D. BONHAUS[1]

Abstract: Synucleinopathies are a family of central nervous system (CNS) degenerative disorders characterized by deposition of insoluble alpha-synuclein-containing protein aggregates, neuronal and/or glial cell death and inflammation. Neurons, astrocytes and microglia activate cellular clearance mechanisms to dispose of misfolded, monomeric or aggregated proteins and damaged organelles. These clearance mechanisms are referred to collectively as autophagy, of which macro-autophagy and chaperone-mediated autophagy handle a large component of the cell's protein clearance. Macro-autophagy involves the bulk degradation of organelles and protein aggregates through engulfment in a membrane-bound vesicle which ultimately fuses with the lysosome, while chaperone-mediated autophagy selectively degrades proteins, identified by an amino acid pentamotif, through chaperone-mediated translocation into the lysosome via the LAMP2A multimeric complex. The phosphoinositide 3-kinase/mammalian target of rapamycin (PI3K/mTOR) signaling pathway can modulate cellular phosphorylation of protein kinase B (pAkt) and has been well-characterized for its role in activation of macro-autophagy. Recent publications suggest pAkt negatively regulates the activation of chaperone-mediated autophagy. Together, these data support reduction of pAkt as a means to increase both macro-autophagy and chaperone-mediated autophagy to reduce cellular protein aggregation. Neuropore Therapies (NPT) has developed novel, potent and kinome-selective PI3K/mTOR inhibitors which are orally bioavailable and are brain penetrant. Using a combination of in vitro rodent reporter cell systems and human microglia, these compounds reduced cellular pAkt and induction of HIF-1α, as well as activated macro- and chaperone-mediated autophagy. Indeed, we uncovered a strong correlation between a compound's cellular pAkt inhibition potency and the compound's ability to reduce HIF-1α induction, and activate macro- and chaperone-mediated autophagy. Importantly, compounds, which significantly activated macro- and chaperone-mediated autophagy, also significantly reduced cell death in a viral alpha synuclein-mediated neurotoxicity

model. Preliminary in vivo data with a reference PI3K/mTOR inhibitor demonstrate a separation between pAkt target engagement and systemic hyperglycemia, supporting a path forward for mechanism-of-action-related efficacy studies. Proprietary NPT compounds are in queue for in vivo evaluation of target engagement and pre-clinical PD model efficacy experiments.

Abstract: Parkinson's disease (PD) is a neurodegenerative disorder that is typically characterized by various motor symptoms and the progressive loss of dopaminergic (DA) neurons in the substantia nigra. However, PD is also associated with numerous non-motor symptoms. Many PD patients suffer from gastrointestinal (GI) abnormalities such as constipation, microbial dysbiosis, and intestinal inflammation that precede motor system dysfunction by many years. Additionally, α-synuclein accumulation has been reported in the enteric neurons of the GI tract in PD patients and it is thought that this possibly contributes to the accumulation of α-synuclein and subsequent DA neuron cell death in the CNS. Here we have developed a platform to investigate GI dysfunction observed in PD based upon our previously published protocol of induced pluripotent stem cell (iPSC)-derived human intestinal organoids (HIOs) containing a functional enteric nervous system (ENS). The vast majority of PD cases have no known genetic mutations, prompting the need to develop sporadic Parkinson's disease models. Through the Cedars-Sinai iPSC Core, we have generated numerous iPSC lines from sporadic PD patients using non-integrating episomal plasmids, along with gender-matched control iPSC lines from the Lothian Birth Cohort, a group of individuals which are free of any known neurodegenerative diseases. Using these lines, we have successfully generated HIOs with an incorporated ENS (control n=4; PD n=3) and have performed transcriptomic profiling, revealing disease-specific changes in gene expression. Additionally, we have combined iPSCs with a scalable microphysiological system (MPS) known as the Organ-Chip (Emulate, Inc). Using the micro-engineered poly(dimethylsiloxane)-based Organ-Chip platform, we have developed a co-culture system of intestinal epithelium and enteric neurons that permits the study of host-microbial interactions. Using this approach, we aim to identify disease-specific changes in iPSC-derived intestinal tissue from PD patients and to characterize the role of gut microbiota in promoting disease progression.

Title: Drug-like small molecules that modulate catalyzed assembly and toxicity ofalpha-synuclein in cell culture models of pd

Authors: S. SELVARAJAH[1], A. MÜLLER-SCHIFFMANN[2], K. PAULVANNAN[1], R. MARREIROS[2], N. DEYARMAN[1], *V. R. LINGAPPA[1], C. KORTH[2]

Abstract: Background: We use an unconventional *de novo* cell-free protein synthesis (CFPSA)-based phenotypic screen to interrogate catalyzed assembly as an essential, but previously inaccessible, step in gene expression, applicable across therapeutic areas. Assembly has been found to be carried out by multi-protein complex (MPC) putative "assembly machines" that are normally hard to detect by conventional proteomics due to their transience/lability. This appears to be a critical weak link in the pathophysiology of many diseases, including PD, in which assembly machine protein composition is found to be strikingly aberrant. A collection of approximately 300 diverse drug-like chemotypes, identified by their modulatory activity against various assembly events, were interrogated for activity in modulating a-synuclein.
Method: We developed a cellular model for robust α-synuclein aggregation in SH-SY5Y and NLF cells using proprietary nucleic acid sequences. We performed toxicity assays in differentiated dopaminergic human LUHMES cells. Rotenone induced toxicity model was used to explore primary rat dopaminergic neuron viability. Drug resin affinity chromatography (DRAC) followed by MS-MS was used for identification of MPCs.
Results: Our cell models revealed different assembly states of α-synuclein, including small aggregates and ring-like structures of α-synuclein associated with lipid droplets. Interestingly, the most potent ring- inducing compound showed the least degree of aggregated α-synuclein, was protective against rotenone and dopamine induced synaptic loss or toxicity. Early structure-activity relationship studies already led to optimized compounds with an EC50 below 200nM. The compounds prevented α-synuclein mediated synaptic loss or cell death of dopaminergic neurons via a novel molecular mechanism, i.e. the increased association of toxic α- synuclein aggregates with LDs, thereby presumably facilitating degradation of α-synuclein.
Conclusions: Assembly modulation is a novel and productive approach to PD therapeutics. DRAC has allowed identification of the protein components of assembly machines and it is composed of proteins previously identified as part of the PD disease interactome – but not previously known to be transiently together as a MPC.

Abstract: Cell lines have provided an invaluable tool in biological research since the isolation of the first immortal cells, HeLa, in 1951. Their use allows for more rapid experimental output, testing of multiple conditions, and reduces the number of animals used. However, it is critical that cell lines are used appropriately and have the best characteristics for the diseases in which they are used to model. One such example is in Parkinson's disease (PD) for which a variety of cell lines are available: PC12, MN9D, SH-SY5Y, N27. Although each of these cell lines has been used in published articles there have been conflicting levels of expression in many of the key proteins associated proteins associated with the dopaminergic (DAergic) cells that are affected in PD, including tyrosine hydroxylase (TH) and dopamine transporter (DAT) reported. Variations should not be unexpected if one takes into account the manner in which the cells were initially produced, the number of times the cells are passed, and the conditions in which they are cultured. We have done an extensive investigation of three DAergic cell lines used in our lab: MN9D, SH-SY5Y, and N27. We used western analysis, qRT-PCR, and immunofluorescence to examine expression of TH, DAT, dopamine beta hydroxylase, α-synuclein, and estrogen receptor β and HPLC to measure DA synthesis, and DA levels, as well as overall morphology of undifferentiated cells over several passages and compared to what has been previously observed across the literature.

Title: Human natural killer cells clear extracellular alpha-synuclein while their effector functions are inhibited

Authors: *J. LEE[1], J. CHUNG[1], R. H. EARLS[2], K. BAKER[2]
[1]Dept. of Physiol. and Pharmacol., Univ. of Georgia Col. of Vet Med., Athens, GA; [2]Neurosci., Univ. of Georgia, Athens, GA

Abstract: The pathological hallmarks of Lewy body dementia and Parkinson's disease (PD) are the presence of Lewy bodies (LBs), which are composed of intracellular fibrillar inclusions of aggregated alpha-synuclein (α-syn). Additionally, the levels of extracellular α-syn are higher in the serum and cerebrospinal fluid in these patients, and have been implicated in modulating immune responses in both the CNS and the periphery. The number of circulating natural killer (NK) cells are modulated in neurodegenerative disorders and their activities are related with disease severity. Nevertheless, the role of NK cells in modulating PD severity has received little attention. Here, we demonstrate that extracellular α-syn attenuates NK cell cytotoxicity in a dose-dependent manner by reducing the level of perforin. The extracellular α-syn also attenuated production of interferon (IFN)-γ, a major proinflammatory cytokine produced by NK cells. Remarkably, NK cells efficiently uptake and degrade extracellular α-syn species via the endosomal/lysosomal pathway. Importantly, NK cells also efficiently uptake and degrade extracellular Aβ species. Our study has demonstrated a novel function of NK cell in clearing extracellular abnormal protein aggregates while extracellular α-syn aggregates did not activate but instead inhibited NK cell effector functions. Our results suggest that NK cell may be a candidate for cell-based therapy due to their capability to clear extracellular protein aggregates without aberrant activation.

Title: Mouse model of manganism: Towards understanding of the phenotype

Authors: *C. G. JANUS[1], G. GIRALDO[1], R. WEISKIRCHEN[3], M. KNUTSON[2]
[1]CTRND and Dept. of Neurosci., [2]Food Sci. & Human Nutr., Univ. of Florida, Gainesville, FL; [3]Univ. Hosp. RWTH Aachen, Aachen, Germany

Abstract: In humans, exposure to excess manganese can result in manganese accumulation in the brain, as well as in neurological and motor disturbances resembling a parkinsonian-like disorder known as manganism. We recently published findings confirming that *Slc39a14*$^{-/-}$ knockout mice have elevated manganese concentrations in the blood, brain, and bone. Brain manganese accumulation in *Slc39a14*$^{-/-}$ mice was associated with locomotor impairments. Additionally, most *Slc39a14*$^{-/-}$ mice also displayed postural abnormalities in the form of torticollis, a condition in which the muscles in the neck contract, causing the head to twist slightly to one side. In this study, we investigated whether this postural defect could confound the performance of mice in the administered locomotor tests, and thus bias the interpretation of the obtained results. To this end, we compared the performance of *Slc39a14*$^{-/-}$ mice which showed torticollis with the performance of the *Slc39a14*$^{-/-}$ mice without any identifiable signs of torticollis and with the performance of the control, wild type mice. The results of our comparative analyses across a variety of locomotor tests demonstrated the unequivocal motor impairment of *Slc39a14*$^{-/-}$ mice in each of these tests, and that the combined index of performance across the tests did not differentiate between *Slc39a14*$^{-/-}$ mice with and without torticollis. Thus, we conclude that in this study torticollis did not significantly confounded the locomotor performance of *Slc39a14*$^{-/-}$ mice in the tests.

Title: *In vivo* analyses on ubiquitin and proteasomal activity in SCA3

Authors: *J. SCHMIDT[1,2], A. GRUN[1,2], T. MEFFERT[1,2], O. RIESS[1,2], T. SCHMIDT[1,2]
[1]Med. Genetics, Univ. of Tuebingen, Tuebingen, Germany; [2]Ctr. for Rare Diseases, Univ. Hospital, Tuebingen, Tuebingen, Germany

Abstract: Spinocerebellar ataxia type 3 (SCA3) or Machado-Joseph disease (MJD) is an inherited neurodegenerative disorder caused by the expansion of a CAG repeat within the *ATXN3* gene resulting in an expanded polyglutamine repeat in the encoded protein ataxin-3. SCA3/MJD therefore belongs to the group of polyglutamine diseases. Up to now, no treatment is available for this disease. One hallmark of this and other neurodegenerative diseases is the formation of inclusion bodies (protein aggregates) in the brain. For the affected protein ataxin-3 deubiquitinating activities have been proven. Ubiquitin has a central role in many cellular pathways. E. g., K48-linked ubiquitin chains represent the main signal for proteasomal degradation. In order to further study the role of ubiquitination in SCA3, we crossed one of our previously generated mouse models for SCA3 with mice transgenic for mutated ubiquitin (K48R mice). The mutation in K48R mice (Lysin at position 48 is replaced by Arginin) leads to premature termination of K48 poly-ubiquitin chain assembly, hence to the formation of higher amounts of short K48-linked ubiquitin chains. Performing rotarod tests to measure the motor-coordinative abilities, we observed that transgenic SCA3 mice which simultaneously express a mutant ubiquitin transgene (MJD/K48R) showed an alleviated motor phenotype compared to single transgenic SCA3 mice. Western blot and immunohistochemical analyses furthermore revealed that transgenic SCA3 mice with mutated ubiquitin (MJD/K48R) showed less transgenic ataxin-3 protein as well as less ataxin-3 positive inclusion bodies. We hypothesize that the presence of higher amounts of short K48-linked ubiquitin chains leads to a higher proteasomal turnover of the expanded transgenic ataxin-3 protein resulting in the alleviated phenotype in MJD/K48R mice. We are currently conducting analyses (e.g. measurement of proteasomal activity) to further explore this hypothesis and the feasibility to translate this approach into a therapeutic strategy.

Title: Deep brain stimulation of the ventral intermediate nucleus/zona incerta as an off-label treatment for anti-GAD65 antibody-positive stiff-person-syndrome-induced tremor

Authors: *K. MARKOPOULOU[1,2], A. LOGGINI[2], P. WARNKE[3]
[1]NorthShore Univ. HealthSystem, Glenview, IL; [2]Neurol., [3]Surgery, Univ. of Chicago, Chicago, IL

Abstract: Introduction Intention tremor is a frequent manifestation of the disruption of cerebello-thalamo-cortical circuits with variable underlying etiologies and is often medication-refractory. Deep brain stimulation (DBS) has been used to treat uncommon tremor disorders e.g., multiple sclerosis associated intention tremor, Holmes tremor, rubral tremor, neuropathic tremor, orthostatic tremor, fragile-X associated tremor/ataxia syndrome (FXTAS) with good outcomes. Stiff person syndrome (SPS) can present with severe intention tremor. Here, we present the first case of anti-GAD65 positive-antibody SPS-associated intention tremor treated successfully with bilateral Vim DBS.
Methods A 79 year-old male with history of anti-GAD65 antibody-positive SPS, of five-year disease duration, characterized by severe ataxia and intention tremor that was refractory to repeated courses of high dose IV methylprednisolone, oral prednisone, IVIG and symptomatic therapy with baclofen and clonazepam underwent bilateral insertion of deep brain stimulator leads at the border of the ventral intermediate nucleus of the thalamus (Vim) and the zona incerta (Zi) using a Medtronic wide-spaced lead (3387). No intra-operative complications were observed as documented by intra-operative CT. A late appearing small (3cc) intra-parenchymal hematoma along the proximal end of the left DBS lead tract caused a transient alteration of consciousness that resolved spontaneously. Tremor was assessed with the Fahn-Tolosa-Marin (FTM) rating scale and video-recorded with DBS OFF and DBS ON.
Results With DBS ON complete elimination of postural tremor was achieved bilaterally. Kinetic tremor resolved completely on one side whereas its severity decreased from severe to moderate on the other. DBS OFF FTM score was 58 and DBS ON 15. With frequent reprogramming sessions at on-average bimonthly intervals, the beneficial effect on the tremor has been maintained with some fluctuation in severtiy for more than two years, without adverse effects.
Conclusion Bilateral Vim/Zi nucleus DBS is a safe and effective off-label symptomatic treatment of medically-refractory intention tremor in anti-GAD antibody positive SPS. The therapeutic effect obtained in this as in other uncommon tremor disorders suggests that irrespective of the underlying pathophysiological mechanisms, the modulation of common cerebellar-thalamo-cortical circuits can result in good tremor control. Thus, DBS Vim/Zi therapy in medication-refractory intention tremor associated with SPS further expands the spectrum of uncommon tremors that can be effectively treated with DBS.

Title: Neurotoxic effect of a polyglutamine expansion in human TATA-binding protein in SCA17 modeled in *Drosophila melanogaster*

Authors: *M. CARDENAS-TUEME[1], C. ALTAMIRANO-TORRES[2], V. GONZALEZ-VILLASANA[2], D. RESENDEZ-PEREZ[2]
[1]Developmental Biol., Univ. Autonoma De Nuevo Leon, Nuevo Leon, Mexico; [2]Developmental Biol., Univ. Autonoma de Nuevo Leon, Nuevo Leon, Mexico

Abstract: Spinocerebellar ataxias (SCAs) are progressive disorders in which the cerebellum and brain stem slowly degenerate. Spinocerebellar ataxia 17 (SCA17) is caused by an expansion of the CAG / CAA trinucleotide in the gene that encodes for the polyglutamine (polyQ) regions in the TBP gene (TATA Binding Protein). Since our laboratory focuses on the study of protein-protein interactions of transcription factors in *D. melanogaster*, and SCA17 is caused by a transcription factor we decided to model it in *Drosophila melanogaster* to study the effect of hTBP polyglutamine expansion and its consequences at brain and motor level. To analyze the neuropathological effect of hTBP with the extended poly 90Q compared with wild type poly 34Q, we addressed expression using the brain tissue-specific promoter ELAV-Gal4 in *D. melanogaster*. Afterwards protein aggregation, cell death and climbing ability were analyzed at 2, 10, 20 and 50 days of age. The expression of hTBP90Q reduced the life of *D. melanogaster* in comparison with the *wild type* fly. As expected, the tissue-specific expression of hTBP with the expansions of 34 and 90 Q, in a span of 50 days, showed a degenerative phenotype in the eye. According to our results, the aggregation of these proteins is present in the brains of both flies hTBP34Q and hTBP90Q with a clear dependence on the age and length of the polyQ expansion. The confocal images did not show aggregates in the *D. melanogaster* brain at an early age, in the case of both 34Q and 90Q expansions; however, starting at ten days of age, hTBP90Q formed protein aggregates in *D. melanogaster's* brain, which increased over time. In contrast, the expansion with 34Q began to form aggregates up until 50 days of age, which demonstrated the dependence of the length of the expansion of polyQ and its correlation with the age of the fly. Cell death was present in a greater proportion in brains expressing hTBP90Q compared to hTBP34Q, and flies expressing hTBP90Q were more affected in the climbing tests compared to flies expressing hTBP34Q. The modeling of SCA17 in *D. melanogaster* allowed to clearly conclude the neurotoxic effect of hTBP80Q in the brain of the fly which shortened its life time and locomotor capacity due to the formation of protein aggregates and cell death. Our results have opened the possibility to evaluate the type of cell death produced in the affected neurons

and the molecular behavior of these polyQs expansions in the neurodegenerative pathology SCA17.

Title: Utilizing apigenin to attenuate the degenerative effects of oxidative stress in the spastic Han-Wistar rat, a model of ataxia

Authors: *M. OLMOS[1], M. A. GILHUYS[2], A. LEMUS[2], R. W. COHEN[2]
[1]Northridge, CA; [2]California State University, Northridge, Northridge, CA

Abstract: Oxidative stress is an accumulation of reactive oxygen species (ROS) to toxic cellular levels resulting in damage to DNA and proteins, which ultimately impedes proper neuronal function. ROS, including superoxide, hydroxyl and hydrogen peroxide arise through a deviant process in which high energy electrons are released during oxidative phosphorylation. Direct correlations have been established between oxidative stress and neurologic disorders such as Parkinson's and Alzheimer's diseases. Important to this presentation, oxidative stress has also been linked to progressive cell death in Purkinje cells in ataxia. Apigenin is a bioflavonoid with anti-oxidant, anti-tumorigenic, and anti-inflammatory properties. Specifically, apigenin exhibits its anti-oxidant ability by donating electrons to ROS to produce more stable and lower energy compounds. Apigenin has been used to treat neurologic diseases that present oxidative stress effects, such as Parkinson's and Alzheimer's Disease. By utilizing apigenin, this study aimed at attenuating the ataxic symptoms of the *spastic* Han-Wistar (*s*HW) rat characterized by fore limb tremors, decreased motor coordination, and hind limb rigidity. At 25-30 days of age, an equal mix of male and female mutant and normal *s*HW siblings were administered intraperitoneal injections with 40 mg/kg apigenin or vehicle (20% ethanol in mammalian saline) three times per week for three weeks. Three behavioral assays were utilized in this study and were performed three times per week: weight was utilized to assess overall animal health, open field test elucidated motor function, and rotarod data determined cerebellar motor coordination. Weight assay data showed apigenin-treated mutants displayed weights similar to untreated normals ($p > 0.05$). Data collected from open field activity tests showed that apigenin-treated mutants were able to retain their motor function when compared to vehicle-treated mutants ($p < 0.05$), implying Purkinje cell survival in apigenin-treated mutants. Data from rotarod activity tests indicated no statistical significance in motor coordination between apigenin-treated mutants and

vehicle-treated mutants ($p > 0.14$). At 60-65 days of age, all animals were sacrificed and perfused in order to collect cerebellar tissue for Purkinje cell counts. Increased Purkinje cell counts in the cerebellum correlated with sustained increased mobility in the apigenin-treated mutants. This study demonstrated the potential effectiveness of apigenin by delaying the onset of neurologic symptoms against neurodegenerative damage caused by oxidative stress.

Title: Reaching strategies when the eye-hand configuration varies in direction and depth in a patient with lesions of the posterior parietal cortex

Authors: *A. BOSCO[1], V. PISERCHIA[1], C. BERTINI[2], E. LADAVAS[2], P. FATTORI[1]
[1]Dept. of Biomed. and Neuromotor Sci., [2]Dept. of Psychology, Univ. of Bologna, Bologna, Italy

Abstract: The accuracy in reaching to targets can be affected by lesions of the posterior parietal cortex (PPC), like those that are observed in Optic Ataxia (OA). OA is a high-order disorder that occurs with unilateral or bilateral PPC lesion; the sites of the lesion typically involve the Parietal Occipital Junction (POJ), the superior parietal lobule (SPL) and areas around the intra parietal sulcus (IPS). Here, we report the case of a female left-handed patient (age: 61) with right posterior parietal lobe damage where we studied the influence of different eye/hand configurations varying in depth and direction on her reaching trajectories and accuracy. The reaching performance of the patient was compared with 5 left-handed healthy controls (4 females, mean age: 47). Trajectories and accuracy were measured by a motion capture system (Vicon) while participants were tested in visually-guided reaching movements to targets presented at different depths and directions in foveal and peripheral viewing conditions. The peripheral and foveal viewing conditions consisted in 3 eye/hand configurations: in the constant-gaze configuration, the eye fixated a central fixation target and the hand reached one of the peripheral reaching targets, in the constant reach configuration, eyes fixated one of the peripheral targets and the hand reached always the central target, and in the foveal reach configuration, the fixation and reaching targets were coincident. The patient showed significant higher reaching errors with respect to controls both in depth and direction and in all the three eye/hand configurations (t-test, $P < 0.05$). In the eye/hand configurations with peripheral viewing, the

patient did not correct the trajectory at the end of movement as the controls (t-test, $P < 0.05$). In the configuration where the targets were foveated, she was able to adjust her behavior in the same direction of controls, although significantly less (t-test, $P < 0.05$). We suggest that the reaching inaccuracies observed in the configurations where the direction of gaze and reach direction differed can be explained by the lack of the "automatic pilot" which is able to adjust in healthy conditions the predefined motor plan. In particular, this lack is specific of the second part of the reaching movement.

Title: Adeno-associated virus-mediated knockdown of Gba in the central nervous system models neuronopathic Gaucher disease

Authors: *K. JACKSON[1], C. VIEL[1], J. C. MATTHEWS[1], J. BU[1], M. CHAN[1], B. WANG[2], L. S. SHIHABUDDIN[1], S. P. SARDI[1]
[1]Neurosci., Sanofi, Framingham, MA; [2]Sanofi, Waltham, MA

Abstract: Pathological mutations in GBA, encoding the lysosomal hydrolase glucocerebrosidase (GCase), cause Gaucher disease (GD). GD is a multi-system disease with great phenotypic variation between individuals. It has been classified into type 1 with primarily systemic involvement and types 2 and 3 with varying degrees of neurological involvement. Type 2 GD progresses rapidly with severe neurological symptoms and death typically by 2 years of age. Type 3 GD has an increased life expectancy compared to type 2 and a slower progression of neurological impairments, including ataxia and tremor. GD is characterized by decreased GCase activity leading to accumulation of lipid substrates, glucosylceramide and glucosylsphingosine. Current murine models of neuronopathic GD mostly replicate the acute aspects of the neurological disease showing rapid progression and early lethality, thus presenting a short window for therapeutic testing. In order to develop a model of chronic neuronopathic GD, we reduced GCase in the central nervous system (CNS) of a mild GD mouse model (Gba(D409V/D409V)) by intracerebroventricular administration of an adeno-associated virus encoding a microRNA to Gba (AAV-miR-Gba). Gba(D409V/D409V) mice have significantly reduced activity of GCase and marginal substrate accumulation in the CNS. Phenotypically, these mice are similar to type 1 GD and only display cognitive impairments. Administration of AAV-miR-Gba into Gba(D409V/D409V) pups in the CNS caused progressive lipid substrate

accumulation. Phenotypically, these AAV-miR-Gba-treated mice were indistinguishable from their littermates until 10 weeks of age, when they started developing progressive neurological impairments, including hyperactivity, abnormal gait, and head retroflexion. Importantly, these impairments can be prevented by simultaneous administration of a miR-resistant GCase, demonstrating that the pathological effects are specifically due to Gba mRNA reduction. This novel model of neuronopathic GD offers several advantages including slower progression of neurological complications and an increased lifespan, which make it more amenable to therapeutic testing.

Abstract: Spinocerebellar ataxia type 3 (SCA3) is caused by a CAG repeat expansionin the *ATXN3* gene, which encodes for ataxin-3 protein containing an expandedpolyglutamine (polyQ). SCA3 is characterized by age-dependent neurodegeneration, which preferentially occurs in the cerebellum. SCA3 patients usually show clinical symptoms in their middle lifewith the typicalsymptom. A number of genetic mouse models of SCA3 have been established and show age-dependent neurological symptoms. However, these models do not show obvious neuronal

cell death and resemble human neurological phenotypes. Using lentiviruscarryingmutant ataxin 3 with 80Q and somatic cell nuclear transfer (SCNT) technology, we generated a transgenic SCA3 pig model.The founder SCA3 transgenic pig shows age-dependent ataxia, and MRI study also revealed cerebellum atrophy in the pig brain.Western blotting using the polyQ specific (1C2) antibody showed that the SCA3 transgenic pig expresses the polyQ-expanded ataxin-3 protein. We have now bred the F0 pigs to obtain F1 SCA3 pigs and areinvestigating these F1 SCA3 pigs.

Abstract: Clinical trials on spinocerebellar ataxias are hampered by the lack of objective measures to precisely measure the disease severity, progression, and clinical efficacy. Gait impairments precede symptoms in patients with spinocerebellar ataxia (SCA) and may be valid surrogate markers of disease severity. We investigated whether gait measures from wearable inertial sensors were sensitive to ataxia and related to SARA scores in patients with SCA. Twenty one patients with SCA (mean age 61 years) and 34 control subjects (mean aged 58 years) underwent SARA testing. SARA total scores ranged from 0 (prodromal) to 25. The subjects wore 2 inertial sensors (Opals by APDM) on their feet and walked for 2 minutes at their normal walking pace. Step duration, double support time, and foot angle at heel strike were all very sensitive to ataxia ($p<.02$). In addition to these gait measure, other gait measures including gait speed, cadence, foot elevation at mid-swing, and toe off angle were significantly ($p<.003$) related to the total SARA score ($r=.53$ -- $.82$). The figure shows the relationship between the total SARA score and double support, calculated as the percentage of gait cycle while both feet are in contact with the ground. Future analysis will determine the most sensitive measures of gait in prodromal SCA, examine test-retest reliability of gait measures, and evaluate sensitivity to progression of disease.
Objective measure of gait with wireless inertial sensors provides promising, practical measures of severity cerebellar ataxia for clinical trials and clinical practice.

Title: Loss of the ataxia protein sacsin impacts on focal adhesion dynamics and cell migration

Authors: L. E. L. ROMANO, *J. P. CHAPPLE
Queen Mary Univ. of London, London, United Kingdom

Abstract: Autosomal Recessive Spastic Ataxia of Charlevoix-Saguenay (ARSACS) is a childhood-onset neurological disease with pyramidal spasticity and cerebellar ataxia. ARSACS results from mutations in the SACS gene that encodes sacsin. Previously we have identified that loss of sacsin results in reduced mitochondrial health and altered organization of the intermediate filament cytoskeleton.

Sacsin is a modular protein with conserved domains that indicate a molecular chaperone linked function. We therefore hypothesized that loss of sacsin would alter solubility of client proteins and/or their interactors. Using a proteomics approach, we identified that cytoskeletal proteins and proteins associated with focal adhesion formation accumulated in an insoluble fraction from sacsin null cells. Confocal microscopy revealed that the number and structure of focal adhesions was altered in sacsin null SH-SY5Y cells (generated by CRISPR/Cas 9 genome editing). Moreover, fluorescence recovery after photobleaching demonstrated that focal adhesion dynamics were altered relative to wild-type controls. Directional cell migration was also impaired in sacsin null cells.
To understand mechanisms underlying the altered focal adhesion dynamics and migration we investigated activation of the focal adhesion kinase signaling pathway. This showed a reduction in phosphorylation of Focal Adhesion Kinase (FAK), c-Jun N-terminal kinases (JNK) and Paxillin. We also observed that levels of Phosphatase and Tensin homolog (PTEN), which is a negative regulator of FAK signalling, were increased in sacsin null cells. Together these data suggest that altered expression of PTEN and FAK signalling contributes to the sacsin null cell adhesion and migration phenotype.
ARSACS has a neurodegenerative phenotype characterized by Purkinje cell loss, however, it is also thought to have a neurodevelopmental component. Normal neurodevelopment is dependent on cell migration and is orchestrated by a multitude of adhesion molecules and their downstream signalling. We are currently investigating if sacsin null cells differentiated along neuronal lineages exhibit altered migration, as this could be relevant to understanding the neurological phenotype of ARSACS patients.

Title: Role of Rnf216/Triad3 on neurondevelopment and degeneration

Authors: *A. CHARLES[1,2], A. MABB[2]
[1]Georgia State Univ., Stone Mountain, GA; [2]Neurosci. Inst., Georgia State Univ., Atlanta, GA

Abstract: The balance between the production of proteins and their breakdown is acknowledged as protein turnover. E3 ubiquitin ligases are a group of enzymes that directly participate in protein turnover by covalently attaching ubiquitin to target substrates. Obstructions in this pathway can lead to a multitude of neurological disorders that span the spectrum from neurodevelopment to neurodegeneration. RNF216/TRIAD3 is an E3 ubiquitin ligase that is disrupted in individuals with Gordon Holmes syndrome (GHS). GHS is characterized by dysarthria, underdevelopment of secondary sex organs, and neurodegeneration in the cerebrum and cerebellar regions. There are no effective therapeutic interventions for GHS. Scientific studies have pinpointed disruption in the ubiquitin pathway as a cause of these symptoms, but it remains unclear how this disruption affects neural development and neurodegeneration in select regions of the brain. To determine how Rnf216/Triad3 alters neuronal morphologies and survival, we selectively deleted the Rnf216/Triad3 gene in cortical neurons using the CRISPR-Cas9 system and a conditional knockout approach. Results from our studies will provide insight into the changes in neural properties that might occur in GHS and will contribute to the development of therapeutic strategies for GHS patients.

Abstract: SCA7 is a neurodegenerative and autosomal dominant disorder caused by the expanded repetition of CAG. Clinical manifestations in SCA7 patients include cerebellar ataxia, visual acuity impairment, ophthalmoplegia, extrapyramidal signs, swallowing difficulties and dysarthria. Transversal MRI studies in SCA7 patients have shown atrophy in olivo-ponto-cerebellar and cortical areas, compared to healthy subjects. However, neurodegenerative progression is currently unknown due to lack of longitudinal studies. Here, we characterized the progressive neurodegeneration in patients with SCA7 and identified whether atrophy in specific brain structures correlates with clinical motor or cognitive assessment. Fourteen SCA7 patients were assessed with the Rey Auditory Verbal Learning Test (RAVLT), the Montreal Cognitive Assessment blind version, and the Scale for the Assessment and Rating of Ataxia (SARA), and subjected to a 3T MRI scan. T1 images were acquired and we performed a VBM (FSL library) analysis to provide intra-subject and inter-subject image alignment and voxel-wise comparison to detect progressive structural changes. Two years later, we performed a follow-up of all tests. Results: SCA7 group exhibited statistically significant progressive gray matter volume reduction in bilateral superior frontal gyrus, left medial frontal gyrus, right superior temporal gyrus, right transverse temporal gyrus, left and right cingulate gyrus, right parahippocampal gyrus, left insula, left cerebellar culmen and midbrain. We found a positive correlation of SARA scores with the loss of gray matter in the right middle frontal gyrus, whereas cognitive performance was non-correlated.

Title: Dynactin-1 implicates autophagosome-lysosome fusion defects in the pathogenesis of neurodegenerative diseases

Authors: *H. ADACHI, Z. HUANG, K. OKADA, K. OHNARI, T. HASHIMOTO, T. TOYOTA, Y. IWANAKA
Dept of Neurol., Univ. of Occup. and Envrn. Hlth., Kitakyushu-Shi, Japan

Abstract: Background and Purposes: Dynactin is a dynein-activator complex required for most of the cellular functions of cytoplasmic dynein. Dynactin is composed of seven to nine polypeptides, including the dynactin-1 (p150Glued) that forms the sidearm of the complex and

binds both to microtubules and to dynein; the Arp1 polypeptide that forms an actin-like filament at the base of the complex; and the dynamitin, or p50, the subunit that localizes to the shoulder between the sidearm and the base. Autophagy is essential for neuronal homeostasis, and its dysfunction has been linked to many neurodegenerative disorders. In this report, we show that regulatory relationship between dynactin-1 and fusion of autophagosomes and lysosomes. Methods: In the present study, we used a combination of molecular biological techniques and morphological methods such as western blot, immunofluorescence, RFP-AcGFP-LC3 reporter assay, and immunoelectron microscopy on lentivirus-mediated dynactin-1 knockdown NSC 34 motor neuron cell line, and we determined the autophagosome-lysosomes fusion efficiency. Results: The levels of dynactin-1 protein expression were decreased in the dynactin-1 knockdown cells. The cell viability was decreased in dynactin-1 knockdown motor neuron cells. The level of the autophagosome marker LC3-II in cell culture was increased and the autophagosome-lysosome fusion was inhibited in dynactin-1 knockdown NSC 34 motor neuron cells. Conclusions: Our study identifies the dynactin-1 as a regulator that controls the fusion of autophagosomes and lysosomes. These findings suggest that dynactin-1 play important roles in the autophagy and implicate autophagosome-lysosome fusion defects in the pathogenesis of neurodegenerative diseases.

Title: Pathophysiologic insights into ataxia and spasticity through structural imaging of a spinocerebellar ataxia type 7 cohort

Authors: *J. PARKER, S. MERCHANT, S. HOROVITZ, M. HALLETT
Human Motor Control Section, NINDS, Bethesda, MD

Abstract: Spinocerebellar ataxia type 7 (SCA7) is a neurodegenerative disease characterized by progressive cerebellar ataxia, retinal degeneration, ophthalmoplegia, and spasticity. Postmortem analysis reveals widespread atrophy of the brainstem and cerebellum, but our understanding of the evolution of this pathology is limited. Methods that quantify differences in brain structure such as voxel-based morphometry (VBM) and diffusion tensor imaging (DTI) tractography may be used to assess these neurodegenerative changes *in-vivo*. The objective of this study was to

quantify the atrophy of various brain regions and white matter tracts with VBM and DTI tractography, and to correlate these metrics with clinical measures of ataxia and spasticity. Such correlations may identify useful biomarkers of disease progression and provide pathophysiologic insights into the mechanisms of ataxia and spasticity. In a cohort of 7 SCA7 patients (5 female), we measured ataxia using the SARA scale, 9-hole pegboard test, keyboard dexterity test, and Timed-Up-and-Go paradigm. Spasticity was quantified using the vibration inhibition index, a measure of H-reflex suppression with homonymous muscle vibration. T1w, T2w, and diffusion weighted images were acquired from this SCA7 cohort and 6 healthy controls (5 female). VBM was used to localize and quantify cerebral and cerebellar gray matter (GM) volumes. DTI tractography was used to determine fractional anisotropy (FA) in the corticospinal (CST), corticoreticulospinal (CRST), dentatothalamocortical (DTCT), and corticopontocerebellar (CPCT) tracts. Results showed a significant decrease in cerebellar GM volume in patients whereas cerebral GM volume was similar between the groups. An ROI-wise comparison in the cerebellum revealed decreased volume in patients in all 28 ROIs assessed. Bonferroni corrected two-sample t-tests revealed that this decrease was significant in the right and left flocculus and vermis region VIIb. The FA of the CST, CRST, and DTCT were also found to significantly differ between patients and controls through Bonferroni corrected two-sample t-tests. Imaging measures found to be significantly different between the two groups were subsequently correlated with clinical measures on a hypothesis driven approach, but no significant correlations were found with the small number of subjects so far investigated. Using this novel approach, we were able to assess in humans the brain regions and pathways previously implicated by animal studies in the pathophysiology of ataxia and spasticity. Longitudinal studies are warranted to reveal the relevance of these findings as potential biomarkers of SCA7 progression.

Title: Small molecule read-through compounds for the treatment of Ataxia-Telangiectasia

Authors: M. F. ABDALLAH[1], *P. J. MATHEWS[2]
[1]UCLA Harbor/LA BioMed, Torrance, CA; [2]Neurol., UCLA Harbor/LA Biomed, Torrance, CA

Abstract: Children stricken with Ataxia-Telangiectasia (A-T) live short (~25 years) lives characterized by a progressive loss of motor function (ataxia), an increased susceptibility to cancer, and immune abnormalities. A-T is an autosomal-recessive disease caused by mutations in the Ataxia-Telangiectasia Mutated (ATM) gene, which encodes a serine/threonine kinase involved in double-stranded DNA repair. In about one-third of A-T patients, the causative mutation is a nonsense mutation that encodes a premature termination codon (PTC) that produces a short-lived, truncated, and nonfunctional protein. There are currently no effective treatments for A-T, in part due to two main roadblocks: 1) we lack therapeutics capable of restoring ATM production, and 2) current animal models of A-T are inadequate for testing new therapeutic strategies. Our ongoing work, which we detail here, seeks to resolve these issues. To restore ATM production we are testing Small Molecule Read-Through (SMRT) compounds recently developed by Dr. Gatti and colleagues that have shown therapeutic promise in overcoming A-T patient-related PTCs, restoring functional ATM protein in both in vitro and ex vivo preparations. Our lab has independently reproduced these findings using human B cell-derived lymphoblastoid cell lines (LCLs) from A-T patients that contain a PTC. Pretreatment of LCLs with SMRT compounds at concentrations at or below 10 μM resulted in the production of ATM protein, and phosphorylation of downstream targets (e.g. p-ATM, p-Chk2, p-H2A-X) after Ultra-Violet (UV) irradiation (50 J/m^2) demonstrating ATM's functionality. To demonstrate that SMRT compounds are capable of restoring ATM production in a living animal we are creating mice harboring a human-related nonsense mutation in the Atm gene (103C>T) to test the drug ─ we denote this mouse as $Atm^{N/N}$ for "N"onsense mutation containing. Unlike wildtype littermates, we find no ATM expression in various tissues including the spleen, forebrain, and cerebellum. Like other mouse models of A-T to date, the $Atm^{N/N}$ mice do not display a progressive loss of motor coordination, thus limiting their use in testing SMRT compounds as a treatment for this characteristic aspect of the disease. For this reason we are utilizing a new genetic strategy to create a new A-T mouse model that preliminarily displays a marked, progressive loss of motor coordination.

Title: Emerging Roles of RNF216/TRIAD3 in the hypothalamic-pituitary-gonadal axis

Authors: *A. J. GEORGE, A. M. MABB
Neurosci. Inst., Georgia State Univ., Atlanta, GA

Abstract: Ubiquitin E3 ligases are substrate-specific enzymes in the ubiquitin pathway that participate in the turnover of proteins in the central nervous system and also control receptor trafficking. Recessive mutations in the E3 ligase *RNF216/TRIAD3* cause Gordon Holmes syndrome (GHS), with symptomologies of hypogonadotropic hypogonadism, cognitive impairment, dysarthria, cerebellar ataxia, and dementia. Individuals diagnosed with GHS have dysfunction at multiple levels of the reproductive endocrine axis also known as the hypothalamic-pituitary-gonadal (HPG) axis. This includes deficiencies in release of hypothalamic gonadotropin-releasing hormone (GnRH) and pituitary gonadotropins, luteinizing hormone (LH) and follicle-stimulating hormone (FSH) with diminished secretion of gonadal hormones, estradiol and testosterone. The role of *RNF216/TRIAD3* in the HPG axis and the selective vulnerability in these neuronal and pituitary cell types is unknown. Previously, we found that RNF216/TRIAD3 localizes at the plasma membrane with clathrin-coated pits in neurons, a region where receptor-mediated endocytosis takes place. Moreover, disruption in RNF216/TRIAD3 was found to alter the trafficking of AMPA receptors. In addition to controlling AMPA receptor trafficking, we found that both knockdown and overexpression of RNF216/TRIAD3 disrupts trafficking of the ubiquitous transferrin receptor suggesting RNF216/TRIAD3 broadly controls receptor trafficking. To test the role of RNF216/TRIAD3 function in regulating receptor trafficking within the HPG axis, we knocked out *RNF216/TRIAD3* using CRISPR-Cas9 in hypothalamic (GT1-7) and pituitary (LβT2) cell lines to determine if the trafficking of key HPG axis receptors such a kisspeptin and GnRH receptors are altered. Taken together, our work will illuminate how disruptions in RNF216/TRIAD3 lead to defects in the HPG axis and will inform translational research for neurological disorders involving HPG axis disruption.

Title: Functional studies of a missense variant in SLIT3 identified in a family with essential tremor

Authors: *Z. ODGEREL[1], S. SONTI[1], R. TABA[1], E. D. LOUIS[2], L. N. CLARK[1,3]
[1]Columbia Univ. Med. Ctr., New York, NY; [2]Dept. of Neurology, Yale Sch. of Medicine, Yale Univ., New Haven, CT; [3]Taub Inst. for Reaesarch on Alzheimer's Dis. and the Aging Brain, New York, NY

Abstract: Essential Tremor (ET) is a prevalent neurological disorder with an estimated prevalence of 5% for individuals aged over 65 and is typically characterized by the presence of an action tremor that occurs during voluntary movements. Genetic factors contribute to the etiology of ET. WGS analysis in ET families (FASET, NS073872) identified the *SLIT3* gene as a candidate gene in one ET family. A disease association of SNPs in the *SLIT3* gene and genetic risk (models: susceptibility, survival and age-at-onset) for Parkinson disease was previously identified in two independent GWAS datasets. Axon guidance pathway molecules are involved in defining precise neuronal network formation during development and in the adult central nervous system play a role in the maintenance and plasticity of neural circuits.
The non-synonymous variant (c.3526G>C, p.Val1176Leu) identified in *SLIT3* is highly conserved evolutionarily, is predicted to be deleterious and damaging by several in silico tools and has an allele frequency of 0.0006407 in ExAC. To determine the functional effect of the *SLIT3* variant identified in an ET family, the variant was expressed in HEK293 and SH-SY5Y cell lines using the pLenti-C-Myc-DKK vector. Our preliminary result shows that there is a difference in the length of dendrites between the cells transduced with wild type SLIT3 compared to those with mutant SLIT3 protein. We are currently performing the Sholl analysis to determine alterations in dendrite morphology including fragmentation of dendrites and changes in branching pattern and will further discuss the findings from the analysis.

Title: Modeling genetic loss of function ataxia phenotypes in zebrafish

Authors: *E. BUGLO, N. MARTUSCELI, E. SARMIENTO, J. DALLMAN, S. L. ZÜCHNER
Univ. of Miami, Miami, FL

Abstract: Introduction: Recessive ataxias are a group of debilitating neurological disorders, which mainly affect balance and movement as a result of cerebellar degeneration. More than

60% of patients are lacking genetic diagnosis due to unknown pathogenic variants. Therefore, many candidate genes require an efficient approach to functional testing. The need for an effective functional approach led us to modeling ataxia in zebrafish, which is a vertebrate system with conserved genetic and circuit homology, as well as optical transparency for convenient visualization of the fluorescently labeled neuronal cells. In this study we model three known ataxia genes with diverse disease phenotypes and mechanisms: slc25a46 involved in mitochondrial dynamics, snx14 involved in lysosomal clearance, and polr3a which works on small RNA transcription. We aim to better understand the commonalities in cellular loss of function phenotypes, and establish cellular and behavioral markers of ataxia in zebrafish.
Methods: We used CRISPR/Cas9 to generate stable knockout lines with frameshift alleles in the targeted genes. We analyzed zebrafish at larval stages up to 6 days by whole-mount immunostaining and confocal imaging of the motor neurons and Purkinje cells of the cerebellum. We performed visual motor response assays to test behavioral swimming phenotypes. The number of animals used for experiments was approximately 500 larvae per gene, with the sample size 30-50 larvae per experiment.
Results: Polr3a mutants show severe brain abnormalities with thinner and flattened cerebellum and forebrain, smaller eyes, deformed gut, and absence of swim bladder. Snx14 and slc25a46 phenotypes, in contrast to previously published reports using morholino knockdown, which showed drastic degeneration of Purkinje cell layer in snx14 morphants and motoneuron degeneration in slc25a46 morphants, our mutant lines show a mild neuronal phenotype: shorter, but well-formed motoneuron axons and smaller, but well-shaped Purkinje cell layer. Neither snx14, not slc25a46 mutants have observed deficiencies in swimming as tested by Noldus Danio Vision movement analysis platform.
Conclusions: The three chosen genes for modeling complex recessive ataxia in zebrafish using CRISPR knockout approach show different levels of cerebellar disruption and behavioral swimming phenotypes. Although snx14 and slc25a46 genetic loss of function is severe in humans, the zebrafish knockout model only has a mild phenotype. Our study serves as an important exploration of zebrafish model of ataxia, and as a checkpoint for discrepancies between knockdown and knockout methodologies for functional gene studies.

Title: Novel genes that modulate levels of mutant ATXN3 in the polyglutamine disorder, Machado-Joseph disease

Authors: N. S. ASHRAF[1], J. R. SUTTON[2], B. RANXHI[2], Y. YANG[1], E. SHAW[1], S. V. TODI[2], H. L. PAULSON[1], *M. COSTA[1]

Abstract: Machado-Joseph disease (MJD), also known as Spinocerebellar Ataxia type 3, is a polyglutamine (polyQ) neurodegenerative disease caused by a CAG repeat expansion encoding an abnormally long polyQ stretch in the disease protein, ataxin-3 (ATXN3). No preventive treatment is yet available for MJD or any other polyQ diseases. Because expanded polyQ proteins accumulate in diseased brain, a compelling therapeutic approach is to reduce levels of the mutant protein by manipulating pathways that control their production, stability, or clearance. Here we sought to identify molecular pathways that modulate levels of expanded-polyQ ATXN3, with the long-term goal of developing therapies for this fatal and untreatable disease. Using a cell-based assay that provides readout of expanded ATXN3 levels, we screened a collection of siRNAs targeting 3,080 human druggable genes encoding GPCRs, kinases, phosphatases, ions channels and proteins involved in protein quality control. From this initial screen, 100 genes for which knockdown resulted in significantly altered signal were selected for follow-up studies. Thirty-three genes were confirmed to selectively affect luminescence signal in AT3-Luc cells but not in control cells expressing Luc alone, suggesting that they are likely regulators of mutant ATXN3 abundance in cells.. A subset of these genes (n= 17) was subsequently validated by immunoblotting as modulators of ATXN3 levels in an independent cell model expressing expanded ATXN3. Network analysis of the 17 genes revealed three hub genes, including a kinase of the NF-kB pathway. Accordingly, expression of this human kinase in a drosophila model of MJD decreases lifespan compared to flies not expressing the kinase. We are currently further defining the role of this kinase in modulating cellular levels of ATXN3. Genes identified in our siRNA screen as modulators of mutant ATXN3 abundance represent candidate therapeutic targets for MJD.

Abstract: Leukoencephalopathy with brainstem and spinal cord involvement and lactate elevation (LBSL) results in a rare, progressive, neurological disease that manifests as white matter signal abnormalities in the cerebral white matter and spinal cord, as well as slowly progressive dorsal column spasticity, dysarthria, and ataxia. Most LBSL patients are compound heterozygotes for mutations in *DARS2*, encoding the mitochondrial enzyme aspartyl-tRNA synthetase. Over 50 disease variants have been recorded in patients with LBSL, with the most frequent mutation causing a frame shift prior to the third exon and downstream errors of splicing. As production of *DARS2* is affected throughout the body, it is thought that the extreme energy demands of the central nervous system make the brain especially susceptible to the consequences of reduced *DARS2* functioning. Although no current animal model recapitulates the genetic composition of LBSL patients, we can model some aspects of disease pathology using conditional knock out mouse models. Furthermore, we have created patient-derived induced pluripotent stem cells (iPSCs) to help to elucidate the effects of these specific disease variants. Complete deletion of *DARS2* within CamKIIα expressing neurons of mice results in progressive and severe cortical atrophy, with brain area reduced by 20% by 9 months of age ($p < 0.001$) and corpus callosum thickness reduced at midline by 40%. In addition, neuroinflammation is present in the cortex, signified by microglia with thickened processes and enlarged soma ($p < 0.001$). These changes are paralleled by an age-dependent increase in locomotor activity ($p < 0.001$). Despite the overall reduced area of the corpus callosum, electron microscopy reveals increased axonal area ($p < 0.05$) and thickness of myelin ($p < 0.05$), as well as increased mitochondrial number ($p < 0.005$). In patient iPSCs, preliminary work reveals reduced efficiency of *DARS2* splicing by approximately 50%, a phenotype preserved when these cells are then differentiated

into motor neurons. Together, these models serve to provide insight into the various aspects of LBSL pathology and can be used to study cell-type specific effects of *DARS2* deficiency. These models may further allow for the testing of therapeutics for the treatment of LBSL.

Title: Mutant ataxin1 disrupts postnatal cerebellar development in spinocerebellar ataxia type 1

Authors: *C. EDAMAKANTI, J. DO, M. MARTINA, P. OPAL
Neurol., Northwestern Univ. Feinberg Sch. of Med., Chicago, IL

Abstract: Background and Objective: Spinocerebellar ataxia type1 (SCA1) is an adult-onset neurodegenerative disease caused by a pathogenic polyglutamine expansion in the protein Ataxin1. Since Purkinje cells bear the brunt of the pathology in SCA1, scientific investigations have focused on characterizing intrinsic deficits within these neurons. Although symptoms appear relatively late in life, primarily in the cerebellum, pathogenesis begins early, with brain-wide transcriptional changes appearing a week after birth in SCA1 knock-in mice. Moreover, delaying expression of Ataxin1 or restoring the aberrant gene expression (YAPdeltaC and RORα) during first three postnatal weeks is enough to ameliorate the pathophysiology of SCA1. During this early period, neurogenesis is still taking place within a niche of postnatal stem cells in the cerebellar white matter, which led us to ask whether early neurodevelopment gone awry in ways that alter the neural circuitry of the cerebellum. Methods: Used SCA1 patients, SCA1 mice (Knock-in, Transgenic and knock-out) and cell culture models to prove hypothesis. Results: We found that the cell-autonomous gain of ATXN1 function stimulates the proliferation of postnatal cerebellar stem cells in SCA1 mice. Using in vitro and in vivo experiments confirmed that these hyper-proliferating stem cells tended to differentiate into GABAergic inhibitory interneurons rather than astrocytes; this significantly increased the GABAergic inhibitory interneuron synaptic connections, disrupting cerebellar Purkinje cell function in a non-cell autonomous manner. We confirmed the increased basket cell-Purkinje cell connectivity in human SCA1 patients. Mutant ATXN1 thus alters the neural circuitry of the developing cerebellum, setting the stage for the later vulnerability of Purkinje cells to SCA1. We propose that other late-onset degenerative diseases in which early transcriptional alterations have been found may also be rooted in subtle

developmental derailments. These interesting findings pave a way to test the novel therapeutic targets in SCA1 field.

Title: FTY720-derivatives increase neurotrophic factor expression and protects oligodendroglia against hydrogen-peroxide-mediated oxidative stress

Authors: *J. VARGAS, I. SEGURA-ULATE, G. VIDAL-MARTINEZ, B. YANG, R. PEREZ
Biomed. Sci., TTUHSC, El Paso, TX

Abstract: Multiple system atrophy (MSA) is a lethal demyelinating neurodegenerative disorder for which there are currently no disease-modifying treatments. MSA pathology includes α-synuclein (aSyn) accumulation in glial cytosolic inclusions (GCIs) inside oligodendroglial cells (OLGs), the myelinating cells of brain. This is believed to induce aberrant expression of brain-

derived neurotrophic factor (BDNF) and glial-cell line derived neurotrophic factor (GDNF) in OLGs in MSA brains and MSA mouse models with GCIs. Yet, it is unclear if oxidative stress also impacts OLG cell viability as aSyn-accumulates. Using the OLG cell line, OLN-93, we stably overexpressed human wild type aSyn or an MSA-associated G51D mutant form of aSyn. aSyn OLN-93 lines were more sensitive to oxidative stress than OLN-93 cells lacking aSyn expression. We further evaluated OLN-93 cells treated with FTY720 (Fingolimod), an FDA approved multiple sclerosis drug, and our novel non-immunosuppressive FTY720-derivatives, FTY720-C2 and FTY720-Mitoxy. All three FTY720s cross the blood brain barrier and OLN-93 cell viability was normal after 48 hr treatments with the various FTY720s [160 nM]. The parent compound, FTY720, as well as FTY720-C2 increased nerve growth factor (NGF) expression at 24 hr. In contrast, our mitochondrial-targeted-FTY720-derivative, FTY720-Mitoxy, increased BDNF, GDNF, and NGF expression at 24 hr. Moreover, pretreating OLN-93 cells with FTY720s for 48 hr totally blocked oxidative cell death associated with 2 hr treatment with H_2O_2 [75 µM] and showed a trend toward protection with H_2O_2 [100 µM]. However, pretreating with FTY720s for 12 hr followed by 24 hr H_2O_2 [100 µM] + FTY720s [160 nM] did not block OLN-93 death. These data suggest that excessive oxidative damage in OLG cells cannot be blocked by FTY720s. However, early treatment of MSA patients with FTY720s may protect OLGs by increasing their expression of major trophic factors. Our data further suggest that the therapeutic potential of FTY720-Mitoxy may be even greater than the parent compound as this FTY720-derivative will not induce immunosuppression yet significantly stimulates OLG expression of BDNF, GDNF, and NGF. We are currently assessing FTY720-Mitoxy in MSA mice.

Title: FTY720-Mitoxy a novel FTY720-derivative improves movement cognition and sweat function in multiple system atrophy mice

Authors: *R. PEREZ, G. VIDAL, B. YANG, J. VARGAS, I. SEGURA, V. DIAZ-PACHECO, J. DE LEON, J. BARRAGAN, S. CHAPARRO
Texas Tech. Univ. Hlth. Sci. Ctr. El Pa, El Paso, TX

Abstract: Multiple system atrophy (MSA) is a progressive neurodegenerative disorder that affects both the central and peripheral nervous systems. MSA pathology occurs due to abnormal alpha-synuclein (aSyn) aggregation inside myelinating glia. Oligodendroglial aSyn-pathology then causes widespread denervation, which in MSA patients' impairs movement, cognition, sudomotor function, and thermoregulation. CNPaS aSyn transgenic (Tg) mice are an MSA mouse model that expresses aSyn under control of the myelinating glia specific 2', 3'-cyclic nucleotide 3'-phosphodiesterase (CNP) promoter. Tg mice form aSyn-containing glial cytoplasmic inclusions (GCI) in brain and spinal cord oligodendroglia between 9 and 12 mo. We have developed FTY720-Mitoxy, which is an analogue of an FDA-approved drug that crosses the blood-brain-barrier and has potent neuroprotective effects in vitro. We hypothesized that FTY720-Mitoxy blocks aSyn pathology to normalize movement, cognition and sudomotor activity. We tested this in wild type (WT) and Tg littermates using Rotarod, Barnes maze, object recognition tests and a iodine-starch sweat test at baseline and after FTY720-Mitoxy or Vehicle control solution. Hindlimb soleus and gastrocnemius muscles were collected to evaluate their potential contribution to movement. At baseline WT and Tg mice performed similarly on all tests. Vehicle treated Tg mice had impaired movement at 10.5 mo with sweat production being reduced only in Tg males. FTY720-Mitoxy treated Tg mice did better on Rotarod and showed an increase in hindlimb muscle mass. Sweat production was restored to normal levels for FTY720-Mitoxy treated Tg males. On cognitive tests, FTY720-Mitoxy treated Tg females were significantly better than Tg males at 11.5 mo. Overall these preclinical data suggest that FTY720-Mitoxy may slow MSA dysfunction making it a promising candidate for clinical development.

Title: Antisense oligonucleotides ameliorate disease in spinocerebellar ataxia type 3 mice

Authors: *H. S. MCLOUGHLIN[1], L. MOORE[1], R. CHOPRA[1], R. KOMLO[1], M. MCKENZIE[1], K. BLUMENSTEIN[1], H. T. ZHAO[2], H. B. KORDASIEWICZ[2], V. G.

SHAKKOTTAI[1], H. L. PAULSON[1]
[1]Neurol., Univ. of Michigan, Ann Arbor, MI; [2]Ionis Pharmaceuticals, Inc., Carlsbad, CA

Abstract: ABSTRACT
Spinocerebellar ataxia type 3 (SCA3) / Machado-Joseph Disease (MJD), is the most common dominantly inherited ataxia in the world. It is caused by an expansion of a polyglutamine-coding CAG repeat in the *ATXN3* gene. There currently is no effective treatment for this relentlessly progressive and fatal disease. Because expression of the mutant protein is an early and necessary step in disease pathogenesis, strategies to reduce expression of the disease gene itself are high on the list of potential therapies. Through a collaboration with Ionis Pharmaceuticals, we recently reported the potential for antisense oligonucleotide therapy to reduce mutant ATXN3 protein after a single ASO treatment. Here we follow up that study to longitudinally investigate whether an anti-*ATXN3* ASO can prevent molecular, neuropathological, electrophysiological and behavioral features of the disease in a SCA3 mouse model. The top *ATXN3*-targeting ASO from our published *in vivo* screen was injected intracerebroventricularly into post-symptomatic transgenic YAC transgenic SCA3 mice, which express the full-length human *ATXN3* disease gene and recapitulate key disease features by 6 weeks of age. Following a single *ATXN3*-targeting ASO treatment at 8 weeks of age, treated mice achieved sustained reduction of polyQ-expanded ATXN3 up to 16 weeks of age. The *ATXN3*-targeting ASO also prevented high molecular weight species and nuclear accumulation of ATXN3 up to 22 weeks of age. To assess effects of ASOs on SCA3 mouse behavior, mice received an additional ASO injection at 21 weeks and were evaluated longitudinally up to 29 weeks for motor performance. Longitudinal ASO therapy led to a complete rescue of motor impairment in SCA3 mice by 29 weeks of age. This behavioral rescue was associated with a recovery of defects in Purkinje neuron firing frequency and afterhyperpolarization in SCA3 mice. Overall, our assessment of an *ATXN3*-targeted ASO established efficacy and supports further efforts to develop ASOs for human SCA3 clinical trials.

Title: Dysregulated IP3R-mediated endoplasmic reticulum-mitochondria calcium signal pathways contribute to mitochondrial bioenergetic deficits and cell death in Friedreich ataxia

Authors: *H. LIN[1,2], E. M. CLARK[2], S. GHURA[2], N. WARREN[1], A. SALOVIN[1], J. MAGRANE[3], D. R. LYNCH[1,2]
[1]Neurol. and Pediatrics, The Children's Hosp. of Philadelphia, Philadelphia, PA; [2]Pediatrics and Neurol., Univ. of Pennsylvania Sch. of Med., Philadelphia, PA; [3]Weill Cornell Med. Col., New York, NY

Abstract: Friedrich ataxia (FRDA) is an autosomal recessive neurodegenerative disease caused by deficiency of a mitochondrial protein frataxin. Mitochondrial dysfunction and dysregulated calcium homeostasis have been implicated in FRDA. IP_3Rs are IP_3-activated Ca^{2+} release channels located on the endoplasmic reticulum (ER) that are crucial for regulating cell survial and death by controlling Ca^{2+} transfer from the ER to mitochondria through mitochondria-associated ER membranes (MAMs). The pathophysiological role of IP3R-mediated ER-mitochondrial Ca^{2+} signaling in FRDA remains unclear. Here we report that dysregulated IP3R-mediated ER-mitochondrial Ca^{2+} signal pathways contribute to mitochondrial bioenergetic deficits and cell death in FRDA patient cellular and animal models. In normal mice and human fibroblasts, type 1 and 3 IP3Rs are highly expressed and widely distributed as puncta in mouse cerebellar Purkinje neurons and human fibroblasts. IP3Rs interact with mitochondrial chaperone protein GRP75 in a multiprotein complex and appear in close contact with GRP75-labeled mitochondrial network. In FRDA mouse cerebellum and patient fibroblasts, IP3R levels, IP3R interactions with GRP75 and contacts with GRP75-labeled mitochondrial network as well as ER-mitochondria contacts are significantly reduced compared with controls. Furthermore, in the isolated MAM fractions of KIKO brains, ER-mitochondria tethering protein MFN2 and mitochondrial calcium uptake proteins VDAC1 and MICU1 are significantly decreased compared with controls, suggesting that impaired IP3R-mediated mitochondrial Ca^{2+} signaling may contribute to mitochondrial Ca^{2+} deficiency and bioenergetic deficits in FRDA. Interestingly, staurosporine- or H_2O_2-induced stress in patient fibroblasts leads to a larger increase in IP3R levels, IP3R contacts with fragmented mitochondrial network and cleaved caspase 3 than in controls. This suggests that FRDA patient fibroblasts may be more vulnerable to stress-induced increase in IP3R-mediated mitochondrial Ca^{2+} signaling, thereby leading to mitochondrial Ca^{2+} overload and cell loss in FRDA. Taken together, our findings demonstrate that dysregulated IP3R-mediated ER-mitochondrial Ca^{2+} signal pathways contribute to mitochondrial bioenergetic deficits and cell death in FRDA, thereby providing novel pathogenic mechanisms underlying selective neuronal vulnerability and potential therapeutic strategies for FRDA patients.

Title: Transcriptome sequencing of spinocerebellar ataxia type 2 (sca2) mouse spinal cord toward identifying therapeutic targets for amyotrophic lateral sclerosis (als)

Authors: *D. R. SCOLES, W. DANSITHONG, L. PFLIEGER, S. PAUL, K. FIGUEROA, S. PULST
Dept. of Neurol., Univ. of Utah, Salt Lake City, UT

Abstract: Objectives: To characterize the spinal cord (SC) transcriptome of spinocerebellar ataxia type 2 (SCA2) mice toward identifying therapeutic targets and biomarkers for amyotrophic lateral sclerosis (ALS). **Background:** CAG repeat expansions in the *ATXN2* gene are the cause of SCA2 and increase the risk of ALS. Patients with SCA2 also often present with motor neuron disease characteristic of ALS. Our past work demonstrated that lowering the expression of *ATXN2* using an antisense oligonucleotide (ASO) delivered to the lateral ventricle improved motor, molecular and neurophysiological phenotypes of two different SCA2 mouse models. In addition, reduction of *Atxn2* expression genetically or by ASO improved the survival of TDP-43 ALS mice. These observations suggest that knowledge of the SCA2 spinal cord transcriptome might aid in understanding targets for ALS therapy and biomarkers useful for drug development. **Methods:** RNA-seq of SC and cerebellar (CB) RNAs was performed using BAC-ATXN2-Q72 mice vs wildtype littermates, including mice of 20-34 wks of age (total *N*=16). Differentially expressed genes (DEGs) were analyzed by weighted gene co-expression network analysis (WGCNA), and pathway analysis (GO, KEGG, IPA). **Results:** The DEG cutoff used was $P<0.05$, $|\log2(FC)| > 0.585$. 12.6% of DEGs were shared between SC and CB. WGCNA identified three SC gene modules significantly correlated with SCA2. Top pathways of each were immune system processes, cholesterol biosynthesis and lipid biosynthesis, three pathways that are dependent on insulin induced gene 1 (*Insig1*) that was significantly downregulated in SCA2 mouse spinal cord. We also identified 9 DEGs in SCA2 mouse SC that are related to ALS pathology, including genes encoding angiotensinogen (*Agt*), EAAT2 (*Slc1a2*), Pcp4, and Fus. **Conclusions:** This study provides new insights into the underlying molecular basis of ALS motor neuron phenotypes observed in SCA2. The presence of ALS-related genes in the SCA2 mouse SC transcriptome validates the SCA2 mouse as an ALS model. This study also suggests

possible therapeutic targets for ALS given that reduction of *Atxn2* increased TDP-43 ALS mouse survival. <!--EndFragment-->

Title: The impact of ataxin-3 isoforms on the pathogenesis of Spincerebellar Ataxia Type 3

Authors: *T. SCHMIDT[1,2], D. WEISHAEUPL[1,3,2], J. SCHNEIDER[1,2], B. PINHEIRO[1,2], C. RUESS[1,2], S. DOLD[1,2], F. VON ZWEYDORF[4,5], C. J. GLOECKNER[4,5], J. SCHMIDT[1,2], O. RIESS[1,2]

Abstract: Ataxin-3 is a deubiquitinating enzyme involved in the ubiquitin-proteasome system and transcriptional regulation. The encoding gene *ATXN3* is alternatively spliced leading to two full-length isoforms which differ in their number of ubiquitin interacting motifs. Both isoforms are additionally modified by single nucleotide polymorphisms that cause amino acid changes and a premature stop in one isoform. An expansion of the polyglutamine repeat within ataxin-3 causes Spinocerebellar Ataxia Type 3 (SCA3), also known as Machado Joseph Disease (MJD), a progressive neurodegenerative disorder. Clinically, SCA3/MJD is characterized by a variability of the age at onset and disease severity. In this study we associate this variability to the combination of different ataxin-3 isoforms. We examined the significance of ataxin-3 isoforms and the effect of the premature stop mutation on major aspects of the physiological function of ataxin-3 as well as their impact on main disease mechanisms. On the physiological level we could show that alternative splicing and the premature stop cause changes in the stability of ataxin-3 isoforms and that ataxin-3 isoforms differ in their enzymatic deubiquitination activity, subcellular distribution and interaction with other proteins. On the pathological level we found that the expansion of the polyglutamine repeat leads to a stabilization of the respective isoform

and that ataxin-3 isoforms differ in their aggregation properties on multiple levels. Interestingly, the interaction of ataxin-3 alleles modifies physiological as well as pathophysiological properties of ataxin-3. Taken together our current data indicates that alternative splicing as well as the mutual interaction of ataxin-3 isoforms affects major aspects of the normal ataxin-3 function as well as the pathogenesis of SCA3/MJD. We believe that our data will lead to an improvement in the prediction of disease severity and age at onset by taking into account the specific combinations of ataxin-3 isoforms which thus may become important additional markers in therapeutic interventions.

Title: Low-frequency dentate nucleus deep cerebellar stimulation treats cerebellar ataxia

Authors: *C. ANDERSON[1], K. P. FIGUEROA[1], A. D. DORVAL[2], S. M. PULST[3]
[1]Neurol., [2]Dept. of Bioengineering, Univ. of Utah, Salt Lake City, UT; [3]Univ. of Utah Clin. Neurosciences Ctr., Salt Lake City, UT

Abstract: Background: Degenerative cerebellar ataxias affect 1 in 5,000 people worldwide, presenting with motor symptoms including incoordination, tremor, and falls. Despite more than twenty years since the first Spinocerebellar ataxia genes were discovered, treatment strategies are limited. Many ataxia forms share the loss of Purkinje cells, a major source of input to the deep cerebellar nuclei. This degeneration dysregulates the dentatothalamocortical network, resulting in reduced transmission of information related to properly coordinated movement. Thus, we have developed an electrical stimulation-based therapy for degenerative ataxias by targeting the dorsal dentate nucleus, aimed at enhancing the throughput of motor-relevant signaling through the dentatothalamocortical network. **Materials and Methods**: We tested this therapeutic strategy in the Wistar Furth *shaker* rat model of degenerative cerebellar ataxia, which presents with a full-body cerebellar tremor, progressing to a shaking ataxia, with frequent falling. We bilaterally, chronically implanted a cohort of *shaker* rats with stimulating electrodes to test the hypothesis

that electrical stimulation targeted to the dorsal dentate nucleus can reduce motor symptoms. We tested a spectrum of frequencies from very low to high frequency, testing the hypothesis that low frequency deep cerebellar stimulation would most optimally reduce motor symptoms. We quantified symptoms in an operator-independent manner via novel methods of our design and characterized the behavioral response to the spectrum of stimulation frequencies. Further, we are currently coupling *in vivo* single unit and local field potential recordings in the dentate nucleus with therapeutic and non-therapeutic stimulation to improve mechanistic understanding. **Results**: We tested dentate nucleus stimulation across a large domain of frequencies, and we found that 20-30 Hz stimulation most effectively reduced motor symptoms. Interestingly, stimulation frequencies over 100 Hz, commonly used for Parkinsonism and essential tremor, were tied to worsened incoordination, while very low frequencies within the tremor physiologic range (sub 10 Hz) contributed to increases in tremor. We will further present results related to the network effects of stimulation and discuss the network effects of stimulation that result in symptomatic improvement. **Conclusions**: Low-frequency deep cerebellar stimulation may provide a novel method for treating the motor symptoms of some forms of degenerative cerebellar ataxia.

Title: Loss of mkp-5 prevent fibrosis accumulation in dystrophic muscle disease

Authors: *T. M. GYLES[1], K. MIN[2], A. M. BENNETT[2]
[1]Morehouse Col., Owings Mills, MD; [2]Pharmacol., Yale Univ. Sch. of Med., New Haven, CT

Abstract: Duchenne muscular dystrophy (DMD) is a degenerative skeletal muscle disease induced by mutations in dystrophin gene. The disease is characterized by progressive skeletal muscle degeneration and cardiac muscle weakness which result in premature death. It has been established that excessive accumulation of fibrosis is a prominent contributor to skeletal muscle dysfunction in DMD. The mitogen-activated protein kinases (MAPKs) are required to promote skeletal muscle myogenesis and function. The MAPKs are negatively regulated by the MAPK phosphatases through direct dephosphorylation. Recently, our group demonstrate that MKP-5 is involved in the progression of dystrophic muscle disease. However, the pathophysiological mechanisms of how MKP-5 regulates the progression of dystrophic muscle disease are unclear.

Therefore, we are investigating the role of MKP-5 in development of fibrosis in dystrophic muscle disease using genetic mouse models. Our data show that phosphorylation of Smad2 was significantly decreased in skeletal muscle from $m;k;p;5^{-/-}$〖mkp5〗^(-/-) mice in response to injury. In order to investigate the role of MKP-5 in TGF-β signaling in dystrophic muscle disease, we intercrossed $m;k;p;5^{-/-}$〖mkp5〗^(-/-) mice into the mdx background in order to generate $m;d;x;m;k;p;5^{+/+}$〖mdxmkp5〗^(+/+) and $m;d;x;m;k;p;5^{-/-}$〖mdxmkp5〗^(-/-) . Our data show that gene expression of fibrosis markers such as Col1a1, Col3a1, and FN1 was significantly decrease in skeletal muscle from $m;d;x;m;k;p;5^{-/-}$〖mdxmkp5〗^(-/-) compared with $m;d;x;m;k;p;5^{+/+}$〖mdxmkp5〗^(+/+) mice. These results may indicate that MKP-5 negatively regulate the signaling of fibrosis in dystrophic muscle disease

Title: Knockin mouse models to understand ALS pathomechanism

Authors: *E. M. FISHER[1], A. DEVOY[1], L. GREENSMITH[1], G. SCHIAVO[1], A. ISAACS[1], P. FRATTA[1,2], T. CUNNINGHAM[2,3], A. ACEVEDO AROZENA[3]

Abstract: Research objective and rationale: Amyotrophic lateral sclerosis (ALS) is a relentless degenerative disease of the motor system, for which there are few treatments and no cures. In order to understand pathomechanisms, we need a multiplicity of systems including mouse models, through which we can study tissue:tissue interactions, for example, over the full course of lifespan. In ALS, approximately 10% of cases are familial, usually autosomal dominant, and we can create mouse models based on the >20 genes that have been found to be causative for this disorder. **Methods and results**: We have a long-term interest in creating knock in mouse models of disease, in order to avoid any confounds from the overexpression that arises

in transgenic models. From our experience we tend to produce mice with milder phenotypes and slower disease course than transgenics, and this enables us to study early stage disease. Here we present new mouse models of ALS (validated by specific tests as below) and new data. (1) the *Sod1*^{D83G} mouse (Joyce et al, 2015); (2) the FUS Delta14 mouse (Devoy et al, 2017); (3) an allelic set of *Tardbp* (TDP-43) mutants, including a new strain with spinal cord motor neuron degeneration, novel splicing changes that we also find in human mutant *TARDBP*-ALS cells, and no other visible phenotype (Fratta et al, 2018), and we give information on other models that we are producing/characterising. **Sample sizes, replication, controls:** Our methods of creating mice range from chemical mutagenesis through to sophisticated humanised targeting constructs for embryonic stem cells. We characterise statistically significant cohorts, separated by sex, via a longitudinal panel of tests including behaviour, physiology, histology, and transcriptomics - which are then validated in human tissue/cell lines. Mice are kept on more than one inbred background which is carefully monitored and all controls are wildtype littermates, age-and sex-matched in comparable cohort sizes.

Abstract: Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disease that affects lower motor neurons in brainstem and spinal cord, and the upper motor neurons in the motor cortex, and leads to a progressive muscle phenotype in patients. Its considerable genetic and clinical heterogeneity indicate that there must be factors that modify the phenotypic expression of the disease. One such modifying factor is the tyrosine kinase receptor EphA4. Genetic and pharmacological inhibition of EphA4 rescued the motor neuron phenotype in zebrafish and rodent models of ALS, and an inverse correlation was found between EphA4 expression levels and disease onset and survival in patients. We aimed to identify whether ephrin ligands would contribute to the EphA4 modifying effect in ALS. Most ephrin-A and ephrin-B ligands are able

to bind and activate EphA4. Here, we determined the contribution of ephrin-A5 in ALS, by genetic knockdown in a mouse model of ALS, the $SOD1^{G93A}$ mouse. We followed the mice during disease progression to determine the decline in their motor behavior as well as their latency to reach an end-stage point of the disease. Although we did not observe differences in disease onset, survival and disease duration were significantly reduced in the mice with lower ephrin-A5 levels. In situ hybridization of ephrin-A5 in the spinal cord of $SOD1^{WT}$ and $SOD1^{G93A}$ mice revealed that this ephrin ligand is mainly expressed in neurons, both ChAT positive and negative. However, a reduction of its levels did not lead to further nerve conduction deficits nor deficits in the percentage of innervated neuromuscular junctions in the gastrocnemius muscle. Finally, no differences could be detected in the expression levels of several biomarkers of neuronal function, astroglial reactivity and microglial activation in the spinal cord of $SOD1^{G93A}$ mice with normal or reduced levels of ephrin-A5. These results suggest that, in contrary to EphA4, ephrin-A5 expression might be beneficial during ALS disease progression. Further work is needed to understand the mechanism of this beneficial role of ephrin-A5 in ALS, and to reveal if its effect on disease progression is EphA4-dependent or independent.

Abstract: Amyotrophic Lateral Sclerosis (ALS) is the most common motor neuron disease leading to progressive paralysis. Previous studies using mouse models expressing mutant hSOD1 (the second most frequent mutated gene in ALS) highlighted the implication of microglial cells/ macrophages in ALS disease progression without, however discriminating their respective role. A special feature of spinal cord motor neurons is that their axon extends at the periphery and is therefore surrounded by peripheral macrophages while their cell body, is surrounded by microglia. Although microglia and peripheral macrophages share common characteristics, both populations have different developmental origins and are localised in different cellular environments, which could lead to different implications in the disease. Since degeneration of motor neuron axons happens early and macrophages at the periphery would be more easily accessible than microglia in the CNS, we studied the potential of peripheral macrophages as therapeutic targets in ALS mice. First, we showed strong and progressive macrophage activation in the sciatic nerve of $hSOD1^{G93A}$ (fast progressing) and $hSOD1^{G37R}$ (slow progressing) ALS mice, suggesting an active role of macrophages in the pathology. We developed a protocol using bone marrow graft to replace macrophages at the periphery without affecting microglia. We replaced mutant hSOD1-expressing macrophages by control (GFP+) macrophages or macrophages with more trophic or less toxic potentials. Our protocol allowed an efficient replacement of monocytes/ macrophages (GFP+) in the blood and in peripheral tissues affected in ALS. We showed that infiltration of peripheral cells remained low during disease, as only few GFP+ peripheral cells were transiently found in the spinal cord of grafted ALS mice and seemed dependant of disease duration. These results were further confirmed by immunostaining of specific markers and by using transgenic reporter mice. The effect of peripheral macrophages in ALS therefore rather comes from the periphery, and this allowed us to perform distinct transcriptomic studies of spinal cord microglial cells, and sciatic nerve macrophages during disease course in ALS mice to find differentially expressed markers in the two populations and according to disease stages. Finally, replacement of mutated macrophages by cells more trophic or less toxic led to an improvement of several pathophysiological markers and delayed the symptomatic stage of ALS grafted mice. In conclusion, we provide new evidence suggesting an active role of peripheral macrophages in ALS, supporting future therapeutic strategies by targeting peripheral macrophages.

Title: Identification and evaluation of disease relevant biomarkers of progressive neurodegeneration in preclinical models of amyotrophic lateral sclerosis

Authors: *J. SUGAM, J. WONG, S. NIROOMAND, H. ZARIWALA, D. ZHOU, R. GENTZEL, Y. HU, T. ROSAHL, S. PARMENTIER-BATTEUR
Merck and Co., Inc, West Point, PA

Abstract: Amyotrophic Lateral Sclerosis (ALS) is fatal neurodegenerative disorder characterized by the selective loss of motor neurons in the brain and spinal cord that leads to progressive motor dysfunction. Several mechanisms have been found to be underlying causes of this motor neuron degeneration including increases in oxidative stress, endoplasmic reticulum stress pathway activity, and neuroinflammation. In order to develop therapeutic strategies that can modify the progression of the disease, it is necessary to identify and validate translatable biomarkers that could reflect this motor dysfunction and neurodegeneration. To this end, two transgenic animal models of ALS consisting in SOD1 G93A mice and TDP43 Tar 6/6 mice were characterized using motor (accelerated rotarod/grip strength), histological (neuromuscular junction denervation), electrophysiological (compound muscle action potential (CMAP)), and biochemical (phospho-neurofilament heavy chain levels (pNF-H), muscle atrophy markers, MAPK pathway activity) assays. The measures of all these markers were performed at various ages in order to determine their relationship with the progression of the disease. In SOD1 mice, we found an age related dysfunction in multiple biomarkers including an increase in pNF-H and in neuromuscular junction denervation that was associated with the progressive decrease in motor functions evaluated by the CMAP, rotarod and grip test scores. Interestingly, these markers all overlapped with each other to effectively reflect disease onset, progression, and terminal limb paralysis. These disease biomarkers were further validated by studying the effect of the administration of the new FDA approved therapy, Edaravone, to SOD1 mice. In contrast to the SOD1 mice, the TDP43 Tar6/6 mice showed moderate modification in a subset of these markers including pNF-H and motor impairments using rotarod, but no changes in CMAP scores or markers of muscle atrophy, suggesting that the muscle function and lower motor neuron-muscle connections were not altered. These data validate multiple disease markers reflecting the major pathological mechanisms of ALS including the motor dysfunction and neurodegeneration. The results in the two ALS mice models also highlights the importance of understanding the specific characteristics of different preclinical models of neurodegenerative diseases to choose the most appropriate model for the evaluation of novel therapeutic strategies.

Abstract: Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disease that leads to the loss of motor neurons. The molecular mechanisms of motor neuron degeneration are largely unknown and there are currently no effective therapies to treat this disease. We have conducted a whole transcriptome profiling using RNA-Seq technology and sequencing cDNA from the total RNA isolated from the spinal cords of mutant transgenic hPFN1^{G118V} mice and their wildtype transgenic hPFN1^{WT} controls. The aim of this study was to identify molecular changes in spinal cords of the hPFN1^{G118V} ALS mouse model at presymptomatic and end stages. To our knowledge, this is the first study to use next-generation RNA-Seq to measure differential gene expression in hPFN1^{G118V} mice at presymptomatic and end stages. The analysis of genes identified in this study revealed that end-stage hPFN1^{G118V} mice had 890 deferentially expressed genes (747 upregulated, 143 downregulated) when compared to presymptomatic hPFN1^{G118V} mice, and they had 836 deferentially expressed genes (742 upregulated, 94 downregulated) when compared to age-matched hPFN1^{WT} controls. Presymptomatic hPFN1^{G118V} mice were not significantly different from age-matched hPFN1^{WT} controls. We further analyzed the genes and their corresponding proteins form the database using ingenuity pathway analysis (IPA) and identified inflammatory pathways significantly activated in end-stage hPFN1^{G118V} samples, suggesting an excess of glial activation at end-stage disease. We have also analyzed the data for gene expression for cell type specificity (astrocytes, microglia, oligodendrocytes, neurons and

motor neurons) and validated the RNA-Seq data by qRT-PCR using randomly selected 12 candidate genes. We will present our RNA-Seq data and graphical representations showing valuable and promising leads into the identification of molecules and pathways revealing the mechanism of neurodegeneration that could potentially serve as therapeutic targets for ALS.

Abstract: Amyotrophic lateral sclerosis (ALS) is a terminal, adult onset neurodegenerative disease causing gradual degeneration of upper motor neurons (UMNs) and lower motor neurons (LMNs) leading to paralysis of the muscles and death within 5 years from the disease onset. About 10% of ALS patients show familial inheritance of the disease (fALS) while 90% are sporadic (sALS). Cytoplasmic inclusions containing truncated and ubiquitinated/hyperphosphorylated forms of the TAR DNA binding protein (TDP-43), encoded by the *TARDBP* gene, are found in almost all ALS cases. TDP-43 is a ubiquitous nuclear RNA/DNA binding protein that shuttles between the nucleus and the cytoplasm and is involved in different steps of the RNA processing and modification. Furthermore mutations in *TARDBP* are causative for ALS. Because cytoplasmic mislocalisation and nuclear depletion of this protein appears to have an important role in the neurodegenerative process, a better understanding of the pathogenic mechanisms is essential. For this reason, we are generating a humanised knock-in TDP-43 mouse which will express the human protein at endogenous levels. Mouse *Tardbp* will be replaced by the corresponding human orthologous *TARDBP* from the start codon (ATG) in exon 2, to the stop codon (TAG) in exon 6. The 5' and 3' UTR's will be maintained as mouse, thus likely maintaining correct gene expression and avoiding the toxicity caused by overexpression of TDP-43. Using a gene targeting strategy which involves the use of Bacterial Artificial Chromosomes (BACs) and BAC recombineering in *Escherichia coli*, we have created

our final modified BAC vector successfully replacing the *Tardbp* gene, from exon 2 to exon 6, with the corresponding sequence from human *TARDBP* together with large flanking homology arms against *Tardbp*. Using the *humanised* BAC, we are currently targeting mouse embryonic stem cells, with the aim of producing a humanised knock-in mouse via homologous recombination. This new model will express a fully human wild type TDP-43 protein under the control of the endogenous mouse promoter. In parallel, we will use CRISPR/Cas9 genome editing technology to introduce ALS/FTD causative point mutations within the *humanised TARDBP* to study normal and pathological functions of human TDP-43.

Title: Modelling the ALS-causing TDP-43 [A382T] variant in zebrafish

Authors: *Z. HARJI[1], V. PETEL-LÉGARÉ[3], E. C. RODRIGUEZ[3], G. A. B. ARMSTRONG[2]
[2]Neurol. & Neurosurg., [1]Montreal Neurolog. Institute, McGill Univ., Montreal, QC, Canada; [3]Montreal Neurolog. Inst., Montreal, QC, Canada

Abstract: Mutations in *TARDBP*, encoding TARDNA-Binding Protein of 43 kDa (TDP-43), cause amyotrophic lateral sclerosis (ALS). Until recently, modelling ALS in animals has relied upon transgenic overexpression of either human mutant or wild type *TARDBP*. Though these models have permitted investigations and added to our understanding of the disease mechanisms, endogenous gene expression many impact the evaluation of disease-causing variants. With the advent of the CRISPR/Cas9 system, researchers now have the opportunity to generate analogous disease-causing mutations in endogenous genes of model system. Using this method, we have a created a zebrafish model of ALS that carries the equivalent A382T TDP-43 (zebrafish A379T tdp-43) variant. The A382T variant shows complete penetrance by the age of 80 and is recognized as the most commonly found disease-associated TDP-43 variant. We believe that this mutant zebrafish line will allow us to more accurately recapitulate the genetic aetiology of familial ALS and permit us to examine both cellular and physiological defects that arise in this neurodegenerative disease. The zebrafish genome contains a paralog of *tardbp* (*tardbpl*), from which a unique splice variant (*tardbpl V1*) can compensate for the loss of zebrafish tdp-43. We

will examine defects that arise in zebrafish that carry the A379T variant both in the *tardbpl*$^{+/+}$ and *tardbpl*$^{-/-}$ genetic background. We anticipate that zebrafish expressing the A379T variant will develop motor deficits and predict that zebrafish with the A379T variant in the *tardbpl*$^{-/-}$ background will develop a more severe motor phenotype.

Title: Amyotrophic lateral sclerosis models of CHCHD10 in zebrafish

Authors: *V. PETEL LEGARE[1], G. A. B. ARMSTRONG[2], Z. HARJI[3]
[2]Dept. of Neurol. and Neurosurg., [1]Montreal Neurolog. Inst. and Hosp., Montreal, QC, Canada; [3]Montreal Neurolog. Institute, McGill Univ., Montreal, QC, Canada

Abstract: Introduction: Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disease characterized by the progressive degeneration of lower and upper motor neurons. While most forms of the disease occur sporadically in the population (sALS), a small subset (~5-10%) is inherited (fALS), which has allowed researchers to model this disease in simple animal models. Recently, dominantly inherited missense mutations in the nuclear encoded gene *CHCHD10* (encoding the mitochondrial protein CHCHD10) were identified in both sALS and fALS cases, implicating mitochondrial dysfunction in ALS pathogenesis. These include the predicted variants P80L, S59L, and A35D. As the function of this protein remains largelyunknown, we propose to use zebrafish (*Danio rerio*) to explore *in vivo* cellular defects that arise following the expression of analogous disease-causing variants in the zebrafish ortholog of *CHCHD10*. **Goal:** To investigate the cellular and pathophysiological consequences of the analogous zebrafish *chchd10* variants: P83L, A35D, and S60L. **Methodology:** Using the clustered regularly interspaced short palindromic repeats (CRIPSR) and CRISPR associated protein 9 mutagenic system along with homology directed repair, we will knockin analogous missense mutations, as well as generate a *chchd10* knockout model. We will characterize motor phenotypes in both knockout (KO) and knockin (KI) models and examine neuromuscular junctions (NMJs). NMJs, will be assessed by examining co-localization of the pre- (synaptogamin 2) and the post-synaptic NMJ marker (α-bungarotoxin-conjugated to sulforhodamine). In addition, we will evaluate differences oxidative

metabolism in both KO and KI models. **Hypothesis:** We hypothesize that the KI mutant zebrafish will display age-related defects, characterized by the loss of muscle connectivity, motor impairment, and premature death, as well as a defect in oxidative metabolism. We believe that KO of *chchd10* will express a phenotype at earlier stages in development, supporting the loss-of-function disease mechanism that is believed to occur in patients expressing CHCHD10 variants. **Results:** A KO model was recently identified and confirmed by Western Blot in one of our founder lines. We are in the process of further characterizing the consequences arising from the loss of *chchd10* expression and are currently screening for KI mutations. **Conclusion:** The data generated from this project will be beneficial to further our understanding of the cellular defects that arise in ALS cases with mutations in *CHCHD10*, as there are currently no KI animal models of *CHCHD10*.

Title: Matrin 3 expression leads to neuromuscular degeneration and RRM-mediated toxicity in *Drosophila*

Authors: *N. RAMESH, I. CASCI[1,2], U. B. PANDEY[1,2]
[1]Univ. of Pittsburgh, Pittsburgh, PA; [2]Children's Hosp. of Pittsburgh, UPMC, Pittsburgh, PA

Abstract: Amyotrophic Lateral Sclerosis (ALS) is an adult-onset, fatal neurodegenerative disease with progressive loss of upper and lower motor neurons. Mutations in Matrin 3 (MATR3), a DNA/RNA-binding protein, have been found in familial and sporadic forms of ALS, as well as in distal myopathy. In addition, Matrin 3-positive cytoplasmic inclusions have been observed in C9orf72 hexanucleotide repeat expansion mediated- as well as sporadic ALS. However, the underlying molecular mechanisms of MATR3-mediated neuromuscular degeneration are still poorly understood. We have developed novel *Drosophila* models of MATR3 that recapitulate key features of neuromuscular degeneration. We found that expression of MATR3 leads to reduced lifespan accompanied by progressive motor defects in flies. Furthermore, we found that ubiquitous expression of MATR3 in *Drosophila* causes early lethality. Strikingly, deletion of the RNA-recognition motif (RRM2) strongly mitigates MATR3 toxicity, suggesting that MATR3 causes degeneration through its RNA-binding properties.

Furthermore, using candidate-gene approach, we have identified *rump*, *Drosophila* homolog of human hnRNP M, as a potential modifier of MATR3-mediated toxicity *in vivo*. We found that decreasing levels of endogenous rump strongly suppresses the lethality phenotype. HnRNP M has been identified as a direct interactor of MATR3 in multiple proteomic screens, and they are also known to be part of a complex that regulates alternative splicing, further indicating a role for dysregulated RNA metabolism in MATR3-mediated degeneration. Collectively, our results establish the MATR3 *Drosophila* model as a promising *in vivo* model to study the mechanism of neuromuscular degeneration and screen for genetic modifiers of MATR3 toxicity.

Title: Genetic modifiers of stress-induced neurodegeneration in a *C. elegans* sod-1 knock-in model

Authors: *K. S. YANAGI[1], J. J. LINS[1], L. A. STINSON[1], M. B. WALSH[2], A. MAHAPATRA[2], S. N. BASKOYLU[1], J. YERSAK[4], A. C. HART[3]

Abstract: Amyotrophic lateral sclerosis (ALS) is a degenerative disorder that typically results in the death of a patient within 3-5 years after symptom onset. One of the classical hallmarks of ALS is the selective degeneration of motor neurons. Over a hundred mutations in superoxide dismutase 1 (SOD1), a gene that encodes an enzyme that catalyzes the breakdown of superoxide radicals, have been linked ALS. One of the patient alleles in SOD1 is G85R, which converts a glycine to arginine at position 85 in the SOD1 protein. Decades of research have advanced our understanding of the role of SOD1 in fALS. Genetic modifiers may provide insight into the molecular mechanisms behind the degeneration of motor neurons. We have undertaken a classical forward genetic screen in *Caenorhabditis elegans* to identify suppressors of glutamatergic neuron degeneration observed in a knock-in SOD-1G85R model. The SOD-1G85R knock-in animals exhibit glutamatergic neuron degeneration after exposure to oxidative stress. Using EMS, we mutagenized SOD-1G85R animals, and then screened for suppression of glutamatergic neuron degeneration. We identified suppressor lines and are using whole genome

sequencing to identify candidate genes. We will determine if the suppressors ameliorate cholinergic motor neuron death and survival defects observed in the SOD-1G85R knock-in model. Further, to determine if common pathways underlie neurodegeneration in ALS, we will test candidate and established ALS suppressor genes in other SOD1 and ALS models. Understanding genetic modifiers of ALS will facilitate treatment development and illuminate molecular mechanisms behind ALS.

Title: Structural CNS changes at presymptomatic stages in the G93A^{HSOD1} ALS model

Authors: *T. MEDIAVILLA, S. PARWEEN, D. J. MARCELLINO, F. SULTAN
Integrative Med. Biol. (IMB), Umea Univ., Umea, Sweden

Abstract: Insertion of human SOD1 G93A copies in transgenic mice has proven to be a useful model to replicate late stages of human amyotrophic lateral sclerosis (ALS). The typical severe phenotype of this model presents spinal motoneuron degeneration together with hind limb paralysis and weight loss. Few studies so far have attempted to look at and characterize early stages of disease to better understand disease onset and progression and to define early therapeutic windows for the evaluation of disease modifying treatments. We used a delayed onset G93A mouse model with a severe phenotype appearing at 7-8 months to allow for an extended pre-onset monitoring of preclinical symptoms. We combined behavioral testing with *in vivo* MRI to correlate behavior with structural imaging of CNS integrity to allow for a better system-level approach. Behavioral testing included measuring the time to fall from an inverted wire screen to monitor muscle strength and the pole test to evaluate motor coordination by measuring the time to reorient and to climb down the pole. We performed in vivo diffusion tensor imaging (DTI) to detect any alterations in CNS white matter tracts. DTI was performed with 4-segment EPI, TE/TR 22.9/3000ms, isotropic spatial resolution of 128µm, 10 A0 scans and 60 different diffusion directions. B-values of 900/1150/1400 s/mm2 were applied and the total scan duration was 38 minutes. DTI data postprocessing was performed with FSL and

included DWI denoising, eddy current and Gibbs ringing removal. We extracted fractional anisotropy, mean and radial diffusivity. Data analysis was carried-out on individually defined ROIs of some of the major fiber tracts of the forebrain. Our preliminary findings indicate that a preclinical phase of motor dysfunction is observed between 3 and 5 months of age before moderate or severe stages of disease are appreciable. This preclinical phase is associated with structural CNS changes detected by DTI.

Title: Deletion of C9orf72 induces an age-dependent decline in reversal learning and olfactory memory

Authors: *Y.-C. YEN[1], W. HO[1], S.-C. LING[1,2,3]
[1]Dept. of Physiol., [2]Neurobiology/Ageing Programme, Natl. Univ. of Singapore, Singapore, Singapore; [3]Program in Neurosci. and Behavioural Disorders, Duke-NUS Med. Sch., Singapore, Singapore

Abstract: Hexanucleotide (GGGGCC) repeat expansions in the noncoding region of *C9ORF72* gene are the most common genetic cause for amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD). In addition to gain-of-toxic mechanisms that result from the aberrant translation of hexanucleotide repeats and trapping of RNA-binding proteins, reduced expression of *C9orf72* has also been proposed to contribute to the ALS-FTD pathogenesis. We and others have previously shown that mice with *C9orf72* ablation develop fetal autoimmune disease and exhibit reduced survival without motor neuron degeneration and overt motor deficits. Here, we examined the effect of *C9orf72* deletion on hippocampus-dependent cognitive functions. While *C9orf72*-knockout mice were normal in general locomotor activity, working memory, and contextual fear conditioning, they exhibited superior performance to wildtype mice in reversal learning and olfactory memory that showed an accelerated age-dependent decline. Taken together, our data suggest that deletion of *C9orf72* induces an age-dependent decline in some aspects of hippocampus-dependent cognition.

Title: Characterization of epigenetic and behavioral alterations in ALS and FTD mouse model

Authors: *N. JURY[1,2], S. ABARZUA[1,2,3], I. DIAZ[1,2], M. V. GUERRA[1], P. CUBILLOS[1,2], E. AMPUERO[1,2], P. MARTINEZ[1,2], M. MONTECINO[1,3], L. VARELA-NALLAR[1], B. ZAN ZUNDERT[1,2]
[1]Univ. Andrés Bello, Santiago, Chile; [2]Ctr. for Aging and Regeneration (CARE-UC), Santiago, Chile; [3]FONDAP Ctr. for Genome Regulation, Santiago, Chile

Abstract: Mutations in *SOD1* cause motoneuron pathology in amyotrophic lateral sclerosis (ALS) disease, while *C9ORF72* repeat expansions (RE) are implicated in both ALS and frontotemporal dementia (FTD). We evaluated if critical epigenetic modifications are altered in hSOD1^{G93A} and C9orf72-RE transgenic mice. Primary astrocyte cultures (P2) and brain tissue obtained from C9orf72-RE (9 months) and hSOD1G93A (4 months) mice were analyzed by immunostaining and western blot with specific antibodies to detect specific histone marks and DNA damage. In cultured astrocytes from hSOD1^{G93A} and C9orf72-RE mice, we observed a similar depletion in the nuclear expression of specific histone marks. Similar alterations were detected in the ALS/FTD astrocytes and neurons in the spinal cord, motor cortex and hippocampus tissue. We determined if the epigenetic alterations were correlated with behavioral changes and we found that object location memory (OLM discrimination in mature C9orf72-RE animals was reduces OLM compared to controls. Our data suggest that a common loss of epigenetic control contributes to pathogenesis and disease development in ALS and FTD. The epigenetic dysregulation in the hippocampus parallels previous undetected cognitive deficits in the ALS and FTD models.

Title: Structural and functional alteration of motor neurons leads to motor deficit in a rat model of Sporadic Amyotrophic Lateral Sclerosis

Authors: *S. DAS, K. SABITHA, L. T. RAO, T. R. RAJU
Neurophysiol., Natl. Inst. of Mental Hlth. and Neurosci., Bangalore, India

Abstract: Introduction: Amyotrophic Lateral Sclerosis (ALS), a late onset neurodegenerative disease causes loss of both upper and lower motor neurons (MNs) in the motor cortex, brainstem and spinal cord. Degeneration of MNs occurs both at the structural and functional levels, which is reflected in the behaviour. **Aim:** The present study has investigated the morphology of MNs and their functional alteration leading to motor deficit in sporadic ALS model, generated by serial intrathecal infusion of CSF from ALS patients in rat pups at post natal (P) days 3, 9 and 14. Structure and function of the MNs and motor behaviour of the rats were tested at P16 and P22. **Methodology:** To evaluate the morphological changes in MNs of cervical and lumbar regions, Cresyl violet and Golgi-cox staining were performed. For functional studies, Multielectrode array recording was carried out from spinal cord slices at the cervical and lumbar levels. Motor function was tested by using rotarod. **Results:** Infusion of ALS-CSF into rat pups has significantly reduced the total number and density of MNs in both lumbar and cervical region of the spinal cord along with the hypertrophy of surviving MNs. Functional study also reveals alterations in spike activity. Further analysis using rotarod indicated infusion of ALS-CSF into rat pups induced motor deficits, with a significant increase in the number of falls when they fail to balance on the rotating rod. **Conclusion:** Accordingly, ALS-CSF, if infused serially into rat pups can cause motor deficits which could be related to structural and functional impairment of MNs.

Title: Motor neuron hypoexcitability in TDP-43 Q331K knock-in mouse model of ALS/FTD

Authors: *J. P. WHITT[1], L. A. STINSON[1], R. H. BROWN, Jr.[2], J. R. FALLON[1], J. SREEDHARAN[3], D. LIPSCOMBE[1]
[1]Neurosci., Brown Univ., Providence, RI; [2]Neurol., Univ. of Massachusetts Med. Sch., Worcester, MA; [3]Babraham Inst., Univ. of Cambridge, Cambridge, United Kingdom

Abstract: Amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD) are progressive, neurodegenerative disorders that overlap clinically and that have common molecular origins. Mislocalization and aggregation of the tar-DNA binding protein 43 (TDP-43) is a hallmark feature of both ALS and FTD, and mutations in the TDP-43 encoding gene (*TARDBP*) can cause both ALS and FTD. Mice homozygous for the Q331K mutation in *Tardbp* exhibit motor and FTD-like cognitive impairment from 3 months and older, even though neuromuscular junction transmission is unaffected (White et al., 2018). *In vivo*and slice studies of various ALS mouse models have shown changes in motor neuron excitability that precede neurodegeneration in both vertebrate and invertebrates. Consistently, we find that motor neurons of 6 month mice homozygous for TDP-43 Q331K have reduced excitability as compared to 2 month mutants, and 2 and 6 month wild-type mice. We used whole-cell patch clamp recording in acute transverse spinal cord slices, and recorded from TDP-43 Q331K knock-in mouse (Q331K) motor neurons projecting to either the tibialis anterior, ~90% fast twitch (type II) muscle fibers, or soleus muscle, ~50% slow twitch (type I) muscle. At 3 months, Q331K homozygous mice exhibit motor defects, so we compared 2 and 6 month old mice as pre- and post-symptomatic groups. We found a slight increase in the rheobase current for 6 month Q331K motor neurons projecting to TA compared to wild-type littermates. In addition, with larger 3x-rheobase current injections, motor neurons from 6 month Q331K mice were hypoexcitable compared to littermate controls, regardless of target muscle. The hypoexcitability phenotype in 6 mth Q331K mice was notcorrelated with intrinsic membrane properties such as input resistance and cellular capacitance. In conclusion, we find that motor neuron hypoexcitability occurs coincident with defects in motor coordination and without alterations in nerve muscle junction transmission. We find hypoexcitability in motor neurons that innervate both fast and mixed twitch muscle types and hypothesize that altered ion channel function underlies this disease phenotype.

Title: Effects of Cu(II)ATSM on phenotype progression in mice with a familial ALS mutation

Authors: *L. M. HODGE, L. CHERRY, C. A. ZIFICSAK, L. D. AIMONE, D. POSAVEC, K. FREITAS, I. J. REYNOLDS, S. E. BROWNE
Small Molecule Discovery Research, Specialty R & D, Teva Pharmaceuticals, West Chester, PA

Abstract: Cu(II)ATSM is in Phase 1 clinical trials for ALS, following reports of improved outcomes in mouse lines expressing familial ALS Cu,Zn-superoxide dismutase (SOD1) mutations. To test the reproducibility of Cu(II)ATSM effects in an independent laboratory, we undertook a preliminary efficacy study in mutant SOD1 G93A/1Gur mice (Jackson Labs line 2726). Replicating a published approach (Williams et. al., 2016, Neurobiol. Dis. 89:1-9) we tested twice daily dermal application of Cu(II)ATSM in male G93A mice, dosed from 6 wks of age. Groups were powered to detect a 20% difference in rotarod score (30/group). Following acclimation, mice were pseudo-randomly ascribed to groups balanced by birthdate, litter, sire, weight, rotarod activity, and coat color. Cu(II)ATSM (50, 100 mg/kg/dose) or vehicle (DMSO, 6.7 ml/kg) was applied by pipette to animals' backs. Littermate wildtype mice received vehicle. Body weight and hind-limb neurological score were tracked twice weekly. Accelerating rotarod and wire hang were assayed from 6 to 16 wks of age. All experimenters were blinded to genotype and groups, and testing order was randomized. After 3 wks of dosing, twice daily administration of 100 mg/kg was poorly tolerated by mice, resulting in premature deaths. 100 mg/kg dosing was modified to alternate days, and then terminated 3 wks later. After 10 wks the 50 mg/kg regimen was modified to alternate days for the remainder of the study. The remaining mice were followed until the IACUC-approved endpoint (no righting response after 10s or 20% weight loss). Within these animals, average life-span of G93A mice receiving Cu(II)ATSM was increased significantly compared to vehicle treatment, by 18 +/- 2 d (13%) and 9 +/- 2 d (7%) after 50 and 100 mg/kg, respectively (mean +/- SEM; ANOVA, post-hoc t-test). G93A mice receiving 50 mg/kg/dose Cu(II)ATSM spent a significantly longer time in early symptomatic stages, gained weight longer, and reached significantly higher weights compared to their untreated counterparts. Rotarod ability was preserved in both 50 and 100 mg/kg groups at 16 wks. Wire hang was not improved by either dose.
These preliminary data suggest that further analyses of Cu(II)ATSM are warranted if an

appropriate dosing paradigm can be achieved. Our observation of tolerability problems underscores the need to understand the optimum dose, route, and frequency. These are fundamental requirements for any *in vivo* study, but in the case of Cu(II)ATSM are confounded by lack of a discrete CNS target engagement measure for Cu(II)ATSM. Understanding target engagement is essential to guide appropriate dose selection with which to interrogate the therapeutic window for Cu(II)ATSM.

Title: Building a plausible model for tdp-43 driven als/ftd pathology

Authors: *J. L. MARTINEZ[1], B. FLORES[2], X. LI[2], S. BARMADA[3], A. BEG[1]
[1]Pharmacol., Uiniversity of Michigan, Ann Arbor, MI; [2]Dept. of Neurol., Univ. of Michigan, Ann Arbor, MI; [3]Neurolog. Disorders, Univ. of Michigan Dept. of Neurol., Ann Arbor, MI

Abstract: Amyotrophic lateral sclerosis (ALS) is a progressive neurodegenerative disease that destroys neurons in the brain and spinal cord leading to the loss of muscle control. Frontotemporal dementia (FTD) is a clinically distinct disorder, characterized by progressive behavioral, language and memory deficits. Although the signs and symptoms of ALS and FTD are unique, ALS and FTD share key pathologic and genetic features, suggesting disease pathogenesis may arise from conserved aberrant mechanisms. The majority of individuals with ALS and FTD exhibit neuronal cytoplasmic inclusions rich in the RNA binding protein TDP43, and changes in TDP43 localization and levels are strongly predictive of neuron loss in ALS/FTD. Over 40 different mutations in the gene encoding TDP43 are responsible for familial ALS and FTD, further supporting the integral contribution of TDP43 to disease. However, the link between TDP43 RNA binding properties and neuronal survival are unclear in an endogenously expressed context. Specifically, the majority of studies rely on overexpression of WT or mutant forms of TDP43 to drive disease pathogenesis, yet there is no data indicating that actual TDP-43 related pathologies are caused by or related to protein overexpression.
TDP-43 is a nuclear RNA-binding protein that participates in transcriptional and translational regulation, pre-mRNA splicing, and neuronal RNA stability. TDP43 binds thousands of UG-rich RNA sequences, and TDP43-dependent toxicity is tightly tied to its ability to recognize RNA.

Intramolecular interactions between the RNA binding domains of TDP43, mediated by a salt bridge, are necessary for maintaining specificity for UG sequences; in the absence of the salt bridge, TDP43 inappropriately recognizes GC-rich sequences. Here, we demonstrate that mutations that eliminate the salt bridge enhance TDP43 mislocalization, decrease UG-rich RNA binding, and abrogate TDP43-dependent toxicity. Using a modified CRISPR-Cas9 targeting strategy we have generated mutations in *tdp-1*, the *C. elegans* ortholog of TDP43. We show that *tdp-1*(R219A) mutants phenocopy loss-of-function alleles in *C. elegans*. In ongoing work, we are investigating the effects that TDP43 salt bridge disruption has on RNA splicing and expression via RNA-sequencing in both mammalian cell lines and in *C. elegans*. These studies highlight previously uncharacterized properties of TDP43 that may serve as targets for therapy development.

Title: Investigating p53 and p21 as mediators of spinal motor neuron degeneration in the $Smn^{2B/-}$ mouse model of spinal muscular atrophy

Authors: *E. REEDICH[1,2], G. COX[3], C. DIDONATO[1,2]
[1]Stanley Manne Children's Res. Inst., Chicago, IL; [2]Pediatrics, Northwestern Univ., Chicago, IL; [3]Genet., The Jackson Lab., Bar Harbor, ME

Abstract: Spinal muscular atrophy (SMA) is a pediatric neuromuscular disease caused by deficiency of the survival motor neuron (SMN) protein. The pathological hallmarks of SMA are spinal motor neuron loss and skeletal muscle atrophy. While the molecular mechanisms of spinal motor neuron degeneration in SMA remain unclear, recent transcriptional profiling and mechanistic studies identify increased activation of the p53 signaling pathway in motor neurons and spinal cord tissue of severe SMA mice and implicate phosphorylated p53 as a mediator of spinal motor neuron death. p53 pathway activation is associated with the increased expression of several p53 transcriptional targets such as the cyclin-dependent kinase inhibitor p21, whose upregulation in skeletal muscle promotes atrophy. To determine whether genetic ablation of p53

or p21 mitigates the SMA phenotype of $Smn^{2B/-}$ mice, we crossed *Trp53* and *P21* knockout alleles onto the $Smn^{2B/-}$ background and performed molecular, phenotypic, immunohistochemical, and electrophysiological studies. We find that p53 ablation impairs survival of $Smn^{2B/-}$ mice while ablation of p21 enhances survival. Notably, neither knockout modulates the timing of motor neuron loss in $Smn^{2B/-}$ mice as determined using the neurophysiological method of motor unit number estimation (MUNE). We will be presenting the results of p53 and p21 ablation on motor neuron morphology as determined using immunohistological approaches. Overall, these results demonstrate that neither p53 nor p21 signaling are the primary drivers of spinal motor neuron loss in SMA, as motor neuron death proceeds in their absence. The negative effect of *Trp53* knockout on survival of $Smn^{2B/-}$ mice is likely caused by consequences of p53 depletion in other organ systems. Interestingly, p21 depletion yielded a significant survival benefit; this may be due to mitigation of p21-driven pathology in other tissues, such as atrophy of skeletal muscle.

Title: Neurotoxic effects of the acute and chronic administration of glutamate decarboxylase inhibitors in the rat spinal cord *in vivo*

Authors: E. COLIN[1], *R. TAPIA[2]
[1]Inst. de Fisiología Celular, [2]Univ. Nacional Autónoma De Mexico, Ciudad de Mexico, Mexico

Abstract: Alterations in the function of GABAergic inhibitory circuits in the spinal cord have been involved in experimental motor neuron (MN) degeneration and in MN diseases (Neuropharmacology 82;101, 2014; ACS Chem. Neurosci. 9:211, 2018; Neuropharmacology 117:85, 2017), but no studies have been carried out on the role of GABA metabolism in the spinal cord. GABA synthesis depends on the activity of glutamate decarboxylase (GAD), which can be pharmacologically inhibited in vivo by the competitive inhibitor 3-mercaptopropionic acid (MPA), by thiosemicarbazide (TSC) and by pyridoxal γ-glutamyl hidrazone (PLPGH), which impede the coenzymatic function of pyridoxal phosphate (Epilepsy Res. 116:27, 2015). In this work these inhibitors were administered directly in the adult rat spinal cord through microdialysis (acute treatment during 62 min) or by means of osmotic minipumps (continuous

chronic infusion during 10 days) (J. Neuropathol. Exp. Neurol. 66:913, 2007). Acute administration of the three drugs, separately, did not cause any significant effect on motor behavior or MN morphology, 24 h after surgery. In contrast, chronic infusion of 3, 10 and 20 mM MPA, as well as 15 mM TSC or 25 mM PLPGH, triggered frequent myoclonies of the ipsilateral rearlimb at the second or third day after pump implantation. The rotarod test showed that control rats did not fall during 120 s, whereas the animals treated with the three concentrations of MPA used or with TSC or PLPGH fell in about 75-100 s, since the first day after implantation, and this performance persisted during the 10 days-test period. Rats were fixed for histology at day 10 and the number of MNs in the infused lumbar spinal cord was counted. As compared with control vehicle-treated rats, in the ipsilateral ventral horn the number of MNs was significantly decreased 35%-50% after 3, 10 or 20 mM MPA, 45% after TSC and 40% after PLPGH. The number of MNs in the contralateral horn was also decreased but only about 10%. These results suggest that chronic inhibition of GABA synthesis results in a decreased GABA inhibitory action and that the consequent deficient function of inhibitory GABAergic circuits in the ventral horn is enough to cause MN degeneration, probably mediated by hyperexcitation. Title: Cell type specific exosomes signaling in disease spreading of ALS

Authors: *S. JIN, Y. TIAN, J. M. YELICK, Y. MEN, R. JARVIS, Y. YANG
Neurosci., Tufts Univ., Boston, MA

Abstract: Exosomes are generated from endosomal membranes and known be released by most cell types including neurons and glia cells in the CNS. These vesicles are involved with the clearance and cell-to-cell spreading of toxic molecules. Recent research suggested that the majority of pathogenic proteins of neurodegenerative diseases such as amyloid beta, mutant SOD1, TDP43, phosphor-Tau are detected in exosomes fraction of patients CSF or in vitro cell model of disease. However, the role of cell type-specific exosomes in the spreading of neurodegenerative disease is still unclear. In the current study, we developed a cell-type specific

exosome reporter mouse line (hCD63-GFP conditional knock-in, CD63-CKI) in which a GFP-fused CD63, an exosome surface marker, can be induced in a particular cell type when bred with the cell-type specific Cre driver mice or stereotaxic injection of viral vectors expressing Cre recombinase. By employing this mouse tool, we found that both neuronal and astrocyte-derived exosomes are widely present in the CNS. We performed stereotaxic injection AAV-CamkII-Cre and AAV-GFAP-Cre virus to ventral horn of lumber spinal cord in $CD63^{f/+}$ or $CD63^{f/+}$G93A SOD1 transgenic mice in disease on set (day90~100). We observed migration of astrocyte migration is significantly decreased in the direction of thoracic (1345±256um) and sacral (3130±632um) in SOD1 transgenic (Tg) mice compare to non-Tg mice. Neuronal secreted exosomes's migration is not changed in SOD1 Tg mice compare to non-Tg mice. We also performed spinal cord stereotaxic injection in $CD63^{f/+}$ mice treated with PLX3397 (selective CSF1R inhibitor) to deplete microglia. The migration distance of astrocyte secreted exosomes is decreased in the direction of sacral (1360±379um), while neuronal exosomes migration is sigenificantly longer without microglia. In summary, we demonstrated that exosomes are widely present in the CNS and astrocyte secreted exosomes are significant changed in SOD1 (G93A) mouse model of ALS. Microglia is implicated in both neuronal and astrocyte secreted exosomes miglation.

Title: Automated continuous behavioral monitoring and traditional behavioral testing reveal early phenotypes in a novel SOD1-G85R knock-in mouse model of ALS

Authors: *L. A. MADIGAN[1], J. PAGE[1], V. VEERABADRAN[1], T. SHARMA[1], J. DOMINOV[2], T. SERRE[1], R. H. BROWN[2], J. R. FALLON[1]
[1]Brown Univ., Providence, RI; [2]Univ. of Massachusetts Med. Sch., Worcester, MA

Abstract: Dominant mutations in the gene encoding Superoxide dismutase 1 (SOD1) are a major cause of familial amyotrophic lateral sclerosis (fALS). Mouse models are a vital tool in revealing fALS pathogenic mechanisms and developing therapeutics for sporadic ALS. Until recently, models have been limited to transgenic mice overexpressing mutant human SOD1 alleles. While valuable, such transgenic lines rely on overexpression and do not reflect

endogenous expression patterns and regulation of these alleles. In particular, it is not clear to what extent these models are useful for delineating early abnormalities. To address these gaps we created a knock-in mouse model harboring the SOD1^{G85R} fALS mutation on the murine ortholog of the human SOD1 gene. We have characterized these animals using Automated Continuous Behavioral Monitoring (ACBM, Jhuang et al., 2010; White et al. 2018). During ACBM mice are video recorded at 30 frames/second for five days (total of ~1.3 x 10^7 frames/mouse/session). Behavioral assessment is then performed using a supervised, machine learning-based, computer algorithm to assign 1 of 8 designated behaviors to each frame. We assessed walking, hanging, rearing, drinking, eating from hopper, eating by hand, grooming and resting in male homozygous and heterozygous SOD1^{G85R} mice in three sessions over 1-6 months of age. In parallel, we have characterized the mice using traditional behavioral assessments including weight monitoring, wire hang, open field, grip strength, and rotorod. We find that homozygous SOD1^{G85R} mice exhibit robust weight and behavioral deficits as early as one month of age—much earlier than those reported for the transgenic SOD1^{G85R} lines. Notably, SOD1^{G85R} heterozygous mice also display these similar deficits, albeit to a lesser extent and/or at later times. We have also observed and characterized a core strength deficit that appears at one month of age and a tremor phenotype that appears at 6 months of age in homozygous animals. In summary, the combined use of ACBM and traditional behavioral measures has revealed behavioral abnormalities at early time in this novel SOD1^{G85R} knock-in model. We propose that the knock-in SOD1^{G85R} ALS disease model will be useful for characterizing early defects that could be important for predicting conversion in human fALS patients as well as revealing biomarkers useful for detecting presymptomatic changes and developing treatments for sporadic ALS.

Abstract: The symptoms of Amyotrophic Lateral Sclerosis (ALS) include muscle weakness and atrophy that progress rapidly to paralysis and eventual death. Symptom onset can occur in the limbs (spinal onset) or in the muscles of the face (bulbar onset). These symptoms result from degeneration of motor neurons in the spinal cord and brainstem motor neurons, as well as in the corticospinal and corticobulbar neurons that innervate them. While bulbar symptoms are associated with a poorer prognosis, most preclinical studies focus on spinal deficits. We have found that the SOD1-G93A rat model of ALS exhibit both spinal and bulbar motor deficits. Bulbar deficits were manifested primarily as decreased tongue motility as disease progressed. As in human ALS, the presence of bulbar deficits in SOD1-G93A rats was associated with poorer survival. The goal of the current study was to determine the extent to which bulbar deficits were expressed differentially in male vs female SOD1-G93A rats, and whether d-amphetamine is able to normalize these deficits. Age-matched male and female SOD1-G93A rats and wildtype littermates were tested for tongue force and tongue motility throughout their lifespan. Rats were administered acute doses of d-amphetamine (1.0 and 2.0 mg/kg). In a separate group of rats, we measured motor cortical neurochemistry using ^{1}H-MRS in presymptomatic SOD1-G93A and age-matched wildtype rats. Results will be discussed in the context of sex differences in disease phenotype and potential non-invasive motor cortical neurochemical biomarkers for ALS.

Abstract: Amyotrophic lateral sclerosis (ALS) is a progressive and fatal neurodegenerative disease characterized by motor neuron cell death and subsequent paralysis of voluntary muscles. Although ALS specifically affects motor neurons, some cells are resistant to disease progression. Most ALS studies have focused on the cellular mechanisms that cause loss of motor neuron viability. Less is known about the surviving neurons, and most of that information has come from gene expression profiling. In this study, we functionally characterize the surviving spinal motor neurons by culturing them from SOD1 ALS mouse models at various stages of disease progression. Surprisingly, we found that in comparison to non-transgenic controls, ALS resistant motor neurons from $SOD1^{G93A}$ mice have enhanced axonal outgrowth and dendritic branching. They also display an increase in the number and size of actin-based structures such as growth cones and filopodia. Increased outgrowth occurs independently of SOD1 enzymatic activity, is cell autonomous, and can be induced in motor neurons from non-transgenic mice by exogenous expression of $SOD1^{G93A}$. Further, the enhanced outgrowth occurs before the mice become symptomatic, but increases with disease progression. These results indicate that ALS resistant motor neurons are primed for regeneration significantly before ALS symptoms are present. Understanding this mechanism of cellular resistance and increased axonal outgrowth could uncover new therapeutic targets for the treatment of ALS

Abstract: Amyotrophic Lateral Sclerosis (ALS), also known as Lou Gehrig's Disease, is a fatal neurodegenerative disorder affecting upper and lower motor neurons. TAR DNA-binding protein

43 (TDP-43) is found in cytoplasmic inclusions in almost all non-SOD1 mediated ALS cases and is thought to play a major role in pathogenesis of the disease. Our lab has previously shown that overexpression of either wild type or mutant human TDP-43 in motor neurons of Drosophila melanogaster induces motor deficits and reduces lifespan. Using this model we have performed global metabolomics profiling and identified several significant changes consistent with alterations in glucose metabolism. Additionally, we have identified transcriptional alterations in the carnitine shuttle pathway within mitochondria leading defects in long chained fatty acid import. Based on our metabolomic data, we hypothesize that altering glucose metabolism through genetic and dietary intervention can bypass mitochondrial defects and provide protection against neurodegeneration. Our data indicate that a high sugar diet, or the genetic expression of either the human glucose transporters 3 or 4 (GLUT3 or GLUT4) in the CNS, suppresses toxic effects caused by TDP-43. Neuromuscular defects caused by neuronal TDP-43 expression are rescued by GLUT3 expression. Pfk mRNA, a key indicator of glycolytic activity, is significantly upregulated in TDP-43 expressing flies and iPSC motor neurons with TDP-43 pathology. Moreover, over-expression of Pfk is sufficient to rescue TDP-43 induced locomotor toxicity in Drosophila, while the knockdown of Pfk aggravates TDP-43 induced impairments. Taken together, our findings indicate specific metabolic alterations in ALS and highlight the predictive power of Drosophila as a model organism.

Title: SMA-specific differences in the axonal and somato-dendritic translatome of motor neurons *in vivo*

Authors: *P. PRICE[1], C.-W. TSAI[2], C. DIDONATO[4], G. J. BASSELL[1], W. ROSSOLL[3]
[1]Cell Biol., Emory Univ., Atlanta, GA; [2]Neurosci., [3]Dept. of Neurosci., Mayo Clin., Jacksonville, FL; [4]Neurosci., Northwestern Univ., Chicago, IL

Abstract: Spinal muscular atrophy (SMA) is a neuromuscular disease caused by insufficient levels of the survival of motor neuron (SMN) protein, yet the molecular mechanisms by which reduced levels of SMN influence pathogenesis remain elusive. In addition to facilitating the assembly of core splicing machinery, SMN acts as a chaperone for the assembly of mRNAs and

mRNA-binding proteins into mRNPs and their axonal localization. As motor neurons are most severely affected in SMA, several studies have identified differences in global and compartmentalized mRNA expression in motor neurons *in vitro,* yet evidence for mRNA processing and localization defects in mature axons *in vivo* remains scarce. By combining motor neuron-specific transgene expression with affinity purification of translating ribosomes, we have performed a comprehensive RNA-seq study to establish the profile of ribosome-bound mRNAs in motor neuron cell bodies and axons at pivotal time points in a mouse model of SMA. Our results show disease-specific differences in the axonal and somato-dendritic transcriptome of motor neurons.

Title: ZPR1 regulates expression of the Hox genes in the spinal cord motor neurons

Authors: *L. D. GANGWANI, N. GENABAI, A. KANNAN, S. AHMAD, X. JIANG
Biomed. Sci., Texas Tech. Univ. Hlth. Sci. Ctr., El Paso, TX

Abstract: The zinc finger proteinZPR1is a modifier of spinal muscular atrophy (SMA) andinteracts with SMN. ZPR1 is down regulated in SMA patients. Reduced expression of ZPR1 causes neurodegeneration in mice. However, the function of ZPR1 in motor neuron survival is unclear. To gain insight into the function of ZPR1 in motor neurons, we examined the effect of deficiency of ZPR1 in motor neurons using *Zpr1* conditional knockout mice that we have created. *Zpr1* gene was inactivated in motor neurons using Hlxb9 (Hb9)-Cre mice that resulted in developmental defects and perinatal lethality. Developmental defects are caused by aberrant expression of *homeobox*(*Hox*) genes during embryogenesis. Therefore, we examined levels of expression of different groups of *Hox*genes 5-13 that mainly express in the spinal cord during embryonic development. We show that selective *Hox*genes are significantly down regulated in the cervical, thoracic and lumbar regions of the spinal cord. Deregulation of *Hox*genes in different regions of the spinal cord show defects in the development of mouse embryo, including defects in the innervation of diaphragm, reduced ossification of sternum and absence of tail. We found that ZPR1 binds to promoter region of the human *HoxA5*gene and the levels of ZPR1

directly correlate with expression of HoxA5 levels. We also show that the ZPR1 deficiency causes down regulation of HoxA5 in the cervical region and results in degeneration of phrenic motor neurons and respiratory failure. In conclusion, ZPR1 is a transcription factor that regulates expression of *Hox*gene in the spinal cord motor neurons. Because death in SMA is caused by respiratory failure, our data suggest that reduced levels of ZPR1 in SMA patients may result in down regulation of Hox A5 leading to respiratory distress in SMA. ZPR1 may represent a potential therapeutic target to prevent neurodegeneration and reduce respiratory distress in SMA.

Title: Overexpression of UCHL1 in neurons extends survival of UCHL1 mutant mice

Authors: *T. W. GOULD, C.-Y. FENG, E. AIYUK, O. REID, D. J. HEREDIA
Physiol. and Cell Biol., Univ. of Nevada Sch. of Med., Reno, NV

Abstract: Loss-of-function mutations in ubiquitin C-terminal hydrolase L1 (UCH-L1) cause motor neuron (MN) disease in mice and neurodegeneration in humans. In contrast to other mouse models of MN disease, UCH-L1 mutants exhibit a selective loss of peripheral innervation without the degeneration of MN cell bodies in the spinal cord. Whether this distinction reflects a preferential role of UCH-L1 in the presynaptic terminals of MNs or not is unclear. In order to begin to address this issue, we generated transgenic mice overexpressing epitope-tagged UCH-L1 in neurons under the Thy1.2 promoter. Transgenic UCH-L1 was observed throughout MNs in UCH-L1 overexpressing mice. When crossed to UCH-L1 mutants, UCH-L1 overexpressing mice prevented paralysis and death and greatly reduced muscle weakness. Ongoing studies are examining the effect of UCH-L1 overexpression on MN disease in other models, as well as whether restricted transgenic overexpression of UCH-L1 to different regions of the neuron are as neuroprotective as overexpression targeted throughout the neuron.

Title: Investigating synaptic aging and neurodegeneration in developmentally arrested *Drosophila* larvae

Authors: *S. PERRY, P. GOEL, D. DICKMAN
USC, Los Angeles, CA

Abstract: The *Drosophila* larval neuromuscular junction (NMJ) has been established as a powerful model system for studying synaptic growth, structure, function, and plasticity. However, because of the short duration of the larval stage, this system is suboptimal for resolving processes that require longer time scales to manifest, such as aging and neurodegeneration. To more establish a more tractable model to probe these processes, we have terminally extended the larval stage. Utilizing recent insights into the developmental signals required for transition to pupal stages, we have fully arrested late-stage larval development in *Drosophila*, leading to arrested third instars (ATI). While wild-type larvae spend ~72 hours (3 days) in the third instar larval stage before transitioning to pupae, ATI larvae persist for over 700 hours (35 days) before dying, never reaching the pupal or adult stage. We have leveraged this system to characterize synaptic structure and function as NMJs grow, age, and degrade over the 700 hours as ATIs. We find that at day 5, ATI animals resemble wild-type controls in terms of muscle size, and synaptic growth, structure, function, and plasticity. However, by day 17, ATI larvae exhibit enhanced muscle size and a corresponding increase in synaptic growth and active zone number. In contrast, by terminal day 33, active zones are reduced in number and size and reduced presynaptic neurotransmitter release is observed. Interestingly, overall synaptic strength is maintained through a compensatory increase in postsynaptic neurotransmitter receptor levels, suggesting a novel form of homeostatic plasticity is expressed as ATIs reach the terminal life stage. Further, ATI synapses can express a homeostatic enhancement in presynaptic neurotransmitter release throughout larval lifespan, underscoring the robust homeostatic plasticity mechanisms with which these synapses are endowed. Finally, current efforts are focused on characterizing synaptic degeneration using the ATI model. In particular, we are investigating several models of neurodegenerative diseases and testing where neuroprotective mechanisms can counteract NMJ degradation. Together, this work will establish a robust model for interrogating synaptic aging and neurodegeneration in an accessible and genetically tractable system.

Title: TDP43 interacts with translational machinery in a *Drosophila* model of amyotrophic lateral sclerosis

Authors: *R. BEAR, B. ZAEPFEL, S. YAMADA, L. PHAM, D. ZARNESCU
Mol. and Cell. Biol., Univ. of Arizona, Tucson, AZ

Abstract: Amyotrophic Lateral Sclerosis (ALS) is a fatal disease that causes progressive neurodegeneration of motor neurons. TAR DNA Binding Protein (TDP-43) has been implicated in the progression of ALS, as well as at the level of pathology. TDP-43 is an RNA-binding protein that is known to regulate many steps of RNA processing, and in ALS it delocalizes to the cytoplasm. However, little is known of TDP-43's role in the dysregulation of translation and its translational targets. Several eukaryotic initiation factors (eIFs) have been identified in TDP-43-positive stress granules. Here we show that changing expression levels of several eIFs to modulate translation is neuroprotective in a Drosophila model of ALS. Specifically, when various eIFs are co-altered in the context of human TDP-43 overexpression in motor neurons of Drosophila, locomotor deficits and retinal neurodegeneration are suppressed. We are working to establish the mechanisms of this functional interaction and determine how TDP-43 physically interacts with translational machinery. We are further exploring the interaction between TDP-43 and the translational machinery in patient-derived lymphoblastoid cells. As we identify specific translational mechanisms that are dysregulated by the presence of cytoplasmic TDP-43, new targets may emerge for the development of novel therapies for ALS.

Abstract: Cadmium (Cd) is a toxic metal and classified as a carcinogen whose exposure could affect the function of the Central Nervous System. There are studies that suggest that Cd promotes neurodegeneration in different regions of the brain, particularly the hippocampus. It is proposed that its mechanism of toxicity maybe by an oxidative stress pathway, which modifies neuronal morphology and causes the death of neurons, and consequently affecting cognitive tasks. However, this mechanism is not yet clear. The aim of the present work was to study the effect of Cd administration on recognition memory for 2, 3 and 4 months, neuronal morphology and immunoreactivity for caspase-3 and 9 in rat hippocampi. For this work, one-month old male Wistar rats with an approximate weight of 80 to 100 g were used. Animals were randomly divided into two groups (n=45/ group): 1) control (drinking water) and 2) treatment with Cd. 32.5 ppm of Cd was added to the water in the form of cadmium chloride ($CdCl_2$) for the treatment group, while the control group received only purified water to, provided daily "ad libitum". Each group was subdivided into three (n = 15), with the purpose of evaluating the effect of Cd-exposure over two, three and four-month periods. The data were reported as the mean ± standard error (SE). A Two-Way ANOVA followed by a Bonferroni post-test was used to analyze the novel object recognition, dentritic length, branch order and spine density. The number of cells immunoreactive to Caspase-3 was analyzed by a Student's t-test. The results

show that the administration of Cd decreased recognition memory. Likewise, it caused the dendritic morphology of the CA1, CA3 and dentate gyrus regions of the hippocampus to decrease with respect to the time of administration of this heavy metal. In addition, we observed a reduction in the density of dendritic spines as well as an increase in the immunoreactivity of caspase-3 and 9 in the same hippocampal regions of the animals treated with Cd. These results suggest that Cd affects the structure and function of the neurons of the hippocampus, which contribute to the deterioration of recognition memory. Our results suggest that the exposure to Cd represents a critical health problem, which if not addressed quickly, could cause much more serious problems in the quality of life of the human population, as well as in the environment in which they develop.

Title: Protective effect of calcium ions on prostaglandin E_2-induced apoptosis in rat cortical cells

Authors: *T. TAKADERA, S. UEMA
Hokuriku Univ., Kanazawa-Shi, Japan

Abstract: Calcium ions mediate a variety of neuron physiological responses, including cell death and survival. The purpose of this study was to examine the effect of calcium influx through the L-type calcium channel (LTCC) or the NMDA receptor on prostaglandin E_2 (PGE_2)-induced apoptosis in rat cortical cells.
Cultures of rat cortical cells were prepared from an embryonic day 18 rat neocortex. Apoptosis was quantified by scoring the percentage of cells that exhibited apoptotic nuclear morphology at the single cell level. Intracellular calcium levels were measured using the Ca^{2+}-reactive fluorescent probe Fluo4/AM.
After culture for 2 or 8 days in vitro (DIV), the rat cortical cells were subjected to PGE_2 treatment for 48 h, which induced caspase-dependent apoptotic cell death through activation of EP2 receptors. LTCC agonists such as FPL64176 protected the cells at 2 and 8 DIV from PGE_2-induced apoptosis. The EP2 receptors, Cav1.2 and Cav1.3 channels were expressed in the cells at 2 and 8 DIV. On the other hand, *N*-methyl-D-aspartate (NMDA), an agonist of the NMDA receptor, protected the cells at 8 DIV, but not at 2 DIV, from PGE_2-induced apoptosis.

FPL64176 increased the cortical cell calcium levels at 2 and 8 DIV, while NMDA increased the calcium levels at 8 DIV, but not at 2 DIV.
Treatment of cells with LY294002, an inhibitor of phosphatidylinositol-3 kinase (PI-3K), also induced apoptosis. Addition of FPL64176 to the cells at 2 and 8 DIV protected neurons from LY294002-induced apoptosis. NMDA protected the cells at 8 DIV, but not at 2 DIV, from LY294002-induced apoptosis. In addition, caspase-dependent apoptosis induced by PGE_2 and LY294002 was prevented by glycogen synthase kinase-3 inhibitors.
Our results suggest that LTCC modulates the cell death of cortical neurons induced by EP2 receptor activation in a PI-3K-independent manner.

Title: Phosphorylation of neuroLSD1 modulates Nur77 expression

Authors: M. OLIVARES COSTA[1], *M. E. ANDRES[2]
[1]Pontificia Univ. Católica, Santiago, Chile; [2]Pontificia Univ. Catolica De Chile, Santiago, Chile

Abstract: Nur77 (NR4A1) is a transcription factor encoded by an immediate early gene (IEG) that belongs to the nuclear receptor superfamily. The expression of Nur77 is highly regulated by dopaminergic projections from the mesencephalon to the striatum and the prefrontal cortex. Drugs of abuse, stress and other stimuli modify the expression of Nur77 in these nuclei, although the mechanisms that regulate this expression have not yet been elucidated. Lysine-specific histone demethylase 1A (LSD1) is an epigenetic modifier that regulates the expression of IEGs in the brain. LSD1 has four splice variants, two of them with exclusive expression in neurons (neuroLSD1). NeuroLSD1 isoforms differ from the ubiquitous LSD1 only in the retention of a phosphorylatable four amino acid microexon (exon 8a). Here, we show that the phosphorylation of neuroLSD1 regulates the expression of Nur77. Also, both increment and decrease of Nur77 expression are associated with a change of neuroLSD1/LSD1 ratio. In a reporter gene assay in HEK293T cells, LSD1 and neuroLSD1 induced the expression of Nur77. A similar effect was observed with the phospho-deficient neuroLSD1, while phosphomimetic neuroLSD1 did not

modify the reporter. Additionally, in vivo experiments show that acute treatment with the dopamine D2 receptor antagonist haloperidol increased neuroLSD1 and concomitantly induced the expression of Nur77 in adult male and female mice striatum. Conversely, chronic amphetamine administration induced a significant increase of neuroLSD1, but a decrease of Nur77 in the striatum. Together, these data suggest that neuroLSD1 phosphorylation limits its function as an IEG inductor and that Nur77 expression results from neuroLSD1 phosphorylation rather than neuroLSD1/LSD1 ratio.

Title: Taurine supplementation during gestation increases oxidative and nitrosative stresses, impairs motor skills, and causes tissue damage in the brain of neonate rats

Authors: *V. VARGAS-CASTRO[1], A. GONZALEZ-VAZQUEZ[1], C. TOMAS-SANCHEZ[1], A. K. AGUILAR-PERALTA[1], V. M. BLANCO-ALVAREZ[1], J. R. EGUIBAR[1], A. UGARTE[1], D. MARTINEZ-FONG[2], G. SOTO-RODRIGUEZ[1], B. A. LEON-CHAVEZ[1]
[1]Benemerita Univ. Autonoma De Puebla, Puebla, Mexico; [2]Fisiologia, Biofisica y Neurociencias, Ctr. de Investigaciones y Estudios Avanzados del IPN, Ciudad de Mexico, Mexico

Abstract: In the CNS, taurine acts in the osmotic regulation, cellular membrane stabilization, ionic transportation, immune system regulation and, it also increases mitochondrial efficiency. It is well known that taurine has an essential role in neonatal brain development, even though the endogenous taurine concentrations tend to diminish over time. Furthermore, taurine supplementation during gestation has been reported to have significant benefits on injury models, such as intrauterine growth restriction, traumatic brain injury, and cerebral ischemia. Nevertheless, the effects of taurine supplementation on growth and development of healthy subjects have not yet been reported. This work aimed to determine whether the taurine supplementation in both gestational and postnatal periods may affect motor skills, nitric oxide levels, lipid peroxidation, and causes tissue damage. Healthy gestational Sprague Dawley rats were supplemented with taurine at a 50-ppm dose, in drinking water, from gestational day 15 and continued for the first month of life. We evaluated the neonate rats with a set of motor tests, which included ambulation, hind limb foot angle, surface righting, and negative geotaxis, fore limb and hind limb suspension, grip strength, and cliff aversion. We dissected out cerebral

cortex, subcortical nuclei, cerebellum, brainstem, and spinal cord from one-month-old specimens. We assessed nitrites levels of these regions by Griess methods and lipid peroxidation by Gerard-Monnier technique, in the supernatant of the homogenized tissue. We also determined brain cellular viability by Triphenyltetrazolium chloride (TTC) staining. The results showed that the taurine supplementation decreased the latency of front limb suspension, and increased the latency of cliff aversion, suggesting a motor injury. The taurine supplementation also increased lipid peroxidation in both frontal and occipital cortex and the cerebellum. Overall, these results allow us to conclude that the taurine supplementation in gestational stage can cause motor deficits and encephalopathy in healthy rats.

Title: Behavior, growth and gene expression changes following exposure to pesticides and environmental stressors using *Caenorhabditis elegans* as a model

Authors: *K. M. RALEY-SUSMAN, E. WHIDDEN, M. RODMAN, C. HARDMAN
Biol., Vassar Col., Poughkeepsie, NY

Abstract: *C. elegans*, a powerful model organism for nervous system development and behavior, is an important soil nematode and, as such, is frequently exposed to a host of environmental stressors like thermal stress. In addition, a growing combination of pesticides in a variety of commercial formulations contaminate most soil and aquatic environments, creating a risk for non-target organisms including nematodes. We examined the effects of thermal stress alone and together with pesticide exposure on *C. elegans* growth, lifespan, behaviors and gene expression of the stress gene, *hsf-1*. We evaluated responses to imidacloprid, alone and in a commercial formulation called “Tree and Shrub.” Imidacloprid is a neonicotinoid insecticide directed at the insect acetylcholine receptor. It acts as an agonist, specific for the insect isoform of the nicotinic ACh receptor, leading to CNS dysfunction that results in disruption of behaviors like navigation that might be involved in honey bee colony collapse. Recent work has

demonstrated unexpected toxic effects on non-target organisms, including nematodes. We also examined the interactions between pesticide exposure and avocado oil as a possible mitigator of pesticide damage. Neither imidacloprid nor the commercial formulation was lethal to *C. elegans*. However, growth was reduced and *C. elegans* exposed to the oxidative stressor paraquat exhibited dysfunction in behaviors like pharyngeal pumping, which is crucial for feeding and survival. Paraquat is an herbicide with known effects in non-target organisms, causing substantial lethality in *C. elegans* after a 48 hr exposure in young adulthood. Aging nematodes exposed as young adults to paraquat exhibited a greater age-dependent reduction in pharyngeal pumping rate. Surprisingly, our results suggest that avocado oil significantly enhanced the pharyngeal pumping deficit in day 7 and day 10 nematodes, particularly in conjunction with paraquat exposure. Our results provide additional support for the enhanced vulnerability to environmental stressors resulting from even short duration exposure to pesticides.

Title: Deciphering the ASK1 phosphorylation code used to trigger downstream signaling cascades

Authors: *A. M. PALUBINSKY[1], B. N. LIZAMA[1], D. SZYMKIEWICZ[2], M. V. GARRETT[2], J. W. MCLAUGHLIN[3], B. A. MCLAUGHLIN[2]

Abstract: Apoptosis signal regulating kinase 1 (ASK1) is an essential mediator of cell survival in response to oxidative, environmental and inflammatory stress. Given the large size (155kDa) and ubiquitous expression, we hypothesized that ASK1s ability to effect changes in viability, proliferation, transcription and signaling was dependent upon novel protein partners and phosphorylation status. Identifying protein interactions and post-translational modifications provides a unique opportunity to understand how this redox-activated protein kinase affects cell survival in a discrete and systematic manner. Using shotgun and targeted mass spectrometry to catalogue ASK1 protein-protein interactions, we previously identified 14 proteins that undergo dynamic shifts in ASK1 association when exposed to the proteotypic lipid electrophile, HNE.

This data demonstrates that ASK1 signalosomes are much smaller and more exclusive than previously thought. Moreover, it suggests that the dozens of putative phosphorylation sites within the protein may play a greater role than expected. Only three ASK1 phosphorylation sites have been tied to functional outcome. Our screens revealed 12 previously unknown phosphorylation sites that are dynamically regulated by stress. We generated phospho-specific antibodies to four of these sites (Tyr140, Ser966, Ser1004 and Ser1059). Here, we present data demonstrating activation of ASK1 based on phosphorylation events at these novel sites in primary neuronal cultures and cell lines. Cells were exposed to short periods of oxidative or electrophilic stress and phosphomapping was performed for ASK1 as well as the downstream effector molecules p38, JNK and ERK. Using immunocytochemistry, we also present data characterizing the cellular localization of phospho-specific pools of ASK1 at baseline and in response to stress. Taken together, our data reveal an ASK1 phosphorylation code that may provide a targeted approach for generating therapeutics to promote cell survival over cell death in response to environmental stress.

Abstract: Soman (GD) is a potent organophosphate acetylcholinesterase (AChE) inhibitor that increases levels of acetylcholine and can lead to cholinergic crisis, including seizures and convulsions which, if left untreated, can lead to death. This issue is of increasing concern for both military and civilian populations Developing methods for detection and treatment requires understanding the acute and chronic effects of GD. Accordingly, we assessed the changes in patterns of gene expression associated with soman exposure and resultant seizure activity in rats. Adult male Sprague-Dawley rats were exposed to subcutaneously adminsistered soman, with or without medical countermeasures (atropine, HI-6, diazepam). Seventy-two hours after exposure, samples were collected from heart, kidney, liver, lung, spleen, and brain regions, (amygdala, hippocampus, hypothalamus, piriform cortex, medial prefrontal cortex, parietal cortex, and thalamus). RNA was extracted from each tissue and quantified on whole genome microarrays. Expression patterns demonstrated significant differences between animals that seized vs those that did not. The magnitude of gene expression changes across tissue types mapped closely to previously characterized patterns of histopathological damage, with the most significant changes occurring in the piriform cortex. Those dysregulated genes associated with seizure activity exhibited enrichment in several cellular functions including protein binding, cell division, phosphorylation, and the immune/inflammatory response. These patterns were generally well conserved across those tissues that exhibited robust histopathologic effects of seizure activity, namely amygdala, hippocampus, and piriform. In the liver, seizing animals showed significant downregulation of genes involved in the oxygen reduction process. Ongoing work will fully characterize the genes and pathways altered by soman exposure, especially those associated with soman-induced seizure responses across different organs to identify genes and pathways which might have diagnostic, prognostic, or exposure surveillance utilities. Disclaimers: Research was conducted in compliance with the Animal Welfare Act, and all other Federal requirements. The views expressed are those of the authors and do not constitute endorsement by the U.S. Army.

Title: Nrf2 activation in the striatum after quinolinic acid administration is an oxidative stress independent process. Participation of p62 and DPP3 proteins

Authors: *C. A. SILVA[1], M. E. CHÁNEZ-CÁRDENAS[1], D. BARRERA-OVIEDO[2], M. E. IBARRA-RUBIO[3], P. D. MALDONADO-JIMÉNEZ[1]
[1]Patología Vascular Cerebral, Inst. Nacional de Neurología y Neurocirugía, Ciudad de México, Mexico; [2]Facultad de Medicina, [3]Facultad de Química, Univ. Nacional Autónoma de México, Ciudad de México, Mexico

Abstract: Nrf2 is a transcription factor involved in the defense against oxidative stress in homeostatic cells, Keap1 mainly regulates Nrf2 levels by its sequestering, ubiquitination and proteosomal degradation; however in non-homeostatic conditions, Nrf2 is activated by different stimuli increasing its nuclear translocation and inducing the expression of antioxidant enzymes and detoxified proteins. There are two mechanisms involved in Nrf2 activation, the canonical and non-canonical pathway. In the canonical pathway electrophilic compounds induce Nrf2 activation by oxidation of some cysteine residues in Keap1. On the other hand in the non-canonical pathway the Keap1-Nrf2 interaction is disrupted by direct interaction of Keap1 with some proteins such as p62, DPP3, WTX and others, inducing Nrf2 stabilization and activation. It has been reported that DPP3 and p62 are able to induce Nrf2 activation in IMR-32 human neroblastoma cells; however, in an *in vivo* model this has not been studied, for this reason we evaluated the participation of DPP3 and p62 on the Nrf2 activation though the non-canonical pathway in the quinolinic acid (QUIN) model, an excitotoxic molecule associated with the pathophysiology of neurodegenerative disorders, as a possible pharmacological target. We administrated 1 µL of isotonic saline solution or QUIN at different doses (15, 30, 60, 120 and 240 nmol) in the right striatum of male Wistar rats (260-300 g), and the striatum were extracted 30 min after injection. We evaluated Nrf2 activity by ELISA assay, and the oxidative stress by GSH/GSSG ratio, DHE assay and activity of antioxidant enzymes. Nrf2, Keap1, p62 and DPP3 levels were measured using western blot and cellular localization of Nrf2 and p62 by immunofluorescence. Finally we evaluated Keap1-DPP3 and Keap1-p62 interaction by immunoprecipitation. QUIN administration increased Nrf2 activation in striatum at 30 min, without increasing ROS production or modifying the redox cellular state. An increase in p62, Nrf2 and Keap1 nuclear levels were observed. Additionally the interaction between Keap1 and DPP3, and Keap1 and p62 increased 30 min after QUIN administration. Finally we found that this process is carried out in striatal neurons. Our results show that *in vivo*, p62 and DPP3 activate the Nrf2 pathway through the non-canonical pathway in striatal neurons.

Title: Excitotoxic cell death inducing megachannel within the ATP synthase: Mitochondrial permeability transition pore?

Authors: *N. MNATSAKANYAN[1], H.-A. PARK[2], J. WU[1], B. MURTISHI[1], P. MIRANDA[3], E. A. JONAS[1]
[1]Dept. of Intrnl. Med., Yale Univ., New Haven, CT; [2]The Univ. of Alabama, Tuscaloosa, AL; [3]New York Univ., New York, NY

Abstract: Mitochondrial permeability transition (mPT) is one of the main causes of necrotic and apoptotic cell death during neurodegenerative diseases and stroke. The opening of the mitochondrial permeability transition pore (mPTP) leads to mitochondrial inner membrane permeabilization and dissipation of membrane potential, followed rapidly by cell death. Despite the vital importance of mPTP in controlling cell life and death pathways, the molecular structure and identity of mPTP is not yet fully understood. We have growing evidence that F_1F_o ATP synthase c-subunit ring forms a large conductance ion channel the gating of which is performed by the F_1 hydrophilic portion of ATP synthase. We observed significant decrease in ATP synthase F_1 subunit levels under glutamate-induced excitotoxic conditions, which is prevented by the mPTP inhibitor cyclosporine A. This suggests that structural disassembly of ATP synthase subdomains unmasks the c-subunit channel, placing mitochondria at increased risk for permeability transition. We have now generated a mutant c-subunit channel with a markedly reduced conductance that we find protects from excitotoxic death of hippocampal neurons. In addition, in our recent studies we have successfully overexpressed and purified human ATP synthase c-subunit from *E. coli*, free of any potential contamination by other mitochondrial proteins. When human c-subunit purified from *E. coli* is reconstituted into artificial lipid bilayers, recordings reveal a large multi-conductance channel with the biophysical characteristics of mPTP. We are currently studying the role of c-subunit leak channel in mPT by using ATP synthase c-subunit CRISPR knockdown and knockout mouse embryonic stem cells. We find that ATP synthase c-subunit CRISPR knockdown cells have significantly smaller conductance channel activity compared with the wild type cells. These findings will provide us with an increased understanding of the molecular composition and structure of mPTP.

Title: Methylmercury (MeHg)-induced neuronal cell death via unfolded protein response

Authors: *H. HIRAOKA[1], K. NAKAHARA[1], M. FUJIMURA[2], Y. KUMAGAI[3], T. UEHARA[1]
[1]Dept. of Medicinal Pharmacol., Grad. Sch. Med.Dent. Pharm. Sci. Okayama Univ., Okayama-Shi, Japan; [2]Dept. Bas. Med. Sci. Natl. Inst. Minamata Dis., Minamata-Shi, Japan; [3]Doc. Prog. Biomed. Sci. Grad. Sch. Comp. Hum. Sci. Univ. Tsukuba, Tsukuba-Shi, Japan

Abstract: [Background]
MeHg known as a causative factor of Minamata disease induces neuronal cell death and damage the central nervous system, but the mechanism is poorly understood. Previously, we reported that MeHg induces S-mercuration at cysteine 383 or 386 in protein disulfide isomerase (PDI), and this modification induces the loss of enzymatic activity. Because PDI is a key enzyme for the maturation of nascent protein harboring a disulfide bond, the disruption in PDI function by MeHg results in endoplasmic reticulum (ER) stress via the accumulation of misfolded proteins. However, the effects of MeHg on unfolded protein response (UPR) sensors remain unclear. In the present study, we examined whether UPR is regulated by MeHg.
[Methods]
To investigate the activations of UPR sensors and downstream signaling by MeHg stimulation, we used western blot analysis and RT-PCR. To measure apoptosis cells induced by MeHg, we assessed the chromosomal condensation using the fluorescent dye Hoechst 33342.
[Results]
We found that MeHg activates protein kinase RNA-like endoplasmic reticulum kinase (PERK) and activating transcriptional factor 6 (ATF6) branches. Although phosphorylated inositol-requiring enzyme 1α (IRE1α) was detected, MeHg did not induce the cytosolic splicing of immature x-box binding protein 1 (XBP1) mRNA (a selective substrate of IRE1α). Then, the IRE1α-null MEFs were transfected with vectors encoding wild-type hemagglutinin (HA)-tagged IRE1α or cysteine mutants. MeHg-induced inhibition of IRE1α endonuclease activity was significantly ameliorated in the MEFs that expressed IRE1α cysteine-to-serine mutant (C931S). These results suggested that cysteine 931 in IRE1α could be a predominant target of MeHg. A

previous study has shown that the IRE1α-XBP1 branch functions as an anti-apoptotic pathway. In contrast, the PERK/ATF6 branches are involved in the induction of cell death. Therefore, these signals may be implicated in the MeHg-induced loss of cell viability. Indeed, treatment with GSK2606414, a specific PERK inhibitor, significantly attenuated MeHg-induced cell death. [Conclusions]
We demonstrated that MeHg disrupts anti-apoptotic signaling based on the IRE1α-XBP1 branch and simultaneously promotes pro-apoptotic signaling via the PERK/ATF6 branches. These findings may be utilized in the development of novel therapeutic approaches for MeHg-induced neurotoxicity.

Abstract: O-GlcNAc modification (also known as O-GlcNAcylation) is a dynamic posttranslational modification which is associated with neurodegenerative diseases and implicated in neuronal death. However, it still remains elusive how O-GlcNAcylation contributes to neurodegeneration. Here, we employed CHFR (Checkpoint with FHA and RING finger domains) ubiquitin ligase as a model protein to unveil the effect of O-GlcNAcylation on the protein function and neuronal survival. CHFR is a checkpoint protein and a tumor suppressor that plays an important role in cell cycle progression and is known to regulate protein deacetylases which are crucial for neural development and neuronal health. We have shown that CHFR interacts with and destabilizes SIRT1 by ubiquitylation and subsequent proteolysis. We found that CHFR is modified with O-linked N-acetylglucosamine (O-GlcNAc) by OGT (O-GlcNAc transferase) at the N-terminal region and this was further validated by mass

spectrometric analysis. Since CHFR protein levels are controlled by its auto-ubiquitination activity, we examined the half-life of CHFR wild-type (WT) and O-GlcNAcylation-defective mutant to investigate the effect of O-GlcNAcylation on its activity. The O-GlcNAcylation-defective mutant of CHFR was less stable than CHFR WT, suggesting that O-GlcNAcylation of CHFR may decrease its Ub-ligase activity. Upon oxidative stress, CHFR was destabilized and neuronal apoptotic death was prominent. Taken together, our results indicate that O-GlcNAcylation modulates its Ub-ligase function of CHFR and play important roles in neuronal stress response pathway.

Title: Function of novel S-nitrosylated proteins identified by biotin switch method with LC-MS/MS analysis

Authors: *K. NAKAHARA[1], H. HIRAOKA[1], A. ITO[2], T. UEHARA[1]
[1]Dept. of Medicinal Pharmacol., Grad. Sch. Med. Dent. Pharma. Sci., Okayama Univ., Okayama, Japan; [2]Lab. of Cell Signaling, Tokyo Univ. of Pharm. and Life Sci., Hachioji, Japan

Abstract: Nitric oxide (NO) is a key signaling molecule that exerts diverse physiological effects via S-nitrosylation, a reversible type of post-translational modification that affects activity, localization, and stability of proteins. Comparable to protein phosphorylation, S-nitrosylation is regulated precisely in time and space. To date, a number of targets of S-nitrosylation have been identified and linked to functional consequences. Many reports have demonstrated the dynamic regulation of protein function by reversible modification; they play a pivotal role in physiological and pathophysiological functions. Previously, we found some S-nitrosylated protein including protein disulfide isomerase and IRE1 that play a crucial role in the pathogenesis of neurodegenerative diseases, including Alzheimer's and Parkinson' diseases. In the present study, we attempted to isolate S-nitrosylated proteins by liquid chromatography coupled with tandem mass spectrometry (LC-MS/MS).
To identify novel S-nitrosylated proteins and the modification sites, we prepared extracts from cells treated with NO donor (S-nitrosocysteine, SNOC) and specifically labeled with biotin. Next, we pulled down the biotinylating proteins using streptavidine beads. Then, the trypsinized samples were subjected to LC-MS/MS.
We detected several known S-nitrosylated proteins such as glyceraldehyde-3-phosphate

dehydrogenase (GAPDH), peroxiredoxin-4 and peroxiredoxin-6. In addition, we succeeded to identify some novel S-nitrosylated proteins including inosine-5'-monophosphate dehydrogenase 2 (IMPDH2). We examined the effect of S-nitrosylation on IMPDH2 activity. Unfortunately, its enzymatic activity of IMPDH2 was not affected by SNOC treatment. This result indicates that IMPDH2 is not regulated by S-nitrosylation. We are now examining the role of S-nitrosylation in other target proteins.

Title: Comprehensive gene expression analysis and neurotoxicity testing of human iPSC derived neural progenitor cells and neurons

Authors: *L. P. JACOB, H. DESAI, M. SPENCER, D. YIN
ATCC, Gaithersburg, MD

Abstract: Human induced pluripotent stem cells (iPSC)-derived neural progenitor cells (NPCs) and neurons are an attractive *in vitro* model to study neurological development, neurotoxicity and to model diseases. However, there is a lack of validated NPCs and media that support differentiation into multiple types of neurons for disease modeling, drug screening, and toxicity screening. Here, we investigated the expression of genes associated with the differentiation of NPCs during three weeks in dopaminergic differentiation media. Known early neuron markers, MAP2 and Tuj1 genes reached peak expression at two weeks while expression of dopaminergic neuronal genes (TH, Nurr1, VMAT2, AADC) was significantly increased in a time-dependent manner ($p < 0.05$) in two types of normal NPCs. Furthermore, expression of genes associated with GABAergic (GABRB3) and glutamatergic (vGLUT1, vGLUT2, GLS2) neurons was also induced and peaked at the end of three weeks. This shows that our NPCs and dopaminergic differentiation media are capable of producing GABAergic and glutamatergic neurons, in addition to dopaminergic neurons. To validate that our NPCs and dopaminergic neuron differentiation media are suitable for drug screening, we conducted neurotoxicity screenings in three types of NPCs (non-reporter NPCs, MAP2-NanoLuc-HaloTag reporter NPCs, and Parkinson's disease NPCs) and NPCs-derived neurons using Reliablue™ cell viability reagent assay and high content imaging analysis. We found that paclitaxel, a microtubule-stabilizing chemotherapeutic agent, significantly induced neurotoxicity ($p < 0.001$) in the three types of NPCs evaluated, but not in NPC-derived neurons. Vincristine, amiodarone, and chlorhexidine

significantly decreased viability of both NPCs and neurons, whereas piperine, cisplatin, and hydroxyurea did not induce any significant neurotoxicity in either NPCs or neurons. This study demonstrates that our iPSC-derived NPCs and dopaminergic differentiation media are suitable for studying neurological development and neurotoxicity screening.

Title: Cross talk between ER and mitochondria in hypoxia adaptation in Andeans

Authors: *H. ZHAO[1], G. C. SIECK[2], G. HADDAD[1,3,4]
[1]Univ. of California San Diego, Sch. of Medicine, Dept. of Pediatrics, La Jolla, CA; [2]Physiol. & Biomed. Engin., Mayo Clin., Rochester, MN; [3]Neurosci., Univ. of California San Diego, La Jolla, CA; [4]The Rady Children's Hosp., San Diego, CA

Abstract: Chronic mountain sickness (CMS) is a disease that potentially threatens a large segment of high-altitude population (more than 100 million highlanders) that has been living at above 2500m for an extended period. Patients with CMS suffer from severe hypoxemia, excessive erythrocytosis and neurologic deficits including migraine, headache, and mental confusion. The mechanisms underlying CMS neuropathology remain unknown. Our previous studies have shown that iPSC-derived CMS neurons have fragmentated mitochondria, decreased ATP level and increased susceptibility to cell death under stress. Genome analysis from the same population identified several genes including C-Jun activation domain-binding protein 1 (JAB1, also called COPS5) and suggested that such genes play an important role in hypoxia adaptation. JAB1 is known to a) act as a modulator of intracellular signaling and to affect cellular proliferation and apoptosis and b) participate in unfolded protein responses by association and disassociation with IRE1, one of three major pathways under endoplasmic reticulum (ER) stress. Since the ER forms physical contacts with mitochondria through mitochondria-associated membranes (MAM) and several genes such as VDAC and MFN2 located in MAM were decreased in expression in CMS neurons, we hypothesized that 1) ER-mitochondrial contacts and signaling regulation may contribute to CMS phenotype; 2) altered binding activity between JAB1 and IRE1 may lead to an increased ER stress through activation of IRE1 pathway in CMS neurons. Our preliminary data showed that increased Grp78 and phos-PERK expression in CMS

neurons as compared to non-CMS neurons, suggesting an increased ER stress in CMS neurons. Further studies are ongoing to investigate which specific ER stress signaling pathway is involved and whether the binding activity between IRE1 and JAB1 is a contributing factor of ER stress in CMS neurons.

Abstract: Epilepsy is a neurological disorder characterized by recurrent spontaneous seizures due to an imbalance between cerebral excitability and inhibition, with a tendency towards uncontrolled excitability. Two main types of epilepsy are generally recognized, mesial temporal lobe epilepsy (MTLE) and lateral temporal lobe epilepsy (LTLE). Epilepsy has been associated with oxidative and nitrosative stress due to prolonged neuronal hyperexcitation and loss neurons during seizures. Experimental animals models report level ATP diminished, increase on lipid peroxidation, catalase and glutathione altered activity in brain. The aim of this study was examines the immunohistochemical expression of oxidative stress markers such as: 4-Hidroxynonenal (4-HNN) Catalase (CAT), Glutathione peroxidase (GPx) and Super Oxide Dismutase 1 (SOD1) in rat brains treated with KA and PTZ considered animal models of epileptic seizures. Evident immunoreactivity of GPx, SOD and CAT was observed mainly in astrocytes and neurons of hippocampal brain region in rats exposed at KA similar results was observed in rats treated with PTZ at the first hours, the quantitative analysis is in process. These preliminary results provide evidence supporting the role of activation of antioxidant systems pathway Nrf2 against oxidative stress effects in experimental models of epileptic seizures.

Title: Neuronal necroptosis is induced by vitamin C oxidation

Authors: *L. E. FERRADA[1], F. J. NUALART[2]
[1]Univ. de Concepción, Concepcion, Chile; [2]Univ. de Concepción, Concepción, Chile

Abstract: Vitamin C is found in two states: reduced ascorbic acid (AA) and oxidized dehydroascorbic acid (DHA). In pathophysiological conditions, such as cerebral ischemia and reperfusion (IR), AA is oxidized to DHA. Interestingly, IR induces a particular type of cell death called necroptosis, which is characterized by activation of RIPK1, RIPK3 and MLKL. DHA alters neuronal metabolism and induces cell death; however, the pathway is unknown. Here, we propose that vitamin C oxidation and intracellular DHA production induces neuronal death by activation of necroptosis in vitro. The neural lineage cells, N2a and HN33.11, were supplemented with 200µM AA for accumulation of vitamin C. *"Ischemic-like"* oxidative stress was induced by deprivation of glucose and 0.5mM H2O2 for 30 min. A *"reperfusion-like"* condition was induced by leaving cells in complete medium for 3h. Intracellular AA concentration was measured by FRASC method, cell viability by XTT and confocal real-time live-cell microscopy. In addition, 3D reconstructions were performed in Imaris software. Morphology was analyzed by elliptical parameters: oblate, prolate, spherical. Cellular size was analyzed by Bounding-Box tool. Necroptosis was evaluated using necrostain-1 (RIPK1 inhibitor), compound-1 (MLKL inhibitor) and zVAD.FMK (apoptosis control). Characteristics of cell disintegration were analyzed by 4D real-time live-cell confocal-spectral microscopy, using the following fluorescent probes: mitotracker CMXRos (mitochondrial activity), Cellmask (plasma membrane stain and morphology), Hoechst 33342 (integrity of nuclei) and Phalloindin-alexa-488 (integrity of plasma membrane). DHA production induces 50% neuronal death and necroptotic disintegration. Necroptosis inhibition with necrostatin-1 and compound-1 prevents neuronal death. However, apoptosis inhibition with zVAD does not. During necroptosis, live cell imaging shows bubbles formation prior to loss of plasma membrane integrity and cytoplasm

shedding. In conclusion we propose that DHA could regulates activation of necroptosis in neuronal cells *in vitro.*

Title: Opioid-induced accumulation of carbonylated protein aggregates in rat brain and blood

Authors: *N. KORNEEVA[1], R. FAN[2], L. SCHROTT[3], T. ARNOLD[4]
[1]Pharmacology/Emergency Med., Louisiana State Univ. Hlth. Sci. Center-, Shreveport, LA; [2]Emergency Med., Louisiana State Univ. Hlth. Sci. Center-Shreveport, Shreveport, LA; [3]Pharmacology, Toxicology and Neurosci., [4]Emergency Med., Louisiana State Univ. Hlth. Sci. Ctr. in Shreveport, Shreveport, LA

Abstract: Opioids are the most effective drugs commonly prescribed to treat pain. Despite widespread abuse of opioids, we know little about the long-term consequences of chronic use. Recently, concern regarding the effect of chronic opioid exposure on neuronal degeneration has emerged. Toxic effect of opioids has been documented not only for heroin abusers but also for patients with a history of long-term use of prescription opioids. Currently, there is no inexpensive, minimally invasive method to monitor neuronal degeneration. Recently, an increase in protein carbonyl content was found to be associated with the development of neurodegenerative diseases such as Alzheimer's and Parkinson's diseases, as well as with cancer and aging. We have developed a method to detect the carbonyl content in protein aggregates in rat blood plasma. Using this method we demonstrated that prolonged oxycodone administration causes an increase in carbonylated protein levels in both rat brain and blood plasma, which correlates with the appearance of biomarkers for neuronal degeneration. We hypothesize that opioid-induced toxicity is associated with the accumulation of insoluble carbonylated protein aggregates in the brain and blood, allowing the level of carbonylated protein aggregates in blood to serve as a biomarker for opioid-induced neuronal degeneration. We also demonstrated that the integrated stress response (ISR) is activated in the brain and blood of animals chronically treated with oxycodone or morphine. The key event in the ISR is phosphorylation of translation initiation factor 2 alpha (eIF2α), which modulates the expression and translation of specific mRNAs important for adaptation to the stress. Activation of the ISR helps cells to cope with

stress and promotes their survival. However, under severe or prolonged stress, over-active ISR may lead to an increase in protein synthesis and accumulation of large molecular protein complexes and cell death. Elevated eIF2α phosphorylation is correlated with neuronal degeneration and has been observed in the brain samples of Alzheimer's disease patients. We hypothesize that over-activated ISR is responsible for the accumulation of toxic protein aggregates in the brain and blood of animals chronically treated with opioids. Detection of protein aggregates in whole blood may serve as a diagnostic tool to monitor drug-induced neuronal degeneration in research and clinical settings.

Title: The oxidizing thiol reagent 2,2'-dithiodipyridine (DTDP) induces an increase in intracellular mobile zinc in oligodendrocytes, but toxicity is not blocked by zinc chelation

Authors: *C. M. ELITT[1,2], M. ROSS[1], N. W. HODGSON[3], C. J. FAHRNI[4], K. VAN LEYEN[5], E. AIZENMAN[6], P. A. ROSENBERG[1,2]

Abstract: Oxidative stress plays an important role in white matter injury in preterm infants, in stroke in adults, and in multiple sclerosis. We have previously demonstrated that mature oligodendrocytes (OLs) treated with peroxynitrite undergo a pathway of non-apoptotic cell death involving increase in intracellular free zinc, ERK1/2 phosphorylation, 12/15-lipoxygenase activation, and generation of reactive oxygen species (Zhang et al., *Journal of Biological Chemistry*, 2006). Similarly, the oxidizing thiol reagent 2,2'-dithiodipyridine (DTDP), which induces zinc release from metallothioneins, has been shown to induce a programmed cell death

pathway in neurons. DTDP has the advantage over peroxynitrite as an oxidative stress agent of being more stable and more specific in its actions. Therefore, we tested its effects in OLs. Developing OLs were prepared from P2 rat glial cultures using selective detachment and plating of isolated OLs. Stage-specific cultures were produced by using FGF and PDGF in serum free medium for developing OLs, and T3 and CNTF for mature cells, according to published methods. Using chromis-1, a recently published ratiometric zinc probe (Bourassa et al., *ACS Sensors*, 2018), we first confirmed that 100uM DTDP causes a robust increase in free zinc in both developing and mature OLs within minutes. We next assessed DTDP toxicity. Developing and mature OLs were treated with a brief 10 minute exposure to 100uM DTDP and survival was assessed after 20-24 hours using the Alamar Blue cell viability assay. In contrast to OL death following peroxynitrite exposure that can be blocked using the high-affinity zinc chelator N,N,N',N'-tetrakis (2-pyridylmethyl) ethylenediamine (TPEN), OL toxicity in response to DTDP could not be blocked by 10uM TPEN. Furthermore, inhibition of other targets in the cascade activated by peroxynitrite in OLs or DTDP in neurons, including ERK1/2 and 12/15-lipoxygenase, had no effect on OL survival in response to DTDP. Because the redox potential in OLs is highly dependent on glutathione, we hypothesized that there could be differential effects using DTDP compared to peroxynitrite as an explanation for the different types of cell death observed with these two agents. However, there was no significant change in GSH/GSSG ratio in response to DTDP or peroxynitrite . In summary, although peroxynitrite produces programmed cell death in OLs that can be interrupted at several downstream steps, DTDP appears to produce unregulated OL toxicity. Further studies into the mechanism by which OLs respond to oxidative stress induced by DTDP are warranted, as elucidating death pathways may provide a strategy to prevent white matter injury.

Title: Astrocytes determine pathway of cell death triggered by oxidative stress in neurons

Authors: *M. ROSS[1], C. M. ELITT[1], N. W. HODGSON[1], K. A. HARTNETT[2], K. VAN LEYEN[4], C. J. FAHRNI[5], E. AIZENMAN[3], P. A. ROSENBERG[1]

Abstract: Understanding how oxidative stress contributes to the pathogenesis of chronic neurodegenerative diseases is of critical importance. One well-characterized neurodegenerative pathway studied in vitro involves increase in free zinc, p38 phosphorylation, enhancement of potassium channel-mediated currents, and caspase activation following exposure to the thiol oxidant 2,2'-dithiodipyridine (DTDP) . Previous studies left ambiguous the role of astrocytes in execution of this neuronal programmed death pathway. To investigate this issue, we compared the effect of DTDP on neurons grown in astrocyte rich (AR) and astrocyte poor (AP) cultures derived from embryonic rat forebrain. We used a ratiometric zinc sensor, chromis-1, to confirm that brief DTDP exposure causes a rapid increase in intracellular free zinc in AP neurons. Similar to previous studies, DTDP was toxic to neurons in both AR and AP cultures. A 10 minute exposure to 75 μM DTDP reduced neuronal survival in AR cultures to 14 ± 4%. Zinc chelation with the high-affinity zinc chelator N,N,N,N',N'-tetrakis (2-pyridylmethyl) ethylenediamine (TPEN; 3 μM) increased neuronal survival to 58 ± 1% ($p<0.0001$), confirming previously published results. We also newly identified 12/15-lipoxygenase as a target in the programmed death pathway activated by DTDP in AR cultures, providing additional evidence for the programmed nature of neuronal death in the presence of astrocytes. Inhibition of 12/15-lipoxygenase increased neuronal survival in AR cultures following DTDP exposure to 49 ± 4% compared to DTDP alone ($p<0.0001$). In contrast, TPEN, 12/15-LOX inhibitors, tetraethylammonium, and caspase inhibitors offered no protection in AP cultures exposed to DTDP. These results suggested that neuronal death in AP cultures is unprogrammed or follows a different program yet to be discovered. Interestingly, in contrast with these results obtained using DTDP in neuronal cultures, peroxynitrite has been reported to cause neuronal death in AP cultures that is programmed and involves elevation of free zinc, activation of 12/15-LOX, and p38 kinase activation. We considered and were able to exclude three possible mechanisms to explain astrocyte dependence for programmed neuronal death induced by DTDP: (1) excitotoxicity, since neurons in cultures without astrocytes are much more sensitive to glutamate excitotoxicity than in cultures with astrocytes, (2) astrocytic metabolism of DTDP, or (3) catastrophic collapse of intracellular GSH levels. Future studies will investigate other possible mechanisms by which astrocytes may influence the pathways of neurodegeneration in the setting of oxidative stress.

Title: The effects of alcohol on neurons, glial cells and memory function in rats

Authors: *J.-Y. WANG[1], S.-Y. CHEN[1], C.-L. CHEN[2], C.-H. YANG[3], S.-N. YANG[3]
[1]Dept Nursing (Basic Med. Sci), Hungkuang Univ., Taichung, Taiwan; [2]Li-Shin Hosp., Taoyuan, Taiwan; [3]Departments of Pediatrics and Med. Research, E-DA Hospital; Col. of Medicine, I-Shou Univ., Kaohsiung, Taiwan

Abstract: Alcohol (EtOH) is considered to be one of the most commonly abused chemical. Excessive alcohol consumption induces damage to neurological function including change of neuroinflammatory response and impairment in normal learning and memory function. It is known that neuroinflammation is an important factor in neurodegeneration, and the activation of glial cells (including astrocytes and microglial cells) may play the key role. Alzheimer's disease (AD) is the most common neurodegenerative disorder. It is associated with neuroinflammatory response, too. Evidence indicated that ethanol exposure induced microglial abnormal activation to release TNF-α and nitric oxide (NO) and decreased the number of neurons in mice brain. However, some data indicated that the microglial activation was not equivalent to neuroinflammation in EtOH-induced neurodegeneration. Even though glial cells are very important constituents in the brain, but investigation of the effects on EtOH in glial cells are not clear. In this study, we wanted to estimate the role of glial cells and the changes of behavior following alcohol exposure in rats. Male SD rats fed with various concentration of alcohol for 1 week (Day 1 and 2: 1 %; Day 3 and 4: 5 %; Day 5, 6 and 7: 10 % alcohol). The diet of rats was restricted in order to decrease 20 % body weight. Then we started operating the behavioral experiment and estimated the memory functions by 8 arm maze. Rats were sacrificed after about 1 month and prepared brain section for immunocytostaining. Our data indicated that the latency time of alcohol group was longer at Day 3, 7 and 11 than control group. The memory task (total time) was significantly increased in alcohol group at Day 2, 3, 4 and 6. The total working memory error (WME) and working reference error (WRE) were increased in alcohol group, too. The results of immunocytostaining of brain revealed that the number of neuron and astrocyte were decreased significantly in prefrontal cortex and hippocampus (CA1); however, the activation of microglial cells and the expression of iNOS were increased significantly. We

suggested that alcohol will impair the normal memory function via induced the microglial cells activation.

Title: Chronic oxidative stress primes glial cells to generate exaggerated cytokine expression after secondary TLR4 activation

Authors: *R. S. DUNCAN, P. KOULEN
Biomed. Sci. and Ophthalmology, Univ. of Missouri - Kansas City, Kansas City, MO

Abstract: Objective: to determine whether exposure of C6 glioma cells to chronic oxidative stress enhances toll-like receptor 3 (TLR3)- and toll-like receptor 4 (TLR4)-mediated expression of inflammatory markers.
Background/Rationale: Oxidative stress occurs in many neurodegenerative diseases contributing to neuronal damage and death. Chronic oxidative stress in the CNS is associated with other pathophysiological events including excitotoxicity and glial-mediated neuroinflammation. The vulnerability of neurons to inflammatory mediators generated by TLRs, such as proinflammatory cytokines, makes targeting of cytokine-expressing glia a promising therapeutic strategy.
Hypothesis: We hypothesized that exposure of C6 cells to sublethal concentrations of the lipid peroxidizer, tert-butylhydroperoxide (tBHP), for 72 hours leads to a potentiation of TLR3- and TLR4- mediated nuclear factor kappa B (NFkB) and pro-inflammatory cytokine expression above that of control conditions.
Methods: C6 cells were grown on glass coverslips and exposed to 10μM tBHP for 72 hours to induce chronic sublethal oxidative stress. Cells not exposed to oxidant were used as controls. Cells in both the control and tBHP-exposed groups were treated for 2 – 6 hrs with the TLR3 ligand polyinosinic:polycytidylic acid (pI:C) or the TLR4 ligand lipopolysaccharide (LPS). Cells were fixed with paraformaldehyde and immunocytochemistry was carried out to label TLR3, TLR4, NFkB and interleukin-1 beta (IL-1β). Samples were imaged using a Leica SPX5 laser scanning confocal microscope. Image-J software was used to conduct microfluorimetric analysis.

Data are expressed as normalized integrated density.
Results: Exposure of cells to tBHP, itself, led to a 30% decrease in cell proliferation and a 2-fold and 5-fold increase in NFkB and IL-1beta immunoreactivity, respectively. Treatment of cells with LPS 72hr after onset of tBHP exposure led to a 60% decrease in cell number and an additional 2-fold increase in TLR4-induced NFkB expression and an additional 4-fold increase in IL-1beta expression. In addition, chronic tBHP exposure alone increased TLR3- and TLR4-induced TLR3/4 immunoreactivity, suggesting that oxidative stress causes a positive feedback loop for inflammatory signaling.
Conclusions: Chronic oxidative stress reduces C6 cell proliferation and potentiates TLR4-mediated NFkB and pro0inflammatory cytokine expression. Reducing oxidative stress may reduce subsequent neuroinflammation in the CNS. Furthermore, TLR4 inhibition may be a promising therapeutic strategy for combating neurodegenerative diseases where oxidative stress plays a major role.

Title: Ethanol induces interferon signaling in astrocyte and neuronal cell lines

Authors: *C. J. LAWRIMORE, L. G. COLEMAN, F. T. CREWS
UNC Chapel Hill, Chapel Hill, NC

Abstract: I**ntroduction**: Excessive ethanol (EtOH) consumption causes innate immune signaling in brain that is linked to alcohol use disorders. Previously, we found that EtOH activates pro-inflammatory signaling in SH-SY5Y neurons and BV2 microglia, including toll-like receptor (TLR) 7, a key inducer of interferon signaling. We also previously found that EtOH increases release of let7b, an endogenous miRNA that activates TLR7, in hippocampal-entorrhinal slice culture. While interferons are also upregulated in post-mortem human alcoholic brain, the role of different cell types in brain in EtOH-induced interferon signaling has yet to be elucidated. **Methods**: SH-SY5Y neurons, U373 astrocytes, and BV2 microglia were treated with EtOH (100mM, 24hr) and cell lysates were analyzed for mRNA expression of various interferons, interferon receptors, and interferon stimulated genes. Data is represented at

%CON±SEM. **Results**: In SH-SY5Y neurons EtOH upregulated IFNβ (272±18%,p<0.001), IFNγ (504±75%,p<0.001), IFNAR1 (344±41%,p<0.001), IFNAR2 (297±21%,p<0.0001), IFNγR1 (461±84%,p<0.01), and IFNγR2 (328±29%,p<0.0001). In U373 astrocytes, EtOH upregulated IFNβ (293±54%,p<0.05), IFNγ (258±38%,p<0.01), IFNAR2 (157±16%,p<0.05), and IFNγR2 (137±10%,p<0.05), however there was no significant effect of EtOH on any interferons examined in BV2. Furthermore, EtOH increased let7b in the media of U373. EtOH-conditioned media from U373 also increased expression of IFNβ (236±32%,p<0.01), IFNγ (233±39%,p<0.01), IFNAR1 (222±24%,p<0.01), and IFNγR1 (186%±31,p<0.05) in SH-SY5Y. In addition, EtOH-conditioned media from U373 increased expression of interferon stimulated genes in SH-SY5Y, such as OASL (170±22%,p<0.05), NGFR (113±4%,p<0.01), and TRAIL (177±17%,p<0.05). TRAIL, which further activates death receptors (DRs) 4 and 5, was also released in the media of EtOH-treated U373. Both DR4 (163±12%,p<0.01) and DR5 (137±7%,p<0.05) were increased by EtOH in SH-SY5Y as well. **Conclusion**: EtOH upregulates interferon signaling in both U373 astrocytes and SH-SY5Y neurons, but not BV2 microglia, suggesting possible astrocyte-neuron interferon signaling. EtOH-conditioned media from U373 activated interferon signaling and interferon stimulated genes in SH-SY5Y, suggesting EtOH causes astrocytes to secrete an interferon-activating mediator. The increase in let7b and TRAIL by EtOH in U373, as well as the corresponding increase in receptors TLR7 and DR4/5 in SH-SY5Y, suggest possible let7b-TLR7 and TRAIL-DR4/5 signaling astrocytes and neurons. Further experiments will explore the roles of these respective pathways.

Title: Alcohol produces inflammation to promote enhanced methamphetamine-induced neurotoxicity

Authors: *A. L. BLAKER[1,2], E. A. RODRIGUEZ[1], B. K. YAMAMOTO[1]
[1]Pharmacol. and Toxicology, Indiana Univ. Sch. of Med., Indianapolis, IN; [2]Neurosciences, Univ. of Toledo Col. of Med., Toledo, OH

Abstract: Alcohol and methamphetamine (Meth) are often co-abused but the neurochemical consequences of this co-abuse are unknown. Individually, both drugs cause inflammation which

can contribute to adverse effects in the brain. We tested the hypothesis that ethanol (EtOH) drinking would enhance Meth-induced neurotoxicity based on the known inflammatory properties of EtOH exposure. Male Sprague Dawley rats were allowed a 2 bottle choice with intermittent (24 hr on, 24 hr off) access to 10% EtOH or water for a total period of 28d. Twenty-four hr after the last day of drinking, an increase in lipopolysaccharide (LPS, a component of gram-negative bacteria) was detected in the serum and striatum of EtOH-drinking rats (*$p<0.05$ vs. Water). Likewise, EtOH rats displayed increases in the pro-inflammatory mediator COX-2 in the striatum (*$p<0.05$ vs. Water). To investigate the comorbid effects of Meth, a subset of EtOH-drinking rats was exposed to Meth in a binge-like regimen (10mg/kg x 4 inj) one day after the last day of drinking. Two hr after the last Meth injection, pro-inflammatory cytokines IL-1β and CNTF were elevated in the serum of EtOH+Meth rats compared to EtOH or Meth alone (*$p<0.05$ vs. EtOH+Saline and Water+Meth). Furthermore, microglia in the brains of EtOH+Meth rats displayed increased cell body size compared to controls 2h after Meth. Seven days after Meth, dopamine was depleted in the striatum compared to controls (*$p<0.05$ vs. Water+Saline). Interestingly, EtOH alone did not alter dopamine concentrations in the brain but rats that drank EtOH and were then challenged with Meth exhibited an exaggerated depletion of dopamine to 10% of controls (*$p<0.05$ vs. Water+Saline). The synergistic decreases in dopamine were paralleled by decreases in tyrosine hydroxylase immunoreactivity in the substantia nigra pars compacta and deficits in motor function. Finally, we tested the hypothesis that EtOH-mediated inflammation mediates this enhanced neurotoxicity by administering the COX inhibitor ketoprofen during EtOH drinking. COX inhibition blocked the upregulation of cytokines, enhanced dopamine depletions, and motor deficits. These findings show that EtOH drinking can exaggerate the neurotoxic effects of Meth on dopamine neurons and motor behavior through inflammation.

Title: Effect of oxidative stress on energy metabolism and the expression of HIF-1 caused by ozone exposure

Authors: *A. E. RODRIGUEZ[1], S. L. RIVAS-ARANCIBIA[2]
[1]Univ. Nacional Autonoma de México, City, Mexico; [2]Facultad de Medicina, UNAM, 04510 Mexico DF, Mexico

Abstract: Environmental pollution is a global public health problem. It is known that chronic exposure to environmental pollutants such as ozone, causes a state of oxidative stress. This condition, plays an important role in the development of neurodegenerative diseases, such as Parkinson's disease and Alzheimer's disease. On the other hand, the hypoxia inducible factor-1 alpha (HIF-1α) increases its expression in response to low oxygen conditions, activating cascades of inflammation through the activation of the nuclear factor *Kapa* B (NF*k*B), as well as its signaling on the proteasome. The objective of this work was to study the effect of chronic oxidative stress, caused by low doses of ozone, on the changes in mitochondrial metabolism, and its relation with the loss of the regulation of the inflammatory response, through the activation of HIF-1α. Ninety male Wistar rats, were divided into 5 groups randomly (n = 18), each group received one of the following treatments: exposed to air without ozone (control group), and groups exposed to ozone for 7, 15, 30 and 60 days respectively. Exposure to ozone was for 4 hours daily at 0.25 ppm. Two hours after the end of the ozone treatment, the animals of each group were divided into three subgroups, were deeply anesthetized and processed for immunohistochemistry techniques and western blot for HIF-1α, NF*k*B, IL-1β. IL-10, IL-17, as well as spectrophotometry technique to determine succinate dehydrogenase activity (SDH) and respiratory activity in isolated mitochondria of the hippocampus. The results indicate changes in the expression of HIF-1α from 7 days to 60 days of ozone exposure and a significant immunoreactivity increase in NF*k*B, IL-1β and IL-17 from 15 to 60 days compared to the control group ($p<0.05$), as well as a decrease in IL-10 ($p<0.05$), also western blot indicate a significant decrease in IL-10 and increases of NF*k*B, IL-1β and IL-17 versus control group ($p <0.05$). The activity of the SDH enzyme presents a decrease from 7 to 60 days of exposure ($p <0.05$), also we found a significant decrease in respiratory activity at 60 days of exposure to this gas versus control group ($p <0.05$). Conclusions: The state of oxidative stress caused by chronic exposure to low doses of ozone, produces deficit in mitochondrial metabolism, activation of HIF-1α, increment in NF*k*B, IL-1β, IL-17 and decrease in IL-10, these alterations explain in part, the loss of the regulation of the inflammatory response present in neurodegenerative diseases such as occurs in Alzheimer's Disease.

Title: Zinc dyshomeostasis plays a key role in inflammasome formation in cultured neurons and astrocytes following LPS or OGD exposure

Authors: *H. PARK[1], J.-Y. KOH[2]
[1]Neural Injury Res. Ctr., Asan Inst. For Life Sci., Seoul, Korea, Republic of; [2]Univ. Ulsan Col. Med., Seoul 138-040, Korea, Republic of

Abstract: Inflammasome is a protein complex that plays a key role in the initiation of inflammatory response in diverse pathological conditions. In the brain, following acute insults such as ischemia and seizures, neurons and astrocytes form inflammasomes and release cytokines such as IL-1β and IL-18, which trigger microglial activation and inflammation. If excessive, such inflammation may contribute to the expansion of brain lesions. In the present study, we examined the hypothesis that zinc dyshomeostasis, a key mechanism in acute brain injury, mediates inflammasome formation in mixed cell cultures containing neurons and astrocytes. In mouse cortical cell cultures, exposure to LPS induced inflammasome formation, as indicated by increases in the level of NLRP3, ASC, caspase-1, and IL-1β by Western blot assay and immunocytochemistry. At the same time, LPS increased levels of free zinc in neurons and astrocytes. Indicating that rises in zinc levels play a role in inflammasome formation, the membrane-permeant zinc chelator TPEN blocked the increase in levels of NLRP3 and caspase-1, as well as the release of inflammatory cytokines into the media. Conversely, addition of a zinc ionophore, clioquinol, markedly increased the inflammasome formation by LPS. Similar changes were observed in OGD in cortical cultures, a cell model for ischemia. OGD induced zinc dyshomeostasis and inflammasome formation. Modulation of zinc levels altered the extent of inflammasome formation. These results suggest that zinc dyshomeostasis plays a key role in LPS-induced inflammasome formation. The present study for the first time showed that zinc dyshomeostasis plays a role in inflammasome formation in neurons and astrocytes induced by LPS and OGD. In light of evidence that inflammasome formation may contribute to the expansion of brain injury in ischemia, understanding the mechanism of zinc dyshomeostasis and its suppression may help reduce inflammation-related secondary brain injury.

Title: Inhalation allergen exposure decreases basal expression of innate immune molecules in murine brainstem

Authors: *M. J. CARSON[1], J. M. VALDEZ[2], X. PENZ[2], A. MADANY[2], A. BURR[1], J. C. JANG[1], Y. Y. GRINBERG[1], T. M. NORDGREN[1], M. G. NAIR[1], D. COCKER[1], D. D. LO[1]
[1]Div. of Biomed. Sci., [2]Univ. of California Riverside, Riverside, CA

Abstract: Continuous exposure to aerosolized fine (particle size $\leq$ 2.5 μm) and ultrafine (particle size $\leq$ 0.1 μm) particulates can trigger innate inflammatory responses in the lung and brain depending on particle composition. Most studies of manmade toxicants use inhalation exposure routes while most studies of allergens use soluble solutions administered via intranasal or injection routes. Here, we tested whether continuous inhalation exposure to aerosolized *Alternaria alternata* particulates (a common fungal allergen associated with asthma), would induce innate inflammatory responses in the lung and brain. By designing a new environmental chamber able to control particle size distribution and mass concentration, we continuously exposed adult mice to aerosolized ultrafine *Alternaria* particulates for 96 hours. Despite induction of innate immune responses in the lung, induction of innate immune responses in whole brain samples was not detected by qPCR or flow cytometry. However, exposure did trigger decreases in Arginase 1, INOS, and TNFα mRNA in the brainstem-only samples containing the CNS respiratory circuit (the dorsal and ventral respiratory groups, the pre-Botzinger and Botzinger complexes). Additionally, a significant decrease in the percentage of TLR2-expressing brainstem microglia was detected by flow cytometry. Histologic analysis revealed a significant decrease in Iba1 but not GFAP immunoreactivity in both the brainstem and the hippocampus. Together these data indicate that inhalation exposure to a natural fungal allergen under conditions sufficient to induce lung inflammation, surprisingly causes reductions in baseline expression of select innate immune molecules (similar to that observed during endotoxin tolerance) in the region of the CNS controlling respiration.

Title: The roles of ZNRF1 in neuronal development and neuroinflammation

Authors: *Y.-C. CHANG[1], S.-J. CHOU[2], L.-C. HSU[1]
[1]Inst. of Mol. Med., Col. of Medicine, Natl. Taiwan Univ., Taipei, Taiwan; [2]Academia Sinica, Taipei, Taiwan

Abstract: Neuroinflammation, the inflammatory responses in the nervous system, has emerged as a critical factor in shaping synaptic structure and function. Dysregulation of neuroinflammation has been shown to link to neurodegenerative diseases such as Alzheimer's disease, multiple sclerosis and Parkinson's disease. However, how neuroinflammation contributes to neuronal development and neurodegenerative diseases is still not clear. ZNRF1, a zinc finger/RING finger type E3 ubiquitin ligase, was reported to play an important role in inflammation as it promotes caveolin-1 ubiquitination and degradation to modulate TLR4-triggered inflammation in *in vitro* and *in vivo.* The expression ZNRF1 was found in rat embryonic, adult cerebral cortex and hippocampus, and it was shown to be up-regulated in Schwann cells after peripheral nerve injury to promote Wallerian degeneration and neuronal/axonal degeneration. Based on its expression pattern, and its role in inflammation, we hypothesize that ZNRF1 functions in the central nervous system to regulate neuronal development and neuroinflammation. To test this hypothesis, we generated several *Znrf1* conditional knockout (cKO) mice by crossing *Znrf1* floxed mice with several Cre recombinase-expressing lines to delete *Znrf1* in the nervous system or immune cells. We compared the brain morphology in control and cKO animals at early postnatal stages and found no significant anatomical defects in the *Znrf1* cKO, suggesting that ZNRF1 is not required for the early brain development. To further examine the function of ZNRF1 in neuroinflammation, we employed the experimental autoimmune encephalomyelitis (EAE), a mouse model of human neuroinflammatory disease multiple sclerosis, in control and cKO mice. Our results showed that depletion of ZNRF1 in myeloid cells attenuates EAE development in mice. Our findings indicate

that ZNRF1 may not regulate murine brain development but the function of ZNRF1 in myeloid cell is involved in the development of neuroinflammation.

Title: Effects of pro-inflammatory pathway inhibition on seizure dynamics in mice exposed to the acetylcholinesterase inhibitor soman

Authors: *E. A. JOHNSON[1], K. LAITIPAYA[1], J. K. CHANDLER[1], D. D. PALMER[1], B. C. LAGER[1], T. M. FERRARA-BOWENS[1], C. L. HONNOLD[2]
[1]Pharmacol., [2]Comparative Pathlogy, US Army Med. Res. Inst. of Chem. Def., Aberdeen Proving Ground, MD

Abstract: Exposure to acetylcholinesterase inhibitors such as soman (GD) can initiate status epilepticus (SE) that can lead to progressive brain damage and behavioral impairment. Current treatments targeting the GABA system can ameliorate GD-induced SE, though treatment effectiveness diminishes rapidly following exposure. Therefore, new treatment strategies that do not rely on the GABA system are needed to reduce seizure activity, tissue loss and cognitive deficits. One strategy involves modulation of the pro-neuroinflammatory response, a prominent feature in GD-induced brain injury, which can exacerbate seizure susceptibility, generation and frequency. We have previously shown that reducing interleukin -1 receptor 1 (IL-1R1), tumor necrosis factor receptor 1A (TNFR1A) signaling or inhibition of both pathways can reduce deleterious physiological effects such as mortality and brain damage after SE. This study focused on whether these changes were related to anticonvulsant, seizure activity modulation or neuroprotective mechanisms. Using knockout mouse strains for IL1R1, TNFR1A and a double IL-1R1/ TNFR1A KO and wild type control strains (C57BL/6J and B6129SF/J), seizure incidence, seizure power and progression, neuropathology, mortality, and other relevant physiological responses were compared. Changes in seizure initiation, seizure incidence and seizure latency were noted between the strains and were most pronounced in strains lacking a functional TNFR1A signaling pathway. Seizure progression and power, however, were similar between all strains tested. Reduced neuropathology was also observed in strains lacking a

functional IL1R1 signaling system. These data suggest that inhibition of specific pro-inflammatory pathways may be a useful addition to standard therapies to treat SE.

Title: The role of IL-1 signaling in neuroinflammation after soman-induced convulsions and anakinra treatment in mice

Authors: *T. M. FERRARA-BOWENS[1], J. K. CHANDLER[1], C. L. HONNOLD[2], K. LAITIPAYA[1], B. C. LAGER[1], D. D. PALMER[1], M. D. WEGNER[3], E. A. JOHNSON[1,3]
[1]Pharmacol., [2]Res. Support, USAMRICD, Gunpowder, MD; [3]AFRIMS, Bangkok, Thailand, Thailand

Abstract: Brain injury resulting from status epilepticus (SE) induced by soman (GD) stimulates peripheral macrophages and leukocytes, and microglia and astrocytes to overexpress neurotoxic cytokines, including interleukin-1 (IL-1), resulting in a neuroinflammatory response. IL-1 binds to the IL-1 receptor (IL-1R1) to initiate IL-1 signaling by activating various kinase pathways, including NFκB, which signals the release of IL-6 and TNFα. The IL-1R1 is inhibited by the IL-1 receptor antagonist (IL-1Ra), which competes with IL-1 for binding to the IL-1R1. Although the presence of IL-1, IL-6, and TNFα has been reported after GD-induced SE, the role of IL-1 signaling in the neuroinflammatory response has not been investigated post exposure in knockout (KO) mice. The purpose of these studies was to determine cytokine expression levels of IL-1, IL-6, and TNFα after GD-induced convulsions in wild type (WT), IL-1R1 KO, and IL-1Ra KO mice, and anakinra treatment in exposed WT mice. Results showed early upregulation of IL-1 followed by later downregulation in the KO strains, as well as IL-1 signaling early and later after anakinra treatment. Additionally, IL-6 upregulation was found between 3 and 12 hours in KO mice, whereas TNFα expression was prominent later in WT mice. These results show the regulatory function of IL-1 regarding neuroinflammation after GD-induced convulsions. Additionally, targeting the IL-1 signaling pathway with anakinra changes cytokine expression, and therefore, the neuroinflammatory response.

Title: The dihydropyridine derivative LA1011 does not alter the cerebral blood flow response to somatosensory stimulation and spreading depolarization in the intact and ischemic rat cerebral cortex

Authors: *Í. SZABÓ[1], D. P. VARGA[1], Á. MENYHÁRT[1], F. BARI[1], E. FARKAS[1], I. HORVÁTH[2], Z. TÖRÖK[2], L. VIGH[2]
[1]Dept. of Med. Physics and Informatics, Univ. of Szeged, Szeged, Hungary; [2]Inst. of Biochem., Biol. Res. Centre, Hungarian Acad. of Sci., Szeged, Hungary

Abstract: The dihydropyridine derivative LA1011 has been shown to be neuroprotective via modulating cellular stress response in a transgenic mouse model of Alzheimer's disease. In contrast with other well-known dihydropiridines such as nimodipine or nifedipine, LA1011 has no L-type calcium channel antagonistic effect. Here we set out to explore whether LA1011 achieves neuroprotection by improving the efficacy of neurovascular coupling in the intact or ischemic rat cerebral cortex.
Two open cranial windows were prepared over the parietal cortex of isoflurane-anesthetized, adult, male Sprague-Dawley rats (n=44). Local field potential (LFP) and cerebral blood flow (CBF) were recorded from the rostral craniotomy, with the aid of a glass capillary microelectrode and laser Doppler flowmetry. CBF variation was assessed in response to repeated whisker stimulation, and subsequent spreading depolarization (SD) events triggered by 1 M KCl applied in the caudal craniotomy. Experiments were repeated under global forebrain ischemia induced by bilateral common carotid artery occlusion (2-vessel occlusion, 2VO). In the first set of experiments, LA1011 or its vehicle were injected i.p. (n=12, 2x1mg/kg/day/2 weeks). In the second set of experiments, LA1011 or its vehicle were administered topically to the cortical surface (n=32, 100 μM).

LA1011 had no significant impact on baseline CBF, and did not alter the amplitude of hyperemia in response to whisker stimulation (8.0±3.8 pp vs. 6.2±2.9 pp, LA1011 vs. vehicle in 2VO group) or SD (110.9±30.4 pp vs. 150.7±96.5 pp, LA1011 vs. vehicle 2VO group). Yet, LA1011 significantly increased the amplitude of SD in all LA1011 treated groups (19.0±1.9 mV vs. 15.1±2.1 mV, LA1011 vs. vehicle, intact, acute group).
The data suggest that LA1011 exerts no direct effect on neurovascular coupling, but it augments the elicited SDs under all experimental conditions tested. We propose that LA1011 possesses a potential anti-inflammatory effect, which would be consistent with the previously reported reduction of SD amplitude by tumor necrosis factor-alpha.

Title: Disruption of developmental neurogenesis and apoptosis by perinatal phthalates in the rat medial prefrontal cortex

Authors: *E. P. SELLINGER[1], C. DRZEWIECKI[2], J. WILLING[3], J. M. JURASKA[3]
[1]Neurosci. Program, Univ. of Illinois Urbana-Champaign, Champaign, IL; [2]Univ. of Illinois at Urbana/Champaign, Champaign, IL; [3]Psychology, Univ. of Illinois, Champaign, IL

Abstract: The perinatal period is a time when the developing brain is especially vulnerable to environmental insult. One such environmental concern is exposure to phthalates, a class of endocrine-disrupting chemicals used as plasticizers, solvents, and emulsifiers in a variety of products, which results in ubiquitous human exposure. As phthalates can readily cross the placenta and are transferred to offspring through lactation, exposure can occur during early development. Previous work indicates that exposure to an environmentally relevant mixture of phthalates composed of 35.35% DEP, 21.12% DEHP, 15.12% DiNP, 15.10% DBP, 8.16% DiBP, and 5.15% BBP during early development leads to a decrease in neuron number in the

adult rat medial prefrontal cortex (mPFC). Here, we investigate whether phthalate exposure disrupts neurogenesis or apoptosis. Pregnant and lactating rats consumed a cookie with a dose of 0mg/kg, 1mg/kg, or 5mg/kg of the same phthalate mixture from embryonic day 2 through postnatal day (P)10. Brains were collected at P10 to analyze levels of apoptosis through TUNEL labelling. In order to directly observed the impact of prenatal phthalate exposure on neurogenesis, a second group of pregnant rats received a dose of 0mg/kg, 1mg/kg, or 5mg/kg from embryonic day 2 through parturition. The dams were injected with BrdU, a thymidine analog and marker of cell proliferation, at embryonic days 16 and 17, and the brains of the offspring were collected at P5. Exposure to the 5mg/kg phthalate dose during early development resulted in increased apoptosis across sexes at P10 as assessed through density of TUNEL labelled cells. Prenatal phthalate exposure at both doses significantly reduced BrdU labelling in the mPFC at P5. These results demonstrate a two-hit model in that phthalate exposure dysregulates early neuronal proliferation as well as apoptosis in the mPFC during development, leading to lasting changes in neuron number.

Title: Acute effects of perinatal bisphenol A exposure on cortical apoptosis in rodents

Authors: *C. DRZEWIECKI[1], E. P. SELLINGER[2], J. WILLING[3], S. RHOADS[4], J. M. JURASKA[3]
[1]Univ. of Illinois at Urbana/Champaign, Champaign, IL; [2]Neurosci. Program, Univ. of Illinois Urbana-Champaign, Champaign, IL; [3]Psychology, [4]Univ. of Illinois, Champaign, IL

Abstract: Cell death during development, or apoptosis, is critical for the proper refinement of the nervous system. Apoptosis occurs in region- and sex-specific patterns, and can be influenced by genetic, hormonal as well as environmental factors. One potential environmental threat to apoptosis is bisphenol A (BPA), a nearly ubiquitous endocrine disruptor which acts as both an agonist and antagonist at the estrogen receptor. Previous work from our laboratory has shown that perinatal BPA exposure in males, but not in females, is associated with increased numbers of neurons in the medial prefrontal cortex (mPFC) in adulthood, which may be indicative of an autism-like phenotype (Sadowski et al., 2014). We hypothesize that BPA exposure may prevent

perinatal apoptosis, leading to increased cell numbers later in life. While previous work examined long-term BPA exposure from gestation through the perinatal period, the current study examines the effects of short-term BPA exposure on apoptosis. In the developing mPFC, the number of pyknotic cells per live neurons is highest at P8 and P12 in males and females, respectively, indicating brief windows of development where rapid cell death is occurring (Willing et al., unpublished data). In this study, Long Evans rodent pups were dosed orally with a 0 (control), 40 or 400 μg/kg/day BPA solution across a 3-day window on P6, P7, and P8 (early dose) or P10, P11, and P12 (late dose). All subjects were sacrificed four hours after their last BPA dose, and the brains were collected and stained for TUNEL, a marker of apoptotic cells. A Nissl stain was performed on adjacent tissue slices to quantify the density of live neurons. We found a significant effect of BPA treatment, such that males dosed from P6-P8 with 400 μg/kg of BPA had significantly fewer TUNEL cells per live neurons in the mPFC than controls, suggesting that BPA exposure during this brief window prevented cell death. These results provide evidence that BPA acts in a sex-specific manner to disrupt normal apoptosis, which could result in increased neuron numbers in adulthood. Further work is needed to determine the behavioral implications of these outcomes.

Title: Cocaine elicits autophagic cytotoxicity via a nitric oxide-GAPDH signaling cascade

Authors: *P. P. GUHA
Johns Hopkins Univ., Baltimore, MD

Abstract: Cocaine exerts its behavioral stimulant effects by facilitating synaptic actions of neurotransmitters such as dopamine and serotonin. It is also neurotoxic and broadly cytotoxic, leading to overdose deaths. We demonstrate that the cytotoxic actions of cocaine reflect selective enhancement of autophagy, a process that physiologically degrades metabolites and cellular organelles, and that uncontrolled autophagy can also lead to cell death. In brain cultures, cocaine markedly increases levels of LC3-II and depletes p62, both actions characteristic of autophagy. By contrast, cocaine fails to stimulate cell death processes reflecting parthanatos, monitored by cleavage of poly(ADP ribose)polymerase-1 (PARP-1), or necroptosis, assessed by levels of

phosphorylated mixed lineage kinase domain-like protein. Pharmacologic inhibition of autophagy protects neurons against cocaine-induced cell death. On the other hand, inhibition of parthanatos, necroptosis, or apoptosis did not change cocaine cytotoxicity. Depletion of ATG5 or beclin-1, major mediators of autophagy, prevents cocaine-induced cell death. By contrast, depleting caspase-3, whose cleavage reflects apoptosis, fails to alter cocaine cytotoxicity, and cocaine does not alter caspase-3 cleavage. Moreover, depleting PARP-1 or RIPK1, key mediators of parthanatos and necroptosis, respectively, did not prevent cocaine-induced cell death. Autophagic actions of cocaine are mediated by the nitric oxide-glyceraldehyde-3-phosphate dehydrogenase signaling pathway. Thus, cocaine-associated autophagy is abolished by depleting GAPDH via shRNA; by the drug CGP3466B, which prevents GAPDH nitrosylation; and by mutating cysteine-150 of GAPDH, its site of nitrosylation. Treatments that selectively influence cocaine-associated autophagy may afford therapeutic benefit.

Title: Evaluation of hiPSC-derived neuronal cultures for safety assessment of potential therapeutic compounds against zika virus

Authors: *F. ZANELLA[1], I. SLAVIN[2], S. DEA[3], S. MONTEFUSCO[4], J. SIQUEIRA-NETO[4], C. CARROMEU[1]

Abstract: The recent global threat of Zika Virus epidemic has highlighted the need for sophisticated screening systems capable of detecting unintended toxicity of candidate compounds against this serious infection. Toxicity to the Central Nervous System (CNS) is a key aspect in safety pharmacology evaluation of drugs under development. The characterization of the toxicological profiles of new chemicals to the CNS involves extensive investigation using *in vitro* and *in vivo* models. Currently, primary cultures and animal models are popular platforms for those studies. In spite of their importance, those platforms typically are not amenable to larger scale toxicity screens. Human induced pluripotent stem cell (hiPSC) technology has enabled the ready availability of large and consistent batches of neural cells and tissues for wider toxicity screens, having the potential to change the current paradigm in pharmacological research. Through hiPSCs and state-of-the-art differentiation protocols, researchers now have available unlimited source of neural cells, able to mimic early and late stage of human CNS

development. These sophisticated cellular models hold great potential in reducing the time to assess toxicity of developing drugs. Here we investigate the toxicological profile of 29 compounds recently described in the literature as potential therapeutic compounds against Zika Virus infection. hiPSCs-derived neural cells at different developmental stages were challenged with this library of compounds in two-dimensional cultures as well as three-dimensional mini-brain organoids. We observed greater susceptibility of the neural tissues to compound toxicity at early stages of development, and decreasing toxicity as the neuronal cultures mature *in vitro*. Compounds with the safest profiles were further evaluated in high throughput calcium flux and multi-electrode array assays for assessment of potential functional side effects on the normal function of the CNS. In summary, our work highlights the power of a human CNS model in predicting toxicological profiles of proposed drugs against Zika Virus. Moreover, this system can be applied to investigate the safety profiles on new chemical entities, improving predictivity of clinical outcome and reducing overall drug development costs.

Abstract: Parkinson's Disease (PD) afflicts ~1% of humans and prevalence increases with age. Initial symptoms include tremors in extremities due to loss of dopaminergic neurons in the substantia nigra. Familial PD (fPD, with a family history of PD) accounts for ~10% of cases and is often early-onset (e.g., <60 yrs), whereas sporadic cases (sPD, no family history) make up ~90%. Mutations responsible for fPD occur in protein-coding genes including *SNCA* (encodes α-synuclein [α-Syn]), *LRRK2*, *PARK2*, *PINK1*, *PARK7* and *GBA*. Of these, the A53T mutation in

α-Syn (A53T-α-Syn) has the highest penetrance (~90%, with early onset). The goal of our study was to quantify neuronal function relevant to PD in dopaminergic neurons derived from human induced pluripotent stem cells (iCell Dopa Neurons, Cellular Dynamics International). We studied an isogenic pair of cell lines (hiPSC-wt-α-Syn-DNs, and hiPSC-A53T-α-Syn-DNs) in which the A53T mutation was introduced into hiPSCs derived from a normal donor. Neurons were seeded into either 96- or 384-well dishes, loaded with fluo-4 (for calcium) or FluoVolt (for voltage) and activity was recorded with a Kinetic Image Cytometer^{TM} (KIC), an automated digital microscopy workstation that collects images at up to 1200 frames per second (fps). The digital movies were quantified with CyteSeer^{TM}, which quantifies activity on a cell-by-cell basis. The hiPSC-A53T-α-Syn-DNs exhibited greater spontaneous and synchronized calcium transients vs. wt-α-Syn, and exhibited greater sensitivity to rotenone, a pesticide linked to PD. hiPSC-A53T-α-Syn-DNs also displayed more spontaneous voltage activity (action potentials and more prolonged depolarizations, recorded at 400 fps) and were more responsive to electrical stimulation delivered by the KIC. The results suggest that A53T-α-Syn induces hyperactivity in dopaminergic neurons, likely increasing susceptibility to cytotoxic-stresses. The methods developed in this study will enable high throughput screening of compounds or genetic constructs to identify those with potential toxic or beneficial effects relevant to PD.

Abstract: Calcium regulation is very important for neuronal health, and dysregulation of calcium is linked to multiple neurodegenerative disorders. For example, alpha-synuclein and amyloid β-peptide fragments, associated with Parkinson's Disease and Alzheimer's Disease, respectively, disrupt calcium homeostasis of neurons, in vitro. Human induced pluripotent stem cell (hIPSC) derived neurons are a powerful tool for high-throughput screening of drugs that may

modulate changes in calcium regulation or affect neurite outgrowth and synapse formation. We have developed the IC200 Kinetic Image Cytometer™ (KIC) and with it can perform high-throughput, cell-by-cell analysis allowing us to investigate the effect of drugs on calcium regulation in living neurons cultured in 384-well dishes. Additionally, our IC200 can perform automated scans on fixed neurons that have been immunolabeled to visualize relevant biomarkers and structures, to assess morphological changes. With our CyteSeer Analysis software, we developed algorithms that quantify beta III tubulin expression and localization to assess neurite outgrowth and algorithms to quantify puncta of pre- and post-synaptic markers to access synaptic density. In the current study, we performed experiments to test the capability of our platform to detect changes in calcium activity, neurite morphology, or synapse number using compounds that have been demonstrated to induce changes in cultured neurons. We plated commercially available cortical neurons differentiated from hiPSCs, allowed them to recover from plating and mature, then treated the cells with compounds or DMSO (control). Neuronal activity analysis was performed on live neurons using our KIC technology, and we found that forskolin, which increases c-AMP, reduced calcium transient activity, whereas 4-aminopyridine (4-AP), a K+ channel inhibitor that has epileptic effects, increased calcium transients. Blebbistatin, a myosin inhibitor, was also found to increase neurite outgrowth. Thus, our platform detects changes in iPSC-neuron activity and morphology providing proof of concept for use in future high content screening studies.

Title: Neonatal sevoflurane exposure up regulates cation-chloride cotransporter KCC2 in mouse thalamus

Authors: *O. H. CABRERA, V. TESIC, Q. L. E. TAT, N. QUILLINAN, S. E. CHASTAIN, V. JEVTOVIC-TODOROVIC
Anesthesiol., Univ. of Colorado Anschutz Med. Campus, Aurora, CO

Abstract: Sedative/anesthetic drugs (SADs) are used pervasively in neonatal medicine despite being neurotoxic to developing mammalian brain and linked to neurodevelopmental impairment in children treated with SADs as infants. In neonatal rodents and non-human primates, SADs cause acute neuroapoptosis, but impairments persist into adulthood in animal models and at least early childhood in humans, suggesting long-term perturbation of surviving neurons. Indeed, we have observed altered GABA neurotransmission in sensory and cognition networks of adult rodents exposed to SADs as neonates.

The cation-chloride cotransporters regulate neurotransmission by controlling intracellular chloride concentration $[Cl^-]_i$ and, therefore, polarity of neuronal responses to GABA. During early neurodevelopment, NKCC1 maintains high $[Cl^-]_i$ in immature neurons, and GABA binding causes chloride efflux and neuronal depolarization. As development proceeds, neurons predominantly express KCC2, which maintains low $[Cl^-]_i$. Thus, GABA binding mediates neuroinhibition via chloride influx. These findings led us to hypothesize that SAD-induced dysregulation of cation-chloride cotransporters may be partially responsible for altered GABA neurotransmission observed in our previous studies.

We treated litters of postnatal day (PND) 7 mice with sevoflurane (SEVO) for 6h (3% for 2h; 2.4% for 4h). To prevent hypoxia, we supplemented SEVO with a mixture of 30% O_2 and compressed air. The littermates randomly assigned to control group received only carrier gases. We maintained body temperature of all pups at 35 °C and monitored vitals of SEVO pups. We collected cortex, hippocampus, and thalamus at 6h and 24h after initial exposure, then probed changes in NKCC1 and KCC2 protein expression via Western Blot. SEVO increased KCC2 protein expression in thalamus at 24h, $p = 0.002$, but not at 6h. Cortical and hippocampal KCC2 was unchanged at 6h and 24h in SEVO pups. SEVO challenge did not alter NKCC1 protein expression in brain regions of interest at 6h or 24h. Next, we histologically identified specific thalamic nuclei at the 24h time point as putative targets of KCC2 dysregulation. We observed a statistically significant increase in KCC2 immunoreactivity in ventrobasal (VB) thalamus of SEVO pups versus controls, $p = 0.01$.

The VB participates in thalamocortical oscillations important for normal sensory processing and attention, as well as neuropathological disorders such as epilepsy. In future studies, we will test the possibility that SEVO-induced upregulation of KCC2 in VB may interfere with GABA neurotransmission and thalamocortical oscillations.

Title: Alphaxalone has broader therapeutic index than propofol and shows no neurotoxic effects to developing rat brain

Authors: *V. TESIC[1], S. CHASTAIN[3], Q. TAT[4], O. H. CABRERA[5], N. QUILLINAN[6], K. KATHIRESAN[7], D. F. COVEY[7], S. M. TODOROVIC[5], V. JEVTOVIC-TODOROVIC[2]

Abstract: Recent studies have raised awareness that exposure to GA during childhood may be associated with an increased risk for subsequent deficits in learning, memory and cognition. Thus, there is an urgent need to develop safer GAs.
Alphaxalone (3α-hydroxy-5 α-pregnane-11, 20-dione) is a neuroactive steroid with anesthetic properties. It modulates neurotransmission through interaction with a steroid recognition site on the $GABA_A$ receptor complex causing a positive allosteric modulation of the ligand-gated chloride channel, thus inhibiting neuronal excitability. In addition, alphaxalone inhibits neuronal T-type calcium channels. Propofol, a commonly used GABAergic general anesthetic (GA) which has very little effects on T-type calcium channels, was shown to be neurotoxic to developing brain of both rodents and non-human primates at clinically-relevant doses.
We investigated the hypnotic properties of alphaxalone in comparison with propofol by testing the loss of righting reflex (LORR) in post-natal day 7 Sprague Dawley rats. Alphaxalone and propofol caused dose-dependent hypnosis with higher therapeutic index for alphaxalone (32.1 for alphaxalone and 23.1 for propofol). In terms of LORR, the 50% effective doses (ED_{50}) for alphaxalone and propofol were 1.57 mg/kg and 2.36 mg/kg, respectively. LD_{50} (dose that caused 50% of mortality) was 50.41 mg/kg and 54.55 mg/kg for alphaxalone and propofol, respectively. Next, we compared the number of activated caspase 3 (AC3) positive cells after exposure to alphaxalone and propofol, as AC3 is considered to be the marker of GA-induced neurotoxicity. We exposed the pups to equipotent doses of anesthetics that cause a LORR for 40 min (10 mg/kg

of alphaxalone and 20 mg/kg of propofol every hour for total of 6 i.p. injections). Brains were collected 2h after exposure and immunohistochemical staining was performed. In order to determine neurotoxicity levels, we focused on counting of AC3 positive cells in the subiculum, output structure of hippocampus that is highly sensitive to GA-induced neuroapoptosis. We found that alphaxalone treatment did not cause a statistically significant increase in AC3-positive cells in subiculum when compared to sham-treated group, while propofol caused a ~5-fold increase in neurotoxicity compared to controls.
Our data suggest that alphaxalone is safer than propofol since it has broader therapeutic index. Importantly, we show that alphaxalone does not induce developmental neuroapoptosis. Thus, neuroactive steroid analogues with anesthetic properties, such as alphaxalone may warrant further investigation as new class of anesthetics potentially safe for use in infants and children.

Title: Early postnatal exposure to sevoflurane causes long-lasting changes in expression of synaptic plasticity related genes in rat subiculum

Authors: *S. E. CHASTAIN[1], V. TESIC[2], Q. TAT[3], O. H. CABRERA[1], N. QUILLINAN[4], V. JEVTOVIC-TODOROVIC[1]
[1]Anesthesiol., Univ. of Colorado Anschutz Med. Campus, Aurora, CO; [2]Anesthesiol., Univ. of Colorado, Anschutz Med. Campus, Aurora, CO; [3]Univ. of Colorado Anschutz, Aurora, CO; [4]Anesthesiol., Univ. of Colorado, Aurora, CO

Abstract: Multiple and prolonged prenatal and neonatal exposure to sevoflurane has been shown to cause neurobehavioral and developmental abnormalities, but the mechanisms are incompletely understood. DNA methylation is crucial to normal development and differentiation by acting as a suppressor of gene expression and is found in the promoter region of critical genes. Once formed DNA methylation is extremely stable and possesses a self-perpetuating capacity. For demethylation to occur it requires a prohibitively high degree of energy. 5-hmC is hypothesized to be a potential key intermediate in an active DNA demethylation process. We aimed to elucidate the role of DNA methylation by examining long-lasting 5-mC and 5-hmC

modifications of DNA resulting from postnatal exposure to sevoflurane.
Postnatal day (PND) 7 Sprague-Dawley rats of equal gender were exposed to sevoflurane at 3% for 2h followed by 2.4% for 4h in 30% oxygen, with vehicle group exposed to 30% oxygen for 6h. Brains were collected at PND28 for analysis of methylation in subiculum, the region of the hippocampus known to be highly sensitive to anesthetics. Intensity of 5-mC and 5-hmC were determined in subicular neuronal-nuclei. A single postnatal exposure to sevoflurane resulted in 33.4%$\pm$5.9 reduction of 5-mC DNA methylation and a 29.7%$\pm$6.9 increase in 5-hmC DNA methylation.
Due to the resulting changes in DNA methylation and known neurobehavioral abnormalities we hypothesized that expression of specific genes involved in synaptic plasticity would change. Employing a synaptic plasticity PCR assay we revealed that 21 out of 84 investigated targets were changed by $\geq$30% when exposed to sevoflurane. Of these genes Arc, Cebpb, Junb, Ntf3, Ntf4, Mmp9 and Tnf were examined in more depth due to their function as transcription factors and involvement in neuronal survival and proliferation. Of these genes ARC, Junb, NTF3 were upregulated by $\geq$70%; Cebpb, Mmp9, Ntf4 and Tnf were downregulated by $\geq$50%.
Since we observed a decrease in the 5-mC and sequential increase in 5-hmC DNA methylation we propose it to be, at least in part, responsible for changes in gene expression. Sevoflurane exposures results in a shift in global subicular methylation, inferring altered gene expression, as shown by change in crucial synaptic plasticity gene expression. These genes play vital role in the neurobehavior and development and their changes could contribute to abnormalities seen after exposure to sevoflurane.

Abstract: Cigarette smoke and air pollution are strong risk factors of Alzheimer's disease (AD) and other age-associated chronic diseases. While many effects of these environmental toxicants are well documented, less is known about their interactions with sex and *ApoE* alleles (Cacciottolo et al. 2017, PMID:28140404). This study investigates the pathways of interactions of sex, *ApoE* genotype, and environmental toxicants that contribute to cognitive decline and neurodegenerative diseases. We evaluate correlations of human genomic and phenomic data from the Health Retirement Survey (HRS, U.S. sample) with transcriptomic data from male and female *ApoE* transgenic mice exposed to air pollution. Results from the HRS cohort show *ApoE4* and smoking are risk factors of accelerated cognitive aging (Method from Levine et al. 2018 under review) with stronger trends in women. To complement these human studies, we applied Weighted Gene Co-Expression Network Analysis (WGCNA) to identify gene networks differentially expressed in the mouse cerebral cortex as a function of sex, *ApoE*, and environmental toxins. One WGCNA module enriched for nervous system-associated signaling pathways showed significant interactions among sex, *ApoE* and air pollution. These genes had high overlap with 215 previously-defined polygenic genes for predicting long-lived human smoking survivors. This suggests cigarette smoke and air pollution have convergent molecular toxicities that mediate gene environment interactions in cognitive aging. We further analyzed AD associated genes for susceptibility to each factor and possible genotype-environment interaction. These findings suggest influences of *ApoE4* allele in sex difference of cognitive aging vulnerability to environmental toxins.

Abstract: Traffic-related air pollution (TRAP) is increasingly documented as a risk factor for Alzheimer Disease (AD) onset and for accelerated cognitive decline (Cacciotttolo et al 2017). TRAP exposure increases the levels of endogenous amyloid beta (Aβ) peptides in rodents after chronic exposure (Levesque et al. 2011). Multiple evidences suggest that accumulation or overproduction of Aβ peptides is one of the main cause of Alzheimer disease (AD) (Zhang et al. 2011). Amyloid-β peptides are generated following a proteolytic processing of the amyloid precursor protein (APP) by β- and γ-secretases. γ-secretases generates the most abundant Aβ40 and Aβ42 isoforms and the latest is considered to be the key pathogenic species in AD. γ-secretase modulators (GSMs) are the last generation drugs that target Amyloid peptides (Kounnas MZ et al. 2010). Among them a novel soluble γ-secretase modulator (BPN-15606) has been shown to strongly and selectively decrease Aβ42 levels (Wagner SL et al 2017). To evaluate whether pharmacological inhibition of Aβ production during exposure to a nano-scale subfraction of TRAP (nPM) attenuates the amyloidogenic processing of APP and has impact on pathological AD hallmarks, we treated C57BL/6JN mice with the γ-secretase modulator BPN-15606. 3 months old male mice were exposed to nPM for 8 weeks, 3day/w, 5hr/d and fed with regular diet or 10 mg/kg GSM in the chow for 1 week before and during exposure to air pollution. Cerebral cortices were collected and analyzed by MSD multiplex ELISA for the quantification of Aβ40 and Aβ42 peptides. Mice exposed to nPM had elevated levels of Aβ40 and 42 peptides, which were reduced by 35% and 45%, in mice exposed to both nPM and GSM. Moreover, nPM induction of the microglial marker Iba1, in hippocampal subfields by nPM was significantly attenuated by the GSM. The strong connection between microglia inflammatory responses due to nano-particulate exposure and Aβ peptides confirm the possible role of endogenous Aβ levels in cognitive changes. Our data suggest that cognitive impairment due to air pollution exposure might be ameliorated through the manipulation of the APP processing and the novel γ-secretase modulator drugs could be the lead on this path.

Title: Lipid rafts as novel target of traffic related air pollutant exposure: Evidence from *in vivo* and *in vitro* models

Authors: *M. CACCIOTTOLO[1], T. E. MORGAN[1], A. C. SAFFARI[3], F. SHIRMOHAMMADI[3], H. J. FORMAN[1], C. SIOUTAS[3], C. E. FINCH[2]

Abstract: Traffic-related air pollution (TRAP) is increasingly documented as a risk factor for Alzheimer Disease (AD) onset and for accelerated cognitive decline. Mouse models exposed to a nano-scale subfraction of TRAP (nPM) showed increased brain amyloid levels, concurrently with oxidative damage, as possible mechanism of neurotoxicity (Cacciotttolo et al 2017). Additionally, cell production of Aβ is also increased by oxidative stress. Brain cell oxidative responses to nPM are also shown in *in vitro* models of hippocampal slices and primary brain cell cultures with increased NO (nitric oxide) production and lipid oxidation (4-HNE) (Davis et al 2013; Cheng et al 2016). Air pollutants may affect multiple steps in APP processing. In neurons, APP undergoes an endoproteolytic cleavage mediated by the 'secretases' in which the initial cleavage by α- or β-secretase determines the level of Aβ production. Subsequently, the γ-secretase yields soluble APP fragments (sAPPα and sAPPβ), then processed for Aβ peptides of 38-43 residues. We investigated subcellular lipid rafts, which are the main site of pro-amyloidogenic processing of APP by BACE 1 and γ-secretase catalytic subunit PS1 with J20 mice and N2a cells transgenic for hAPP/Swe (familial AD). Exposure of J20 mice for 150 hours to nPM increased lipid oxidation (4-HNE) and increased proamyloidogenic processing of APP on lipid raft subcellular fractions. The lipid raft responses to nPM were regionally selective, arising in cerebral cortex, but not in cerebellum, which parallels the regionality of Aβ deposits in transgenic mice and humans. *In vitro,* N2a-APP/Swe cells modeled brain responses to nPM, with dose-dependent production of NO, oxidative damage (4-HNE, 3-NT), and lipid raft alterations of APP that increased Aβ peptides. The anti-oxidant n-acetyl-cysteine (NAC) attenuated oxidative

damage and lipid raft alterations of APP processing. These novel findings identify neuronal lipid rafts as targets of oxidative damage in the proamylodogenic effects of air pollution.

Title: Glutamatergic mechanisms in depressive responses to prenatal exposure to traffic-related air pollution

Authors: *R. G. JOHNSON, III[1], A. HAGHANI[1], V. COUSSA[1], F. SHIRMOHAMMADI[2], C. SIOUTAS[2], C. E. FINCH[1], T. E. MORGAN[1]

Abstract: Prenatal exposure to nano-sized particulate matter (nPM), a subset of traffic-related air pollution particulate matter$_{0.2}$ (TRAP-PM$_{0.2}$), causes depressive-like symptoms in rodents (Davis et al 2013; Woodward et al 2017). Based on the collection methods, the nPM used in those studies were devoid of water-insoluble organic materials, such as polyaromatic hydrocarbons, which are known to cause deleterious neurodevelopmental and behavioral effects in children. Here, we used a novel method of collecting TRAP-PM$_{0.2}$ in a slurry (sPM) which retains the water-insoluble organics for mouse exposure. Pregnant mice were exposed to sPM at 340 ug/m^3 or filtered air for five hours a day for three days a week from conception to birth. At sixteen weeks of age mice underwent the forced swim behavioral test to screen for depressive-like symptoms. Male mice exposed to sPM showed a 22% increase in total time immobile and a 16% decrease in latency to first time immobile, compared to filtered air exposed males. Supporting the nPM study (Davis et al 2013), exposed female mice did not show depressive-like symptoms. The forced swim test was repeated 8 days later, after the mice were injected (i.p.) with the NMDA antagonist, MK-801, 0.06mg/kg, or saline. MK-801 reduced the total time immobile of sPM exposed mice back to control levels. We are further exploring the role of glutamatergic pathways by measuring glutamatergic receptor mRNA and protein levels. These results suggest that the glutamatergic pathway may play a critical role in the mechanism by which prenatal exposure to TRAP-PM$_{0.2}$ causes neurodevelopmental and behavioral effects.

Title: Exploring the hormetic effect of dietary polyphenols in fruit flies - The dose makes the poison

Authors: *L. S. VILLALPANDO, J. M. NAPAN, A. M. BRISENO, C. B. BARCENAS, W. L. HARDEMAN, B. TOLAN, A. D. TROFIMOVA, D. PATEL, R. E. HARTMAN
Sch. of Behavioral Hlth., Loma Linda Univ., Loma Linda, CA

Abstract: Polyphenols are phytochemicals produced by plants that protect them from environmental insults such as insects and ultraviolet irradiation, and consuming them can induce beneficial effects by altering various inflammatory pathways and redox mechanisms. Previous research from our laboratory has shown that dietary supplementation with low doses of pomegranate polyphenols can have beneficial effects in Drosophila melanogaster fruit flies (reduced seizure-like activity), mice (radioprotection, cognition and motor improvements, reduced Alzheimer's-like neuropathology, increased neurogenesis), and humans (amelioration of cardiovascular / stroke-related deficits). However, evidence suggests that these same compounds may become toxic at higher doses. The term hormesis refers to a biphasic dose response curve, in which low doses of a substance may have beneficial effects, but higher doses of the same substance become toxic and induce detrimental effects.
The aim of this study was to characterize the dose response curve of dietary polyphenols in Drosophila melanogaster fruit flies with regard to longevity and behavioral functions, and to determine the range at which the dose changes from protective to adverse. We hypothesized that longevity and behavioral performance would be improved by exposure to low levels of dietary polyphenols, but that increasingly larger doses would ultimately become detrimental. Therefore, Drosophila melanogaster were exposed to varying levels of polyphenols in their diet media following eclosion. The flies were put through a behavioral test battery that assessed learning/memory and locomotor activity, and lifespan was recorded. Preliminary data suggest that high levels of dietary polyphenols reduced longevity and may have had detrimental effects on behavior. Identifying the point at which the anti-inflammatory pathways and redox mechanisms affected by dietary polyphenols become harmful, rather than helpful, will illuminate targets that can be specifically manipulated pharmacologically or via lifestyle changes to improve longevity and maintain high function throughout life.

Title: Dopaminergic dysfunction in Sprague-Dawley rats as a potential mechanism for deficits in egocentric and allocentric learning and memory following developmental manganese overexposure

Authors: *R. A. BAILEY[1,2,3], A. GUTIERREZ[1,2,3], J. R. HUFGARD[1,2], C. V. VORHEES[1,2,3], M. T. WILLIAMS[1,2,3]

Abstract: Manganese (Mn) is a crucial cofactor in many functions, such as growth, metabolism, antioxidation, and nervous system function, however, Mn overexposure (MnOE) causes cognitive deficits as well as motor dysfunction in severe cases. Mn deposits in the globus pallidus, leading to dysfunction in the nigrostriatal pathway. The mechanisms of this toxicity are poorly understood especially in developmental exposure models. Sprague Dawley rats were gavaged with Mn or saline every other day from postnatal day (P)4 to P28, and cognitive function was assessed beginning in adulthood (P60). In another cohort of rats, dopaminergic function was assessed on P29, P60, or P111. We found that MnOE impaired egocentric and allocentric learning and memory, indicating striatal and hippocampal deficits respectively. No effects were found for conditioned freezing in MnOE rats. Control procedures to ensure motor deficits were not a factor in the cognitive deficits demonstrated that the MnOE rats only had a transient decrease in motor function that resolved over time. Dopamine and its metabolites in the neostriatum were not affected by MnOE. However, the expression of dopamine receptors, Drd1, Drd2, and σR1, changed in neostriatum from MnOE. MnOE increased Drd1 and Drd2 expression and decreased σR1 at P29. In adult rats, both Drd2 and σR1 were decreased after MnOE with no long-term effect on Drd1. How these changes relate to the egocentric deficits remains to be determined. To test whether MnOE alters dopamine release, fast scan cyclic voltammetry (FSCV) will be used. We hypothesize that MnOE reduces phasic dopamine release without affecting tonic release. (Supported by NIH T32 ES007051.)

Abstract: Several studies in rodents, have shown that exposure to the widely used herbicide atrazine (ATR; 2-chloro-4-ethylamino-6-isopropylamino-s-triazine) causes deficits in the nigrostriatal pathway such as alterations in locomotor activity, decreased striatal dopamine levels, and diminished counts of tyrosine hydroxylase positive cells in substantia nigra pars compacta. However, the effects of ATR on other neurotransmitters such as GABA and glutamate have been scarcely studied. To test if ATR also affects other neurotransmitter systems in this study we evaluated the effects of chronic exposure (one year) to 1 or 10 mg ATR/kg of body weight, on behavior and striatal levels of GABA, glutamine and glutamate and the striatal release of glutamate. Behavioral results showed that chronic ATR exposure to 10 mg ATR/kg causes hyperactivity, and increased anxiety in both groups exposed to ATR. The striatal levels of glutamine were increased in the group exposed to 10 mg ATR/kg, and the levels of striatal glutamate were decreased in the group exposed to 1 mg ATR/kg. Striatal extracellular basal levels of glutamate were increased in the group exposed to 10 mg ATR/kg, in contrast to the control group, none of the ATR exposed groups responded to the high potassium challenge. These data show that chronic ATR exposure causes alterations not only on dopaminergic markers but also on glutamine and glutamate levels and glutamate release in striatum, which in combination could generate the behavioral changes observed.

Title: Characterization of the functional recovery of diaphragmatic muscle fiber populations in a novel sublethal model of botulism

Authors: *J. MACHAMER, E. VAZQUEZ-CINTRON, M. STENSLIK, C. ONDECK, K. PAGARIGAN, A. BRADFORD, P. MCNUTT
US Army Med. Res. Inst. of Chem. Def., Baltimore, MD

Abstract: Botulinum neurotoxins (BoNTs) cleave SNARE molecules required for exocytosis of synaptic vesicles containing acetylcholine, thereby silencing motor neurons and paralyzing muscles. Severe intoxication results in death by asphyxiation due to the paralysis of the diaphragm and accessory respiratory muscles. As no treatments exist to prevent respiratory collapse or accelerate recovery of muscle paralysis, survival in severe cases depends on the use of artificial ventilation until respiratory muscles recover. Therefore, new treatments need to be discovered that promote the recovery of respiratory muscles. Although many studies have modeled recovery from botulism in locally paralyzed limb muscles, these muscle are structurally and functionally distinct from respiratory muscles, and local delivery of BoNT does not model clinical cases of botulism. Therefore, developing a systemic sublethal model of botulism that targets respiratory muscles would facilitate 1) investigation of the cellular and molecular mechanisms underlying the recovery of diaphragmatic function and 2) testing of potential therapies to promote recovery of respiratory muscle function. Here we describe a novel sublethal model of botulism resulting in ~75% of exposed animals developing symptomatic botulism that peaks at 3 d post-exposure. In surviving animals (~60%), clinical manifestations subside between 7-14 d post-exposure. In contrast, by measuring voluntary running wheel activity in recovering mice, we find that motor activity recovers between 14-21 d. Consistent with running behavior, ex vivo diaphragm contraction strength measurements indicate that aggregate diaphragm function remains impaired at 14 d and does not recover until 21 d post-exposure. To further understand how the diaphragm recovers from systemic intoxication, we used intracellular electrophysiology to measure synaptic transmission at diaphragm endplates. By sampling a large number of diaphragmatic muscle fibers, we found that severity of intoxication and recovery from intoxication were endplate-specific. Additionally in recovering diaphragms we identified

multiple secondary changes in neuromuscular physiology that both act to both promote and inhibit muscle contraction. Moving forward, this model will be useful for both characterizing the molecular mechanisms of endogenous compensatory and inhibitory changes in neuromuscular function that could serve as potential physiological targets for therapeutic intervention as well as testing novel treatments to enhance respiratory recovery relevant to clinical botulism.

Title: High-content imaging of iPSC-derived human neurons for toxicity screening

Authors: *M. L. HENDRICKSON[1], L. ZHANG[2], M. XIA[2], Z.-W. DU[1]
[1]BrainXell, Inc., Madison, WI; [2]NCATS, Rockville, MD

Abstract: There is a significant need for in vitro systems that more closely model the human nervous system and its response to environmental toxins. Such a platform would have greater predictive power to indicate which compounds pose a risk. Toward this goal, we have developed a platform centered on the use of iPSC-derived human neurons. First, iPSCs were gene-edited to ubiquitously express eGFP. We then patterned these iPSCs to a neuroepithelial fate and next to neuronal progenitors before finally differentiating them into neurons. Spinal motor neurons were generated in this manner and used for this proof-of-concept project. They were plated in 384-well format for high-content imaging. Optimizing imaging in this manner required attention to the source of cells, plate surface coating, medium composition, staining protocol, imaging parameters, and the timeline for neuron maturation and neurite outgrowth. Optimization of all parameters yielded a sensitive and robust system with a Z-prime value greater than 0.5.

Title: Inorganic scintillators are biocompatible with neuronal and circuit function

Authors: *A. F. BARTLEY[1], K. ABIRAMAN[2], L. T. STEWART[2], M. K. BURDETTE[3], S. H. FOULGER[3], L. E. DOBRUNZ[1], L. L. MCMAHON[2]
[1]Neurobio., [2]Cell, Developmental, and Integrative Biol., Univ. of Alabama at Birmingham, Birmingham, AL; [3]Materials Sci. and Engin., Clemson Univ., Anderson, SC

Abstract: In recent years, optogenetics has become a widely used technique for neuroscience research. However, the use of optogenetics in vivo is limited by the invasive nature of current methods to deliver light, which cause damage to delicate brain tissue. The creation of noninvasive optogenetic methods could transform the field of optogenetics, and multiple labs are in the process of developing novel noninvasive strategies for light delivery. One potential method could employ x-ray activation of radioluminescent particles (RLPs), enabling localized generation of light within the brain. RLPs can be made from inorganic scintillators, which emit light of different wavelengths depending upon their composition. Whether inorganic scintillators themselves impact neuronal processes and circuit function is unknown. Lutetium oxyorthosilicate (LSO:Ce), an inorganic scintillator that emits blue light in response to x-ray or UV stimulation, could potentially be used to activate channelrhodopsin-2 (ChR2). Here we used electrophysiology to investigate effects of LSO:Ce particles on neuronal health and circuit function in acute hippocampal slices. We find that LSO:Ce particles have no effect on cell health measurements, including resting membrane potential and input resistance. Basal synaptic excitatory field potentials are also unaltered, even with incubation times up to 3 hours. However, there is a trend for a decrease in the frequency of spontaneous EPSCs and IPSCs measured in CA1 pyramidal cells. Next, we tested for effects of LSO:Ce particles on long term potentiation, a more robust measurement of synaptic health and integrity, and found no effect. Together, these results indicate that neuronal function and synaptic plasticity are intact during exposure to LSO:Ce particles, demonstrating their biocompatibility. As proof of principle that light emitted from LSO:Ce particles can activate ChR2, we applied UV stimulation (315 nm) to LSO:Ce particles on slices from mice that expressed ChR2 in excitatory neurons (Emx-cre:ChR2 mice). This caused an increase in the frequency of spontaneous EPSCs. Therefore, the LSO:Ce inorganic scintillator is potentially a viable tool for use in noninvasive optogenetic methods.

Title: Activation of glutamatergic receptors promotes endoplasmic reticulum calcium depletion in primary cortical neurons

Authors: *A. M. DOSSAT[1], L. V. FORTUNO[2], B. K. HARVEY[2]
[2]Mol. Mechanisms of Cell. Stress and Inflammation Unit, [1]Natl. Inst. On Drug Abuse, Baltimore, MD

Abstract: Glutamate is the most ubiquitously expressed excitatory neurotransmitter within the central nervous system. Glutamate acts upon many postsynaptic receptor subtypes to promote neuronal depolarization and cellular plasticity. Excitotoxicity results from elevated synaptic glutamate and hypersynchronous neuronal firing and has been documented in conditions like epilepsy. The contribution of extracellular calcium (Ca^{2+}) to the expression of seizure-like neuronal activity and excitotoxicity are well established. However, the role of endoplasmic reticulum (ER)-sourced Ca^{2+} in the pathophysiology of epilepsy remains to be elucidated. The ER maintains Ca^{2+} levels like that of the extracellular space, which is roughly 1000 times higher than what is found in the cytosol. This makes the ER a likely contributor to the pathophysiology of epilepsy.
Using a previously described secreted Gaussia luciferase reporter of ER calcium (GLuc-SERCaMP), and we compared the effects of a known ER calcium dysregulator, Thapsigargin (100 nM, Tg), to glutamate (100 µM) and kainic acid (100 µM). GLuc-SERCaMP activity was induced by AAV vector transduction using mixed-sex primary cortical neurons. Treatment with Tg, glutamate, and kainic acid induced GLuc-SERCaMP secretion, indicative of ER calcium depletion. Pre-treatment with antagonists for IP3 receptors (IP3R) and ryanodine receptors (RyR) significantly blunted the GLuc-SERCaMP secretion induced by Tg, glutamate, and kainic acid. Taken together, our findings indicate that in addition to promoting influx of Ca^{2+} from the extracellular space, glutamate and kainic acid also promote efflux of Ca^{2+} from the ER. Ongoing studies with the GLuc-SERCaMP reporter also support a change in the ER proteome in response to glutamate and kainic acid. The depleted ER calcium stores may contribute to the excitotoxicity observed in epilepsy and other conditions characterized by excessive neuronal

activity. Future studies will investigate the role of other ER calcium stabilizers to mitigate ER calcium dysregulation in conditions of excitotoxicity using *in vivo* models.

Title: Activation of proline synthesis pathway protects neurons from methamphetamine-induced toxicity

Authors: *B. JONES, JR[1], M. BALASUBRAMANIAM[2], C. DASH[2], J. PANDHARE[3]
[1]Microbiology/Immunology, [3]Sch. of Grad. Studies and Research, Ctr. for AIDS Hlth. Disparities Rese, [2]Meharry Med. Col., Nashville, TN

Abstract: Methamphetamine (METH) is a highly addictive psychostimulant drug. METH induced neurotoxicity is known to cause long-lasting effects especially on the dopaminergic neurons in the CNS. Therefore, METH abuse has been linked to increased risk of developing several neurodegenerative diseases, such as Parkinson's disease, HIV-Associated Neurocognitive Disorder (HAND) and others. It has been suggested that METH increases extracellular concentrations of both dopamine (DA) and glutamate (GLU) in the striatum. Release of these neurotransmitters with repeated METH administration has been suggested to elicit oxidative stress and excitotoxicity to DA nerve terminals. Despite the well documented effects of METH on glutamate neurotoxicity, the molecular mechanisms remain poorly understood. In this study, we demonstrate an essential role of pyrroline-5-carboxylate reductase 2 (PYCR2), the enzyme that catalyzes the final step of proline biosynthesis in METH-induced glutamate neurotoxicity. We hypothesize that sequestration of excess glutamate for proline synthesis protects DA neurons from glutamate-induced neurotoxicity. To test this hypothesis, we used "SH-SY5Y" neuroblastoma cell line as a model to mimic DA neuronal phenotype. Acute METH exposure for 24 h did not induce cytotoxicity or increase levels of ROS, however, a marked induction in expression of PYCR2 was observed. To elucidate the role of the PYCR2 in METH-induced effects we knocked down PYCR2 in neurons. Interestingly, knockdown of PYCR2 increased

extracellular glutamate levels upon METH treatment suggesting that in the absence of PYCR2 excess glutamate cannot be converted into proline allowing its accumulation and release. Therefore, we believe that the induction of PYCR2 may be necessary for protecting neurons from METH-induced glutamate toxicity. These studies will help unravel a novel role of proline metabolism as stress response pathway in coping neurotoxicity.

Title: A perfused three-dimensional culture model of human cortical tissue

Authors: *J. VUKASINOVIC[1], J. T. SHOEMAKER[1], M. C. LAPLACA[2]
[1]Lena Biosciences, Inc., Atlanta, GA; [2]Georgia Inst. of Technol., Atlanta, GA

Abstract: Human neural tissue can be exceedingly difficult to model in vitro. Issues of cellular survival and maintaining in vivo-like function pervade, often affecting study validity and translatability. Planar cultures have long been the standard method of growing cells in vitro, but they fail to capture the complexities of the in vivo environment. This is particularly applicable to the delicate balance of microglia-mediated inflammatory responses. Three-dimensional (3D) cultures have been shown to be more physiologically relevant models of in vivo tissue. However, even they fail to fully mimic living tissue and suffer from the lack of active oxygen and nutrient transport. Lena Biosciences has developed a groundbreaking in vitro system that facilitates long-term survival of 3D cultures and significantly improves cellular metabolic function. PerfusionPal offers a simple method for simultaneously perfusing twelve statistically independent 3D cultures using only a single tube and pump. Utilizing a unique blood substitute, cultures grown in SeedEZ 3D scaffolds receive superior oxygenation, resulting in significant functional improvements and allowing for growth of denser cultures with increased longevity. Using this system, Lena Biosciences has developed a human cortical model comprising iPSC-derived neurons (acquired from BrainXell), primary astrocytes, and cells from the HMC3 microglia cell line. Both

glutamatergic and GABAergic neurons were combined to generate a more accurate model. Exploratory studies assessing cell viability and function were carried out in PerfusionPal with and without active perfusion. These data were compared with 3D cultures grown in multi-well plates. The results showed that growth in PerfusionPal improved cellular viability after two weeks in culture as determined by live/dead assay and improved cellular respiration as measured by alamarBlue. The model is uniquely positioned to serve as a test-bed for inflammation-induced neurotoxicity. Preliminary studies in which the cultures were treated with pro-inflammatory reagents have confirmed they are inducible into a state of neuroinflammation. PerfusionPal will allow for study of the complex interplay between pro- and anti-inflammatory responses to insult and the long-term effects of activating these pathways.

Title: Long-term outcome of low-level light therapy in focal ischemic mouse model

Authors: *H. LEE[1,2], Y.-I. SHIN[1,2]
[1]Res. Inst. for Convergence of Biomed. Sci. and Technol., Pusan Natl. Univ. Yangsan Hosp., Yangsan, Korea, Republic of; [2]Dept. of Rehabil. Med., Pusan Natl. Univ., Yangsan, Korea, Republic of

Abstract: Low-level light therapy has a promising modality for a variety of wound healing, physical medicine and rehabilitation medicine. LLLT facilitates wound healing by proliferative effects on dividing cells, exerts potent inflammatory effects, products growth factor. However, its long-term
effect on functional recovery are unknown. In this study, we aimed to investigate the effects of long-term outcomes after cerebral ischemia, and the timing of initiation of LLLT affects functional recovery. We used focal cerebral ischemia following photothrombosis and LLLT treated to mice at different time point. Immediately after the infarct, the animals administrated Bromodeoxyuridine for 5 sequential days post-infarct. Proliferation of astrocyte, migroglia, immature and mature neuron, endothelial cells were examined at behaviroal, structural levels. Aucte, subacute LLLT-treated group significantly improved motor function, not brain atrophy at

28 days. Furthermore, the LLLT increased the survival proliferating GFAP, DCX, NeuN, CD31-positive cells, especially subacute LLLT-treated group, whereas decreased proliferating microglia. Furthermore, BDNF was significantly upregulated in Subacute LLLT. Our results suggest that Subacute LLLT may have long-term protective effect through proliferation of cell survival, concentrations at 28 days resulting in increased gliogenesis, neurogenesis, angiogenesis through releasing of promoting mBNDF.
These findings have important implications for timing of initiation of LLLT of focal cerebral ischemia, that appropriate subacute phase associated with neurovascular network and remodeling.

Title: Time-course of the development of inflammation in a model of transient cerebral ischemia in the rat

Authors: *E. ESNEAULT[1,2], G. PEYON[1], F. SIMON[2], P. KITCHENER[2]
[1]Porsolt, Le Genest St Isle, France; [2]Fluofarma, Pessac, France

Abstract: Inflammation plays an important role in the pathogenesis of ischemic stroke and is characterized by a rapid activation of resident cells (mainly astrocytes and microglia) followed by the infiltration of circulating inflammatory cells. Microglia activation involves caspase 1 activation through the NLRP3 inflammasome which controls the release of proinflammatory cytokines such as Il1beta. The aim of the present study was to determine the kinetics of inflammatory responses in a model of transient cerebral ischemia in the rat. In parallel, sensory-motor deficits were evaluated to identify the potential therapeutic window for targeting inflammatory pathways.
Cerebral ischemia was induced by an embolus placed at the origin of the middle cerebral artery (MCA). The filament was maintained during 90 minutes and was then removed to allow reperfusion. Rats were sacrificed at different time-points after cerebral ischemia, (24 hours, 72 hours and 7 days) and brain sections were stained with markers assessing neurons (NeuN), astrocytes (GFAP) and microglia (Iba1). NLRP3 and caspase-1 were also evaluated as actors of the inflammatory response. In parallel, the ischemic rats were evaluated with a battery of functional tests, and compared with sham-operated rats.
Neuronal/glial death, mainly localized in the cortex and in the striatum, increased over 72 hours following cerebral ischemia after which there was no further progression of the ischemic insult.

Recruitment of reactive astrocytes increased until Day 7 at the border of the infarct region. The number of active microglial cells started to increase from 72 hours after MCAo into the infarct region with a maximum at Day 7. In parallel, caspase 1 positive cells and caspase 1 expression increased in the infarct region from 24 hours to 7 days with a maximum observed at 7 days. Sensory-motor deficits appear from 24 hours in the neurological score and were confirmed at 72 hours in the adhesive removal test and the foot-fault test. A partial and spontaneous recovery was observed in the ischemic rats from Day 7.
These results show that the inflammatory response is progressively established over several days following transient MCA occlusion in the rat, as a reaction to the massive initial neuronal cell death, and is still highly present while rats are showing signs of functional recovery. Modulation of inflammation at an early stage may be of interest to improve sensory-motor impairment. A comprehensive understanding of the time-dependent recruitment of inflammatory cells is a prerequisite for developing new therapeutic strategies targeting inflammatory pathways for the treatment of acute ischemic stroke.

Title: Coumestrol administration attenuates cognitive deficits and reactive astroglyosis caused by neonatal hypoxia-ischemia in Wistar rats

Authors: *J. B. ANASTÁCIO, E. F. SANCHES, F. NICOLA, R. FABRES, C. A. NETTO
Univ. Federal do Rio Grande do Sul, Porto Alegre, Brazil

Abstract: Introduction: Neonatal Hypoxia-ischemia (HI) is one of the major causes of morbidity and death in neonates. HI is the result of impaired blood flow and oxygen delivery to the brain, and no effective therapies have been developed so far. Following HI injury, a robust glial response starts in the brain involving astrocytes and microglia that are important for a variety of physiological and pathological processes in the developing brain. Phytoestrogens are nonsteroidal plant substances that are structurally and functionally similar to estrogen. Here, we tested the effects of the phytoestrogen coumestrol, a potent isoflavonoid, for treating HI rats. Methods: At 7th postnatal day (PND), Wistar rats were submitted to the Levine-Rice model of

neonatal HI (permanent occlusion of the right common carotid artery with subsequent exposure to hypoxia - 8% O_2 and 92% N_2 for 60 min). Animals were randomly allocated into four groups: sham, HI+vehicle, HI+coumestrol pre-hypoxia and HI+coumestrol post hypoxia. Intraperitoneal injections of coumestrol (Sigma), in a dose of 20mg/kg, were administered immediately pre-hypoxia or 3 hours post-hypoxia. Sham animals were injected with vehicle (DMSO). Results: The Morris water maze task showed cognitive deficits induced by HI at PND60, both in reference and working spatial memory. Following behavioral analysis, histological assessment showed HI tissue loss of ipsilesional hemisphere and hippocampus, this effect was counteracted by coumestrol treatment. Moreover, reactive astroglyosis, a determining factor for severity of HI injury, was decreased in the CA1 region in coumestrol treated rats. This indicates that HI caused an increase in GFAP expression that was prevented by coumestrol administration. A negative correlation was found between performance in the last day of training in the reference memory protocol and GFAP expression, in which animals with better performance showed smaller astrocyte reactivity. Conclusions: It is shown that coumestrol is able to prevent behavioral and histological deleterious effects caused by HI, suggesting its possible use as a therapeutic strategy for neonatal hypoxia-ischemia in humans.

Title: Transcortical photothrombotic pyramidotomy model with persistent motor deficits

Authors: J.-Y. PARK[1], H. SONG[1], B.-M. CHOI[2], M.-S. KIM[3], W.-G. KIM[4], M.-C. LEE[5], *H.-I. KIM[1]
[1]GIST, Gwangju, Korea, Republic of; [2]Dept. of Anesthesiol. and Pain Med., Asan Med. Ctr., Seoul, Korea, Republic of; [3]Wonkwang Univ. Sch. of Med., Iksan, Korea, Republic of; [4]Nambu Univ., Gwangju, Korea, Republic of; [5]Chonnam Natl. Univ. Med. Sch., Gwangju, Korea, Republic of

Abstract: Introduction:Traditional pyramidotomy models have a high mortality rate from breathing difficulties and show early recovery from the induced motor deficits. This study

establishes a novel pyramidotomy technique that generates persistent motor deficits and has a reduced mortality rate. Material & method: We used viral neural tracing to identify the course and relative distribution of forelimb and hindlimb motor fibers (n = 9). On basis of the neural tracing data, the medullary pyramid was targeted dorsally from the cerebellar cortex for photothrombotic infarct lesioning (n = 20). Our target specifically included the medial portion of the medullary pyramid. Results: Neural tracing demonstrated that forelimb motor fibers(FMFs) and hindlimb motor fibers (HMFs) are intermingled and it is difficult to distinguish the relative location of the FMFs and HMFs. However, the density of FMFs is higher than that of HMFs in the medial portion of the pyramid, indicating that it is essential to destroy the medial portion of the pyramid during pyramidotomy. The photothrombotic technique selectively destroyed the corticospinal fibers in the medullary pyramid with relative preservation of neighboring grey-matter tissue because of the different degree of light scattering in the white and grey matter. There was a significant and persistent decrease in motor and sensory function in the contralateral limb following pyramidotomy, as demonstrated by performance in the single pellet reaching task, the foot-fault test, and the adhesive-removal test. There was no operative mortality or loss of respiratory function in this study. Conclusion: These results indicate that photothrombotic pyramidotomy with a dorsal transcortical approach is a safe technique for generating a reliable pyramidotomy model with persistent motor deficits.

Title: Evaluating estetrol as a neuroprotectant in cerebral ischemia

Authors: *S. MUKHERJEE, G. KUMAR, B. VERMANI, R. P. PATNAIK, 221005
Indian Inst. of Technol. (BHU) Varanasi, Varanasi, India

Abstract: RIPK1 is the molecular mediator of non-apoptotic DR-mediated cell death pathway, which has been termed as necroptosis, a pathway intrinsically involved in ischemic cell death. Several studies have suggested that RIPK1 inhibition ameliorates cerebral ischemic conditions *in-vivo*. Though Necrostatins has been designed as chemical inhibitors of RIPK1, their low pharmacokinetics property and lower metabolic stability causes the need of designing new RIPK1 inhibitors an absolute necessity. Neuroprotective ability of Estrogen molecules is long reported and Estetrol, which was thought to be the weakest among the Estrogen hormones, has been recently reported to successfully combat neonatal ischemic hypoxia. *In-silico* screening of

Estrogen molecules reveal that Estradiol and Estetrol bind to RIPK1 with affinity higher than Necrostatin-1 and Necrostatin-4. Also, analysis of hydrophobic interactions and hydrogen bonds between the enzyme and inhibitors represent Estetrol as possible strong inhibitor of RIPK-1. The *in-silico* study is supported by in-vivo experiments, where Estetrol shows neuroprotection in rat model, by ameliorating cerebral ischemia in rat models. The neuroprotective ability of Estetrol was evaluated by analyzing infarct volume of brain, blood-brain barrier permeability of Evan's Blue and Cerebral Blood Flow (CBF) measurement. The study suggests that neuroprotective ability of Estetrol might be further exploited and the molecule can be designed into neurotherapeutics.

Title: Intracerebral delivery of brain-derived neurotrophic factor using HyStem®-C hydrogel implants improves functional recovery and reduces neuroinflammation in a rat model of ischemic stroke

Authors: *D. BRIGGS[1], K. RAVINA[1], S. KISLAL[1], Z. WARRAICH[1], T. NGUYEN[1], R. LAM[1], T. ZAREMBINSKI[2], M. SHAMLOO[1]

Abstract: Ischemic stroke is a leading cause of death and disability worldwide. Potential therapeutics aimed at neural repair and functional recovery are limited in their ability to permeate the blood-brain barrier and may exert systemic or off-target effects. We examined the effects of brain-derived neurotrophic factor (BDNF), delivered via an extended release HyStem®-C hydrogel implant or vehicle, on sensorimotor function, infarct volume, and neuroinflammation, following permanent distal middle cerebral artery occlusion (dMCAo) in rats. Sprague Dawley rats aged 64-69 days received dMCAo lasting 60 min or sham surgery. Eight days later, treatments were implanted directly into the infarction site. Rats received either vehicle, BDNF-only (0.167 µg/µL), hydrogel-only, hydrogel impregnated with 0.057 µg/µL of BDNF (hydrogel+$BDNF_{LOW}$), or hydrogel impregnated with 0.167 µg/µL of BDNF (hydrogel+$BDNF_{HIGH}$). The 28-point Neuroscore (28-PN) and adhesive removal tests (ART) were used to evaluate sensorimotor function up to two months post-stroke. The hydrogel+$BDNF_{HIGH}$ group showed significant improvements on the ART 6-8 weeks following

treatment and their behavioral performance was consistently greater on the 28-PN. Infarct volume was reduced in rats treated with hydrogel+$BDNF_{HIGH}$ as were levels of Iba1, CD68, and GFAP in the corpus striatum. These data suggest that targeted intracerebral delivery of BDNF using hydrogels may mitigate ischemic brain injury and restore functional deficits by reducing neuroinflammation.

Title: Metformin improves neurological outcome via AMPK mediated autophagy activation in a rat model of cardiac arrest and resuscitation

Authors: *S. PAN[1], J. ZHU[2], Y. HU[2], K. HUANG[2], Z. JI[2], Y. GU[2], K. LIU[2]
[1]Dept. of Neurology, Nanfang Hospital, Souther, Guangdong, China; [2]Nanfang Hospital, Southern Med. Univ., Guangzhou, China

Abstract: Background: Sudden cardiac arrest (CA) often results in severe injury to the brain, and neuroprotection after CA has proven to be difficult to achieve. Here, we sought to investigate the effects of metformin pretreatment on brain injury secondary to CA and cardiopulmonary resuscitation (CPR).
Methods and Results: Rats were subjected to 9-minute asphyxia CA after receiving daily metformin treatment for 2 weeks. Survival rate, neurologic deficit scores, neuronal loss, AMPK and autophagy activation were assessed at indicated time points with the first 7 days after return of spontaneous circulation. Our results showed that metformin pretreatment elevated the 7-day survival rate from 55% to 85% and significantly reduced neurologic deficit scores. Moreover, metformin ameliorated CA-induced neuronal degeneration and glial activation in the hippocampal CA1 region, which was accompanied by augmented AMPK phosphorylation and autophagy activation in affected neuronal tissue. Of note, inhibition of AMPK or autophagy with pharmacological inhibitors abolished metformin-afforded neuroprotection, and augmented autophagy induction by metformin treatment appeared to downstream of AMPK activation.
Conclusions: Taken together, our data demonstrate for the first time that metformin confers

neuroprotection against ischemic brain injury after CA/CPR by augmenting AMPK-dependent autophagy activation.

Title: Quantitative susceptibility mapping (GSM) MRI in a collagenase rat model of intracerebral hemorrhage (ICH)

Authors: *K. LEHTIMÄKI, A. SHATILLO, E. LATONUMMI, A. J. NURMI
Charles River Discovery, Kuopio, Finland

Abstract: Intracerebral hemorrhage (ICH) is a significant cause of mortality throughout the world. Management of ICH in terms of clot lysis and iron scavenging after the initial insult is critical for the recovery and appropriate imaging methods to detect and follow the process are needed (Morgenstern et al., Stroke 2010). The objective of this study was to validate quantitative susceptibility mapping (QSM) methodology in a collagenase-induced ICH model in Wistar rats. Working hypothesis was that QSM could show window to observe the susceptibility changes both in the edematous processes and iron environment.
Male Wistar rats weighing 230-300 g were used for the experiment. Intracerebral hemorrhage was induced by intra-striatal infusion of collagenase IV (MacLellan et al., J Cereb Blood Flow Metab. 2008). In vivo T2 and diffusion mapping MRI were performed at sub-acute 6 hours, 1, 3 and 14 day time-points to characterize the lesion development. Subgroups of rats were perfused and fixed brains were subjected to QSM MRI at 1 and 3 days post-ICH.
In vivo T2 mapping showed large hypointense lesions corresponding to actual acute hemorrhage at 6 hours which developed progressively hyperintense lesions at later time points (1, 3 and 14 days). Diffusion values showed clear increase (while T2 remaining roughly at the same level) from day 1 to day 3, most likely reflecting reduced cytotoxic contribution in the lesion development. QSM revealed large collagenase-induced ICH lesions with low susceptibility core and high susceptibility outer rim (high iron contribution) surrounded again by low susceptibility region outside the actual lesion. This “rim-around-rim” is assumed to reflect ongoing cytotoxic edema process whereas the low susceptibility in the core of the lesion relates to vasogenic edema and cell death. Total lesion QSM results by histogram comparison show clear modulation of spread of susceptibility values from day 1 to day 3; namely, day 1 distribution contain significantly higher proportion of both oedema processes and iron content than day 3. Based on

these data, QSM method seems particularly suitable for the in vivo application in a rat model of ICH due to proper lesion size and the clear presence of iron. This combination of methodology and animal model may provide the window to study novel treatments of ICH.

Title: Functional imaging of thromboembolic stroke in rats using PET, ultrasound and MRI

Authors: *E. LATONUMMI[1], J. RYTKÖNEN[1], A. SHATILLO[1], K. LEHTIMÄKI[1], P. POUTIAINEN[2], T. HUHTALA[1], D. MISZCZUK[1], A. J. NURMI[1]
[1]Charles River Discovery, Kuopio, Finland; [2]Kuopio Univ. Hosp., Kuopio, Finland

Abstract: Embolic stroke is a significant cause of mortality and neurological deficits e.g. paralysis, throughout the world. It is a devastating complication resulting from blood clots forming elsewhere in the body and traveling through the blood stream to the brain where it enters a blood vessel that is too small to allow it to pass and blocks the flow of blood to the brain area. It is associated with multiple risk factors including atrial fibrillation, atherosclerosis and hypertension. Fast diagnosis and early start of thrombolytic treatment is critical for limiting the ischemic damage and for the patient's well-being. The objective of this study was to visualize clot dissolving treatment during hypoxia PET scanning in a thromboembolic stroke (TBE) model in SHR rats. Further, the efficacy of treatment was assessed with ultrasound imaging (US) and magnetic resonance imaging (MRI).
Male SHR rats weighing 230-300 g were used for the experiment. TBE was induced injection of autologous blood clots in suspension into the internal carotid artery. Dynamic PET scan was performed 60-180 minutes after the stroke with hypoxia radiotracer ^{18}F-FMISO. Treatment with vehicle or tissue plasminogen activator (tPA, Alteplase) was performed during the PET scanning, 120-180 minutes after the stroke. On the following day animals were scanned with fUS and MRI for vascular map and lesion volume, respectively.
^{18}F-FMISO localization to hypoxic areas could be visualized from the PET images. Thrombolytic treatment with tPA was shown to correlate with reduced lesion size in individual animals. This combination of functional imaging and animal model may provide the tools to study novel treatments of ischemic stroke.

Title: Longitudinal population characteristics of volume-behaviour measures in a non-human primate model of stroke

Authors: *K. A. HARRISON[1], G. RAMÍREZ-GARCÍA[4], J. FERNANDEZ-RUIZ[5], J. Y. NASHED[2], J. LECLERC[3], D. J. COOK[2]
[1]Ctr. for Neurosci. Studies, [2]Neurosci., [3]Queen's Univ., Kingston, ON, Canada; [4]Inst. Nacional de Neurología y Neurocirugía, [5]Dept. de Fisiología, Univ. Nacional Autónoma de México, Ciudad de México, Mexico

Abstract: Stroke is the second leading cause of death worldwide. Brain imaging data from rodent stroke models suggest size and location of ischemic lesions relate to behavioural outcome. However, such a relationship is not well established in Non-Human Primate (NHP) models. Thus, we evaluated size, location, and severity of stroke following controlled Middle Cerebral Artery Occlusion (MCAO) in NHP to neurological outcome. Cynomolgus macaques underwent structural T2 scans prior to, 48h, and 30-days post-MCAO. Neurological function was assessed with the Nonhuman Primate Stroke Scale (NHPSS). T2 whole lesion volume was calculated per subject. The longitudinal lesion volume evaluation showed a positive correlation with the NHPSS score, whereas the remaining brain volume negatively correlated with the NHPSS. Following ROI parcellation, NHPSS outcome correlated to lesion volume at 30- days of frontal, temporal, occipital, and middle white matter, as well as the internal capsule, and the superior temporal and middle temporal gyri, and the caudate nucleus. This supports the notion that stroke regionality and severity predicts outcome. The NHP model provides a fairly homogenous stroke in terms of regionality, and this outcome correlated with severity. This research represents an important step in stroke translational research by defining characteristics of the NHP stroke model; though to have greater similarities to the clinical population of interest.

Title: Generation of Notch3 mutations in marmoset using CRISPR/Cas9 system

Authors: *J. PARK[1], X. ZHANG[1], K. C. YOUNG[1], S. HA[2], A. C. SILVA[1]
[2]TNS/NINDS, [1]NIH, Bethesda, MD

Abstract: Cerebral autosomal-dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL) is an inherited cerebral small vessel disease caused by the notch homolog protein 3 (NOTCH3) mutation. The molecular mechanisms underlying CADASIL remain poorly defined and studies in animal models of CADASIL will shed light on potential disease mechanisms. The common marmoset (Callithrix jacchus) is an important nonhuman primate model for studying human neurological disorders. Recent advances of genome editing in marmosets provide even wider opportunities for the development of new marmoset models of disease. The aim of this study was to generate Notch3 mutant marmosets using CRISPR/Cas9 system to model CADASIL. In group 1, specific CRISPR gRNAs for exon 8 regions of the marmoset notch3 gene were designed and gRNA/Cas9 protein complexes were microinjected into single cell stage marmoset embryos. In group 2, a single-stranded oligonucleotide donor template containing the desired point mutation was microinjected with gRNA/Cas9 protein complexes for more precise genome editing. The microinjected embryos were cultured in Sequential Cleav culture medium for 3 days and noninvasively transferred to recipient females. The presence of Notch3 gene mutation in microinjected embryos were confirmed by T7E1 assay and sanger sequencing of PCR amplicons spanning the targeted exon. In group 1, 164 embryos were transferred to 56 recipient females and 16 recipients (28.6%) were confirmed by ultrasonography to be at early stages of pregnancy. Four recipients took the pregnancy to term and 6 neonate were born alive. Of those, five neonates died within the first week of age, but one neonate survived and exhibits mutations of the Notch3 gene. In group 2, 40 embryos were transferred to 12 surrogate mothers and 4 recipients (33.3%) were confirmed to be at early stages of pregnancy. Among the pregnant recipients, one is currently in advanced stage of her gestation period. These results are important steps in establishing a marmoset model of CADASIL, the most prominent known cause of inherited stroke and neurovascular disorders in human. We are confident that these animals will bring about novel and exciting opportunities to investigate the pathogenesis of CADASIL and for developing innovative therapeutics.

Title: Orexin-A suppresses the central post-stroke pain through the activation of the descending pain inhibitory system

Authors: *S. HARADA, W. MATSUURA, S. TOKUYAMA
Kobe Gakuin Univ., Kobe, Japan

Abstract: Central post-stroke pain (CPSP), an intractable secondary disease, is a serious problem that occurs following cerebral stroke. However, the detailed mechanisms underlying CPSP and standard treatments for it are not well established. That is, it is necessary to establish for new therapeutic strategy for CPSP. The orexin-A is a identified group of neuropeptides that are mainly expressed in the lateral hypothalamic area (LHA), perifornical area and posterior hypothalamus. They play roles in many physiological functions including arousal and energy metabolism such as glucose metabolism, feeding behavior, sleep and wakefulness. Recently, it was also reported that orexin-A regulates the several pain behavior. However, it is unknown about interaction of CPSP and orexin-A. The aim of the present study was to determine the involvement of orexin-A in the CPSP in an animal model of global cerebral ischemia.
Male ddY mice were subjected to 30 min of bilateral carotid artery occlusion (BCAO). The development of hind paw mechanical allodynia was measured using the von Frey test. On day 3 after BCAO, mice were intracerebroventricular (i.c.v.) injected orexin-A (50, 150 pmol/mouse), after then we performed the von Frey test. SB334867 (orexin-1 receptor antagonist) i.c.v. injected at 30 min, and yohimbine (α_2 receptor antagonist) or WAY1000635 (5-HT_{1A} receptor antagonist) intrathecal (i.t.) injected at 15 min before orexin-A i.c.v. injection.
The number of escape behaviors, called for mechanical allodynia, in response to the stimulation applied by the von Frey filament was significantly increased on day 3 after BCAO as compared with sham group. The BCAO-induced mechanical allodynia was significantly suppressed by i.c.v. injection of orexin-A. Orexin-A-induced suppressive effect was significantly despaired by i.c.v. injection of SB334867. In addition, that effect also canceled by i.t. injection of yohimbine,

a α_2 receptor antagonist, or WAY1000635, a 5-HT_{1A} receptor antagonist.
We conclude that orexin-A may involve in alleviation of CPSP. As one of its mechanism, it is possible that effect of orexin-A is mediated by activation of the descending pain inhibitory system.

Title: Thalamic neurodegeneration following distal middle cerebral artery occlusion in rats is not associated with thermal or mechanical hypersensitivity

Authors: *J. E. ANTTILA, S. PÖYHÖNEN, M. AIRAVAARA
Inst. of Biotech., Univ. of Helsinki, Helsinki, Finland

Abstract: Introduction: Central post-stroke pain (CPSP) is a neuropathic pain syndrome that may develop after a stroke in the somatosensory pathways. Patients suffering from thalamic infarcts have a higher risk of developing CPSP as the thalamus has a prominent role in pain processing. The symptoms often include hyperalgesia, which has also been described in rodents after direct ischemic or hemorrhagic damage of the thalamus. A cortical infarct induces neuronal loss in the ipsilateral thalamus as a secondary effect due to connecting thalamocortical and corticothalamic pathways. However, the behavioral consequences of secondary neurodegeneration are unclear. By inducing a cortical ischemia-reperfusion injury, we investigated the amount of secondary neurodegeneration in the thalamus, and whether it is associated with hyperalgesia.
Methods: Unilateral cortical infarction was induced in adult male Sprague Dawley rats (n=9) by transiently ligating the distal branch of the right middle cerebral artery with a 10-0 suture and occluding both common carotid arteries for 90 minutes. Thermal hyperalgesia was examined with Hargreaves' test and mechanical hyperalgesia with modified Von Frey test. Sham-operated

(n=9) and naïve (n=10) rats were used as controls. At 4 weeks after the stroke/sham operation the number of neurons and phagocytic microglia/macrophages in the thalamus were quantified.
Results: At 4 weeks post-stroke, 38% of the neurons in the ipsilateral thalamus were lost ($p<0.0001$), and the number of phagocytic microglia/macrophages was over 30-fold greater compared to sham-operated and naïve rats ($p<0.0001$). There were no differences between the stroke and sham groups in thermal or mechanical sensitivity.
Conclusions: We observed extensive neuronal degeneration and microglial activation in the ipsilateral thalamus at 4 weeks post-stroke but found no hyperalgesia. Therefore, thalamic neurodegeneration and inflammation alone are not enough to trigger hyperalgesia after experimental stroke, but the development of hyperalgesia may require direct ischemic or hemorrhagic injury of the thalamus.

Title: Accelerated collateral failure in aged rats during ischemic stroke

Authors: *J. MA[1,2], Y. MA[2], A. SHUAIB[1,3], I. R. WINSHIP[1,2]
[1]Neurosci. and Mental Hlth. Inst., [2]Neurochemical Res. Unit, Dept. of Psychiatry, [3]Div. of Neurology, Dept. of Med., Univ. of Alberta, Edmonton, AB, Canada

Abstract: Background and purposes: Cerebral collateral circulation and age are critical factors in determining outcome from acute ischemic stroke. Cerebral collaterals are recruited in the hyper acute phase of ischemia and are significant determinants of tissue outcome and response to therapy. Aging may lead to rarefaction of cerebral collaterals and thereby accelerate ischemic injury in brain tissues by reducing penumbral blood flow. However, dynamic changes in cerebral pial collaterals after onset of the cerebral ischemia in different ages of rats has not been well studied.
Methods and Results: In this study, two imaging methods, Laser speckle contrast imaging(LSCI) and two photon laser scanning microscopy(TPLSM) were combined to continuously monitor cerebral pial collaterals between the anterior cerebral artery (ACA) and the middle cerebral artery (MCA) in young (2 months) and aged (16 months) male Sprague Dawley

rats during distal middle cerebral artery occlusion (dMCAo). LSCI showed that both cerebral collateral perfusion declined over time after stroke ("collateral failure") in both aged and young rats. However, this decline was significantly accelerated in aged rats. TPLSM confirmed that pial arterioles narrowed faster after dMCAo in aged rats compared to young rats. Notably, while arteriole vessel narrowing was comparable by the experimental endpoint in aged and young rats, red blood cell velocity and the overall flux of blood through pial arterioles were significantly reduced at all time points in aged rats relative to young rats. Infarction measurement in Hemotoxylin-Eosin stained tissue showed aged rats had significantly ischemic damage than young rats.
Conclusions: Our findings show that cerebral pial collateral failure is accelerated in aged rats than young rats. Interestingly, while arteriole constriction was accelerated in aged rats, within 3hours vessel diameters were comparable between aged and young rats. However, blood flow velocity and flux remained significantly lower at all time points in aged rats.These findings confirm that aging has detrimental effects on pial collateral dynamics in rats in the hyper acute phase of stroke.

Title: Novel high-density quantitative μECoG recordings to record spreading depolarizations after permanent cerebral ischemia in awake freely moving rats

Authors: K. PALOPOLI-TROJANI[1], M. TRUMPIS[1], J. VIVENTI[2], D. A. TURNER[3], *U. HOFFMANN[4]
[1]Electrical and Computer Engin., Duke Univ., Durham, NC; [2]Electrical and Computer Engin., Duke Univ. Dept. of Electrical and Computer Engin., Durham, NC; [3]Neurosurg., [4]Anesthesiol., Duke Univ. Med. Ctr., Durham, NC

Abstract: BACKGROUND: The dynamic concept of the penumbra and the impact of cortical spreading depolarizations (CSDs) on ischemic cerebral stroke evolution are mainly based on short-term neurophysiological and functional imaging studies in anesthetized animals subjected to focal ischemia. The transfer of this concept to awake, freely moving animals is challenging, and therefore, has been limited due to technical considerations. To resolve these challenges, we demonstrate the simultaneous recording of both: ongoing spontaneous cortical activity and ultra-slow signals, such as CSDs, using novel high density microelectrocorticographic (μECoG) technology to create a real-time functional map of stroke boundaries. **METHODS:** μECoG

arrays. Passive, high-density µECoG arrays featuring very thin wires (25 µm) to allow high-density interconnections. Individual contacts 200 µm in diameter, provide a low-impedance interface and the 61 electrodes are arranged in an 8x8grid with 400-µm spacing. The total recorded area is ~3.5 mm x 3.5 mm. Data acquisition. We developed a high-density data acquisition system for highly miniaturized multiplexed neural signal acquisition. It is critically important to this project that this data acquisition system has DC-coupled amplifiers that allow us to record ultra-slow signals from the brain, particularly cortical spreading depressions (CSDs). Using this system, we can simultaneously record ultra-slow signals, including near DC and neural signals concurrently, in awake, freely moving animals. Implantation of µECoG array and induction of focal cerebral ischemia: a craniotomy was made over the right hemisphere, the electrode array was epidurally placed over the parietal-temporal cortex and encapsulated in cement. After three days recovery, rats were subjected to permanent middle cerebral artery occlusion; µECoG array was hooked up to the recording system via a tethered ultra-flexible µHDMI cable in the home cage of the animal and recordings were started. **RESULTS:** We demonstrate the detection of cortical spreading depolarizations (CSDs, slow DC field potential shifts) using the 61 channel µECoG array after induction of ischemic stroke in awake, freely moving rats continuously for up to seven days. The high density recordings reveal the evolving features of ongoing cortical activity after the initial ischemia, demonstrating the dynamic nature of stroke boundaries. **CONCLUSION:** In these novel experiments, we use high density µECoG continuous monitoring in non-anesthetized rats after focal ischemia revealing the dynamic nature of stroke boundaries as well as the role of CSD occurrences in secondary stroke expansion.

Title: Glial engagement at the hematoma after intracerebral hemorrhage in the mouse

Authors: *K. GIORDANO[1,2], C. R. DENMAN[1,3,2], R. K. ROWE[1,2,4], J. LIFSHITZ[1,2,4], M. AKHTER[1,2,5]

Abstract: Intracerebral hemorrhage (ICH) has the highest rate of mortality and one of the highest rates of morbidity among all stroke subtypes with as few as 20% of survivors regaining complete independence by 6 months post-injury. As a component of the ICH pathophysiology, the inflammatory response includes immune cell migration and glial activation. Brain microglia are dynamic sentries of the extracellular environment and activate morphologically and thereby functionally in response to stresses, such as injury. Microglia activation involves retraction and thickening of processes while producing immunoactive cytokines. Full activation manifests with an amoeboid morphology, whereas rod microglia are an alternative morphology. We hypothesized that in response to experimental ICH, microglia are activated and migrate to the injury site as evidenced by a change in morphology and cell number over time. CX3Cr1-eGFP mice were subjected to collagenase or saline intracerebral injection (0.5U in 1 µl over 4 min) through the cortex into the striatum (-0.10mm posterior, +2.0mm lateral, -2.5mm ventral from Bregma). At 7 days post-injury, microglia morphology and number in the cortex and striatum were analyzed by skeleton analysis to assess microglial process length, process endpoints, and cell counts. In ipsilateral ICH striatum, microglia had decreased process length and process endpoints compared to the contralateral hemisphere and saline controls, consistent with microglial activation. The perihematomal striatum and ipsilateral cortex of the needle track contained more microglia per field-of-view compared to the contralateral hemisphere and saline controls. Rod microglia were present in both the perihematomal striatum and ipsilateral cortex of ICH animals only. Thus, a key inflammatory response following ICH is microglia deramification (shorter and fewer processes/cell), indicating injury-induced activation localized to the injury site. More cells suggest either a proliferation or migration of microglia towards the injury site, likely through chemotaxis. Further, this is the first study to show the activated rod microglia morphology in ICH. Translationally, it is critical to investigate the time course of microglia activation in response to ICH in order to target anti-inflammatory treatments for ICH.

Title: Timing matters: The impact of hypothermia on human neural stem cell action *in vitro* supports the need to find optimal timing for combined cell-based therapy with hypothermia for perinatal hypoxic ischemic injury

Authors: *J. LAW[1,2], C. D. PERNIA[2], W. D. NILES, II[2], E. Y. SNYDER[2]
[1]Pediatrics, UCSD, La Jolla, CA; [2]Sanford Burnham Prebys Med. Discovery Inst., La Jolla, CA

Abstract: Purpose: As many as 8 of every 1000 live births experiences a lack of oxygen to the brain near the time of delivery, an injury called perinatal hypoxic ischemic injury (HII). If left untreated, up to 65% of these babies may have lifelong neurologic sequelae including cerebral palsy, epilepsy, learning disabilities, and autistic behaviors. Although hypothermia (HT) is standard-of-care (SOC) in treating HII, it is only marginally effective in moderate cases and ineffective in severe HII. We and others have reported the efficacy and safety of transplanted human neural stem cells (hNSCs) for salvaging injured brain parenchyma (aka the penumbra) leading to improved histologic and behavioral outcomes in rodent models of HII. None of these reports, however, evaluated hNSC action under SOC HT conditions. It remains uncertain whether HT antagonizes or complements hNSC function.
Methods: hNSCs were studied in vitro under normothermic (NT) (37°C) and SOC HT (33.5°C) conditions and evaluated on days 0, 1, 2, 3, and 6. Change in hNSC colony size over time was measured as a marker of colony growth, and migration was assessed using scratch assays. Total protein production was evaluated by BCA protein assay. For western analysis, antibodies to β3-tubulin (an immature neuronal marker) and proliferative cell nuclear antigen (PCNA - a marker of cell proliferation) were used.
Results: HT decreased the rates of hNSC proliferation and migration ($p=0.0006$ and $p<0.0001$, respectively) over time compared to NT. The doubling time for NT hNSCs was 5.2 days compared to 21.1 days for HT hNSCs. HT hNSCs exhibited significant differences in protein abundance over time by BCA analysis ($p=0.0004$) relative to NT hNSCs. Western blot analysis demonstrated no difference in β3-tubulin presence in NT vs. HT cells, however there was a strong trend toward a decrease in markers of cell division in HT compared to NT hNSCs ($p=0.06$). Most of these changes were not apparent until after three days of HT.
Conclusion: HT significantly altered hNSC proliferation, migration, and protein production in vitro. However, given that SOC HT is instituted for only three days following HII and most changes in HT hNSCs were not apparent until after three days of exposure, combining these two neuroprotective therapies seems feasible. Alternatively, optimal timing for the introduction of cell-based therapy may be after HT is completed. Coordinating therapies, whether concurrently or in sequence, to improve outcomes must be tested in animal models of HII. Furthermore, our results raise the question of whether endogenous hNSCs, required for repair and regeneration of the neonatal brain after HII, are also affected by HT.

Title: Recent advances in hemorrhage-induced vasospasm: *In vivo* vasoactivity of heme degradation products (HDPs) on mouse cerebral vasculature using two-photon microscopy and MR perfusion imaging

Authors: A. JOERK[1], K.-H. HERRMANN[2], D. FREITAG[3], M. RITTER[5], N. LANGGUTH[1], A. SCHAEFGEN[1], R. A. SEIDEL[5,4], M. KRAEMER[2], G. POHNERT[5], M. WESTERHAUSEN[5], J. WALTER[3], R. KALFF[3], J. REICHENBACH[2], *O. W. WITTE[6], K. HOLTHOFF[1]

Jena, Jena, Germany; [5]Inst. of Inorganic and Analytical Chem., Jena, Germany; [6]Hans Berger Dept. of Neurol., Friedrich Schiller Univ. Jena, Jena, Germany

Abstract: BACKGROUND: Delayed ischemic neurological deficit (DIND) caused by symptomatic cerebral vasospasm is supposed to be the most common determinant of unfavorable prognosis in patients suffer from subarachnoid hemorrhage (SAH). Actually, the guideline-based recommendations of vasospasm treatment fail to improve the clinical outcome. We hypothesize that heme degradation products (HDPs), originating from the intracranial hematoma surrounding the ruptured aneurysm, are involved in vasospasm pathogenesis by inhibiting BK_{Ca} potassium channels in vascular smooth muscle cells. HDPs, comprising propentdyopents (PDPs) and bilirubin oxidation products (BOXes), are present in the cerebrospinal fluid of SAH patients and induced an acute vasoconstrictive effect on arterioles in acute mouse brain slices.
METHODS: After subarachnoid HDP application in adult wildtype and BK channel deficient mice, we analyzed acute changes in blood flow velocity and diameter of pial and intracortical arterioles *in vivo* using two-photon laser scanning microscopy. To study the long-term effect of HDPs on cerebral perfusion, SAH was experimentally induced in mice by injection autologous blood or HDP isomers into the cisterna magna, followed by temporally high-resolution echo-planar MR imaging at 9.4T.
RESULTS: Consistent with our investigations on acute brain slices, subarachnoidally administered PDP and BOX isomers caused a sustainable diameter decrease of pial arterioles *in vivo*. Both, vasoconstriction and BFV reduction depend on BK_{Ca} channel activity, because it was absent in Slo1 knockout mice. These data were complemented by MR perfusion imaging where intrathecally injected blood and PDPs induced long-term cerebral perfusion deficits in living mice.
CONCLUSION: In addition to the acute vasoactivity, our data demonstrate a long-term effect of HDPs on cerebral perfusion which correlates with the onset of delayed vasospasm in SAB patients. These findings may promote novel strategies for vasospasm treatment.

Title: Evaluation of persistent microcirculatory dysfunction in salvageable ischemic penumbra due to dynamic stalls in capillary red blood cell flow

Authors: *E. ERDENER[1], J. TANG[1], K. KILIÇ[1], D. POSTNOV[1], S. KURA[1], S. SAKADZIC[2], D. A. BOAS[1]
[1]Boston Univ. Neurophotonics Ctr., Boston, MA; [2]Massachusetts Gen. Hosp., Charlestown, MA

Abstract: Objective: We previously identified temporary flow interruptions in individual capillaries under physiological conditions using optical coherence tomography-angiography (OCTA). These stalls can potentially influence capillary transit time and oxygen extraction in pathological tissue . In this study, we characterized the frequency and duration of stalls in ischemic penumbra in a mouse model of distal middle cerebral artery (dMCA) stroke. **Methods:** C57BL/6 mice (n=10, male, ~3-month-old) were anesthetized with isoflurane. A craniotomy over dMCA, and a parietal closed cranial window were prepared. dMCA was occluded by compression with a blunted micropipette and was recanalized after 1 hour. Cerebral blood flow (CBF) was continuously monitored via laser speckle contrast imaging to confirm ischemia and reperfusion. OCTA time-series, and phase-resolved Doppler OCT data were collected at baseline, by 1 hour of ischemia, 1 hour and 2 hours after reperfusion. **Results:** Ischemic core was identified as the area that totally lacked capillary flow and also had decreased OCT signal penetration because of cellular swelling. In the surrounding ischemic penumbra, there was decreased CBF, decreased capillary density but relatively preserved signal penetration. CBF dropped to 13±4% and 47±6% of baseline in core and penumbra, respectively. In ischemic penumbra, fraction of stalled capillaries raised from 4±1% to 21±4% by 1 hour of ischemia. For 2 hours after recanalization stall fraction remained high (19±5% and 16±4%, respectively). Cumulative stall duration was 19±3% of observation time at baseline, increasing to 32±3% during ischemia and persisted at 35±3% and 29±2% after recanalization. No significant change in CBF or stall parameters was observed in sham group (n=4). **Conclusion:** Temporary stalls in capillary flow dramatically increases in the salvageable penumbra and remains high despite

recanalization. Measures to increase cellular passage through capillaries to improve microcirculation may have potential for decreasing stalls and preserving ischemic tissue at-risk.

Title: Chemogenetic modulation of noradrenergic tone in the pathogenesis of ischemic stroke

Authors: D. BRIGGS, K. RAVINA, S. KISLAL, R. LAM, C. XU, *M. SHAMLOO
Stanford Behavioral and Functional Neurosci. Lab., Stanford Univ. Sch. of Med., Palo Alto, CA

Abstract: The noradrenergic (NA) system is directly implicated in processes that govern cognitive function and neuroinflammation. Adrenergic receptors on microglia regulate neuroinflammation and the engagement of protective mechanisms critical to neuronal function and survival. Evidence suggests that degeneration of the locus coeruleus (LC), the primary source of noradrenaline in the brain, may reduce NA tone in the aging brain and increase the risk of stroke and neurological impairments. The aim of this study was to investigate the role of LC NA tone in the development of neuronal injury, neuroinflammation, and behavioral impairments following stroke. Using targeted designer receptors exclusively activated by designer drugs (DREADD) chemogenetic technology, we examined the functional consequences of inhibiting NA neuronal firing rates and experimentally reducing NA tone in the LC in a mouse model of stroke. Wild-type mice expressing Cre recombinase from the tyrosine hydroxylase or dopamine β-hydroxylase locus received bilateral injections of either control or inhibitory (Gi)-mCherry virus into the LC. Two weeks later, one cohort of mice received intraperitoneal injections of the DREADD agonist clozapine-N-oxide (CNO; 5 mg/kg) 15 min prior to and 2 h following 30 min of transient middle cerebral artery occlusion (tMCAo). Mice were sacrificed 6 h following occlusion onset. A second group of mice received CNO (2 mg/kg) via subcutaneous osmotic pumps implanted 24 h prior to or following 45 min tMCAo. Sensorimotor function was evaluated using the Beam-walk test and Neuroscore up to 15 days following stroke. Upon completion of behavioral testing mice were sacrificed and their brains assessed for neuroinflammatory markers and levels of inflammatory cytokines using qRT-PCR and immunohistochemistry. Down-regulating NA tone prior to stroke impaired sensorimotor function and enhanced neuroinflammation whereas down-regulating NA tone after stroke improved sensorimotor function and reduced neuroinflammation. Furthermore, treatment with xamoterol, a highly-selective β-adrenoreceptor 1 (ADRB1) agonist, improved functional recovery, reduced infarct volume, and mitigated neuroinflammation in rats following tMCAo. Collectively, these data suggest selective ADRB1 activation may confer neuroprotection against late-stage secondary injury and that NA tone plays a key role in the pathophysiology of ischemic stroke and the mechanisms that govern functional recovery.

Title: The effects of intraventricular hemorrhage injection in rats on spatial memory and dentate neurogenesis

Authors: T. BINYAMIN, K. KAMAL, A. IZADI, K. ONDEK, R. BERMAN, F. SHARP, *G. G. GURKOFF, B. WALDAU
Univ. California Davis, Davis, CA

Abstract: Intraventricular hemorrhage from hypertension or aneurysm rupture can cause a range of neurological deficits and death. Cognitive deficits may prevent the return to work after recovery in over half of these patients, and impairments in memory can be seen over 10 years after initial insult. The etiology of the persistent memory impairment has not been characterized well on a cellular level. We created a rat intraventricular hemorrhage model to shed light on the cellular mechanism of memory decline after intraventricular hemorrhage. Rapid infusion of 200 microliters of blood or artificial CSF (aCSF) into the lateral ventricle in rats showed a significant increase in size of the lateral ventricles after one week compared to animals, which received no injection ($p<0.05$). Therefore, rapid ventricular volume expansion alone caused prolonged hydrocephalus. Next we examined four groups of animals after intraventricular hemorrhage in the Morris water maze: Group 1 received an intraventricular injection of 200 microliters of autologous blood over two minutes, Group 2 received an intraventricular injection of 200 microliters of aCSF over two minutes, Group 3 received an intraventricular injection of five microliters of thrombin over 15 minutes, and Group 4 received an intraventricular injection of five microliters of aCSF over 15 minutes. After one week of recovery, all groups received an intraperitoneal injection of 5-bromo-2'-deoxyuridine (BrdU) twice daily for 5 days. The animals subsequently underwent Morris water maze testing four weeks after injury. The intraventricular hemorrhage group (Group 1) performed with higher latencies than its control (Group 4), but a rapid 200 microliter aCSF (Group 2) injection as well as small volume thrombin injection (Group 3) also increased latencies compared to Group 4. BrdU analysis of the subgranular zone of the dentate gyrus showed decreased dentate neurogenesis after intraventricular hemorrhage compared to control. We conclude that intraventricular hemorrhage may decrease dentate neurogenesis, and decreased dentate neurogenesis may lead to a worse performance in the Morris water maze.

Abstract: Dapsone (DDS) is a drug used as a first line option therapy against leprosy and several dermatologic diseases. Since some N,N'-dialkylated analogues of DDS have shown remarkable properties as antiepileptic and anti-excitotoxic molecules in addition of a better toxic profile producing significant lower levels of metabolic methemoglobinemia, we have synthesized a homologous series including: N,N'-dimethyldapsone (Me-DDS), N,N'-diethyldapsone (Et-DDS), N,N'-dipropyldapsone (Pr-DDS) and N,N'-dibutyl dapsone (Bu-DDS) and evaluated their neuroprotective effect in a focal ischemia/reperfusion model in rats.
Wistar male rats (270-300gr; n=4-6) were administered with either DDS or any of the four N,N'-dialkylated analogues (i.p. 0.05 and 0.1 mmol/Kg), using a control group injected only with dimethylsulfoxide as vehicle (440 µL/Kg). Each treatment was injected 30 minutes after occlusion of middle cerebral artery and reperfusion was established 120 minutes before. Rats were evaluated for neurological and behavioral outcomes every 24 hour until sacrifice at 96 hours with Capdeville and Thiyagarajan scales. Sacrificed rats were perfused and fixed with a 4% paraformaldehyde solution, brains were dissected-out, embedded in parafin, cut for corpora striata and hippocampi observation and finally hematoxylin and eosine stained to measure infarction area using J image software.
When comparing striatal infarction areas from animals receiving the 0.05 mmol/Kg dose to those observed in control group, we found significant reduction for DDS, Me-DDS, Et-DDS and Pr-DDS groups (29-40%). Animals receiving 0.1 mmol/Kg of DDS, Me-DDS, Et-DDS and Bu-DDS also reduced striatal damage between 12-32%. Hippocampal infarction areas comparison between control group and rats receiving 0.05 mmol/Kg dose of DDS and Bu-DDS showed significant protection (25 and 33% respectively). Group administered with 0.1 mmol/ Kg of Me-DDS also showed a 42% reduction in damaged area (Mann-Whitney test;$p<0.05$). Likewise, neurological and behavioral outcomes assessed by the Capdeville and the Thiyagarajan scales showed significant protection against deficit for most of the groups treated with DDS and the N,N'-dialkylated molecules when compared to scores observed in control groups (repeated measures ANOVA, $p<0.05$).

Title: The contribution of TRPV1 channels to 20-HETE-aggravated ischemic neuronal injury

Authors: *Z. YANG[1], J. R. FALCK[3], R. C. KOEHLER[2]
[1]ACCM, [2]Dept Anesthesiol Critical Care Med., Johns Hopkins Univ., Baltimore, MD;
[3]Biochem., Univ. of Texas Southwestern Med. Ctr., Dallas, TX

Abstract: 20-Hydroxyeicosatetraenoic acid (20-HETE), a cytochrome P450 (CYP) 4A/4F-derived metabolite of arachidonic acid, contributes to ischemic brain injury in adults and the newborns. Our previous work has indicated that 20-HETE can aggravate injury directly within neurons. However, little is known about mediators of 20-HETE neurotoxicity after ischemia. Transient receptor potential cation channel subfamily V member 1 (TRPV1), the nonselective cation channels with massive Ca^{2+} permeability, are widely distributed in the brain and interact with 20-HETE in neural and non-neural tissues. Therefore, we hypothesize that TRPV1 plays a role in 20-HETE's toxicity in primary cortical neurons after oxygen-glucose deprivation (OGD) and in neonatal mouse brains after hypoxia-ischemia (H-I). Double-immunofluorescent staining indicated that TRPV1 and CYP4A signals were colocalized in neurons. Fluo-4 NW calcium assay results revealed that the 20-HETE mimetic agonist 20-5,14-HEDGE significantly increased early neuronal Ca2+ signals, which were attenuated by the TRPV1 antagonist capsazepine. Furthermore, genetic or pharmacologic TRPV1 inhibition attenuated 20-5,14-HEDGE-induced toxicity in cultured neurons. TRPV1 genetic inhibition and CNS-penetrable TRPV1 antagonist A784168 also protected neurons after OGD, and 20-HETE synthesis inhibitor HET0016 did not produce additional effects. Moreover, A784168 and HET0016 individually attenuated brain injury in mixed-sex groups of neonatal mice at 1 d after H-I, but the drug combination did not provide additional protection. TRPV1 genetic inhibition also protected neonatal brains at 1 d after H-I, but further analysis indicated that the protective effects were observed only in male TRPV1 knockout mice. PKC-or Src-dependent phosphorylation directly potentiates NMDA receptor-mediated neurotoxicity. H-I induced PKC-dependent phosphorylation at NMDA NR1 Ser896, phospho-Src at Tyr416 (indicative of Src activation),

and Src-dependent phosphorylation at NR2B Tyr1472 in brain tissues at 3 h of recovery. HET0016 and A784168 each attenuated H-I-induced phosphorylation of these sites. HET0016 and A784168 in combination, however, did not provide additive effects. Moreover, we did not find significant changes in total NR1, NR2B, or Src after H-I or/and HET0016 and A784168 treatment. Therefore, we conclude that TRPV1 channels are involved in 20-HETE's neurotoxicity after ischemia.

Title: Role of TRPV4 and PLA2g6 in post-stroke hydrocephalus

Authors: *J. W. SHIM[1], F. NIPA[2]
[1]Med., Boston Univ., Boston, MA; [2]Boston Univ. Sch. of Med., Boston, MA

Abstract: Aim: Permeability and intracranial compliance are known to contribute to barrier dysfunction and pressure-volume regulation within the brain but how either or interaction of both are involved in pathogenic mechanisms of hydrocephalus remains elusive. The objective of this study was to better understand the role of permeability and vascular stiffness, a critical determinant of intracranial compliance in post-stroke hydrocephalus through transient receptor potential cation channel subfamily V member 4 (TRPV4) and phospholipase A2 group6 (PLA2g6). **Methods**: Wistar polycystic kidney (wpk) rats with hydrocephalus were used to characterize the localization of TRPV4 in choroid plexus, ependyma and cerebral cortex. Aortic stiffness was assessed in vivo using ultrasound and compared to age-, diet-, and gender-matched mice with constitutive deletion of PLA2g6. Gene expression analysis was conducted on aortic medial RNA and validated by elastic fiber staining. Elastin gene expression was quantified in the thoracic aorta of male mice with young and old age and of young mice fed with high fat high sucrose (HFHS) diet. Cell-specific effect on elastin gene expression and arterial stiffness was further tested in a mouse model with smooth muscle cell (SMC)-specific impairment of PLA2g6. **Results**: TRPV4 was elevated in choroid plexus and ependyma of wpk rats with rapidly developing severe hydrocephalus. We found reactive astrocytosis and neural identity of TRPV4+ cells in an early postnatal brain of the wpk rats. Strikingly, when double-stained with doublecortin (DCX) in a midbrain region in which dorsal hippocampus lies (bregma -3.4 mm), more than 50 % of TRPV4+ cell and its extension were co-labeled with DCX+ cells in the

coronal section adjacent to the ventricular surface. In vascular stiffness study, mice experiments revealed that aging and HFHS-diet induced arterial stiffening in wild type (WT) animals but not in PLA2g6 knockout mice. The SMC-specific knockout of PLA2g6 recapitulates the protective effect in that PLA2g6 impairment in SMC alone was sufficient to prevent the development of diet-induced arterial stiffening in young mice. **Conclusion**: These results suggest that targeting TRPV4 should be regionally specified for cerebral epithelia but not neural cells in the cortex while vascular cell-specific impairment of PLA2g6 may provide a protective effect against loss of vascular compliance in the brain. Molecular targets promoting cerebral epithelia-specific inhibition of TRPV4 and vascular SMC-specific PLA2g6 may provide novel therapeutic approaches for the treatment of post-stroke hydrocephalus.

Title: Azithromycin has an innovative neuro-protective role in a neonatal mouse model of periventricular leukomalacia (PVL)

Authors: *N. ZAGHLOUL[1], K. R. AYASOLLA[2], M. N. AHMED[3]
[1]Pediatrics, Cohen's Children Med. Ctr., Manhasset, NY; [3]Pediatrics, [2]Feinstein Inst. for Med. Res., Manhasset, NY

Abstract.Abstract1:

Background: PVL is the most common cause of cerebral palsy in premature infants. Microglia is the main inflammatory cell involved in the pathogenesis of PVL. In this study, we propose that azithromycin administration ameliorates the inflammatory process leading to decreased brain injury induced by Hypoxia-ischemia (HI).

Objective: To examine the neuroprotective function of azithromycin as a new therapeutic approach in neonate mouse model of PVL.

Design/Methods: PVL neonate mouse model was established by temporary bilateral carotid ligation at P5, followed by hypoxia exposure 8% for 20 min. Three neonate groups were studied. N=30 pups /group. RA control, (HI) + saline injection and (HI) + azithromycin injection. 2 doses of Azithromycin were injected IP at a dose of 20mg/kg at P5 (2 hours after HI insult) and at P6. At defined time points following HI, brain inflammatory cytokines, immunostaining (neurons: NeuN; astrocytes:GFAP; for Microglia: Iba1,CD68,arginase 1; oligodendrocyte: CNPase; apoptosis:caspase 3) and western blots for phosphor stress kinases (

pAKT, pp38, pSAPK, pERK, pCREB and pP65) were performed. Oxiselect ROS assay was performed. MicroRNA profile panel was studied using a custom designed microarray plate.

Results: Azithromycin treated pups showed minimal paresis and co-ordination deficits as compared to saline treated HI group, which had severe insult. Histopathology showed ventriculomegally, neuronal necrosis and apoptosis in saline treated HI group which was ameliorated in azithromycin treated HI group. There was a significant decrease in IL 12p70, IL6, KC GRO in the azithromycin treated HI vs. saline treated HI. Quantitative immunostaining showed significantly less injury in HI azithromycin treated (more NeuN, olig 2, CNPase and less expression of GFAP, caspase 3) associated with a shift towards an M2 microglial phenotype (increased arginase 1 and decreased in CD68), vs. the saline treated group. There was a significant decrease in pAKT, pP38, pSAPK, pERK, pCREB and pP65 in the HI azithromycin treated vs. saline treated pup brains. There was a significant decrease in brain intracellular ROS levels in the HI azithromycin treated vs. saline treated pups. MicroRNA, analysis showed a unique and innovative role of azithromycin in attenuating specific microRNA expression among HI treated group. (Table 1)

Conclusion(s): Azithromycin offers significant protection in PVL. It shifts microglia towards an M2 phenotype. It decreases the inflammatory milieu by decreasing pro-inflammatory cytokines, NF-KB activity and intracellular ROS levels. Azithromycin has an innovative role by ameliorating specific microRNA expression which was previously were linked to brain hypoxia and neuro-inflammation and demylenation.

Title: Investigating the expression of neuroserpin and its role in neonatal hypoxic-ischaemic encephalopathy

Authors: *J. FISCHER, A. HOERDER-SUABEDISSEN, K. PARLEY, Z. MOLNÁR
Univ. of Oxford, Oxford, United Kingdom

Abstract: Background: Perinatal hypoxic ischaemia is one of the most prevalent causes of neonatal morbidity and mortality worldwide. Hypothermia is currently the only available treatment option with limited clinical efficacy. Neuroserpin, an inhibitor of tissue plasminogen activator, has been shown to result in a reduction in brain damage and overall functional improvements in models of adult cerebral infarction (Millar et al. 2017, Front Cell Neurosci. 11: 78). It has therefore been hypothesised that it may also reduce damage caused by perinatal hypoxic ischaemia. Previous work in the lab using a rat model of unilateral mild and moderate hypoxic injury (Okusa et al. 2014, Ann Clin Transl Neurol, 1: 679-691) suggested an increase in neuroserpin expression on the affected side prompting further research in the mouse model.
Methods: Our study had two goals. (1) We determined the expression pattern of neuroserpin in the developing human fetal brain using late first as well as second trimester brain sections to track its expression. A particular focus was placed on the expression within the subplate. (2) We studied a neuroserpin knock-out mouse to shed light on potential neuroprotective properties that this protein may possess (Madani et al. 2003, Mol Cell Neurosci, 23, 473-494). A modified Rice-Vannucci model was employed which involves unilateral carotid artery ligation with subsequent hypoxia to induce hypoxic ischaemic encephalopathy in one brain hemisphere of P8 mice. This model attempts to replicate perinatal hypoxic injury in humans. Mice were sacrificed at P10 and brains were extracted and cut into 1.0-1.5mm sections. Sections were stained with Triphenyltetrazolium chloride to determine the area of ischaemic damage. Sections of wild-type mice were then resectioned after fixation to carry out immunohistochemistry to determine neuroserpin expression on the affected and unaffected side. GFAP and IBA have been used as further markers of damage.
Results: (1) Neuroserpin was shown to be widely expressed throughout the cortex of the developing human fetal brain. The highest levels of expression are found in the subplate in the second trimester. (2) Our experiments in the neuroserpin KO mouse show that neuroserpin has no statistically significant effect on ischaemic damage following hypoxic-ischaemic injury in the

knockout versus the wild-type mice (7.53 mm^2 vs. 6.18 mm^2 respectively, p=0.35, n=25). An effect size of 21% was non-significant in part due to high variability that is common in the outcomes of the Rice-Vannucci model.

Title: Effect of GH and IGF-1 treatments after hypoxic-ischemic injury in chicken cerebellar cell cultures

Authors: M. BALTAZAR[1], J. AVILA-MENDOZA[2,4], C. MARTÍNEZ-MORENO[1], M. CARRANZA[2], C. ARAMBURO[2], *M. LUNA[3]
[1]Celular y Mol., [2]Mol. y Celular, [3]Inst. de Neurobiologia,UNAM, Queretaro, Mexico; [4]Molecular, Celular and Developmental Biol., Univ. of Michigan, Ann Arbor, MI

Abstract: Perinatal hypoxic-ischemic (HI) brain damage is a major cause of mortality and long-term neurological impairment in children. The rapid growth of the cerebellum in the last half of fetal development makes it more vulnerable to a HI injury. Several studies have shown that growth hormone (GH) and insulin-like growth factor-1 (IGF-1) are upregulated in different brain areas after damage by hypoxia. Moreover, there is increasing evidence suggesting that GH and IGF-1 treatments are able to induce neuroprotection and neural-regeneration in the CNS. In this study, we evaluated the effects of GH and IGF-1 treatment on cell survival after an acute HI injury in primary cell cultures of embryonic chicken cerebellum. In addition, we evaluated the cerebellar expression of GH and IGF-1 mRNA in normal and hypoxia-low glucose (HLG) conditions. To induce neural damage in primary embryonic cerebellar cultures, cells were maintained in hypoxic conditions (0.5-5% O2), and incubated in low glucose media (1 g/L) for 12 h, and subjected to a 24 h of reoxygenation. Cell cultures were treated with 1 nM recombinant chicken GH (rcGH) and/or 40 nM recombinant human IGF-1 (hIGF-1) to examine their neuroprotective effects. We observed that incubation of cells in HLG caused a significant

decrease in cell viability (51.6 ± 2.9 %) as well as a pronounced increase in apoptosis (122.0 ± 4.5 %,) and necrosis (538.6 ± 92.1 %), while treatment with GH increased cell viability (76.1 ± 4.1 %), and decreased apoptosis (105.0 ± 3.9 %) or necrosis (73.8 ± 11.1 %), On the other hand, IGF-1 treatment only increased cell viability (70.1 ± 4.2 %) without affecting apoptosis (105.0 ± 3.9 %) and necrosis (73.8 ± 11.1 %). After incubation in HLG conditions, cerebellar cell cultures significantly increased GH and IGF-1 mRNA expression were increased by (~3 fold). GH gene silencing with small interfering RNA (siRNA) decreased both, GH mRNA expression (1.6-fold) and IGF-1 (0.5-fold) mRNA expression in the HLG group, suggesting that GH regulates IGF-1 expression under HLG conditions. Our results strongly suggest that both, local and exogenous GH act as a neuroprotective factor and they regulate IGF-1 expression under HLG conditions. We thank Gerardo Curtois, Nydia Hernández, Dra. Olivia Vázquez Martínez, for technical assistance.

Title: Correlation between the serum levels of 24S-hydroxycholesterol and hypoxic-ischemic brain injury in neonatal mice

Authors: *F. LU[1], J. ZHU[2], F. CHEHAB[2], D. M. FERRIERO[3], X. JIANG[3]
[1]Univ. of California, San Francisco, San Francisco, CA; [2]Lab. Med., UCSF, San Francisco, CA; [3]Pediatrics, Univ. of California San Francisco, San Francisco, CA

Abstract: Background/Objective: Maintenance of cholesterol homeostasis is crucial for brain development due to its importance in membrane integrity, myelination, synaptogenesis and neurotransmission. Brain cholesterol relies on de novo synthesis and is cleared primarily by conversion to 24S-hydroxycholesterol (24S-HC) with brain-specific cholesterol 24-hydroxylase (CYP46A1). This study was undertaken to investigate the impact of hypoxia-ischemia (HI) on cholesterol turnover in the neonatal mouse brain. **Methods:** Postnatal day 9 C57BL/6 pups were subjected to HI using the Vannucci model. CYP46A1 expression was assessed by western blotting and its cellular localization was determined by immunofluorescence staining. The amount of brain cholesterol, the levels of 24S-HC in the cortex and in the serum was measured by ELISA. **Results:** There was a transient loss of brain cholesterol at 6hr after HI. CYP46A1

was significantly upregulated at 6hr and 24hr following HI with a concomitant increase of 24S-HC in the ipsilateral cortex and in the serum. The serum levels of 24S-HC correlated with those in the brain, as well as with necrotic and apoptotic cell death evaluated by the expression of spectrin breakdown products and cleaved-caspase 3 at 6hr and 24hr after HI. **Conclusions:** Enhanced cholesterol turnover by activation of CYP46A1 represents disrupted brain cholesterol homeostasis early after neonatal HI. 24S-HC might be a novel blood biomarker for severity of neonatal hypoxic-ischemic brain injury with potential clinical application.

Title: Conventional histological assessment of ischemic damage and defining cerebellar apoptotic Purkinje cell death in rats

Authors: *Z. HE[1], L. CUI[2], T. A. PATTERSON[3], S. A. FERGUSON[4]
[1]Div. of Neurotoxicology, Natl. Ctr. For Toxicology Res., Jefferson, AR; [2]Neurotoxicology, NCTR, Jefferson, AR; [3]Office of the Director, Natl. Ctr. for Toxicological Res., Jefferson, AR; [4]Neurotoxicology, Natl. Ctr. Toxicological Res., Jefferson, AR

Abstract: Assessment of acute ischemic damage to define cerebellar Purkinje cell death is elusive. This study examined Purkinje cell death following transient global ischemia in rats. In sham-operated rats, Purkinje cells display various forms including “dark neurons”, making it difficult to distinguish normal from damaged Purkinje cells. In ischemic groups, as verified by significant hippocampal CA1 neuronal loss, dead cerebellar Purkinje cells were defined with the following morphological criteria (2 or more required): 1) reduced numbers of Purkinje cells/increase in the interval distance between two adjacent Purkinje cells; 2) significantly increased peripheral cellular empty/stainless space; 3) perinuclear or whole-cellular eosinophilia; and 4) significantly condensed granular nucleic aggregation and/or interstitial eosinophilia. Quantitative Purkinje cell loss indicated a significant difference between ischemic groups and sham controls. Triple fluorescent labeling including TUNEL- and caspase 3 active peptide (C3AP)-immunoreactivity and DAPI labeling defined cerebellar Purkinje cell death. In young adult female rats subjected to 20 minutes of ischemia and surviving for 4 days, single or collected Purkinje cells displayed TUNEL-positive immunoreactivity with or without cytosolic

C3AP immunoreactivity. A subset of Purkinje cells simultaneously displayed three biomarkers termed “apoptotic trilogy” (Fig. 1A1), by which occurrence of apoptosis was both immunohistochemically and morphologically defined: nucleic TUNEL immunoreactivity and blebbing and cytosolic C3AP immunoreactivity. Apoptotic bodies limited to the cytosolic compartment were found in a subset of the Purkinje cells. In conclusion, histological methods, while requiring a higher morphological standard, remain indispensable in defining cerebellar Purkinje cell death. A subset of cerebellar Purkinje cells does experience caspase-dependent apoptosis following ischemia.

Title: Characterization of the spinal ejaculation generator in male mice

Authors: *S. GAIKWAD[1], M. D. STAUDT[2], L. M. COOLEN[3]
[1]Neurosci., [3]Physiol. & Biophysics, [2]Univ. of Mississippi Med. Ctr., Jackson, MS

Abstract: Spinal Cord Injury (SCI) is a debilitating life changing event. Surveys among SCI men place recovery of sexual function as a high priority issue, but research on effects of SCI on sexual function is hindered by limited understanding of spinal control of sexual reflexes. A spinal ejaculation generator (SEG) has been delineated in male rats and has been shown to be anatomically and neurochemically identical in humans. The SEG consists of a population of lumbar spinothalamic cells (LSt) that control ejaculation via axonal projections to sacral nucleus of bulbocavernosus and autonomic centers. LSt cells control ejaculation via release of the neuropeptides galanin, cholecystokinin (CCK), gastrin releasing peptide (GRP), and enkephalin. Thus far, the SEG has been delineated in male rats, revealing important information. However, understanding of ejaculatory function will be improved with use of transgenic mouse models and molecular tools. Hence, the goal of this study was to investigate the neuroanatomy, neurochemistry, and functionality of the SEG in male mice. Adult male C57Bl/6 adult mice were perfused and spinal cord sections were immunoprocessed for galanin, a marker for LSt cells. LSt cells were found to be distributed at L3 and L4 spinal levels in grey matter surrounding the central canal, a pattern similar to that observed in rat and human SEG. Moreover, LSt cells co-localized galanin, CCK, and GRP, and neurokinin-1 and androgen receptors. As in rats, LSt cells made axonal connections with choline acetyltransferase-positive autonomic and motor neurons. Using unilateral hemisection at the lumbar level, it was demonstrated that LSt cells also project to the thalamic parvocellular subparafascicular nucleus. To establish the functional involvement of the mouse SEG, male mice were perfused after different elements of mating behavior for visualization of LSt cell neural activation. Ejaculation, but not mounts or intromissions, induced cFos activation of LSt cells. Finally, a commonly used paradigm to study ejaculatory reflexes was investigated: the dorsal nerve of penis (DPN) was stimulated in anesthetized and spinalized male mice and penile striated muscle EMG was recorded. DPN stimulation yielded bursting of the bulbocavernosus muscle. However, the stimulation parameters required and the characteristics of the bursting patterns slightly differed from those used and observed in male rats. Together, these findings show that the morphological and physiological characteristics of

mice SEG are similar to those found in rats and humans and thus allow for the use of mouse models to study the SEG.

Title: Contusion spinal cord injury decreases glutamatergic axon inputs to spinal ejaculation generator in male rats

Authors: *K. K. SONI[1], J. E. SLEDD[2], J. W. WIGGINS[3], L. M. COOLEN[4]
[2]Physiol. & Biophysics and Neurobio. & Anatom. Sci., [3]Neurosci., [4]Physiol. & Biophysics, [1]Univ. of Mississippi Med. Ctr., Jackson, MS

Abstract: Spinal cord injury (SCI) is a devastating trauma leading to widespread disruption of motor, sensory, and physiological functions, including an-ejaculation in >85% of SCI patients. Regaining sexual function is of high priority to SCI patients. Ejaculation is a reflex controlled by a spinal ejaculation generator (SEG), consisting of a population of lumbar spinothalamic cells (LSt cells) in lumbar 3-4. LSt cells convert sensory inputs during sexual activity into coordinated autonomic and motor output required for ejaculation. We recently demonstrated that sensory stimulation was unable to trigger ejaculatory reflexes in male rats with contusion injury, suggesting a similar severe ejaculatory dysfunction as in human patients. Sensory inputs critical for ejaculatory function originate from the dorsal penile nerve and trigger ejaculation via activation of glutamatergic receptors expressed in LSt cells. Therefore, we hypothesize that SCI causes a disruption of glutamatergic inputs to the spinal ejaculation generator, thereby disrupting the relay and processing of sensory signals required to trigger ejaculation. Male Sprague Dawley rats received a contusion injury at spinal levels T6-7 or a sham surgery. Locomotor activity was recorded weekly and confirmed a moderate deficit in locomotor activity in SCI animals. Six weeks following contusion or sham injury, animals were perfused and spinal cords were immunohistoprocessed for galanin (LSt cell marker), synaptophysin (axon terminal marker), and either vesicular glutamate transporter 1 (Vglut1) or 2 (Vglut2). Confocal analysis was conducted to quantify the putative synaptic inputs to LSt cells. Results showed that SCI did not alter the numbers of galanin-positive cells, hence did not ablate LSt cells. However, SCI significantly reduced both VGlut1- and VGlut2-inputs to LSt cells. In contract, SCI did not affect galanin-inputs on LSt cells, suggesting that LSt cell connections to other LSt cells remained intact.

Finally, SCI did not affect the numbers of synaptophysin-only inputs to LSt cells. The latter finding is somewhat surprising as it suggests that SCI did not impact supraspinal inputs onto LSt cells. However, at this time, the supraspinal inputs to LSt cells are unidentified and thus remain an area of active investigation. Together, these data suggest that SCI impairs excitatory glutamatergic inputs to LSt cells, which in turn contribute to the loss of sensory processing and ejaculatory dysfunction. Future studies will confirm if Vglut2 along with Vglut1 is expressed in dorsal penile nerve afferents.

Title: Effects of contusion spinal cord injury on neuropeptide expression in the spinal ejaculation generator in rats

Authors: *J. W. WIGGINS[1], J. E. SLEDD[2], L. M. COOLEN[3]
[1]Program in Neurosci., [3]Dept. of Physiol. & Biophysics, [2]Univ. of Mississippi Med. Ctr., Jackson, MS

Abstract: Spinal cord injury (SCI) causes sexual dysfunction including anejaculation in men. Ejaculation is a spinal reflex controlled by a spinal ejaculation generator (SEG) located in the lumbosacral spinal cord. The SEG is comprised of a population of lumbar spinothalamic (LST) neurons located in the L3 - L4 spinal cord, lateral to the central canal in lamina X and VII. LST neurons express the neuropeptides gastrin releasing peptide (GRP), galanin, enkephalin and cholecystokinin. These neurons control ejaculation via intraspinal connections to autonomic and motor nuclei, where all four neuropeptides are released from LST axonal projections to trigger ejaculation. We have previously shown that chronic contusion injury impairs ejaculation in male rats 4-6 weeks after injury. Here, we tested the hypothesis that contusion injury causes a disruption of the neuropeptides that are expressed in LSt cell bodies and their axonal projections to autonomic and motor nuclei. Male Sprague Dawley rats received either a contusion or sham surgery at spinal levels T6-7. Six weeks later, animals were perfused, and spinal cords were immunoprocessed for galanin and GRP for cell counts, and for galanin, choline acetyl-transferase (ChAT) and synaptophysin for axon projection analysis. Results show that numbers of cells immunoreactive for galanin are not altered by SCI, suggesting that LSt cells are not ablated by SCI. In addition, preliminary analysis of numbers of galanin on ChAT positive cell

soma in the sacral parasympathetic nucleus showed no reduction in LSt projections to this nucleus after SCI. In contrast, GRP immunoreactivity was decreased in LSt cells following SCI, evident by fewer GRP and galanin/GRP dual labeled cells. To further investigate this specific loss of GRP expression in LSt cells, an in-situ hybridization analysis was conducted. Male rats received SCI or sham surgery and were perfused 8 weeks later. Lumbar spinal cord tissue was sectioned and galanin and GRP mRNA visualized using dual fluorescent RNAscope. Immunofluorescent signal for galanin and GRP mRNA was imaged by confocal microscopy and optical density analysis was performed in ImageJ. Preliminary results showed that SCI caused reduction in both GRP and galanin mRNA in SCI animals compared to controls. In conclusion, chronic contusion injury decreased neuropeptide expression for galanin and GRP in the SEG, with a marked reduction in GRP peptide localization. Since both peptides have facilitative roles for ejaculation, such loss may contribute to ejaculatory dysfunction following SCI.

Title: Correlation or causation - nociceptive fiber sprouting and spinal cord injury induced neuropathic pain?

Authors: *C. SLIWINSKI, M. MOTSCH, N. WEIDNER, R. PUTTAGUNTA
Spinal Cord Injury Center, Lab. for Neuroregeneration, Univ. Hosp. Heidelberg, Heidelberg, Germany

Abstract: A large proportion of patients suffering from spinal cord injury (SCI) develop neuropathic pain (NP). Despite its frequently severe and disabling nature NP remains a largely unexamined consequence of SCI lacking effective treatment options.
Previously, we have shown that aberrant structural plasticity in primary nociceptive afferents is associated with the development of below-level NP after a moderate (50 kDyn) T11 spinal cord contusion injury in female C57BL/6 mice. In particular, peptidergic calcitonin gene related peptide expressing ($CGRP^+$) fibers showed a higher labeling-density in deeper laminae of the lumbar (L4-L6) dorsal horn. Initiation of sensorimotor activity either 7 days post-injury (dpi) or following the establishment of sensory alterations at 42 dpi, ameliorated mechanical allodynia and normalized CGRP-labeling density towards pre-injury levels (35 and 74 dpi).
To further understand if SCI-induced aberrant structural rearrangements arise prior to and may

be responsible for the development of NP, we took advantage of sensory neuron specific ($Na_v1.8$) SNS^{Cre}::$R26^{LSL\text{-}tdTomato}$ (SNS-tdTomato) mice to label all nociceptive fiber projections into the dorsal horn.
Using the same contusion model in female SNS-tdTomato mice, correlates of NP including mechanical allodynia and thermal hyperalgesia were analyzed in the hindpaws using behavioral pain measurements at varying timepoints post injury. Animals were compared at 7 and 21 dpi for nociceptive fiber density at the first time point when mechanical allodynia is reliably detectable and when it is fully established.
Similar to previous wildtype animals, SNS-tdTomato mice showed the SCI-induced aberrant mechanical and thermal sensation. Injured mice developed mechanical hypersensitivity to small-diameter von Frey filaments (0.16g) at 7 dpi, which was stable until the end of the experiment (ANOVA $p<0.001$, PLSD $p<0.0001$ at 21 dpi). Furthermore, SCI animals showed a significant decrease in the response latency to heat stimuli compared to sham mice (ANOVA $p<0.0001$; PLSD $p<0.0001$).
Analysis of $CGRP^+$ and $tdTomato^+$ fibers in deeper laminae (III-IV) of the dorsal horn indicated a higher labeling-density in SCI compared to sham mice both at 7 and 21 dpi (t-test, $p=0.0081$ for CGRP and $p=0.045$ for tdTomato at 7 dpi), suggesting that structural rearrangements in nociceptive fibers parallel the development of mechanical allodynia. To further specify the initiation point of these structural changes, SNS-tdTomato animals will be analyzed at 1, 3 and 5 dpi. Additionally the
ablation of these fibers will allow for the examination of their contribution to the development of NP following SCI.

Title: Neurite outgrowth on inhibitory substrate by delivering Y-27632 using polymeric nanocarriers

Authors: *S. SEBASTIAN[1], R. AMMASSAM VEETTIL[1], S. GHOSH[2], D. HYNDS[1]
[1]Texas Woman's Univ., Denton, TX; [2]Southeast Missouri State Univ., Cape Girardeau, MO

Abstract: The molecular mechanisms directing neurite outgrowth and regeneration involve both stimulatory and inhibitory influences. Chondroitin sulfate proteoglycan (CSPG) is an inhibitory molecule upregulated following spinal cord injury (SCI) and may contribute to unsuccessful axon regeneration. Previous studies have shown that CSPGs activate Rho GTPase and that inhibition of Rho kinase (ROCK) activity with Y-27632 reverses or reduces CSPG inhibition. We demonstrated that 50 to 400µM concentration of Y-27632 treatment resulted in increased neurite outgrowth in B35 cells. However, targeting therapeutics specifically to corticospinal motor neurons (CSMNs) that are damaged during SCI is challenging. To address these concerns, we have developed a bio-compatible polymer encapsulated magnetic nanocarrier system (PE-MNC) with a proven uptake preference by CSMNs compared to glial cells in rat mixed cortical culture. These thermo-responsive PE-MNCs have a diameter of 230nm at room temperature and 180nm at physiological temperature. In the present study, we are loading PE-MNCs with optimum concentration of Y-27632 and determining the release kinetics of Y-27632 at physiological temperature. Moreover, we are determining the neurite outgrowth of B35 cells and P0 rat CSMNs plated on patterned substrata of CSPG stripes by delivering Y-27632 using PE-MNCs. Following treatment, neurite outgrowth of B35 cells and CSMNs on inhibitory substrate is quantified and compared with that of cells treated with Y-27632 alone. Drug release kinetics from PE-MNCs are quantified using HPLC and neurite outgrowth is quantified using Nikon A1 confocal system. Together, these results will lead to the development of a potential nanocarrier system that can be used for targeted drug delivery to damaged CSMNs during SCI treatment.

Title: Modulating the EphB2-NMDA receptor interaction in superficial dorsal horn attenuates neuropathic pain following cervical spinal cord injury

Authors: *N. M. HEINSINGER, W. ZHOU, J. L. WATSON, A. FALNIKAR, E. V. BROWN, B. A. CHARSAR, M. B. DALVA, A. C. LEPORE
Neurosci., Thomas Jefferson Univ., Philadelphia, PA

Abstract: In a rodent model of cervical spinal cord injury (SCI), we examined the contribution of altered EphB2 receptor-NMDA receptor (NMDAR) interaction to both excitatory synaptic neurotransmission in the superficial dorsal horn (DH) and persistent neuropathic pain (NP). The development of NP occurs in a significant portion of individuals affected by SCI, resulting in debilitating and often chronic physical and psychological burdens. Importantly, this pathological pain is particularly refractory to treatment, urgently calling for the identification of mechanistic targets that both robustly regulate pathological pain and avoid the devastating effects of opioid based interventions. Hyperexcitability of DH circuitry ("central sensitization") is a major substrate for NP after SCI. Studies have shown that NP is linked to EphB/ephrinB signaling through potentiation of NMDAR function, suggesting that the EphB-NMDAR interaction may be an important target for control of SCI-induced NP. In particular, we previously reported that EphB2 activation stimulates a direct interaction between EphB2 and the NMDAR via a single extracellular amino acid of EphB2 (Y504), thus promoting NMDAR synaptic localization and excitatory synapse function. Using a rodent model of unilateral cervical contusion SCI, we observe a persistent at-level NP phenotype in the form of forepaw thermal hyperalgesia and mechanical allodynia. We find that EphB2 expression is upregulated in superficial lamina of the ipsilateral DH after cervical contusion in intact cervical regions caudal to the lesion (i.e. at the location of primary afferent input from the plantar surface of the forepaw). Confocal imaging reveals significantly increased co-localization of EphB2 and the GluN1 NMDAR subunit at vGlut1-positive synaptic sites in superficial DH neurons after cervical contusion, indicating an enhanced interaction between EphB2 and the NMDAR at putative excitatory glutamatergic synapses. Lastly, lentiviral shRNA knockdown of EphB2 via anatomically-targeted intraspinal DH injections performed at 7 days post-cervical contusion reversed already-established thermal hyperalgesia. Collectively, these findings suggest that enhanced EphB2 expression and EphB2-NMDAR interaction underlies alterations in excitatory synaptic transmission in the DH and consequently persistent NP following SCI.

Title: Promoting structural and functional reorganization of neuronal circuits after spinal cord injury

Authors: *A. TEDESCHI, M. LARSON, A. ANNETT, W. A. STALKER, W. SUN
Neurosci., The Ohio State Univ., Columbus, OH

Abstract: Spinal cord injury (SCI) causes devastating neurological deficits and long-term disability due to axon regeneration failure. We recently discovered that administration of a potent gabapentinoid commonly used to treat various neurological disorders, promotes robust regeneration of ascending sensory axons in adult mice by blocking Alpha2delta2, a neuronal receptor and intrinsic molecular brake of axon growth and regeneration. Here, we explored the possibility that the same treatment strategy may prove similarly effective in promoting structural plasticity and regeneration of descending motor pathways after a cervical SCI. We also provided evidence that enhanced assembly and function of motor connectivity promotes recovery of forelimb function after SCI. Our findings provide novel insight into structural and functional reorganization of neuronal circuits after SCI, facilitating the design of translational research aimed at regaining neurological functions after injury to the spinal cord.

Title: Myelin modulates macrophage inflammatory responses after spinal cord injury

Authors: *T. J. KOPPER[1], B. ZHANG[2], J. C. GENSEL[3]
[2]Spinal Cord and Brain Injury Res. Ctr. and the Dept. of Physiol., [3]Physiology, Spinal Cord and Brain Injury Res. Ctr., [1]Univ. of Kentucky, Lexington, KY

Abstract: Spinal cord injury (SCI) produces a chronic inflammatory state primarily mediated by resident microglia and infiltrating monocytes (here, collectively referred to as macrophages). These chronically activated SCI macrophages adopt a pro-inflammatory, pathological state that

continues to cause additional damage after the initial injury and inhibits recovery. While the pathological outcomes of this activation state after SCI are well documented, the mechanisms that drive this continued response are poorly understood. Previously we demonstrated that myelin debris directly stimulates M1 macrophages in-vitro (LPS and INF-gamma treated bone marrow derived macrophages) to potentiate their M1 responses as measured by IL10/IL12 cytokine profiles, reactive oxygen species production (ROS). After injury, macrophages clear and accumulate myelin debris long after injury, therefore we hypothesize that this is a key mechanism driving chronic pro-inflammatory macrophage activation after SCI. Here, we propose that the effects of myelin on M1 macrophages may be mediated though the activation of the enzyme cytosolic phospholipase A2 ($cPLA_2$). $cPLA_2$ releases arachidonic acid from cellular membranes. Free, active arachidonic acid invokes direct pro-inflammatory functions or, through synthesis pathways, forms various eicosanoids with pro-inflammatory properties. This is the basis for our central hypothesis that increased $cPLA_2$ activity in myelin laden SCI macrophages releases arachidonic acid thereby driving chronic SCI inflammation and tissue damage. Indeed, we have since identified $cPLA_2$ activity in myelin-laden macrophages in-vivo at 7 and 28 days after SCI. Further we have found that that chemical inhibition of this enzyme In-vitro reduces myelin's neurotoxic effects on macrophages, and reduces ROS production. Ongoing studies aim to definitively link this continued $cPLA_2$ activity to potentiated pro-inflammatory activation in myelin-loaded macrophages, and explore potential therapeutics to block these pathways after SCI.

Title: Moderate pain input, given within days of a contusion injury, can expand the area of hemorrhage and undermine behavioral recovery

Authors: *M. M. STRAIN[1,2], T. JOHNSTON[1], Y. J. HUANG[1], J. A. REYNOLDS[1], R. E. BAINE[1], J. A. DAVIS[1], M. K. HENWOOD[1], G. N. K. FAUSS[1], J. W. GRAU[1]
[1]Texas A&M Univ., College Station, TX; [2]U.S. Army Inst. for Surgical Res., San Antonio, TX

Abstract: Spinal cord injuries are often accompanied by injuries to other parts of the body (polytrauma). The impact of pain input on tissue loss and recovery can be modeled by applying a noxious stimulus (peripheral electrical stimulation at an intensity that engages pain fibers) or the application of the TRPV1 agonist capsaicin. In rats, electrical stimulation or capsaicin treatment a day after a contusion injury increases tissue loss (secondary injury) and impairs long-term recovery. Recent evidence suggests that pain input enhances tissue loss due to a breakdown of the blood-spinal cord barrier and an expansion of hemorrhage. Currently, little is known regarding the circumstances under which this effect emerges. The present study explored this issue by assessing how the effect of stimulation varies as a function of intensity, duration, and time since injury. Male Sprague Dawley rats received a moderate contusion injury at T12 using the MASCIS device. In Experiment 1, noxious stimulation (6 min of intermittent shock at an intensity of 1.5 mA) was applied 1, 4, or 14 days after injury and tissue was collected 3 hrs later. We found that stimulation 1-4 days after injury increased the infiltration of hemoglobin into the injury site. Stimulation 2 weeks after injury had no effect. Next, we assessed the minimum duration of stimulation that induces hemorrhage. A day after injury, contused rats received 14.4, 72, or 360 s of intermittent shock and tissue was collected 3 hr later. Only 72-360 s of shock induced hemorrhage. These shock conditions also produced an acute disruption in locomotor performance. Finally, we compared the effect of stimulation given at 0.17, 0.5, or 1.5 mA applied for 6 min a day after injury. Shocks at an intensity of 0.5 or 1.5 mA produced an acute disruption in locomotor performance and hemorrhage. The results suggest that even moderate pain input can affect the development of secondary injury.

Title: Acute CXCR4 blockage impairs spinal cord injury recovery

Authors: *A. TORRES ESPÍN[1], I. FRANCOS-QUIJORNA[2], J. AMO-APARICIO[2], A. SÁNCHEZ FERNÁNDEZ[2], R. LÓPEZ-VALES[2], K. FOUAD[1]
[1]Physical Therapy, Univ. of Alberta, Edmonton, AB, Canada; [2]Univ. Autonoma De Barcelona, Bellaterra, Spain

Abstract: Hematopoietic stem cell (HSC) recruitment from the blood into damaged tissue is a key component of physiological repair, contributing to the correct development of the wound healing process. Therefore, the pharmacological mobilization of HSC from the bone marrow to the blood has been proposed and studied as a treatment for several pathologies, including neurological disorders. The most successful approach in several published studies consists of blocking the chemokine receptor 4 (CXCR4), an essential regulator of the HSC residence in the bone marrow, to promote recovery. We were asking whether a similar recovery could be achieved in a rat model of spinal cord injury (SCI), and the answer seems to be NO. In fact, we found the opposite effect. Immediately after a thoracic contusion SCI in rats, the selective CXCR4 antagonist AMD3100 (or vehicle) was administered and the locomotion of the animals was studied for 4 weeks using the BBB rating score and kinematics. Here we show that indeed, immediate blocking of CXCR4 after SCI increases the mobilization of CXCR4+ cells into the blood analyzed by flow cytometry, but instead of improving motor recovery, it prevents it. Consequently, we conducted experiments to understand this phenomenon. For example, blocking CXCR4 might distort the cell mobilization and injury infiltration dynamics after SCI, affecting the process of scarring and damage control at the lesion site. CXCR4 is also involved in the niche and injury homing of several cell types beyond HSCs, including granulocytes, monocytes, lymphocytes, mesenchymal stem cells, pericytes and neural stem cells. Therefore, disturbing the physiological process that 'fights' against tissue degeneration after SCI by blocking CXCR4 can enlarge the damage, ultimately reducing functional recovery.

Title: Gene expression changes in ascending dorsal column sensory neurons after spinal cord injury

Authors: *E. E. EWAN, M. MAHAR, D. CARLIN, V. CAVALLI
Neurosci., Washington Univ. in St. Louis, Saint Louis, MO

Abstract: Spinal cord injury (SCI) damages long projecting axons leading to loss of sensory and motor function. In contrast, injury to the peripheral branch of dorsal root ganglion (DRG) sensory neurons leads to axon regeneration and functional recovery, mostly through the activation of a pro-regenerative program. Many studies indicate that SCI fails to activate a pro-regenerative program in DRG neurons, which consequently do not regenerate their centrally projecting axons after injury. Our understanding of the extent to which, if any, DRG sensory neurons produce a pro-regenerative response following SCI is limited by the fact that previous studies have analyzed whole lumbar DRG responses to SCI. Since most lumbar DRG neurons synapse locally upon entering the spinal cord, a very small percentage of DRG neurons ascend the spinal cord dorsal column and are injured after thoracic SCI. Furthermore, neurons account for 10% of all cells within the DRG. To address this problem, we analyzed the transcriptional response of proprioceptive and low threshold mechanoreceptive (LTMR) L4 DRG neurons after thoracic SCI or sciatic nerve crush injury (SNC). We used FACS sorting of YFP positive L4 DRG neurons from the YFP16 mouse line, in which YFP is expressed in proprioceptive and LTMR sensory neurons, followed by RNAseq analysis. We found that more genes were upregulated after SNC than SCI; yet several unique gene clusters were differentially expressed after SCI compared to PNS injury. Gene ontology analysis of these gene clusters specific to SCI revealed upregulation of transcription factor activity and DNA binding, as well as downregulation of some genes associated with actin binding. As expected, we found that many known regeneration-associated genes had increased upregulation after PNS injury (e.g., ATF3, Jun, Sox11 and SCG10) than after SCI. These results indicate that DRG neurons can respond to an injury to their central axon, albeit to a different extent than after PNS injury. Future studies will assess whether these differentially expressed genes contribute to the lack of a pro-regenerative response after SCI, and whether they can be manipulated to promote axon regeneration.

Title: The role of arginase in macrophage-mediated repair in spinal cord injury

Authors: K. M. MCFARLANE[1], M. B. ORR[1], W. M. BAILEY[1], B. ZHANG[2], T. E. OTTO[1], *J. C. GENSEL[1]

[1]Physiology, Spinal Cord and Brain Injury Res. Ctr., Univ. of Kentucky, Lexington, KY; [2]Col. of Publ. Hlth., Shaanxi Univ. of Chinese Med., Xianyang, China

Abstract: CNS macrophages activated by spinal cord injuries (SCI) have both reparative and pathological properties. Pro-inflammatory (also called M1) macrophages predominate and typically cause neurotoxicity. Anti-inflammatory macrophages (also called M2) are transient and promote axon growth and remyelination. Driving macrophage activation towards anti-inflammatory phenotypes enhances SCI recovery, but the underlying basis of the improvement is not yet fully comprehended. Discerning the mechanism of this macrophage-mediated repair is vital since macrophages express great plasticity and adapt their phenotype in response to microenvironmental cues. Arginase-1 (Arg1) is a hallmark of anti-inflammatory macrophage activation. Arg1 diverts arginine from iNOS to reduce the toxic potential of nitric oxide, a harmful free radical. In addition, byproducts of arginase-mediated arginine breakdown increase axon growth and cellular repair. We hypothesize that the reparative effects of anti-inflammatory macrophages are dependent on the production of Arg1. To test our hypothesis, we generated macrophage-specific arginase knockout animals. Further, azithromycin (AZM) is a macrolide antibiotic with anti-inflammatory characteristics that directly alters macrophage activation. SCI mice treated with AZM have improved functional recovery concomitant with increased anti-inflammatory macrophage activation. Therefore, we used AZM, in combination with our KO animals, to determine the role of arginase in immunomodulatory therapies for SCI. We observed that the efficacy of AZM treatment for reducing pro-inflammatory macrophage-mediated neurotoxicity is dependent upon arginase expression. Ongoing studies are evaluating the long-term (28dpi) effects of knocking out macrophage arginase in SCI recovery and AZM treatment in vivo. Understanding the anti-inflammatory mechanism of macrophage activation will offer novel therapeutic strategies for treating SCI.

Title: Enhancing corticospinal regeneration after spinal cord injury

Authors: *E. V. VAN NIEKERK[1], G. H. POPLAWSKI[2], R. KAWAGUCHI[3], G. COPPOLA[3], M. H. TUSZYNSKI[4]
[1]Neurosciences, UCSD, San Diego, CA; [2]Med., Natl. Univ. of Singapore, Singapore, Singapore; [3]Neurol., Univ. of California San Diego, Los Angeles, CA; [4]Univ. of California San Diego Dept. of Neurosciences, La Jolla, CA

Abstract: The corticospinal tract (CST) is the most important voluntary motor projection in humans and is particularly refractory to regeneration after spinal cord injury (SCI). Recently we reported that CST axons regenerate into neural progenitor cell (NPC) grafts of spinal cord identity placed into sites of SCI. Here we aim to identify transcriptional mechanisms associated with active CST growth and regeneration after SCI. We have successfully isolated the translational profile of growing CST neurons by polyribosome purification from the Glt25d2-BAC-TRAP mouse line. mRNAs actively bound to the ribosome were immunoprecipitated and purified from the motor cortex 10 days, 14 days, and 21 days after injury with or without an NPC graft, constructing a CST transcriptome library to reveal early master regulators responsible for regeneration, followed by effector molecules involved in axon attachment and growth. The CST regenerating transcriptome was compared to the non-regenerating transcriptome where a distinct regeneration profile was identified. We next aim to test the hypothesis that drug-based amplification of the transcriptional growth state will significantly enhance CST growth and regeneration *in vitro* and *in vivo*. To address this we developed a medium-throughput *in vitro* screening system of postnatal day 12 cortical neurons isolated from the UchL1-GFP mouse line in which CST neurons are GFP positive within the motor cortex. We have successfully established a methodology to culture CST neurons *in vitro* where *in silico* signatures of CST regeneration will help identify perturbagens that promote growth.

Abstract: Spinal Cord Injury (SCI) pathophysiology can be attributed to either primary physical injury or the delayed, secondary injury cascades which begins after the initial injury and can persist for several months. A better understanding of the secondary injury mechanisms is essential in developing potential therapies to prevent damage, increase neuroprotection, restore metabolic deficits and finally promote functional recovery following SCI. Indeed, previous studies have shown that a dysregulated metabolism and energetic deficits linked to mitochondrial bioenergetics deficiencies are severely affected after SCI. Thus, neuroprotection and reduced oxidative stress are associated with improved cellular bioenergetics. In this regard, cerebral metabolism of ketones after traumatic brain injury (TBI) it's been previously shown to improve secondary neuropathology by decreasing oxidative stress, increasing antioxidants, and reducing inflammation. Previous work in our lab has shown the neuroprotective and improved behavioral effects of KD after SCI in rats. We hypothesized that ketogenic diet (KD) a high fat, low carbohydrate diet that is been already validated as non-pharmacological treatment for some forms of drug-resistant epilepsy will improve mitochondrial function after SCI. Using a C5 hemi-contusion model in adult male rats we examined the states of mitochondrial respiration and assessed the different components of the electron transport system (ETS). Starting 4 hours following C5 hemi-contusion injury, animals were fed either a standard control diet (SD) or KD. As expected, mitochondrial function was reduced after SCI. However, administration of KD increased mitochondrial biogenesis and partially rescued function of Complexes I, II, and III at 7 days after SCI. KD also triggered changes in the activity and total expression levels in kinases and transcription factors (i.e. mtFAM, ERK1/2, NRF2) involved in signaling pathways previously associated with the activation of the nuclear and mitochondrial transcription machinery. Consequently, these changes might induce an increase in the synthesis of ETS components and antioxidants which could explain the partial bioenergetics recovery observed in our SCI model. Moreover, we observed an increase in the neuronal marker NeuN in the animals treated with KD, suggesting that a neuroprotective effect could also be contributing the bioenergetics rescue. In summary, KD improves the post-SCI metabolism by rescuing mitochondrial bioenergetics dysfunction and might be a beneficial treatment for acute SCI.

Title: Opioid-immune interactions after SCI

Authors: *M. N. TERMINEL, K. BRAKEL, M. HOOK
Neurosci. and Exptl. Therapeut., Texas A&M Hlth. Sci. Ctr., Bryan, TX

Abstract: Opioids are among the most effective and commonly prescribed analgesics for the treatment of acute pain after spinal cord injury (SCI). We have shown, however, that morphine administration in the early phase of SCI undermines locomotor recovery in a rodent contusion model. We found that the adverse effects of morphine appear to be mediated by activation of Kappa Opioid Receptors (KORs). In addition, inhibiting glial activation with minocycline blocks the morphine-induced attenuation of locomotor function. We hypothesize that morphine acts on classic opioid receptors on immune cells to produce excitotoxicity. To test this, we used flow cytometry to determine whether morphine increases the innate immune response after SCI. First, subjects were given a moderate spinal contusion injury. On the day following surgery, half of the subjects were treated with morphine (i.v.) for 1, 3, or 7 days. The remaining subjects served as controls, receiving an equivalent volume of 0.9% saline. Subjects were euthanized on days 2, 4, or 8 (24 hrs after the final dose of morphine). A 1.5 cm section of injured spinal cord was collected and the tissue was enzymatically and mechanically dissociated. Cells were incubated with antibodies to identify macrophage and microglia populations. Additional antibodies were included to differentiate between M1 (pro-inflammatory) and M2 (anti-inflammatory) microglia and macrophages, as well as antibodies for the KOR. Our results indicate that higher numbers of macrophages and microglia can be detected as early as 3 days after morphine administration, relative to saline-treated controls. In addition, morphine increases the expression of KORs on the immune cells. Given the clinical utility of opioid analgesics, it is imperative that we fully understand the effects of morphine in mediating the immune response after SCI. We must develop safe and effective therapeutic strategies for the use of opioids in pain management after SCI.

Title: *In vivo* validation using CRISPR/Cas9 of a putative downstream effector of notch expressed in neurons

Authors: *A. LEONARD, R. EL BEJJANI
Davidson Col., Davidson, NC

Abstract: The highly conserved Notch signaling pathway is required for neuronal differentiation, and it inhibits axon regeneration. The mechanism of function of Notch in some of these neuronal processes is has not been elucidatednow well understood. Using CRISPR/Cas9, we sought to replace the promoter of a putative downstream effector of Notchlin-10/X11, a putative downstream effector of Notch, in order to determine if Notch plays a role in its expressiondescribe the putative regulation by Notch. Our gene of interest, *lin-10*, was chosen due to its significant number of LAG-1 binding sites, coupled with data suggesting that *lin-10* inhibits regeneration. Our goal is to generate two new strains. First, weWe will first, want to delete the *lin-10* promoter using CRISPR/Cas9 genome editing. Second, weWe will then want to replace the promoter with a promoter containing scrambled LAG-1 binding sites. This would allow us to test for a potential connection between Notch and *lin-10* expression *in vivo*. Our initial attempts at deleting the promoter failed. Using a dual-guide RNA approach, we consistently made only one double stranded cut resulting in Indels at the *lin-10* locus but no large deletions. This was confirmed by PCR in 40 strains of injected worms. We have since moved on to new strategies that we hope will produce large deletions. We are using a dual-guide RNA system with the addition of a repair oligo that spans the cut sites, but screening for successful deletions with this strategy has been labor intensive. For this reason, we are also designingmaking use of as a self-excising cassette that, if inserted, should facilitate the process of screening for deletions. We would like to obtain two separate mutants, however, If these strategies to delete and then replace the *lin-10* promoter do not work, we may will resort to trying to replace the promoter all in one step using a SEC described by *Dickinson et al 2015*. This is a last resort for us because we believe a two-step process that gives us both a large deletion and a scrambled promoter strain will be valuable for assessing the interaction between Notch, *lin-10*, and axon regeneration. This work will be important for furthering the understanding of the Notch signaling pathway's effect on axon regenerationmay identify LIN-10/X11 as a novel downstream effector of Notch signaling in neurons.

Title: The spinal transcriptome after cortical stroke — In search of target-derived molecular factors regulating spontaneous compensatory axon growth in the spinal cord

Authors: *J. KAISER, M. A. MAIBACH, I. SALPETER, M. E. SCHWAB
Brain Res. Inst., Zuerich, Switzerland

Abstract: Functional improvements, if they occur, are mostly seen within the first few weeks to months after the stroke in human stroke survivors, highlighting a period of heightened plasticity early after injury. Reorganization of the motor circuitry has been causally linked to the improved outcome in stroke patients, primates as well as rodents. After a large insult to the motor areas of one hemisphere in adult mice, the contralesional corticospinal tract (CST) re-innervates the stroke-denervated hemicord by growing new collaterals across the midline, e.g. on cervical levels of the spinal cord. The underlying molecular mechanisms of growth induction, midline crossing and target innervation of these adult, fully differentiated and functionally integrated CST fibers are yet unclear. In adult mice, following a large insult to the motor cortex, CST sprouting on cervical levels C5-C6 revealed the primary target area of the re-innervating CST fibers as the intermediate pre-motor laminae (Lam5-7). This area was analyzed for gene expression changes after stroke at time points corresponding to key events of post-stroke structural plasticity: initiation of sprouting (4+7dpi), growth phase (14dpi), maximal sprout density (28d) and pruning phase (42dpi). RNA-Seq (Illumina Hi-Seq) reads were mapped to the mouse genome and quantified for differential expression analysis. Genes were ranked by their fold change to controls, and differentially regulated genes for each time point were identified. This unbiased approach allows for evaluation of the spinal transcriptome in response to de- and re-innervation. The differentially regulated transcriptomes were further analyzed using network enrichment analysis, revealing two phases within the spinal target area of re-innervating CST fibers: (1) an early inflammatory phase (4-7dpi), during which activation of microglia in the pre-motor spinal layers can be observed; and (2) a highly dynamically regulated late phase during which molecules involved in tissue repair processes dominate (28-42dpi). Here, differentially up-regulated genes include molecules that are able to rescue neurite outgrowth under inhibitory conditions. These results show that the stroke-denervated spinal grey matter, in particular its intermediate, premotor laminae, express growth factors and represent a growth-promoting environment for sprouting CST fibers originating from the contralesional motor cortex.

Title: TGF-ß1 as a modulator of structural plasticity after large motor cortex stroke

Authors: *M. A. MAIBACH[1,2], J. KAISER[2], I. SALPETER[2], E. PIOVESANA[2], M. E. SCHWAB[2]
[1]Zuerich, Switzerland; [2]Brain Res. Inst., Zurich, Switzerland

Abstract: Functional recovery of skilled forelimb movements after a large insult to the primary motor and premotor cortex involves activation of the contralateral hemisphere with the contralesional corticospinal tract growing new collaterals across the midline into the denervated hemicord on cervical levels of the spinal cord. The underlying molecular mechanisms of growth induction, midline crossing and target innervation ofthese adult, fully differentiatedand functionally connectedcorticospinal tract (CST) fibres are yet unclear. In the current study, we observed an upregulation of gene expression of transforming growth factor ß1 (TGF-ß1) within the stroke-denervated spinal cord at early time points after stroke. In vitro analysis revealed that TGF-ß1 robustly rescues neurite outgrowth in a growth inhibitory environment and signals via the canonical ALK5/SMAD3 axis. Furthermore, we show crosstalk between TGF-ß1 elicited signaling and the inhibitory neurite outgrowth modulator RhoA. These results suggest a regulatory role for TGF-ß1 in the context of post-stroke structural plasticity. Viral overexpression within the spinal cord grey matter allows for assessment of the effect of TGF-ß1 on re-innervation of the stroke-denervated spinal hemicord by contralesional CST fibres and causally linked functional recovery. Additionally, a corticospinal tract specific ablation of TGF-ß1 signalling by knock-down of TGFß-RII will allow to assess the effect of TGF-ß1 on structural CST plasticity directly.

Title: The voltage-gated proton channel Hv1 impairs recovery after mouse spinal cord injury through NOX2/ROS signaling

Authors: M. MURUGAN[1], J. ZHENG[2], Y. LI[3], J. HE[5], B. SABIRZHANOV[6], L.-J. WU[7], *J. WU[4]

Abstract: The voltage-gated proton channel Hv1 is a recently cloned ion channel that rapidly removes protons from depolarized cytoplasm and is highly expressed in the immune system. Hv1 is required for high-level NADPH (NOX)-dependent ROS (reactive oxygen species) production during the phagocyte respiratory burst. Excessive NOX2/ROS production is known to be critical in the pathophysiology of spinal cord injury (SCI) as it non-selectively damages neurons and glia. We previously reported that in the CNS, Hv1 is expressed by microglia but not neurons or astrocytes in the mouse brain. Microglial Hv1 regulates intracellular pH and aids in NOX2-dependent generation of ROS. Thus, Hv1 is a unique target for controlling multiple NOX activities and ROS production. In mouse models of brain ischemia, our studies point to an acute neuroprotection phenotype in Hv1 knockout (KO) mice. However, neither the precise cellular mechanisms underlying this finding nor critical role of Hv1 in the pathophysiology of SCI are fully understood. In the present study we report a rapid and persistent up-regulation (40 folds) of Hv1 mRNA up to 28 days in the injured spinal cord after a moderate contusion. This was confirmed in CD11b-selective microglia/macrophages isolated from adult spinal cord tissue at 3 days post-injury. Western blot (WB) and immunohistochemistry (IHC) showed that SCI elevates Hv1 protein expression predominantly in microglia/macrophages. Hv1 KO mice exhibited significantly attenuated NOX2/ROS production, IL-1β signaling, and neuronal cell death at 3 and 7 days post-injury. Increased spare white matter in Hv1 KO mice is correlated with improved motor function. Furthermore, mice lacking Hv1 appeared reduced mechanical/thermal hyperesthesia after SCI. Taken together our data suggest an important role for Hv1 in regulating NOX2/ROS-mediated functional damage post-SCI. Thus, Hv1 represents a potential therapeutic target that may lead to novel clinical therapeutic strategies.

Title: Activation of cPLA2 contributes to lysosomal defects leading to impairment of autophagy after spinal cord injury

Authors: *Y. LI[1], J. W. JONES[3], C. SARKAR[1], M. A. KANE[3], E. Y. KOH[2], M. M. LIPINSKI[1], J. WU[1]
[1]Dept. of Anesthesiol. & Ctr. for Shock, Trauma and Anesthesiol. Res. (STAR), [2]Dept. of Orthopedics, Univ. of Maryland, Sch. of Med., Baltimore, MD; [3]Dept. of Pharmaceut. Sci., Univ. of Maryland, Sch. of Pharm., Baltimore, MD

Abstract: The autophagy-lysosomal pathway plays an essential role in cellular homeostasis and a protective function against a variety of diseases. However, under certain circumstances pathologically increased autophagy can contribute to cell death. This may occur particularly when lysosomal function is impaired and autophagic degradation is not able to proceed to completion, leading to pathological accumulation of dysfunctional autophagosomes. We have previously shown that autophagy is inhibited and contributed to injury after contusion spinal cord injury (SCI). Here we examine mechanism of autophagy and lysosomal defects following SCI. Expression levels and processing of the lysosomal enzyme cathepsin D (CTSD) were decreased at 2h after SCI. Enzymatic activity of CTSD and another lysosomal enzyme, alkaline phosphatase, were decreased 24h post-injury, indicating lysosomal damage. Sub-cellular fractionation confirmed lysosomal membrane permeabilization (LMP) and leakage of lysosomal content into the cytosol. cPLA2 is an enzyme that cleaves fatty acyl linkage in the phospholipids of cellular membranes and increased activity of cPLA2 may be involved in membrane damage. cPLA2 was activated in the lysosomal fraction, accompanied by increased accumulation of the autophagosomal marker LC3-II and its substrate p62. To directly assess the extent and mechanism of damage to lysosomal membranes, mass spectrometry (MS)-based lipidomics was applied to compare the lipid composition of lysosomal membranes purified from sham or injured spinal cord at 2h post-injury. Our data demonstrate increases in several classes of lysosophospholipids- the products of phospholipases (PLAs), as well as accumulation of PLA activator, ceramide. Inhibition of cPLA2 decreased lysosomal damage, restored autophagic flux, and reduced neuronal cell damage. Taken together our data implicate lysosomal defects in the pathophysiology of SCI and further indicate that cPLA2 activation leads to lysosomal damage

that causes neuronal autophagosome accumulation associated with neuronal cell death.

Title: Characterization of the transcription factor network underlying regeneration reveals novel intrinsic inhibitors

Authors: *Y. CHENG[1], A. ZHANG[2], K. GAO[2], A. BERNSTEIN[2], V. CHANDRAN[1], C. J. WOOLF[3], M. V. SOFRONIEW[4], D. H. GESCHWIND[2]
[1]Neurol., [2]UCLA, Los Angeles, CA; [3]Neurobio., Children's Hosp. Boston, Boston, MA; [4]UCLA Schl Med., Los Angeles, CA

Abstract: Central nervous system (CNS) neurons display highly restricted regenerative capacity compared to their peripheral nervous system (PNS) counterparts and insufficient cell intrinsic growth program contributes to this. We have comprehensively analyzed large scale transcriptomic data from regenerating PNS neurons to identify a transcriptional program associated with regeneration, linking multiple known pathways via a set of core transcription factors (TF). To further characterize the regulatory hierarchy, we used a mutual information based network analysis to compare multiple PNS and CNS injury data sets to identify a core set of five TFs (Jun, STAT3, SOX11, SMAD1, and ATF3) that was preserved across all PNS datasets, but not in the CNS datasets. We observed that two TFs, REST and CTCF, interacted with top-tier TFs in the CNS, but not the PNS, which bio-informatics predicted would disrupt the core regenerative network, thus limiting intrinsic regenerative capacity. We first tested this hypothesis *in vitro* via REST overexpression or deletion experiments in dorsal root ganglia (DRG) neurons. Indeed, REST over-expression inhibited neurite outgrowth, while REST deletion enhanced neurite extension of DRG neurons cultured on CSPG, a growth-inhibitory molecule increased in CNS injured tissue. To further investigate the role of REST in CNS regeneration in vivo, we induced a conditional deletion of REST in mouse cortex, followed by complete spinal cord lesion and anterograde labeling of corticospinal tract (CST) axons. Conditional deletion of REST led to significantly more CST axons proximal to the lesion site that also express more growth associated proteins, including GAP43, indicating that REST deletion promotes axon growth after injury. Lastly, we sorted and profiled the injured CST neurons with or without REST deletion to determine whether regeneration related pathways were

upregulated in regenerating axons. In conclusion, using integrative functional genomics approaches, we identified a hierarchical TF regulatory network underlying regeneration, and potential putative regulators, including REST, which was predicted to inhibit the pro-regenerative components of the network. These data provide a proof of principle and formal experimental testing of network predictions, showing how gene networks can be used to discover effective drugs for neural repair.

Title: Heterogeneous secondary injury response following traumatic injury at different levels of the spine

Authors: *J. HONG[1], M. CHAMANKHAH[2], A. CHANG[2], A. BADNER[2], M. ZAVVARIAN[2], C. AHUJA[2], M. FEHLINGS[2]
[1]Genet. and Develop., Krembil Res. Inst., North York, ON, Canada; [2]Genet. and Develop., Krembil Res. Inst., Toronto, ON, Canada

Abstract: Purpose: Cervical spinal cord injury (cSCI) accounts for the majority of SCI cases, frequently resulting in tetraplegia and poor outcomes. To date, the majority of pre-clinical research into SCI has utilized animal models harboring injuries in the thoracic spinal cord (tSCI). However, anatomical differences in the vascularization and susceptibility to blood-spinal cord-barrier (BSCB) disruption exist between cSCI and tSCI. This, in conjunction with clinical observations of spinal cord level-specific heterogeneity in response to surgical and pharmacological intervention, warrants a rigorous delineation of the differential vertebral level-specific molecular pathology of SCI.
Method: Female Wistar rats were subjected to moderate-severe clip-compression SCI to the C6-7 and T6-7 spinal cord with level and time-matched laminectomized shams serving as controls. The rats were then sacrificed at 3, 7, 14, and 56 days post-surgery. Ultrasound and Power Doppler imaging was used to assess the gross pathology of the injured cord. RNA sequencing was used to evaluate the genome-wide changes over time. Protein analyses were performed using Western blotting and ELISA, while tissue level work was done using immunohistochemistry.
Results: We have observed striking variability in the formation of the cystic cavity and hemorrhage after cSCI and tSCI as early as 3-days post-SCI. Moreover, RNA-sequencing at this time-point identified over 1500 genes differentially expressed (DEGs) between cSCI and tSCI.

By cross-referencing recently published single-cell RNA-sequencing databases, we mapped these DEGs and found the majority to be associated with structural and functional components of astrocytes and pericytes—both key regulators of the BSCB. We then surveyed each component of the neurovascular unit and found baseline reductions in pericyte coverage within the cervical cord along with rapid contractile pericyte differentiation exclusively in cSCI—a hallmark of BSCB disruption. Moreover, there was a striking loss of ZO1, occludin and claudin-5, all key tight junction (TJ) proteins of the BSCB in cSCI, but not tSCI.
Conclusions: Collectively, these findings provide strong evidence that acute tissue loss in cSCI compared to tSCI may be a result of an increased anatomical susceptibility to BSCB disruption, and that the mitigation of acute BSCB disruption may be—hierarchically—a better upstream therapeutic target than the current immune and neuroprotective strategies in trial.

Abstract: Spinal cord injury (SCI) results in cell death, demyelination, and axonal loss. The spinal cord has a limited ability to regenerate and current therapies for SCI are not efficacious. Encouraging results using epidural electrical stimulation (EES) to elicit volitional control of motor function in humans with SCI has been largely attributed to the presence of functionally silent fibers and to the combination of EES with locomotor training. Currently there is limited knowledge on the mechanisms underlying EES efficacy. This limitation is partially due to a lack of a SCI animal model that represents humans clinically diagnosed with complete spinal cord

injury, who possess functionally silent connections. Another area of investigation has been the use of biodegradable scaffolds to fill areas of lost tissue. Our lab has developed a novel hydrogel scaffold composed of oligo(poly(ethylene glycol) fumarate) (OPF) in a multichannel design. The transplantation of these scaffolds seeded by glial cell derived neurotrophic factor (GDNF) secreting Schwann cells or containing rapamycin microspheres and Schwann cells aid recovery after injury in rats. These studies demonstrate that a combinatorial approach to therapy is likely to have the most beneficial effect given the heterogenic nature of SCI pathophysiology. In this study we combined EES with scaffolds incorporated with rapamycin and GDNF secreting Schwann cells implanted in rats with complete thoracic (T9) spinal cord transection. We hypothesized that electrical field applied within the region of regeneration (T8 and T10) and at the locomotor circuitry (S1 spinal segment) below the injury would increase neural tissue reconnection through the scaffold and improve motor function in rats following injury. Our results show consistent motor evoked responses in hind limb muscles when stimulating rostral to the injury level by 2 weeks post-implantation. These observations of regeneration across the scaffold were further confirmed when the spinal cord was transected a second time 6 weeks post initial SCI, which resulted in complete loss of EES-evoked activity across the scaffold implantation site. Open field evaluation of hind limb motor functions showed that combination of OPF scaffold and EES can facilitate functional recovery already at 1-2 weeks after transection. After re-transection at 4 weeks, rats hind limb motor function declined to levels that were not different from controls. These results suggest EES with hydrogel scaffolds containing GDNF expressing Schwann cells and rapamycin-releasing microspheres promotes functional reconnection across the spinal cord injury.

Abstract: Propriospinal neurons can relay functional information past incomplete spinal cord injuries (SCI) and are good candidates to target for restoring neural connectivity across anatomically complete SCI. Propriospinal neurons do not regrow spontaneously across complete SCI lesions and the molecular requirements to stimulate or improve such regrowth are not characterized. In this study we are examining, individually and in combination, various mechanisms with the potential to stimulate or improve propriospinal axon regrowth in both mice and rats, including (i) biomaterial depots that locally deliver axon-specific chemoattraction in the form of glial cell-derived growth factor (GDNF) that has previously been reported to stimulate propriospinal axon growth after SCI; (ii) inducing growth supportive extracellular matrix by increasing the local expression of laminin; and (iii) activating propriospinal neuron intrinsic growth programs by using adeno-associated viral vectors (AAV) to deliver manipulations previously reported to activate intrinsic growth programs of other central nervous system neurons. Title: Delaying pharmacological inhibition of spinal soluble tumor necrosis factor alpha (sTNFa) signaling diminishes the development of autonomic dysreflexia after complete high thoracic spinal cord injury

Authors: *E. MIRONETS[1], P. OSEI-OWUSU[2], V. BRACCHI-RICARD[4], R. FISCHER[4], T. M. SALTOS[3], E. COLLYER[3], J. R. BETHEA[4], V. J. TOM[3]

Abstract: Cardiovascular disease and peripheral immune dysfunction are two major causes of mortality and morbidity in people with spinal cord injuries (SCI). These consequences are attributed to the development of autonomic dysreflexia (AD), a life-threatening syndrome characterized by intense episodes of hypertension in response to sensory stimuli caudal to the injury. Over time, AD intensifies partly due to excitability driven by aberrant plasticity of circuits that participate in the spinal sympathetic reflex. Since sTNFa signaling has been correlated with neuronal hyperexcitability, we hypothesize sustained sTNFa signaling plays a crucial role in AD. We previously demonstrated that inhibition of sTNFa signaling via intrathecal administration of a sTNFa biologic (XPro1595) below a complete T3 transection (T3Tx) immediately post-SCI mitigates AD and attenuates consequent immunosuppression and vascular dysfunction. Here, we explored if delaying intrathecal XPro1595 administration for a more clinically-relevant timeframe of 3 days post-SCI also effectively diminishes AD and ensuing immune and vascular dysfunction. We found that XPro1595 rats had less severe colorectal distension-induced AD than saline animals for the duration of the experiment (up to 8 weeks post-T3Tx). To determine if this attenuated AD is associated with improved peripheral immune function, we extracted spleens for flow cytometric analysis of leukocytes 8 weeks post-SCI. We found that T3Tx-saline animals had splenic atrophy, suggestive of diminished immunity. T3Tx-XPro1595 had spleen weights that were undistinguishable from uninjured animals. These data suggest that spinal sTNFa signaling plays a critical role in AD development and ensuing peripheral consequences. In ongoing experiments, we are assessing whether mesenteric arteries from XPro1595-treated animals have more normal responses to vasopressors than saline-treated ones and how inhibiting sTNFa affects injury-induced plasticity of the spinal sympathetic reflex circuit (i.e. nociceptive primary afferents; sympathetically-associated interneurons) histologically. We will also assess the immune profile of rats with chronic SCI in response to a viral influenza. This will allow us to better understand how SCI rodents respond to an immune challenge. Furthermore, we will assess whether intrathecal XPro1595 treatment can improve the immune response to influenza. Collectively, our data provide further demonstration that the neuroimmune response plays a crucial role in the development of AD.

Title: Drug repurposing: High dose human intravenous immunoglobulin g for treatment of traumatic cervical spinal cord injury

Authors: *J. CHIO[1,2], J. WANG[1], A. BADNER[1,2], J. HONG[1,2], M. CHAMANKHAH[1], M. FEHLINGS[1,3]
[1]Genet. and Develop., Krembil Res. Inst., Toronto, ON, Canada; [2]Inst. of Med. Sci., [3]Neurosurg., Univ. of Toronto, Toronto, ON, Canada

Abstract: After spinal cord injury (**SCI**), neuroinflammation exacerbates damage from initial trauma. Severity of neuroinflamation depends on integrity of the blood-spinal cord-barrier (**BSCB**), which consists of astrocytes, pericytes and endothelial cells. After SCI, a compromised BSCB enhances neuroinflammation by facilitating immune cell migration. Through targeting neuroinflammation, immunosuppressants are used to treat SCI patients. However, as selective components of neuroinflammation are beneficial after SCI, immunomodulation is more effective than general immunosuppression. Human intravenous Immunoglobulin G (**hIgG**) is a clinically-approved immunomodulatory therapy for neuroinflammation. Although we have shown that administration of hIgG (0.4g/kg) at 15 minutes post-SCI is beneficial for functional recovery and tissue preservation, the optimal dose and mechanism of hIgG are unknown.
We use a clinically-relevant rat model of C7/T1 SCI, where female Adult Wistar rats received a 35 g clip compression-contusion injury. At 15 minutes post-SCI, a single bolus hIgG (0.02, 0.2, 0.4, 1, 2g/kg), methylprednisolone (0.03 g/kg, immunosuppressant) or vehicle was administered intravenously. Tissue was collected at 24 hours and six weeks post-SCI to evaluate hIgG's acute and chronic effects. Weekly functional assessments were performed to study functional recovery. At 24 hours post-SCI, hIgG co-localized with rat pericytes, astrocytes and endothelial cells in the spinal cord. Relative to hIgG (0.4g/kg), hIgG (2g/kg) achieved superior protective effects on spinal cord vasculature and reduced spinal cord inflammation. Intriguingly, despite the anti-inflammatory effects on spinal cord, hIgG (2g/kg) increased serum levels of inflammatory cytokines. The reduction of inflammation may be mediated by interfering will immune cell infiltration, as hIgG co-localized (without decreasing protein expression) of vascular cell adhesion molecule-1; an adhesion molecule used by immune cells to extravasate into inflamed

tissue. Furthermore, relative to hIgG (0.4g/kg), the early effects mediated by hIgG (2g/kg) translated into significantly better long-term benefits. These were indicated by enhanced tissue preservation, blood flow and functional recovery at six weeks post-SCI.
Together, this work supports the underlying rationale of immunomodulatory therapy in attenuating the effects of the acute inflammatory response after SCI. hIgG (2g/kg) is an exciting therapeutic approach, where administration of a clinically-relevant biomolecule with a minimally invasive technique mitigates SCI pathology through antagonizing immune cell infiltration.

Title: Bad to the bone: Spinal cord injury disrupts hematopoietic and immune cell function in the bone marrow niche

Authors: *R. S. CARPENTER, J. M. MARBOURG, A. M. DORRANCE, P. G. POPOVICH
The Ohio State Univ., Columbus, OH

Abstract: Systemic immune system dysfunction is a major consequence of spinal cord injury (SCI). The injury disrupts spinal circuitry that is essential for maintaining homeostatic control between the brain and peripheral immune tissues. The result is that SCI individuals have suppressed systemic immunity and are more susceptible to infection than are abled-bodied individuals. Post-SCI immune suppression is due in part to the death or dysfunction of mature immune cells in the spleen. Because spinal autonomic circuitry also innervates bone marrow, a primary generative lymphoid organ, SCI may adversely affect the formation of new white blood cells from hematopoietic stem and progenitor cells (HSPCs) in bone marrow. Here, we used a mouse model to determine how SCI affects the activity of HSPCs in bone marrow, blood and spleen. *In vivo* imaging and flow cytometry reveal a rapid increase in HSPC proliferation in bone marrow niches during the first 7 days after SCI, peaking at 3 days post-injury (dpi). SCI bone marrow (3 dpi) plated in an *ex vivo* MethoCult culture assay generated fewer mature immune cells than sham-injured bone marrow indicating that SCI impairs HSPC differentiation.

However, these same cells have superior engraftment potential when injected into transplant recipient mice when compared with bone marrow grafts derived from naïve or sham-injured mice. Phenotypic and molecular analysis of SCI bone marrow revealed that SCI increases CXCL12 and CXCR4 expression. Since CXCL12-CXCR4 signaling is critical for HSPC retention in bone marrow, an increase in this ligand-receptor pair after SCI could impair HSPC mobilization. New data show that after SCI HSPCs and mature leukocytes become trapped in bone marrow and that this sequestration is due in part to increased CXCL12-CXCR4 signaling. Importantly, we can boost HSPC mobilization after SCI by injecting mice with Plerixafor (AMD3100), an FDA-approved CXCL12-CXCR4 antagonist. Daily injections of AMD3100 for 3 days post-SCI increased HSPC mobilization into blood, improved HSPC trafficking to the spleen, and reversed SCI-induced leukopenia in blood (vs. vehicle controls). Future experiments will determine if dysregulated CNS communication to bone marrow after SCI impairs HSPC function and mobilization, and whether targeting CNS-bone marrow and CXCL12-CXCR4 signaling can boost innate and adaptive immune function. These data indicate that the bone marrow niche is a novel target for improving immune system function and preventing immune-related morbidity and mortality after SCI.

Title: Microbiome transplant attenuates anxiety/depression-like behavior in a rat model of spinal cord injury

Authors: *E. K. SCHMIDT, P. J. F. RAPOSO, K. K. FENRICH, K. FOUAD
Univ. of Alberta, Edmonton, AB, Canada

Abstract: Microbiome transplant attenuates anxiety/depression-like behaviour in a rat model of spinal cord injury
Secondary consequences of spinal cord injury (SCI) beyond paralysis can negatively affect a person’s quality of life. For example, SCI is frequently associated with increased incidences of depression and anxiety; however, beyond a possible contribution of post injury- inflammation, the mechanisms of this relationship are currently not well understood. Human and animal studies suggest that depression and anxiety are associated with changes in the composition of the

intestinal microbiome population (dysbiosis). Recent research in mice has found that SCI increases intestinal permeability and induces dysbiosis. We propose that SCI-induced dysbiosis may provide a link to the increased rate of mental health disorders following SCI. The objective of the current study is to establish a model of depression and anxiety following SCI in female rats and to determine whether the microbiome plays a role in the observed behavioural changes. To test this, rats underwent a battery of tests to assess baseline levels of depression- and anxiety-like behaviour. Microbiome composition was analyzed using CHROMagar orientation plates and 16s rRNA analysis. Rats then received a mild cervical contusion or sham operation. Following injury, SCI rats displayed increased symptoms of anxiety and depression compared to sham controls as measured using the elevated plus maze. Rats with a SCI also displayed an altered microbiome composition compared to sham animals. To determine if there is a link between SCI-induced dysbiosis and behavioural changes we administered a microbiome transplant immediately after injury to restore/maintain a healthy microbiome composition. Not only did this treatment decrease SCI-induced dysbiosis, the microbiome transplant also increased exploratory behaviour in the elevated plus maze. These results indicate that a mild SCI can induce behavioural changes and intestinal dysbiosis, and that treating dysbiosis can prevent the development of depression- and anxiety-like symptoms following SCI.

Title: Acute but sustained treatment with cannabinoid receptor-2 agonist preserves hind limb bone density in mice after SCI

Authors: *R. J. GRILL[1], S. SEREDUCK[1], Y. PRIDE[1], A. CHADE[2]
[1]Neurobio. and Anatom. Sci., [2]Physiol. and Biophysics, Univ. of Mississippi Med. Ctr., Jackson, MS

Abstract: Spinal cord injured individuals exhibit a greater risk of developing osteoporosis compared to uninjured individuals with the prevalence of osteoporosis in SCI patients ranging as high as 75%. The development of age-dependent osteoporosis represents a significant health risk

in the general population, but such risk carries a far greater burden for those living with SCI. Bone fractures in patients with SCI often occur in areas devoid of normal sensory function. As a result, these individuals may be unaware that a fracture has occurred, leading to potentially fatal consequences. Current therapies for SCI-induced osteoporosis are focused mainly on bisphosphonates, most commonly used to treat osteoporosis in the ageing population. Unfortunately, bisphosphonates are only mildly effective in treating SCI-induced osteoporosis and can, paradoxically, exacerbate bone loss in SCI patients when used for long-term, chronic treatment. Cannabinoids, particularly agonists of the cannabinoid receptor-2 (CB2) class, have shown promise as therapeutic agents in experimental models of age-dependent osteoporosis by modulating the ratio of osteoblast-to-osteoclast activity. However, it is unknown whether CB2 agonists would improve osteoporosis in SCI. We therefore hypothesized that a selective CB2 agonist, HU-308, would attenuate onset of osteoporosis in a mouse model of SCI. Methods: Adult, male, C57BL6 mice received a full spinal transection lesion at T9. Treatment with either vehicle or CB2 agonist HU-308 (10 mg/kg) was initiated at 3 hours post-SCI and continued once daily for 40 days by IP injection. Non-injured mice served as age-matched controls. Mice were euthanized at 40 days with hind limb femurs and tibiae collected, processed and scanned using 3D micro-CT. Bone density measurements were made in tibiae (rostral and proximal) and femur (rostral and proximal). Results: HU-308 preserves bone density in the distal tibia compared to vehicle-treatment ($p>0.001$) with drug-treated bone showing nearly age-matched, control levels. Drug-treated proximal tibiae were significantly preserved compared to vehicle-treated ($p>0.05$). HU-308 efficacy was not observed in proximal or distal femur. Conclusions: HU-308 shows promise as a novel treatment to attenuate onset of osteoporosis following spinal cord injury. We are currently exploring whether a delay in CB2 agonist treatment can elicit a reversal of hind limb osteoporosis in chronically-injured mice.

Title: Sexual difference on neuroinflammation and functional recovery after SCI

Authors: *T. CAO[1], Y. LI[2], L. LIU[2], A. FADEN[2], J. WU[3]
[2]Dept. of Anesthesiol. & Ctr. for Shock, Trauma and Anesthesiol. Res. (STAR), [3]1Department of

Anesthesiol. & Ctr. for Shock, Trauma and Anesthesiol. Res. (STAR), [1]Univ. of Maryland, Sch. of Med., Baltimore, MD

Abstract: Spinal cord injury (SCI) causes not only sensorimotor deficits, neuropathic pain, and autonomic dysfunction but also varying degrees of neuropsychological abnormalities including cognitive impairment and depression, with no effective treatment. Biological sex differences in the epidemiology of SCI have been reported that males have a higher likelihood of getting a SCI than females. Sexual disparities in response to SCI in human and rodent have been previously reported, however, little is known about the effect of biological sex on remote brain dysfunction as well as injury mechanisms. In the present study, young adult male and female C57BL/6 mice subjected to moderate/severe thoracic contusion injury were evaluated for their functional outcomes using a battery of behavioral tests including motor function, cognition, and depression. In assessment of motor function, female mice were generally more active, as evidenced by greater distance traveled in the open field and higher numbers of total arm entries in the Y-maze. After SCI, female mice had better Basso Mouse Scale than that in male animals beginning 4 weeks post-injury. CatWalk analysis showed similar motor coordination in two sex groups. SCI in male mice caused poor performance in the novel object recognition and Y-maze tests indicating impairment of cognition, however, injured female mice showed less deficits in these tasks. To assess depressive-like behavior, tail suspension, forced swim, and novelty-suppressed feeding were employed. Male mice after SCI were more likely to develop depression, but not female animals. In contrast, both sexes had similar response to mechanical and thermal stimulation at the hind-paws. To explore the effects of sex on SCI-mediated neuroinflammation, about 800 genes selected from Neuroinflammation panel were analyze in injured spinal cord tissues and cerebral cortex by NanoString technology. The data showed robust differential changes between sexes not only in injured site but also in the remote cerebral cortex. Collectively, these findings indicate that SCI leads to a more aggressive neuroinflammatory profile in male compared with female mice. Different functional recovery after SCI suggests that biological sex should be considered when designing new therapeutic agents.

Title: Immediate elimination of the axon-glial complex achieves successful axon regeneration in cordotomized adult rats

Authors: *T. NISHIO[1], H. FUJIWARA[2], I. KANNO[3]
[1]Kyoto Univ., Kyoto-Shi, Japan; [2]Kanazawa Univ., Kanazawa-Shi, Japan; [3]Kobe Univ., Kobe-Shi, Japan

Abstract: After a transection of the spinal cord in mature mammals, severed axonal ends show a rapid retraction within 0.5-1 hour of axotomy and then attempt regeneration in 6 hours. It is known that the initial growth response by axons is robust, but regenerative axons hardly grow across the lesion site. Regarding the cause of this limited regeneration, the presence of several types of axon-growth inhibitors has been shown in mature mammalian central nervous system (CNS), such as myelin-associated inhibitors or glial scar-related extracellular matrix molecules. However, the actual cause remains elusive.
We focused on the early axonal responses to transection of the spinal cord in adult rats. Local axonal tracing and quantitative analysis revealed that axonal regrowth had already started within 4 hours of cordotomy, and we called axons that would start regenerating within hours of corodotomy as “regenerative pioneering axons”. Notably, the regenerative pioneering axons reached the lesion site in 4 hours of cordotomy showing a characteristic snaking morphology. At the lesion site, we found abnormal axon fragments, which frequently formed an aggregate. Electron microscopy further revealed that the aggregate was composed of unmyelinated axons and astroglial processes, which made a direct contact with axons. Thus, we named the aggregate as “axon-glial complex”, AGC. Considering a possible role of the AGC as physicochemical barriers for regenerative pioneering axons, we examined the effects of prompt elimination of the barriers on axonal growth beyond the lesion site. To be more specific, we surgically eliminated the AGC by making additional cord section near the primary section and removing the injured white matter tissue from the lesion site (surgical debridement). Under the treatment, the regenerative pioneering axons successfully traversed the lesion site through an AGC-eliminated area within 4 hours of cordotomy. To exclude axonal sparing, we made an epoxy-based sheet with pores (pore size was 125 micrometer in diameter) using SU-8 photoresist and inserted it into the AGC-eliminated lesion site. The pioneering axons successfully extended beyond the sheet and formed fascicles 24 hours post-surgery.
We further tested a chemical elimination of the AGC with a protease. We injected a Bromelain solution near the lesion site one hour after a cordotomy and found a successful regeneration. These results suggest that the AGC at the lesion site would be a novel cause of failed regeneration and that regenerative pioneering axons have a powerful growth engine even in mature CNS.

Title: Immune-evasive gene switch allows regulated delivery of chondroitinase and long term delivery restores reaching and grasping function after cervical spinal cord injury

Authors: *E. R. BURNSIDE[1], F. DE WINTER[2], N. I. ROOPNARINE[1], A. DIDANGELOS[1], N. D. JAMES[1], J. VERHAAGEN[2], E. M. MUIR[3], E. J. BRADBURY[1]
[1]King's Col. London, London, United Kingdom; [2]Neth Inst. Neurosc, Amsterdam, Netherlands; [3]Univ. of Cambridge, Cambridge, United Kingdom

Abstract: Chondroitinase ABC is a promising preclinical therapy that promotes functional neuroplasticity after CNS injury by degrading extracellular matrix inhibitors. Efficient delivery of chondroitinase ABC to the injured mammalian spinal cord can be achieved by viral vector transgene delivery. This approach dramatically modulates injury pathology and restores sensorimotor functions. The ability to exert control over chondroitinase gene expression would further optimise this system and enable the therapeutic time window to be explored. Prior experimental gene regulation platforms are likely to be incompatible with the non-resolving adaptive immune response known to occur following spinal cord injury. Therefore, here we apply a novel immune-evasive dual vector system, in which the chondroitinase gene is under a doxycycline inducible regulatory switch, utilizing a chimeric transactivator designed to evade T cell recognition. Using this novel vector system, we demonstrate tight temporal control of chondroitinase ABC gene expression, effectively removing treatment upon removal of doxycycline. This enables a comparison of short and long term gene therapy paradigms in the treatment of clinically-relevant cervical level contusion injuries in adult rats. We reveal that transient treatment (2.5 weeks) is sufficient to promote improvement in sensory axon conduction and ladder walking performance. However, in tasks requiring skilled reaching and grasping, only long term treatment (8 weeks) leads to significantly improved function, with rats able to accurately grasp and retrieve sugar pellets. The late emergence of skilled hand function indicates enhanced neuroplasticity and connectivity and correlates with increased density of vGlut1+ innervation in spinal cord grey matter, particularly in lamina III-IV above and below the injury. Thus, our novel gene therapy system provides an experimental tool to study temporal effects of extracellular matrix digestion as well as an encouraging step towards generating a safer chondroitinase gene therapy strategy, longer term administration of which increases

neuroplasticity and recovery of descending motor control. We are currently utilising this system to compare acute and delayed administration of chondroitinase in order to assess its potential in the treatment of chronic spinal cord injury.

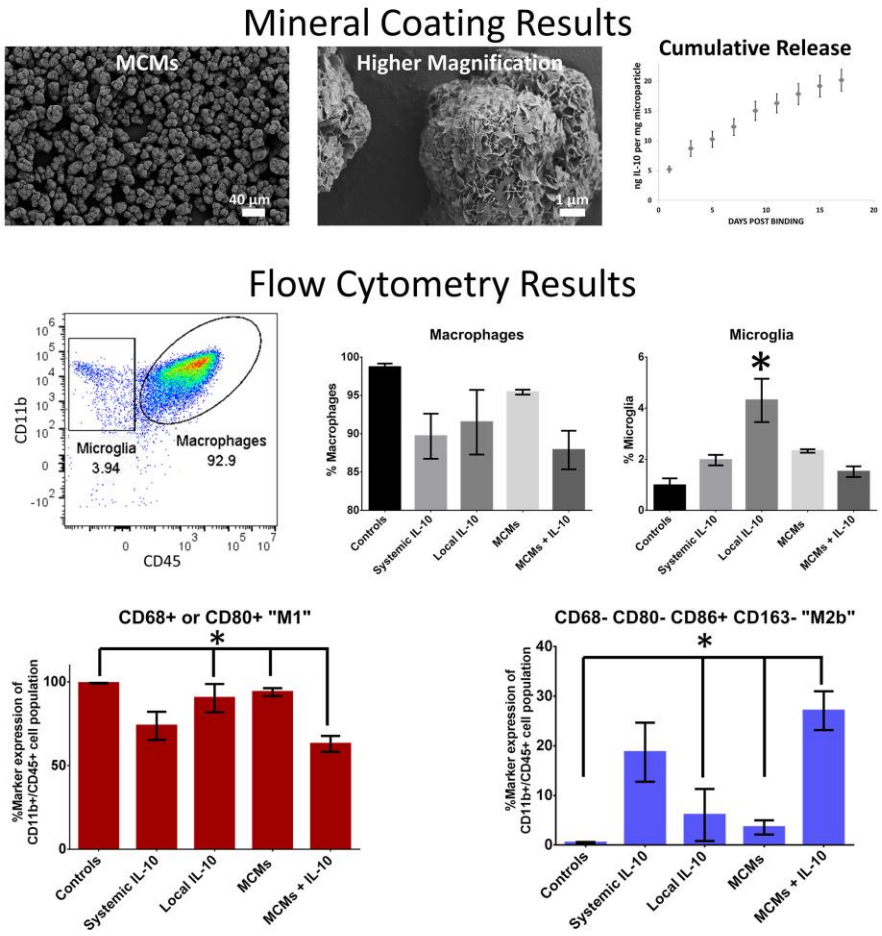
Title: Local sustained interleukin-10 delivery reduces inflammation and improves motor function after spinal cord injury

Authors: *D. J. HELLENBRAND, A. G. GABLEMAN, E. DAI, J. B. SPORLEDER, S. HENRY, S. D. ORTMANN, J. C. GOTCHY, A. S. HANNA
Neurolog. Surgery, Univ. of Wisconsin, Madison, WI

Abstract: The anti-inflammatory cytokine interleukin-10 (IL-10) has been explored previously as a treatment method for spinal cord injury (SCI) due to its ability to attenuate pro-inflammatory cytokines and reduce apoptosis. Primary limitations when using IL-10 are that it is rapidly cleared from the injury site and that it does not cross the blood spinal cord barrier. Here, mineral-coated microparticles (MCMs) were used to obtain a local sustained delivery of IL-10 directly into the injury site. Female Sprague-Dawley rats were contused at T10 and treated with either an intraperitoneal injection of IL-10, an intramedullary injection of IL-10 or MCMs bound with IL-10 (MCMs+IL-10). After treatment, cytokine levels were measured in the spinal cord, functional testing and electrophysiology were performed, axon tracers were injected into the brainstem and motor cortex, macrophage levels were counted, and lesion size was measured. When treated with MCMs+IL-10, IL-10 was significantly elevated in the injury site, inflammatory cytokines were significantly suppressed, prompting a larger ratio of M2 to M1 antigen expressing macrophages. Significantly more axons were preserved within the rubrospinal and reticulospinal tracts through the injury site when treated with MCMs+IL-10; however, there was no significant difference in corticospinal tract axons preserved, regardless of treatment group. The rats treated with MCMs+IL-10 were the only group with a significantly higher functional score compared to

injured controls 28 days post-contusion. These data demonstrate that MCMs can effectively deliver IL-10 for an extended period of time, aiding in functional recovery after SCI.



Mineral coated microparticles deliver a sustained release of interleukin-10 . Flow cytometry, performed 7 days after spinal cord injury in rats, reveals a shift in CD45+ CD11b+ macrophages to an early stage M2 phenotype.

Title: Inhibition of IL-17A promotes tissue repair by ependymal cells after spinal cord injury

Authors: *H. MIYAJIMA[1], S. TANABE[2], M. FUJITANI[3], T. YAMASHITA[1,2,4]
[1]Dept. of Mol. Neurosci., Grad. Sch. of Frontier Biosciences, Osaka Univ., Osaka, Japan; [2]WPI Immunol. Frontier Res. Center, Osaka Univ., Osaka, Japan; [3]Dept. of Neurosci., Grad. Sch. of Medicine, Shimane Univ., Suita, Japan; [4]Dept. of Mol. Neurosci., Grad. Sch. of Medicine, Osaka Univ., Osaka, Japan

Abstract: Spinal cord injury (SCI) results in the loss of neurons and axonal connections, leads to impairment of neurotransmission in central nervous system. In mammals, although the spontaneous tissue recovery is observed after SCI, it is not sufficient to restore the neural functions. Thus, it is required to reveal the molecular mechanism of spontaneous tissue repair after SCI to develop the effective treatment. In this study, we focused on ependymal cells (ECs), lining the central canal, which act as neural stem cells after SCI. Recent studies revealed that ECs are involved in tissue repair by differentiation into astrocytes and oligodendrocytes. On the other hand, peripheral immune cells infiltrate into the injured spinal cord, and induce the inflammation by secreting various pro-inflammatory cytokines. However, it remains unclear whether inflammatory signals are associated with ECs functions. Here, we examined the role of inflammatory signals for the ECs activity after SCI.
To clarify whether ECs express the receptor for pro-inflammatory cytokines after SCI, we isolated the ECs from the injured spinal cord, and found that ECs express the receptor for interleukin (IL)-17A, which is a pro-inflammatory cytokine. IL-17A was significantly increased after 7 days of SCI, and γδT cells were the main source of IL-17A. Neurosphere assay showed IL-17A inhibits the proliferation of ECs in vitro. In addition, we investigated whether IL-17A inhibition promotes the motor recovery and tissue repair by treatment with anti-IL-17A neutralizing antibody, or lentivirus injection, encoding flox-flanked dominant negative form of IL-17A receptor, into FoxJ1-CreERT2 mice (ECs specific Cre mouse line). As a result, inhibition of IL-17A signaling improved the motor function and promoted the ECs proliferation. These results suggest that IL-17A signaling disturbs tissue repair by inhibiting the proliferation of ECs after SCI. Thus, we propose that inhibition of IL-17A can be an effective treatment for repairing the tissue.

Title: Ursodeoxycholic acid inhibits inflammatory responses and promotes functional recovery after spinal cord injury in rats

Authors: *S. SOHN[1], W.-K. KO, 13496[2]
[1]Neurosurg., CHA University, CHA Bundang Med. Ctr., Gyeonggi-do, Korea, Republic of;
[2]CHA Univ., Gyeonggi-do, Korea, Republic of

Abstract: Purpose: The aim of this study was to investigate the anti-inflammatory effects by ursodeoxycholic acid (UDCA) in rats with a spinal cord injury (SCI).**Methods:** A moderate mechanical compression injury was imposed on adult Sprague-Dawley (SD) rats. The post-injury locomotor functions were assessed using the Basso, Beattie and Bresnahan (BBB) locomotor scale and the tissue volume of the injured region was analyzed using hematoxylin and eosin staining. The pro-inflammatory factors were evaluated by immunofluorescence (IF) staining, a quantitative real-time polymerase chain reaction (qRT-PCR) and enzyme-linked immunosorbent assay (ELISA). The phosphorylation of the extracellular signal-regulated kinase (ERK), c-Jun N-terminal kinase (JNK), and p38 in mitogen-activated protein kinase (MAPK) signaling pathways related to inflammatory responses were measured by western blot assays.**Results:** UDCA improved the BBB scores and promoted the recovery of the spinal cord lesions. UDCA inhibited the expression of glial fibrillary acidic protein (GFAP), tumor necrosis factor-α (TNF-α), ionized calcium-binding adapter molecule 1 (iba1), and inducible nitric oxide synthase (iNOS). UDCA decreased the pro-inflammatory cytokines of TNF-α, interleukin 1-β (IL-1β), and interleukin 6 (IL-6) in mRNA and protein levels. UDCA increased the anti-inflammatory cytokine interleukin 10 (IL-10) in the mRNA and protein levels. UDCA suppressed the phosphorylation of ERK, JNK and the p38 signals. **Conclusion:** UDCA reduces pro-inflammatory responses and promotes functional recovery in SCI rats. These results suggest that UDCA is a potential therapeutic drug for SCI.

Title: Molecular and cellular responses of immune cells following therapeutic targeting of the extracellular matrix after spinal cord injury

Authors: *I. FRANCOS-QUIJORNA[1], E. R. BURNSIDE[1], J. VERHAAGEN[2], E. J. BRADBURY[1]
[1]Inst. of Psychiatry, Psychology & Neurosci., King's Col. London, London, United Kingdom; [2]Neth Inst. Neurosc, Amsterdam, Netherlands

Abstract: Spinal cord injury (SCI) causes irreversible axonal damage and neuronal death, resulting in permanent disability for which there are no effective treatment. In addition to the initial mechanical injury, a wide range of secondary cellular and molecular events occurs after SCI, constituting the secondary injury, which lead to further tissue damage and consequently functional impairments. One major contributor to this pathological cascade is the inflammatory response which is aggressive and unresolved. The factors that impede the clearance of immune cells after the injury have not been fully characterized and several lines of evidence imply a role for chondroitin sulphate proteoglycans (CSPGs) in SCI inflammation. Recent work has shown that modifying CSPGs in the extracellular matrix (ECM) with the enzyme chondroitinase-ABC (ChABC) can reduce secondary injury pathology. However, the mechanisms that underlie immunomodulatory effects of ChABC after SCI are not yet understood.
To evaluate whether ECM alteration modulates the inflammatory response after SCI we performed a large-scale digestion of inhibitory scar matrix with ChABC delivered via lentiviral vector (LV-ChABC) after thoracic SCI in adult female rats. By flow cytometry, we then assessed the number of microglial cells, macrophages and neutrophils within the injury epicentre. Our results show that ECM digestion by LV-ChABC promotes inflammatory resolution after SCI revealed by accelerated clearance of neutrophils (Ri: 48.9 vs 37.1hr) and reduced accumulation of macrophages (1803 ± 405 vs 790 ± 120 cells) and microglial cells (5540 ± 834 vs 3181 ± 636 cells) 7 days after the injury compared with control animals (LV-GFP). We next evaluated which immune cell populations are modulated by LV-ChABC. Following assessment of the expression of CSPG receptors in each immune cell type, we analysed the mRNA expression of different phenotypic markers within the FACS sorted immune cell populations and found that microglial cells from LV-ChABC treated animals had significantly higher expression of anti-inflammatory

markers (Arginase I and CD206) 7 days post- injury. We are currently assessing changes in cytokine and chemokine expression and potential signalling pathways involved in ECM-immune interactions. These data suggest that ECM alteration after SCI impedes the inflammatory resolution which contributes to tissue damage and functional impairments. Understanding the cellular and molecular mechanisms underlying ECM-mediated modulation of the inflammatory response may lead to more effective therapies to treat SCI.

Title: Vitamin D improves the wellness of myelin sheath after experimental spinal cord injuries in normal and induced vitamin D-deficient rats

Authors: N. LI, Y. MIN, *G. K. LEUNG
The Univ. of Hong Kong, Hong Kong, Hong Kong

Abstract: Background: Demyelination occurs immediately after traumatic spinal cord injury (TSCI) and lasts for months. Spontaneous remyelination is reported incomplete that may result in limited neurological recovery. Several lines of evidence showed that vitamin D (VD) is a promising molecule in improving functional recovery after spinal cord trauma, and it was often linked its anti-inflammatory effects. A recent study demonstrated that VD promoted oligodendrocyte maturation in vitro, shedding light on another potential mechanism of its therapeutic benefit after TSCI. Thus, our study aims to examine its effects on myelin wellness in animal TSCI models. Methods: Two cohorts of rats were used: 1) Sprague-Dawley rats fed with normal diet; and 2) induced VD-deficient SD rats raised with non-VD diet. Two TSCI models were conducted to each cohort: i) moderate injury using vessel clip contusion (10g x 5 min); ii) severe transection injury with a blade cut. Animals were either treated with coconut oil vehicle or VD (500IU/kg/day) for two months. Hindlimb motor function was evaluated every week after injury. Myelin sheath was examined by transmission electron microscopy (TEM) and western blotting. Rat oligodendrocytes and dorsal root ganglions were co-cultured to investigate the impact of VD on myelin formation *in vitro.* Results: VD-treated rats displayed a better functional recovery in both models, but this therapeutic effect was attenuated by pre-deficiency. TEM scanning showed that: 1) myelin damage was more severe in the transection model than the contusion model, and demyelination was obvious not only in the epicenter but also in the 0.5 cm rostral area; 2) VD treatment increased the thickness of myelin when compared with vehicle

control. 4) myelin was thinner in deficient animals than that in normal ones. These results were further confirmed in the proteomic tests. In vitro administration of 1,25(OH)D3 favored the maturation of oligodendrocyte, and promoted the myelin formation with DRG axons in co-culture system, suggesting that VD-enhanced oligo maturation might partially contributed to the in vivo myelin protection. Conclusions: Our study provides mechanistic evidence that VD favors neurological recovery by increasing the myelin wellness after TSCI. We also value the importance of maintaining VD sufficiency in TSCI as deficient animals respond worse to VD treatment.

Title: Using metformin to activate endogenous neural precursor cells in the spinal cord

Authors: *E. A. GILBERT, W. XU, C. M. MORSHEAD
Univ. of Toronto, Toronto, ON, Canada

Abstract: Spinal cord injuries (SCI) result in devastating functional deficits with minimal treatment options. Endogenous neural precursor cells (NPCs) exist within the spinal cord and are located in the periventricular region lining the central canal. While normally relatively quiescent and non-neurogenic, these NPCs are activated in response to injury. Enhancing and harnessing the potential of resident NPCs may improve structural and functional outcomes following SCI. The FDA-approved drug metformin (MET) has demonstrated efficacy in promoting neural repair in the injured brain where it expands the size of the NPC pool and promotes both oligogenesis and neurogenesis from NPCs. Here, we seek to determine whether it has a similar effect on NPCs within the spinal cord. Using the in vitro colony forming assay (neurosphere assay) we examined the size of the neural stem cell pool in the spinal cord following 7 days of *in vivo* MET treatment. Females demonstrated a three-fold increase neural stem cells, while males did not show any expansion in response to MET treatment. Interestingly, the sex dependent expansion of the neural stem cell pool was not coincident with the effects of MET on the differentiation profile the neural stem cell progeny. Neurospheres were plated in the presence of differentiation media, and then stained for markers of mature neural cell phenotypes. We found neurons (β-III-

tubulin), oligodendrocytes (O4) and astrocytes (GFAP) within the spheres, and determined that in both sexes, MET increases oligogenesis compared to vehicle-treated controls. Our data reveal that MET has differential effects on spinal cord NPCs of males and females. By expanding the NSPC pool in females, and augmenting oligogenesis in both sexes, MET treatment represents a viable therapeutic strategy for enhancing neural repair post spinal cord injury.

Title: Mesenchymal stem cell treatment reduces astrogliosis and microglial reaction and improves motoneuron survival after spinal ventral root crush in mice

Authors: *L. P. CARTAROZZI[1], M. PEREZ[1], F. KIRCHHOFF[3], Â. C. M. LUZO[2], A. L. OLIVEIRA[1]
[2]Med. Fac., [1]Univ. of Campinas, Campinas, Brazil; [3]Univ. of Saarland, Homburg, Germany

Abstract: Rupture and stretching of spinal roots are common incidents that take place in high energy accidents. The proximal axotomy of motoneurons by crushing of ventral roots is directly related to the degeneration of half of the lesioned population within the first two weeks. Moreover, only a small percentage of surviving motoneurons can successfully achieve regeneration after such a proximal lesion, and new treatments are necessary to improve this scenario. In this sense, mesenchymal stem cells (MSC) are of great interest once they secrete a broad spectrum of bioactive molecules that are immunomodulatory and can act in the restoration of the environment after lesion. The present work aimed at studying the effects of human mesenchymal stem cells (hMSC) therapy after ventral root crush (VRC) in mice. We evaluated motoneuron survival, glial reaction, and synapse preservation at the ventral horn. For this purpose, C57BL/6J were submitted to the crush of L4 to L6 ventral roots, and treatment with a single intravenous injection of adipose-derived hMSC. Evaluation of the results was carried out 7, 14 and 28 days after injury. Analysis of motoneuron survival and astrogliosis showed that hMSC treatment resulted in higher motoneuron preservation (motoneuron survival ipsi/contrataleral ratio: VRC group = 0.53, VRC + hMSC group = 0.66; $p<0.01$), combined with reduction of astrogliosis (ipsi/contralateral GFAP immunolabeling: VRC group = 4.7, VRC +

hMSC group = 2.5; p<0.001). Microglial reaction was more intense in non-treated animals, becoming reduced in about 20% after hMSC injection (ipsi/contralateral Iba-1 immunolabeling: VRC group = 3.7, VRC + hMSC group =2.5; p<0.05). The glial reactivity modulation directly influenced synaptic inputs in apposition to axotomized motoneurons. Thus, in the hMSC-treated group, synaptic maintenance was increased (ipsi/contralateral synaptophysin immunolabeling: VRC group = 0.53, VRC + hMSC group = 0.64; p<0.05). Overall, the present data show that systemic injection of hMSC has neuroprotective and anti-inflammatory effects, decreasing reactive astrogliosis and microglial reaction. Also, such cell therapy results in motoneuron preservation, combined with significant maintenance of spinal cord circuits, in particular, those related to the ventral horn.

Abstract: Traumatic spinal cord injury (tSCI) is an unforeseen catastrophic event that profoundly change the life of affected individuals. The phase of secondary damages induced after lesion is characterized by strong inflammatory processes leading to further neuronal and functional losses. In this study, we assessed the impact of systemic application of purified extracellular vesicles (EVs) secreted from human umbilical cord mesenchymal stromal cells (hUC-MSCs), on the functional and structural outcomes following tSCI in a rat model. SCI was obtained in female Fisher 344 rats of 10 weeks of age by applying a 200 kdyn contusion lesion at thoracic level 8 resulting in a moderate to severe incomplete SCI. The rats were randomly

divided in treatment groups receiving acutely an intravenous application of either vehicle, $1x10^6$ hUC-MSCs, or purified EVs secreted by the corresponding amount of cells, and again 24 hours after contusion. Sham rats underwent the same surgical procedure but did not receive a contusion. Histological analyses were performed 14 days after contusion. Treatment with EVs or hUC-MSCs significantly reduced the local inflammation, compared to vehicle-treated rats, as revealed by the lower density of microglia/macrophages residing in the peri-lesion area. Similarly, a significant reduction of astrogliosis, according to the GFAP expression level, and scarring, based on collagen accumulation within the lesion and peri-lesion areas, were observed in the spinal cords of hUC-MSCs and EVs-treated groups, in comparison to the vehicle-treated group. In conclusion, our study demonstrated that treatments with hUC-MSCs and EVs efficiently decreased the inflammatory response and scarring associated with the phase of secondary damages during the 2 weeks following tSCI.

Title: Effect of human mesenchymal stromal cells (hMSCs) on CCL5 expression and macrophage polarization after spinal cord injury

Authors: *H. OHTAKI[1], K. YAGURA[1,3], T. TSUMURAYA[3], A. SATO[3], J. WATANABE[5], K. MIYAMOTO[4], Y. HIRAIZUMI[2], K. HONDA[1]

Abstract: Spinal cord injury (SCI) is mainly caused by traffic and sports accidents, and is often subjected to permanent motor dysfunction. Mesenchymal stem/stromal cells (MSCs) have been attracted to be suppressed and/or resolved the SCI in animal and clinical experiments. Microglia/macrophages (MG/MΦ) mobilize to injury site and contribute to both deterioration

and resolution of the inflammation. We have reported that transplantation of human MSCs (hMSCs) suppressed neural injury along with an induction of alternative activating MG/MΦ (M2-type MG/MΦ) after brain ischemia and SCI. However, it remains unclear the mechanism of hMSCs with MG/MΦ. In the present study, we determined that a chemokine, CCL5 and M2-type MG/MΦ markers were increased after hMSCs transplantation. Then we determined cellular localization CCL5 and the receptors to estimate the role of CCL5 after the SCI. Male C57/BL6 mice were subjected to SCI between TH9 and 10 intervertebral with thin razor. The hMSCs (5 $x10^5$ cells) injected one caudal vertebral at day 1. The mice were monitored locomotor activity with Basso mouse scale, and evaluated the injury size at 14 days. Moreoevr, the spinal cord (TH7 to 12) was collected and carried out quantitative PCR and immunohistochemistry for CCL5, the receptors, and MG/MΦ markers. The expression *ccl5* drastically increased 14 days after SCI. Although all receptors increased at day1, and *ccr1* and *ccr3* were returned to basal level by day 7, *ccr5* kept higher level for 2 weeks. The CCL5 and CCR5 localized in neurons and microglia. hMSCs injection further increased *ccl5* expression but not CCR5, and increased significantly M2-type MG/MΦ marker, *arg1*, *chil3* and *il4* gene expressions at day 14. The mice injected hMSCs improved locomotor activity and suppressed injury area. Injection of mouse recombinant CCL5 also increased the expression of *chil3*. These results suggest that CCL5 which increased the expression by hMSCs might be migrated macrophages into injury region and polarized to M2-type MG/MΦ activation communicating with hMSCs.

Title: Spinal cord injury site modulation platform with nanotechnology and stem cells

Authors: *J. L. PALUH[1], Z. T. OLMSTED[1], A. SCIMEMI[2], Y. XIE[1]
[1]Nanobioscience, SUNY Polytechnic Inst., Albany, NY; [2]SUNY Albany, Albany, NY

Abstract: Extensive efforts to accelerate treatments in spinal cord injuries (SCI) are challenged in part by a need for comparative uniformity and reproducibility. The overarching goal of our research is to test a generalizable strategy for cell delivery and modulation of both therapeutic cells and the injury site to optimize integration and repair. A uniform platform would more coherently bring together the most exciting research strategies in the SCI field being evaluated

by many laboratories to create synergistic rapid advances. Towards this goal we are applying biocompatible hydrogel ribbon platforms with human iPSC-derived neural stem cell technologies and nanoparticle delivered enzymes in a dual spinal treatment enhancing platform (2STEP). This platform will be tested for re-establishment of neural connectivity and behavior in a rat hemicontusion model of SCI. Nanoparticle delivered modulators include chondroitinase enzymes to block inhibitory extracellular matrix signals as well as modulators of neural stem cell differentiation when multipotent cells are used and regulators of spinal motor neuron maturation as well as optimizing ratios of oligodendrocyte co-delivery. The current work focuses on the hydrogel ribbon-cell + modulator studies to validate release times and electrophysiological potential of cells in ribbons. Scientific rigor is being ensured by appropriate controls, replicate sizes and quantitative assays to complement any qualitative analyses and with validated reagents. These initial studies use published hiPSC lines developed and comprehensively characterized in the Paluh laboratory that are from population diverse sources that include self-defined African American and Hispanic Latino original tissue sources. The current exploratory research brings together expertise in population diverse analysis of pluripotent and neural human stem cell biology, neuronal microtubule cytoskeleton and electrophysiology, nanotechnology and materials engineering. This work is supported by a grant from the New York State Department of Health Spinal Cord Injury Review Board (NYSCIRB).

Title: Olfactory ensheathing cell transplantation combined with epidural stimulation and climb training enhances axonal connectivity across a severe spinal cord injury

Authors: *K. L. INGRAHAM, M. A. THORNTON, M. D. MEHTA, T. MORAD, P. AKKARA, A. TIERNO, A. YEUNG, E. A. DALE, H. ZHONG, V. R. EDGERTON, P. E. PHELPS
Integrative Biol. and Physiol., Univ. of California Los Angeles, Los Angeles, CA

Abstract: The transplantation of olfactory ensheathing cells (OECs) is a promising treatment for spinal cord injury (SCI) in part because of their beneficial effects on axonal outgrowth. This study asks if combining OEC transplantation with long-term epidural stimulation and climb

training, another effective treatment for SCI, would improve axonal outgrowth and connectivity with hindlimb motor circuits. Two weeks after a severe SCI at T8-T9, the injury sites of young adult female Fischer-344 rats (n=9) were transplanted with either OECs, or media within a fibrin matrix. Spinal rats received epidural stimulation while performing a climbing task 3 times/week for 5 months. A trans-synaptic retrograde tracer, Psuedorabies Virus (PRV), was injected into two hindlimb muscles before perfusion. Compared to media controls, we found that OEC-treated rats had more 5-HT-positive axons and a greater density of neurofilament (NF)-positive axons in the injury site and that many of these axons were associated with OECs. We also detected several PRV-labeled cells rostral to the injury site that often suggest some reconnectivity with hindlimb locomotor circuits. Axon myelination and the presence of myelinating cells within the injury site were also analyzed. Together, these findings show that long-term treatment with OECs, epidural stimulation, and climb training can improve axonal connectivity in a severe SCI model.

Title: Migration and differentiation of astroglia after transplantation of human neural stem cells into site of spinal cord injury

Authors: B. LIEN[1], M. TUSZYNSKI[2,3], *P. P. LU[2,4]
[1]Univ. of California San Diego, La Jolla, CA; [2]UCSD, LA Jolla, CA; [3]VA San Diego Healthcare Syst., San Diego, CA; [4]VA-San Diego Healthcare Syst., San Diego, CA

Abstract: Neural stem cells (NSCs) can differentiate into both neurons and glia after transplantation into site of spinal cord injury (SCI). The neuronal component of stem cell grafts has the potential to form functional relays across sites of SCI. The glial component, on the other hand, may re-form a blood-brain barrier (BBB), support neuronal function and potentially contribute to remyelination. We performed a long-term, 18-month study focused on astrocyte maturation, migration and safety following implantation of human NSCs into a site of right-sided C5 hemisection in immunodeficient rats. 23 rats were enrolled in the study; 18 were grafted. Animals were sacrificed either 1 mo (N=3), 3 mo (N=3), 6 mo (N=5), 12 mo (N=3) or 18 mo (N=4) after grafting and were compared to lesion controls (N=5). Notably, NSCs that adopted a neuronal fate did not migrate from the lesion site (Lu et al, J Clin Invest 2017; 127:3287-3299). In contrast, grafted cells that adopted astrocyte fates exhibited long-distance migration from the implantation site, through host white matter, both rostral and caudal to the lesion. Cells migrated from the lesion slowly, at a mean rate of 2-3 mm per month. By 18 months, astrocytes migrated 9 spinal cord segments, caudally to the mid thoracic level, and rostrally into the brainstem. Human cells divided continuously as they migrated. The migrating human astrocytes joined the endogenous population of astrocytes in the host spinal cord and formed gliovascular units with human astrocytic processes interacting with host endothelial cells. No adverse consequences of this extended glial migration were detected.

KY; [4]Spinal Cord & Brain Injury Res. Center, Dept. of Neurosci., Univ. of Kentucky, Lexington VAMC, Lexington, KY

Abstract: mitoNEET is a homodimer protein present within the outer membrane of mitochondria comprising a redox active [2fe-2S] cluster that has an essential role in regulating energy metabolism, iron homeostasis, and production of reactive oxygen species in mitochondria. mitoNEET is also a primary target of type II diabetes drug, pioglitazone (Pio), which we have recently shown to be neuroprotective after contusion spinal cord injury (SCI) and traumatic brain injury in mice. Accordingly, the current study was designed to test the novel hypothesis that Pio maintains mitochondrial respiration following SCI via its specific interaction with mitoNEET protein. Adult male C57BL/6 (n=80) or mitoNEET knockout (n=32) mice received either T9 laminectomy (sham; n=16) or contusion SCI (75 kdyn, IH Impactor; n=96), and 3 hr later they were treated i.p. with either Vehicle (1:1 DMSO + polyethylene glycol 400), Pio (1, 10, 20 or 40 mg/kg) or NL1, a specific mitoNEET ligand (10, 20 or 40 mg/kg), followed by boluses at 24 and 48 hr post-injury. At 49 hr post-injury, mitochondria were isolated from 5 mm of spinal cord centered on injury site and assessed for their respiration in terms of oxygen consumption rate (OCR) using Seahorse XF$^{(e)}$ 24 Extracellular Flux Analyzer. The OCR for naïve mitoNEET KO mice mitochondria was found to be ~25% lower than for naïve WT mitochondria, and SCI significantly reduced OCR in both WT and mitoNEET KO mice; the latter ~25% lower than WT. However, while treatments with Pio or NL1 in WT injured mice significantly maintained mitochondrial OCR to near normal levels in a dose-dependent manner, neither Pio nor NL1 were effective in preserving OCR in mitoNEET KO mice. These results indicate that the protection afforded by Pio is related to its interactions with the mitochondrial protein, mitoNEET, and not entirely dependent upon activation of Peroxisome Proliferator Activated Receptor (PPAR) as customarily reported. Ongoing experiments are extending the effective therapeutic time windows after SCI for both Pio and NL1 before assessing their long-term effects on functional neuroprotection.

Title: An innovative chondroitin sulfate proteoglycan reduction peptide (CRP) to repair chronic spinal cord injury

Authors: *C.-Y. LIN[1], K. LI[1], J. SILVER[2], A. SPARKS[1], Y.-S. LEE[1]
[1]Neurosci, Cleveland Clin., Cleveland, OH; [2]Dept Neurosci, Case Western Reserve Univ., Cleveland, OH

Abstract: No effective therapeutic strategy has been developed to treat chronic spinal cord injury (SCI), which is the major condition among most patients with SCI. Chondroitin sulfate proteoglycans (CSPGs) are the major inhibitory extracellular matrix components of the glial scar and perineuronal net (PNN) and they are significantly upregulated after SCI. Here we describe the development of approaches to globally modulate CSPGs using a novel CSPG Reduction Peptide (CRP) that eliminates CSPGs through lysosomal degradation as a potential therapeutic strategy to treat chronic SCI. An initial *in vitro* study, using axon growth inhibitory Neu7 astrocytes, showed the efficacy of CRP to remove CSPGs through the lysosomal degradation mechanism. We further tested in vivo, the effects of CRP and its combination with the Intracellular Sigma Peptide (ISP) that targets the CSPG receptor in repairing a chronic T8 contusive SCI in the adult rat. There were five experimental groups including sham, SCI + scrambled peptides, SCI+CRP, SCI+ISP, and SCI+CRP+ISP. The contused animals received peptide treatments beginning at 2 months post injury. All peptides were delivered systemically through daily subcutaneous injections in the back above the injury site for 3 months. The BBB open field test and kinematic analyses on a treadmill showed locomotor improvements in both CRP and CRP+ISP cohorts but not in the ISP alone or scrambled peptide groups when results were compared between the baseline scores (2 months post injury) and those at the end of the observation period (5 months after SCI). Bladder functional improvements (observed using metabolic cages as well as urodynamic analyses) were only present in the CRP and CRP+ISP groups. The improved bladder activities were inhibited by a 5HT-1A receptor antagonist indicating a contribution of the serotonergic system to recovery. Our anatomical studies revealed that CRP and CRP+ISP promoted substantial axonal regeneration through and beyond the lesion and/or sprouting of serotonergic and tyrosine hydroxylase fibers far distal to the lesion site. Interestingly, NG2+ cells in the lesion epicenter appeared to provide a substrate upon which regenerating axons crossed through the scar. In addition, the CRP and CRP+ISP treatments clearly reduced scar as well as PNN CSPGs, increased intensity of serotonergic fiber immunoreactivity, and increased intensity of synaptic markers at lumbo-sacral levels. Our data suggest that CRP and the combination of CRP+ISP can reduce both scar and PNN associated CSPGs to enhance both regeneration and sprouting to promote the restoration of locomotor and bladder function after chronic T8 contusive SCI in adult rats.

Title: Functional improvement by human neural progenitor cells following severe spinal cord injury (SCI) is supported by tissue-type plasminogen activator

Authors: Y. SHIGA[1], A. SHIGA[1], P. MESCI[2], H. KWON[1], C. BRFAULT[3], J. KIM[4], E. MANTUANO[3], S. OHTORI[5], A. MUOTRI[2], S. L. GONIAS[3], *W. M. CAMPANA[1]

Abstract: Spinal cord injury (SCI) is associated with severe motor and sensory impairments. Chronic pain develops in 70% of SCI patients. Recently neural stem cells (NSCs) grafted into injured spinal cords show great promise by extending large numbers of axons that are associated with motor improvement, albeit after one year (Lu et al., 2017). Effects of NSCs on pain outcomes remain unknown. Study goals were: 1) to optimize grafting conditions to better facilitate motor recovery; and 2) to relieve neuropathic pain behaviors associated with SCI. We optimized grafting conditions by using human induced pluripotent stem cells (iPSCs) derived neural progenitor cells (*h*NPCs) expressing high levels of nestin (Chailangkam et al., 2016). *h*NPCs also express LDL-receptor-related protein-1 (LRP1), that we have shown promotes cell survival. *h*NPCs were grafted using an optimized fibrinogen/thrombin matrix, and growth factor cocktail. We also studied the effects of adding enzymatically-inactive tissue plasminogen activator (EI-tPA). This derivative of an FDA-approved drug demonstrates anti-inflammatory activity (Mantuano et al., 2017) and functions as a neurogenesis factor via NMDAR/LRP1 cell-signaling. In cultured *h*NPCs, EI-tPA increased nestin, sox2 and a pre-neuronal marker CD24 mRNA, by 2-3 fold in 48 hrs. Adult immunodeficient rats received severe T3 spinal cord compression (T3SCI) or sham surgeries. One week following SCI, *h*NPCs expressing GFP, were grafted into the lesion site. BBB and forelimb neuropathic pain behaviors scores were evaluated weekly for four months. Significant functional motor recovery occurred after 6 weeks and continued to improve over 4 months in *h*NPCs treated with EI-tPA (***$P<0.005$). Accordingly, tibialis anterior muscle weights were greater in EI-tPA groups (*$p<0.05$). *h*NPCs differentiated into mostly neurons and integrated into host tissues. Graft-derived βIII-tubulin positive axons

emerged from grafts within 8 weeks and extended through T8 after 4 months. Density of graft-derived axons was greater in EI-tPA treated groups. Markers of motor neuron maturity, ChAT and MNX1, appeared by 8 weeks. T3SCI lesions induced the development of forelimb spontaneous lifting and tactile allodynia, as we described (Lee-Kubli et al., 2016) but remained unchanged by any treatment group. Notably, graft-derived neurons expressed, Lbx1, a marker of sensory relay neurons, suggesting some development of sensory fates. Thus, grafted *h*NPCs treated with EI-tPA in the injured spinal cord facilitate functional motor recovery without exacerbating or mitigating pain, supporting the feasibility and safety of this approach for clinical translation.

Title: Paired brain and spinal cord stimulation augments muscle responses through convergence of the corticospinal tract and large diameter afferents on spinal interneurons

Authors: *H. PARK, A. PAL, J. B. CARMEL
Burke Neurolog. Inst., White Plains, NY

Abstract: We have developed a neuromodulation paradigm that pairs stimulation of motor cortex and dorsal spinal cord to strengthen spared neural circuits after neurological injuries that cause damage to the corticospinal tract (CST). Sub-threshold spinal cord stimulation strongly augmented cortical motor evoked potentials (MEPs) when they arrive synchronously in the spinal cord. However, the circuit-level mechanism of the augmentation has not been determined. We hypothesized that the CST and large diameter afferents converge onto premotor spinal interneurons during paired stimulation. To test our hypothesis, we selectively inactivated each of these tracts with a chemogenetic method (Designer Receptor Exclusively Activated by Designer Drug, DREADD) during paired stimulation. For CST inactivation, we injected an AAV into the forelimb area of a motor cortex and another into the cervical spinal cord; doubly infected corticospinal neurons express inhibitory DREADD (Fig. 1A). For inactivation of large diameter afferents, we injected AAV5 into cervical dorsal root ganglia (Fig. 1B); the tropism of this virus

is for large-diameter neurons. When the CST was inactivated with the designer drug, clozapine N-oxide (CNO), the number of paw adjustment in pasta manipulation test was decreased and the MEPs augmentation was abolished in the targeted forelimb. Inactivation of large diameter afferents also abolished the MEPs augmentation in the targeted forelimb. In both cases, paired stimulation effects returned when CNO washed out (Fig. 1C). In addition, interneurons were activated after repeated paired stimulation in the deep dorsal horn and medial intermediate zone where the CST axon and large diameter afferents overlap. Thus, we demonstrate that the CST and large diameter afferents are necessary for the effects of paired stimulation, and the site of their convergence is likely interneurons in deep dorsal horn and medial intermediate zone. Understanding the systems-level mechanisms of paired stimulation could help to improve its targeting and efficacy for restoring function after injury.

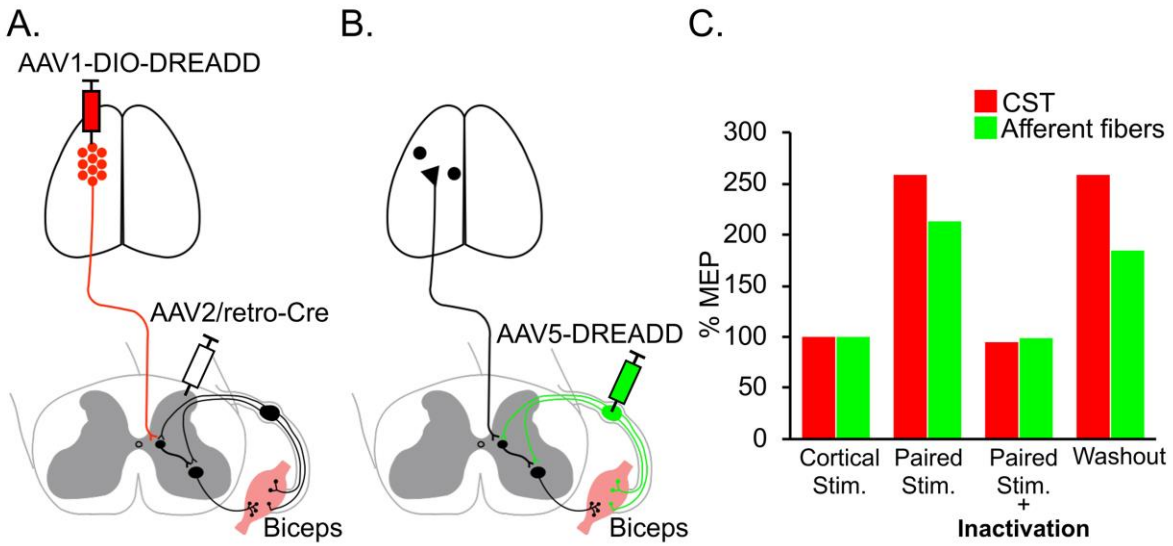

Figure 1. Selective inactivation of CST or large diameter afferents. A. Method for CST inactivation. AAV1-hSyn-DIO-hM4D(Gi)-mCherry was injected into the forelimb area of a motor cortex and AAV2/retro-hSyn-EBFP-Cre was injected into the cervical spinal cord at C5, C6 contralaterally. B. Method for large diameter afferent inactivation. AAV5-hSyn-hM4D(Gi)-mCherry was injected into C5, C6 and C7 dorsal root ganglia. C. % MEP augmentation before, during, and after inactivation.

Title: Injectable polypeptide hydrogels and Ribotag neural stem cells as tools to study cell grafting survival and differentiation outcomes in spinal cord injury

Authors: *T. M. O'SHEA[1], A. L. WOLLENBERG[2], J. H. KIM[1], Y. AO[1], A. CZECHANSKI[3], L. G. REINHOLDT[3], T. J. DEMING[2], M. V. SOFRONIEW[1]

Abstract: Repopulating non-neural lesion cores of traumatic spinal cord injuries (SCI) with neural tissue via grafting of neural stem/progenitor cells (NSPC) can aid axon regeneration and reorganization of damaged neural circuits. However, NSPC graft necrosis, cell migration away from lesions as well as spontaneous and uncontrollable graft cell differentiation remain key challenges limiting the translational potential of NSPC transplantation. To address these challenges we developed two tools to facilitate rigorous cell and molecular biological evaluation of NSPC grafting in murine SCI studies. Firstly, an injectable polypeptide hydrogel based on non-ionic methionine-sulfoxide was synthesized to act as a cell carrier to protect transplanted cells during injection and initial exposure to the hostile SCI lesion microenvironment. The hydrogel was combined with a neural stem cell line that was derived via neural induction of mouse embryonic stem cells that contain a Ribotag allele to facilitate cell specific genetic evaluation of grafted cells from whole tissue *in vivo* as well as identification of NSPC and their progeny by immunohistochemistry. NSPC suspended in hydrogels showed cell viability comparable to standard culture conditions. Owing to its non-fouling sulfoxide functionality, the hydrogel showed superior preservation of NSPC stemness and multipotency in serum rich environments *in vitro* compared to various cell adhesive materials. NSPC in hydrogels injected into both uninjured forebrain and crush SCI showed enhanced survival compared to cells in media and remained local to the injection site or lesion compartment. Without the inclusion of specific molecular cues to drive differentiation, NSPC displayed an immature astroglial phenotype *in vivo*. In acute and chronic crush SCI, these immature astroglial cells integrated into preserved neural tissue immediately adjacent to the lesion compartment and acted as cellular substrates that supported regrowth of propriospinal axons. Inclusion of various differentiation directing small molecule morphogens into hydrogels altered the phenotypic distribution of grafted cells *in vitro* and *in vivo*. These findings suggest that the polypeptide hydrogel and Ribotag NSPC are powerful tools for the study of NSPC transplantation in CNS injury.

Title: Restauration of sensory-motor integration after dorsal rhizotomy and repair with platelet-rich plasma (PRP) associated with transgenic human embryonic stem cells (hESC) overexpressing FGF-2

Authors: *M. V. DE CASTRO[1], S. KYRYLENKO[2], M. SANTANA[1], Â. LUZO[1], A. OLIVEIRA[1]
[1]Univ. of Campinas (UNICAMP), Campinas, Brazil; [2]Med. Inst. of Sumy State Univ., Sumy, Ukraine

Abstract: Motor coordination involves specific neural processes including sensory input, perceptual and cognitive processing. It is dependent on delicate sensory-motor integration, which is particularly evident in the spinal cord. In this sense, primary afferent inputs enter the spinal cord through dorsal roots, projecting directly or indirectly to the motoneurons present in the ventral horn. Dorsal roots can be affected by a wide range of lesions, leading to a significant loss of sensorial information, greatly affecting motor behavior. Due to the possibility of generating inflammation and neuropathic pain, surgical procedures do not prioritize the repair of the afferent component. In this context, new therapies need to be developed for dorsal root repair. A promising treatment is the use of platelet-rich plasma (PRP), an adhesive and inductive element for nerve regeneration. Therefore, the present study evaluated the motor and sensory improvement following dorsal root repair with PRP associated with modified human embryonic stem cells. Thus, female adult Lewis rats (LEW/HsdUnib; n=5 per group) were subjected to unilateral rhizotomy (RZ) of the L4-L6 dorsal roots and divided into the following groups: (1) Unlesioned/Control; (2) RZ without repair; (3) RZ followed by root repair with PRP (RZ+PRP); (4) RZ followed by root repair with PRP associated with modified human embryonic stem cells (RZ+PRP+hESC). PRP was obtained from human blood subjected to centrifugation steps. It was characterized regarding platelet concentration, integrity, and viability. For cell therapy, hESCs were bioengineered to overexpress a human fibroblast growth factor 2 (FGF-2). The reflex arc recovery was evaluated daily through the electronic von-Frey method, during eight weeks, while changes in the glial response (GFAP and Iba1) and excitatory synaptic circuits (VGLUT1) were evaluated by immunofluorescence, eight weeks after lesion. The results indicate that PRP is

efficient to repair dorsal rhizotomy, allowing the reentrance of VGLUT1 positive primary afferents within the spinal cord. PRP application did not exacerbate astroglial (GFAP) and microglial (Iba1) reactivity, restoring the reflex of paw withdrawal over time. No signs of allodynia were observed. Cell therapy further enhanced such rewiring process. In conclusion, the repair with PRP and hESC is efficient and may be considered an approach to improve sensory-motor recovery following dorsal rhizotomy, fulfilling a critical gap in reparative procedures after this type of injury.

Title: Activity signaling to induce axon sprouting and regrowth after complete spinal cord injury

Authors: *S. L. BARLATEY[1], M. A. ANDERSON[1], J. COTTET[1], L. ASBOTH[1], L. D. P. BAUD[1], J. BLOCH[2], M. V. SOFRONIEW[3], G. COURTINE[1,2]

Abstract: Neuro-prosthetic rehabilitation promotes the recovery of voluntary leg movements through the reorganization of residual reticulospinal projection pathways. However, restoring supraspinal control of movement after an anatomically complete SCI will require robust regrowth and sprouting of severed axons across the injury. Here, we studied various strategies to enhance sprouting and activate growth programs of reticulospinal neurons. Our ultimate goal is to restore anatomical connectivity across a complete SCI, and to promote the functional integration of these new axons through targeted neuroprosthetic rehabilitation programs. To promote regrowth and sprouting of severed reticulospinal axons across an anatomically complete SCI in mice, we are manipulating various factors including the lesion environment with hydrogels and growth factors, the establishment of chemical axon guidance, the activation of intrinsic growth programs in neurons, and activity-dependent pathways. These interventions are

delivered with a spatiotemporal profile that is consistent with the growth of axons during development. While we obtained regrowth of severed reticulospinal axons within a complete SCI, the axons did not grow across the lesion, indicating the importance of identifying complementary strategies to attract the axons caudal to the injury in the future.

Title: Early activation and recruitment of endogenous stem cells for the treatment of spinal cord injury

Authors: *Z. ZABARSKY, T. D. LUO, X. MA, T. L. SMITH
Orthopaedic Surgery Res., Wake Forest Univ., Winston Salem, NC

Abstract: Spinal cord injury (SCI) is a devastating neurologic event with complex pathophysiological mechanisms that currently has no effective therapies available. The spinal cord has endogenous neural stem/progenitor cells (NSPCs) and after injury, neuroinflammation prevents NSPC-mediated neuroprotection and repair. The majority of regenerative medicine strategies for SCI overlook native NSPCs and transplant exogenous cells into the injured spinal cord during the later stages of injury, when inflammatory-associated tissue loss has developed, with limited success. This research aims to use a philosophically different approach by employing a multimodal combinatory treatment of regenerative pharmacologics that not only support the endogenous stem cells directly, but to also provide a sustainable microenvironment for growth and repair through immunomodulation of the surrounding tissue.
Using adult female Sprague-Dawley rats, a moderate-to-severe contusion-based SCI was employed following laminectomy by an Infinite Horizons Spinal Cord Injury Impactor at the T9 level. After injury, animals were treated with 1) Pioglitazone, 2) Granulocyte Colony Stimulating Factor, 3) Both drugs in combination, or 4) Vehicle (DMSO) control. Animals were transcardially perfused with PBS followed by 4% paraformaldehyde to prepare spinal cord tissue for histological and immunohistochemical analysis. Functional recovery was assessed by the Basso, Beattie, Bresnahan (BBB) locomotor rating scale on 1, 3, 7, 14, 21, and 28 days post injury (DPI) by two blinded observers. Repeated measures ANOVA was performed to trend the change in BBB scores over time (n=8/group). Animals treated with both drugs had significantly

higher BBB scores at 1 ($p<0.001$), 3 ($p<0.001$), 7 ($p<0.05$), and 14 ($p<0.05$) DPI compared to vehicle treated controls.
Histological analysis and functional recovery assessments may reveal how effective the treatments can increase NSPC numbers, decrease overall tissue damage, and prevent motor function loss. Findings may provide a better understanding of how key cellular functions can influence the microenvironment and viability of NSPCs to repair the injured spinal cord and potentially support the advancement of acute critical care interventions for SCI patients.

Title: Spinal cord injury perturbs circadian rhythms

Authors: *A. D. GAUDET[1], L. K. FONKEN[2], M. T. AYALA[1], E. M. BATEMAN[1], W. E. SCHLEICHER[1], E. J. SMITH[1], H. M. D'ANGELO[1], S. F. MAIER[1], L. R. WATKINS[1]
[1]Psychology & Neurosci., Univ. of Colorado Boulder, Boulder, CO; [2]Univ. of Texas at Austin, Austin, TX

Abstract: Spinal cord injury (SCI) can disrupt many physiological functions. The circadian system helps maintain homeostasis throughout the body by regulating daily rhythms in physiology and behavior. Circadian rhythms likely exist in all cell throughout the body, yet whether SCI alters daily rhythms remains under-studied. Here, we hypothesized that SCI in rats would disrupt several prominent circadian outputs including glucocorticoids, core temperature, activity, and circadian gene expression. Female and male rats were subjected to clinically relevant thoracic (T-) 8 moderate-to-severe contusion SCI (or laminectomy sham surgery). Circadian measures - including rhythms of plasma corticosterone, body temperature and activity (using small implanted transmitters), plasma glucose, and gene expression - were studied prior to and after surgery. First, we found that SCI disrupted intraspinal and peripheral rhythms of clock and inflammatory gene expression. Circadian rhythms in peripheral cells are entrained by key “oscillatory factors”, including glucocorticoids, body temperature, and activity. SCI caused overall increases and disrupted rhythms of the major rodent glucocorticoid, corticosterone. Pre-

surgery and sham rats displayed expected rhythms in activity and body temperature, whereas rats with SCI had blunted daily rhythms in activity and body temperature. In parallel, SCI increased plasma glucose levels and liver expression of glucose metabolism genes. Our data show that moderate SCI in rats causes wide-ranging circadian dysfunction that is severe at acute time points and gradually recovers over time. Normalizing post-SCI circadian rhythms could enhance recovery of homeostasis and quality-of-life.

Title: Hyperalgesia mediated by mu-opioid receptors in spinal GABAergic neurons

Authors: *X. ZHANG, Y. SUN
Inst. of Neuroscience, Chinese Acad. of Scie, Shanghai City, China

Abstract: Mu-opioid receptors (MORs), which is critical for analgesic effect of morphine, are highly expressed at the spinal level. MORs expressed in spinal excitatory neurons and projection

neurons play important roles in mediating analgesic effect of morphine. However, the functional role of MOR in spinal GABAergic neurons in nociception remains unknown. We investigated the role of MORs expressed in spinal GABAergic neurons in nociception using a new genetic approach, which enables selective expression of MORs in distinct neuronal populations. We found that selective activation of MORs expressed in spinal GABAergic neurons induced hyperalgesia, and evoked spontaneous nocifensive behavior. Consistently, blockade of endogenous activation of MORs expressed in spinal GABAergic neurons attenuated formalin-induced nocifensive behavior, which is likely mediated by suppression of spinal GABAergic synapses as shown in electrophysiological experiments. These results demonstrated that MOR-mediated disinhibition at the spinal level plays an important role in the development of hyperalgesia in inflammatory pain.

Abstract: Opioid analgesics, such as morphine and fentanyl, continue to be the cornerstones for treating moderate to severe pain. However, upon chronic administration, their efficiency is limited because of prominent side effects such as tolerance and dependence. One hypothesis for the occurrence of these side effects is that the chronic stimulation of the opioid system may trigger its endogenous counterparts, anti-opioid systems, producing hyperalgesia (opioid-induced

hyperalgesia, OIH) and analgesic tolerance. Previous data from our lab and others have shown that RF9, an antagonist of neuropeptide FF receptors (NPFF1R and NPFF2R), efficiently blocks opioid-induced hyperalgesia and tolerance when co-administered with fentanyl or morphine in rodents. In this study, we designed multi-target molecules that display mu-opioid receptor (MOR) agonist activity, as well as NPFF receptor antagonist properties. To this purpose, a set of unnatural peptide ligands was generated, which combines an already known high affinity mu-opioid receptor agonist together with the carboxyl-terminal RF-amide signature of NPFF. In vitro characterization of these compounds led to identification of KGFF03 and KGFF09 as G protein-biased MOPr agonists with full agonist or antagonist activity at NPFFRs, respectively. In agreement with their biased MOPr agonism, KGFF03/09 showed reduced respiratory depression in mice, as compared to the unbiased parent opioid agonist KGOP01. Chronic subcutaneous administration of KGOP01 and KGFF03 in mice rapidly induced hyperalgesia and analgesic tolerance, effects that were not observed upon chronic treatment with KGFF09. This favorable profile was further confirmed in a model of persistent inflammatory pain. In addition, we showed that KGFF09 induced less physical dependence compared to KGOP01 and KGFF03. Altogether, our data establish that combining, within a single molecule, the G protein-biased MOPr agonism and NPFFR antagonism, have beneficial effects on both acute and chronic side effects of conventional opioid analgesics. This strategy can lead to the development of novel and potent antinociceptive drugs with limited side effects upon acute and chronic administration.

Title: Hyporesponsivity to morphine in the Wistar-Kyoto rat model of hyperalgesia associated with negative affective state

Authors: *M. I. FERDOUSI[1,3], P. CALCAGNO[1,2,3], M. CLARKE[1,2,3], S. AGGARWAL[1,2,3], C. SANCHEZ[4], K. SMITH[4], J. P. KELLY[1,3], M. ROCHE[2,3], D. P. FINN[1,3]

Abstract: Background and aim: The role of the endogenous opioid system in pain-negative affect interactions and the influence of genetic background is poorly understood. Wistar-Kyoto (WKY) rats, a genetic model of negative affect that also exhibit hyperalgesia, show hyporesponsivity to systemically administered mu-opioid receptor (MOP) agonists. The ventrolateral periaqueductal grey (vlPAG) plays a key role in MOP-mediated antinociception. We compared the effects of systemic and intra-vlPAG administration of morphine (MOP agonist) on nociceptive responding to noxious thermal and inflammatory stimuli in WKY *versus* Sprague-Dawley (SD) rats and associated alterations in c-Fos expression in the nucleus raphe magnus (NRM) of the rostral ventromedial medulla (RVM) downstream of the vlPAG. Methods: Male WKY and SD rats (n=8-11/group) were allocated to groups across three experiments using within-subject design to investigate the effects of morphine (0.5-7.5 mg/kg, s.c.) in hot plate (HP) and formalin tests. In a subsequent study, the effects of intra-vlPAG administration of vehicle or morphine (1, 2.5, or 5 µg) on formalin-evoked nociceptive behaviour was investigated in male WKY and SD rats (n=6-7/group). Immunohistochemical staining of c-Fos in perfused brain sections was carried out. MOP expression in the vlPAG of the two strains was assessed using western immunoblotting. Data were analysed using repeated measures or two-way ANOVA followed by Student-Newman-Keuls *post hoc* test ($p<0.05$ significant). Results: In the HP test, the minimal effective dose of systemically administered morphine was 2 and 0.5 mg/kg in WKY and SD rats, respectively. Morphine significantly reduced formalin-evoked nociceptive behaviour in SD, but not in WKY, rats; the antinociceptive effects of morphine were attenuated by cyprodime (MOP antagonist). Plasma morphine levels did not differ between the two strains. Intra-vlPAG administration of morphine 1 µg reduced formalin-evoked nociceptive behaviour in SD, but not in WKY, rats; morphine 2.5 and 5 µg was antinociceptive in both strains. Intra-vlPAG administration of morphine dose-dependently increased c-Fos expression in the NRM of both strains, being more pronounced in SD than WKY rats. MOP expression in the vlPAG did not differ between strains. Conclusions: These data provide further evidence that WKY rats exhibit hyporesponsivity to the antinociceptive effects of MOP agonism. The results identify the vlPAG as a key locus for this hyporesponsivity in WKY versus SD rats and suggest that opioid-induced engagement of descending pain circuitry downstream of the PAG (within the NRM) is reduced in WKY rats versus SD counterparts.

Title: Effects of intrathecal PZM-21, a biased mu receptor ligand in rats

Authors: *S. KOKUBU[1,2], K. EDDINGER[1], P. GMEINER[3], T. L. YAKSH[1]
[1]Univ. California San Diego, LA Jolla, CA; [2]Dokkyo Med. Univ., Tochigi, Japan; [3]Emil Fischer Ctr., Erlangen, Germany

Abstract: PZM-21 is a mu receptor preferring ligand that signals though Gi protein with minimal activation of ß arrestin, e.g. a biased ligand. Methods: Using male adult Sprague Dawley rats prepared with chronic lumbar intrathecal (IT) catheters, we focused on: i) effects of IT PZM21 on thermal escape, formalin evoked flinching; ii) effects of naloxone (a pan MOR antagonists) and naltrendole (a delta receptor preferring antagonist) on IT PZM-21 effects; iii) adverse motor effects; iv) effects of repeated bolus delivery on tolerance and cross tolerance with IT morphine and v) effects of continuous IT PZM21 infusion on thermal escape. Results. i) IT bolus morphine and PZM-21 resulted in a dose dependent increase in acute thermal escape latencies, with a 3-4 hr duration of action. Additionaly IT PZM-21 resulted in a robust dose

dependent suppression of Phase 1 and phase 2 formalin evoked flinching. ii) Effects were blocked by IP naloxone but not by naltrindole. iii) IT morphine resulted in a naloxone resistant Straub tail. In contrast to IT morphine, motor dysfunction was observed with PZM21 only at the highest supra-analgesics dose. iv) Following 4 daily IT bolus injections to assess tolerance and cross tolerance, morphine but not PZM21 treated animals showed a loss of analgesia as compared as compared to saline treated animals. Animals tolerant to IT morphine showed a normal response to IT PZM-21. Animals treated with 4 days of IT PZM-21 showed no loss of response to IT morphine. v) IT infusion of PZM-21 or morphine resulted in a significant increase in thermal escape with recovery to baseline, e.g. tolerance by day 7-10. Significance: These results show that PZM-21 is analgesic as a mu opioid agonist. In many ways it resembles morphine though time course of tolerance may be slightly different and there is a suggestions of an asymmetric cross tolerance after bolus delivery. However, continuous IT infusion of PZM21 at equi-analgesic doses to morphine resulted in a comparable loss of effect over time. (NIH NIDA 5 R01 DA015353; TY; NIMH Screening Program, Bryan Roth)

Title: Mitogen-activated protein kinase signaling mediates opioid-induced presynaptic NMDA receptor activation, hyperalgesia and tolerance

Authors: *M. DENG, S.-R. CHEN, H. CHEN, Y. LUO, Y. DONG, H.-L. PAN
The Univ. of Texas MD Anderson Cancer Ctr., Houston, TX

Abstract: Opioid-induced hyperalgesia and analgesic tolerance can lead to dose escalation and inadequate pain treatment with μ-opioid receptor agonists. Opioids cause tonic activation of glutamate NMDA receptors (NMDARs) at primary afferent terminals, increasing nociceptive input. However, the signaling mechanisms responsible for opioid-induced activation of presynaptic NMDARs in the spinal dorsal horn remain unclear. In the present study, we determined the role of mitogen-activated protein kinase (MAPK) signaling in opioid-induced presynaptic NMDAR activation caused by chronic morphine administration. Whole-cell recordings of excitatory postsynaptic currents (EPSCs) were performed on dorsal horn neurons in rat spinal cord slices. Chronic morphine administration markedly increased the frequency of

miniature EPSCs, increased the amplitude of monosynaptic EPSCs evoked from the dorsal root, and reduced the paired-pulse ratio of evoked EPSCs. These changes were fully reversed by an NMDAR antagonist and normalized by inhibiting extracellular signal-regulated kinase 1/2 (ERK1/2), p38, or c-Jun N-terminal kinase (JNK). Furthermore, intrathecal injection of a selective ERK1/2, p38, or JNK inhibitor blocked pain hypersensitivity induced by chronic morphine treatment. These inhibitors also similarly attenuated a reduction in morphine's analgesic effect in rats. In addition, co-immunoprecipitation assays revealed that NMDARs formed a protein complex with ERK1/2, p38, and JNK in the spinal cord and that chronic morphine treatment increased physical interactions of NMDARs with these three MAPKs. Our findings suggest that opioid-induced hyperalgesia and analgesic tolerance are mediated by tonic activation of presynaptic NMDARs via three functionally redundant MAPKs at the spinal cord level.

Title: Cdk5-mediated phosphorylation of the delta opioid receptor: A key process for the regulation of cell surface receptors

Authors: *F. BERGERON, S. BERTHIAUME, B. QUIRION, E. ST-LOUIS, V. BLAIS, J.-L. PARENT, C. LAVOIE, L. GENDRON
Univ. de Sherbrooke, Sherbrooke, QC, Canada

Abstract: Under basal condition, the delta opioid receptor (DOP) is mainly located in intracellular compartments and is therefore hardly accessible to ligands. Interestingly, others and we have shown that the level of DOP at the cell surface can be increased. In particular, stimulation of DOP with an agonist, inflammatory pain, as well as prolonged treatment with morphine all increased the cell surface availability of DOP. The molecular mechanisms regulating the trafficking/targeting of DOP to the plasma membrane remain however poorly understood. We have previously shown that the cyclin-dependent kinase 5 (Cdk5) participates in the regulation of DOP-mediated analgesia. Here, we hypothesized that the retention of DOP in the endoplasmic reticulum (ER) can be decreased, and hence the level of DOP at the cell surface

increased, by targeting the interaction between p35, Cdk5 and DOP. When coexpressed in HEK293T cells, we found that both p35 and Cdk5 interact (co-immunoprecipitate) together in the presence or absence of DOP. Interestingly, both proteins were also found to individually interact with the receptor, but only when the other counterpart was absent. Indeed, the interaction with the receptor was lost when p35 and Cdk5 were expressed together. Once activated by its neuronal-specific activator p35, Cdk5 is thought to phosphorylate the T161 of a consensus sequence [(S/T)PX(K/H/R)] located within the second intracellular loop of DOP (ICL2). This threonine residue is important in the trafficking of DOP because when mutated to an alanine (T161A), a significant decrease in its surface expression was observed. Interestingly, the phosphorylation motif of Cdk5 (T161-K164) overlaps with the binding site of COPI (K164-K166), a coatomer complex involved in the retrograde transport of DOP from the Golgi to the ER. We believe that once the consensus sequence is phosphorylated by Cdk5, the association of COPI to DOP is compromised, allowing DOP to escape the Golgi and reach the plasma membrane. Supporting this idea, an increase of DOP at the cell surface was observed when the receptor is coexpressed along with the mu opioid receptor (MOP). This effect was however abolished when MOP was coexpressed with the T161A DOP mutant, further supporting that the Cdk5-mediated phosphorylation of T161 plays a key role in the morphine-induced trafficking of DOP. A better understanding of the mechanisms underlying this process may lead to the identification of a new pharmacological strategy to increase the levels of DOP at the cell surface, and hence the DOP-mediated analgesia for the treatment of pain.

Title: Morphine promotes breast cancer cell proliferation via mechanism independent of m-opioid receptor: An *in vitro* study

Authors: *R. RAMACHANDRAN[1], Y. ZHU[1], Y. HE[1], P. W. MANTYH[2], T. L. YAKSH[1]
[1]Anesthesia, UCSD, La Jolla, CA; [2]Univ. of Arizona, Tucson, AZ

Abstract: Abstract:
Background: Systemic morphine results in significant pain relief in patients that are in advanced stage of cancer. However, extra analgesic effects of morphine in facilitating tumor development is a recent concern. Several pre-clinical studies have showed that morphine can enhance tumor angiogenesis and promote cancer growth reducing long time survival with few contradictory

studies. The present study therefore dissects the effects of morphine on cell proliferation using a rat mammary adenocarcinoma cell line (MTLn3).
Materials and Methods: MTLn3 cells were cultured in MEM-alpha growth media supplemented with 5% heat-inactivated fetal bovine serum and 0.5 % pen-strep. Cells were Incubated at 37°C in a humidified 5% CO_2 environment and grown to 70-90% confluence. To assess proliferation MTLn3 cells were seeded (1 x 10^4 cells/well) in a 12 well plate and incubated for 24 hrs, followed by 48 hrs incubation with test material. The cells were incubated with Morphine (3 nM - 30 μM), fentanyl (0.03 pM - 0.3 μM) , Naloxone (3 nM - 30 μM) and PZM 21 (3 nM - 30 μM) and cell proliferation assay was performed after 48 hrs by counting total number of cells using a hemocytometer by the observer blinded to the treatment.
Results: Morphine enhanced the proliferation of MTLn3 cells following 48 hrs incubation. A peak effect was observed with 0.03 μM morphine. This effect was not reversed by naloxone or naltrexone. Further, fentanyl did not promote cell proliferation. Moreover, PZM-21 a potent μ-opioid receptor agonist did not have any effect on proliferation.
Conclusion: These results show that morphine enhanced proliferation of breast cancer cells and that the tumor enhancing effects of morphine may independent of μ-opioid receptor. MAS related g-protein coupled receptor (MRGPR) may be of particular interest.

Title: *Ex vivo* receptor occupancy at mu and kappa opioid receptors in rat brain

Authors: *S. C. CHEETHAM, A. NEEDHAM, L. JAGGER
RenaSci Ltd, Nottingham, United Kingdom

Abstract: The opioid system has been implicated in a number of behavioural and physiological responses including control of pain and mood. Opioids exert their pharmacological actions via mu (μ)-, kappa (κ)- and delta (δ)- opioid peptide receptors. This study investigated the *ex vivo* receptor occupancy of the μ-opioid receptor agonists, morphine and buprenorphine, and the κ-opioid receptor agonist, (-)-pentazocine, in various brain regions following peripheral administration in the rat. Male Sprague-Dawley rats (300±50 g) were administered vehicle, morphine [3, 10 or 30], buprenorphine [0.1, 0.3 or 1] or (-)-pentazocine [5, 10 or 20] and terminated 60 (morphine, buprenorphine) or 30 mins later ((-)-pentazocine). Doses in square brackets are [mg/kg ip]. Brains were removed. Coronal sections (20 μm) containing regions of

interest (cortex, striatum, hippocampus and periaqueductal grey (PAG)) were cut and incubated in buffer containing either [^{3}H]DAMGO (2 or 5 nM) or [^{3}H]U-69,593 (2.5 nM) for 10 or 90 mins, respectively. Non-specific binding was determined by 50 μM (-)Naloxone or 10 μM U-69,593 for [^{3}H]DAMGO or [^{3}H]U-69,593 autoradiography, respectively. Binding was terminated by aspiration and sections washed in buffer (3 x 5 mins). Radioactivity bound to the section was determined using a Beta-Imager. Results are expressed as % occupancy (determined from mean specific binding using 100 % for the vehicle group), n = 3-5 rats/group. Significant differences from control are denoted by $^{*}p<0.05$, $^{**}p<0.01$, $^{***}p<0.001$. Morphine [10 and 30] significantly occupied μ-opioid receptors labelled by [^{3}H]DAMGO in the cortex (49** and 61 %***), striatum (52** and 74 %***), hippocampus (48* and 56 %**) and PAG (33%*, top dose only). Buprenorphine [0.3 and 1] significantly occupied μ-opioid receptors in the cortex (92*** and 93 %***), striatum (87*** and 89 %***) and hippocampus (88 %***, both doses). The lowest dose of buprenorphine tested also significantly occupied μ-opioid receptors in the cortex (49 %*). (-)-Pentazocine [5, 10 and 20] significantly occupied κ-opioid receptors labelled by [^{3}H]U-69,593 in the striatum (54*, 44* and 55 %**). Morphine and buprenorphine significantly occupied central μ-opioid receptors in a dose-dependent manner. (-)-Pentazocine significantly occupied central κ-opioid receptors at the doses tested. This technique can be used to determine CNS penetration and receptor occupancy of novel drugs at μ- and κ-opioid receptors in rodent brain.

Title: NKTR-181: Relationship between mu-opioid receptor binding kinetics and *in vivo* pharmacodynamics

Authors: *L. VANDERVEEN, T. MIYAZAKI, S. K. DOBERSTEIN, J. ZALEVSKY
Nektar Therapeut., San Francisco, CA

Abstract: NKTR-181 is a novel mu-opioid receptor agonist with a slow onset of neuropharmacological effects in preclinical and human studies that is attributable, in part, to its slow rate of entry into the CNS. It is likely that mechanisms at the molecular level also contribute to NKTR-181's pharmacodynamic profile. In competitive receptor radioligand binding assays, NKTR-181 was found to have moderate binding affinity (K_d = 240 nM) to mu-opioid receptor (MOR) that was approximately 10-fold lower relative to oxycodone. *In vitro* receptor binding kinetic studies showed that NKTR-181 had an approximately 10-fold slower k_{on} but a similar k_{off} relative to oxycodone, demonstrating that on-rate defines the reduced affinity of NKTR-181 for MOR. The impact of association rate on receptor pharmacology was assessed by comparing the differential effects of NKTR-181 and oxycodone on kinetic signaling responses using *in vitro* functional assays, such as [^{35}S]GTPγS binding and cAMP. To establish the kinetics of MOR pharmacology in the CNS, *in vivo* pharmacodynamic studies were conducted that measure dopamine in microdialysis samples collected from the nucleus accumbens shell of awake rats. NKTR-181-dependent dopamine induction in the nucleus accumbens was more gradual compared to oxycodone following intravenous administration; however, the response was sustained for much longer. Together, these data suggest that the onset of NKTR-181 pharmacology is governed initially by its low concentration in the CNS, a result of slow CNS entry rate, coupled with slow association with its target receptor. The consequence is slow MOR occupancy that produces an initially modest response to NKTR-181 that develops into a substantial and sustained pharmacodynamic effect. In conclusion, receptor binding kinetics play a key role in understanding the cellular response and *in vivo* pharmacodynamic profile of NKTR-181.

Title: Phosphatidylethanolamine-binding protein reduces βarrestin2 recruitment to the mu opioid receptor, thus promoting opioid anti-nociception

Authors: *J. E. LAVIGNE[1], C. KIM[2], K. A. EDWARDS[4], J. M. STREICHER[3]
[1]Dept. of Pharmacol., Univ. of Arizona Col. of Med., Tucson, AZ; [3]Pharmacol., [2]Univ. of Arizona, Tucson, AZ; [4]Mol. and Systems Biol., Dartmouth Col., Hanover, NH

Abstract: The United States has roughly 100 million people suffering from chronic pain, which has been poorly managed by opioid treatment with attendant side effect and abuse liabilities. Recent efforts to create novel therapies that avoid these problems include making biased ligands at the mu opioid receptor (MOR) and targeting other receptors such as the cannabinoid system; however none have been truly successful. A likely reason for this is due to a lack of understanding of the mechanisms of ascending and descending pain pathways. Although the general mechanisms and circuits are well known, less is known about the micro-circuitry, cell types, receptor distribution and receptor signaling mechanisms within these pain pathways. Our lab has identified a novel regulator of MOR signaling, phosphatidylethanolamine-binding protein (PEBP), and characterized its role in MOR signaling and MOR mediated behavior. PEBP in its unphosphorylated monomeric form binds and inhibits Raf-1, and when phosphorylated by PKC it will dimerize, bind, and inhibit GRK2. Thus we hypothesized that inhibiting PEBP will increase free GRK2 and thus increase desensitization and decrease MOR analgesic effects. Indeed, when using a small molecule PEBP inhibitor, locostatin, injected in mice intrathecally (*it*) or intracerebroventricularly (*icv*), there was a 45.2% (*icv)* and 57.7% (*it*) decrease in morphine's antinociceptive effect in the tail flick assay. We next sought to identify which component of PEBP signaling was mediating the reductions in antinociception. We first examined PEBP's role in ERK signaling using siRNA to knockdown PEBP in two different cell lines, which showed no differences in MOR mediated ERK signaling. We also observed no differences in spinal cord ERK with PEBP inhibition. Next we sought to determine PEBP's role in βarrestin2 (βarr2) recruitment to the MOR, which is downstream of GRK2. Using two different assays we measured βarr2 recruitment to the MOR after knockdown or inhibition of PEBP. We observed a consistent 30% increase in βarr2 recruitment to the MOR, while PEBP activation with PMA led to a reciprocal decrease in βarr2 recruitment. We are currently utilizing a GRK2 inhibitor to directly link the behavioral and signaling changes due to PEBP inhibition to GRK2 activity at the MOR. Furthermore, we will investigate whether PEBP has a role in gating descending pain control: nociceptive input leads to PKC and thus PEBP activation, leading to

GRK2 sequestration and more effective MOR response to endogenous opioids. These insights will help meet the need to understand how distinct signaling regulators act within a circuit, potentially leading to improved future therapies for pain.

Abstract: Cellular interactions between delta and mu opioid receptors (DORs and MORs) are thought to regulate pain and opioid analgesic efficacy. However, the identity of the nociceptive neurons in which such interactions could occur *in vivo* remains elusive. Here, we used knockin reporter mice, as well as immunohistochemical, *in situ* hybridization, and electrophysiological techniques in wild type mice, to resolve the functional organization of DORs and MORs along pain neural circuits. In the spinal cord dorsal horn, we found that DORs and MORs are mostly segregated in different populations of lamina II excitatory interneurons, and that DOR-MOR co-expression is limited to subpopulations of lamina I projection neurons of the anterolateral tract. Similarly, DOR-MOR co-expression is rare in several brain regions that process nociceptive information and shape the different dimensions of pain experience, including the parabrachial nucleus, amygdala, and anterior cingulate cortex. Unexpectedly, we found that DOR-MOR co-

expression predominates in neuronal populations of motor circuits, in pre-motor neurons of the spinal cord ventral horn, and in cerebellum-projecting neurons of the pontine and lateral reticular brain nuclei. Collectively, these data provide the fundamental neuroanatomical basis for understanding the mechanism of action of endogenous and exogenous opioids and for developing improved opioid analgesics, an urgent need given the chronic pain and opioid epidemics.

Title: Examining sex differences in analgesic tolerance to a peripherally-restricted opioid combination

Authors: *D. J. BRUCE[1], C. PETERSON[2], K. KITTO[2], C. FAIRBANKS[3], G. WILCOX[4]
[1]Pharmacol., [2]Neurosci., [3]Pharmacology, Neuroscience, Pharmaceutics, [4]Pharmacology, Neuroscience, Dermatol., Univ. of Minnesota, Minneapolis, MN

Abstract: The development of analgesic tolerance to opioid pharmacotherapies presents a persistent issue in the treatment of chronic pain, resulting in dose escalation and increased risk for dependence and respiratory depression. Recent studies have demonstrated the involvement of peripheral opioid receptors in the development of opioid tolerance to classical opioids like morphine and oxycodone. There have also been reports of differences in opioid analgesia, tolerance and addiction between males and females. Therefore, we studied whether peripherally-restricted opioid combinations would differentially induce tolerance in a rodent model of neuropathic pain. For these studies, we used loperamide (Lo), a peripherally-restricted mu-opioid agonist, in combination with oxymorphindole or N-benzyl-oxymorphindole (OMI, BOMI), which are partial and full agonists at the delta-opioid receptor, respectively. The Lo-OMI and Lo-BOMI combinations have been shown to synergistically reverse numerous pain states in mice, including neuropathic pain. After the induction of a neuropathic pain phenotype with spared nerve injury, male or female mice and rats were given once daily injections of saline, Lo-OMI, Lo-BOMI or morphine for 10 days, and daily mechanical sensitivity was monitored by an electronic von Frey apparatus. Initial experiments indicate that male mice do not develop

tolerance to either peripherally-restricted combination, but that female mice rapidly become tolerant to the analgesic effects of Lo-BOMI. From these results, we conclude that there is a sex difference in the development of peripherally-mediated opioid tolerance in mice, and that this phenomenon is dependent on the delta opioid component of a synergistic pair.

Title: Impact of advanced age and sex on μ opioid receptor expression, affinity, and signaling in the rat periaqueductal gray: Implications for analgesia

Authors: *E. FULLERTON[1], M. RUBAHARAN[1], M. C. KAROM[1], R. I. HANBERRY[1], A. Z. MURPHY[2]

Abstract: An estimated 45-80% of the aging population (65 and above) suffers from chronic pain on a daily basis. Pain in the elderly is severely under-treated; it is currently estimated that 47-80% of community-dwelling and 16-27% of institutionalized individuals do not receive adequate treatment for their pain. While opiate-based analgesics are the standard for pain management, clinical studies indicate that the elderly are less sensitive to the pain-relieving properties of opiates. Remarkably, very little is known regarding the impact of advanced age on opioidergic signaling in the midbrain periaqueductal gray (PAG), a key neural site for opiate action. The present studies test the hypothesis that reduced efficacy of opioids observed in the aged population is due to changes in mu opioidergic expression, affinity, and signaling in the PAG. Using immunohistochemistry and autoradiography, we report decreases in both μ opioid receptor (MOR) expression and [^{3}H]-DAMGO binding in the ventrolateral PAG (vlPAG) in aged (16-20 months) vs. adult (2-3 months) rats. In addition, MOR protein expression and binding are consistently higher in males versus females, regardless of age. Furthermore, our behavioral studies show that the antihyperalgesic effect of morphine is significantly attenuated in aged male rats compared to adults; no shift in morphine ED_{50} values was observed in females. These analyses indicate that age and sex impact MOR expression in the PAG. Current studies are underway assessing the impact of age and sex on MOR binding affinity (using ligand binding

assays) and MOR signaling (using GTPγS assays). Collectively, the data provide novel insight into the impact of age and sex on the molecular mechanisms mediating opioid analgesia.

Title: cMyc mediated the expression of EZH2 in an epigenetic manner in morphine tolerance in rats

Authors: K. TAKAHASHI[1], H. YI[2], D. IKEGAMI[4], Y. KASHIWAGI[1], S. LIU[1], D. LUBARSKY[1], *S. HAO[3]

Abstract: The opioid epidemic has recently taken a vast toll on American society. Repeated opioid induces analgesic tolerance, dependence, or hyperalgesia. Morphine modulates mRNA expression of c-Myc in the kidney fibroblasts. Enhancer of zeste homolog 2 (EZH2), an epigenetic writer, is a histone methyl transferase subunit of a polycomb repressor complex. It is not clear about the role of c-Myc and EZH2 in the morphine tolerance (MT) state. In the present study, we hypothesized that c-Myc played an important role in MT through mediating EZH2 in an epigenetic manner in rats. MT was induced by repeatedly intrathecal morphine twice daily for 7 days. Mechanical threshold and thermal latency was measured using von Frey test and hot plate test. Intrathecally c-Myc antisense-oligodeoxynucleotide (AS-ODN) or GSK126 (a EZH2 inhibitor) was given before morning morphine once daily for 7 days. C-Myc or EZH2 proteins was measured using western blots and immunohistochemistry. Chromatin immunoprecipitation (ChIP)-qPCR and RT-PCR assays were used for the cMyc gene promotor enrichment and transcription. Chronic morphine induced MT at day 7. Immunohistochemistry shows that the expression of cMyc and EZH2 are localized in the neurons of the spinal cord dorsal horn in MT rats. The expression of cMyc and EZH2 was increased at the spinal cord dorsal horn in MT rats using western blots. Intrathecal cMyc-AS-ODN against or GSK126 reduced MT development in the von Frey test and hotplate test. ChIP-qPCR assay demonstrated that MT increased the

enrichment of cMyc bound at the EZH2 gene promotor area. The present findings suggest that cMyc and EZH2 are involved in spinal MT, and that cMyc mediated EZH2 expression in MT in an epigenetic manner.

Title: Acute fasting induces analgesia via activation of opioid system

Authors: *J.-Y. LEE[1], Y. KANG[2], S. OH[3]
[1]Brain and Cognitive Sci., Seoul Natl. Univ., Seoul, Korea, Republic of; [2]Osaka Univ. Grad. Sch. Dent., Osaka, Japan; [3]Sch. of Dent, Seoul Nat'l Univ., Seoul, Korea, Republic of

Abstract: Pain is considered to be both sensory and emotional experience. Since emotion is affected by homeostasis such as temperature, hunger, satiety and thirsty, the perception of pain is also likely to be regulated by homeostatic control. Feeding behavior is crucial for maintaining homeostasis and it is well investigated that pain perception is changed in eating disorder patients. Opioid system, especially is known to modulate pain as well as feeding homeostasis. However, little is known about the relationship between feeding homeostasis and pain. In the present study, we examined whether pain perception is affected by change of feeding homeostasis, with focus on opioid system. We found that 24h acute fasting suppressed formalin-induced paw licking behavior in the second phase. Intraperitoneal administration of opioid receptor antagonist (Naloxone, 10 mg/kg) inhibited acute fasting-induced analgesic effect. Taken together, our results suggest that acute changes in feeding homeostatic lead to analgesic effects, which are related to opioid receptor.

Title: Glycine receptor-targeted analgesics for the treatment of chronic pain

Authors: *J. CAPOROSO, M. WELLS, P. TANG, Y. XU
Anesthesiol., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Glycine receptors (GlyRs) are inhibitory ligand-gated ion channels that regulate signal transduction in the central nervous system. They are important targets for many anesthetics and analgesics, including Δ9-tetrahydrocannabinol (THC). The undesirable psychoactive effects of THC are independent of this glycinergic mechanism for analgesia. Using *in vitro* electrophysiology, we tested a group of top-ranked compounds from computational screening that were predicted to bind to the THC site in α3GlyR. The compound with the best potency and selectivity (MJPY1) was used as a scaffold to select analogs for *in vivo* optimization of the analgesic effects. MJPY1 and 13 analogs were tested for analgesic effects using CD1 strain mice with CFA-induced inflammation to a hind paw. Mice were treated with MJPY compounds and the analgesic effects were measured using a Hargreaves or Thermal Plate Preference apparatus. The lead compound MJPY1 and 7 of the analogs produced analgesia against inflammatory chronic pain in the Hargreaves test. One compound (MJPY2) showed even greater analgesia than MJPY1 in both behavioral tests. The effects of these compounds are observed within 30 minutes of treatment and last for at least 90 minutes. MJPY1 and MJPY2 were also examined for tolerance via the Hargreaves test with repeated doses: no tolerance or decrease in analgesia was observed for MJPY1 or MJPY2. Both compounds were also tested for mutagenicity via the Ames test and showed negligible activity. Qualitative behavioral observations suggest that none of the MJPY compounds produce any negative psychoactive effects. In conclusion, we have discovered a novel class of analgesics acting at the THC-binding site in GlyRs that produce analgesia without tolerance, mutagenicity, or psychoactive effects. More intensive testing is required to fully characterize the structure-activity relationship of these compounds and optimize their analgesic effects. The analgesic action of these novel compounds may have a significant impact on chronic pain management and help curb the use of popular analgesics with addictive side effects.

Title: MAGL inhibition attenuates cancer-induced bone pain

Authors: *A. L. THOMPSON[1], S. GRENALD[4], H. CICCONE[2], W. STAATZ[1], T. M. LARGENT-MILNES[2], B. CRAVATT[5], T. W. VANDERAH, Ph.D.[3]

Abstract: Many types of cancer metastasize to the bone, but one of the most prevalent cancers that does is breast cancer. The localized destruction of the bone causes severe, chronic pain that leads to a significant reduction in quality of life and functional status. Bone cancer pain proves to be very difficult to manage due to its progressive nature and multi-modal etiology. The current treatment of cancer induced bone pain (CIBP) is opiate therapy but has drawbacks due to the severe side effect profiles including respiratory depression, hyperalgesia and addiction. Cannabinoids have long been known to inhibit neuropathic and inflammatory pain, but cannabinoids have undesirable psychotropic effects that have decreased interest for further drug development. The endogenous cannabinoids (eCB) system, though, has proven to be a viable target for novel analgesics. The eCB system synthesizes cannabinoid compounds from long chain fatty acids. The primary catabolic enzymes of these compound are MAGL and FAAH. Previous studies have demonstrated that inhibition of FAAH and MAGL leading to increased eCBs are effective as anti-nociceptive and anti-allodynic compounds in models of neuropathic pain. In our studies, we explored the effects of the MAGL inhibitor, MJN110, at varying doses on spontaneous pain behaviors in murine models of CIBP. Female BALB/cAnH mice (15-20g, 2 months old) underwent implantation of 80,000 66.1 breast adenocarcinoma cells into the right femoral cavity. Sham operated animals underwent the procedure, but were injected with cell media alone. We performed spontaneous pain behaviors, flinching and guarding, at baseline, 7, 10 and 14 days post-surgery. MJN110 or vehicle was administered as i.p. injection once daily from days 7 to 14. Changes in inflammatory cytokines were measured by ELISA, bone degradation was analyzed via radiographs and analysis of tumor burden were performed via H&E staining. All analysis was performed by blinded observer. Animals reliably displayed significant increase in spontaneous pain behaviors 7 days post-surgery as compared to sham surgical animals and to baseline. The administration of MJN110 significantly decreased the pain behaviors observed in a dose-dependent manner as compared to vehicle treated controls. Treatment with MJN110 caused a significant decrease in inflammatory cytokines (e.g. IL-1, IL-6, TNFa, MCS-F) within the bone microenvironment compared to the vehicle. Tumor burden and bone degradation were unaffected by MJN110. Modulation of the eCB system via MAGL inhibition significantly reduces spontaneous pain behaviors in a CIBP model and lowers inflammatory cytokines within the tumor microenvironment.

Sch. of Med., Saint Louis, MO; [4]Dept Developmental Biol., Washington Univ. Sch. Med., Saint Louis, MO; [5]Anesthesiol., Univ. of Virginia Dept. of Anesthesiol., Charlottesville, VA

Abstract: When undertreated, post-operative pain severely impacts patient recovery, and can develop into chronic pain which can interfere with patient's quality of life. Hence, proper treatment for post-operative pain is crucial. Currently, most effective therapy for treating post-operative pain are opioid drugs. However, opioids are overprescribed and carry risk of many dangerous side effects, including respiratory depression, addiction and tolerance. Using an incisional pain model, we study the analgesic effects of neurosteroid anesthetic alphaxalone (ALPH), in an effort to seek a possible treatment to reduce the usage of morphine.
We generated an incisional pain model by performing skin and deep tissue incisions in adult female Sprague Dawley rats. For preemptive analgesia studies, we administered ALPH (60 µg or 180 µg) intrathecal (IT) 30 min prior to surgery, then assessed mechanical hypersensitivity 2h, 1 day, 2 days, 3 days, and 5 days post-incision. At the dose of 60 µg ALPH, the mechanical hypersensitivity post-surgery was decreased while the thermal hyperalgesia remained unaffected. An even more profound decrease in mechanical hypersensitivity post-surgery was found at the dose of 180 µg ALPH.
For post-surgical injection testing, we administered ALPH or morphine at 2h post-incision after pain development was confirmed. With a dose of 60 µg ALPH, the mechanical threshold remained the same, while doses of morphine (0.25 µg, 0.75 µg, and 1.5 µg) showed an increase in mechanical hyperalgesia threshold in a dose-dependent manner.
Our preliminary data strongly suggests that ALPH helps alleviate the mechanical hypersensitivity when applied prior to surgery. The use of neurosteroids like alphaxalone may provide superior perioperative analgesia and potentially diminish the risk for drug addiction resulting from opioid overuse.

Title: Pharmacodynamic mechanisms underlying the antinociceptive actions of fingolimod (FTY720) in a mouse model of nerve injury-induced neuropathic pain

Authors: *L. J. SIM-SELLEY, G. DONVITO, V. MCLANE, P. KARLSSON, S. SPIEGEL, K. F. HAUSER, A. H. LICHTMAN, D. E. SELLEY
Virginia Commonweatlh Univ., Richmond, VA

Abstract: Modulation of the sphingosine-1-phosphate (S1P) system regulates nociception in models of acute and chronic pain. We showed that agonist actions of the S1PR prodrug FTY720 mediated analgesia to an acute thermal stimulus and that repeated FTY720 produced tolerance and desensitized S1P receptor (S1PR)-mediated G-protein activity. However, both agonism and functional antagonism have been proposed to underlie FTY720-mediated antinociception in chronic pain models. The present study assessed the effect of single or repeated dose FTY720 treatment in mice with chronic constriction injury (CCI) to determine whether repeated FTY720 acted as an agonist or functional antagonist in this model of neuropathic pain. Mice received sciatic nerve ligation or sham surgery. After one week of recovery, separate groups were administered daily injections (i.p.) of vehicle or FTY720 (0.01, 0.03, 0.1, 0.3, 1, 3 mg/kg) for 14 days. Mechanical allodynia was assessed with Von Frey filaments 1 h after injections on days 1, 7 and 14. After final testing, the lumbar spinal cord (L4-L6) and brain were collected for agonist-stimulated [^{35}S]GTPγS binding and sphingolipid analysis using LC-MS/MS. Repeated administration of FTY720 produced dose and time-dependent antinociception to mechanical allodynia in CCI mice, such that moderate doses were effective after 1-7 days, but low doses required 14 days of treatment. Repeated FTY720 treatment reduced [^{35}S]GTPγS binding stimulated by S1P or the S1PR1 agonist SEW2871 in the lumbar spinal cord in a treatment dose-dependent manner. [^{35}S]GTPγS autoradiography similarly revealed treatment dose-dependent desensitization of S1P, SEW2871 or FTY720-phosphate-stimulated activity in regions including the periaqueductal gray. CCI did not affect [^{35}S]GTPγS binding in vehicle-treated mice. Lipidomic analysis revealed elevated S1P, sphingosine, dihydro-S1P and ceramide in the lumbar spinal cord of CCI mice in both groups, indicating an injury-induced increase in de novo synthesis. FTY720 did not affect sphingolipid levels in either group. These results show that

repeated FTY720 treatment enhanced antinociception to CCI-induced mechanical allodynia despite producing S1PR desensitization, consistent with a functional antagonist mechanism.

Title: Supra additive interaction between topiramate and ketorolac, locally administered in the rat formalin test

Authors: E. SANCHEZ-SERRANO[1], M. Y. GAUTHEREAU-TORRES[1], C. CERVANTES-DURAN[1], *L. F. ORTEGA-VARELA[2,3]
[1]Facultad de Ciencias Médicas y Biológicas “Dr. Ignacio Chávez”, Univ. Michoacana de San Nicolas de Hidalgo, Morelia, Mexico; [2]Univ. Michoacana De San Nicolás De Hidalgo. Salud, Morelia, Mexico; [3]Escuela de Enfermeria y Salud Publica, UMSNH, Morelia, Mexico

Abstract: Combination therapy approaches to manage acute and chronic pain are commonly used. Here, we attempted to characterize a supra additive interaction between topiramate and ketorolac in the inflammatory pain model of formalin test. Female Wistar rats were used (200-300g), and injected with 50 µl of 1% formalin in the dorsal surface of the right hind paw. This substance causes a typical flinching pain-related behavior. The antinociceptive effect was determined by the administration of topiramate (10, 30, 100 and 300 µg/paw), ketorolac (25, 50, 100 and 200 µg/paw) and their combination; by local peripheral route. Isobolographic analysis was used in a fixed dose combination (0.5:0.5) to analyze the nature of the interaction of this combination; based on the ED_{30} of topiramate (391.34 ± 51.70 µg/paw) and ketorolac (53.06 ± 7.97 µg/paw). The combination of these two drugs significantly reduced the number of flinches in the second phase of the test. Theoretical ED_{30} of the combination ($ED_{30}T$) was 222.20 ± 64.99 µg/kg. Experimentally, the ED_{30} of the combination ($ED_{30}E$) had a significantly lower value: 60.41 ± 15.72 µg/paw; indicating the presence of supra additive effects (interaction index was 0.27). The results show that local peripheral administration of the combination can interact synergistically to reduce inflammatory pain in the formalin test, suggesting that combination could be useful in the treatment of inflammatory pain.

Title: Evaluation of AM1710 as a broad spectrum analgesic and its impact on morphine tolerance and physical dependence

Authors: *A. LI[1], X. LIN[1], A. S. DHOPESHWARKAR[1], A. C. THOMAZ DOS SANTOS[1], L. M. CAREY, IV[1], Y. LIU[2], S. P. NIKAS[2], A. MAKRIYANNIS[2], K. MACKIE[1], A. G. HOHMANN[1]
[1]Dept. of Psychological and Brain Sci., Indiana Univ., Bloomington, IN; [2]Ctr. Drug Discovery, Northeastern Univ., Boston, MA

Abstract: AM1710, a cannabilactone CB2 agonist, has shown promising anti-allodynic efficacy in suppressing neuropathic pain without producing tolerance or unwanted side effects associated with CB1 receptors (Deng, *et al.* (2015) *Biological Psych* 77: 475-87). In this study, we characterized the signaling profile of AM1710 in vitro and further evaluated whether it behaved as a broad spectrum analgesic agent in vivo. We assessed efficacy of AM1710 in suppressing inflammatory nociception evoked by complete Freund's adjuvant (CFA) inflammation of the hind paw as well as neuropathic pain induced by either traumatic nerve injury produced by partial sciatic nerve ligation (PSNL) or toxic challenge with the chemotherapeutic agent paclitaxel. We also verified whether AM1710 behaves as a functional CB1 antagonist in vivo. In vitro, AM1710 inhibited forskolin-stimulated cAMP in a manner that was sensitive to pertussis toxin, indicating it was Gi/o protein-mediated. AM1710 also produced a long lasting activation of ERK1/2 phosphorylation in HEK cells expressing mCB2. However, significant species differences in the signaling profile of AM1710 were observed between HEK cells stably expressing mCB2 and hCB2. In vivo, AM1710 suppressed paclitaxel-induced neuropathic pain without producing tolerance. Prior history of AM1710 treatment (5 mg/kg/day x 12 day, i.p.) delayed, but did not eliminate, the development of morphine analgesic tolerance in paclitaxel-treated mice. AM1710 also attenuated morphine-induced physical dependence as measured by naloxone-precipitated opioid withdrawal. Moreover, AM1710 (10 mg/kg, i.p.) did not precipitate

CB1-receptor mediated withdrawal symptoms in mice rendered tolerant to Δ^9-tetrahydrocannabinol, suggesting that AM1710 does not behave as a CB1 antagonist *in vivo*. Furthermore, AM1710 (1, 3, 10 mg/kg, i.p.) did not suppress established mechanical allodynia induced by either CFA or PSNL. Similarly, prophylactic and chronic dosing with AM1710 (10 mg/kg, i.p.) showed no antiallodynic efficacy in the CFA model. Both models responded to the anticonvulsant agent gabapentin. Our results indicate that AM1710 is not a broad spectrum analgesic agent in mice. Our results also emphasize the importance of future medicinal chemistry efforts aimed at developing CB2 agonists that are efficacious at both rodent and human CB2 to better exploit their therapeutic potential for clinical translation.

Title: Early and late anti nociceptive effects of sucrose on neonatal inflammatory pain; comparison to a non-steroidal anti-inflammatory drug

Authors: *K. NUSEIR[1], A. TASSLAQ[1], A. ALTARIFI[1], K. H. ALZOUBI[2]
[1]Jordan Univ. of Sci. and Technol., Irbid, Jordan; [2]Jordan Univ. of Sci. & Technol., Irbid, Jordan

Abstract: Management of neonatal pain is not only ethical but is also essential. Barriers to pain management in infants include lack of safe and effective medications and fear of adverse effects of conventional pain medications. Sweet solutions given intraorally had been shown to reduce pain behaviors and associated symptoms. Sucrose and other sweet inducing solutions are being increasingly used at the NICUs and immunization clinics. Sucrose for mild invasive procedures is effective and safe for those procedures that need to be repeated multiple times during the day. Only few studies examined the efficacy of sucrose for the management of inflammatory pain during infancy. In this study, CFA was used to induce inflammation in 5 day old rat pups; CFA also produce inflammation that last for more than a day thus can also a model for chronic pain. Sucrose or Ibuprofen (NSAIDs) was given to subset of pups shortly after CFA intraplantar injections. Thermal as well as mechanical pain sensitivity was assessed on subsequent days and also during adolescent and early adulthood. Sucrose and ibuprofen were both effective in preventing hyperalgesia and allodynia produced by CFA. Interestingly, sucrose was even more

effective than ibuprofen, and the analgesic effects continued further to adolescent and adult life of the rat. BDNF, an important factor in the consolidation of memory through enrichment of neurogenesis and synapses proliferation in the hippocampus was not affected by CFA, sucrose or ibuprofen before CFA when measured at the age of 8 weeks.

Title: Treating pain with a cell-penetrating neurotensin type 1 receptor (NTS1) pepducin

Authors: *R. L. BROUILLETTE[1,2], É. BESSERER-OFFROY[1,2], C. MONA[1,2], S. LAVENUS[1,2], J. CÔTÉ[1,2], M. SOUSBIE[1,2], J.-M. LONGPRÉ[1,2], R. LEDUC[1,2], M. GRANDBOIS[1,2], É. MARSAULT[1,2], P. SARRET[1,2]

Abstract: To date, the single most successful protein target class in drug discovery is a receptor family known as G protein-coupled receptors (GPCRs). In recent years, new and innovative approaches have been developed to better exploit their therapeutic potential, such as the design of cell-penetrating lipopeptides termed “pepducins”. These pepducins are composed of a peptide sequence mimicking one of the intracellular loops of a GPCR of interest, conjugated to an N-terminal palmitic acid. The lipid moiety effectively anchors the pepducinto the cell membrane and facilitates its translocation into the cell, where it functionally interacts with its cognate GPCR at the receptor-effector interface and modulates its signaling output. Thus, pepducins may behave as allosteric agonists or allosteric modulators of the receptors they target. We recently designed a series of pepducins derived from the intracellular domains of the human neurotensin type 1 receptor (hNTS1), a GPCR which mediates many of the physiological effects of the neurotensin (NT) tridecapeptide, including analgesia, hypotension and hypothermia. Here, we report the cellular and physiological actions of an ICL1-derived pepducin, named PP001. In CHO-K1 cells stably expressing hNTS1, we determined that high PP001 concentrations ($\geq 10^{-5}$M) partially inhibited NT orthosteric binding, while the non-palmitoylated control did not do so. Using BRET-based biosensors monitoring the pepducin’s ability to engage G protein-dependent

and G protein-independent signaling pathways, we further found that PP001 preferentially promoted GαoA and Gα13 activation over β-arrestin recruitment, and inhibited NT-mediated β-arrestin recruitment, thus acting as a biased allosteric agonist and negative allosteric modulator of NTS1.Additionally, PP001 administration enhanced hNTS1 homomerization in a BRET titration experiment. *In vivo*, we found that i.t. administration (275 nmol/kg) of PP001 significantly reduced the rat nociceptive behaviors in acute (tail-flick), tonic (formalin), and chronic (chronic constriction injury) pain models. Finally, in order to elucidate which residues are critical for these actions, we synthesized an Ala-scan of PP001, and monitored its effects on a CHO-hNTS1 cell monolayer by Electric Cell-substrate Impedance Sensing. In doing so, we determined a critical ARKK motif. Altogether, our results indicate that PP001 clearly participates in the cellular and physiological actions linked to NTS1 activation and may thus constitute a valuable tool to inform the design of novel NT-based drugs that could better cater to the needs of chronic pain patients.

Title: Analgesia and abuse potential of acetaminophen and a bioisostere acetaminophen analogue in mice

Authors: *T. L. YAKSH[1], N. A. REGEN[1], H. HOSHIJIMA[1], K. A. EDDINGER[1], K. D. BUNKER[2], C. D. HOPKINS[2]

Abstract: Acetaminophen (*N*-acetyl-*para*-aminophenol: APAP) is one of the most commonly used over-the-counter analgesic drugs in the United States. Robust trials show that APAP is well tolerated, significantly decreases pain, and decades of clinical use reveal no abuse liability. In recent work, we have constructed an APAP-mimetic (D-112) built on a bioisostere of the APAP backbone and herein we examined its analgesic activity (formalin flinching) after intrathecal (IT) and intraperitoneal (IP) delivery. Additionally, re-enforcing properties of APAP and D-112

agents after IP delivery of approximately equi-analgesic doses were compared to morphine using the conditioned place preference (CPP) model.
Methods: In adult male C57BL6 mice, IP and percutaneous IT delivery of APAP and D-112 was undertaken and the effects upon formalin evoked flinching assessed. To define abuse potential, the effects of vehicle, morphine, APAP and D-112 were compared using the conditioned place preference (CPP) model.
Results: In these studies, both IP and IT dosing of either APAP (200 mg/kg and 100 µg/5 µL, respectively) or D-112 (30 mg/kg and 30 µg/5 µL, respectively) resulted in suppression of Phase 2 formalin flinching at doses that had no effect upon motor function. In the CPP model, IP delivery of morphine resulted in a significant place preference 1 or 5 days after the last drug place pairing. In contrast, APAP, D-112 or saline had no effect on drug place pairing selection.
Significance: Thus, D-112, like APAP, can produce a significant effect upon facilitated pain processing after systemic and spinal exposure but, in contrast to morphine, they do not support a place preference, suggesting a minimal abuse potential. Title: Exercise dosing: A meta-analysis of existing exercise paradigms in the treatment of chronic pain

Authors: *A. POLASKI[1], A. L. PHELPS[2], M. C. KOSTEK[3], K. A. SZUCS[4], B. J. KOLBER[1]
[1]Dept. of Biol. Sci., [2]Palumbo Donahue Sch. of Business, [3]Dept. of Physical Therapy, [4]Dept. of Occup. Therapy, Duquesne Univ., Pittsburgh, PA

Abstract: Increasing evidence implicates exercise as a first line therapy for the treatment of nearly all forms of chronic pain. Physical activity has been shown to be associated with decreased symptoms of depression and anxiety, further suggesting that exercise could be

particularly advantageous in the context of chronic pain comorbid with psychiatric illness. However, knowledge of efficacious dosing respective to exercise type and pain condition is virtually absent in the literature. Therefore, understanding dose will provide insight into the mechanisms underlying treatment and the conditions themselves. The purpose of this analysis was to calculate the extent to which exercise treatment shows dose-dependent effects similar to what is seen with pharmacological treatments. Data was extracted and analyzed from existing clinical trials, focusing specifically on the dose of exercise intervention and the pain effect size in these studies. Dose was defined as the time exercising per week (minutes/week), frequency of exercise per week (# of sessions/week), intensity of the intervention (MET-minutes/week) and duration of intervention (in weeks). Univariate linear regression analysis was done to look at correlations between each component of exercise dose with pain effect. Results of multiple linear regression modeling of these data helped to predict interaction effects between different aspects of exercise dose. Overall, these results suggest the presence of a dose effect of exercise in pain, but also reinforce the need to explicitly test the question of dose in specific patient populations.

Title: Attenuated dopamine receptor signaling in nucleus accumbens core in a rat model of chemically-induced neuropathic pain

Authors: *D. E. SELLEY[1], M. F. LAZENKA[1], D. N. POTTER[2], L. J. SIM-SELLEY[1], W. A. CARLEZON, Jr[2], S. S. NEGUS[1]

Abstract: Neuropathy is major source of chronic pain that can be caused by mechanically or chemically induced nerve injury. In a rat model of chemically-induced neuropathic pain, bilateral formalin injection into the hind paw produced mechanical hypersensitivity (allodynia) and depressed responding for intracranial self-stimulation (Leitl et al. Mol. Pain, 10:62, 2014). To determine whether dopamine receptor responsiveness was altered in mesolimbic brain regions in response to formalin-induced neuropathy, we examined dopamine D_1-like and D_2-like receptor ($D_{1/2}R$) signaling and expression in male Sprague-Dawley rats with bilateral formalin injection.

D_2R-mediated G-protein activation, measured by agonist-stimulated [^{35}S]GTPγS binding, was reduced in nucleus accumbens (NAc) core, but not in NAc shell, caudate-putamen (CPu) or ventral tegmental area (VTA) of formalin- compared to saline-treated rats. Likewise, decreased expression of D_2R long, but not short, isoform protein was observed in formalin-treated rats by immunoblot in NAc core, but not shell. In contrast, formalin treatment did not alter CB_1 cannabinoid receptor activity in NAc core, or any other region examined. D_1R signaling was also reduced in NAc core, but not in NAc shell or prefrontal cortex of formalin-treated rats, as assessed by agonist-stimulated adenylyl cyclase (AC) activity. However, D_1R protein levels in NAc or any other regions examined were unaffected by formalin treatment. Adenosine A_1 receptor-stimulated AC activity in NAc was unaltered by formalin treatment. Expression of other proteins involved in dopamine neurotransmission in NAc and VTA, including dopamine transporter and tyrosine hydroxylase, were unaffected by formalin treatment. These results reveal selective decreases in D_2R_L signaling and expression, and D_1R signaling, in NAc core of male rats with formalin-induced neuropathic pain, suggesting that reduced DA receptor signaling contributes to pain-depressed behavior.

Title: Acupuncture alleviates cognitive impairment and pain via increased glutamate receptors and synaptic plasticity in the hippocampus in chronic neuropathic pain mice

Authors: *J.-H. JANG[1], Y.-K. KIM[1], E.-M. SONG[2], J.-Y. OH[1], J.-Y. PARK[3], M.-Y. SONG[2], H.-J. PARK[1]
[1]Acupuncture and Meridian Sci. Res. Ctr., Seoul, Korea, Republic of; [2]Dept. of Physical Med. and Rehabil., Seoul, Korea, Republic of; [3]Col. of Korean Medicine, Daejeon Univ., Daejeon, Korea, Republic of

Abstract: Background and aims: Growing evidence reveals that neuropathic pain is frequently accompanied with emotional disorder, such as cognition. We investigated that specific acupoints of acupuncture have analgesic effects, and also improve cognitive dysfunction induced by neuropathic pain.
Methods: One week after the left partial sciatic nerve ligation (PSNL), acupuncture treatment on the acupoints Hwando (GB30)/Yanglingquan (GB34), Sinmun (HT7)/Baekhoe (GV20), or control points were performed for 4 weeks. We assessed the effect of repeated acupuncture on

mechanical and cold allodynia, and also evaluated cognitive impairment at the pre- and post-acupuncture.
Results: In the PSNL model, nociceptive behavior and cognitive impairment was increased in the 1 week after surgery. We found that the acupoints GB30/GB34 treatment significantly attenuated mechanical and cold allodynia in PSNL model, and also significantly attenuated cognitive impairment symptom (in the novel object recognition and Y maze). The acupoints GB30/GB34 treatment significantly increased expression level of N-methyl-d-aspartate receptor including the NR2B subunit and α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid receptor including the GluR1 subunit in the hippocampus in PSNL model. Moreover, we assessed the expression of the Ca^{2+}/calmodulin-dependent protein kinases II (CaMKII), presynaptic components synapsin-1 and postsynaptic density protein 95 (PSD-95) and found that CaMKII, synapsin-1 and PSD-95 were increased in hippocampus of PSNL mice after acupuncture treatment.
Conclusions: We suggested that GB30/GB34 acupuncture might be a good candidate for the comorbidity of pain and cognitive impairment through increased expression of glutamate receptors and synaptic plasticity in the hippocampus in chronic neuropathic pain.
Key words: Acupuncture, partial sciatic nerve ligation (PSNL), analgesia, cognitive disorder, emotional disorder

Title: New bioisosteres and hybrids of NSAIDs with antinociceptive properties

Authors: *M. DECIGA-CAMPOS[1], M. E. GONZÁLEZ-TRUJANO[2], G. NAVARRETE-VÁZQUEZ[3]
[1]SEPI, Escuela Superior de Medicina IPN, Ciudad de Mexico, Mexico; [2]Dirección de Investigaciones en Neurociencias, Inst. Nacional de Psiquiatría "Ramón de la Fuente Muñíz", Mexico City, Mexico; [3]Farmacia, Univ. Autónoma del Estado de Morelos, Cuernavaca, Morelos, Mexico

Abstract: The therapeutic options that are currently on the market to deal with pain, inflammation and fever pathophysiology have a series of adverse drug reactions, such as damage

to the digestive, kidney and cardiovascular systems. For this reason, the search for new bioactive molecules with non-steroidal anti-inflammatory effects that produce minimal adverse effects continues. Drug discovery for pain medications aims to develop new NSAIDs with a good analgesic effect to side effect ratio. The aim of this study was to assess the anti-nociceptive and/or anti-inflammatory activities of synthesized molecules that were designed as bioisosteres and hybrids of paracetamol, ibuprofen and naproxen in a rat model. 4-(acetylamino)phenyl (2S)-2-(6-methoxy-2-naphthyl)propanoate (A), 4-(acetylamino)phenyl 2-(R,S)-(4-isobutylphenyl)propanoate (B), 2-(R,S)-(4-isobutylphenyl)-N-1H-tetrazol-5-ylpropanamide (C), (2S)-2-(6-methoxy-2-naphthyl)-N-1H-tetrazol-5-ylpropanamide (D), (2-(R,S)-N-hydroxy-2-(4-(2-methylpropyl)phenyl) propanamide) (E), and (2S)-N-hydroxy-2-(6-methoxy-2-naphthyl)propanamide (F) were synthesized as bioisosteres of the NSAIDs paracetamol, ibuprofen, and naproxen, respectively. All these compounds were characterized by spectroscopic and spectrometric analysis. Antinociceptive activity was evaluated using the formalin test in rats. Pharmacological responses of A, B (hybrids), and E (bioisostere) compounds demonstrated significant antinociceptive effects; thus these compounds were assayed in an inflammation test like carrageenan-induced paw oedema in rats. Complete molecular docking of cyclooxygenase and the A and B hybrids showed high docking scores, compared to the reference drugs. Our data demonstrate that compounds A, B, and E possesses antinociceptive and antiinflammatory activities resembling and improving those known for the traditional NSAIDs, paracetamol, naproxen and ibuprofen.

Title: Quercetin reduces the antinociceptive effect of diclofenac in a model of inflammatory pain

Authors: *R. VENTURA-MARTINEZ[1], A. BUSTAMANTE-MARQUINA[2], M. DECIGA-CAMPOS[2], M. Y. HERNANDEZ-ARAMBURO[3], R. RODRIGUEZ[1], G. E. ANGELES-LOPEZ[1], M. E. GONZALEZ-TRUJANO[3]
[1]Farmacologia, Fac Med, UNAM, Mexico, Mexico; [2]Escuela Superior De Medicina IPN, Mexico, Mexico; [3]Natl. Inst. of Psichiatry “Ramon de la Fuente Muñiz”, Mexico, Mexico

Abstract: In this study, the antinociceptive effect of diclofenac, a non-steroidal anti-inflammatory drug used at clinical level, was determined in the absence and in the presence of quercetin, a bioflavonoid present in many food, in a model of arthritic pain type gout. For this, male Wistar rats (200 g) were used, in which the food was removed 12 hours before. In the day of the experiment, animals were administered with 50 µl of uric acid in the femoro-tibial-patellar articulation of the right hind paw of each rat. The index of functionality of each animal was determined every 30 min and when they presented a total dysfunction of the extremity administered with uric acid (approximately 2.5 h after); then, they were distributed in groups of 6 animals per group. Several treatments were administered in each group as follows: diclofenac (0.1, 0.31, 1 or 3.16 mg/Kg, p.o.) alone or in combination with quercetin (100 mg Kg, i.p.). In this model, the recovery of the index of functionality of each animal after treatment was considered as antinociceptive effect. Results showed that diclofenac induced an antinociceptive effect from the lower doses with a maximal effect of 69.7 ± 2.7% at dose of 3.16 mg/Kg; whereas, quercetin did not produce a significant antinociceptive effect (9.3 ± 3.2%). On the other hand, when diclofenac was administered together with quercetin its antinociceptive effect decreased to 39.0 ± 8.5% at the same dose. These results suggest that quercetin induces an interaction like antagonism on the analgesic effect of diclofenac, in which pharmacokinetic and/or pharmacodynamic mechanisms may be involved.
This study was supported by PAPIIT (IN204416).

Title: Exploration of effective connectivity of the mouse somatosensory neurons for whisker object localization using dynamic causal modeling

Authors: *K. JUNG[1,3], J. KANG[3], H.-J. PARK[1,2,3,4]
[1]Nuclear Med., [2]BK21 PLUS Project for Med. Sci., Yonsei Univ. Col. of Med., Seoul, Korea, Republic of; [3]Ctr. for Systems and Translational Brain Sci., [4]Dept. of Cognitive Sci., Yonsei Univ., Seoul, Korea, Republic of

Abstract: The computational modeling to estimate the effective connectivity among neuronal populations may unravel the encoding mechanism for the stimuli. The purpose of this study is to estimate effective connectivity among neuronal populations of the somatosensory cortex during an object localization task.
To investigate the encoding process during the task, we analyzed functional calcium imaging data of neuronal responses in the barrel cortex evoked by a single whisking, which was downloaded from a public database (https://crcns.org/data-sets/ssc/ssc-1) [1]. Calcium image data were measured while a mouse was performing a pole localization task. To estimate the effective connectivity among clusters of neurons, we used dynamic causal modeling (DCM) [2] with Jansen and Rit model [3] and a calcium image time series evoked by touching whiskers. We performed waveform sorting of valid neuronal responses in the barrel cortex using principal component analysis for time series of behaviorally successful trials. We visually identified 9 representative calcium signal modes evoked by whisker stimulation. Using time series of these modes, we estimated effective connectivity among these modes using DCM, a Bayesian method for inferring a causal architecture in the dynamic system. For the DCM, we used a convolution-based model for neural state transition model, which was initially proposed by Jansen and Rit. We also made an observation model for the calcium imaging, which maps neuronal state to calcium imaging data. The calcium imaging data with a given external input were used to fit both neural state transition model and calcium imaging observation model. Among several possible models with different inputs, we chose an optimal model after Bayesian model comparison. As a result, we found different effective connectivity between hit and error trials on the shared modes. The current method provides a method to explore the relationship between amplification and suppression of the canonical microcircuit in the cortex using DCM for calcium imaging data set. In this framework, we are further working on establishing more precise models for calcium imaging data and validation test using simulation studies.

Abstract: We present a mathematical framework for formulating and testing rules of synaptic organization on both sparse and dense connectomics data. Our approaches will make it possible to implement hypotheses of synaptic organization in terms of mathematically formulated rules. We generated a structurally dense model of the rat barrel cortex and formulated a null hypothesis rule that synaptic wiring is based on axo-dendritic overlap. This null hypothesis states that synapses form (1) proportional to the locally available pre- and postsynaptic target structures, (2) locally random and (3) globally independent. The rule predicts distributions of pair-wise connectivity that are non-Gaussian and non-Poisson. We show that (sparse) pair-wise connectivity measurements obtained with different experimental methods cannot reject the null hypothesis. The rule predicts a wide range of 2nd and higher order connectivity patterns. These predictions can be used in the future to reject the null hypothesis and to identify wiring specificity that cannot be explained by axo-dendritic overlap. The framework will make it possible to (1) interpret sparse or dense connectivity measurements in a rule-based context, (2) identify which structural features are predictive of synaptic connections, (3) quantify how well a connectivity rule is constrained by data and (4) provide unbiased statistical tools for determining which set of rules is most consistent with empirical data.

Title: Gap junctions mediate the connectivity among different subtypes of parvalbumin-positive interneurons in layer 4 of the mouse barrel cortex

Authors: *N. SHIGEMATSU, T. FUKUDA
Dept. of Anat. and Neurobio. Grad. Sch. of Life Sci., Kumamoto Univ., Kumamoto, Japan

Abstract: Layer 4 of the rodent barrel cortex receives excitatory inputs from barreloids in the thalamus. Distribution pattern of these inputs shows typical cortical columnar structure. Although there are many studies about excitatory neurons in this area, local circuits composed of GABAergic interneurons remain poorly understood. Parvalbumin (PV)-positive interneurons form dendritic gap junctions with one another, but the connectivity among gap junction-coupled dendrites remains uninvestigated in most neocortical areas.
In the present study we visualized PV neurons including gap junctions in layer 4 of the mouse barrel cortex using immunohistochemical methods. Barrels were visualized by immunolabeling of vesicular glutamate transporter 2 (VGluT2), the thalamocortical afferent marker, and were reconstructed three-dimensionally based on serial 3.3 μm-thick optical slices in CLSM images using Neurolucida software. Then we reconstructed dendrites of PV neurons and analyzed their positional relationship to barrels. PV neurons were classified into four groups depending on their dendritic morphologies and somatic locations as follows:
Type1. All dendrites were within a single barrel
Type2. Dendrites crossed barrel/ septa border, soma was located in a barrel cortex
Type3. Dendrites crossed barrel/ septa border, soma was located outside the barrels
Type4. All dendrites were within the interbarrel septa
Next we observed gap junctions between different types of PV neurons. The majority (33/38, 86.8%) of dendritic gap junctions were within 75 μm from at least 1 of 2 paired somata. Type1 PV neurons formed dendrodendritic gap junctions with Type2 and Type3 neurons, but never with one another.
From these results, we focused on the Type1 PV neuron because this type restricts their dendrites within one barrel but never make contacts with the same type through gap junctions inside a limited space of a single barrel. One of the major challenges is how single axon originating from a barreloid distributes boutons on the Type1 PV neurons residing in a single barrel. To visualize the individual axons, we injected biotinylated dextran amines (BDA), the anterograde tracer, into the mouse ventral posteromedial thalamic nucleus (VPM). PV and BDA were visualized by immunohistochemical methods and serial optical slices were taken in CLSM. PV neurons and the BDA-labeled axons in one barrel were reconstructed by the same method as described above. We observed the appositions of BDA-labeled boutons against Type1 PV neurons and discussed the structural relationship between the boutons and the targeted PV neurons.

Title: Neuronal responses of the rat barrel cortex to highly predictable multi-whisker deflection patterns

Authors: *M. A. GOLDIN, D. E. SHULZ
Unite Neurosciences Information Complexite (UNIC), Ctr. Natl. Recherche Scientifique (CNRS), Gif Sur Yvette, France

Abstract: Processing of sensory information depends on the nature of the input but is also determined by previous stimulation history. A violation of an expectation can trigger neuronal responses that show the preparedness of the nervous system for an expected input. Within the predictive coding hypothesis (Friston 2005), these expectancy signals are determined by the mismatch between sensory input and a prediction coming from higher cortical areas. However, in a primary sensory cortex it still needs to be determined if these signals can appear in a pre-attentive manner. In this work, we used the rat whisker system to study the effect of repetitive spatio-temporal patterns of stimulation that provide a strong predictability in space and time. We used a dedicated multi-whisker stimulator that delivers controlled micrometric displacements to the 24 caudal whiskers of the snout of the rat (Jacob et al. 2010), while simultaneously recording multiple single units and local field potentials (LFP) in the primary somatosensory cortex of animals anesthetized with isoflurane. We designed stimulation patterns converging into a whisker and made our measurements in its corresponding cortical column across all layers using multielectrode silicone probes. Complete patterns were used during a training phase while truncated patterns were given as tests in a pre- and post-test phase. Random occurrences of truncated sequences with a 10 % chance were also present during the training phase to follow the evolution of the putative expectancy signals. We found that LFP signals become stronger after training together with many single units responses to the truncated stimulations. These preliminary results show that the stimulus history can reconfigure the activity in the barrel cortex in a manner that responses to truncated inputs resemble those to the full pattern of stimulation.

Title: Neural coding of vibrissa set-point in layer 5 cortical neurons measured in basal dendrites and spines by two-photon imaging with adaptive optics

Authors: *R. LIU[1], M. DESCHÊNES[2], D. KLEINFELD[1]
[1]Dept. of Physics, Univ. of California San Diego, La Jolla, CA; [2]Univ. Laval, Québec, QC, Canada

Abstract: Active sensing by rodents involves multi-sensory coding and integration at the cellular level. In mouse vibrissa cortex, layer 5 pyramid neurons receive distinct inputs from multiple separated brain regions (Petreanu et al. *Nature* 2009) including, either directly or via interneurons, efference control input from vibrissa motor cortex (Hill et al. *Neuron* 2011; Petreanu et al. *Nature* 2012; Xu et al. *Nature* 2012). This suggests that layer 5 pyramid neurons are a computational hub that integrates and processes multiple inputs for subsequent output, including subcortical premotor regions. Further, layer 5 pyramid neurons can be directly activated by thalamus through inputs to their basal dendrites (Constantinople et al. *Science* 2013). This leads to the hypothesis, that layer 5b neurons, through inputs to the basal dendrites, can function as a "single computational layer" for input to and output from cortex. We have begun to address this hypothesis in the context of control on vibrissa set-point during active sensing. We use adaptive optics with a vascular-based wavefront sensing method to achieve near diffraction-limited two-photon imaging in cortical layer 5b (depth ~ 800 μm). This permits us to measure calcium dynamics throughout jRGECO1a-labelled layer 5b pyramidal somata, dendrites, and spines. In preliminary work, we observe robust signals to changes in the set-point during freely whisking, in response to air flow, and in response to active touch. We will test the hypothesis that layer 5b neurons function as a "single computational layer" in terms of concurrent measures of neuronal input and output.

Title: Comparison of mesoscale dynamics in layer 6 and layer 2/3 of mouse neocartex during texture discrimination

Authors: *D. LORENZO MERCADO[1,2], A. GILAD[1], Y. GALLERO-SALAS[1,2], F. HELMCHEN[1,2]
[1]Brain Res. Institute, Univ. of Zurich, Zuerich, Switzerland; [2]Neurosci. Ctr. Zurich, Zurich, Switzerland

Abstract: The complexity of the mammalian neocortex is reflected in one of its most prominent anatomical features: its laminar organization in six horizontal layers. Each one of these layers is presumed to engage in information processing differently. Especially the role of layer 6 (L6) in mesoscale cortical dynamics and during behavior is not well understood. In mouse primary visual cortex it has been shown that the activity of L6 cortico-thalamic pyramidal cells suppresses the activity of neurons in superficial layers during visual stimulation. Whether such a modulatory effect of L6 on layer 2/3 (L2/3) occurs during sensory processing and short-term memory in a discrimination task is not known. Here, we used wide-field calcium imaging in head-restrained mice to measure task-related activity patterns across the entire dorsal cortex in one hemisphere. We selectively targeted L6 and L2/3 by using the Ntsr1-Cre and Rasgrf2-2A-dCre transgenic mouse lines, respectively, crossed to a GCaMP6f reporter line. The mice were trained to perform a 'go/no-go' texture discrimination task, where they sensed and differentiated with their whiskers between two presented textures: rough (P100), and soft (P1200) sandpaper. After the sensation period, the mice have a >2 s response delay, during which they maintain task-relevant information to finally report their response: lick in order to obtain a reward for the 'go' texture (hit), or refrain from licking in order to avoid a white noise punishment for the 'no-go' texture (correct rejection). We found that it is possible to perform wide-field calcium imaging with indicator expression in deep cortical layer 6. We observed mesoscale calcium signals that were clearly correlated with the task and trial types. As preliminary finding, we found in three L6-CaMP6f mice higher activity in posterior association areas during the delay period in correct rejection trials than in hit trials. This observation is opposite to what we previously found for L2/3 activity. Our results thus appear consistent with a modulatory effect between L6 and L2/3 for the maintenance of short-term memory in the mouse cortex during sensory discrimination.

Title: A comprehensive study of layer 6A synaptic microcircuits in rat barrel cortex using paired patch-clamp recordings

Authors: *G. QI[1], D. YANG[1], D. FELDMEYER[1,2,3]
[1]Res. Ctr. Jülich, Jülich, Germany; [2]Dept. of Psychiatry, Psychotherapy and Psychosomatics, RWTH Aachen Univ., Aachen, Germany; [3]Jülich-Aachen Res. Alliance-Brain, Translational Med., Aachen, Germany

Abstract: Neocortical layer 6A (L6A) is the principal source of cortico-thalamic feedback which is involved in the top-down control of attention and gain modulation. Principal cells (PCs) in this layer fall into three distinct groups with different axonal projection patterns, namely cortico-thalamic (CT), cortico-cortical (CC) and cortico-claustral (CCl) neurons. In addition, diverse types of L6A GABAergic interneurons exist. L6A synaptic microcircuits are not as well investigated as those in other cortical layers. Here we studied the electrophysiological and morphological properties of L6A synaptic connections using paired patch-clamp recordings and simultaneous biocytin labeling in the somatosensory (barrel) cortex of rats. L6A excitatory-excitatory (E-E) connections (n=44) had a low efficacy with a mean EPSP amplitude of 0.4 ± 0.3 mV. In response to paired presynaptic APs, EPSPs showed either weak depression or facilitation with a mean paired-pulse ratio (PPR) of 1.3 ± 0.7. Presynaptic neurons were predominantly CC (n=38/44) with rest being either CCl (n=3) or CT (n=3) cells. When presynaptic neurons were CT cells the connections showed strong short-term facilitation. Four E-E pairs between CC cells were reciprocally coupled. In addition, connections between L6A PCs located in two neighbouring columns were also recorded. Notably, in nearly all (n=5/6) transcolumnar connections, presynaptic neurons are CC cells and postsynaptic neurons are CT cells. L6A excitatory-inhibitory (E-I) connections (n=20) had an average EPSP amplitude of 0.6 ± 0.7 mV and a PPR of 2.2 ± 2.2. Presynaptic neurons were predominantly CC cells (n=15/20) and postsynaptic neurons both fast spiking (FS) (n=10) and non-FS (n=10) interneurons. L6A inhibitory-excitatory (I-E) connections (n=15) had a mean IPSP amplitude of 0.7 ± 1.1 mV and a PPR of 0.9 ± 0.3. Pre- and postsynaptic neurons were predominantly FS interneurons (n=12/15) and CC cells (n=13/15), respectively. Nine E-I/I-E pairs between CC cells and FS interneurons were reciprocally connected. For connections between CC cells and interneurons, FS and non-FS interneuron connections showed depression and facilitation, respectively while for connections between CT cells and interneurons, all (n=5/5) showed facilitation regardless of interneuron type. In conclusion, L6A synaptic connections are mainly formed by CC cells and their synaptic connectivity does not markedly decline with increasing inter-soma distance. L6A E-I/I-E connections are mainly between CC cells and interneurons; their short-term synaptic plasticity and hence neurotransmitter release probability depends on pre- and postsynaptic neuron types.

Title: Exploring the role of microglia and the perineuronal net as effectors of plasticity during barrel cortex development

Authors: A. C. BARRIENTOS[1], J. E. MUNOZ[3], *J. C. BRUMBERG[4,2]
[1]Behavioral adn Cognitive Neuroscience, Psychology, [2]Psychology and Biol., The Grad. Center, CUNY, New York, NY; [3]Psychology, Queens College, CUNY, Flushing, NY; [4]Dept Psychology, Queens Col., Flushing, NY

Abstract: Organisms rely on touch to make sense of their environment and adapt to it. To better understand how tactile experience shapes the brain, it is necessary to study the interaction of the cellular and molecular constituents in the primary somatosensory cortex (S1) during critical period development. Using the mouse barrel cortex as a model system, we examined two key components in neural development and plasticity: Microglia (MG) and the Perineuronal Net (PNN). In early post-natal development, MG fine-tune the cortical grand wiring diagram in an experience-dependent manner by strengthening synapses while also removing weak or dying synapses. Mature PNNs emerge at the closure of developmental critical periods, “cementing in” past alterations, thereby restricting plasticity into adulthood. Previous work from the laboratory has shown that sensory deprivation via whisker trimming leads to activation of MG, and a reduction in PNN density across cortical laminae. To determine whether extrinsic manipulations that trigger MG activity during S1 critical period development would yield similar effects on the PNN comparable to sensory deprivation, we altered the physiological state of MG with pharmacological agents through random assignment of IP injections of saline (control), minocycline (a MG inhibitor) and lipopolysaccharide (LPS; an inflammatory agent) to C57BL/6 mouse litters. Pups received injections every third day until post-natal day 30. We examined MG density, morphology and PNN density using immunohistochemical and histochemical staining and stereology (Neurolucida, StereoInvestigator). We hypothesized that LPS-treated mice would show greater activated MG and fewer PNNs relative to minocycline- and saline-treated mice. Preliminary work indicates that minocycline and LPS treatment led to significant differences in the morphology of the MG. In general MG soma contours and process features varied between the two groups. We found no significant differences in PNN density. This suggests that MG activity may not be sufficient to effect alterations in PNN density. Perhaps other cellular mechanisms interact with PNNs to modify them or destroy them during cortical development.

Title: Opposing influence of distinct cortical inputs on striatal circuitry and behavior

Authors: *A. J. YONK[1], C. R. LEE[2], J. WISKERKE[3], K. G. PARADISO[4], J. M. TEPPER[6], D. J. MARGOLIS[5]

(IKE) / Ctr. for Social and A, Linköping Univ., Linköping, Sweden; [4]Cell Biol. and Neurosci., [5]Cell Biol. & Neurosci., Rutgers Univ., Piscataway, NJ; [6]CMBN, Rutgers University-Newark, Newark, NJ

Abstract: The striatum is the main input nucleus of the basal ganglia and receives excitatory afferents from neocortex and thalamus. It is largely unknown 1) how corticostriatal inputs from specific cortical areas influence striatal projection neurons and interneurons and 2) whether afferent input from sensory and motor cortical areas have distinct effects on behavior. Here, we interrogated the synaptic connectivity of corticostriatal inputs from primary somatosensory (S1) and motor (M1) cortex and determined their roles in modulating behavior. Channelrhodopsin-2 (AAV1.CamKIIa.hChR2(H134R)-eYFP.WPRE.hGH) was expressed in either S1 or M1. Ex vivo whole-cell recordings were carried out in identified D1 and D2 receptor-expressing medium spiny neurons (MSNs) and parvalbumin (PV)-expressing fast spiking interneurons. Optogenetic activation of either S1 or M1 axon terminals in the striatum revealed marked differences in postsynaptic potential (PSP) amplitude recorded in each of the neuron types depending on the afferent stimulated. Optogenetic activation of S1 terminals elicited larger PSPs in PV interneurons compared to D1 or D2 MSNs, while activation of M1 terminals elicited large and non-preferential responses in all three neuron types. We examined how this circuitry relates to behavior in a sensory-guided discrimination task. Thus, we tested the hypothesis that discrete corticostriatal input biases responding towards facilitation or suppression based on the relative balance of PV and MSN innervation. Head-fixed mice were trained to perform a Go/No-Go task using their whiskers to discriminate between two textures for a water reward. Activation of S1 projections decreased responding, while M1 projections increased responding to Go and No-Go

trials. Given the preferential functional innervation of PV interneurons by S1 inputs, we further tested in PV-ChR2 mice whether direct activation of striatal PV interneurons during the discrimination task induced similar effects to S1 stimulation. Strikingly, activation of PV interneurons decreased responding during Go and No-Go trials. These effects were not observed in open field and rotarod tasks, suggesting that the observed differences in responding were due to task-specific rather than general motor effects of optogenetic stimulation. Overall, we show that S1 and M1 corticostriatal projections induce behavioral suppression and facilitation, respectively. These effects are likely mediated through differential functional innervation of striatal circuitry by these cortical regions.

Title: Functional connectivity of diverse long-range inputs to the primary somatosensory cortex

Authors: *S. NASKAR, J. QI, S. LEE
NIMH, NIH, Bethesda, MD

Abstract: The mammalian neocortex is divided into specialized areas that communicate with one another through long-range projections, enabling sensory processing, sensorimotor integration and motor control. However, it is not clear whether there are specific rules that govern circuit mechanisms for cortico-cortical communication. A previous study has demonstrated that excitatory inputs from primary motor cortex (M1) strongly recruit vasointestinal peptide (VIP)-expressing GABAergic interneurons (IN) in primary sensory cortex (S1). The recruitment of VIP INs results in disinhibition of pyramidal neurons by inhibiting somatostatin (SST)-expressing GABAergic INs. A similar circuit has been observed in other primary sensory areas, including visual and auditory cortices. We asked whether the VIP interneuron-mediated disinhibition constitutes a canonical circuit motif for cortico-cortical interactions. Using retrograde viral tracing methods, we first identified the major input areas to the superficial layers of S1. These areas include primary vibrissa-related motor cortex (vM1), secondary somatosensory cortex (S2), contralateral primary somatosensory cortex (cS1), perirhinal cortex (Prh) and posteromedial thalamic nucleus (POm). Based on this anatomical study, we then investigated the functional connectivity from these major input areas to the different neuronal elements in the superficial layers of S1 using optogenetics and whole-cell patch clamp recordings in *ex vivo* preparations. We found that, in contrast to the VIP IN-

mediated disinhibitory circuits from vM1 to S1, long-range projections from different areas preferentially engage specific sets of GABAergic neurons in the superficial layers of S1. For example, projections from S2 and cS1 strongly recruit fast-spiking parvalbumin (PV)-positive neurons. Regardless of the input areas, SST neurons received the weakest long-range inputs. Our results imply that sensory-related feedback information is transmitted to S1 by engaging PV IN-mediated feedforward inhibition, while motor-related feedback information propagates to S1 through VIP IN-mediated disinhibition. Thus, primary sensory cortex may parse information from diverse feedback projections by means of input area-dependent, preferential recruitment of specific types of GABAergic interneurons.

Title: Persistent gamma spiking in nonsensory fast-spiking cells predicts perceptual success

Authors: *C. I. MOORE, H. SHIN
Neurosci., Brown Univ., Providence, RI

Abstract: Gamma oscillations (30-55Hz) are mediated by fast-spiking interneurons (FS) and are believed to serve as a 'template' for temporal coordination of stimulus 'content,' thereby enabling sensory perception. In general support of this view, a prior study found that optogenetic stimulation of FS in the primary somatosensory 'barrel' neocortex (SI) at gamma frequency (40 Hz), starting before and continuing during the sensory input ('peristimulus'), could benefit tactile detection. The view that peristimulus gamma contributes to sensory encoding through temporal alignment of spiking poses a conundrum: How can an oscillation serve as a template for sensory encoding when the stimulus itself drives the mediators of the rhythm (FS), and perturbs its maintenance? Here we found that FS in SI that are not driven by sensory stimuli ('nonsensory FS') show a strong peristimulus gamma in their spiking, and the strength of its expression robustly predicts threshold-level perception. Using tetrode recordings during vibrissa detection in mice, we recorded 197 well-isolated FS. On detected 'hit' trials, nonsensory FS (N = 121) showed persistent spiking at gamma (~25ms peak in inter-spike interval (ISI) distribution) that began before and continued, unperturbed, after vibrissa deflection. These nonsensory FS were

also intrinsically more periodic, with higher regularity in their ISIs than sensory FS (as assessed by coefficient of variation). Within nonsensory FS, a subset (N=60) had distinct peak in the ISI distribution in the gamma range (18.18-33.33ms), and they also showed higher regularity. Nonsensory FS spiking showed only weak coupling with the gamma band local field potential (LFP), while sensory FS showed significantly stronger coupling. This dissociation may explain why prestimulus LFP power negatively predicted detection. A key implication of these results is that a distinct subgroup of interneurons, that is not 'distracted' by sensory input, is the carrier of perceptually-relevant oscillations.

Title: *In vitro* investigations of predictive coding in the mouse somatosensory system

Authors: *S. DELENIV, E. MANN
Dept. of Physiology, Anat. and Genet., Univ. of Oxford, Oxford, United Kingdom

Abstract: According to the logic of predictive coding, sensory representations fundamentally consist of two main pieces of information: i) internal predictions about the expected patterns of sensory stimulation, formed on the basis of experience and ii) prediction error signals stemming from comparisons between predictions and feedforward inputs which sensory systems are purportedly hard-wired to perform. Here, we present a series of experiments aiming to capture sensory prediction error signals *in vitro*, in the activation patterns of mouse somatosensory cortex exposed to optogenetic stimulation patterns with divergent statistical properties. Moreover, we set out to test the possible anatomical and spectral segregation of the predictive and error signals, based on proposals that prediction errors may be selectively affiliated with gamma-oscillatory activity generated by the superficial cortical layers. In the first series of experiments, S1 slices expressing channelrhodopsin under the CaMKII promoter are exposed to 4 sec. trains of sinusoidally modulated light (10 Hz) which linearly ramps up in amplitude over time. We examine the cortical LFP response during a small fraction of trials (5%) which feature an oddball pulse of an amplitude which exceeds the average at that time-point by 64%, and compare this to conditions under which the same oddball pulse is the statistically dominant type of stimulus (80% frequency). The experiments reveal that, on average, power in the gamma-band (60-150Hz) increases and peak gamma frequency shifts towards higher values (up to 120 Hz) as light

amplitude increases over the course of a stimulus train, and during exposure to the high-amplitude oddball. However there is no evidence that these aspects of oscillatory activity are significantly influenced by whether the oddball stimulus represents the statistical norm versus anomaly. In the second series of experiments, individual barrel columns are exposed to temporally varying (50Hz) custom-made random-dot light mosaics generated using a digital micro-mirror device, designed to engage distinct cell populations in a prescribed sequence. With the use of dual electrode recordings for simultaneous sampling of the superficial and deep layers of the barrel column during stimulation, we are in the process of characterising the oscillatory dynamics of sensory responses to normal versus oddball stimulation patterns.

Title: Exploring circuit plasticity deficits in fmr1 mice during tactile learning

Authors: S. WALKER[1], *S. A. HIRES[1], A. MCGEE[2]
[1]Biol. Sci., USC, Los Angeles, CA; [2]Univ. of Louisville, Louisville, KY

Abstract: Fragile X Syndrome (FXS) is the most inheritable cause of mental impairment and autism, typically caused by transcriptional silencing of the *Fmr1* gene and the loss of expression of FMRP (fragile X mental retardation protein). FMRP is known to regulate the translation of numerous messenger RNAs, many of which encode synaptic proteins and regulate plasticity. In humans, FXS can be characterized by impaired cognition, hypersensitivity to sensory stimuli, autistic behaviors, and defects in synaptic plasticity. No treatment to reverse the collective pathology has been found, and there is a fundamental gap in our knowledge of how FXS causes mental impairments through alterations in neural circuitry. Mice lacking a functional *Fmr1* gene exhibit several phenotypes similar to FXS and can be used to help us understand what links learning impairments to specific changes in neural circuit organization. We hypothesize that impairment in learning tactile learning assays is driven by reduced synaptic structural plasticity and hypersensitive touch responses in the somatosensory cortex. In this investigation, we perform juxtacellular loose-cell recordings of single neurons in targeted barrels of S1 while the mice perform head-fixed localization tasks with a single whisker. We pair high-speed tracking of whisker positions with the activity of neurons in the corresponding barrel during localization to quantify the force and direction selectivity of excitatory neurons in layers 2-4 of S1 in *Fmr1* and

wild type control mice. We quantify the extent to which tactile discrimination and cortical representation of afferent sensory activity in somatosensory cortex are abnormal in *Fmr1* mutant mice.

Title: *In vivo* structure and function of pyramidal tract neurons and their long range inputs

Authors: *J. M. GUEST, D. UDVARY, M. SEETHARAMA, M. OBERLAENDER
In Silico Brain Sci., Ctr. of Advanced European Studies and Res., Bonn, Germany

Abstract: Pyramidal tract neurons (PTs) represent the major output cell type of the neocortex. We have previously shown on the example of the rat barrel cortex that a functional property of PTs is to broadcast cortically processed sensory information to downstream targets and that PTs relay this information in target related manner. In order to further explain the role of PTs in sensory information processing, we found it is necessary to investigate how this specific neuronal cell type receives sensory information. Therefore this study aims to focus on the structure and function of long range inputs of PTs using the example of the rat barrel cortex. We show that by injecting different subcortical regions with an anterograde virus expressing channel rhodopsin coupled with single cell attached in vivo recordings, allows for both mapping long range inputs to PTs and gives access to their electrophysiological responses during optogentic stimulation of these mapped inputs. By reconstructing the full dendritic morphology of individual recorded PTs and quantifying the number of synapses according to long range input region, we report for the first time the relationship between the 3D distribution of synapses along the dendrites of PTs according to input region and their electrophysiological responses to optogenetic stimulation of these different long range inputs.

Abstract: Norepinephrine is an important neuromodulator playing roles in regulation of arousal, memory formation and focused attention. While the importance of norepinephrine is largely appreciated, the fine details on when and where the norepinephrine is released when it functions are still unknown. This is mainly due to the lack of tools with high spatial and temporal resolution to identify norepinephrine release. Recently two G-protein-coupled receptor activation-based norepinephrine indicators (GRAB-NE2.1 and GRAB-NE2.2) with different affinity to norepinephrine were developed. In vitro responses are highly specific to norepinephrine with a δF/F ~200%. Here, we assess these indicators' suitability for imaging norepinephrine dynamics in awake, behaving mice. We packaged these GRAB-NE variants in AAV, and determined optimal injection parameters for expression in mouse barrel cortex. Both GRAB-NE2.1 and GRAB-NE2.2 show strong and dense expression in neurons of S1 cortex. We then characterized the response of these 2 variants of GRAB-NE in 6 mice. We quantify the speed and magnitude of responses to following stimulation paradigms: direct chemical activation of GRAB-NE in S1, chemical stimulation of Locus Coeruleus, and whisker-mediated object localization.

Title: Neuronal mechanisms driving kin recognition in zebrafish larvae

Authors: *S. KUMAR, I. DUBOVA, S. CHALASANI
Mol. Neurobio. Lab., Salk Inst. for Biol. Studies, La Jolla, CA

Abstract: Many animals have evolved machinery to distinguish between their kin from non-kin facilitating altruism in the young and preventing inbreeding in adults. Despite this, less is known about the underlying neuronal pathways driving these behaviors. The transparent vertebrate, zebrafish larva, with large progeny sizes and robust behaviors is ideally suited for a comprehensive analysis of kin recognition. We designed a novel behavioral paradigm and found that larvae that are at least 7 days post-fertilization are able to recognize their kin. Additionally, we used pharmacology to reveal that these animals recognize their kin using olfactory cues. Furthermore, we identified a cluster of neurons in the telencephalon of the 7-day old zebrafish larvae that is specifically activated by kin, but not non-kin cues. Together, our results show that zebrafish larva engages distinct neural pathways to identify kin using olfactory information and generating robust behavior.

Title: Remapping of odor representations in the zebrafish forebrain by inhibitory network plasticity

Authors: *T. FRANK[1], N. R. MOENIG[1], S.-I. HIGASHIJIMA[2], R. W. FRIEDRICH[3]
[1]Friedrich Miescher Inst., Basel, Switzerland; [2]Okazaki Inst. for Integrative Biosci., Okazaki-Shi, Japan; [3]Friedrich-Miescher-Institute For Biomed Res., Basel, Switzerland

Abstract: Intelligent behavior depends on the ability to associate high-dimensional sensory representations with low-dimensional, behaviorally relevant qualities such as valence. Learning of associations involves plasticity at excitatory synapses but it remains poorly understood how this process reorganizes information flow in networks. Moreover, it remains unclear whether learning also modifies inhibitory subnetworks. To address these questions we trained adult zebrafish in an appetitive odor discrimination task and analyzed odor representations in a specific compartment of telencephalic area Dp, the homolog of olfactory cortex. Associative conditioning enhanced the intensity and selectivity of responses to the positively conditioned odor (CS+). Moreover, conditioning reorganized coding space such that the direction of maximal variance represented the appetitive value of odors. Hence, associative conditioning remapped odor space onto a behaviorally relevant axis of valence. Variations in coding space were highly correlated to behavioral variations among individuals. Optogenetic hyperpolarization of interneurons attenuated the representation of the CS+, reversed odor remapping, and reduced inter-individual variations in coding space. These results reveal an individualized odor-to-valence map that is reorganized during learning by plasticity of inhibitory subnetworks.

Title: Optimal encoding of odor concentration for olfactory navigation is approximated by the Hill nonlinearity

Authors: *J. D. VICTOR[1], S. D. BOIE[1], E. G. CONNOR[2], J. P. CRIMALDI[2], G. B. ERMENTROUT[3], K. I. NAGEL[4]
[1]Feil Family Brain and Mind Res. Inst., Weill Cornell Med. Col., New York, NY; [2]Civil, Environmental, and Architectural Engin., Univ. of Colorado, Boulder, CO; [3]Mathematics, Univ. of Pittsburgh, Pittsburgh, PA; [4]Neurosci. Inst., NYU Langone Med. Sch., New York, NY

Abstract: Olfactory navigation is a sensorimotor behavior that is critical to the survival of a wide range of organisms. It is made computationally challenging by the turbulent nature of

natural olfactory plumes. Evolutionarily successful organisms accomplish olfactory navigation by making navigation decisions on a moment-by-moment basis. These decisions are necessarily based on a limited knowledge of the odor plume. Limitations arise not only because measurements are restricted to sensor's locations, but also because the sensors have limited accuracy and bandwidth. Our focus here is how these limited resources are best used. We take an information-theoretic approach: how can odor concentration be encoded into a fixed number of bits in a way that maximizes information about location within a plume? Recently, we showed that for single samples, little is gained by increasing the resolution for odor concentration beyond 3 to 4 bits (8 to 16 levels). Here, we ask how these levels are best used, i.e., how can the range of odor concentrations be segmented into a set of coding levels, to maximize information about location. To answer this question, we developed a dynamic-programming algorithm to determine this optimal segmentation. The algorithm was then applied to spatiotemporal odor distributions obtained via planar laser-induced fluorescence measurements of real plumes. We analyzed five plumes, with realistic advection speeds (5 to 20 cm/s), with and without a nearby boundary or obstacle, and nine sampling-point grids within each plume. Across conditions, the optimal segmentation strategy emphasized resolution at the higher odor concentrations, indicating that while infrequent, high concentrations provide a disproportionate amount of location information. Next, we compared this coding strategy to histogram-equalization (HE). HE, in which the range is divided into segments of equal probability, is optimal for reconstructing a sensory input, but not necessarily for other tasks. Compared to HE, the optimal coding strategy for navigation devoted more resources to discriminating among the high odor concentrations. Finally, we considered a process in which odor concentration is first transformed by a Hill nonlinearity associated with receptor binding, and then the fraction of bound receptors is linearly encoded. This results in near-optimal allocation of coding levels, provided that the binding constant is near the mean odor concentration at the sampling points. These findings suggest that the saturation nonlinearity associated with the biophysics of the earliest stage of olfactory information processing plays an important computational role in navigation.

Title: Olfactory function is impaired in Olfaxin-deficient mice

Authors: *S. ISLAM[1,2], M. UEDA[1,3], E. NISHIDA[1], M. WANG[1], M. ITOH[1], K. NAKAGAWA[1], T. ANA[1], T. NAKAGAWA[1]
[1]Gifu Univ. Grad. Sch. Med., Gifu, Japan; [2]BCSIR laboratories Chittagong, Chittagong, Bangladesh; [3]Inst. for Developmental Research, Aichi Human Service Ctr., Achi, Japan

Abstract: We found that Olfaxin is involved in odor preference and olfactory memory influencing the expression of NMDAR subunits.
PRUNE2, one of Bcl-2/adenovirus E1B 19 kDa-interacting proteins (BNIPs), plays critical roles in several cellular processes such as cellular transformation, apoptosis, neuronal differentiation, and synaptic function through the BNIP2 and Cdc42GAP homology (BCH) domain. *PRUNE2* has five isoforms: PRUNE2: BCH motif-containing molecule at the carboxyl terminal region 1 (BMCC1)-1; C9orf65: BMCC1-2; BMCC1: BMCC1-3; BNIP2 Extra Long (BNIPXL): BMCC1-4; and Olfaxin/BMCC1s. Olfaxin share 56.3% amino acid identity with Caytaxin. Olfaxin and Caytaxin are alike in their glutamatergic terminal localization, kidney-type glutaminase (KGA) interaction, and caspase-3 substrate. Olfaxin is predominantly expressed in mitral and tufted cells in the olfactory bulb (OB), while Caytaxin is localized in cerebellar granule cells, whose deletion causes Cayman ataxia. At the present, the role of Olfaxin in glutamatergic neuron is largely unknown.
In order to characterize Olfaxin, we generated a *Prune2* gene mutant mice ($Prune2^{Ex16-/-}$; knock out [KO] mice) using the CRISPR/Cas9 system, which deletes the exon 16 containing start codon of *Olfaxin* mRNA. Although four of five Prune2 isoforms including PRUNE2, BMCC1, BNIPXL, and Olfaxin/BMCC1s contain Ex 16, homozygous KO mice were born at the expected Mendelian ratios and morphological change was not observed in the brain. Olfaxin mRNA and protein were deficient in OB and piriform cortex. Using video recording and an automated tracking system, we measured time spent sniffing in the door preference test by urinary scents of the opposite-sex and nonsocial odor stimuli (almond extract), as well as in the odor-aversion test. We observed the impairment of odor preference and olfactory memory in KO mice. Interestingly, the switching of NMDAR2A/NMDAR2B subunits composition in the piriform cortex was affected in KO mice, coinciding with decrease of BDNF expression and increase of Kv 4.2 expression at postnatal day 14 in KO mice.
Since 87% of amino acids are identical between mouse and human Olfaxin, investigation of the role of human Olfaxin will be really interesting because impairment of odor perception is confirmed in patients with early-stage Alzheimer's disease.

Title: Mouse detection of fluctuating odors based on odor plume properties

Authors: *A. GUMASTE[1,2], E. CONNOR[3], J. CRIMALDI[3], K. NAGEL[4], J. VERHAGEN[2,1]
[1]Neurosci., Yale Univ., New Haven, CT; [2]John B Pierce Lab., New Haven, CT; [3]Dept. of Civil, Envrn. and Architectural Engin., Univ. of Colorado, Boulder, CO; [4]Neurosci. Inst., NYU Langone Med. Sch., New York, NY

Abstract: Odor-based navigation is critical to animal survival as animals depend on olfactory cues to locate food sources, find mates, and avoid predators. Odors in nature are often carried by turbulent air flow, producing plumes with complex spatiotemporal structure. In large naturalistic environments, odor plumes become filamentous and characterized by odor fluctuations with highly varying intermittency. Such complex odor information must be actively sampled through sniffing, integrated by the olfactory system, translated into odor identity, and ultimately, drive behavior. However, little is known about how animals actively sample fluctuating odor stimuli to detect relevant stimulus properties and how this sniff-dependent odor sampling is encoded by olfactory sensory neurons. In a collaborative effort, we have designed a go-nogo task that implements turbulent odor plumes, characterized by Planar Laser Induced Fluorescence (PLIF), as stimuli. More specifically, we have trained water-regulated OMP-GCaMP6f mice to discriminate between static and dynamic odor sequences as well as between dynamic odor sequences with varying plume statistics. If animals lick following the presentation of a S+ stimulus (in some instances a static odor), they receive a water reward, however if they lick following the presentation of a S- stimulus (in some instances a dynamic odor), they receive an aversive salt solution. As animals are performing the task, we simultaneously record sniffing responses as well as image neural activity of mature olfactory sensory neurons in the dorsal olfactory bulb. Using this behavioral paradigm, we have been able to expand the current understanding of the sniffing strategies implemented by animals to detect fluctuating stimuli and the extent to which animals can detect certain properties (mean, variance, and intermittency) of dynamic odor plumes. Additionally, we have explored how neural encoding of fluctuating stimuli depends on sniffing patterns.

Title: Sensorimotor transformation in odor modulation of locomotion

Authors: *L. TAO, S. OZARKAR, J. BECK, V. BHANDAWAT
Biol., Duke Univ., Durham, NC

Abstract: Odors affect many aspects of an animal's behavior including its locomotion. Different odors activate different patterns of olfactory receptor neurons (ORNs). Understanding the strategy by which an animal searches its environment and how this search pattern is affected by the different patterns of ORNs activated will give insight into the sensorimotor transformations along the olfactory system. *Drosophila* is an excellent model organism to study this transformation because of its relative simplicity, the availability of genetic tools and because odors have a marked effect on its locomotion. In this study we employ optogenetic stimulation, *in vivo* physiology, quantitative behavioral analysis and computational modeling to uncover the principles underlying odor modulation of locomotion.

This study focuses on 7 ORN classes out of ~60 in the flies that were previously shown [1] to be activated by apple cider vinegar, a food odor and a potent attractant which has a marked effect on a fly's locomotion. We created a circular arena 8 cm in diameter; within this arena a central 2.5 cm circular region was irradiated with red light. Different combinations of the 7 ORN classes were activated by genetically controlling which ORNs expressed red-light activated channelrhodopsin - *Chrimson*. Using the instantaneous head position of the flies and the measurement of light intensity in the arena, we were able to recreate the light stimulus in an electrophysiological rig to measure the spike responses in the ORNs to measure ORN input. The fly's behavior was modeled using a 2-layered Hierarchical Hidden Markov Model (HHMM) which was fit to instantaneous kinematics of the fly's locomotion.

We found that a fly's locomotion in our arena is characterized by 6-12 locomotor features such as stop, slow walking with sharp turn, fast left turn etc., which describes its locomotion over a few hundred milliseconds to seconds. Odors do not alter the locomotor features employed by the fly; rather they modulate the frequency with which each locomotor feature is employed by the fly. Activation of different ORN classes affects different locomotor features differentially

suggesting a modular organization between ORN activation and its effect on locomotion.

Abstract: Odorants evoke precise spatio-temporal patterns of activity in the olfactory bulb (OB). Previous studies suggest that fine spatial or temporal features in these patterns can potentially encode odor information. However, it remains unclear how olfactory perception is structured on OB patterns. Specifically, how does perception vary along individual and combined feature dimensions? To test this, we developed a novel experimental framework using optogenetic stimulation patterns as 'artificial odors'. This allowed us to achieve fine, parametric manipulation of OB patterns that was not previously possible using conventional odorant manipulations. We first trained mice on a two-alternative-forced choice task to discriminate target patterns from non-target patterns. After mice were well trained (>80% accuracy), we performed perturbations on target patterns and quantified animals' target recognition.
Our results reveal that both small spatial or temporal perturbations in the target pattern impaired target recognition, in line with several prevailing hypotheses of the olfactory code. Furthermore, spatial components occurring earlier in time have a greater impact on target recognition than later-occurring components, supporting a previously-found 'primacy' code for odors.
Unpredicted by previous hypotheses, perceptual distances are linear or graded in proportion to the size of perturbation. We quantified these results by building logistic regression models, and tested the possibility of higher-order structure in patterns which are revealed by non-linear interaction effects between perturbations. Finally, a combined process model can account for the behavioral data.

Title: Strategies for odor source localization in mice

Authors: *A. E. PAPALE[1], A. LIU[2], J. HENGENIUS[3], K. PATEL[4], B. ERMENTROUT[3], N. N. URBAN[1]
[1]Dept. of Neurobio., [2]Sch. of Med., [3]Dept. of Mathematics, [4]Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Navigation across an odor landscape to locate a food source is a critical foraging behavior for mice. To study this behavior, we developed an odor source localization task where mice forage for a small food reward placed at an odor spot on a large open field table. We then examined search and approach behavior as they navigated toward the odor source. Hungry mice were trained to associate a methyl salicylate (wintergreen) odor stimulus with a food reward. After training, mice were able to successfully locate odor sources above chance levels, even in the absence of a food reward at the odor source. Data show that mice reliably display several behaviors as they approach the odor source. At greater than 20cm away, mice orient toward the source during successful trials. Within 20cm, mice display progressively increasing dwell times closer to the source, increased 'casting' behavior, defined as the absolute curvature of the nose, and, finally, decreases in velocity. Velocity decreases during approach were only seen during successful trials, suggesting the possibility of a speed-accuracy trade-off in search behavior. While modeling suggests that success rate and search time should be concentration-dependent, we did not find any effects of concentration on these variables. Planned future studies will test for concentration-dependent effects using a wider range of concentrations, and with different solvents for the methyl salicylate odor. We have also developed an automated odor source localization task that does not require baiting the odor source with a food reward, allowing for greater numbers of trials per session. Preliminary analysis of the automated task supports our conclusions about odor source localization strategies in mice. Together, these results suggest that mice proficiently use olfactory sensory cues to locate an odor source, and their approach behaviors vary systematically as a function of distance from the odor source.

Title: Retro- and orthonasal olfaction interaction in rats

Authors: *R. HE[1,2], L. M. KAY[1,2]
[1]Psychology, The Univ. of Chicago, Chicago, IL; [2]Inst. of Mind and Biol., Chicago, IL

Abstract: Odorants entering orthonasally are frequently related to external environments, whereas retronasal odorants are integrated with taste and orosensory stimuli to generate flavor perception. We aim to examine whether the two olfactory routes give rise to similar perceptual qualities and interact during a learning process. Rats were pre-conditioned to odorized solutions retronasally with a customized lick spout and a vacuum nearby, which removed orthonasal odorants away from the animal's nares. We then tested the animals in an orthonasal Go/No-Go odor discrimination task but failed to find significant improvements in learning rate and overall performance for the retornasally pre-exposed odors. The negative result is consistent with the hypothesis that an odorant may generate qualitatively different percepts. Local field potential recordings in the olfactory bulb, the olfactory tubercle and the piriform cortex show odor-evoked oscillation power in beta and gamma band for both routes. However, preliminary power spectral density and coherence analysis indicate different temporal patterns of oscillatory events and coherence structure, suggesting that retro and orthonasal learning may be supported by different olfactory network configurations, perhaps leading to different perceptual quality.

Title: Nasal breathing modulates functional connectivity of the bed nucleus of the stria terminalis

Authors: *G. LANE[1,2], G. ZHOU[2], T. NOTO[2], J. JIN[4], G. ARABKHERADMAND[3], N. ARORA[2], C. ZELANO[2]
[1]Chicago, IL; [3]Feinberg Sch. of Medicine, Neurol., [2]Northwestern Univ., Chicago, IL; [4]Psychology, Stony Brook Univ., Middle Island, NY

Abstract: Nasal breathing, which is synonymous with olfactory sampling, impacts local field potential (LFP) oscillations in both olfactory and non-olfactory limbic brain regions, including the amygdala, which is heavily connected to olfactory structures. In the human amygdala, nasal (not oral) inhalation enhances delta and theta range (1-8 Hz) amygdala LFPs. Furthermore, electrical stimulation of the amygdala causes respiratory arrest, but only during nasal, not oral, breathing. These findings suggest a key role for the amygdala in respiratory control that is unique to the nasal breathing route, raising the possibility that the amygdala plays a role in complex sniffing behaviors. In order for sniffing to occur, autonomic respiratory centers must be overridden, allowing conscious control over nasal respiration. The amygdala may impact autonomic breathing via the bed nucleus of the stria terminalis (BNST), an extended region of the amygdala with extensive anatomical connections to the brainstem. Here, we set out to test the hypothesis that breathing route (nasal/oral) alters the intrinsic functional circuitry of the BNST. Resting functional magnetic imaging data were collected from 17 subjects who performed 15 min of both nasal and oral breathing. Seed-based whole-brain functional connectivity maps were calculated for each condition using the BNST as a region of interest. Preliminary analyses suggest that the BOLD time series in BNST and the pons are more strongly correlated during nasal compared to oral breathing (whole-brain corrected $p < 0.05$). These findings suggest that interactions between autonomic respiratory centers and limbic regions may contribute to the neural mechanisms underlying nasal breathing, sniffing and emotional processing. This study was supported by National Institutes of Health Grants (NIDCD) R00-DC-012803 and R01-DC-016364 (to C.Z.).

Title: The effect of aroma inhalation on cortical oscillation recorded by magnetoencephalography

Authors: *S. YAMAMOTO[1], T. YANAGISAWA[2], R. FUKUMA[2], A. TANIYAMA[2], M. SAKAUE[2], K. MAEDA[2], H. KISHIMA[2]
[1]Dept. of Neurosurg., Osaka Univ. Grad. Sch. of Med., Suita, Japan; [2]Osaka Univ., Osaka, Japan

Abstract: *Background*
Aroma inhalation has been found to change cortical oscillation, while the linalool which is contained in lavender essential oil (LEO) has been found to inhibit glutamate binding in the cerebral cortex. Based on these findings, we hypothesized that aroma inhalation has two effects on cortical oscillation: the odor effect and the pharmacological effect.
Previous research suggests that different essential oils target specific areas of the brain, Whereas previous analyses used electroencephalography, we used magnetoencephalography (MEG), which has higher spatial resolution than electroencephalography, to analyze which finely parcellated areas of the brain are affected by aroma inhalation in more detail.
Method
The participants were 17 healthy volunteers. Each of them inhaled three kinds of aroma (LEO, grapefruit essential oil [GEO], and synthetic lavender fragrance oil [SLFO]) in random order as a cross-over trial. Each participant's mood was evaluated using a Short Form of the Profile of Mood States (POMS), which measures six different dimensions of mood, before and after inhaling each essential oil, and MEG signals were recorded while participants were at rest. Cortical currents were estimated on 15,000 vertices by the minimum norm method. The mean power spectrum was calculated for six frequency bands (δ: 1–3 Hz, θ: 3–8 Hz, α: 8–13 Hz, β: 13–25 Hz, low γ: 25–50 Hz, and high γ: 70–110 Hz) in 360 regions of interest (ROIs) based on the Human Connectome Project.
Results
POMS scores for confusion and vigor were significantly lower after inhalation of GEO compared to LEO. The POMS score for confusion was significantly lower after inhalation of GEO compared to SLFO.
According to a one-way ANOVA, each aroma had a different effect on cortical oscillation. In ROI-based analysis, the effects of LEO and SLFO on beta frequency band power spectrum were significantly different at the left perientorhinal cortex and the left temporal fusiform cortex ($p < 0.05$, paired t-test, FDR corrected). We found no ROIs that had a significant correlation with the POMS scores.
Discussion
Both odors and pharmacological agents affect brain activity. The same odors may have different effects on cortical oscillation, possibly due to their specific pharmacological effects.
We could not find the enough supporting evidence to show that specific areas of the brain are related to certain mood dimensions. This is because mood may be related to activity of the deep part of the brain (such as the limbic system), the signals of which are difficult to record with MEG.

Title: Functional magnetic resonance imaging of awake behaving mice performing a go/no-go odor discrimination task

Authors: *E. BERGMANN[1], A. RESULAJ[2], G. YONA[1], D. RINBERG[3], I. KAHN[1]
[1]Technion – Israel Inst. of Technol., Haifa, Israel; [2]Northwestern Univ., Evanston, IL; [3]New York Univ., New York, NY

Abstract: Brain research in animal models, and specifically in mice, provides powerful techniques for precise molecular and cellular manipulations. In contrast, human brain research, which is usually limited to non-invasive imaging methods, focuses on brain-wide network level neural correlates of perceptual and cognitive processes. A fundamental challenge in neuroscience is developing experimental platforms that allow brain-wide network characterization of the mouse brain to support parallel research across species, and to identify new targets for cellular- and systems-level investigations in mice. The current event-related fMRI study combines a temporally precise odor-delivery system, a non-invasive sniff recording methodology and MRI-compatible instruments for water-delivery and lick detection, in order to characterize brain-wide responses in head-fixed mice performing a go/no-go odor discrimination task. Leveraging the high relevance of olfaction to rodent behavior, we were able to train mice on this task in the relatively short period of 4-7 daily sessions and collect hours of data per animal. Using fMRI we identified odorant-specific localized activations in the olfactory bulb, both for the go and no-go odorants, demonstrating topographical organization. In addition, it revealed that correct responses in go trials (‘hits’) are accompanied by activation of the premotor cortex, which precede an extensive recruitment of multiple brain regions including somatosensory and association (prelimbic, anterior cingulate and retrosplenial) cortices, sub-cortical reward areas (nucleus accumbens, ventral tegmental area), caudoputamen, hippocampus and thalamus. Collectively, these results show the engagement of cortical and sub-cortical systems in goal-directed behavior, and establish the feasibility of whole-brain functional imaging of the behaving mouse. Future examinations will utilize the precise control enabled by this setup in combination with molecular tools to uncover the neural correlates of perception and cognition in the mouse brain in order to map the information pathways from nose to muscle.

Abstract: For most animals, including humans, external stimuli typically lead to sensory perception in the wake state, but not during sleep states. Such state-dependent gating of information flow likely involves the thalamus for most sensory modalities; however, olfactory information, originated in olfactory sensory neurons (OSNs) and transmitted to the olfactory bulb, can reach the olfactory cortices such as the piriform cortex and subsequently the orbitofrontal cortex without the relay of the thalamus. Previous studies suggest that gating occurs in the piriform cortex as odor-evoked responses are reduced during the anesthesia-induced slow-wave state or natural sleep, but interpretation of these studies may be confounded by either the use of anesthesia or different odor stimulations due to state-dependent changes in breathing patterns. To ensure consistent peripheral inputs under different brain states, we used an optogenetic approach by expressing channelrhodopsin-2 (ChR2) in all mature mouse OSNs (OMP-ChR2) or a subset of OSNs (M72-ChR2). We optically stimulated these neurons while recording local field potentials (LFPs) and single-unit activities from olfactory areas in freely behaving mice that naturally switch between brain states. In contrast to previous studies, we surprisingly found similar or larger stimulation-evoked responses in the piriform and orbitofrontal cortices for M72-ChR2 (n=4) or OMP-ChR2 (n=10) mice, respectively, during the sleep state compared to the wake state. Additionally, natural odor stimulations delivered directly into the nasal cavity show similar results. These findings suggest that rather than reduced information flow into the olfactory cortex, the lack of smell perception during sleep is likely due to other mechanisms, which are currently under investigation.

Title: The behavior of biologically-inspired olfactory navigation algorithms in realistic turbulent odor environments

Authors: *J. HENGENIUS[1], A. E. PAPALE[2], A. LIU[3], J. P. CRIMALDI[4], N. N. URBAN[2], G. B. ERMENTROUT[1]

Abstract: Olfaction provides animals with vital navigational cues that allow them to avoid threats, find mates, and forage for food. However, the spatial scales of animal navigation are dominated by turbulent fluid flow that produces olfactory stimuli with high spatiotemporal variability. This prevents animals from using gradient ascent methods to localize odors. Experimental evidence suggests that mice use spatiotemporal sniff-to-sniff concentration comparisons during lateral head movements to decide which direction to move in odor trail-following and odor point-finding behavioral tasks. Models provide a means of representing such hypotheses and testing their predictions against data. To that end, we have developed agent-based models A) of the spatiotemporal head "casting" strategy, B) of navigation driven by simultaneously-measured left-right concentration comparisons (representative of arthropod antennal olfaction), and C) of a nonbiological algorithm that navigates using statistical features of a turbulent odor plume (intermittency of concentration fluctuations) to perform both trail-following and source localization tasks. We assess the models' navigation behavior in stochastic simulated odor environments representative of turbulent mixing and in real turbulent plume data obtained by planar laser-induced fluorescence (PLIF). We evaluate each model's performance on trail-following and spot-finding tasks in the stochastic simulated environments and plume source-finding in the PLIF plume. Despite the implicit gradient estimation approaches of the biological models (A, B), we find that they localize sources even in stochastically fluctuating environments. Finally, we compare the behaviors of biologically-inspired (A, B) and nonbiological (C) models with experimental mouse data. We find that, though the spatiotemporal casting strategy (A) conforms most closely to mouse behavior, the left-right spatial strategy (B) outperforms both remaining models on source localization and trail-following tasks.

Title: Behavioral state-specific responses of ventral tenia tecta neurons

Authors: *K. SHIOTANI[1,2], K. MURATA[3], J. HIROKAWA[1], K. MORI[4], Y. SAKURAI[1], H. MANABE[1]
[1]Grad. Sch. of Brain Sci., Doshisha Univ., Kyoto, Japan; [2]Res. Fellow of Japan Society for the Promotion of Sci., Tokyo, Japan; [3]Univ. of Fukui, Fukui, Japan; [4]The Univ. of Tokyo, Tokyo, Japan

Abstract: Ventral tenia tecta (vTT) is an area of the olfactory cortex located in the ventromedial part of the olfactory peduncle in mice. vTT neurons receive olfactory sensory signals from axons of tufted and mitral cells in the olfactory bulb. However, little is known about the anatomical connections among other olfactory cortical areas and other brain regions and functional roles of vTT in odor-guided behavior. First, we performed anterograde and retrograde tracing from vTT and observed that vTT has reciprocal connections with many olfactory areas, including anterior olfactory nucleus and anterior and posterior piriform cortex. We also found that vTT received direct inputs from medial prefrontal cortex. These results suggest that vTT neurons can be driven not only by the olfactory bulb afferent input that conveys odor information but also by association fiber inputs and top-down inputs from many olfactory areas and medial prefrontal cortex. To address the question whether vTT neurons encode behavior-specific signals during odor-guided behavior, we recorded spiking activity of vTT neurons when the mice changed their behaviors between food seeking and eating. For this purpose, mice were trained to associate some odors with sugar reward. After the learning, the mice quickly approached the presented sugar with one of the associated odors on a dish and showed eating behavior. We also conditioned these mice to associate a different odor with aversive consequence after eating. After the learning, the mice approached the sugar with the odor on the dish but then left the dish without eating behavior. Many neurons in vTT showed either increased or decreased in their firing rates during the sequence of approaching and eating behaviors. We also recorded spiking activity of vTT neurons when the mice performed an odor-guided Go/No-Go discrimination task. Because this task can separate the timings of presentation between odors and reward, we can

elucidate whether vTT neurons encode behavioral states or not. Many neurons in vTT changed their firing rates not only during odor exposure but also during approaching, anticipating, and getting reward. These results suggest that many vTT neurons receive behavior-specific signals from the higher centers during odor-guided behaviors.

Abstract: How animals track odors in their environment has become a challenging question. Olfactory navigation is a critical and complex process by which animals can locate food, detect predators and find mates. In order to study strategies of odor navigation, we modified an Arduino robot with two optimized active gas sensors for odor detection, one light sensor to confirm odor source acquisition and three proximity sensors to avoid hitting the walls in the arena. The robot was placed in a plastic acrylic box (1x1x0.3m) with a laminar air flow rate of 5cm/sec and a turbulent odor plume of an iso-kinetically released odorant. We designed four algorithms as follows: A) the robot turned in the direction of higher odor concentration with constant forward movement, B) as A but also backward movement when the odor concentration was below the baseline, C) the heading was based on the odor concentration gradient change over time and D) as A but constant rotating movement when odor concentration was below the baseline. Every code was tested 10 times under eight different starting positions and four different configurations of the gas sensors (based on distance and angles between them). The control of the plumes and the robot tracking behavior was setup using Noldus Ethovision. Finally, we compared the robot's

data with previous experiments from our lab testing c57bl/6 mice under the same experimental conditions, as well as in silico behavior of models closely approximating the environment and algorithms.

Title: Behavioral state affects response to stimuli of competing valence

Authors: *C. H. FAWCETT[1], G. J. SUN[2], C. DIAZ-VERDUGO[3], P. ZHU[4], M. C. FISHMAN[5]
[1]CBT, Novartis Inst. For Biomed. Res., Cambridge, MA; [2]Novartis Inst. for Biomed. Res., Cambridge, MA; [3]Novartis Inst. for BioMedical Researc, Cambridge, MA; [4]Novartis Inst. For Biomed. Res. Inc., Cambridge, MA; [5]Novartis Inst. for BioMedical Res., Cambridge, MA

Abstract: Reproduction and self-preservation are two fundamental, innately driven needs acted upon by natural selection. Animals must make adaptive decisions based upon sensory input and internal states to engage in behaviors that satisfy these critical needs. Such behaviors are often mutually exclusive: for instance, engaging in mating behaviors may expose one to predation; fleeing or hiding from unfamiliar bodies or environments may preclude propagation of the next generation. How animals make such adaptive decisions at the behavioral and neurophysiological levels is not well understood. Here we have utilized the zebrafish model organism to understand the neurobiology of competing reproductive and self-preserving needs. We developed a novel behavior assay to probe the competition of these needs. We then leveraged the optical accessibility of our model system to perform in vivo multiphoton neural activity imaging with genetically encoded calcium indicators to discover neural substrates mediating these behaviors and their control. We found that animals decisively choose just one behavioral outcome as opposed to indecision or a mix of outcomes, and that a trace of this choice can be directly observed from the animals' neural activity patterns. These results demonstrate how animals perform adaptive behaviors when presented with conflicting survival needs, which may represent an evolutionarily optimal strategy.

Title: Linking olfactory codes to behavior using holographic optogenetics

Authors: *J. V. GILL[1,2], G. M. LERMAN[2], S. SHOHAM[3], D. RINBERG[2]
[1]Ctr. for Neural Sci., New York Univ., New York, NY; [2]Neurosci. Inst., [3]Inst. for Engin. in Biomedicine, New York Univ. Sch. of Med., New York, NY

Abstract: A fundamental goal of neuroscience is to understand how the activity of specific neuronal circuits supports behavior. Determining which aspects of neural activity are used by downstream circuits to guide behavior requires simultaneously manipulating activity while monitoring behavioral readout. The mouse olfactory system is emerging as an ideal model for investigating spatiotemporal coding, given its ease of access for recording and manipulation, as well as its behavioral relevance for the animal. Recent studies have revealed that fine temporal scales are essential to olfactory information processing, but it is unknown which precise features of this code are behaviorally accessible. Recently, we developed a system for simultaneous large-scale 2-photon calcium imaging and holographic stimulation in the olfactory bulb of awake, behaving mice, permitting recording and manipulation of groups of neurons with high spatiotemporal resolution. With this system we have measured odor-evoked activity in broad populations of mitral and tufted cells (MTCs), the projection neurons of the olfactory bulb, and demonstrated the use of this system for closed-loop optogenetic feedback, mimicking natural, stimulus-evoked activity temporally patterned across an intrinsic biological rhythm (respiration). This resolution permits a series of theory-driven experiments to establish the basic rules of MTC code readability by higher brain areas. Specifically, we ask what features of spatiotemporal neuronal activity in the olfactory bulb are *detectable* and *discriminable* by downstream circuits to guide behavior. Initial results of these experiments indicated that mice can detect synchronous optogenetic activation of <20 neurons with high accuracy, suggesting exquisite sensitivity. Further experiments explore how this sensitivity changes as a function of timing, cell type and the odor tuning of targeted neurons.

Title: Learning-dependent and -independent enhancement of olfactory bulb odor responses following olfactory fear conditioning in awake mice

Authors: *J. M. ROSS, M. L. FLETCHER
Anat. and Neurobio., Univ. of Tennessee Hlth. Sci. Ctr., Memphis, TN

Abstract: The olfactory bulb (OB) glomerular layer is the first site of sensory input to the central nervous system and contributes to cortical processing of olfactory stimuli and subsequent behavioral output. Previous work from our lab in anesthetized animals suggests that olfactory fear learning induces plasticity observed at the post-synaptic glomerular level of the OB, presumably affecting downstream processing; however, there is a paucity of data regarding the extent to which this occurs in awake mice. In addition, associative fear learning often produces fear toward the conditioned stimulus (CS) as well as to similar, unlearned stimuli, a process referred to as generalization. How fear learning affects early sensory processing in awake mice of both learned and unlearned stimuli in relation to behavioral fear responses to these stimuli remains unclear. To address this, odor-evoked glomerular activity patterns were assessed in awake transgenic mice expressing the genetically encoded calcium indicator, GCaMP, in excitatory post-synaptic OB cell populations. Mice were subjected to simple, classical fear conditioning by paired presentations of an odor with foot shock. Before and after associative conditioning, glomerular representations to a panel of similar and dissimilar odorants were imaged, allowing us to investigate glomerular activation to the trained stimulus as well as neutral, untrained stimuli. The results demonstrate that odor-shock pairing non-specifically enhances glomerular odor representations in a learning-dependent manner and increases representational similarity between the CS and non-conditioned odors, potentially priming the system towards generalization of learned fear. Additionally, CS-specific glomerular enhancements remain even when associative learning is blocked; suggesting two separate mechanisms lead to enhanced glomerular responses following odor-shock pairings. As wide-field glomerular imaging encompasses a combination of responses, it is still unclear how these enhanced responses reflect somatic output. Current work is focused on investigating this question using 2-photon imaging of mitral cell activity in awake animals. Future directions include elucidating the mechanisms of fear learning induced OB glomerular potentiation. All

together, these studies will further our understanding of learning-induced plasticity at the initial stages of olfactory sensory processing and how neuromodulation influences this plasticity and shapes behavioural generalization in awake animals.

Title: NRG1-IV mice outperform control mice in focused go-no go olfactory discrimination

Authors: *D. RAMIREZ-GORDILLO[1], D. RESTREPO[2], A. J. LAW[3]
[2]Dept. of Cell and Developmental Biol., [3]Dept. of Psychiatry, [1]Univ. of Colorado Anschutz, Aurora, CO

Abstract: Schizophrenia is a complex neuropsychiatric disorder characterized by impaired concentration, working memory, perception and social dysfunction. Several factors including environment and genetics play a role in the development of schizophrenia. Increased expression of alternative transcript IV of Neuregulin 1 (NRG1-IV) has been associated with a increased genetic risk for schizophrenia (Law et al, 2006; Proc Natl Acad Sci U S A. 2006 Apr 25;103(17):6747-52). A novel transgenic NRG1-IV model of schizophrenia risk exhibits abnormal behaviors including impaired sensorimotor gating, discrimination memory and social behaviors (Papaleo et al. J. Neurosci. 36:4859, 2016). Here we conducted a preliminary study of behavioral performance and neural oscillations in the prefrontal cortex and the CA1 region of the hippocampus in NRG1-IV male mice and their littermate controls, using awake behave recording. Mice learned to associate one of two odorants with reward in the associative learning go-no go task. Subsequently, NRG1-IV mice and litter mate controls received double tetrode implants targeted to the medial prefrontal cortex and the CA1 region of the hippocampus. All mice learned to differentiate different pairs of odorants in the go-no-go task. A receiver operating characteristic (ROC) analysis showed that there was difference in the power of local field potential (LFP) oscillations as the mice became proficient in discriminating between two odorants. Unexpectedly, when mice discriminated between low concentrations of mixtures of odorants, the NRG1-IV outperformed the control littermates in odorant discrimination. These novel observations suggest a key role of NRG1-IV in associative learning and the development

of fronto-hippocampal circuitry. How this relates to procedural or sensorimotor learning in schizophrenia, requires further study.

Title: Modeling the physicochemical basis of diverse human olfactory percepts

Authors: *J. J. KOWALEWSKI[1], A. RAY[1,2]
[1]Interdepartmental Neurosci., [2]Molecular, Cell, & Systems Biol., Univ. of California, Riverside, Riverside, CA

Abstract: The neurophysiological basis of human auditory and visual perceptual content is better defined than olfaction. While olfactory circuits encode molecular identities that drive reflexive behaviors for many species, human olfaction appears filtered by culture, language and individual experience. Traditional olfactory research is limited by the low throughput of human subjects testing. There is subsequently a key role for modern computation and simulation. Using a dataset of 480 odorants, rated by the general public along 21 perceptual qualities, we identified approaches that could improve upon models where the perceptual quality proved challenging to predict by an initial effort to use machine learning algorithms trained on physicochemical features to predict select perceptual qualities. Molecular features that optimally predicted percepts for a completely different sample of trained professionals also mapped onto those selected for semantically similar percepts on the general public data. Given the expectation that odor language and culture should limit such comparisons, we tested models cross-study. A model predicting “sweet” for the professional survey could be used to predict “sweet” from the general public. Yet the perceptual space is large and incompletely understood. We therefore developed an approach to map optimal molecular features onto 147 different odor percept ratings. Clustering based on network density reverse engineered much of the perceptual space. Models using these features were predictive out of sample. Where models failed or succeeded, adding human odorant receptor activities from heterologous assays improved predictions with molecular features alone. These data emphasize human olfactory perception is more structured than thought. Our approach can subsequently be applied to assemble very large theoretical spaces in which algorithms can traverse, offering testable hypotheses for how molecular structure and receptor activity might map onto diverse perceptual qualities.

Title: Labels transform the human olfactory perceptual space

Authors: *S. CORMIEA, J. FISCHER
Psychological and Brain Sci., Johns Hopkins Univ., Baltimore, MD

Abstract: We continually encounter odors in daily life, but we are notoriously bad at identifying their sources. There are few odors we can readily identify and many that we struggle to give any label at all. A correct label seems to transform an odor – to snap its perceptual features into sharper focus. Just how distinct and reliable is our perception of an odor prior to identifying it? And how does learning an odor's identity change its perceptual qualities? One barrier to addressing these long-standing questions has been the challenge of efficiently characterizing a perceptual space for everyday odors. Here, we present a novel method for mapping human olfactory perceptual space. We employ this approach to test whether assigning labels to everyday odors alters their perceived similarity. In three sessions, participants reported the similarity of sets of stimuli by dragging and dropping icons into a circular arena on a computer screen. In Session 1, the stimuli consisted of sixteen unlabeled odors from common food products (e.g. onion, carrot, grapefruit, vanilla), delivered in opaque squeeze bottles. Subjects sniffed the odors and then arranged the icons on the screen, placing similar-smelling items close together and different-smelling items far apart. In Session 2, participants performed the same task, but this time with labels on the bottles identifying the sources of the odors. In Session 3, participants performed the arrangement task based on the odor labels alone, reporting how similar they imagined the odors would smell. To control for any learning that might take place over repeated sessions, we also tested a separate set of participants on each of the three sessions in isolation. For each session, we computed an individual perceptual similarity space for each participant based on his/her collected responses. We found that the spaces were reliably correlated across participants, demonstrating shared structure in how participants perceived the relationships among the odors (leave-one-out correlation analysis; $p<0.001$). Further, the addition of labels in Session 2 altered the perceptual space in a reliable way that could not be fully accounted for by a linear combination of the spaces obtained for the odor-only arrangements (Session 1) and the label-only arrangements (Session 3). These results demonstrate an interaction between the

perceptual qualities of odors and the labels assigned to them: labels systematically shift the perceived similarities of odors from one reliable space to another.

Title: Perception and neural representation of dichorhinic odor stimuli in humans

Authors: G. ARABKHERADMAND, G. LANE, J. GOTTFRIED, G. ZHOU, *C. ZELANO
Northwestern Univ., Chicago, IL

Abstract: Unlike most sensory modalities, olfactory connections from periphery to cortex are mostly ipsilateral. While some cross-talk likely occurs across hemispheres, little is known about the extent of such connections in humans. Here we used psychophysics and functional neuroimaging to ask two questions about human olfaction: 1. Do ensemble patterns in olfactory regions reflect ipsilaterally- or contralaterally-delivered stimuli?, and 2. How does this inform the neural underpinnings of conscious perception of odors? 15 human subjects participated in an odor identification task. The odor stimulus was either monorhinic (same odor to both nostrils) or dichorhinic (different odor to each nostril). Following odor presentation, subjects were asked to select from one of four choices indicating what they smelled: odor A only, odor B only, both, or "other". When presented with dichorhinic stimuli, subjects responded with equal frequency that they smelled either odor A only or odor B only. By examining fMRI ensemble patterns in response to trials where subjects received a dichorhinic mixture but perceived only a single component of that mixture, we were able to ask if the non-perceived odor was still encoded in ipsilateral cortex and how far along the olfactory hierarchical pathway the subliminal odor representation was maintained. Preliminary analysis of data from 15 subjects suggests that subliminal odor representations persist to the level of anterior olfactory nucleus but not in any other subregions of primary olfactory cortex. Interestingly, in orbitofrontal cortex, odor patterns appear to reflect the perceived odor only, even on the side of the brain ipsilateral to the nonperceived odor. While still preliminary, these data suggest that odors are primarily coded ipsilaterally, and that OFC may play a role in conscious perception of odor.

Abstract: The olfactory system is an important alerting system that detects life-endangering stimuli in rodents as well as in humans. In real life situations, the perception of a smell can come to awareness without active sniffing, which suggests that olfactory brain areas monitor the contents of ongoing autonomic breaths. Previous studies have demonstrated that natural nasal breathing entrains local field potential oscillations in both olfactory and non-olfactory brain regions. Furthermore, odor stimulation can also induce phase synchronization between piriform cortex and hippocampus. Whether this synchronization occurs during natural breathing, in the absence of odor, is unknown. Given the role of the hippocampus in memory encoding during ongoing sensory sampling, we hypothesized that natural breathing could modulate its coupling with primary olfactory regions, such as piriform cortex. In this study, fifteen minutes of resting local field potential data were recorded from 7 epilepsy patients. Functional connectivity between piriform cortex and hippocampus was examined with inter-trial phase locking value (PLV). We found rhythmic modulations in coupling between piriform cortex and hippocampus occurring in phase with natural breathing such that low frequency band PLV (1-8 Hz) increased following inhalation and decreased during exhalation. This finding suggests that resting-state coupling between piriform cortex and hippocampus is tied to the natural respiratory cycle, which might be an energy-efficient implementation of the olfactory alerting system.

Title: Identity prediction errors in human midbrain are computed based on abstract state representations

Authors: *J. SUAREZ[1], T. KAHNT[2]
[1]Neurol., Feinberg Sch. of Med., Chicago, IL; [2]Dept. of Neurol., Northwestern Univ., Chicago, IL

Abstract: Adaptive behavior requires the ability to update associations between predictive stimuli and outcomes. Errors induced by mismatches between expected and received outcomes (prediction errors, PE) are thought to provide a computational basis for updating these associations and have been linked to the activity of dopaminergic midbrain neurons. Model-free PE's are defined as discrepancy between the expected and received outcome value. However, recent evidence suggests that midbrain neurons also respond to value-neutral violations in outcome identity. Such identity PE's could be used to update the associative structure of the task environment and may play an important role in model-based learning and decision-making. However, it is unknown whether the brain computes identity expectations and errors in the form of abstract state representations or based on the perceptual identity of the outcome. If PEs are computed based on the perceptual similarity of expected and received outcomes, unexpected outcomes that are dissimilar to expected ones should elicit larger PE's compared to perceptually similar outcomes. If PE's are computed in an abstract space, neural responses should be independent of the perceptual similarity between expected and received outcomes. To test this, we designed a Pavlovian task involving value-matched food odors from two food categories (two sweet and two savory) as outcomes. During fMRI data acquisition, subjects (N=19) performed an outcome prediction task based on learned associations between visual cues and food odors. Unexpectedly to the subjects, associations were changed throughout the task to elicit both between-category and within-category PE's. We found that fMRI activity in the midbrain, dlPFC, and piriform cortex (PC) was significantly correlated with PE's derived from a computational model of identity learning. However, responses to between- vs within-category PE's did not differ in these areas, indicating that PE's do not scale with the perceptual similarly of the outcome. This suggests that PE's are computed based on abstract state representations rather than a space defined by perceptual similarity. Encoding expectations in abstract spaces

allows for sensitive error signals that can detect and update perceptually small mismatches between expected and received outcomes.

Title: Electrophysiological response to trigeminal stimuli in patients with Parkinson's disease

Authors: *C. TREMBLAY[1], R. EMRICH[2], A. HAEHNER[2], A. CAVAZZANA[2], T. HUMMEL[2], J. FRASNELLI[1,3]
[1]Univ. Du Québec À Trois-Rivières, Trois-Rivières, QC, Canada; [2]Dept. of otorhinolaryngology, Smell and taste clinic, Tech. Univ. of Dresden, Dresden, Germany; [3]Res. Ctr. of the Sacré-Cœur Hosp., Montreal, QC, Canada

Abstract: Olfactory dysfunction is a highly sensitive pre-motor symptom of Parkinson's disease (PD). In order to use olfactory testing to screen for PD, it is important to differentiate olfactory dysfunction associated with PD from other olfactory dysfunctions. One potential avenue to do so is the measurement of the trigeminal sensitivity. While there is evidence that patients with olfactory dysfunction show a reduced trigeminal sensitivity compared to controls, previous studies suggested that the trigeminal system does not seem to be impaired in PD. Our objective was, therefore, to measure peripheral (from the mucosa, negative mucosal potential, NMP) and central (event-related potential, ERP) electrophysiological responses to the trigeminal stimulus carbon dioxide in patients with Parkinson's disease and compare them to patients with non-parkinsonian olfactory dysfunction and to healthy controls. Our results show that patients with non-parkinsonian olfactory dysfunction show longer NMP latencies and amplitudes than controls and patients with Parkinson's disease. Moreover, PD patients show larger ERP components than patients with non-parkinsonian olfactory dysfunction. This was despite the fact that olfactory function was significantly diminished in both groups of patients compared to controls. These

results suggest a specific pattern of chemosensory impairment in patients with Parkinson's disease.

Title: Structural plasticity of mushroom body-related dopaminergic neurons in dependence of the nutritional value of food

Authors: *B. COBAN, H. POPPINGA, T. RIEMENSPERGER, A. FIALA
Mol. Neurobio. of Behavior, Univ. Of Goettingen, Goettingen, Germany

Abstract: The experience of food with high or low nutritional value can influence behavior, e.g. food-related memory formation and feeding prevalence. The neuronal basis of these alterations that are dependent on the flies' dietary remain unclear. In this study, we use d*rosophila melanogaster* to address the question how the caloric value of the animals' dietary affects behaviors such as olfactory associative learning and food uptake. In particular, we investigated functional and structural changes in neuronal connectivity between dopaminergic neurons (DANs) and intrinsic mushroom body neurons (Kenyon cells).
In order to analyze the effects of long-term feeding experience, three days old adult flies were kept on either hypocaloric, isocaloric or hypercaloric food for seven days. Subsequently, we have quantified the flies' food uptake using a capillary feeder assay (CAFE assay), and we have analyzed the flies' appetitive olfactory learning and short-term memory. Our results show that the calorie restriction causes an increased food uptake and enhancement in appetitive learning, while aversive olfactory conditioning remained unaffacted when the flies were starved for 6 hours before the experiment.
The mushroom body (MB) is a key brain structure involved in associative learning and memory formation. The reinforcing effects of rewarding sugar stimuli or punitive signals are mediated by modulatory DANs innervating distinct compartments of MB. We investigated if modulatory DANs undergo structural rearrangement dependent on the dietary of the flies by measuring the intensity of reconstituted split GFP ("GRASP") across putative synaptic contacts between DANs and Kenyon cells. We found that DANs innervating specifically the γ3 compartment of the MB undergo structural remodeling in dependence of the nutritional value of food, whereas DANs

innervating the other compartments remain unmodified. Upon calorie restriction γ3 DAN innervations onto Kenyon cells decreased significantly. Furthermore, we have investigated if there is any functional change in γ3 DANs which can perhaps be causative for their restructuring. Thus, we have measured intrinsic calcium activity of the cells over a long-term period in a cumulative way using the GFP- based Ca^{2+} indicator CaLexA. We found an increase in the activity of the γ3 DANs upon restriction of the caloric food value. In summary, the caloric value of food re-structures brain connectivity in that it shapes the contacts between specific DANs and Kenyon cells.

Title: Sublethal dose of thiacloprid impairs honeybees olfactory learning ability by damaging nervous system

Authors: *Y. LIU[1], Z.-W. JING[2]
[1]Inst. of Apicultural, CAAS, Beijing, China; [2]Res. Ctr. for Eco-Environmental Sciences, CAAS, Beijing, China

Abstract: The dramatic loss of bees is a major concern worldwide and has been related to the use of neonicotinoid insecticides which mainly impair nerve cells of bee brain and can cause their behavior abnormalities. Thiacloprid was declared less toxic to bees and used increasingly in the last years. However, little is known about how bees are affected by sublethal dose of thiacloprid. We treated *Apis mellifera L.*with sublethal concentrations of thiacloprid (0.2, 0.6, 1,2 ppm) and determined the effect on behaviors, neuronal apoptosis,and synaptic units in the mushroom bodies. Learning and Memory were significant impaired by 0.2 ppm thiacloprid at 12 d which can induce nerve cell apoptosis in the brain of honeybees. We also found that the synaptic units density in the calyces of mushroom decreased after exposed to sublethal dose of thiacloprid.Here, we provide evidence that thiacloprid damages nervous system and thus impairs the olfactory learning ability.

Title: Cellular cartography of the organ of Corti based on tissue clearing <and> machine learning

Authors: *S. URATA, T. IIDA, Y. MIZUSHIMA, C. FUJIMOTO, Y. MATSUMOTO, T. YAMASOBA, S. OKABE

Abstract: Spatial organization of hair cells in the organ of Corti, the mammalian auditory sensory epithelium, is a critical parameter that affects sensitivity and ability of frequency discrimination of mammalian hearing. Frequency discrimination is achieved by spatial tuning to specific frequencies along the longitudinal axis of the organ of Corti. The basic tuning pattern is simple, with higher frequencies on the base of the cochlear spiral and lower frequencies on the apex. However, multiple structural, mechanistic, and cell biological factors influence the real shape of the tonotopic map. Therefore, complete understanding of auditory perception requires imaging technology that enables accurate re-construction of the intact, three-dimensional structure of the organ of Corti. Here we report a tissue clearing-based analytical pipeline for the construction of a single-cell resolution map of the organ of Corti. A newly developed clearing method enabled imaging of the entire cochlea, with resolution sufficient to detect intricate subcellular structures of hair cells. We combined the tissue clearing method with machine learning-based pattern recognition. This analytical pipeline enabled high-fidelity detection and determination of total hair cell positions along the entire longitudinal axis of the organ of Corti. We applied this method to samples along the normal course of development and those with noise exposure. The pattern of hair cell damage revealed distinct impacts of aging and noise on hair cell pathology. Thus, our method of cellular mapping is highly effective in system-level phenotyping of the organ of Corti under both physiological and pathological conditions.

Title: Development of intratympanically administered neurotrophic factor BDNF for the treatment of speech-in-noise hearing difficulties (cochlear synaptopathy)

Authors: *B. E. JACQUES, N. TSIVKOVSKAIA, R. FERNANDEZ, X. WANG, A. JONES, T. ALTMANN, J. HOU, F. PIU
Otonomy Inc., San Diego, CA

Abstract: Recent evidence from both preclinical and clinical studies indicates that a loss or dysfunction of the ribbon synapses that connect inner hair cells in the cochlea with spiral ganglion neurons (SGNs), whose axons form the cochlear nerve, contributes to hearing impairment. This ribbon synaptopathy is proposed as an underlying pathology in age-related and noise-induced hearing dysfunction and has been hypothesized to explain speech-in-noise hearing difficulties that occur despite normal audiometric thresholds. The application of exogenous neurotrophins, such as Brain-Derived Neurotrophic Factor (BDNF) or Neurotrophin-3 (NT-3), as well as selective high affinity monoclonal antibodies (mAbs) with agonist activities at the Trk receptors, has been investigated as a therapeutic approach based on their ability to provide trophic support to spiral ganglion neurons in the cochlea. In recent studies, BDNF, NT-3 and several Trk agonist mAbs were found to promote survival, neurite extension and synapse restoration in ex-vivo cochlear cultures. The in vivo pharmacokinetic and efficacy profile of OTO-413, a thermosensitive sustained-exposure formulation of BDNF developed for intratympanic round window delivery, was determined in a rat model of noise-induced cochlear synaptopathy. This delivery method provided significant and dose-dependent sustained-exposure of BDNF to the inner ear for several weeks, as determined by ELISA. The evaluation monitored several functional (ABR, wave 1 amplitude) and histological (ribbon synapse counts, hair cell viability) parameters. Following noise-exposure, BDNF administration statistically improved all measures of cochlear synaptopathy throughout the one-month duration of the study. Overall, OTO-413, a sustained-exposure formulation of BDNF, was effective in alleviating noise-induced cochlear synaptopathy in-vivo and demonstrated a suitable pharmacokinetic profile, thereby constituting an attractive and novel therapeutic approach for the treatment of cochlear synaptopathy-associated hearing loss and the preservation of cochlear neurons.

Title: Enhancement of the medial olivocochlear system prevents hidden hearing loss

Authors: *L. E. BOERO[1,2], V. C. CASTAGNA[2], J. D. GOUTMAN[1], A. B. ELGOYHEN[1,2], M. E. GÓMEZ-CASATI[2]

Abstract: Hearing loss is a major public health problem, given that its impact on human communication and quality of life is devastating. Noise exposure has gained relevance as one of the most important sources, although the underlying causes of noise-induced hearing loss are still unknown. Recently, it has been demonstrated that acoustic trauma (AT) producing only transient auditory threshold shifts also produces long-term structural damages to the inner ear, such as a

reduction in the number synapses between inner hair cells (IHCs) and afferent neurons. This has been called hidden hearing loss (HHL) because it is not apparent in an audiogram. Medial olivocochlear (MOC) efferent neurons form a negative feedback gain-control system that inhibits amplification of sounds by the action of acetylcholine on a9a10 cholinergic nicotinic receptors at the base of outer hair cells (OHCs). It has been proposed that activity of the MOC fibers can ameliorate AT effects.
Here we explore the role of the MOC system in HHL by comparing the performance of two different mouse models after AT: an a9 nicotinic receptor subunit *knock-out* (*Chrna9* KO) which lacks cholinergic transmission between efferent neurons and OHCs, and a gain of function *knock-in* (*Chrna9L9'T* KI) bearing an a9 point mutation that leads to enhanced MOC activity. Animals of either sex were exposed to 1-16 kHz noise of 100 dB SPL for 1 hour. This sound pressure levels produced in WT mice transient auditory brainstem responses (ABRs) threshold shifts, a decrease in neural response amplitudes and loss of ribbon synapses, indicative of cochlear synaptopathy. In *Chrna9* KO ears, we also found cochlear synaptopathy but the ABR threshold shifts were permanent. In contrast, the *Chrna9L9'T* KI was completely resistant to the same acoustic exposure protocol. These results show a positive correlation between the degree of HHL prevention and the level of cholinergic activity. Notably, enhancement of the MOC feedback promoted new afferent synapse formation, suggesting that it can trigger cellular and molecular mechanisms to protect and/or repair the inner ear sensory epithelium.
Additionally, we were interested in elucidating if AT could affect the capacity of IHCs to release glutamate. Patch-clamp recordings were performed on IHCs in an ex-vivo cochlear preparation of exposed and control mice. Glutamate release from IHCs was estimated by monitoring cell membrane capacitance with a lock-in amplifier. We found an increase in capacitance changes and Ca2+ currents in noise exposed animals. These results suggest presynaptic overcompensation after acoustic overexposure.

Title: Auditory signal envelope processing by the organ of Corti of the guinea pig cochlea

Authors: G. BURWOOD, 97239[1], A. FRIDBERGER[2], R. WANG[3], *A. L. NUTTALL[1]
[1]Oregon Hearing Res. Ctr., Oregon Hlth. & Sci. Univ., Portland, OR; [2]Dept. of Clin. and Exptl.

Abstract: The structure and function of the mammalian cochlea permits the perception of speech and music via the envelope of the otherwise complex acoustic signal. Much of this ability is clearly due to post-sensory processing, as cochlear implant users may understand speech with sparse frequency coding provided by their electrode arrays. The organ of Corti itself may possess the ability to relay envelope information, which is not necessarily reflected in the tuning and motion of the basilar membrane. Using optical coherence tomography vibrometry and electrophysiological measures of the intact guinea pig cochlea, we determined the ability of the cochlea to "extract" the signal envelope of a three tone complex at several stimulus intensities. Each tone complex possessed an f1, f2 and f3 subsequently separated by 50Hz, producing a quadratic difference tone of 50Hz. Varying the phase of the f2 had the effect of reducing the amplitude of the envelope component, and this effect was less pronounced at higher stimulus intensities. Based upon these observations of round window cochlear microphonic and mechanical motion of the organ of Corti, it is likely that envelope information is produced by cellular mechanosensory pathways that introduce distortion due to their non-linear nature. Such tissue displacement non-linearities could feasibly permit envelope information to be transduced by the auditory nerve, enabling the interpretation of complex acoustic signals.

Title: Outer hair cell motility can suppress the organ of Corti vibrations

Authors: *J.-H. NAM, T. JABEEN, J. BECKER
Univ. of Rochester, Rochester, NY

Abstract: The organ of Corti (OoC) vibrates differently depending the existence of outer hair cell motility. The OoC micro structures vibrate roughly in-phase when passive. In contrast, they vibrate out-of-phase when outer hair cell motility contributes to the vibrations. Theories are divergent on how this difference in OoC vibration modes is related to the cochlear function such as sound amplification or tuning. We used isolated cochlear turns to investigate the vibration

patterns of the OoC when mechanical and electrical stimulations are applied simultaneously. Fresh cochleas were harvested from young gerbil (15-20 days old). To expose a targeted section of the OoC, the bones and tissues of the cochlea were removed so that approximately a single turn of the cochlear coil left. The cochlear turn was attached to a custom-designed micro-chamber. The micro-chamber has two ports for fluid circulation and two ports for pressure application and release (analogous to oval and round windows in the cochlea). It also has a slit on which the cochlear turn is attached. While acoustical pressures and electrical currents were delivered, the vibration amplitudes of the OoC complex were measured along the transverse and radial directions using a laser interferometer. The mechanical stimulations were applied with different time delays (phases) from the electrical stimulations. The measurement data was compared with computer model simulations of the OoC complex. At the measurement location (approx. 8 mm from the basal end), the vibration amplitudes were greater at the tectorial membrane than at the basilar membrane for both stimulation methods. We observed both constructive and destructive interactions between the mechanically and electrically agitated vibrations. This suggests that the outer hair cells' electromotility can not only amplify the OoC vibrations, but also suppress them. The computer model predicts that both constructive and destructive interactions exist under physiological cochlea.

Title: A computational model for the effects of auditory nerve heminode disruption on hearing

Authors: *M. BUDAK[1], K. GROSH[2], V. BOOTH[3], M. R. ZOCHOWSKI[4], G. CORFAS[5]
[1]Biophysics, [2]Mechanical & Biomed. Engin., [3]Mathematics & Anesthesiol., [4]Physics, [5]Kresge Hearing Res. Inst., Univ. of Michigan, Ann Arbor, MI

Abstract: Hidden hearing loss (HHL) is an auditory neuropathy characterized by normal hearing thresholds but reduced amplitude of the sound-evoked auditory nerve (AN) compound action potential (CAP). It has been proposed that in humans HHL leads to speech discrimination and intelligibility deficits, particularly in noisy environments. Animal models originally indicated that HHL can be caused by moderate noise exposures or aging, and that loss of inner hair cell (IHC) synapses could be its cause. However, Wan and Corfas (2017) provided evidence that transient loss of cochlear Schwann cells also causes HHL in mice. In this animal model, HHL

occurs early in the demyelination process and persists for the animal's lifespan even after Schwann cells regenerate and axons remyelinate. The only histological finding in the mice after Schwann cell regeneration is a permanent disruption of the heminode at the AN peripheral terminals, i.e. while in the normal ear all heminodes are located at the same distance from the hair cell, in the remyelinated animals the heminodes are disorganized and some unmyelinated segments are observed. We constructed a reduced biophysical model for a population of IHCs with 15 postsynaptic AN fibers to elucidate the role the disruption of heminode position has on the transmission of action potential. We then used a probabilistic model to simulate neurotransmitter release from the IHC's synapses in response to different sound levels. Neurotransmitter released at the IHC-AN synapse causes brief axonal depolarizations in the biophysical models. By varying the position of heminodes in the different axons to model the pathology seen after remyelination, we found that the amplitude of simulated sound-evoked AN CAPs is lower and has a greater delay when the heminodes are disorganized, i.e. they are placed at different distances from the hair cell rather than at the same distance as seen in the normal cochlea. Thus, our model confirms that heminodal disruption causes desynchronization of AN spikes leading to a loss of temporal resolution and reduction of the sound-evoked AN CAP.

Title: To explore the function of C1QL1 protein in cochlea and sound perception

Authors: *J. BISWAS[1], R. PIJEWSKI[2], B. THOMPSON[2], R. MAKOL[2], T. MIRAMONTES[2], A. BURGHARD[2], T. C. SUDHOF[3], D. KIM[2], D. OLIVER[2], D. C. MARTINELLI[2]
[1]Neurosci., Uconn Hlth., Farmington, CT; [2]Neurosci., UConn Hlth., Farmington, CT; [3]Stanford Univ., Stanford, CA

Abstract:
Hearing requires functional inner and outer hair cells of the cochlea. The inner hair cells (IHCs) transduce noise signals to the brain through afferent synapses whereas the electromotile outer hair cells (OHCs) provide sound amplification hence enhancing cochlear sensitivity. The OHCs are susceptible to damage as a result of noise exposure, ototoxic medications, or aging. This is

concerning because hair cells do not regenerate resulting in sensorineural hearing loss. C1QL1 is a presynaptically released secreted protein which promotes synapse maintenance in CNS. Our experimental finding demonstrates the cochlear expression of *C1ql1* selectively in OHCs. To determine the functional relevance of *C1ql1*, a novel conditional knock out (cKO) allele for *C1ql1* in OHCs was developed, allowing a unique opportunity to study the synaptic physiology of OHCs. Using a series of auditory tests, like DPOAE (Distortion Product Otoacoustic Emission), ABR (Auditory Brainstem Response), and AMFR (Amplitude-Modulation Following Response), we observed that cKO mice have lower thresholds for hearing compared to control littermates suggesting that they have enhanced OHC electromotility and improved hearing for low-level sounds compared to wildtype (WT) mice. Moreover, cKO mice startled more than control mice in a test for the acoustic startle response further suggesting their altered hearing abilities. Our findings show that the presence/absence of *C1ql1* affects the OHC's physiological response to acoustic stimuli through a yet-to-be-determined mechanism and makes it a prospective drug target for auditory therapeutics.

Title: Compartmentalization of antagonistic Ca^{2+} signals in developing cochlear hair cells

Authors: *M. J. MOGLIE[1], P. A. FUCHS[2], A. B. ELGOYHEN[1,3], J. D. GOUTMAN[1]
[1]INGEBI-CONICET, City of Buenos Aires, Argentina; [2]Otolaryngol, Head & Neck Surgery, Johns Hopkins Univ., Baltimore, MD; [3]Inst. de Farmacología, Facultad de Medicina, Univ. de Buenos Aires, City of Buenos Aires, Argentina

Abstract: During a critical developmental period, cochlear inner hair cells (IHCs) fire sensory-independent action potentials, crucial for the normal maturation of the auditory pathway. During each action potential, IHCs operate as a presynaptic terminal and Ca^{2+} influx through voltage-

dependent channels triggers the release of glutamate onto afferent dendrites of the auditory nerve. At the same developmental stage, IHCs are the postsynaptic target of efferent cholinergic neurons from the brainstem. This efferent synapse combines the entry of Ca^{2+} through cholinergic α9α10 receptors with the activation of nearby SK2, Ca^{2+}-dependent potassium channels to hyperpolarize the IHC. Thus, efferent Ca^{2+} signals are inhibitory, opposing IHC transmitter release. The aim of our work was to investigate the mechanisms that allow segregation of excitatory versus inhibitory Ca^{2+} effects within the limited diffusional space of the IHCs synaptic pole.
Electrophysiological recordings combined with swept–field confocal Ca^{2+} imaging experiments revealed the existence of multiple Ca^{2+} entry hotspots per IHC upon efferent fiber electrical stimulation. They were concentrated in the basal pole of the IHC in close apposition and intermingled with the afferent hotspots encountered following IHC depolarization. Using serial section electron micrographs we were able to perform IHC reconstructions at a nanometer scale. We estimated an average distance between efferent hotspots and closest afferent neighbors of 1.62 ± 1.11 µm. The intimate localization of antagonist Ca^{2+} entry sites encountered suggests that during normal operation of developing IHCs, efferent Ca^{2+} spread could potentially occur over other synapses. Finally, in order to evaluate a possible efferent to afferent crosstalk, recordings from afferent boutons were performed. Despite the close proximity, even high frequency (80 Hz) electrical stimulation of efferent fibers failed to evoke an increase in the frequency of postsynaptic excitatory currents. On the contrary, locally applied saturating concentrations of ACh elicited Ca^{2+} signals capable of cross-activating afferent release. Electrophysiological and Ca^{2+} imaging experiments in IHCs showed that physical barriers imposed by efferent synaptic cisterns, Ca^{2+} extrusion mechanisms and strong Ca^{2+} buffering prevent efferent to afferent synaptic crosstalk during synaptic activation of cholinergic release. Thus, efferent fibers maintain its inhibitory signature and operate at low frequencies to modulate spontaneous action potential firing in the developing IHC.

Abstract: Prior to the onset of hearing, inner hair cells in the developing cochlea fire spontaneous calcium action potentials, evoking glutamate release from ribbon synapses and modulating firing rates of type I spiral ganglion neurons. This spontaneous activity involves an interplay between calcium transients in supporting cells and hair cells, and is essential to the development of hearing and maturation of tonotopy in the brainstem and higher auditory centers (1-3). In the present work we examined the hypothesis that spontaneous calcium transients are also present during early postnatal development in hair cells and supporting cells in the mouse vestibular organs. All animal experiments were approved by the University of Utah Institutional Animal Care and Use Committee. A transgenic mouse with the calcium indicator GCaMP5G and constitutive reporter tdTomato (4) was crossed with a Gad2-IRES-Cre- driver line (5). GCaMP5G imaging of the utricle was performed ex vivo using a swept field confocal microscope (Prairie) with a 60x water immersion objective (Olympus). Spontaneous G5 (ΔF/F) fluorescence modulation was recorded at a 100ms frame rate over successive optical sections.Results. GCaMP5G imaging revealed spontaneous calcium transients restricted almost exclusively to type I hair cells at birth (P1). By postnatal day 3 (P3) calcium transients in hair cells diminished, while extensive calcium transients developed in supporting cells. Transients in supporting cells at P3 were at the apical end where direct contacts are made with type I hair cells. Spontaneous transients diminished as calyces developed to envelop type I hair cells. Results confirm the hypothesis that spontaneous calcium transients are present in developing utricular hair cells and juxtaposed supporting cells. The temporal sequence of activity suggests that spontaneous calcium transients in type 1 hair cells and neighboring supporting cells likely modulates activity in calyx-bearing vestibular afferents during the first postnatal week, and may play a key role in the maturation of vestibular neural circuits. Title: Expression of group II metabotropic glutamate receptors at ribbon synapses of inner hair-cells

Authors: *R. ENZ, L. KLOTZ
Univ. Erlangen-Nürnberg, Erlangen, Germany

Abstract: Glutamate is the most important excitatory neurotransmitter in the central nervous system, acting on ion-channel associated (ionotropic) and G-protein coupled (metabotropic) glutamate receptors. In contrast to the post-synaptically localized group I metabotropic glutamate receptors mGluR1 and mGluR5, the localization of pre-synaptic receptors belonging to group II (mGluR2 and mGluR3) and group III (mGluR4, mGluR7 and mGluR8) in hair-cells of the cochlea is largely unknown. General expression of mGluR7 and mGluR8 in inner and outer hair-cells was observed, but a synaptic localization was not investigated in detail. Therefore, we analysed expression and synaptic localization of mGluRs in the cochlea. Reverse-transcription PCR detected mRNA encoding for all known mGluR types in the adult mouse, including common splice-variants, except for the retina specific mGluR6. The sub-cellular distribution of corresponding receptor proteins was analysed in cochlear wholemounts of adult gerbils and mice. Tissue was co-stained with immunesera recognizing various mGluR types and antibodies directed against the C-terminal binding protein CTBP2, a marker for synaptic ribbons localized in pre-synaptic hair-cell terminals. Using confocal microscopy, antibodies binding a conserved epitope in mGluR2 and mGluR3, or immunesera recognizing mGluR4 or mGluR8 resulted in a punctate label in both species, indicating synaptic localization of these receptors. While mGluR4 and mGluR8 were not co-localized with CTBP2, we observed a close proximity between mGluR2/3 and the pre-synaptic ribbon at inner hair-cells synapses. Finally, stimulated emission depletion (STED) microscopy described the distribution of mGluR2/3 relative to the pre-synaptic ribbon in more detail. In summary, we detected expression of all mGluR types, except mGluR6 in the mouse cochlea. MGluR2/3, mGluR4 and mGluR8 showed a punctate appearance, but only mGluR/3 were localized close to pre-synaptic ribbons of inner hair-cells in gerbil and mouse. There, mGluR2/3 might be involved in inhibitory feedback loops that control the amount of glutamate released into the synaptic cleft, thus protecting hair-cells against noxious stimuli. Interestingly, mGluR2 and mGluR3 are both absent from ribbon synapses formed by photoreceptors of the retina. Thus, our data suggests that different sensory neurons need a tailor-made regulation of their neurotransmitter systems.

Title: Adaptation of spontaneous and evoked activity in the Zebrafish lateral line

Authors: *D. FROLOV[1,2], E. ISKO[2], S. A. SHORT[2], T. F. SOMMERS[2], J. G. TRAPANI[2]
[1]Univ. of Massachusetts Amherst, Amherst, MA; [2]Amherst Col., Amherst, MA

Abstract: Adaptation dynamically excludes irrelevant or unchanging stimuli from sensory processing. The posterior lateral line (PLL) of zebrafish larvae is an accessible hair-cell (HC) sensory system for the study of adaptation. During mechanical stimulation of hair cells of the zebrafish lateral line while recording action potentials (spikes) from individual afferent neurons, we delivered paired-pulse stimuli with varying stimulus window length and inter-stimulus intervals (ISIs). We observed substantial adaptation between the responses to the first and second pulse. We quantified paired-pulse ratios (PPR) for first spike latency (FSL) and spike rate (SR). By varying the length of ISIs, we calculated time constants of recovery (τ) of adaptation. Preliminary results suggest that adaptation of FSL and SR recovers at different rates, which we hypothesize result from differential replenishment of two distinct vesicle pools at synaptic ribbon. To support this hypothesis, we expanded our dataset across a broader range of physiologically relevant ISIs. Examination of the entire time course of recovery for FSL and SR adaptation showed that FSL fully recovers before SR, consistent with our initial hypothesis. These two forms of adaptation were next shown to be mechanotransduction-independent via paired-pulse stimulation of hair cells with Channelrhodopsin-2. To further probe the role of the synaptic vesicle pools in spike train adaptation, we examined recovery of spontaneous spikes after single-pulse stimuli. First spontaneous spike latency (FSSL) recovery rates were longer than for evoked activity, suggesting a different mechanism of vesicle replenishment at the presynaptic ribbon. The synaptic architecture of the PLL is similar to mammalian vestibular synapses, highlighting its use as model system for the understanding of vestibular encoding.

Title: Effect of Trk receptor monoclonal antibodies and recombinant neurotrophins on neuron survival, neurite morphology, and synaptogenesis in rat *ex vivo* models relevant to hearing loss

Authors: *S. SZOBOTA[1], P. D. MATHUR[1], S. SIEGEL[1], H. SARAGOVI[2], A. C. FOSTER[1]

Abstract: Hearing loss is the most common sensory disorder, affecting approximately 15% of adults in the US. Loss of spiral ganglion neurons (SGNs) and their synaptic connections with the cells of the inner ear plays a major role in decreased speech-in-noise discrimination and other forms of hearing loss. One treatment that has been investigated is the application of BDNF and NT-3, neurotrophins that provide trophic support to SGNs through activation of TrkB and TrkC receptors, respectively. Monoclonal antibodies (mAbs) with agonist activities also have the potential to activate TrkB or TrkC, while providing the potential advantage of biostability. Recombinant BDNF, NT-3, and mAbs were generated and their selectivity for TrkB or TrkC and cross-reactivity between human and rat Trk receptors were evaluated by AlphaLISA and Biacore. Agonist activity was detected as increased phosphorylation of Erk1/2, PLC-gamma, and AKT in Western Blot and AlphaLISA using cell lines that stably express Trk receptors. The ability of BDNF, NT-3, and mAbs to activate native cochlear Trk receptors and promote neuron survival was determined by counting surviving neurons in 96-well cultures containing dissociated rat SGNs that were fixed, immunostained, and imaged on the PerkinElmer Operetta. The most active molecules were then tested in SGN explants and organotypic cochlear cultures from postnatal rats to examine their ability to stimulate neurite growth and synaptogenesis. Effects on neurite length and branching were analyzed using Harmony software neurite detection features (PerkinElmer).
The mAbs selectively bound to either TrkB or TrkC with low nanomolar affinity and activated downstream signaling in TrkB or TrkC -expressing cell lines. The degree of agonism of the different mAbs varied, ranging from partial to full, relative to BDNF and NT-3. Survival of dissociated SGNs was increased significantly with BDNF, NT-3 and mAbs, compared to control cultures. Treatments also increased the number of primary neurites and total neurite tree length. In explanted SGNs, neurotrophic factors increased the number of neurites, the number of branch

points, and the number of extremities. In explanted cochlear cultures, selected treatments increased the number of PSD-95 puncta and neuron fiber density.
BDNF, NT-3, and the Trk agonist mAbs evaluated are potent activators of neurotrophin signaling in several ex vivo models that are relevant to hearing loss. Their ability to promote survival, neurite extension, branching, and synapse restoration make them attractive therapeutic candidates for the treatment of hearing loss.

Title: Investigating FOXO3's role in cochlear preservation and hearing recovery in a mouse model of noise-induced hearing loss

Authors: *H. BEAULAC[1], P. WHITE[2]
[1]Neurosci. Grad. Program, Univ. of Rochester Sch. of Med. and Den, Rochester, NY; [2]Univ. of Rochester Sch. of Med. and Dent., Dept. of Neurosci., Rochester, NY

Abstract: Approximately 16% of global cases of adult-onset hearing loss are attributable to excessive, occupational noise exposure. An individual’s susceptibility to noise-induced hearing loss (NIHL) and the severity of their condition depend on interactions between underlying genetic networks and the environment. We have previously established that the forkhead transcription factor FOXO3 is required for hearing recovery and outer hair cell (OHC) preservation after noise exposure (Gilels et al. 2017). The present study used immunohistochemistry and RNA sequencing to assess changes in protein and RNA expression in

the cochleae of adult mice with Foxo3 deletion ($Foxo3^{KO/KO}$) and their wild type (WT) littermates prior to and following noise exposure. Hearing threshold shifts were induced using a 105 dB unilateral octave-band noise centered between 8-16 kHz, exposed for 0.5 hours. $Foxo3^{KO/KO}$ and WT mice, including both control and noise-exposed individuals, were sacrificed at 0.5, 4, and 24 hours post-noise onset (HPN) (n=4 cochleae per condition). Both males and females were used, all were between the ages of P60-90, and all were FVB/nJ strain. Preliminary findings show that OHC numbers are comparable in both genotypes prior to noise but rapidly decline along the organ of Corti at 0.5 HPN, continuing through 24 HPN in the $Foxo3^{KO/KO}$. This loss does not appear to result from programmed cell death in response to noise or from increased oxidative stress in the absence of FOXO3. At 0.5 HPN in the $Foxo3^{KO/KO}$, increased pJNK activity is concentrated at the Deiter cells, inner hair cell, and nerve terminals. Disruption of OHC morphology is visible in the mid basal cochlear turn, and they appear to be progressively phagocytosed. Increased pJNK expression was present in the inner hair cell and nerve terminals, but not seen in the Deiter cells of WT littermates following noise. FOXO3 primarily regulates via transcription and its absence may result in altered gene expression. Both genotypes' cochleae were collected at 0, 4, and 24 HPN (n=6-7) for mRNA extraction. Changes in cochlear gene expression between WT and $Foxo3^{KO/KO}$ mice were examined using RNA-sequencing. Gene Ontology was used to perform enrichment analysis on our derived gene set. Clusters of genes associated with mechanical cell integrity and those with FOXO3 binding sites were investigated. Our preliminary findings show that FOXO3 is important in the preservation of OHCs and hearing maintenance prior to any stress incursion. We are continuing to examine how this major cell survival regulation is possible with the goal of identifying noise susceptibility genes modulated by FOXO3.

Title: Noise-induced damage to auditory hair cells and their synapses in the zebrafish lateral line

Authors: *K. J. LAWTON, P. M. URIBE, B. K. VILLALPANDO, A. B. COFFIN
Washington State Univ., Vancouver, WA

Abstract: Noise-induced hearing loss is a prevalent issue in modern human society, with few therapeutic options. Larval zebrafish are a tractable model for studying acoustic trauma *in vivo*,

due in part to their externally located lateral line system. The zebrafish lateral line is comprised of discrete clusters of hair cells which are both experimentally accessible and share cellular homology with mammalian systems. Previous work in our lab successfully used this system to identify potential otoprotective drug targets for pharmacologically-induced ototoxicity. We now extend the utility of this model system to understand the mechanisms of noise-induced hearing loss, via an acoustic trauma system developed in our lab. To induce acoustic trauma, we created a novel noise damage device to deliver a broadband underwater acoustic stimulus that targets lateral line hair cells. Using this method, we sought to characterize the timing and extent of noise-induced hair cell damage. For the present experiments, larval fish were exposed to noise stimulus parameters that induced partial hair cell loss in both the anterior and posterior lateral line. Noise-induced hair cell death was assessed via direct counts of surviving hair cells at several time points post-noise exposure. After 24 hours, hair cell survival was comparable to controls, but by 48 hours, noise-damaged fish showed a 40% reduction in hair cell number. As an initial step towards understanding intracellular signaling cascades underlying noise-induced cell death, we wished to identify the timing of initiation of key cell death events. For this we used TUNEL staining of apoptotic cells following noise exposure. We observed an increase in the number of TUNEL+ hair cells at 48 and 72 hours post-noise exposure, consistent with the timing of reduced hair cell survival. This increase is not seen in surrounding non-hair cells, indicating that noise-induced damage is specific to hair cells. In mammals, noise-induced auditory damage is also known to occur at the level of the synapse, even in the absence of hair cell death, so we asked if this synaptopathy also occurs in the zebrafish lateral line. We assessed synaptic integrity between hair cells and their afferent fibers following noise exposure using immunohistochemistry to colocalize the hair cell ribbon synapse protein RibeyeB and the post-synaptic density protein MAGUK. We found an increase in orphaned ribbons in noise damaged fish, indicating that fish exhibit noise-induced synaptopathy. This research can inform how noise induces damage at the level of hair cells and their afferent synapses in an *in vivo* model, with potential to identify targets for otoprotective drug development.

Title: Treatment of severe noise-induced hearing loss by oral SENS-401 is not affected by concomitant prednisolone administration

Authors: *J. DYHRFJELD-JOHNSEN, M. PETREMANN, C. ROMANET, C. TRAN VAN BA, P. LIAUDET, V. DESCOSSY
Sensorion SA, Montpellier, France

Abstract: Off-label use of corticosteroid therapy is not recommended in the current practice guidelines for sudden sensorineural hearing loss (Stachler et al., 2012) and recent meta-analysis concluded no significant treatment effect (Crane et al. 2015). However, as no approved pharmaceutical treatment currently exists for sudden sensorineural hearing loss (SSNHL), corticosteroids remain an accepted standard-of-care (SoC).
SENS-401 is small molecule, orally administered clinical drug candidate in development for the treatment of sudden sensorineural hearing loss which has demonstrated efficacy in a number of preclinical studies, including improvement of ABR threshold recovery, improvement of DPOAE amplitude recovery and enhanced survival of outer sensory hair cells (Petremann et al., 2018). We here evaluate whether co-administration of prednisolone at human equivalent dose (HED) in a rat model of severe SSNHL affects otoprotective treatment with SENS-401.
Following baseline bilateral ABR recordings, 7-week old awake and behaving male Wistar rats were exposed to 120 dB octave band noise (8-16 kHz) for 2 hours on a slowly rotating platform in a sound-attenuating cubicle. After ABR recordings 24h after acoustic trauma, rats were randomized to receive either oral SENS-401 13.2 mg/kg twice daily for 28 days with placebo intraperitoneal injection for 14 days (n=9) or SENS-401 for 28 days in combination with 8.3 mg/kg prednisolone sodium sulfate intraperitoneally once daily for 14 days (n=10) before final ABR recordings on D29 after acoustic trauma. Results of treatment with SENS-401 alone or in combination with prednisolone at HED were compared for the ear most severely affected by acoustic trauma. At 24h, ABR thresholds ranged from 84-94 dB SPL, with no significant difference in acute ABR threshold shifts between animals randomized to receive SENS-401 or SENS-401 + prednisolone (67±5.9 dB vs 69.5±5.7, p=0.402, two-tailed t-test). At D29, the mean ABR threshold shift across frequencies was not statistically different between SENS-401 or SENS-401 + prednisolone treatment groups (51.4±11.6 dB vs 58.4±927, p=0.163, two-tailed t-test). Neither was ABR threshold recovery across frequencies (15.8±10.8 dB vs 11.0±9.7, p=0.317, two-tailed t-test).
These results suggest that the efficacy of otoprotective treatment with the small molecule clinical candidate drug SENS-401 is not affected by concomitant administration of a standard-of-care corticosteroid following a clinical treatment regimen at human equivalent dose.

Title: Age-related hearing loss - How a monoallelic single point mutation impairs auditory processing

Authors: *A. BURGHARD, D. L. OLIVER, N. MOREL
Neurosci., UConn Hlth., Farmington, CT

Abstract: The *Ahl* mutation in the Cdh23 gene ($Cdh23^{753A>G}$) is known to lead to the age-related hearing loss phenotype observed in many inbred mouse strains. This phenotype involves an early onset of age-related high frequency hearing loss, which leads to moderate hearing deficits at only 6-months of age, and severely hearing impaired animals within one year. While previous studies on Cdh23 mutations have focused on the comparison of homozygous for the mutation vs homozygous wild-type, we investigated how the *Ahl* mutation on a single allele alters auditory capabilities of mice over age. To compare auditory phenotypes to the specific genotype, animals were genotyped via Saenger sequencing of genomic DNA. The hearing thresholds were established using click-evoked auditory brainstem response (ABR) and amplitude-modulation following response (AMFR) measurements. The latter was also used to assess the temporal processing abilities of the animals. For the audiogram, the AMFR stimuli had a 0.3 octave narrow-band noise carrier frequency and a 42.9 Hz modulation frequency shaped by a sine wave raised to the exponent 8. To test the temporal processing abilities, the frequency with the lowest threshold was stimulated at 30 dB above threshold and the modulation frequency was varied from 17-544 Hz. Mice homozygous for the $Cdh23^{753A/A}$ mutation showed a high frequency hearing loss beginning at 3 months of age which progressed until no high frequency hearing was detectable at one year. In contrast, the $Cdh23^{753G/A}$ mice did not show hearing loss and showed no differences in hearing thresholds across ages or compared to $Cdh23^{753G/G}$ mice. However, other aspects of hearing function of heterozygous mice were affected. We looked at sound intensity coding via amplitude (amplitude growth function) at the level of the auditory nerve

(ABR wave I). While it shows a steep growth for young animals, the curve flattens for the one-year old group in $Cdh23^{753A/A}$ and $Cdh23^{753A/G}$ mice, but not $Cdh23^{753G/G}$ mice. This indicates an intensity coding deficit in $Cdh23^{753A/A}$ and $Cdh23^{753A/G}$ mice. Moreover, when the temporal precision of the AMFR was tested, we found a decline in peak synchrony for high modulation frequencies in mice homozygous and heterozygous mice for the mutation. This also indicates a peripheral deficit. In conclusion, the *Ahl* ($Cdh23^{753A>G}$) mutation has effects on auditory abilities besides hearing thresholds. These deficits in temporal precision and intensity coding were also present in animals heterozygous for this mutation. Since Cdh23 mutations are seen in mouse and human, it is important to assess auditory processing and hearing in both heterozygous and homozygous individuals in more detail.

Abstract: The elderly need optimal hearing for their personal and social life that helps them maintain physical and mental well-being. Presbycusis is progressive deterioration of hearing associated with aging. It is multifactorial disorder. Animal studies suggest that imbalance of neurotransmitters and/or other environmental factors result in decreasing number of SGNs with aging. The calcium current produced during neuronal activity can be neurotoxic if it is not buffered by calcium-binding proteins (CBPs). We have already shown that Parvalbumin (PV) is the predominant CBP of the SGNs. But even with adequate CBPs an imbalance between the excitatory Glutamate and the inhibitory GABA, probably related to loud sounds may lead to neurotoxicity and decrease the total number of first order neurons of the auditory pathway. Therefore, the present study aims to provide estimates of total number of SGNs using Nissl-staining, and immunoreactivity to PV, GABA and NMDAR-2B (receptor for Glutamate) using unbiased stereology in 35 human temporal bones from cadavers of 11 to 80 years of age at the time of death. These were obtained from the mortuary with approval from Institute ethics committee. Cochleae were divided into two groups, group I (n=25) included cochleae from 11-60 years and group II (n=10) had cochleae ranging from 61-80 years. The cochleae containing

the SG were dissected, fixed, decalcified, cryoprotected and serially sectioned (30μm) in horizontal plane. Every 7th section was stained with Nissl or for PV, GABA and NMDAR-2B and used for counting the total number of SGNs with the Optical Fractionator. The mean number of SGNs stained by Nissl and PV in group I was 25,675 ± 3607 and 25,119 ± 3251 and in group II was 12,101 ± 1729 and 12,580 ± 480 respectively. Mean GABAergic and NMDAR-2B positive SGNs in group I was 25,242 ± 596 and 24,001 ± 633 and in group II was 12,211 ± 526 and 13,142 ± 519 respectively. No significant changes were observed in the estimates of Nissl, PV, GABA and NMDAR 2B positive SGNs from age 11-60 years, but after the age of 60 years SGNs population was halved ($p<0.001$). The present study demonstrated that there are age-related changes in the number of PV, GABA, and NMDA receptor-expressing SGNs that might contribute to neural degeneration as a function of age, the critical age being 60-years of age.

Abstract: Introduction Cholinergic decline and sensory regression are commonly associated with the effects of ageing (1). The peripheral vestibular organs of the inner ear receive a significant cholinergic efferent innervation that can modify peripheral sensory activity before it reaches the CNS (2). A sensitive assay of peripheral vestibular function is the vestibular-ocular reflex (VOR), which is dependent on the normal activity of the vestibular organs. Interestingly, the basic VOR is not drastically affected by age (3), however, it has been shown recently that subtle features of the VOR such as *adaptation* and *compensation* are significantly impaired in aged mice (4). We therefore investigated the impact of ageing on the expression of cholinergic receptors and on the strength of cholinergic signalling as a potential source of impairment in peripheral vestibular function.
Methods All procedures were approved by and conducted in accordance with the University of

Newcastle Animal Care and Ethics Committee (ACEC). Changes to the cholinergic efferent vestibular system were examined in the cristae of male mice from three age groups; juvenile - 3 weeks, adult - 4-6 months, and aged - 24 months or more. Whole cristae were homogenized and mRNA expression of nicotinic ACh receptor (nAChR) subunits and Ca^{2+}-activated K^+ channels were compared using qPCR. Patch clamp recordings were obtained from type II vestibular hair cells, and whole-cell responses to exogenous ACh application were compared across the three age groups. Cholinergic efferent fibres and terminals were also qualitatively compared using immunofluorescence and confocal microscopy.
Results A significant reduction in the expression of alpha1, alpha9, and alpha10 nicotinic ACh receptor subunits, and the BK channel, was observed in the cristae of aged vs. adult C57BL/6 mice. In type II hair cell recordings, whole-cell responses to ACh were significantly reduced in aged vs. adult type II hair cells. We observed no qualitative differences in the morphology or distribution of cholinergic efferent terminals across the three age groups tested.
Conclusion Results show that there is a decline in postsynaptic cholinergic function in the cristae of aged C57BL/6 mice. This decline would reduce the impact of central control over vestibular sensory organs, and may contribute in part to age-related presbyastasis.

Title: Topographic distribution of efferent projections in murine vestibular epithelia

Authors: *J. J. SALDATE[1], S. JOBBINS[2], F. E. SCHWEIZER[3], L. F. HOFFMAN[4]
[1]Dept. of Head and Neck Surgery, [2]Geffen Sch. of Med. at UCLA, Los Angeles, CA; [3]Neurobio., UCLA, David Geffen Sch. of Med., Los Angeles, CA; [4]Head & Neck Surgery, Geffen Sch. of Med., Los Angeles, CA

Abstract: Sensory epithelia of the vestibular labyrinth receive projections from efferent vestibular neurons, which are thought to provide centrifugal feedback. Vestibular efferent neurons are well-characterized with respect to their principal mode of neurotransmission (i.e.

cholinergic), laterality (both ipsi- and bi-lateral projections have been identified), and effects on afferent discharge. While the predominant receptor types mediating cholinergic feedback to inner ear sensory epithelia are nicotinic, recent evidence indicates that muscarinic neurotransmission also makes important contributions to vestibular efferent modulation (Holt et al. 2016; Lee et al. 2017). These data support the notion that this feedback component alters the dynamic coding capabilities by attenuating the influence of Kv7.4 (aka KCNQ4) channels within the inner face of the dendritic calyces. These channels exhibit a unique topographic distribution within the vestibular epithelia, where calyces exhibiting heaviest expression are found in a region extending beyond the utricular striola and crista central zone (Spitzmaul et al. 2012). The present investigation tested the hypothesis that efferent terminals within vestibular epithelia exhibit a similarly heterogeneous distribution, supporting a consequential role of muscarinic-driven efferent modulation. Sensory epithelia from adult mouse labyrinths were harvested and immunohistochemically processed using methods previously described (Hoffman et al. 2018). Anti-vesicular choline transporter (VChT) was used to identify efferent terminals within whole mounts of utricular and crista epithelia. The specificity of VChT immunolabeling was verified through experiments examining colocalization with choline acetyltransferase (ChAT). Notably, anti-KCNQ4 immunolabeling elucidated epithelial regions exhibiting the heaviest expression in afferent calyces. Furthermore, we found that efferent terminal density was not homogeneous across utricular and crista topography; the region of highest density VChT-positive terminals expanded beyond the utricular striola or crista central zone. This finding indicates that the heterogeneous distribution of efferent terminals is not specifically confined by factors related to these specialized regions. However, the region of greatest efferent terminal density was coincident with the regions of epithelia that harbored calyces exhibiting high KCNQ4 expression. These data infer that centrifugal modulation by efferent neurons may result from muscarinic tuning of the dendritic generator potential by modifying the “m” current through KCNQ4.

Title: Somatostatin analog pasireotide promoted cochlear hair cells protection, survival and function after aminoglycoside treatment *in vivo*

Authors: *V. PETKOVIC[1], K. KUCHARAVA[1], M. SEKULIC-JABLANOVIC[1], L. HORVAT[2], D. BODMER[3]

Abstract: Hair cells of the mammalian auditory system do not regenerate. Loss of sensory hair cells of the inner ear due to aminoglycoside exposure is major cause of hearing loss. The neuropeptide somatostatin and its selective analogs have provided neuroprotection by activating five somatostatin receptor (SSTR) subtypes. We previously demonstrated that somatostatin receptors are expressed in the mammalian inner ear and somatostatin, octreotide and pasireotide can protect hair cells from gentamicin-induced hair cell death in vitro. The aim of the presented study was to investigate the neuroprotective properties of the most metabolically stable somatostatin analog pasireotide against gentamicin in the mice model in vivo. After 5 days pasireotide pre-treatment and 10 days subcutaneous administration of the pasireotide and gentamicin, the ototoxicity was inhibited as confirmed by auditory brainstem responses (ABR) measurement. We observed a significant threshold shift compared to the gentamicin group at 8, 16 and 24 kHz. Additionally, we found that the pasireotide protects auditory hair cells from gentamicin ototoxicity by activating Pi3k - Akt signaling transduction pathway proved on gene and protein level by using of SH6 specific Akt inhibitor. A drug as pasireotide with a proven safety record could provide an faster path to an approved new treatment.

Title: Auditory learning and perception modulates neuronal activity in the auditory midbrain

Authors: *C. CHEN[1], L. DE HOZ GARCÍA-BELLIDO[2]
[2]Dept. of Neurogenetics, [1]Max Planck Inst. of Exptl. Med., Goettingen, Germany

Abstract: Neural networks are extremely dynamic, and neuronal activity can be modulated by many factors, such as the environment, hormone level and mental states. Changes in network states could further influence sensory stimulus perception. It has been shown that neural activity and representations can be modulated to affect sensory processing in the auditory cortex. As the first convergence station in the auditory pathway, the inferior colliculus (IC), a subcortical

region, might change its neuronal activity during behavior. However, whether and how auditory learning and perception modulate activity in the auditory midbrain has not been well studied. To address this issue, we compared IC neuronal activity in different behavioral contexts -- during a tone discrimination task (conditioned learning) and during passive listening. In the task, mice required to discriminate a 'safe' tone paired with reward and a 'conditioned' tone paired with punishment. We found that IC responses to the conditioned tone were suppressed during behavioral engagement, while those to the safe tone were enhanced. Spontaneous activity increased significantly during task engagement compared with passive listening. This increase was paralleled by a global increase in response gain and signal-to-noise ratio during passive hearing after conditioning.
Previous research from our group found that statistical learning (no rewards/punishment) changes the IC neuronal response patterns in anesthetized mice. We further tested whether statistical learning alters neural activity also in behaving animals. Mice were exposed to predictable sounds, initiated by the animal, and random sounds (unpredictable). We did not observe significant changes in spontaneous activity during sound exposure. Interestingly, we found that exposure to predictable, but not random sounds, decreased the baseline local field potential in the IC. This result suggests that expectation regulates the ongoing local field potential, thereby possibly influencing signal detection.
In summary, these findings suggest that the inferior colliculus activity is modulated transiently during behavioral training, and this modulation differs between conditioned and statistical learning. These changes may play a role in regulating sensory gating during auditory learning and perception.

Title: Closed-loop stimulation reveals the brain state-dependence of auditory perceptual sensitivity

Authors: *L. WASCHKE, J. OBLESER
Dept. Of Psychology, Univ. of Luebeck, Luebeck, Germany

Abstract: Instantaneous brain states, that is neural activity prior to stimulus onset, affect the processing of sensory information and subsequent conscious perception in a host of ways.

Particularly, the degree of pre-stimulus neural synchronization as captured by low-frequency power is thought to affect the encoding and perception of auditory stimuli in non-human animal models, with less synchronization resulting in more thorough encoding. We recently demonstrated a strikingly similar pattern in human subjects by using time-resolved entropy of the EEG signal to approximate pre-stimulus neural synchronization and relate it to ensuing perceptual decisions.
In an endeavour to confirm and extend those findings, we constructed a closed-loop experimental setup within which we recorded EEG and pupillometry data from human subjects (N = 18) and processed it using a near real-time algorithm: Time-varying entropy of EEG-signals from auditory cortical regions was calculated before a continuously adapting criterion was used to determine periods of relatively high (peaks) or low entropy (troughs). Tone stimuli were then presented into these high- and low-entropy brain states, respectively, and subjects performed a challenging pitch discrimination task upon these tones. We expected that peak-entropy states would not only be accompanied by reduced low oscillatory power, but also lead to enhanced tone-evoked responses and neural encoding, and ultimately greater perceptual sensitivity (as determined by the modelled psychometric curve).
Replicating our previous results, we found higher entropy to be associated with decreased low-frequency oscillatory power and an increase in phase coherence shortly after tone onset. Furthermore, inverted u-shaped relationships between pre-stimulus entropy and both phase coherence and ERP magnitude were found, with medium entropy resulting in the strongest evoked response. Importantly, this pattern of neural activity was mimicked by behaviour: response speed was higher for tones presented at peaks as compared to troughs but highest at medium levels of pre-stimulus entropy. Importantly, the same relationship was present for perceptual sensitivity. Thus, pre-stimulus entropy likely impacts perceptual sensitivity by altering evoked activity and the encoding of sensory information.
These results validate a promising conceptual approach to quantify states of neural synchronization in the EEG and additionally offer new insights into the brain state-dependence of human perception. We discuss our findings in the context of rapid fluctuations in arousal and associated neuromodulatory changes.

Title: O-15 Water PET study of speech-in-noise processing in cochlear implant patients

Authors: *P. E. GANDER[1], L. L. PONTO[2], I. CHOI[2], B. J. GANTZ[2], B. MCMURRAY[2], T. D. GRIFFITHS[3]
[1]Dept. of Neurosurg., [2]Univ. of Iowa, Iowa City, IA; [3]Newcastle Univ., Newcastle-Upon-Tyne, United Kingdom

Abstract: One of the most important issues in hearing impairment (HI) is difficulty with speech in noisy real-world environments. Recent research in normal hearing listeners indicates that auditory cortex is active while abstracting speech objects from noise and provides input to fronto-temporal networks for further perceptual, attentional, and semantic analysis. We sought to understand whether the neural mechanisms by which cochlear implant (CI) listeners detect speech in noisy environments are similar to individuals with normal hearing. We tested a group of hearing-preservation (hybrid) CI users with devices that combine residual low frequency acoustic hearing with high frequency electric hearing.
N = 9 CI users were compared to N = 10 age-matched normal-hearing (NH) control participants. Cerebral blood flow was measured using [15O]Water positron emission tomography while the participants listened to 2-min blocks of continuous sentences-in-noise or noise alone (matched on RMS sound level). On a given run for speech-in-noise (+7 dB), 30 unique sentence tokens (~2.5 sec length) were presented (1.5 sec inter stimulus interval). Twelve scans (6 each condition, random order) were acquired to allow for single-subject inference.
Robust activations were found in single subjects for the contrast speech-in-noise vs noise in the auditory cortex (lateral Heschl's gyrus, planum polare, and planum temporale) and inferior frontal cortex (frontal operculum and inferior frontal gyrus) bilaterally ($p<0.05$). The activity patterns were very similar across subjects.
The NH control participants were compared to the CI users for evaluation of the neural substrate of the network and overall activity level. No significant interaction was demonstrated between group and the speech-in-noise minus noise contrast in auditory and inferior frontal cortex. Six NH control participants were also scanned for a second session within six months of the previous scan to evaluate the reliability of activation patterns. Across 78 anatomically-defined regions-of-interest, regional activation levels normalized to global activity were compared between time 1 and time 2 for both noise and speech-in-noise conditions. All correlations between the sessions were above 0.9.
A frontal and temporal network of brain activity was demonstrated for speech-in-noise in hybrid CI users. These results were reliable at the single-subject level, which allows for a longitudinal investigation of CI users after device activation. The results support a similar system for speech-in-noise processing in hybrid CI patients and normal hearing listeners.

Title: Neuronal activity of the primary- and the secondary auditory cortices during elicitation of mismatch negativity (MMN) in freely-moving rats

Authors: *E. JODO[1], S. EIFUKU[2]
[1]Fukushima Med. Univ., Fukushima, Japan; [2]Dept. of Systems Neurosci., Fukushima Med. University, Sch. of Med., Fukushima, Japan

Abstract: The mismatch negativity is a change-specific event-related potential that is usually invoked by auditory stimuli deviating from established patterns of regularity. The reduction of MMN is a reliable biological property of patients with schizophrenia. The main electrical source of MMN is now considered to be located in the auditory cortex (AuC). However, it remains to be elucidated how the unit activity of AuC neurons is during elicitation of the MMN. In this study we recorded the MMN from the surface of the frontal cortex (FC) and unit activity of AuC neurons simultaneously during auditory stimulation in freely-moving rats. Recording was executed under two different conditions. In one condition two auditory stimuli with different frequency (3000, 6000Hz) and different probability of occurrence (10, 90%) were sequentially presented with stimulus onset asynchrony of 0.3s (odd-ball condition). In the other condition (many-standard condition) ten frequency-different auditory stimuli including former two stimuli (3000, 6000 Hz) were sequentially presented with the equal probability of occurrence (10%). The duration of each stimulus is 0.1s in both conditions. The human MMN-like potential with a peak latency of about 50 ms was recorded from the surface of FC near the midline. This MMN-like potential was notably larger to the deviant tone (10%) in the odd-ball condition than that both to the standard tone (90%), and to the non-deviant tone that was presented in the many-standard condition with the same probability of occurrence and pitch as the deviant tone. The waveform of local field potential (LFP) recorded in the primary AuC (pAuC) had notable bimodal peaks that temporally correspond to the rise and decay of the tone, and exhibited no significant change between deviant- and non-deviant tones. The LFP in the secondary AuC (sAuC) ventral to the pAuC exhibited a MMN-like waveform, and its amplitude depended on whether the stimulus was deviant or non-deviant. The unit activity of sAuC neurons differentially responded between deviant- and non-deviant tones, while pAuC neurons did not exhibit such change-specific differential responses. However, most of sAuC neurons exhibited not excitatory responses, but inhibitory responses during elicitation of the MMN.

Title: Auditory sensory gating effect study using EEG source localization techniques

Authors: *D. GUPTA[1], F.-S. CHOA[1], E. HONG[2]
[1]Computer Sci. and Electrical Engin., Univ. of Maryland Baltimore County, Baltimore, MD;
[2]Maryland Psychiatric Res. Ctr., Baltimore, MD

Abstract: Auditory paired click paradigm is a simple non-invasive model where two audio clicks, denoted as S1 and S2 that are 500ms apart, are administered to a subject. S2 is the second redundant click and hence, gated out in the neurological processing. This is characterized by the fact that amplitude of the P50 wave has lower amplitude post S2 than post S1. However, people suffering with schizophrenia cannot suppress or filter the redundant and unnecessary stimuli and therefore, their neurological response to S2 is not suppressed. Studies show that their P50 wave in response to S2 is reduced by 10-20% only as compared with 80-90% in controls (Wan, Li, et al. International Journal of Psychophysiology, 2008). Although the result has demonstrated the sensory gating effect difference of normal controls and patients, however, the mechanism remains to be elucidated. In our study, we use EEG sLORETA techniques to analyze auditory processing from 18 subjects, 9 controls and 9 schizophrenia patients. By using auditory paired click paradigm as the stimuli, we investigate alpha wave propagation along the brain pathways for all subjects post both S1 and S2. We focused on the alpha wave activity because studies suggested that alpha wave is associated with inhibition given that our study focuses on sensory gating (Klimesch et al Brain research reviews, 2007). Overall, we see that less Region Of Interest (ROI) are active during S2 in controls than that post S1 whereas patients show overall more active brain regions during S2 than S1 as summarized in the table below. As a part of the auditory cortical network, frontal lobe plays a major role in processing sound after cochlea, temporal lobe and auditory thalamus. Within the frontal lobe, post the auditory clicks, we observed that higher number of regions activated in less time for controls and lesser number of regions activated in patients with the alpha activity (p-value=0.0473<0.05) thereby indicating speeded processing. These conclusions contribute towards a better understanding of our auditory processing.
Table: Summary of active common ROIs across 9 controls and 9 patients post first and second auditory click (S1 and S2 respectively) during paired auditory click paradigm

Summary of active common ROIs across 9 controls and 9 patients post first and second auditory click

Title: Learned context dependent categorical perception in songbirds

Authors: *T. SAINBURG[1], M. THIELK[2], T. GENTNER[1]
[1]Psychology, UCSD, La Jolla, CA; [2]Neurosci., UCSD, San Diego, CA

Abstract: Songbirds and humans rely on categorical perception of smoothly varying acoustic spaces to discretize (and discriminate) the elements in their vocal communication signals. In humans, the boundaries between perceptual categories (phonemes) are often not fixed, but can shift based upon long-term language exposure and short-term contextual cues, such as preceding phonemes within a word or multisensory cues as in the McGurk effect. Recent work with Europeans starlings, a species of songbird, has revealed a shared perceptual space for song syllable categories that, like speech, is shaped directly by the learning environment (Thielk et al., 2016). Whether or not syllable category boundaries can be shifted by short-term contextual cues

remains an open question. To investigate this, we trained European starlings (n=6) to categorically label smoothly varying natural song syllables, generated from the latent-space of a convolutional neural network, using a two-alternative-choice operant conditioning procedure. Once the birds learned this basic syllable categorization, we introduced a second set of song syllables that acted as contextual cues on each trial. Thus, on each trial the bird heard two syllables, a cue followed by a target, where the cue carried information about the likelihood that the target syllable was in one category or the other. We show that the contextual information provided by these cues differentially alters the birds' perception of categorical syllable boundaries, producing predictable shifts in their psychometric functions. To explore the neurophysiological basis of this short-term contextual modulation, we recorded extracellular spiking responses to playback of syllables in the learned categories and cues using multichannel arrays in the secondary auditory cortical regions CM and NCM (caudal mesopallium and caudo-medial nidopallium) of trained birds. Initial analyses reveal many neurons that respond categorically, with more similar responses to acoustic variability within a category compared to variability that spans the learned categorical boundary. Additional analyses investigate the degree to which NCM and/or CM neuromorphic functions are directly altered by the presence or absence of the contextual cue.

Title: Understanding speech in background noise relies on similar processes to figure-ground segregation

Authors: *E. HOLMES[1], T. D. GRIFFITHS[2,1]
[1]Inst. of Neurol., Univ. Col. London, London, United Kingdom; [2]Inst. of Neurosci., Newcastle upon Tyne, United Kingdom

Abstract: Speech-in-noise (SIN) perception is a critical everyday task that varies widely across individuals and cannot be explained by the pure-tone audiogram, which measures thresholds for detecting sounds in quiet. This finding is unsurprising, because speech is usually heard at suprathreshold levels. Instead, the difficulty likely arises because listeners must separate speech from simultaneously-occurring background sounds. We predicted that the neural processes that

underlie successful SIN might partially overlap with those that underlie successful auditory figure-ground segregation. As a first step, we examined how much common variance links speech-in-noise perception to auditory figure-ground perception, and how this relationship depends on the properties of the figure to be detected.
We presented sentences from the Oldenburg matrix corpus (e.g., "Alan has two old sofas") simultaneously with multi-talker babble noise. We adapted the target-to-masker ratio to determine the participant's threshold for reporting 50% of sentences correctly. Our figure-ground stimuli included one based on Teki et al. (2013; PMID 23898398) in which each 50 ms time window contains random frequency elements; subjects were required to detect certain elements (the figure) that remained fixed from one time window to the next. We also tested figures that changed in frequency over time, mimicking the formants of speech, and participants had to discriminate gaps that occurred in the “figure” and “background” components.
Performance for the fixed-frequency figure explained ~7% of the variance in SIN perception in previous work, and our preliminary results (N=15) replicate this relationship. Preliminary results suggest that performance for the speech-like figures explain a greater proportion of the variance. These results in normally-hearing listeners support a source of variance in speech-in noise perception related to figure-ground analysis that is unrelated to audiometric thresholds, consistent with previous work demonstrating cortical contributions to both speech-in-noise and figure-ground perception. Furthermore, our results imply that different types of figure-ground stimuli index different cognitive processes, which contribute differently to speech-in-noise perception.

Title: Similarities and differences in cortical dynamics during sensation and short-term memory in mice performing auditory and somatosensory discrimination

Authors: *Y. GALLERO-SALAS[1,2], A. GILAD[2], B. LAURENCZY[1,2,3], F. HELMCHEN[1,2]
[1]Brain Res. Institute, Univ. of Zurich, Zuerich, Switzerland; [2]Neurosci. Ctr. Zurich, Zurich, Switzerland; [3]ID Res. Informatics. ETH, Zurich, Switzerland

Abstract: Sensory information may immediately lead to a behavioral response or it may be temporally stored in short-term memory. These processes involve many and distant neocortical areas. It is currently unknown how sensory inputs of different modalities are processed and transformed into actions and where information is held during short-term memory. To answer these questions, we used wide-field calcium imaging in head-restrained mice expressing GCaMP6f in layer 2/3 excitatory neurons. Animals were trained in a 'go/no-go' auditory discrimination task (4 kHz versus 8 kHz) or in an analogous whisker tactile task (rough texture, P100 grit size, versus smooth texture, P1200). Both task types required a delayed response after a few seconds. Some animals were trained in both tasks. For both tasks we found that sensory stimuli evoked a larger response for 'go' compared to 'no-go' trials in the respective sensory areas (auditory and barrel cortex). During the subsequent short-term memory phase the cortical activation pattern depended on the animal's behavioral strategy during sensation, with animals either being active (motor-engaged) or passive. For active animals and in both task types, neuronal activation during the delay consistently occurred in a medial frontal premotor area (M2). In contrast, a region posterolateral to primary visual cortex was prominently engaged during the delay in passive animals. Our results suggest that reward-predicting stimuli ('go') of different sensory modalities are first integrated in the respective sensory areas and then may converge along common pathways to either M2 or P, depending on behavioral strategy, for maintaining information in short-term memory.

Abstract: $GABA_B$ receptors ($GABA_BRs$) are the G protein-coupled receptors for γ-aminobutyric acid (GABA), the main inhibitory neurotransmitter in the central nervous system. Native $GABA_BRs$ assemble from principal $GABA_{B1}$ and $GABA_{B2}$ subunits and auxiliary KCTD

subunits that increase $GABA_BR$ surface expression and accelerate kinetics of the receptor response. Recent studies suggested the KCTD12 isoform as a risk modifier in chronic tinnitus, phantom perception of sound in the absence of external stimuli. In this study we used KCTD12 null mutant (KCTD12-/-) mice to test the role of KCTD12 in an animal model of tinnitus. Compared to C57BL (wild type, WT) mice, KCTD12-/- mice showed significantly elevated hearing thresholds estimated by recording of auditory brainstem responses (ABR) and the middle latency responses (MLR). Tinnitus was induced by exposure of mice to narrow band noise (116 dB SPL centered at 10 kHz, 1h) and its presence was monitored by measuring the gap prepulse-induced inhibition of the acoustic startle reflex (GPIAS) before and 2 weeks after the noise exposure. We observed that KCTD12-/- mice had lower basal GPIAS than WT mice (35.5 ± 14.6% vs. 52.5 ± 9.2%, $p < 0.001$). As a reduction of GPIAS could be due to masking the gap by phantom sounds, the results suggest that KCTD12-/- mice might have a chronic tinnitus. Exposure to noise strongly impaired the ability to detect gap in sound in both animal groups. Two weeks after the exposure, GPIAS dropped to insignificant levels in 60% of WT mice and in 100% of KCTD12-/- mice. Thus, the results indicate a higher sensitivity of KCTD12-/- mice to tinnitus induction. Our experiments also showed reduced amplitudes of click-evoked ABR but not MLR in control KCTD12-/- or noise-exposed WT mice. This together with our previous observation of high expression levels of KCTD12 in the auditory brainstem supported the link between tinnitus incidence and impaired GABAergic transmission in the dorsal cochlear nucleus (DCN). Indeed, our further experiments showed a significant reduction of both $GABA_B$ receptor surface expression and baclofen-evoked membrane currents in the fusiform but not cartwheel or stellate cells in DCN slices from control KCTD12-/- or noise-exposed WT mice. This indicated the importance of KCTD12 for subcellular distribution of $GABA_B$ receptors in DCN neurons and suggested that tinnitus might be a symptom of decreased $GABA_B$ function in the auditory brainstem.

Title: Attentional modulation of neural speech tracking and alpha power independently support speech comprehension in middle-aged adults

Authors: *S. TUNE, M. ALAVASH, L. FIEDLER, J. OBLESER
Univ. of Luebeck, Luebeck, Germany

Abstract: Speech comprehension in noisy, multi-talker situations is facilitated by the engagement of auditory selective attention and by the generation of context-based semantic predictions. Here, we investigated how healthy aging and its associated gradual decline in sensory acuity and cognitive functioning affect the relative balance of these cognitive strategies. Specifically, we asked whether age changes at the performance level would be mediated by concomitant changes at the neural level.
In an EEG study focused on healthy middle-aged human adults (*N*=73; 39–70y), participants listened to two competing, dichotically presented sentences. They were probed on the last word in one of the two sentences. Critically, two visual cues preceded auditory presentation. First, a spatial-attention cue either indicated the to-be-probed side, thus invoking selective attention, or did not provide any information about the to-be-probed side, thus invoking divided attention. The second cue specified a general or a specific semantic category for the final word of both sentences, thus allowing to utilize a semantic prediction.
At the behavioral level, we observed a general performance benefit for informative compared to uninformative cues. Following a specific semantic cue, participants responded faster but not more accurately. Selective-attention cues lead to more accurate and faster responses. In addition, this relative, cue-related benefit in performance increased with age.
The analysis of EEG data revealed a similar modulation of neural dynamics by the two cues. Selective attention trials yielded a pronounced lateralization of 8–12 Hz alpha power during sentence presentation. Moreover, in selective attention trials the to-be-attended sentence envelopes were neurally tracked more closely, as indexed by better reconstruction accuracies in a linear decoding model. However, reconstruction accuracy was co-modulated by the semantic cue: under divided but not selective attention, reconstruction was more accurate for the specific compared to the general cue. Notably, both the degree of alpha lateralization and neural speech tracking predicted task performance but they did so independently of one another and independent of age.
In sum, our results provide evidence for the joint influence of attentional control and semantic predictions on listening success. They point towards a segregation of age-related changes at the neural and performance level in middle-aged adults. Moreover, our results indicate an independent attentional modulation of low-frequency auditory tracking and the lateralization of alpha power.

Title: Top-down and bottom-up predictions in auditory decision-making

Authors: *L. SURIYA-ARUNROJ[1], J. I. GOLD[2], Y. E. COHEN[3]
[1]Dept. of Neurosci., Univ. of Pennsylvania, Philadelphia, PA; [2]Dept. of Neurosci., Joshua Gold, Philadelphia, PA; [3]Dept. of Neurosci., Yale Cohen, Philadelphia, PA

Abstract: Auditory perceptual decision-making is mediated by both bottom-up (i.e., incoming sensory stimuli) and top-down (e.g., different cognitive and task-relevant pieces of information) processes. For example, changes in stimulus salience, such as regularity violation, can bias perceptual decision-making through bottom-up attention. Likewise, prior knowledge can also modulate decisions by prioritizing specific features of stimuli (top-down processing). However, the effects of top-down and bottom-up processing on auditory decision-making are not well understood. We investigated how both bottom-up regularity violations and top-down instructed expectations affect auditory decisions.
Human subjects listened, via headphones, to sequences of high-frequency (2000 Hz) or low-frequency (500 Hz) tone bursts (duration: 300 ms with a 10-ms $\cos^2$ ramp; inter-burst interval: 100 ms) that were embedded in a background of broadband noise. The subjects reported whether the last tone in each sequence (the "test tone") was "low frequency" or "high frequency" by pressing the left or right button, respectively, on a gamepad. We titrated difficulty by varying the sound level of the test tone relative to the noisy background. Bottom-up processing was manipulated by varying the sequence of tone bursts presented just before the test tone ("pre-tones") in terms of (1) the ratio of high- and low-frequency pre-tones (5:1 and 1:5), and (2) the number of pre-tones, which were selected from an approximately exponential distribution (range: 0-14) to minimize the ability of the subject to predict the onset of the test tone. Top-down processing was manipulated by presenting, before sequence onset, a visual cue that indicated the prior probability that the test tone could be high or low frequency within a given block of trials (corresponding to ratios of low- versus high-frequency test tones of 5:1, 1:1, 1:5).
Preliminary results indicate that both the top-down and bottom-up manipulations caused choices biases. These biases were largest when stimulus discriminability was lowest, consistent with principles of signal detection theory. For the top-down manipulation, increasing the prior probability for one alternative biased choices and simultaneously decreased response times for that alternative. For the bottom-up manipulation, choices were biased toward the frequency value of the preceding tones, whereas choices toward the opposite frequency showed reduced reaction times. Further analyses and modeling of choices and response times in a drift-diffusion framework will help identify the computations used to incorporate these two sources of information into perceptual decisions.

Title: Tracking stimulus statistics from sensory cortices to frontal cortex

Authors: *J. LAWLOR BLONDEL[1], C. BIMBARD[1], S. A. SHAMMA[2], Y. BOUBENEC[1]
[1]Ecole Normale Superieure, Paris, France; [2]Neural Systems Lab, Univ. of Maryland, Washington, MD

Abstract: Complex, cluttered acoustic environments, such as a busy street, are characterised by their ever-changing dynamics. Despites their complexity, listeners can readily detect changes in continuous acoustic streams. However, the neural basis of the extraction of relevant information in complex continuous streams for goal-directed behavior is currently not well understood. As a model for change detection in complex auditory environments, we designed spectrotemporally broad tone clouds whose statistics change at a random time. Ferrets were trained to detect these changes. Hence, they are faced with the dual-task of estimating the baseline statistics and detecting a potential change in those statistics at any moment, mimicking real-life challenges. To characterize the extraction and encoding of relevant sensory information along the cortical hierarchy, we performed electrophysiological recordings in the primary auditory cortex (A1), secondary auditory cortex (PEG) and frontal cortex (FC) of the behaving ferret. A1 neurons exhibited strong onset responses and change-related discharges specific to neuronal tuning. PEG population showed reduced onset-related responses, but more categorical change-related modulations. Finally, a subset of FC neurons (dlPFC/premotor) presented a generalized response to all change-related events only during behavior. We show using a GLM that the same subpopulation in FC encodes for the sensory and decision signal.
In addition, PEG and FC population dynamics showed a time-dependent evolution within trials and before the change occurred, possibly reflecting an online estimation of the ongoing baseline statistics, a necessary process in this dual-estimation task. All together, these area-specific responses suggests a behavior-dependent mechanism of sensory extraction and generalization of task-relevant event.

Title: Speaker-normalized vowel representations in human auditory cortex

Authors: M. J. SJERPS[1,2], *N. P. FOX[3], K. JOHNSON[4], E. F. CHANG[3,5,6]
[1]Donders Inst. for Brain, Cognition and Behaviour, Ctr. for Cognition, Radbound Univ., Nijmegen, Netherlands; [2]Max Planck Inst. for Psycholinguistics, Nijmegen, Netherlands; [3]Dept. of Neurolog. Surgery, Univ. of California San Francisco, San Francisco, CA; [4]Dept. of Linguistics, Univ. of California, Berkeley, Berkeley, CA; [5]Ctr. for Integrative Neurosci., [6]Dept. of Physiol., Univ. of California, San Francisco, San Francisco, CA

Abstract: Speech perception is a computationally challenging task, in part because the acoustic dimensions critical for distinguishing among speech sounds are the same as those that distinguish among different speakers. For example, while a given speaker's /u/ has a lower first formant (F1) than his or her /o/, vowels produced by tall speakers (with long vocal tracts) have lower F1 formants than those of short speakers (with short vocal tracts). Consequently, a tall man's /o/ and a short man's /u/ might be acoustically identical. Behavioral research has shown that listeners overcome such ambiguity by relying on context: an ambiguous vowel between /u/ and /o/ is perceived as /o/ after a sentence spoken by a tall man (low F1), but as /u/ after a sentence spoken by a short man (high F1). To investigate the neurobiological basis of speaker-dependent "normalization," we recorded neural activity directly from parabelt auditory cortex via subdurally-implanted high-density electrocorticography (ECoG) grids while human participants listened to and identified vowels from a synthesized /u/-/o/ continuum after context sentences with high or low F1 ranges. Behavioral data replicated past normalization results. Analysis of the ECoG recordings revealed direct evidence that context-dependent (i.e., normalized) vowel representations emerged rapidly within parabelt auditory cortex. Distinct cortical sites that were sensitive to vowel F1 also responded differentially to the same acoustic token depending on whether it was preceded by a low or high F1 speaker. These normalized vowel representations were preceded by a brief window (~80ms) during which acoustically veridical (context-independent) encoding of target sound acoustics dominated, suggesting that normalization first emerges in cortical processing. Normalization may partly emerge as a result of local sensitivity to the contrast between spectral properties of the context and the incoming speech. These results highlight the key role auditory cortex plays in the integration of incoming sounds with their

preceding acoustic context, leading to the emergence of talker-normalized encoding of speech sounds which is critical to resolving the lack of invariance in speech perception.

Title: Intermodal audiovisual attention differentially modulates Spontaneous Otoacoustic Emissions (SOAEs) at low frequencies

Authors: *N. WEISZ[1], M. KÖHLER[2], G. DEMARCHI[2]
[1]Ctr. for Cognitive Neurosci., [2]Univ. of Salzburg, Salzburg, Austria

Abstract: The auditory system is marked by rich efferent connectivity with fibers reaching even into the periphery to modulate activity at the hearing nerve either directly (lateral olivocochlear pathway) or indirectly (medial olivocochlear pathway; MOC). While mainly protective functions have been emphasized in the past, this unique neural architecture could in principle enable the modulation of cochlear activity by top-down processes such as attention. Indeed, direct efferent pathways exist from the auditory cortex to the Superior Olivary Complex, from which relevant fibers originate that innervate parts of the cochlea. Attentional modulations of cochlear activity have been repeatedly shown for the MOC via the assessment of sound-evoked optoacoustic emissions. Early works were unable to demonstrate attentional modulations of SOAEs and works in this domain have been scarce from thereon. In the current study (N=22) we focus on this issue by implementing a Posner-style cued attention task, in which a visual cue at the beginning of the trial indicated whether to attend to the visual or auditory modality of an upcoming bimodal stimulus. The task was to perform a simple discrimination task in the cued modality, while ignoring the input in the task-irrelevant modality. Recording otoacoustic emissions, the focus of our analysis was on the silent cue-target interval (2 seconds). We implemented a novel analysis approach in which band-restricted power fluctuations were derived by shifting band-pass filters from 500-2500 Hz and calculating instantaneous power via Hilbert transformation. A Fourier transformation was then performed on these otoacoustic emission time-series and the spectra were compared between attend auditory and attend visual trials. This analysis revealed significant differences, which were noticeably strongest in the relevant sound frequency range of the discrimination task (~1000-2000 Hz) and dominant at low frequency modulations (<10 Hz). This study is the first to clearly show an attentional modulation of SOAEs and underline that the MOC can be engaged by top-down processes in absence of any sound stimulation. In current

works we are investigating simultaneously recorded MEG signals to disclose the cortical networks that putatively drive the MOC during silent periods.

Title: Interactions between intra- and inter-areal connections of human insula in processing emotional sounds

Authors: *Y. ZHANG[1,2], W. ZHOU[3], J. HUANG[1], B. HONG[2], X. WANG[1,2]
[1]Johns Hopkins Univ., Baltimore, MD; [2]Tsinghua Lab. of Brain and Intelligence (THBI) and Dept. of Biomed. Engineering, Tsinghua Univ., Beijing, China; [3]Dept. of Epilepsy Center, Tsinghua Univ. Yuquan Hosp., Beijing, China

Abstract: Previous studies have demonstrated that the human insula are involved in two complementary sub-networks (Zhang et al., 2018 and Cauda et al., 2011), in which the posterior insula (PI) is connected to the sensory cortex and shows selective responses to sensory stimuli including auditory stimuli, where the anterior insula (AI) is connected to the limbic system and shows selective responses to emotional stimuli. To dissect the contributions of PI-to-Heschl's gyrus (HG) and AI-to-Amygdala sub-networks during emotional and non-emotional sounds processing in passive and active attention conditions, we applied conditional Granger causality analysis to assess the directional influences among the neural signals (iEEG) simultaneously recorded from HG, PI, AI and Amygdala of epilepsy patients. Our results showed that connections of the PI-HG sub-network were significantly stronger for emotional stimuli than non-emotional stimuli, but attention level showed no influence. While the connections of the AI-Amygdala sub-network were significantly influenced by both stimuli types and attention level. Furthermore, we found the connections of the PI-HG sub-network were highly dependent on the feedback signals from the AI-Amygdala sub-network during emotional stimuli condition, where the PI-HG sub-network had no influence on the connections of the AI-Amygdala sub-network. In addition, we found the connections between sub-networks are influenced by lateral interactions within the sub-network. Our findings suggest that feedback signals from higher order sub-network and lateral connections within the sub-network closely interact to mediate emotion perception from auditory stimuli.

Title: Human superior temporal gyrus tracks spectral entropy during speech perception

Authors: *F. KHATAMI[1], M. K. LEONARD[2], E. F. CHANG[3]
[1]Neurolog. Surgery, Univ. of California, San Francisco, CA; [2]Neurolog. Surgery, [3]Neurosurg., UCSF, San Francisco, CA

Abstract: Speech is a highly dynamic signal, composed of complex spectral and temporal modulations, which map onto linguistic units like phonetic features and words. Previous work has shown that the superior temporal gyrus (STG) encodes fine-scale acoustic-phonetic representations of speech, and has identified two functional-anatomical zones, one that responds primarily to onsets and fast temporal modulations (posterior STG), and another that responds to post-onset input and a wide range of spectral modulations (middle-anterior STG). It remains unclear precisely what features of acoustic speech input these sub-regions encode. To understand how speech-evoked activity in these regions relates to the actual spectrotemporal information content of the acoustic input, we applied an information-theoretic approach that describes speech in terms of spectral entropy. Specifically, we investigated the encoding of spectral multiscale entropy (MSE), a measure that describes the degree of structure in the acoustic power spectrum. We found that MSE successfully characterizes the structure of the acoustic signal for natural speech, such that speech sounds with more spectral structure (e.g., vowels containing formants) have lower entropy than speech sounds with less spectral structure (e.g., fricatives, characterized by high-frequency broadband noise). To understand whether MSE correlates with brain activity, we recorded direct neural population activity using electrocorticography (ECoG) in neurosurgical patients while they listened to ~400 naturally-spoken sentences. We correlated activity in the high-gamma (HG; 70-150Hz) range with MSE calculated on the power spectrum using non-overlapping 15ms windows. We found that activity in the two functional-anatomical zones on STG was correlated with MSE differently: posterior STG neural populations showed relatively weak positive correlations (stronger HG responses for higher entropy sounds), while middle STG neural populations showed strong negative correlations (stronger HG responses for lower entropy sounds). Together, these results demonstrate that speech-evoked neural activity in

human secondary auditory cortex tracks the spectral complexity and information of the acoustic input, as well as its spectrotemporal and phonetic properties.

Title: Behavioral modulation of sound processing in mouse auditory cortex during a virtual foraging task

Authors: *R. J. MORRILL[1,2], J. DEKLOE[2], J. BIGELOW[2], A. R. HASENSTAUB[2]
[2]Otolaryngology / Ctr. for Integrative Neurosci., [1]Univ. of California, San Francisco, San Francisco, CA

Abstract: The brain is tasked with processing and providing meaning to sensory inputs in a variety of contexts. For example, while hunting, the snap of a twig may signal the approach of a prey animal, but in another context it may simply mean the presence of a friendly conspecific. The valence of sensory stimuli changes between contexts, and such contextual changes are known to modulate neural responses in sensory cortex. Because these early sensory areas occupy a nexus between the ascending sensory pathway and top-down inputs from areas involved in coordinating action, contextually-modulated responses are believed to be directly related to behavioral outcomes. To test how task engagement modulates sound processing in auditory cortex, we have developed a virtual foraging task in which head-fixed mice run on a floating trackball and receive rewards for licking during a ‘go’ sound stimulus and time-out punishments for licking during a ‘no-go’ stimulus. Here we present results from a set of experiments in which rewarded stimuli were either upward or downward frequency-modulated sweeps. After achieving proficiency on this task, acute extracellular physiological recordings in auditory cortex were performed using multichannel translaminar probes over a period of multiple days and behavioral sessions. During these recordings, we presented the same stimulus set in a passive context for comparison with task-engaged neural responses. Consistent with previous studies, we find many

instances of neural response suppression during task engagement relative to the passive condition. However, we also find that responses in task-engaged auditory cortex are sometimes enhanced, and that such enhancement appears to be related to the cortical depth of the recording site. We also find that neural response onset latencies shift during task, but that the degree and sign of these shifts is heterogeneous. By varying the sound level of both 'go' and 'no-go' stimuli during task-engaged and passive physiological recordings, we also show that the degree of neural response modulation is related to task difficulty. We interpret these results in the context of a circuit model in which sound processing in the auditory cortex is modulated by behavioral context.

Title: Enhancing categorical sound perception with envelope timing cues

Authors: *H. L. READ[1,2], P. J. SATONICK[2], C. R. CODY[3], T. P. NOLAN, Jr[2]
[2]Biomed. Engin., [3]Psychological Sci., [1]Univ. of Connecticut, Storrs, CT

Abstract: Our ability to classify temporally dynamic sounds such as speech and non-speech vocalizations is highly robust to variations in tonal frequency composition due to the ability to perceive timing cues in the sound envelope (Shannon et al., 1995). Vocalization sequences are acoustically distinguished by timing cues including the acoustical edges created by abrupt onsets and characteristic vocalization durations (Khatami et al., 2018). Humans and other mammals can use these timing cues to discriminate stationary sound bursts (Friedrich and Heil, 2017; Heil et al., 2003, Kelly et al., 2006). However, it remains an open question as to whether we perceive onset and duration timing cues independently and whether this translates well to sound burst sequences. Since auditory cortices are specialized to respond to onset or sustained duration of transient sounds (Osman et al., 2018, Hamilton et al., 2017), we wondered if having both timing cues provides a perceptual advantage. Here, we hypothesize that the combination of onset and duration timing cues enhances categorical perception of synthetic vocalization sequences that lack tonal cues but have onset and duration timing cues. First, we examined categorical two-alternative forced choice discrimination of a set of sound burst sequences that varied in plateau

duration of the sound burst from short (100ms) to long (200ms) where the sounds lack fixed tonal cues (unfrozen white noise), onset cues (jittered onset) and amplitude (roved amplitude) cues. Furthermore, we were able to independently vary the slope of the sound envelope surrounding each sound burst in order to examine the combined sensitivity to onset slope and duration timing cues. Subjects performed a binomial (two) choice paradigm where they were to choose the right and left sides for short and long sounds, respectively. The Palamedes MatLab toolbox was used to fit a cumulative normal four-parameter sigmoid psychometric function to percent correct data points across a behavioral test session. We found that humans and rodents readily discriminate short versus long duration sound bursts in sequences and that training improves this categorical discrimination. In humans, the temporal resolution for plateau duration discrimination was enhanced with the addition of slow onset slope cues (e.g., reduced from 38 ms to 8 ms). These results support our hypothesis that combining onset and duration timing cues enhances categorical perception of extended and variable sound sequences.

Title: Auditory prosthesis with an infrared laser: Replication of acoustic intensity information

Authors: *Y. TAMAI, Y. ITO, K. HORINOUCHI, K. MATSUMOTO, S. HIRYU, K. I. KOBAYASI, T. FURUYAMA
Doshisha Univ., Kyoto, Japan

Abstract: Cochlear implants bypass damaged hair cells in a cochlea and stimulate cochlear nerves electrically. One of the greatest drawbacks of the cochlear implant is that the devices require surgical intervention. Infrared laser stimulation is a novel method for neural stimulation. It stems from optical absorption of water. The laser causes instantiable temperature rise and opening of heat-sensitive ion channel. In contrast to electric stimulation, infrared laser stimulate nerves without contacting the tissue. Our goal is to develop a novel auditory prosthesis by applying infrared laser stimulation to a hearing aid. The auditory prosthesis with the infrared laser does not need invasive surgery because the laser can generate neural responses without contacting tissues. The purpose of this study was to investigate whether the infrared laser could stimulate cochlear nerves from an ear canal through a tympanic membrane, and the stimulation

could replicate ‘acoustic intensity information’ by changing radiant exposure. Mongolian gerbils (*Meriones unguiculatus*) were used as subjects. An optic fiber was inserted into their ear canals and irradiated cochlear nerves through their tympanic membranes with the infrared laser. A pulsed infrared laser (0.5 - 20.5 µJ/pulse) and a clicking sound (30 - 90 dB pe SPL) were presented. As results, cochlear microphonic and compound action potentials (CAPs) were recorded when a clicking sound was presented, while infrared laser stimulation only induced CAPs. As radiant exposure increased, the CAP amplitude increased from 0 to 317 µV, and the CAP latency decreased from 2.2 ms to 1.6 ms; similar tendency was observed for clicking sounds (CAP amplitude: 0 - 332 µV, CAP latency: 2.8 - 1.7 ms). In subsequent experiments, flavoprotein fluorescence imaging of auditory cortex was performed to reveal whether the intensity coding of infrared laser stimuli was observed in auditory cortex. Results show that auditory cortex was activated by infrared laser irradiation, and the greater response was recorded as radiant exposure increased. These results suggest that infrared laser stimulation could bypass the need for hair cell depolarization and directly create cochlear nerves responses, and that the laser stimulation could replicate ‘acoustic intensity information’ in auditory pathways.

Abstract: The transduction of acoustic input into perception requires auditory scene analysis (ASA) and the subsequent grouping of stimuli into one or more “auditory objects”. Music, an emergent property of sound, can be thought of as an auditory object resulting from the grouping of disparate sounds into a unified percept. Thus, auditory cognition depends on the relationship between low-level properties of auditory stimuli and resultant musical gestalts. Our previous behavioral research has shown that manipulations of low-level properties (i.e., amplitude,

timbre) can modulate the perceived musicality of auditory sequences (Randall & Greenberg, 2016), however, the neural instantiation of these processes remains unexplored. We presented participants with auditory stimuli comprised of randomly generated pure tone sequences for which they provided perceived musicality ratings. We replicated the findings of Randall & Greenberg (2016) by demonstrating that the manipulation of ASA cues had an attenuating effect on musicality judgements. We then used fMRI to measure neural activation elicited by the most and least musical sequences (musicality manipulation), along with those same sequences altered in either amplitude or timbre (ASA manipulation). To explore the functional architecture underlying ASA and auditory object analysis, we uncovered 2 partially distinct networks: (1) a music processing network (via a separate music localizer), and (2) an ASA network (via a contrast of base sequences vs. ASA manipulated sequences). Mean BOLD response time-courses from regions of interest (ROIs) within each network produced functional profiles that appeared to be modulated by musicality manipulations, ASA manipulations, or both. Thus, based on their patterns of functional activation, we identified sub-networks of ROIs that seem to perform common computations. Some regions seem to be involved in discriminating music from non-music while others track low-level features that comprise an auditory perceptual object. Finally, we examined the correlations between behavior (musicality ratings) and BOLD activation for each ROI. Overlapping regions of both the musicality and ASA networks appeared to show stronger correlations between behavior and neural activity. The existence of shared neural mechanisms that correlate with behavioral ratings and underlie both ASA and music perception suggests that low-level features of auditory stimuli play a direct role in auditory object perception.

Title: Spectrotemporal processing of consonant clusters in theta and high gamma in native-English and native-Polish bilingual adults

Authors: *M. WAGNER[1], S. ORTIZ-MANTILLA[2], V. L. SHAFER[3], A. BENASICH[2]
[1]St. John's Univ., Jamaica, NY; [2]Rutgers Univ. Newark, Newark, NJ; [3]Speech-Language-Hearing Sci., The Grad. Center, City Univ. of New York, New York, NY

Abstract: Studies examining cortical responses to speech sound sequences using ECoG have revealed maximal neural activity in high gamma between 70 to 150 Hz. Few studies, however, have examined native-language phonological processing in this range. In the current study, we

used dense array EEG to examine left auditory cortical responses to native and nonnative consonant clusters, comparing measures of high gamma and theta oscillatory activity. As short-duration phonemic segments are sampled within high gamma, we predicted native-language processing of the phonological segments within consonant clusters to be reflected in measures of high gamma, but not theta. EEG was recorded as 24 native-English and 24 native-Polish bilingual adults listened to same and different nonsense word pairs. Nonsense words contained the onset clusters /st/ and /pt/. Whereas the /st/ cluster occurs in both the Polish and English languages, the /pt/ cluster is never heard in word onset in the English language. A three-dipole source model was fit at the time intervals for N1 (94-124 ms) and P2 (176-206 ms), which explained 90% of the data within the time frame reflecting sensory processing (24 to 388 ms). Using time-frequency analysis, we examined induced temporal spectral evolution (TSE) oscillatory activity between -100 to 900 ms in high gamma (62-90 Hz) and theta (2-8 Hz) bands in source space. Statistical analysis was conducted using data clustering in combination with permutation testing. Results revealed language group differences to the /pt/ cluster in high gamma, but not theta. Reduced high gamma was found in English listeners relative to Polish listeners to the /pt/ cluster during early stage sensory processing and increased activity was found between 400 and 900 ms, which may reflect re-analysis of the unfamiliar cluster. In response to the /st/ cluster, no language group differences were found in high gamma, but greater activation was found in the theta band for the Polish listeners relative to the English listeners. Interestingly, within group comparisons examining responses to the clusters in both theta and high gamma found the English listeners to have increased activation to the /pt/ relative to the /st/ cluster, whereas, the Polish listeners showed a reversed pattern, with increased activation to the /st/ relative to the /pt/ cluster. These results suggest that native-language processing is reflected at early stages within left auditory cortex in high gamma. As /pt/ is never heard in word onset in English and /st/ is less common in the Polish language, increased activation in both theta and high gamma bands may indicate increased processing for the less familiar speech sound sequences.

Abstract: The correspondences or differences between human and nonhuman primates in connectivity between auditory cortex and other brain regions remain open questions: What is the evidence for evolutionary conservation or specialization in effective connectivity between auditory cortex and brain regions that in humans are implicated in language, memory or learned vocal production? Here we had the opportunity to directly compare electrical microstimulation of site specific contacts available in human epilepsy patients being monitored for surgical resection. We also conducted comparative auditory cortex microstimulation in two rhesus macaques. Microstimulation was combined with functional Magnetic Resonance Imaging (fMRI) to assess the directed effective connectivity induced by electrically stimulating auditory cortical sites. Stimulation of primary auditory cortex (field A1) in the macaques resulted in significant fMRI responses in several brain regions ($p < 0.05$, cluster corrected), including the inferior frontal cortex (areas 44 and 45), regions of the hippocampus and the anterior cingulate cortex. In the monkeys, we also compared the stimulation of primary field A1 to sites in the caudal belt adjoining the non-primary fields CL and CM. In human patients with clinically implanted depth electrodes in Heschl's gyrus (HG), we microstimulated contacts located in the medial HG (a primary like region of auditory cortex; $n = 17$; 2 excluded from a total of 19 because of poor MRI registration). Stimulation of the medial HG resulted in significant fMRI responses in inferior frontal cortex, parts of the hippocampus and anterior cingulate cortex. These observations suggest a considerable amount of correspondence between humans and monkeys in effective connectivity between auditory cortex and other brain regions, which in humans have been implicated in various language functions, cognition or learned vocal production.

Title: Predictive sequence learning modulates inter-regional oscillatory coupling in human intracranial recordings

Authors: *Y. KIKUCHI[1], C. K. KOVACH[2], R. CALMUS[1], P. E. GANDER[2], A. E. RHONE[2], K. V. NOURSKI[2], H. KAWASAKI[2], T. D. GRIFFITHS[1,2,3], M. A. HOWARD, III[2], C. I. PETKOV[1]

Abstract: Dynamic environments generate sequences of sensory events that affect brain oscillations at different frequencies. Moreover, feed-forward and feed-back interactions are evident in oscillatory phase and frequency interactions, yet little is known about how learning-related plasticity changes oscillatory dynamics in neural networks. Using intracranial recordings from both human and monkey auditory cortex, we previously reported phase-amplitude coupling between low-frequency phase and gamma amplitude in auditory cortex after the learning of temporal relationships in sequences of speech sounds drawn from an Artificial Grammar (AG; Kikuchi et al., PLoS Biology, 2017, 15(4):e200219). In the monkeys as an animal model, the prior results pointed to oscillatory influences on auditory cortex neurons emanating from other brain regions. Here, we sought to identify the sources of these influences using the extensive coverage with depth and grid recording electrodes offered by human intracranial recordings in epilepsy patients being monitored for surgery. We used the same AG learning paradigm as in the prior study, where participants were first exposed to representative rule-based sequences of nonsense words. In the subsequent testing phase, we presented the participants with sequences that were either consistent with the AG or contained specific violations of learned ordering relationships. Inter-regional phase interactions were measured by phase angle differences between recording sites weighted by the evolution of the transitional probabilities over all previously encountered sequences. Sequencing-related modulation of oscillatory phase coupling

was observed between auditory cortex (Heschl's gyrus, HG) and a number of sites, including the hippocampus, lateral superior temporal gyrus, anterior temporal lobe and inferior frontal gyrus (IFG). Further analyses showed that frequency-specific phase coupling tracked the changes in transitional probabilities within three oscillatory bands (theta: 3-8 Hz, beta: 15-29 Hz, gamma: 40-100 Hz). Moreover, during initial learning, HG interacted with the hippocampus and IFG most prominently in the theta band. A more extensive network was involved after the learning phase, with cortical network modulation in response to violations of the learned sequencing relationships involving a broader set of regions. Oscillatory phase-based coupling in human intracranial recordings provides insight into inter-regional neural interactions at different stages of predictive sequence learning, which may refine hypotheses for further testing using monkeys as a model system.

Title: Contour feature representation in monkey V4

Authors: *R. JIANG, S. TANG
Peking Univ., Beijing, China

Abstract: We recorded responses of macaque V4 layer 2/3 neurons to 5000 nature visual stimuli by two-photon calcium imaging. We found that the orientation pinwheel derived by orientation components within nature images is almost identical to that derived by bar stimuli. We also found that neurons favoring nature images containing curvatures are spatially separated form those preferring images with polygonal lines, which we confirmed by examining with contour feature stimuli containing curvatures and polygonal lines directly. Many of the curvature preferring neurons are located in the center of one of the pinwheels. In addition, we found some neurons that are sensitive to the orientation of the symmetry axis of the contour feature rather than the orientation of the contours. Our results reveal the spatial organization of contour feature representation in V4.

Title: Patterned optogenetic stimulation of ferret V1 to examine cortical mechanisms of cross-orientation suppression

Authors: *S. WANG[1], K. D. MILLER[2], S. D. VAN HOOSER[1]
[1]Biol. Dept., Brandeis Univ., Waltham, MA; [2]Columbia Univ., New York, NY

Abstract: The study of how neural circuits integrate sensory information and generate functional behaviors has long been a pursuit of the neuroscience field. To understand the principles that underlie the neural computations is critical to understand the intelligence in general. A recently proposed theory, *stabilized supralinear network (SSN)*, has shed light on how canonical computations can be implemented in neural circuits. It uses simple constructions based on biologically plausible parameters, yet it is able to explain many widely studied sensory responses. In particular, it predicts that cortical responses to multiple inputs sum sublinearly when the inputs are not very weak, providing a circuit basis for the phenomenological "normalization" model.
Guided by this theory, we are interested in testing the neural mechanisms of a phenomenon observed in the visual cortex, *cross-orientation suppression*, in order to understand the operating principles of cortical circuits. Cross-orientation suppression refers to fact that visual responses are strongly suppressed when two orthogonally overlapped grating stimuli are presented simultaneously compared to the sum of the responses to the single grating stimuli presented alone. Though previous work suggests the origin of the suppression comes from thalamocortical connections, cortex itself may still contribute to the suppression, which is indeed indicated by the SSN model about the role of local cortical circuits in cross-orientation suppression. We adopted optical and optogenetic tools to directly activate the orientation columns of ferret visual cortex, in a way akin to the visual stimulation using gratings with various orientations, to test whether suppression could be generated directly from the cortical circuits.
A novel optical system, "ProjectorScope 2", is developed in the lab that allows us to perform brain surface imaging to identify orientation columns, and subsequently activate these local areas that have channelrhodopsin-2 expression. Preliminary results showed that simultaneous optogenetic stimulation of both preferred and orthogonal orientation columns produced suppressed responses compared to a linear summation of the responses to the optogenetic stimulation of preferred orientation columns alone and orthogonal columns alone. The responses

of visual stimulation of the preferred orientation and optogenetic stimulation of the orthogonal orientation columns also elicited sublinear responses. These results suggest that the cortex may operate in the SSN regime, but further experiments are needed to test this hypothesis.

Title: Local organization of spatial frequency tuning dynamics in the cat primary visual cortex

Authors: *H. TANAKA[1], I. OHZAWA[2]
[1]Kyoto Sangyo Univ., Kyoto-shi/Kyoto, Japan; [2]Osaka Univ., Suita, Osaka, Japan

Abstract: Spatial frequency (SF) is a prominent visual feature to which most neurons in the primary visual cortex (V1) exhibit tuning selectivity. To fully understand the role of V1 in processing of SF, details should be explored by which the population of V1 neurons cooperatively works to transmit and process SF information. At the level of individual neurons, it is known that V1 neurons often show SF tuning dynamics, typically shifting toward high values, but exhibiting a variety of time courses. However, on the population level, it remains unknown how neurons with a variety of SF tuning dynamics are locally clustered, and how these clusters systematically mediate the wide range of SF signals transmitted in V1 that could change dynamically during response time. To explore these issues, we vertically penetrated cat V1 with a multi-electrode array and recorded the activities of a large number of V1 neurons covering the dominant SF range in V1. The time courses of SF tuning of these neurons were measured by a subspace reverse correlation technique using a random sequence of flashed sinusoidal gratings. We found that the range of SFs transmitted by the whole population rapidly increased in the early response phase, and that a wide range of SFs were continuously signaled for most of the V1 response period. Locally, nearby neurons exhibited various tuning dynamics. Typically, they were first tuned to relatively similar SFs, whereas later their tunings became more diverse. The mean values of optimal SFs of local clusters of neurons increased uniformly and slightly over time, as is consistent with the theory of coarse-to-fine processing. Therefore, our results indicate that local SF tuning clusters increase their SF coding range with time, and as a whole systematically share the wide and increasing range of SFs coded in V1, keeping SF signal

transmission stable during response time, as well as allowing functional diversity within a cluster.

Title: Network structure within and between marmoset V1 and MT facilitates natural image coding

Authors: *E. ZAVITZ, M. A. HAGAN, B. H. OAKLEY, Y. T. WONG, N. S. C. PRICE
Monash Univ., Clayton, Australia

Abstract: The middle temporal area (MT) computes motion direction based on the inputs it receives from direction-selective neurons in primary visual cortex (V1). Existing models of the hierarchical computations between these areas are among the best defined of any model of cortical processing, yet the stimulus space of visual inputs on which they have been tested remains poorly explored. While most studies characterise neural responses using only gratings or dots, the natural visual world contains information at a range of spatial scales, and this information is often phase aligned. There is evidence that this structure shapes the nervous system so that natural images are encoded efficiently by single neurons. In this work, we examined how the structure of visual information impacts the way it is represented by both single neurons and populations, across two levels of the visual hierarchy. To reveal how visual information is successively represented by V1 and MT, we made extracellular electrophysiological recordings in five anaesthetised marmoset monkeys (Callithrix jacchus). We used separate multielectrode arrays in each area to record simultaneously from dozens of neurons in each of V1 and MT with overlapping receptive fields. We implanted a Utah array in V1, and a linear array in MT; the linear array was implanted perpendicular to the brain's surface to characterise neurons within the same cortical column. We recorded activity in these populations while we presented motion stimuli with a range of spatial structures: dots, sine waves, square waves, and phase-randomised square waves. These patterns evoke strong direction-tuned responses in MT, but recruit distinct V1 populations, which allows us to examine the representation produced in MT as a function of the representation in V1. We assessed whether

the functional network we engaged was changing by measuring the variability of single neuron responses (Fano factor), and the shared variability between neurons (spike count correlations). We found that both response variability and shared variability were lowest during broadband, phase-aligned stimulation within and between areas V1 and MT. This suggests that the network architecture in both areas is optimised to represent broadband, phase aligned contours.

Title: Inhibition stabilization is a widespread feature of mouse cortical networks

Authors: *B. C.-Y. AKITAKE[1], A. SANZENI[1], C. E. LEEDY[1], N. BRUNEL[2], M. H. HISTED[1]
[1]NIH/NIMH, Bethesda, MD; [2]Neurobio., Duke Univ., Durham, NC

Abstract: Strong recurrent synaptic coupling in networks like the cortex can provide several advantages for computation, allowing networks to track fast feedforward inputs, amplify weak signals, and perform noise-robust classification.
A signature of strongly coupled networks is that excitatory neurons are unstable and activity is stabilized by recurrent inhibition, which tracks and balances excitation. However, modeling studies have suggested that inhibition stabilization, and thus a significant amount of recurrent input, may arise only in the presence of external or sensory activity (Ahmadian, 2013).
Here we show that several cortical networks in the mouse -- visual, auditory, and somatosensory cortex -- are stabilized by inhibition even at rest, i.e. when sensory stimuli are not being delivered. Further, we found inhibitory stabilization even when network activity was reduced by light anesthesia, suggesting that inhibition stabilization is a widespread phenomenon in cortical areas across a range of activity levels and network states.
We expressed a depolarizing opsin in all inhibitory cells using VGAT-ChR2 mice (n=6). Inhibitory stabilized networks show paradoxical suppression of inhibitory neurons when inhibitory cells are directly excited (Tsodyks, 1997), so to assess inhibition stabilization, we recorded neurons extracellularly while stimulating inhibitory cells optogenetically. We classified inhibitory cells (N=70 well-isolated single units, over 10 experiments) as those that responded to optogenetic stimulation when most recurrent network activity was pharmacologically blocked (CNQX, APV, and bicuculline). Consistent with previous measurements, waveform widths had a bimodal distribution and inhibitory neurons had narrower spikes compared to excitatory cells.

Identified inhibitory cells showed clear paradoxical suppression when animals were awake (49% ± 8 (sem) reduction in inhibitory firing with optogenetic stimulation) and after light (0.25% isoflurane) anesthesia (65% ± 10 (sem)).
These results suggest that strong coupling and inhibition stabilization are fundamental principles of cortical circuits.

Title: Mice improve their ability to detect novel, "off-manifold" stimuli after learning

Authors: *L. N. RYAN, S. P. DUFFY, P. K. LAFOSSE, M. H. HISTED
NIH/NIMH, Bethesda, MD

Abstract: Sensory stimuli evoke patterns of activity that are constrained by brain functional and structural properties, such as the pattern of synaptic inputs in a brain region. Other -- non-natural -- patterns of activity can be elicited by external stimulation. Such “off-manifold” patterns may be difficult to process for brain circuits as they do not lie on the space or manifold that encompasses the set of sensory-evoked patterns. While neurons can be trained to generate novel patterns of activity within the intrinsic manifold (Golub et al. 2018), it is unknown if and how cortical circuitry must change to support an animal’s ability to recognize novel off-manifold patterns of activity. Here, we train mice to report off-manifold optogenetic stimuli delivered to excitatory cells (Emx1-Cre; Chrimson) and find that animals improve their detection performance for such stimuli over the course of days, showing learning that encompasses both gradual improvement in response speed and response sensitivity. Animals are first trained to detect visual stimuli, and when performance is stable, an optogenetic stimulus is added to the near-threshold visual stimulation. Animals take an average of 4.25 days (∓3.3 s.d., n=4; 1450.25 trials ∓934.97 s.d., n=4) to begin to report the optogenetic stimulus. After first acquisition of the optogenetic task, we track learning in two steps. First, mice shorten their reaction times for constant stimulus intensity (mean reaction time decrease over 6 days = 80.39 ms ± 14.04 ms s.d., n=4). Second, we lower stimulus intensity and animals’ detection threshold decreases as they become more sensitive to the stimulus (mean final max power = 11% ± 7.28% of starting power, s.d., n=2). It will be important to understand the underlying circuit changes associated with our observed behavioral effects.

Title: Cortical circuits implement optimal context integration

Authors: *R. IYER[1], S. MIHALAS[2]
[1]Allen Inst. for Brain Sci., Bothell, WA; [2]Allen Inst. for Brain Sci., Seattle, WA

Abstract: Neuronal responses in early visual cortex are primarily driven by inputs to the classical receptive field and are influenced by stimuli in the surround. This type of response modulation is thought to arise due to the statistical structure present in natural scenes, with the surround providing context for the information in the classical receptive field. Lateral connections between neurons in the same cortical area are thought to be responsible for transmitting information in the near surround. Recent experimental studies have demonstrated like-to-like connectivity between excitatory neurons coding for the same feature (e.g. orientation) and specific rules for connectivity of inhibitory neuron types. On the other hand, normative models of lateral interactions, relying on sparsity and saliency in the optimal representation of natural images, predict functional inhibition between excitatory neurons. Assuming that an excitatory neuron represents the probability of a feature being present in the sensory stimulus, we hypothesize that lateral connections serve to optimally (in a Bayesian sense) integrate evidence from the surround. We show that such optimal integration of contextual information can be implemented by a neuronal network. Using natural scene statistics obtained from the Berkeley Segmentation DataSet and in-vivo electrophysiological data from awake mouse V1 neurons, we compute the synaptic weights resulting from optimal integration of contextual information.
We show that this network has like-to-like connectivity between excitatory neurons, in agreement with experimental observations. The distance dependence of connections is similar to those observed experimentally and these results generalize to other classes of receptive fields. The network also needs multiple types of inhibition - local normalization, surround inhibition and gating of inhibition from the surround - which we map to the parvalbumin (PV), somatostatin (SST) and vasoactive intestinal peptide (VIP) expressing interneuron cell classes respectively.
We explore the capacity to include higher order correlations in our network via multiple applications of the surround influence. We are also exploring the relation between normative models of classical receptive fields and the optimal context integration model which is used to

generate extra classical receptive fields.
We hypothesize that optimal integration of context is a general computation of cortical circuits.

Title: Convolutional neuronal networks with optimal lateral connections are more robust to noise and predict signal and noise correlations in mouse visual cortex

Authors: B. H. HU, *S. MIHALAS
Allen Inst. for Brain Sci., Seattle, WA

Abstract: Convolutional neuronal networks have had great success in many applications as well as in describing neural responses in the ventral stream of primates. In contrast to what is known from biology, these networks focus on feedforward visual processing, largely ignoring the influence of recurrent connections. They also focus on supervised rather than unsupervised learning. Visual processing in the brain makes use of lateral connections and information from extra-classical receptive fields. The brain is also able to learn structured representations in a largely unsupervised manner with little to no labeled data. We leverage recent work demonstrating how Bayes-optimal lateral connections can be learned through an unsupervised method, a modified version of Hebbian learning rule. We combine this optimal context integration with deep learning to not only learn different features within a convolutional neuronal network, but also the optimal lateral connections between the neurons encoding these features. These connections can be implemented using a collection of cell types and lateral connections which match well biological observations in cortical circuits. We then demonstrate the influence of lateral connections by testing our model on two standard image datasets: MNIST and CIFAR-10. In additional to the original images, we also generate noisy versions of the images by adding additive white gaussian noise and salt-and-pepper noise in increasing levels. Importantly, we only train our model on the original images. As expected, increasing levels of noise degrades model performance for both the MNIST and CIFAR-10 datasets; however, models with optimal lateral connections are more robust to this noise and are able to achieve higher classification accuracies on both datasets, especially at higher noise levels. We also use these noisy images to test for signal and noise correlations among pairs of neurons in the model. We find positive correlations between noise and signal correlations in our model, which is consistent with two-photon recordings from neurons in the Allen Brain Observatory. This finding is in contrast to sparse coding hypotheses, which predict a negative correlation between noise and signal

correlations. Furthermore, we find that these positive correlations increase in deeper layers of the model. Our findings have implications for how correlations may limit information transmission within convolutional neuronal networks. Our results also suggest that the integration of lateral connections into convolutional neuronal networks is an exciting avenue of future research.

Abstract: Cortical circuits work on different levels of fluctuations, with behavioral relevance even in very local neuronal populations. This diversity of states has been observed during both evoked and spontaneous activity. A recent framework used to deal with complexity underlying the diversity of states is the critical brain hypothesis. It proposes that the brain operates near a critical state, at the border between qualitatively different types of cortical dynamics. Power-law distributions of avalanche sizes and durations have been employed as a key signature of such a critical state in neuronal activity. We investigated the changes of the properties of spiking avalanches throughout the different levels of fluctuations in spiking activity from large neuronal populations in primary sensory cortical areas of urethane-anesthetized rats. We found a striking difference in spiking avalanche properties across different levels of spiking variability, especially in which spiking avalanche distribution are best fitted by power laws (under the AIC criterion), with statistical self-affinity similar to 1/f noise. Based on this information, we propose that there is an intermediate level of variability in which the corresponding neuronal population activity in primary sensory cortices best approach its critical point.

Title: Inter-areal coordination and dendritic integration in visual cortex

Authors: *M. FISEK, D. HERRMANN, A. EGEA-WEISS, T. LEE, M. HAUSSER
UCL, London, United Kingdom

Abstract: A striking feature of the mammalian neocortex is its laminar structure. Cortical layers are specialized both morphologically and physiologically, but the ultimate functional roles different layers subserve has remained elusive. One of the most prominent differences between layers is the apical dendrites of their constituent neurons. Neurons in superficial layers, in comparison to deeper neurons, have shorter apical dendrites - suggesting that inputs to their apical dendrites, which tend to come from other cortical areas, might have more influence on the soma. In order to provide a link between dendritic activation patterns, inter-areal coordination, and laminar specialization, we performed in vivo two-photon calcium imaging experiments simultaneously in two visual cortical areas, primary visual cortex (V1) and the higher visual area LM. We presented a diversity of visual stimuli, and allowed head-fixed animals to run freely on running wheels without reward. We imaged spontaneous, sensory-evoked and locomotion-related activity in layer 2/3 or layer 5A using a combination of driver-Cre lines, and transgenic or viral reporter expression. By examining pairwise correlations across the two cortical areas, we show laminar specialization in terms of inter-areal coordination. In a separate set of experiments under similar conditions, we co-expressed the green glutamate indicator iGluSnFR and the red calcium indicator jRGECO1a and performed dual-color volume imaging of activity in apical and basal dendritic domains. We imaged activity in V1 or area LM separately, and examined sensory stimulus-evoked as well as locomotion-evoked changes in input (glutamate) and output (calcium) signals recorded across large fields of view, representing bulk signals in the tissue. Our results show that the correlation between apical dendritic glutamate signals and somatic calcium signals depends on stimulus and locomotor state. We find similar dependences in both V1 and LM. We are currently extending these experiments to monitor glutamate and calcium signals in

V1 and LM simultaneously. Together, these experiments will improve our understanding of the dendritic and synaptic mechanisms underpinning inter-areal coordination during visual processing.

Title: *In vivo* quantification of single-cell targeted optogenetic stimulation with a digital micro-mirror device

Authors: *R. AOKI, A. BENUCCI
RIKEN Ctr. for Brain Sci., Wako City, Saitama, Japan

Abstract: Circuit optogenetics with spatial-temporal patterned illumination at single-cell resolution is gaining much attention as a tool to dissect the neuronal functional connectivity within and across brain regions. Current methodologies are often cost ineffective, require high, possibly tissue-damaging laser power, and are note easily integrated with optical systems targeting deep brain regions (Yang and Yuste, 2018, Curr. Opin. Neurobiol.). Here, we present an approach based on a digital micro-mirror device (DMD) for a cost-effective, low laser power manipulation of neural activity with single-cell precision, millisecond temporal resolution, and easy integration with optical systems for patterned optogenetic stimulations in deep brain regions. First, using cortical slices of different thicknesses, we quantified the XYZ volumetric power density profile associated to a small excitation disk. At the focal plane, 120 um deep from the surface, a 25 um diameter disk (640 nm wavelength, via a 16x objective) was confined to a very small region (sigma = 11.6 +- 0.6 um, mean +- sem, Gaussian fit, peak 0.956 +- 0.126 mW/mm^2, n=5 measurements). With depth, the disk diameter increased, as measured by a calibrated CCD camera focused on the bottom side of the sample and the light power rapidly and significantly decreased (sigma = 14.8 +- 0.8 um, peak 0.494 +- 0.040 mW/mm^2, n=5 at z=170 um, sigma = 21.2 +- 0.8 um, peak 0.131 +- 0.010 mW/mm^2, n=5 at z=220 um). Above the focal

plane, we estimated the power increase from standard measures of light absorption and scattering in brain tissue (Helmchen and Denk, 2005, Nat. Methods). We then used the measured volumetric intensity profile, to estimate in-vivo the XYZ probability of single-cell excitation in neurons expressing ChrimsonR and GCaMP8 in mouse V1. At the focal plane, we reproduced z-slices of the volumetric intensity profile for a 25 um disk by corresponding adjustments of the excitation disk diameter and the light intensity. We then measured the probability of eliciting a response in a targeted cell by displacing the center of illumination at various lateral distances from the cell's center. This measure provides an upper-bound estimate since responses can be induced not only by direct illumination but also indirectly by excitation of en-passant neurites. In conclusion, our data supports the notion that single-cell excitation can be achieved *in vivo* with DMD technology. We are currently planning to test this methodology with gradient-index (GRIN) lens implantation for patterned optogenetic stimulation in deep brain regions.

Title: Tauopathy in primary visual cortex causes feature-specific changes in visual function

Authors: *C. WU[1], A. BLOCKEEL[2], S. G. SOLOMON[1], K. D. HARRIS[1], K. G. PHILLIPS[2], A. B. SALEEM[1]
[1]Univ. Col. London, London, United Kingdom; [2]Eli Lilly, Windlesham, United Kingdom

Abstract: The overexpression and aggregation of tau is observed in a class of neurodegenerative diseases termed tauopathies. Individuals with tauopathy, and animal models of the disease, show a loss of behavioural and cognitive function - the mechanisms of which are yet unknown. We asked how tauopathy changes information processing capabilities of neural populations. Specifically, we investigated how information processing is altered in the Tg4510 model of tauopathy in primary visual cortex (V1); an area where the relationship between stimulus features, single unit responses, and the circuits and mechanisms underlying them, is relatively well characterised.
For this study, we took advantage of the fact that the expression of Tau in Tg4510 mice can be

suppressed by doxycycline. Thus, at 2.5 months old, mice were assigned to tau positive (Tau+) and tau suppressed (Tau-) groups. Tau- animals were administered doxycycline through drinking water (experimenters were blinded to the group identity). We conducted chronic awake head-fixed recordings in V1 of 5-6.5 month old mice, presenting a variety of visual stimuli, including drifting grating stimuli that varied across feature dimensions such as orientation, contrast, or size. Recording sessions were repeated over the course of several weeks, allowing us to obtain multiple recordings from each mouse.
Tau+ and Tau- mice showed clear differences in the oscillatory local field potentials in V1, with Tau+ mice showing a suppression of narrow-band gamma (55-65 Hz) power. Single unit responses (2201 cells for Tau+, 2230 for Tau-) to a sparse noise stimulus were less selective and less reliable in the Tau+ group. To characterise information processing, we fit response models to single unit responses to drifting grating stimuli which varied along specific feature dimensions. Responses to other stimulus features, such as spatial frequency, were unchanged between the two groups. Surprisingly, Tau+ mice showed enhanced orientation selectivity, measured by both model fit quality and the orientation selectivity index. They also showed a larger suppression of response after being adapted to a specific orientation.
In conclusion, tauopathy shows clear effects on information processing in the visual cortex. This was not through a non-selective decrease in responsiveness, but instead enhanced some types of processing, such as orientation selectivity, while disrupting others such as responses to sparse noise. These selective effects on neural function may reflect selective patterns of tauopathy within visual areas.

Title: Role of higher visual areas in detecting orientation and contrast changes

Authors: *M. JIN, L. L. GLICKFELD
Duke Neurobio. Dept., Durham, NC

Abstract: Mouse visual cortices are highly interconnected, but form orderly processing streams that refine visual information to accurately guide behavior. While neurons in mouse primary visual cortex (V1) are functional heterogeneous, neurons in higher visual areas (HVAs) are

specialized for processing distinct features of visual stimuli. This indicates that HVAs might have distinct perceptual roles and if so, specialized sensory information must be routed via distinct pathways to guide different behaviors. Therefore, we first aim to test the requirement of HVAs (AL, LM and PM) in visually guided behaviors such as detecting orientation or contrast changes. We train water-restricted mice to report visual changes by manipulating a lever and optogenetically silence each HVA via exciting inhibitory interneurons to determine if this can impair animal's perceptual ability. We found that silencing area V1 (n=6), LM (n=4) and AL (n=7) caused significant reductions in both hit and false alarm rate in an orientation change detection task, resulting in an increase in orientation detection threshold and a decrease in sensitivity (d-prime). However, silencing PM (n=3) did not affect any of the perceptual measurements, despite the efficacy of neuronal recruitment by task stimuli and silencing by optogenetic activation having been validated electrophysiologically. Since contrast detection might be more broadly encoded by visual circuits, we tested if PM is required for contrast detection instead. However, while silencing areas V1 (n=4), LM (n=5) and AL (n=3) consistently increased contrast detection thresholds, silencing area PM (n=6) had no effect on contrast detection. Overall, our data shows that area V1, AL and LM, but not PM are required for orientation and contrast change detection. This suggests that 1) information necessary for visual perception is routed through V1, LM and AL; and 2) similar circuits/computations may be used to detect orientation and contrast changes. Ongoing experiments are aimed at dissociating the function of areas LM and AL in visual processing, and determining whether area PM is specialized in detecting changes in other features such as speed.

Title: The electrical stimulation of the dorsal raphe nucleus (DRN) changes visual responses of neurons in primary visual cortex

Authors: *S. ROSTAMI, P. GHADERI, L. DARGAHI, M.-S. SAFARI
Neurosci. Res. Ctr., Tehran, Iran, Islamic Republic of

Abstract: Introduction: Serotonergic system is involved in many basic functions including motor control, sleep, learning and memory, pain and sensory processing. Serotonin (5-HT)

transmission forms a major modulatory network within sensory systems. This network influences various information-processing mechanisms. Serotonin has been shown to be involved in visual processing, specifically orientation processing, at the cortical and retinal level. We investigated subthreshold and supra threshold responses of excitatory and inhibitory neurons using in vivo patch-clamp recording in layer II/III of primary visual cortex(V1).
Method: Naive mice of either sex (postnatal days 40-70) are used. Animals were anesthetized and craniotomy was done on the region of interest in V1. For electrical stimulating of the DRN serotonergic system, a bipolar tungsten electrode was inserted into the DRN. Whole-cell recordings from putative inhibitory and excitatory neurons in layer II/III of V1 was performed. In order to data acquisition and visual stimulation, square-wave grating (0.04 cycle/deg) at 100% contrast moved on an LCD in 12 directions at 30 degree steps (0-360 degrees) and 5 contrast patterns. Membrane potentials (subthreshold and supra threshold) were recorded at current-clamp mode. Data were analyzed by matlab software. For statistical analysis, values without and with DRN stimulation from the same cells were compared with T-test.
Results: Electrical stimulation of the serotonergic system seems to be decrease spontaneous and evoked potentials (subthreshold and supra threshold responses) of putative excitatory and inhibitory neurons in V1 during orientation selectivity and contrast response function. By Calculating of mean neuronal firing rate in different orientations and contrasts, then fitting a cousinous function, the shape of the response curve has changed, as well as the reduction of the response amplitude was observed with the stimulation of DRN. In such cases, serotonin seems to have a gain control function. The response curve become wider at preferred orientation and neuron more sensitive to direction of visual stimulus. Moreover, tendency to respond in higher contrast in this series of neurons was observed.
Conclusion: We are interested to find how serotonergic system change tuning curve of neurons in v1. Temporal and spatial dynamic of serotonin neuromodulation are another goals of our study. We suppose that the serotonergic system plays an important role in neural network dynamics in visual cortex sensory processing, which is essentially different cell-type and layer specific.

Title: Neurotransmitter receptor bases for spatial summation in visual cortex by in-vivo single-unit recording and juxtacellular injection

Authors: *X. SONG[1], T. AN[2], C. ZHENG[2]
[1]Zhejiang Univ. Interdisciplinary Inst. of, Zhejiang, China; [2]Interdisciplinary Inst. of Neurosci. and Technol., Hangzhou, China

Abstract: In primary visual cortex, modulation of neuronal response by stimuli in the extraclassical receptive field play important roles in visual information processing. Based on the presence or absence of surround suppression, we subdivided the neurons into two categories: surround-suppressive (SS) cells, and surround-non-suppressive (SN) cells. It is unknown whether these two types of spatial summation properties are related to neurotransmitter receptor distributions on these cells. Using in vivo single-unit recording and juxtacellular injection of tracer, combined with receptor immunocytochemistry, we have studied the immunocytochemical features of the SS and SN neurons. Significant differences were found in density of excitatory and inhibitory neurotransmitter receptors between the two types of neurons. SN neurons have densely distributed Glu2/3 receptors and relatively small amount of $GABA_A$ receptors on the surface of proximal dendrites and cell body. We found the reverse is true for SS neurons. As Glu2/3 receptors are the main targets of excitatory synaptic input and $GABA_A$ receptors are the main targets of inhibitory synaptic input, the differences in receptor characteristics between the SS and SN neurons may underlie the distinct surround modulation effects of these two types of neurons.
Key words: primary visual cortex; surround-suppressive neurons (SS); surround-non-suppressive neurons (SN); $GABA_A$ receptor; Glu2/3 receptor

Title: Large-scale system identification of mouse primary visual cortex

Authors: *D. LINSLEY, T. SERRE
CLPS, Brown Univ., Providence, RI

Abstract: The presence of significant nonlinearities in visual cortex neuron responses has impeded their characterization. Recent progress in representational learning, a branch of machine learning concerned with the discovery of optimal representations to predict data, combined with the availability of large-scale neural recordings and computational resources offer a unique opportunity to tackle this challenge. Here, we leveraged machine learning methods to model calcium imaging data from the Allen Brain Observatory. We fitted computational neuroscience models to predict neural activity from nearly 4,000 cells in layers 2/3 and 4 of the mouse primary visual cortex (VISp). We found that end-to-end trainable convolutional neural networks (CNNs) which learn filters from data offer a better fit compared to the fully-connected difference-of-gaussian (DoG) filters of previous work (Antolik et al. 2016). This is consistent with prior work on smaller datasets (Klindt et al., 2017) and suggests that feature learning and weight-sharing across the visual field supports system identification. How do these models relate to classical receptive field mapping methods? We explored this by comparing model fits to the estimated spatial profile of first-order receptive fields derived from the same neurons using sparse correlation methods. CNN fits were significantly more correlated with these receptive field profiles in layer 4 than in layers 2/3, suggesting that CNN models account for nonlinearities in the neural response not captured by linear methods. In contrast, DoG models were correlated consistently with receptive field properties across cortical layers. Together, these results emphasize the need to develop new computational- and data-based solutions for modeling the nonlinearities in neural response profiles. We expect that better neural characterizations will emerge from computational architectures which combine feedforward mechanisms with recurrent connections that implement nonlinear neural computations.

Title: Aberrant population receptive fields in albinism reveal new types of retino-cortical miswiring

Authors: *E. J. DUWELL[1], J. MATHIS[2], J. CARROLL[3], E. A. DEYOE[2]
[1]Biophysics, [2]Radiology, [3]Opthalmology, Med. Col. of Wisconsin, Milwaukee, WI

Abstract: In albinism, the temporal retinal afferents decussate pathologically at the optic chiasm, resulting in partially superimposed right and left hemi-field representations in visual cortex. Previous fMRI studies in albinism have suggested that single voxels in these regions of hemi-field overlap respond to two mirror image locations across the vertical meridian (Hoffmann et al., 2003). However, population receptive fields (pRFs) in regions of hemifield overlap in albinism have not yet been quantitatively modeled. To address this, we used conventional ring and wedge stimuli with fMRI at 3T to map cortical retinotopy and model single voxel pRFs throughout the visual hierarchy in 5 subjects with albinism. We hypothesized that voxel time courses in regions of hemi-field overlap would be best modeled by a dual rather than a single gaussian pRF model, and that these dual gaussian profiles would be positioned at approximate mirror image locations across the vertical meridian. To test these hypotheses, all voxels in visual areas V1, V2 and V3 were fit with both single and dual gaussian pRF models. We then compared the model fits by using the residual sum squared error and number of model parameters to compute Akaike's information criterion. To assess the degree to which dual pRFs were precisely mirrored across the vertical meridian, we calculated the angle formed by the line transecting the two pRF centers and the horizontal meridian. RESULTS: On average, 44.3% of all voxels in V1-V3 occurred in hemi-field overlap zones with 55.7% in non-overlap zones as determined by monocular right and left hemi-field expanding ring activation maps thresholded at a correlation coefficient of 0.3. As predicted, we found that overlap regions had a significantly higher percentage of dual pRF voxels than non-overlap regions (14.1% vs. 9.5% respectively, $p = 0.03$) and the incidence of dual pRFs was similar across all three visual areas. However, we also found that a large percentage (48.5%) of dual pRF voxels fell outside the regions of hemi-field overlap. Additionally, of the nearly 1500 dual pRF voxels which met thresholding criteria in V1-V3, 38.4% were oriented at greater than a 45-degree angle with respect to the horizontal meridian. Of this group, 38.4% were straddling the horizontal meridian rather than the vertical meridian and some dual pRFs were aligned parallel to the vertical meridian. These data reveal that the pattern of right-left hemi-field overlap in albinism is more complicated than previously appreciated and suggest that a second type of misrouting may also occur in albinism: the miswiring of the upper and lower hemi-fields to the proper side of the calcarine sulcus in V1.

Title: Circuit mechanisms of correlated neural variability

Authors: *L. NURMINEN[1], A. M. CLARK[2], A. ANGELUCCI[3]
[2]Dept. of Ophthalmology and Visual Sci., [1]Univ. of Utah, Salt Lake City, UT; [3]Ophthalmol, Moran Eye Inst., Univ. of Utah, Salt Lake Cty, UT

Abstract: Neural responses to repeated presentation of the same stimulus vary stochastically from trial-to-trial and this variability is correlated across neurons. While experimental studies have produced a detailed picture of the parameters affecting the magnitude of correlated variability, a mechanistic understanding of this phenomenon has mainly come from theoretical studies.
To uncover how feedback circuits contribute to correlated variability in primate V1, we recorded single and multi-unit responses (24-channel V-probe) through a V1 column while optogenetically inactivating feedback connections from V2. The neural silencer ArchT was expressed in V2 neurons by injecting 1:1 mixture of Cre-expressing AAV9 (AAV9.CaMKII.Cre) and Cre-dependent AAV9 carrying the genes for ArchT and GFP (AAV9.Flex.CAG.ArchT-GFP) into V2. Three 360 nl injections were made parallel to the V1-V2 border (identified using optical imaging). The axon terminals of feedback neurons projecting from V2 to V1 were selectively inactivated by targeting 565 nm light to V1 while V2 was shielded from light.
The relationship between stimulus size and correlated variability was investigated by varying the diameter of a grating centered on the receptive fields of the recorded neural population. As stimulus size was increased, correlations first increased to a peak and then began to decrease until a plateau was reached. Qualitatively, the correlation vs. size functions resembled stereotypical size tuning functions of V1 neurons. Quantitatively, however, these functions systematically peaked at a smaller stimulus diameter than the simultaneously measured size tuning functions. Thus, the relationship between firing-rate and correlation was non-monotonic. The magnitude of the correlations at the function peak was on average 0.4 vs 0.2 at the largest diameter. In some neuron pairs, positive correlation at small stimulus size turned to negative correlation when the stimulus was large. The effect of inactivating V2-to-V1 feedback depended on stimulus size. When the stimulus was small, inactivating feedback reduced correlations whereas the correlations were increased when the stimulus was of intermediate size.
Here, we provide causal evidence that feedback from extra-striate cortical areas contributes to correlated variability in primate V1. Our results suggest that evaluating the impact of correlated variability on visual information processing using a feedforward framework may prove inadequate.

Title: Neural response variability and divisive normalization

Authors: *R. COEN-CAGLI
Albert Einstein Col. of Medicine, Inc., Bronx, NY

Abstract: Variability is a widespread feature of neuronal activity in sensory cortex: repeated measurements of neuronal spike counts in response to the same sensory input are variable. Much work has been devoted to understanding how this neuronal variability might limit the reliability of perception, and what processes are in place to control it. Variability may also be a genuine coding dimension of neuronal activity, beyond average firing rate, as it is modulated by stimulus onset, stimulus dimensions (e.g. contrast, orientation), and non-sensory signals (e.g. attention, locomotion). For this reason, it is important to develop models of cortical activity that capture how changes in the stimulus affect both firing rate and variability. Linear-Nonlinear-Poisson models rely on restrictive assumptions of static nonlinearity and Poisson variability. Several extensions exist that go beyond Poisson, but they typically oversimplify, or ignore altogether, the nonlinear stimulus dependence. This nonlinear behavior is often accurately described by divisive normalization (DN), a canonical computation evident across multiple brain areas: the firing rate of a neuron is the ratio between the stimulus drive to its receptive field, and the stimulus drive to an ensemble of other neurons (termed normalization signal). However, DN models typically ignore response variability. Recent work suggests DN may also modulate variability, beyond firing rate, but this work relies entirely on simulations. To address these issues, here we derive new mathematical results linking DN and the across-trial spike count distribution. We treat the numerator and the normalization signal in DN as random variables, and derive an estimator of the mean and variance of their ratio, which provides an excellent approximation. Under plausible assumptions, this model displays Poisson-like behavior and rate-dependent Fano factors consistent with cortical data. While it is not possible to measure the normalization signal experimentally, we demonstrate how to infer its latent state using our model. We then show analytically and in simulation, that increasing the strength of the normalization signal always decreases the Fano factor. This leads us to the general prediction that experimental manipulations that engage DN should stabilize cortical activity regardless of the specific brain area and experimental manipulation. This prediction is supported by our analysis of macaque V1 data for contrast (N=3 animals) and size (N=8) tuning, and we are currently testing it in areas V2 and MT.

Title: Neighboring cortex diversely shapes stimulus responses in V1, as revealed by optogenetic suppression

Authors: *A. R. ANDREI[1], S. R. DEBES[1], R. JANZ[1], J. L. SPUDICH[2], V. DRAGOI[1]
[1]Neurobio. & Anat., [2]Biochem. & Mol. Biol., McGovern Med. Sch., Houston, TX

Abstract: Understanding how the local network context changes the responses of cortical neurons is a fundamental problem in systems neuroscience. Visual cortical neurons are embedded into local circuits consisting of excitatory and inhibitory interactions. Although local circuits are generally assumed to be homogeneous in structure, mounting evidence suggests that the variability and strength of local inputs vary significantly across the cortex. Here we examined the role that neighboring, lateral networks play in shaping stimulus responses in the V1 of awake macaque. It has been proposed that nonlinear neural responses, such as contrast response normalization, are mediated by local networks. However, this relationship has never been causally tested. To address this, we inhibited the activity of glutamatergic neurons using Gt-ACR2, a chloride-conducting channelrhodopsin, and recorded the activity of neurons several hundred microns away, while monkeys performed a contrast detection task. In the absence of a visual stimulus, the optogenetic suppression had little-to-no effect on the firing rate of the neighboring neurons. However, in the presence of a visual stimulus, we observed a striking range of contrast-dependent changes in firing rate in the neighboring cells. We report here that the neighboring network shapes stimulus responses according to 4 general motifs - weak suppression/facilitation across contrast levels, facilitation/suppression at low/high contrasts, and facilitation/suppression at high/low contrasts - present in specific proportions throughout the cortical column and within cortical layers. These response patterns are well captured by the standard normalization model, which presumes that local network provides both an additive and a divisive component to individual neurons. Our study provides the first causal evidence that the circuitry capable of mediating normalization effects is located within the local lateral network. Further, we propose that these 4 motifs are indicative of distinct classes of connection patterns between cortical columns.

Title: Corticalee column as an information-preserving decoder of neural inputs

Authors: *T. O. SHARPEE[1], J. BERKOWITZ[2]
[1]CNL-T, Salk Inst., La Jolla, CA; [2]Salk Inst. for Biol. Studies, San Diego, CA

Abstract: Cortical tissue has a circuit motif termed the cortical column, which is thought to represent its basic computational unit but whose function remains unclear. Here we propose, and show quantitative evidence, that the cortical column performs computations necessary to decode incoming neural activity with minimal information loss. The cortical decoder achieves higher accuracy compared to simpler decoders found in invertebrate and subcortical circuits by incorporating specific recurrent network dynamics. These recurrent dynamics also makes it possible to choose between alternative stimulus categories. The structure of cortical decoder predicts quadratic dependence of cortex size relative to subcortical parts of the brain. We quantitatively verify this relationship using anatomical data across eighteen mammalian species, including rodents, insectivores, and primates. The analysis identified two factors that control brain expansion within and across mammalian orders. The first factor that controls brain expansion within orders, e.g. within primates, is the average dimensionality of inputs processed by each column. Among primates, humans have the largest value. The estimated input dimensionality for the mouse matches experimental reports on the number of layer 5 projection neurons in the mouse motor cortex. The second factor, which controls brain expansion across orders, is the number of neuronal types per input dimension. It is 10 times larger in primates compared to rodents. The results account for recent observations for the small number of excitatory cell types in rodents. The also explain co-variation between the number of projection and intratelecephalic neurons in layer 5 mouse motor cortex. Overall, the results reveal a new constraint on the evolution of brain circuits and offer a new perspective on the computational function of cortical columns.

Title: Neural straightening of natural videos in macaque primary visual cortex

Authors: *Y. BAI[1], O. J. HÉNAFF[2], J. CHARLTON[1], I. M. NAUHAUS[1], E. P. SIMONCELLI[2], R. L. GORIS[1]

Abstract: Many behaviors rely on predictions about the future state of the environment derived from recent observations. Prediction is most robust along a straight, or linear trajectory. Yet, under natural circumstances, the stream of visual input typically evolves according to highly non-linear dynamics. It thus stands to reason that computations within the visual system work to linearize the temporal dynamics of visual representations, thereby enabling more robust predictions of future states of the environment. Recent psychophysical work has provided strong evidence for this hypothesis by showing that the human visual system selectively straightens the temporal trajectories of natural image sequences, thus facilitating their extrapolation (Hénaff, Goris, Simoncelli, 2018).
How does straightening emerge from the cascade of transformations performed by the visual system? We hypothesize that the successive stages of processing incrementally linearize the dynamics of visual representations. Here, we investigated the straightness (conversely, curvature) of representations of natural image sequences in the primary visual cortex (V1). We recorded neural population activity in area V1 of anesthetized macaque monkeys using multi-electrode laminar arrays while briefly presenting individual video frames taken from natural videos. As a control, we also presented stimuli taken from “unnatural” synthetic videos to determine whether neural straightening is specific to behaviorally relevant sequences. We developed a new computational analysis technique to quantify the “straightness” of a population vector’s trajectory.
Preliminary results from five V1 populations (ranging in size from 26–61 units) reveal that neural representations of natural videos exhibit trajectories that are on average straighter than the trajectories described by the stream of incoming light intensities. Moreover, neural straightening is limited to natural videos. For our synthetic, unnatural videos, we found an increase in the curvature of the neural representation relative to the intensity domain. Together, these results

suggest that computations in the early visual system contribute to realizing a major behavioral goal: making the visual environment predictable in time.

Title: Rat posterior striatum and frontal orienting fields are part of a modality-independent circuit for decision-making

Authors: *L. CHARTARIFSKY, S. PISUPATI, A. K. CHURCHLAND
Cold Spring Harbor Lab., Cold Spring Harbor, NY

Abstract: Decision-making often relies on information from diverse sources. Existing work has begun to uncover individual areas supporting this process, but structures are usually probed using sensory signals from only one modality. Therefore, little is known about whether common circuits support decisions about multiple modalities, e.g., auditory vs. visual signals. Furthermore, a major emphasis of current work is the cortex; the contribution of subcortical structures remains largely mysterious. Here, we aimed to determine whether there are brain areas causal to decisions about different sensory modalities, focusing on the frontal orienting fields (FOF) and posterior striatum (pStr). FOF, and more recently, pStr have been implicated in auditory decision-making, but little is known about their role in visual decisions. To test this, we trained freely moving rats to report whether the underlying rate of a visual, auditory or multisensory stimulus was higher or lower than an abstract category boundary. Using precise models to characterize specific perceptual parameters, we were able to describe psychophysical data and understand the involvement of pStr and FOF in multisensory decision-making. In keeping with previous findings, unilateral muscimol inactivation of FOF (n=5 rats, 0.1-0.4 ug) and pStr (n=5 rats, 0.075-0.125 ug) drove an ipsilateral bias on auditory trials. Interestingly,

decisions on visual trials showed similar bias. Our model suggested that the bias did not arise from changes in how evidence was accumulated, but instead from an increased tendency to make "guesses" in the ipsilateral direction. To determine whether changes in decision-making simply reflected an increased tendency to favor the ipsilateral side, we compared behavior on a "sure bet" task in which the rat was explicitly instructed (via a salient LED) which side would be rewarded. Performance was preserved on the sure-bet task, suggesting that behavioral effects were restricted to situations in which there was uncertainty about the correct outcome. Moreover, changes in movement time to the left vs. right reward port were small and idiosyncratic across animals and sites, suggesting that effects on decision-outcome were not due to a muscimol-induced motor impairment. Taken together, these results argue that FOF and pStr are part of a circuit common to decisions about multiple sensory modalities that is engaged during uncertain situations. Our model suggests that these areas may confer value to choices and that inactivation leads to devaluation of the contralateral choice.

Title: Dynamic representations of multiple stages of sensory-motor transformation in the lateral intraparietal cortex during decision making

Authors: *Z.-Q. LIN, Z. ZHANG, C. YIN, T. YANG
Inst. of Neuroscience, CAS, Shanghai City, China

Abstract: During decision making, one often has to accumulate multiple pieces of evidence. Previous studies have shown that neurons in the lateral intraparietal area (LIP) encode accumulated evidence for eye movement decisions. However, it is hotly debated whether accumulation occurs in the LIP or somewhere else. Here, we approach this problem with a task in which each piece of evidence has first to be assembled from different stimulus dimensions before it is accumulated. We reason that one would be more likely to observe the representations of each information processing step in the LIP if it is where the accumulation occurs.
In this two-alternative forced-choice task, the monkey viewed 6 shapes sequentially in each trial and made an eye movement choice afterwards between a red and a green target. The shapes were selected randomly with replacement from a pool of 6. Each shape could be either red or green, and was associated with a weight. The sum weight from the shapes with the same color indicated the log ratio between the likelihoods of the target with this color yielding a reward and not. Therefore, the decision of eye movements had to be accumulated from each single piece of

evidence that combined the shape's weight, color, and the target configuration.
After the monkey learned the task, we recorded LIP neurons' activities when it performed this task. We selected neurons with delay-period activity and spatial selectivity in a memory saccade task. During recordings, either the red or the green target could appear in the receptive field of the recorded neuron (T_{in}), and the other target was placed in the opposite hemifield. Consistent with the previous studies, we found that the LIP neurons encoded accumulated evidence during decision making. Furthermore, we observed that the neurons also encoded each shape's weight independently from either color or target configuration, and whether the shape's color was consistent with the T_{in} color. The representations of the weight and the color consistency were only in a transient window after each shape's onset, while the representation of the accumulated evidence for eye movements was maintained and updated when new shapes were presented throughout a trial. We, however, did not observe the representation of single piece of evidence for eye movements in the LIP. These observations suggested the LIP was likely where the sensory-motor transformation occurred during decision making.

Title: A recursive bayesian updating scheme to model the effect of prediction on individuation

Authors: *B. M. URGEN, H. BOYACI
Neurosci., Bilkent Univ., Ankara, Turkey

Abstract: Predictive computation has become a prominent alternative to model the brain function. Consistent with such computational models, previous studies showed that prior information speeds up perceptual decisions for the detection of the location of a stimulus. In this study we present a recursive Bayesian updating scheme, in which posterior of an iteration is used as the prior of the next, to model empirical results of an individuation (detection of spatial location) task within the framework of predictive computation. In the behavioral experiment centrally presented task irrelevant cues, face or house, provided information about the prior probability of the upcoming image category. Next, an intact (target) image was shown on either left or right periphery. On the opposite side a scrambled version of the same image was presented. This was followed by presentation of masks, which were different scrambled versions of the target image. Participants' task was to indicate the spatial location of the intact target

image while maintaining their fixation on the fixation dot during the trial. The validity of the category cue was set at 100%, 75%, 50%, 25% in different experimental sessions, and participants were informed about the probability of cue-validity prior to the experiments. In each trial, the duration of the target presentation was determined using an adaptive staircase procedure in a 2-AFC paradigm. Duration thresholds were computed in congruent and incongruent trials separately (in terms of cue-target category associations). Two-sample paired t-tests were conducted to investigate whether task irrelevant predictive cues (as priors) have an effect on duration thresholds in congruent and incongruent trials. The results showed that thresholds were higher in incongruent trials than in congruent trials only in 75%-validity condition, suggesting that prediction has an effect on individuation only when the prediction's validity is relatively high ($t(6)=-2.8919$, $p<0.0276$). Our Bayesian scheme was able to successfully capture the pattern observed in human observers, suggesting that schemes with iterative priors may lead to better models of human behavior than approaches using static priors.

Title: Prior information guides perceptual decision making in a remarkably flexible manner

Authors: *J. CHARLTON, Y. BAI, R. L. GORIS
Univ. of Texas, Austin, TX

Abstract: Perceptual systems operate in the presence of uncertainty. When the sensory input is ambiguous, prior experience guides our interpretation of the environment, suggesting perception obeys the laws of probabilistic inference. While some characteristics of the sensory environment are stable, others vary with context. Here, we seek to determine the limits of our ability to integrate context-specific priors with incoming sensory information when the context changes over short timescales. We measured perceptual judgments of stimulus orientation under three different task contexts, each associated with a different distribution of stimulus orientation. Stimuli were drifting sinusoidal gratings (diameter: 1.25 deg. of visual angle), presented for 500 ms in the near-periphery (eccentricity: 3.2 deg.). Prior to stimulus onset, task-context was communicated to the observer via the color of the fixation mark. Crucially, after an initial training phase, task-context could switch from trial to trial. We estimated observers' reliance on prior information by fitting their behavioral reports with an observer model in which stimuli are represented by 1-D Gaussian distributions and perceptual decisions arise from comparing the internal representation to a fixed decision-criterion. We found that different task contexts were

associated with different decision-criteria, consistent with the optimal inference strategy. Moreover, reducing stimulus contrast yielded a stronger dependency of criterion on task context, and hence a stronger reliance on prior information. Interestingly, criterion placement did not depend on the level of context stability across trials. Thus, even immediately upon switching task context, context-specific information is readily accessible to be integrated with sensory signals. Together, these findings demonstrate that the visual system flexibly deploys optimal inference strategies when performing perceptual tasks, and hence is well adapted to operate in rapidly changing environments.

Title: Sensory and decision-making processes underlying perceptual adaptation

Authors: *L. SHA[1], N. WITTHOFT[2], J. WINAWER[3], R. KIANI[4]
[1]Ctr. for Neural Sci., New York Univ. Sch. of Arts and Sci., New York, NY; [2]Psychology, Stanford Univ., Stanford, CA; [3]Psychology, [4]Ctr. for Neural Sci., New York Univ., New York, NY

Abstract: Perceptual systems adapt to their inputs. As a result, prolonged exposure to particular stimuli alters judgments about subsequent stimuli. This phenomenon is commonly assumed to be sensory in origin. Changes in the decision-making process, however, may also be a component of adaptation. Here, we quantify sensory and decision-making contributions to adaptation in a facial expression paradigm. As expected, exposure to happy or sad expressions shifts the psychometric function toward the adaptor. More surprisingly, response times show both an overall decline and an asymmetry, with faster responses opposite the adapting category, implicating a substantial change in decision-making process. Specifically, we infer that sensory changes from adaptation are accompanied by changes in how much sensory information is accumulated for the two choices. We speculate that adaptation influences implicit expectations

about the stimuli one will encounter, causing modifications in the decision-making process as part of a normative response to a change in context.

Title: Representation of the dynamics of decision-making process in the lateral intraparietal cortex during face discrimination

Authors: *G. OKAZAWA, R. KIANI
Ctr. for Neural Sci., New York Univ., New York, NY

Abstract: Past studies have shown that a frontoparietal network, including lateral intraparietal cortex (LIP), represents the dynamics of integration of evidence for sensory decisions based on simple stimuli such as stochastic moving dots or geometric shapes in probabilistic classification tasks. Our perceptual decisions, however, often involve more complex visual stimuli such as objects and faces, which are composed of multiple features. Decisions based on these stimuli are likely to rely on integration of evidence over space as well as time. Do similar decision-making processes underlie discrimination of simple and more complex stimuli? We studied population responses of LIP neurons, while monkeys performed a fine face discrimination task by reporting facial identity or expression with a saccadic eye movement. Three key features of our task made it possible to infer the computations that furnished the monkey's choice: 1) a custom-made morph continuum between two prototype faces in which different facial features could vary independently enabled us to quantify spatial integration of facial features; 2) a special masking paradigm enabled us to introduce subliminal fluctuations in the features and quantify temporal integration of evidence; 3) variable stimulus viewing duration on different trials enabled us to probe termination criterion for the decision. Similar to humans (Okazawa et al, SfN 2016), monkeys performed the task by integrating sensory evidence over space and time and varied the weighting of facial features depending on task characteristics (facial identity or expression). Compatible with previous studies, LIP neurons modulated their responses to reflect

spatiotemporal integration of sensory evidence. However, many neurons showed only small response modulations during the stimulus viewing and large modulations that reflected the choice after stimulus offset, while the monkey waited for a Go cue to initiate its saccade. Further, although response modulations during stimulus viewing represented stimulus strength, the ordering of the responses of many neurons deviated from expectations based on past studies: stimuli closest to the category boundary evoked the strongest responses for both choices. The results point at subtle but significant differences in LIP neural responses during face discrimination and direction discrimination, indicating that the same set of computations may differentially engage parietal cortex in the two tasks.

Title: Representation of choice bias in the activity of prearcuate gyrus during perceptual decision making

Authors: *G. MOCHOL[1], R. KIANI[2], R. MORENO BOTE[1]
[1]Ctr. for Brain and Cognition, Pompeu Fabra Univ., Barcelona, Spain; [2]Ctr. for Neural Sci., New York Univ., New York, NY

Abstract: Optimal decision making often depends on integration of current sensory information with prior history of choices, rewards and stimuli. Such biases may be beneficial especially when sensory information is weak or ambiguous, and prior history carries relevant information about upcoming stimuli or rewarding actions. However, little is known about the neuronal correlates of such biases and how they influence the decision-making process. Here, we report the existence of history-dependent biases in the behavior of highly-trained monkeys performing a motion direction discrimination task and demonstrate a neuronal representation of the bias in the activity of prearcuate gyrus (PAG) neurons. In our task, stimulus direction and strength varied randomly

from trial to trial, making previous history uninformative for future choices. Nonetheless, monkeys showed small but significant biases that fluctuated at two distinct time scales: slow (tens to hundreds of trials) and fast (previous trial). On each trial, fast bias reflected previous choice and outcome, while slow bias reflected the monkey's choice preference within tens of neighboring trials. Knowing these biases significantly improved our ability to predict monkeys' upcoming choice on individual trials. Importantly, the highest increase in the prediction accuracy was observed for trials with weaker motion strengths, suggesting a stronger role of prior history in shaping the choice when sensory information was limited (accuracy increase >2.5% for difficult stimulus with p(correct)<0.75, compared to a reference model with the stimulus strength as the only predictor). The pre-stimulus population activity of PAG neurons represented the fast and slow biases, indicating a correlate for both types of bias in the prefrontal cortex. The same activity was also informative about the monkey's upcoming choice with higher prediction accuracy for sessions with stronger representation of bias in PAG activity. Further analyses of a descriptive model suggested that this predictive power was a consequence of representing bias signals. Since the same PAG neurons also represented past choices and feedback that shaped the subjective bias, they could offer a compact circuit for the computation of prior history signals and leveraging those signals to guide behavior.

Title: Confidence about choices informs changes of strategy based on feedback

Authors: *M. ESTEKI[1], B. PURCELL[2], R. KIANI[2]
[1]New York Univ. Ctr. for Neural Sci., New York, NY; [2]Ctr. for Neural Sci., New York Univ., New York, NY

Abstract: Natural environments are dynamic and their changes can render known reward associations and previously successful decision strategies ineffective. When environment changes are not explicitly cued, we can learn about them and adjust our decision strategy only

based on the outcome of ongoing and past decisions. An essential computation for such learning is to determine whether negative feedbacks can be attributed to changes of the environment. We had previously shown that a Bayesian decision maker would depend on the expected accuracy of past choices to solve this attribution problem (Purcell & Kiani, 2016). Here, we test whether humans rely on their subjective confidence about choices that led to negative feedback in order to detect environment changes and update their decision strategy. Six participants performed a variant of the direction discrimination task (Britten et al, 1992). On each trial, subjects observed a patch of random dots surrounded by four targets. Each target was an elongated bar. The net motion direction was either rightward or leftward, and the targets were arranged into two pairs of right-left above and below the dots. We refer to the pairs as the upper and lower environments. Only one environment was active on each trial. The active environment stayed fixed for a random number of trials and then switched without an explicit cue. Subjects made a single saccade to one of the targets to simultaneously report their direction choice (right or left), environment choice (upper or lower), and confidence about motion direction (saccade landing point along the target). Feedback was not dependent on confidence and positive feedback was given only if the chosen target represented both the correct motion direction and the active environment. Consequently, subjects could receive negative feedback because of their mistakes about motion direction or because of changes in the environment. We show that human subjects were much more likely to switch environment following negative feedback on trials in which they were more confident about motion direction. Further, subjects were more likely to switch after a sequence of negative feedbacks, especially when they were associated with higher confidence. Finally, the influence of confidence on environment switches could not be explained by objective difficulty, as negative feedback on trials with similar motion strengths could lead to staying in the old environment or switching, depending on confidence. The results indicate that humans integrate their confidence across past choices to guide future decision strategy, mimicking a Bayesian decision maker.

Title: Visual search strategies: Performance monitoring by macaque supplementary eye field during speed-accuracy tradeoff

Authors: *T. R. REPPERT, R. P. HEITZ, J. D. SCHALL
Vanderbilt Univ., Nashville, TN

Abstract: Continuing our investigation of the neural mechanisms of speed-accuracy tradeoff (SAT), we report new observations about strategic adjustments of performance and associated neural activity in the supplementary eye field (SEF). Two macaque monkeys were trained to emphasize speed or accuracy of responding cued by the color of a central fixation stimulus. Response time (RT) was adjusted with associated changes in error rate. Monkeys had difficulty with-holding responses on trials that cued accuracy. The probability of a mis-timed response was higher in the Accurate relative to the Fast condition, particularly on trials immediately following a cue switch from Fast to Accurate responding. Thus, monkeys produced two types of errors: (1) mis-directed responses, and (2) mis-timed responses. We recorded from 72 neurons in SEF. Visually responsive neurons did not signal the location of the search target as observed (Purcell, Weigand, Schall 2012). Baseline activity and response magnitude of visually responsive neurons was higher on Fast relative to Accurate trials. Neurons signaled both mis-directed and mis-timed errors. Mis-directed errors were signaled immediately post-saccade, but mis-timed errors were signaled only after the absence of expected fluid reward. These results complement our previous findings in frontal eye field and superior colliculus (Heitz & Schall 2012; Reppert, Servant, Heitz, Schall 2018), generalize to visual search our previous findings during saccade countermanding (Stuphorn, Taylor, Schall 2000), and extend our understanding of modulation of cortical neural activity during speed-accuracy tradeoff.

Title: Visual search strategies: Priming of pop-out in macaques

Authors: *J. A. WESTERBERG, A. V. MAIER, J. D. SCHALL
Dept. of Psychology, Vanderbilt Univ., Nashville, TN

Abstract: Repetition in task performance is known to induce changes in behavioral measures. The priming of pop-out variant of visual search is one such example. In sequences of the same pop-out task (e.g. repeated trials of a red target among green distractors) response times become faster and accuracy improves with repetition. Previous work has demonstrated that concurrent with these behavioral changes are modulations in neural responses in the Frontal Eye Fields, namely enhancement of visual activity when the target appears in the receptive field of the neuron, and suppression when the receptive field contains a distractor (Bichot & Schall 2002). While priming of pop-out modulates activity in this attentional-control structure, the influence of earlier visual areas, such as V4 is unclear. Behavioral and physiological data was collected from monkeys performing a color pop-out visual search task. Target and distractor combinations were presented for ten trial blocks before a switch occurred. Each switch entailed the target color becoming the distractor and the distractor color becoming the target. The observed behavior replicated previous human and macaque work in the form of faster response times and greater accuracy with repetition across a block of trials. Further analysis of response time distributions revealed that repetition did not simply speed up response times. Specifically, rather than an overall shift in the long-tailed distribution of response times with repetition in a block, the distribution evolved to be bimodal with repetition. This finding suggests that a fast target selection process is facilitated with repetition and during task performance, both fast and slow processes can be observed.

Title: Visual search strategies: Induction of shape selectivity in macaque frontal eye field

Authors: *K. A. LOWE[1], T. REPPERT[2], J. D. SCHALL[1]
[1]Psychology, [2]Vanderbilt Univ., Nashville, TN

Abstract: Visual search task performance is influenced by rules, demands, and reward contingency. In difficult tasks, sub-optimal shortcuts may be discovered that offer a satisfying rate of reward. Sato and Schall (2003) introduced a visual search task to assess functionally distinct processing stages through the logic of separate modifiability. Monkeys attended to an elongated color singleton among distractors to encode the orientation, cuing either a pro- (vertical) or anti- (horizontal) saccade. We introduced elongated distractors, in which case the singleton cues either congruent or incongruent responses. Errors revealed three patterns: (1) errant anti-saccades avoided the singleton; (2) errant anti-saccades were concentrated on stimuli closer to the correct endpoint than to the singleton; and (3) errant saccades were directed to vertical distractors. We recorded from 141 neurons in the frontal eye field (FEF). In early sessions, where performance was markedly impaired on anti-saccade trials, Type II visual neurons, which only select saccade endpoint, were common, but Type I visual neurons, which select first the color singleton and then the saccade endpoint, were not. Unexpectedly, ~30% of the sample showed shape selectivity, even when responses were restricted to stimuli that were neither looked at nor task-relevant. This selectivity was exhibited in two ways: (1) responses to vertical stimuli were categorically distinct from responses to horizontal or square stimuli, which in turn showed identical responses; or (2) responses were graded along an aspect-ratio continuum. This finding replicates a previous discovery that feature selectivity can be induced in FEF depending on performance strategy (Bichot, Schall, Thompson 1996). These results indicate that a monkey discovered that sufficient reward could be earned just by shifting gaze to any stimulus cuing pro-saccade and demonstrate the influence of strategic factors in visual search performance.

Title: What goes where: Using stimulus representations from both visual streams to guide behavior

Authors: *W. J. JOHNSTON, K. MOHAN, D. J. FREEDMAN
Univ. of Chicago, Chicago, IL

Abstract: The primate visual system is divided into two anatomically segregated visual processing streams: The ventral “what” stream is specialized for object recognition and shape processing, culminating in the inferotemporal cortex (ITC), and the dorsal “where” stream is specialized for spatial processing and the production of visually guided behaviors, culminating in posterior parietal cortex (e.g., the lateral intraparietal area (LIP)). Here, we ask how image representations and familiarity encoding in the ventral stream region ITC can be leveraged by dorsal stream regions, such as LIP, to inform visually guided behavior.
We trained two monkeys on a preferential looking task (PLT) in which the animal freely views two natural images, each one of which the animal has seen either 0 - 10 times (novel) or >1000 times (familiar). On average, the animals viewed novel images 380 ms longer than familiar images in the first second of the free viewing period -- and made 66% of their initial saccades to the novel image. How does image familiarity influence saccade choice? Here, in each animal, we recorded from one of two brain regions believed to be involved in this task: ITC and LIP. Neurons in both regions were modulated by image familiarity during the task (50/70 units in ITC, $p < .05$, permutation test; 40/71 units in LIP, $p < .05$, bootstrapped AUC). Both regions also encoded familiarity prior to the first saccade: 75 - 100 ms prior for the ITC population (population average, $p < .05$, permutation test) and 39 - 89 ms prior for the LIP population (17/40 units, $p < .05$, Mann-Whitney U-test) -- indicating that both regions may be involved in guiding saccadic choices. In a second behavioral task in which making saccades based on image familiarity would cause the animal to make errors, we show that 37/40 LIP units reduce the strength of their familiarity modulation ($p < .05$, Mann-Whitney U-test).
We hypothesize that (1) ITC computes image familiarity and (2) LIP integrates the familiarity representation from ITC only when familiarity is relevant to the animal’s behavior (as in the PLT, but not in the second task). How is this integration performed given the differences between ITC and LIP representations? We show that two interacting populations of recurrently connected units -- one analogous to the dorsal stream, the other to the ventral stream -- can perform the integration so long as both populations encode one common, stimulus-unique feature. We argue that this commonly encoded feature is likely to be stimulus position in retinotopic space, and show how integration is altered by differences in the accuracy and resolution of ventral stream position representations.

Title: Stable encoding of visual categories during task switching in the parietal cortex

Authors: *K. MOHAN, O. ZHU, S. K. SWAMINATHAN, D. J. FREEDMAN
Dept. of Neurobiology,The Univ. of Chicago, Chicago, IL

Abstract: Primates exhibit exceptional flexibility in their behavior. Indeed, we can use the same visual input to guide a variety of decisions and actions. To understand the neural basis of flexibility, we trained monkeys to categorize the same random-dot motion stimuli under two different task paradigms - with an eye-movement versus a hand movement depending on a colored cue shown at the start of the trial. In both motion categorization tasks, monkeys grouped 360° of motion directions into two categories according to the same category boundary. In the first task (a one-interval categorization task (OIC)), a single sample stimulus was presented and the monkeys rapidly reported its category membership by making a saccade to either a red or green target to report "category 1" or "category 2" respectively. In the second task (a delayed match-to-category task (DMC)), a single sample stimulus was followed by a second test stimulus after a 1 second delay and the monkeys reported whether they belonged to the same category by releasing a manual lever to report "category match". We recorded from 102 lateral intraparietal (LIP) neurons in two monkeys during flexible switching between the OIC and DMC tasks. LIP neurons exhibited a diversity of complex response profiles with mixed tuning and dynamics to various task-relevant variables. While single neurons represented complex mixtures of task-relevant variables in both tasks, the neural population showed robust category selectivity that was remarkably similar across the two tasks. Employing SVM classifiers to quantify direction and category selectivity, we find that stimulus direction and category can be reliably decoded (75% direction decoding, 90% category decoding) during the sample period in both tasks. Critically, we show that a category decoder trained on one task can accurately generalize and decode category on the untrained task, suggesting that shared representations mediate categorical decisions in both tasks. While category-dependent responses were conserved in both tasks, other task-relevant variables such as motion direction and choice were influenced by cognitive demands unique to the OIC and DMC tasks. First, neuronal populations encoded more direction information in the OIC task than in the DMC task as evidenced by single neuron ROC measures and population decoding. Second, choice signals were independently encoded in both tasks since choice decoders trained on one task did not generalize and predicted choice accuracies at chance. Our findings demonstrate that parietal neural circuits can mediate flexible task-switching by differentially formatting relevant information in a task-dependent manner.

Title: Roles of cingulate cortex in controlling sensory-guided motor actions

Authors: *J.-H. KIM, S.-H. LEE
Biol. Sci., KAIST, Daejeon, Korea, Republic of

Abstract: Sensory information guides animals to carry out well-controlled motor actions by updating reinforcements associated with it. Rewards facilitate 'go' actions to the stimuli, whereas less reward or punishment make animals adequately take 'no-go' actions. During the perceptual behaviors, robust activities are recruited at many cortical regions, from the sensory cortex to the frontal motor areas. The cingulate cortex (Cg) has been identified as a key structure that mediates top-down modulation of visual responses in the primary visual cortex (V1) of mice. However, contribution of Cg activity in making proper motor actions to the sensory cues remains to be determined. Here, we investigated functional roles of Cg in performing the visual detection task in head-fixed mice. Pharmacological inactivation of Cg impaired both go (licking after stimuli) and no-go (no-licking without stimuli) actions with increasing impulsive licking actions. By recording single unit activities in Cg and V1, we found that Cg neurons show stronger visually-evoked responses in hit trials than miss trials. Moreover, subset of Cg neurons that are not driven by the stimuli show clear reduction in their activity during the impulsive licking in no-go trials. These action-related activities were not observed in V1 neurons, indicating that Cg neurons receiving visual inputs play crucial roles in transforming sensory information into proper motor actions. Collectively, our data demonstrate that Cg neurons encode both sensory-evoked signals that are transformed to go actions and motor inhibition signals that prevent impulsive actions to execute goal-directed behaviors in mice.

Title: Modeling three-dimensional prey capture in larval zebrafish

Authors: *A. D. BOLTON[1], M. HAESEMEYER[1], J. JORDI[1], V. MANSINGHKA[3], F. ENGERT[2]
[2]MCB, [1]Harvard Univ., Cambridge, MA; [3]MIT, Cambridge, MA

Abstract: Predatory animals rely on accurate sensory perception, predictive models of prey motion, and precise striking movements to catch moving prey. Larval zebrafish robustly intercept moving paramecia during feeding, providing a tractable model system for the study of sensorimotor integration, trajectory prediction, and spatial attention. No studies, however, have ever examined the movement patterns of hunting zebrafish in their natural 3D setting, neglecting clear vertical movements during hunting sequences. Moreover, the precise movements of paramecia have never been recorded, preventing analysis of spatial attention and trajectory prediction by the fish. To address these issues, we have constructed a 3D-imaging setup to simultaneously record the movements of fish and paramecia during prey capture. We analyze this data using BayesDB, a probabilistic programming tool used to estimate the full joint distribution of zebrafish bout statistics and paramecia movement variables. Regression models, BayesDB generated models, and ideal models generated from machine learning are compared, pointing to possible strategies fish use to capture their tortuously moving prey.

Title: Development of optogenetic tools in the optic flow circuits of birds

Authors: *M. S. ARMSTRONG[1], D. R. WYLIE[2], D. L. ALTSHULER[1]
[1]Zoology, Univ. of British Columbia, Vancouver, BC, Canada; [2]Neurosci. and Mental Hlth. Inst., Univ. of Alberta, Edmonton, AB, Canada

Abstract: As an animal moves through its environment, visual motion occurs across the entire retina. This large-field visual motion, known as optic flow, provides the primary sensory input for a diverse set of visual guidance strategies used by animals with image-forming eyes, and is used for controlling posture, locomotion and navigation. Information derived from optic flow is conveyed to the cerebellum by two specialized pathways through the midbrain, identified here by their distinct destinations in the cerebellum; the vestibulocerebellum (VbC) and the oculomotor cerebellum (OCb). Anatomical and electrophysiological studies of these circuits in birds generated the hypothesis that the midbrain-oculomotor cerebellar pathway integrates local motion with optic flow for movements involved in obstacle avoidance or flight through cluttered environments, while the midbrain-vestibulocerebellar pathway controls velocity, centering and odometry. To test this hypothesis, we have developed optogenetic protocols in these midbrain-cerebellar pathways in zebra finches (*Taeniopygia guttata*) to manipulate optic flow circuits during free flight. We have imaged successful expression of channelrhodopsin-2 (ChR2) and archaerhodopsin (Arch T) in visual nuclei in the tectofugal and visuocerebellar pathways, and we have confirmed that these regions respond to light stimulus with multi-unit optrode recordings. We chronically implanted ChR2 expressing birds with fiber optics and flew them in a tunnel with visual stimulus while tethered to a 473nm laser. Once birds acclimated to flight with the tether, we stimulated them mid-flight and tracked changes in flight behavior. To target each pathway separately, we have simultaneously begun development of terminal field stimulation and retrograde expression of opsins in the VbC and OCb. These techniques will allow us to determine whether these parallel midbrain-cerebellar pathways are responsible for different responses to visual information depending on environmental conditions like obstacle avoidance vs. centering and odometry.

Title: Modulation of visuomotor behaviour by a cholinergic midbrain circuit

Authors: *P. M. HENRIQUES, I. H. BIANCO
Neuroscience, Physiol. and Pharmachology, Univ. Col. London, London, United Kingdom

Abstract: A long-standing question in ethology is how animals are able to sustain behavioural routines that allow multiple elementary behaviours to be combined to achieve an overall goal. One example is the hunting behaviour of zebrafish larvae, which is characterized by a set of discrete visuomotor events that begin with prey detection, followed by goal-directed turns and swims and ultimately end with prey capture. The optic tectum (OT), the largest retinorecipient structure in the teleost brain, is critically required for hunting: OT neurons are tuned to prey-like visual features, tectal activity immediately precedes hunting initiation and OT ablation abolishes hunting. However, the tectum is interconnected with numerous other brain regions and little is known about how OT activity might be modulated and how activity is coordinated during behavioural routines tracking a single prey. Here we show that the nucleus isthmus (NI; homologous to the parabigeminal nucleus of mammals), a conserved midbrain cholinergic nucleus, is required for sustaining hunting routines in zebrafish larvae. We identified two types of NI neurons characterised by distinct axonal projection patterns: The first cell type targets both ipsilateral anterior OT as well as AF7, a retinorecipient pretectal region thought to be involved in hunting. The second type of NI cell projects bilaterally to the deep OT layers. Laser ablation of the NI, with subsequent analysis of naturalistic hunting behaviour, revealed that while hunting initiation rates and motor kinematics were unaltered, ablated animals showed an elevated probability of aborting their hunting routines midway through prey tracking. Other features of hunting and other visuomotor behaviours remained unaltered. Moreover, 2-photon Ca^{2+} imaging of tethered larvae under closed-loop virtual reality conditions showed that NI neurons are active during hunting behaviour. These results suggest that the NI modulates pretectal and tectal activity to allow the animal to sustain a target-directed hunting response and ultimately capture its prey. In line with a role for the NI in a midbrain attentional network in other vertebrates, this may fit within a conserved role in controlling attention to salient, ethologically relevant stimuli, thereby allowing for the maintenance of behavioural routines in the presence of competing distractors.

Title: Neuronal mechanisms of minute-long evidence accumulation in the larval zebrafish brain

Authors: *A. BAHL[1], F. ENGERT[2]
[1]Dept. of Mol. and Cell. Biol., [2]MCB, Harvard Univ., Cambridge, MA

Abstract: Signals in the natural world are often weak, noisy, or even conflicting. Hence, animals need to integrate information in both the spatial and temporal domain to decide on the next favorable behavioral action. It might take a significant amount of time until a reliable decision can be made. This poses a computational challenge for neuronal networks consisting of neurons operating on millisecond timescales. Electrophysiological recordings in primates during decision-making tasks have found brain regions with accumulating neuronal activity (area LIP). So far, due to technical difficulties in primates, comprehensive descriptions of the underlying neural mechanisms were only possible for local circuits.
Here we present a novel assay to study sensory integration and decision-making, using the larval zebrafish as a model. When presented with stimuli consisting of hundreds of moving dots, freely-moving as well as head-embedded larval zebrafish follow the overall motion coherence and improve performance over the time of stimulus presentation. We find that with increasing motion coherence, responses become more correct and occur earlier. Modeling reveals that the behavior is quantitatively explained by a classical leaky diffusion-to-bound model.
We performed brain-wide two-photon functional calcium imaging experiments and found that neurons in the anterior hindbrain have very slow dynamics, and that network as well as single neuron activity can ramp for up to a minute. More specifically we find a cluster of excitatory neurons with dynamics closely following our expectations from a slow leaky integrator. We also find an adjacent cluster of inhibitory neurons which reflect a state of stimulus uncertainty. Measuring behavioral decisions while simultaneously imaging these clusters reveals that the decision threshold for a directional swim is reached whenever the excitatory integrator population activity exceeds the uncertainty inhibitory population.

Title: Constructing behaviorally-relevant central brain representations from naturalistic motion computation in the retina

Authors: *B. T. YILDIZOGLU[1], C. RIEGLER[2], J. E. FITZGERALD[3], R. PORTUGUES[4]
[1]Max Planck Inst. for Neurobio., Muenchen, Germany; [2]Dept. of Mol. and Cell. Biol., Harvard Univ., Cambridge, MA; [3]Howard Hughes Med. Inst., Ashburn, VA; [4]Max Planck Inst. of Neurobio., Martinsried, Germany

Abstract: Sighted animals use visual information to compute environmental motion signals that guide behavior. Prior studies have shown that visual processing in multiple species is tuned for computational cues that accurately predict motion under naturalistic stimulation conditions. However, the circuits implementing naturalistic motion-guided behavior in vertebrate nervous systems remain unclear. Here we show that neurons in the larval zebrafish pretectum integrate retinal signals tuned for naturalistic motion cues to represent visual motion stimuli according to their relevance for optomotor behaviors. We focus on behavioral responses to glider stimuli, a set of complex stimuli that have previously been linked to naturalistic motion processing. We observed that zebrafish exhibit strikingly similar behavioral responses to those found in flies. We then imaged fluorescence calcium responses of neurons in the pretectum, which is implicated in several motion-guided behaviors. Interestingly, we found that we could accurately model the responses of pretectal neurons as a threshold-linear combination of stimulus response patterns corresponding to several elements of optomotor behavior, and neurons were spatially-clustered according to their behavioral correlates. Finally, we imaged functional signals from RGC axon terminals, using transgenic larvae that expressed presynaptically localized SypGCaMP6s under control of the RGC-specific promoter Islet2b, to find retinal ROIS with response patterns sufficient to construct the pretectal representation. Thus, the zebrafish retina extracts diverse higher-order motion cues necessary for naturalistic behavior. The principles, algorithms, and circuits of visual motion processing seem remarkably conserved across the animal kingdom, so our results likely pertain to motion-guided behaviors in diverse vertebrate nervous systems.
All experiments were performed on larval zebrafish (6-7 dpf) in four experimental cohorts. Behavioral responses in freely swimming zebrafish were measured for 140 fish. Fluorescent calcium responses in the zebrafish pretectum were imaged in 35 head-embedded fish. We simultaneously measured pretectal and behavioral responses in 8 tail-free but head-embedded fish. Finally, fluorescent calcium responses from retinal ganglion cell arborization field in the central brain were measured in 42 fish.

Abstract: Simultaneous recordings of large populations of neurons in behaving animals allow detailed observation of high-dimensional, complex brain activity. However, experimental design and analysis approaches have not sufficiently evolved to fully realize the potential of these methods. We recorded whole-brain neuronal activity for larval zebrafish presented with a battery of visual stimuli while recording fictive motor output. These data were used to develop analysis methods including regression techniques that leverage trial-to-trial variations and unsupervised clustering techniques that organize neurons into functional groups. We used these methods to obtain brain-wide maps of concerted activity, which revealed both known and heretofore uncharacterized brain nuclei. We also identified neurons tuned to each stimulus type and motor outputs, and revealed nuclei in the anterior hindbrain that respond to multiple stimuli that elicit the same behavior. However, these convergent sensorimotor representations were not tuned to instantaneous motor behavior, suggesting that they inform, but do not directly generate, behavioral output. These findings motivate a novel model of sensorimotor transformation spanning distinct behavior contexts, within which these hindbrain convergence neurons likely constitute a key step. We make these data and analysis resource publicly available to facilitate reuse of our methods and enable further community efforts for mining these datasets.

Abstract: Neuromodulatory systems can introduce flexibility in the way neural circuits process information and generate behavior, allowing animals to adapt to changing environments and behavioral demands. Modulations in swim vigor of larval zebrafish can be induced by cells in the serotonergic system, as their neural responses track the outcomes of actions and adjust behavior when these outcomes are of an unexpected magnitude. Here we extend the investigation of brainwide experience-dependent neuromodulation to other neuromodulatory systems by combining whole-brain light-sheet imaging in virtual environments with anatomically-specific delineation of neuronal populations and with brainwide activity perturbations. We imaged the entire brain at single cell resolution across multiple behavioral paradigms, and systematically searched the brain for signals that preceded, coincided, and followed behavioral switches. We implemented an automated cell-detection algorithm, factorized the resulting spatiotemporal data into groups of cells with similar activity, and standardized these brain areas across fish. By searching for neuromodulatory systems activated during behavioral switches, we found that the noradrenergic system modulates behavior and tracks the outcomes of swim actions in a complementary way to the serotonergic system. We identified downstream populations of cells that modulate neural dynamics in premotor circuits, and describe the computational properties of the neuromodulatory systems to delineate which experiences trigger their neuromodulatory output. Together these neuromodulatory systems enable experience-dependent modulation of brain state and behavior across different behavioral regimes.

Abstract: Vertebrate eye movements are implemented largely in the brainstem by distinct nuclei where multiple sensory afferent axons converge very close to motor nuclei that control eye muscles.This includes inputs from the vestibular and saccadic neurons and outputs to abducens and oculomotor motor neurons. Many aspects of how unique sensory signals from these distinct neurons converge and transform to result in coordinated eye movement is not well understood. To understand the mechanisms by which this signal transformation occurs, we aim to anatomically reconstruct neurons involved in this circuit at synaptic resolution using serial-section electron microscopy (ssEM). To do this we combined two-photon functional calcium imaging followed by ssEM in the larval zebrafish. By registering functional calcium images to ssEM images we located neurons that carried eye-position sensitive signals, within the EM volume. This includes neurons that perform a velocity-to-position integration or neural integrators. Next, using machine learning and a crowd-sourced platform, we reconstructed ~3000 neurons that were synaptically connected to neurons that carried eye-position sensitive signals. We reconstructed neurons from areas involved in saccade production, neurons near vestibular nuclei, neurons involved in velocity-to-position integration and neurons in the abducens motor complex. This encompasses the flow of eye-position related signals, from sensory to motor neurons. From these reconstructions, we observed that the integrator neurons were comprised of at least three distinct groups of neurons, two of which are putative excitatory and one which is putative inhibitory. We further observed direct synaptic contacts between integrator neurons, consistent with our understanding of how integration can be performed by means of positive feedback. Similarly, we observed direct synaptic contact between the putative saccadic and vestibular neurons onto the abducens motor neurons. Finally, we classified the reconstructed neurons based on their features and constructed the connectivity matrix of all reconstructed neurons to reveal the organization of neurons that carry eye-position signals.
