Title: Characterizing retinal regeneration in a genetic mouse model of glaucoma

Authors: *J. R. PARIS[1], N. C. SKLAR[2], C. L. LINN[1];
[1]Biol. Sci., Western Michigan Univ., Kalamazoo, MI; [2]Homer Stryker MD Sch. of Med., Kalamazoo, MI

Abstract: Glaucoma is a degenerative retinal disease characterized by loss of vision due to progressive loss of retinal ganglion cells (RGCs). Previous studies in this lab have shown that the application of a specific α7 nicotinic acetylcholine receptor agonist, PNU-282987 (PNU), to the murine eye induces neurogenesis of numerous retinal cell types, including retinal ganglion cells (Webster et al., 2017). The aim of this study is to characterize the short-term and long-term effects of PNU in a glaucoma model. To address this issue, the effects of PNU were analyzed in a DBA/2J mouse model that auto-induces a glaucoma-like condition in adulthood. These mice manifest an elevated intraocular pressure (IOP) starting at 6 months, followed by loss of ganglion cells. We hypothesized that PNU would act to regenerate new retinal neurons in a genetic mouse model of glaucoma. PNU (1mM) and BrdU (1 mg/mL) were applied as eye drops for 2 weeks to male and female DBA/2J mice at various ages (3, 6, and 10 months) to determine the regenerative effects that occur at each of these time points. After two weeks of treatment, the retinas from both the control animals and from the treatment animals were removed, fixed, processed using IHC procedures, and RGC regeneration was assessed and compared. Antibodies against BrdU were used to identify new cells. Retinal ganglion cells were identified using antibodies against Thy-1.2. Cell counts were obtained using confocal images of flat mounted retinas. Four images were taken of the retinal ganglion cell layer of each retina, each image taken from a different quadrant of the retina and RGC counts were averaged. A one-way ANOVA was used to compare the number of cells between the different time points. IOP measurements were obtained under control and treated conditions. IOP measurements in untreated animals significantly changed from an average of 10.79 to an average of 19.79 mmHg ($p \leq 0.01$; $n=8$). Results showed a significant loss of retinal ganglion cells between the 3-month-old and the 10-month-old control mice ($p \leq 0.01$; $n=5$). The average number of RGCs dropped from 310($\pm$21) in 3 month DBA/2J animals to 221($\pm$12) in 10 month DBA/2J animals, a loss of about 30%. Similarly, the 10-month-old DBA mice had about 25% fewer cells than non-DBA control mice

at the same age ($p \leq 0.01$; n=5). The addition of PNU caused about a 15% increase in the number of retinal ganglion cells in all time points compared to the untreated DBA/2J retinas ($p \leq 0.01$, n=4). These were verified to be new cells using BrdU labeling. PNU treatment had no effect on IOP measurements. These results suggest the future clinical potential of PNU-282987 in the treatment of degenerative retinal diseases.

Abstract: Although new neurons continuously generated in the ventricular-subventricular zone (V-SVZ) migrate toward the lesion, the ability of the mammalian brain to regenerate neuronal circuits for functional recovery is quite limited. We investigated the mechanism regulating migration of the new neurons and their involvement in functional regeneration using a mouse

model for ischemic stroke. By time-lapse imaging and immunohistochemistry, we found that migration of immature new neurons referred to as neuroblasts was restricted by astrocytes activated in response to the tissue damage in and around the lesion. The neuroblasts secreted a diffusible protein Slit1 to disrupt the actin cytoskeleton in activated astrocytes at the site of contact via its receptor Robo2 for their migration through the meshwork of the astrocytic processes. By enhancing the Slit1 expression, V-SVZ-derived neuroblasts transplanted into the post-stroke brain could migrate closer to the lesion in the dorsolateral striatum. Some of the transplant-derived cells differentiate into mature neurons possessing morphological and electrophysiological properties of the striatal projection neurons. The proportion of the transplant-derived axons projecting into the lateral globus pallidus, where neurons in the lateral striatum preferentially project under physiological conditions, was significantly increased in the Slit1-overexpressing group compared with the control, suggesting that the new neurons that were positioned close to the injured area functionally replaced the neurons lost by stroke. Slit1-overexpression further caused long-lasting functional recovery in the post-stroke animals. Taken together, these results suggest that the positioning of new neurons is critical for functional neuronal regeneration in stem/progenitor cell-based therapies for brain injury.

Title: Endocannabinoid signalling during axolotl spinal cord regeneration

Authors: M. TOLENTINO, M. MORNEAULT, G. SPENCER, ***R. L. CARLONE**;
Brock Univ., St. Catharines, ON, Canada

Abstract: Research into the molecular mechanisms of the psychoactive effects of cannabis has led to the discovery of the endocannabinoid system (ECS), a neuromodulatory system conserved in many organisms. Although evidence for its modulatory role in normal CNS development is increasing, far fewer studies have focussed on its function in response to trauma in the CNS in mammals. Moreover, little is known regarding the role of endocannabinoids in CNS regeneration-competent amphibian species like the axolotl, one of the few vertebrates that can

regenerate a functioning spinal cord. We provide preliminary evidence that expression of the two main ECS receptors in the CNS (CB1 and CB2) are upregulated in the regenerating caudal spinal cord and tail tissues of larval axolotls at 7 and 14 days post amputation. In addition, bath application of the CB1 selective antagonist/reverse agonist, AM251, significantly inhibited caudal growth of the spinal cord and tail by 7 days post amputation. Preliminary immunofluorescence studies demonstrate expression of this receptor primarily in the ependymal cells of the spinal cord and dermal tissue of regenerates. The determination of CB1 and CB2 mRNA levels by qPCR and further immunofluorescent analyses to identify the tissue and cellular distribution of both receptors during specific stages of regeneration and after inhibition with AM251 (and AM630, a selective CB2 reverse agonist) are presently underway. Studies to assess the effects of CB1 and CB2 inhibition on proliferation and differentiation of ependymoglial cells as well as the production of transgenic animals expressing optogenetically regulated CB1 and CB2 receptor reporter constructs are in progress. These studies are the first to determine the role of the ECS during spinal cord regeneration in a regeneration-competent vertebrate, and may aid in developing novel therapies for human nervous system injuries or pathologies.

Title: Glia-like cells from human adult stem cells protect against ischemic stroke through IGFBP-4

Authors: J. SON[1], J. PARK[2], Y. KIM[1], J. HA[2], D. PARK[1], S.-H. KOH[1], ***M.-S. CHANG**[2]; [1]Hanyang Univ. Col. of Med., Seoul, Korea, Republic of; [2]Seoul Natl. Univ., Seoul, Korea, Republic of

Abstract: Early-passage human mesenchymal stem cells (hMSCs) are typically used in clinical trials because of safety and efficacy issues. However, obtaining sufficient cells for treatment is difficult and expensive. Many more late-passage hMSCs can be obtained at lower cost, although efficacy is a large hurdle in clinical trials. The use of late-passage MSCs with better efficacy

would be a revolutionary solution for reducing cost and facilitating clinical trials. In the present study, glia-like cells (ghMSCs) were induced from hMSCs and used for both in vitro and in vivo models of ischemia, effectively protecting neurons from ischemia and restoring brain tissue damaged by cerebral infarction. These beneficial effects were significantly blocked by insulin-like growth factor-binding protein-4 (IGFBP-4) antibody. The current study demonstrated that late-passage hMSCs can be efficiently induced into ghMSCs with a better neuroprotective effect against ischemic stroke and that IGFBP-4 may be a key neuronal survival factor secreted by ghMSCs.

Title: Single cell transcriptional profiling of the corticospinal tract

Authors: *N. GOLAN[1], K. P. LUTTIK[1], W. B. CAFFERTY[2];
[2]Dept. of Neurol., [1]Yale Univ., New Haven, CT

Abstract: In addition to regeneration of axotomized CNS axons, localized sprouting or plasticity of intact axons plays an integral role in functional recovery after spinal cord injury (SCI). Therefore, defining and exploiting the molecular machinery that drives growth of intact axons post-injury could be a valuable approach to repair after SCI. The corticospinal tract (CST) presents a unique opportunity to explore the molecular mechanisms that are required to 'build' and 'rebuild' a spinal tract, as it transitions early postnatally from a growth competent mode (P0-10, build phase), to a circuit refinement mode (P14-P28, 'critical period'), to an adult growth incompetent mode (P56 and beyond), and critically, undergoes functional plasticity after partial SCI (re-build phase).
To explore the molecular mechanisms of these growth phases, we utilized the CST-specific *crym*-GFP mouse line to selectively isolate and transcriptionally characterize corticospinal motor neurons (CSMNs) in neonatal (P5), adolescent (P28) and adult (P56) mice using laser capture microdissection followed by bulk RNAseq. At P5, we identified differentially expressed genes associated with axon guidance, including *Robo1* and *sema6D*, consistent with CSMN pathfinding; at P28, genes associated with synaptic refinement, such as the *synaptotagmins*, consistent with CSMN synaptogenesis and pruning; and at P56, genes associated with synaptic

transmission, such as *Grik3* and *Grik4*, consistent with synaptic homeostasis. These temporal differential gene expression analyses reveal that a spectrum of cell autonomous growth machinery is engaged to build and sculpt a functional CST. However, while bulk sequencing of CSMNs broadly uncovers robust transcriptional events defining these growth epochs, it lacks the resolution to identify discrete anatomical and/or functional sub-populations.
To address this, we developed a method to identify and isolate single CSMNs at P5, P28, and P56. To gain functional specificity we used a layer V specific *cre* line (retinol binding protein-4, *rbp4-cre*) crossed with a Ai14 reporter line. To gain anatomical specificity we used retrograde viral tracing from the cervical spinal cord. We then leveraged fluorescent activated cell sorting (FACS) and single cell RNA sequencing (scRNA-seq) to comprehensively characterize CSMN heterogeneity and uncover the emergence of CSMN populations during these critical time points. These data will lay groundwork for identifying key intrinsic modulators of CST patterning to singularly or sequentially exploit after SCI.

Title: Sequential generation of neuronal cell types in the regenerating adult zebrafish retina

Authors: *M. LAHNE, D. R. HYDE;
Biol. Sciences, Ctr. for Stem Cells and Regenerative Med., Univ. of Notre Dame, Notre Dame, IN

Abstract: Müller glia in the damaged adult zebrafish retina reenter the cell cycle to produce neuronal progenitor cells (NPCs) that continue to proliferate and ultimately differentiate into both the lost neuronal cell types and those unaffected by the damage stimulus. Generating all neuronal cell types raises the questions, whether NPCs commit to different neuronal cell fates in a sequential order that is similar to retinal development and whether additionally-produced neuronal cell types integrate into the retinal circuit. To test whether retinal neurons in the regenerating retina are generated sequentially, *albino;Tg[atoh7:GFP]* or *albino;Tg[ptf1a:GFP]* zebrafish, which drive GFP expression under the control of either the ganglion or amacrine/horizontal cell commitment factors, respectively, were exposed to constant intense light for up to 96 hours (hLT). While Müller glia and NPCs proliferated at 36 and 48 hLT,

atoh7:GFP was only robustly expressed in a subset of NPCs in the inner (INL) and outer nuclear layers (ONL) starting at 60 hLT. In contrast, GFP expression under the *ptf1a* promoter began at 72 hLT in the INL and ONL, suggesting that amacrine/horizontal cell fates are induced subsequent to ganglion cell fates. Similarly, *atoh7:GFP*-positive cells expressed the postmitotic ganglion/amacrine cell marker, HuC/D, in the INL at 72 hLT prior to the presence of HuC/D in *ptf1a:GFP*-positive cells at 84 hLT. The *atoh7:GFP* and HuC/D double-positive ganglion cells began to accumulate in the ganglion cell layer (GCL) at 84 and 96 hLT. Retinal flatmounts revealed that these GCL-based *atoh7:GFP*-positive cells displayed neurite/axonal outgrowth at 84 hLT and subsequently at 96 hLT, *atoh7:GFP*-positive axons began fasciculating to form nerve tracks. A subset of INL-based *ptf1a:GFP*-positive amacrine cells also properly projected their axons to the inner plexiform layer at 96 hLT. In summary, temporal ganglion and amacrine/horizontal specification in the light-damaged retina mimics the sequential order of cell type determination in development and these newly produced ganglion/amacrine cells, which were not lost in response to light-damage, display properties of cells integrating into the neuronal circuit in the adult regenerating zebrafish retina.

Title: Application of an alpha7 nicotinic acetylcholine receptor agonist in the adult mammalian retina causes retinal pigment epithelium mediated neurogenesis and regeneration in a murine glaucoma model

Authors: *S. E. WEBSTER[1], N. C. SKLAR[2], M. K. WEBSTER[1], D. M. LINN, Jr[3], C. L. LINN[1];
[1]Biol. Sci., Western Michigan Univ., Kalamazoo, MI; [2]Western Michigan Univ. Homer Stryker MD Sch. of Med., Kalamaoo, MI; [3]Biomed. Sci., Grand Valley State Univ., Allendale, MI

Abstract: Neurodegenerative diseases of the eye cause blindness and are incurable. Application of PNU-282987 (PNU), an α7 nicotinic acetylcholine receptor agonist (nAChR), causes neurogenesis of the retina in the adult mammal (Webster et. al. 2017). These new neurons arise from the Müller glia (MG) which mirrors regeneration in other vertebrates. However, the MG lacks α7 nAChRs. Our objective was to better understand where PNU acts in the mammalian eye

to initiate neurogenesis and determine if PNU causes regeneration of new retinal ganglion cells (RGCs) in a glaucoma model. Our hypothesis was that PNU activates retinal pigment epithelium (RPE). To test this, RPE-J cell lines were treated with PNU for 24 hours before extensive washing. After 72hr in culture, the supernatant was collected and injected into both male and female adult mouse eyes. BrdU (1mg/mL) eyedrops were given for 7 – 14 days. IHC demonstrated incorporation of BrdU in all three nuclear layers after supernatant injection. In the INL, treated-RPE supernatant induced 50% (±10) BrdU-positive cells. To validate that PNU works through the α7 nAChRs in the RPE-J cell line, cells were pre-treated with an α7 antagonist, MLA, before PNU treatment. MLA decreased BrdU-positive cells to less than 5% (±1) which represents a significant reduction from those treated with PNU-modified supernatant ($n=6, p\leq 0.01$). To analyze potential genes involved in this process, RNAseq was performed on PNU-treated RPE-J cells. Cells were treated with PNU for 0.5, 1, 3, 8, and 12 hours before total RNA was collected (RIN ≥ 7.0). Controls were DMSO-treated, MLA-treated, and nicotine-treated. RNA was processed by GeneWiz; fold-change data was analyzed in Excel and pathway analysis through Reactome software. Resulting signaling molecules were mapped for fold-change expression over time. To determine if PNU can act in a regenerative capacity, we examined the effect of PNU in an induced mouse model of glaucoma. Control retinas with glaucoma show an average loss of 25% (±5) of Thy1.2-positive RGCs 28-days post induction surgery, which were correlated with an average increase of IOP to 14.38 mmHg (±1.7). Glaucomatous retinas treated with PNU for 7 days showed regeneration and RGC cell counts returned to control levels. This research demonstrates a novel mechanism for mammalian retinal neurogenesis mediated through RPE cells and indicates the influence of several important signaling molecules. Further, this work shows that PNU treatment caused regeneration of RGCs after damage has taken place. This is significant as it points to a potential therapeutic approach to the millions affected by neurodegenerative retinal diseases.

Title: Changes in gene expression associated with dedifferentiation of Müller glia in response to an alpha7 nicotinic acetylcholine receptor agonist

Authors: *M. L. STANCHFIELD, S. E. WEBSTER, M. K. WEBSTER, C. L. LINN;
Biol. Sci., Western Michigan Univ., Kalamazoo, MI

Abstract: The adult mammalian retina does not typically regenerate. As a result, there is no cure for neurodegenerative diseases, such as glaucoma. We have found dedifferentiation of Müller glia (MG) occurs in the adult mammalian retina after application of an α7 nicotinic acetylcholine receptor (nAChR) agonist, PNU-282987 (PNU), to retinal pigment epithelial (RPE-J) cells in adult rodents (Webster, et al., 2019). RNAseq was performed in a MG cell line to determine changes in gene expression profiles following contact with RPE-J cells treated with PNU. RPE cultures were treated for 24 hours with 100 nM PNU and thoroughly washed to remove any residual PNU. MG were then exposed to treated RPE cells using a transwell system for 8, 12, 24 and 48 hours. A separate RPE culture was treated with DMSO for 48 hours as a vehicle control. Total RNA extracted from MG was sent to GeneWiz for Next Generation Sequencing (RIN>7) and basic bioinformatics was performed to determine significant changes in expression following transwell culture with treated RPE-J cells compared to control conditions. Up or down-regulated genes were compared with published literature of MG dedifferentiation that occurs in lower vertebrate regeneration or during early mammalian development. Between 8-12 hours, upregulation was observed in heparin-binding epidermal-like growth factor (HB-EGF) (log_2 fold change (FC) increase of 1.92). HB-EGF is rapidly induced in MG residing at an injury site in the neuronal retina of zebrafish and has been found to regulate the expression of Ascl1 (Goldman, et. al., 2012). After 48 hours, significant upregulation was found in genes Ascl1 (log_2 FC increase of 3.99) and Lin28a (log_2 FC increase of 4.77). Both Ascl1 and Lin28a are rapidly induced in dedifferentiating MG following injury in zebrafish. Ascl1 is a transcription factor essential for retinal regeneration in zebrafish (Goldman, et. al., 2008). Lin28a is an RNA binding protein whose expression has been found to share characteristics with embryonic stem cells (Nimmo & Slack, 2009). Importantly, downregulation was observed in BMP4 (log_2 FC decrease of -1.43) after 8 hours, which is a glial differentiation signal found to be necessary to fully repress glial gene expression for neurogenesis in early development in mice (Ueki, et al., 2015). These results suggest that MG are dedifferentiating in response to PNU-treated RPE-J cells. Analyzing these changes in gene expression could lead us to further our understanding of the barriers associated with adult mammalian neurogenesis and provide potential strategies to treat neurodegenerative diseases.

Title: The involvement of reactive glial cells in the formation of ectopic corticofugal projections after cortical ablation

Authors: L. CHANG, *N. SUGO, N. YAMAMOTO;
Osaka Univ, Grad Sch. Frontier Biosci, Suita, Osaka, Japan

Abstract: The brain function is known to recover after the injury by reorganizing neural circuits. After a unilateral cortical lesion, descending axons from the intact cortex are known to project ectopically to the contralateral midbrain nuclei, contributing to the functional recovery. However, the molecular mechanism for the lesion-induced axonal remodeling remains unknown. To address this issue, we investigated gene expression in the midbrain after unilateral cortical ablation, under the hypothesis that growth promoting factors are expressed in the denervated midbrain. For this, RNA-Seq analysis and the subsequent *in situ* hybridization were performed in the midbrain 2-4 days after hemispherectomy at P6 mice. The analyses demonstrated that a significant number of genes were upregulated in the denervated midbrain compared to the intact side and control midbrains, and were mostly found to be those expressed by astrocytes or microglia. Immunohistochemistry further revealed that GFAP-positive reactive astrocytes were distributed not only at the cerebral peduncle of the denervated midbrain but also at the area near the midline. Iba1-positive ramified microglia were broadly distributed in the midbrain after hemispherectomy, and Arg1-positive M2 microglia, a fraction of microglia, which are known to produce axon growth factors were also present in the denervated midbrain. Moreover, corticofugal axons labeled with EGFP by *in utero* electroporation at E12.5 were found to grow in the vicinity of the region where reactive glial cells emerged after hemispherectomy. Taken together, the present results demonstrate that reactive astrocytes and microglia cells emerge in the denervated midbrain and around the midline after hemispherectomy, suggesting that growth-promoting factors produced by reactive glial cells may contribute to the reorganization of axonal projections after the cortical injury.

Title: Enhanced stem cell therapy as a delayed treatment strategy for neonatal stroke

Authors: A. LARPTHAVEESARP[1], P. PATHIPATI[1], A. RAJAH[1], S. OSTRIN[1], D. M. FERRIERO[2], *F. GONZALEZ[1];
[1]UCSF, San Francisco, CA; [2]Pediatrics, Univ. of California San Francisco, San Francisco, CA

Abstract: Background: Stroke in the newborn period is a significant cause of mortality and life-long morbidity. In recent years, cell-based therapies have emerged as a potential treatment for different various CNS diseases. These improved outcomes occur even in the absence of survival of engrafted cells, suggesting transplanted cells may induce repair by stimulating secretion of growth and differentiation factors that provide an environment to enhance repair. It is possible that growth factors that have specific effects on stem cell function, including their role in the development of the neurovascular unit and cell fate, may provide additional benefit. **Objective**: To compare the efficacy of single-dose mesenchymal stem cells (MSC) pretreated with erythropoietin [EPO] (MSC-EPO) into the rat CNS versus MSC alone following transient neonatal focal ischemia-reperfusion on long-term histological and behavioral outcomes. **Design/Methods**: Focal cerebral ischemia-reperfusion was performed in P10 Sprague-Dawley rats by transient right middle cerebral artery occlusion (MCAO) for 3 hours, or sham surgery under isoflurane anesthesia. This age is considered equivalent to the full-term human newborn. Either vehicle, MSC ($1x10^6$ cells) or MSC pre-treated with EPO (1 IU/mL x 24 hours) were administered intranasally 72 hours following reperfusion. N=8 per group. Animals underwent sensorimotor (cylinder rearing) and cognitive (novel object recognition) testing at 8 weeks of age, after which brains were harvested for histological analysis. **Results**: MSC alone and MSC-EPO groups had a significant improvement in calculated hemispheric brain volumes (ipsi/contra ratio) at 2 months of age. While both treatment groups had improved sensorimotor function and cognitive memory retention testing compared to vehicle-treated MCAO animals, MSC-EPO animals had a significant improvement in both functional measures compared to MSC alone animals. **Conclusions**: A delayed, single-dose combination strategy to enhance cell type-specific effects using MSC and EPO provides the most long-term benefit following early stroke, lasting until young adulthood. The specific effects of this strategy on vasculogenesis, cell proliferation and fate remains to be determined.

Title: Development of clarified tissue scaffold using oil-based decellularized method for tissue engineering

Authors: *Y.-J. JANG, B. HA, S.-J. JEONG;
Korea Brain Res. Inst., Daegu, Korea, Republic of

Abstract: Tissue engineering is a field of regenerative medicine ranging from cells to artificial organs. It is based on a discipline that deals with biological and engineering techniques from biomaterials to materials that can help restore tissues and organs. Various methods have been studied to understand the relationship between structures and function of living tissue, and further to make a living body substitute and implant, thereby restoring, maintaining and improving the functions of the body. Particularly, one of the key technologies of tissue engineering is to produce scaffolds that support cells to grow, and the scaffolds are usuful for the biomedical engineering. The scaffolds can be made of a variety of materials, and the related studies are being actively conducted to develop a scaffold for tissue regeneration using natural materials, synthetic polymers, bioceramics, and polymer-ceramic composite materials. Among various tissues in the human body, brain tissue has higher cell density and weaker mechanical strength of tissues than other body tissues. When cells are removed by applying a general decellularization method for the production of scaffolds, the various problems have to be considered because the tissue is easily to be damaged and the shape is not completely preserved occurring the low reproducibility. In order to develop the suitable decellularization method for brain tissue, several attempts have been made to solve these problems by changing various parameters such as concentration of several chemical components, appropriate temperature and time. In this study, we confirmed that it is possible to preserve the intact form of brain and microarchitecture when the fixed brain tissues were decellularized with 4% hydrogel followed by the immersion in oil. Moreover, the protein and extracellular matrix present in the tissue are observed as an intact form without any damaging. Therefore, we suggest that this method can be widely used in various fields requiring tissue regeneration.

Title: High resolution 3D imaging and analysis of axon regeneration in unsectioned spinal cord with or without tissue clearing

Authors: *B. J. HILTON[1], O. BLANQUIE[1], A. TEDESCHI[2], F. BRADKE[1];
[1]Deutsches Zentrum Für Neurodegenerative Erkrankungen E.V. (DZNE), Bonn, Germany;
[2]Neurosci., The Ohio State Univ., Columbus, OH

Abstract: Here we present a protocol for analyses of axon regeneration and density in unsectioned adult mouse spinal cord. This includes methods to injure and trace dorsal column sensory and corticospinal axons; clear and stain unsectioned spinal cord; visualize axon degeneration and regeneration in cleared and uncleared specimens using 2-photon microscopy; and analyze axon density and regeneration in 3-dimensional space either manually or semi-automatically using Imaris and ImageJ software. This protocol can be used to understand the molecular and cellular mechanisms underlying nervous system degeneration and regeneration and to establish the therapeutic efficacy of candidate neuroregenerative treatments. By obviating tissue sectioning, this protocol enables unambiguous evaluation of regeneration and greatly accelerates the speed at which analyses can be conducted. Surgical procedures take <30 min per mouse, with a wait period of 2 weeks between axonal injury and tracing and 2-8 w between tracing and tissue processing. Clearing and immunolabelling take ~1-2 w depending on the size of the sample. Imaging and analysis can be performed in 1 d. All these procedures can be accomplished by a competent graduate student or experienced technician.

Title: RGDS and IKVAV peptide-modified capillary alginate hydrogels to improve axon regeneration after spinal cord injury

Authors: *P. KUMAR[1], R. MÜLLER[2], A. BLESCH[1];
[1]Dept. of Neurolog. Surgery, Indiana Univ. Sch. of Med., indianapolis, IN; [2]Dept. of Physical and Theoretical Chem., Univ. of Regensburg, Regensburg, Germany

Abstract: Biomaterials in combination with other experimental approaches such as cell grafts have shown some promise in promoting tissue sparing, increasing remyelination and enhancing axonal regeneration in the injured spinal cord by providing physical and chemical guidance cues. Frequently, biomaterials with a random spongy microstructure, which only promote randomly oriented axonal growth, have been examined limiting the lesion distance that can be bridged. To overcome these problems, we have used alginate-based hydrogels with linear anisotropic capillaries.
Previously, we have shown that these alginate hydrogels are stable, biocompatible and support linear host axon growth into and beyond a lesion site. In the current study, we modified the surface of the hydrogels with RGDS and IKVAV peptides, the active fragment of fibronectin and laminin, respectively. An N-terminal positively charged poly-L-lysine tail was included in active peptides (K12-QAAGRGDS and K12-QAASIKVAV) for electrostatic binding to -at physiological pH- negatively charged hydrogels. Uncoated and poly-D-lysine (PDL) coated gels served as controls. ELISA depletion assays with hydrogel blocks (2×2×1.3 mm) showed that the blocks were saturated with 50-100 µg of each peptide after incubation at 37°C for 16h. *In vitro*, hydrogel slices (7×7×0.2 mm) modified with RGDS peptide resulted in a 2-fold increase in the attachment of postnatal day 4 astrocytes compared to PDL-coated hydrogels after 16h. The same effect was also observed when coated hydrogels were first incubated for one week at 37°C in PBS with daily washing. Furthermore, surface modification using IKVAV peptide showed a 27% increase in neurite length from differentiated E14 neural stem cells (NSCs) compared to PDL-coated hydrogels 48h post cell seeding. To evaluate whether peptide modification enhances *in vivo* bridging of neural stem cell transplants across a lesion site, adult female F344 rats underwent a C4 unilateral hemisection (removing 2 mm spinal tissue) followed by implantation of hydrogel blocks and grafting of E14 NSCs rostral to the lesion site. Ongoing tissue analyses examine whether peptide-modified hydrogels improve bridging of grafted axons into the distal spinal cord, and/or promote host axon regeneration.

Title: Effects of neuronal loss and regeneration on learning and memory in adult zebrafish

Authors: *K. SKAGGS;
Biol., Univ. of Findlay, Findlay, OH

Abstract: Zebrafish (*Danio rerio)* have become a popular model vertebrate organism for analyzing disorders of the nervous system because, unlike mammals, they have the ability to regenerate neurons following brain injury or degenerative neuronal loss. The genomic and cellular mechanisms of neuronal regeneration following brain injury have been investigated by many groups; however, the functional implications of neuronal loss and regeneration have received relatively less attention. Recent studies using learning and memory tasks have provided evidence that zebrafish can also be useful models for investigating cognitive function, such as investigation of the effects of drugs of abuse on learning. The purpose of these experiments was to examine the effect of brain injury and regeneration on learning and memory. We examined several established tasks to determine their sensitivity of neuronal loss and recovery following telencephalic injury in adult zebrafish. The tasks selected use natural behaviors, such as shoaling and exploration, to assess learning and memory: light-dark preference (LDT), associative learning (AL), and novel object recognition (NO). Groups of adult zebrafish (equal numbers of males and females) were randomly assigned to task, condition within the task (if appropriate) and injury condition. Results indicated that LDT, AL, and NO were potentially sensitive to the effects of injury on behavior and recovery but that intra-individual differences evident on all tasks confounded attribution of results to the effects of injury and neuronal regeneration. Modifications to test conditions and exclusion criteria were employed to minimize inter- and intra-individual variability in behavior on all tasks both before and after injury.

Title: Fluorescent screen for identifying axon regeneration genes

Authors: *N. W. F. GROOMS, S. E. URENA, M. Q. FITZGERALD, S. H. CHUNG; Bioengineering, Northeastern Univ., Boston, MA

Abstract: Central nervous system (CNS) injuries are prevalent and currently lack effective therapies. A "conditioning" lesion of a peripheral sensory axon triggers robust central axon regeneration in mammals. Lesion conditioning could drive powerful therapies for CNS injuries. We established a model for lesion-conditioned regeneration in the invertebrate roundworm *C. elegans* in their ASJ neuron. This approach allows for a more comprehensive and faster search for neuronal regeneration genes compared to mammalian models. The *C. elegans* model permits unbiased screening. We used ethyl methanesulfonate to stochastically introduce mutations and disrupt the regeneration pathway. In our screen, we used the intensity of green fluorescence protein (GFP) as a proxy for neuronal regeneration. We selected candidate worms based on reduced GFP intensity by eye. The mutations in these worms, however, may underlie fluorescence but not regeneration. Under physiological stress, disruptions to sensory pathways in *C. elegans* produce ectopic axon outgrowths, which are mediated by the same genetic pathway as lesion conditioning. Therefore, we measure ectopic outgrowth to determine if candidate genes are involved in regeneration pathways. Ectopic outgrowth of dim strains is assessed via fluorescent microscopy by counting axonal outgrowths after culturing at 25°C. Following mutagenesis, we isolated twelve strains, originating from six distinct F1s. These mutations have varying penetrance. In each selected strain, around 30-50% of the worms have reduced fluorescence. Ectopic outgrowth studies in some mutagenized strains show decreased axonal outgrowths (~59%) compared to the original strain (~72%). After identifying strains with reduced outgrowth, laser surgery will be performed to assess regeneration. To identify the afflicted gene, we will perform one-step whole genome sequencing. We are also measuring the fluorescent intensity of each strain's ASJ neuron. Maximum intensity projections of 3D images were taken of worms. The quantification of fluorescent intensities allows us to correlate intensity with regeneration on an individual and an overall population basis. The identified genes will provide a roadmap for accelerating vertebrate lesion conditioning research and help guide future studies. This study permits future translation into CNS regeneration research to drive the development of innovative treatments.

Title: Aligned fibrous scaffolds containing glycosaminoglycan mimetics promotes neurite extension and myelination

Authors: *S. HASHEMI[1], P. MAUREL[2], M. OUDEGA[3], T. L. ARINZEH[4];
[1]Biomed. Engin., New Jersey Institue of Technolgoy, Newark, NJ; [2]Dept. of Biol. Sci., Rutgers - The State Univ. of New Jersey, Newark, NJ; [3]Dept. of Neurolog. Abstract: Spinal cord injury (SCI) causes axon damage resulting in functional impairments for which there is no effective treatment available at the present time. Tissue engineered scaffolds mimicking the native extracellular matrix may be a promising strategy to promote growth of the damaged axons. Glycosaminoglycans (GAGs), specifically chondroitin sulfate (CS), can elicit axon growth depending upon the degree and pattern of sulfation. We have developed a GAG mimetic derived from cellulose that can be tailored to have varying degrees of sulfation similar to native GAGs. Schwann cells (SCs) are of interest to be used in combination with this scaffold since they secrete neurotrophic factors stimulating neuron survival and axon growth.
The aligned fibrous scaffolds were prepared by electrospinning a solution of gelatin (bovine skin) with GAG mimetics. Partially sulfated cellulose (pCelS) mimicking chondroitin sulfate-C (CS-C) has ~0.5 sulfates per glucose monomer unit. Fully sulfated cellulose (fCelS) has ~3 sulfates per glucose unit. The scaffolds were crosslinked using EDC/NHS. Fiber morphology was evaluated using SEM. SCs were cultured for up to 14 days to evaluate cell survival. Purified dorsal root ganglion (DRG), from the spinal cord of rat embryos (E-16), were seeded onto scaffolds with or without SCs. Neurite extension was evaluated by confocal microscopy and the length was measured using ImageJ. SC myelination was investigated by purifying dissociated DRGs on scaffolds for 2 weeks followed by seeding SCs and maintaining the culture for 3 more weeks.
The scaffolds had a uniform morphology with 90% alignment. Significantly longer neurite outgrowth was determined for DRGs cultured with or without SCs on fCelS scaffolds in comparison to the other groups. More myelination was observed on both pCelS and fCelS scaffolds in comparison to Gel alone. The fCelS group appeared to have the greatest myelination.

A combination of SCs and GAG-mimetic scaffolds can be used as a novel approach to promote and direct axon growth. The significant neurite growth and myelination on fCelS scaffolds suggest that neurite outgrowth can be promoted, and it may depend on the degree of sulfation. A combination of SCs and GAG-mimetic scaffolds may be a novel approach to effectively promote and direct axon growth after SCI.

Abstract: Optic nerve lesions affect retinal ganglion cells (RGCs), which can lead to irreversible visual loss. The potential of allogeneic therapy with mesenchymal cells in a model of optic nerve injury in animals has been demonstrated by our group to increase the RGC survival and regeneration. It is necessary to investigate the potential of mesenchymal cells of human origin for future clinical studies. In the present study, the efficacy of human umbilical cord-derived mesenchymal stromal cells (hWJ-MSCs), stimulated or not by serum deprivation, and its

extracellular vesicles, was investigated in a optic nerve crush model. The hWJ-MSCs, subjected or not to serum deprivation, demonstrated a neuroprotective effect on RGCs 14 days after optic nerve lesion, evidenced by Tuj1 immunostaining in flat mounted retinas. However, the dose used for administration of vesicles did not result in neuroprotection. The neuroprotective effect of hWJ-MSC persists for at least 120 days after lesion, especially for larger soma RGCs, which include the αRGC population.Treatment with hWJ-MSCs promoted axonal regeneration observed by a great number of $GAP43^{+}$ axons at 14 days after lesion, and cholera toxin staining along the entire extension of the optic nerve, and in the lateral geniculate nucleus and superior colliculus 120 days after lesion, resulting in active synapse formation evidenced by the enhancement of NGFI-A-expressing cells. The electrophysiological analysis showed a decrease in the bioelectrical response of the external and inner layers of the retina 90 days after injury to the optic nerve, that were not recovered by administration of hWJ-MSCs. Visual tests for optomotor responses, looming response and light/dark behavior, did not show any improvement of visual responses of treated animals. We conclude that administration of hWJ-MSCs protects and promotes complete regeneration of a fraction of RGCs after injury to the optic nerve, but not results in visual recovery by the evaluated tests.

Title: The combinatorial effect of constituatively active Rheb and Taxol on axon outgrowth *in vitro* on inhibitory and growth-promoting substrates

Authors: *L. R. BENITEZ-RAMOS[1], L. MARTIN[1], C. LE[1], N. ALEGER[1], V. VELEZ[1], A. L. HAWTHORNE[2];
[2]Burnett Sch. of Biomed. Sci., [1]Univ. of Central Florida, Orlando, FL

Abstract: Central nervous system (CNS) injury can lead to irreversible paralysis and other clinical manifestations due to the inability of axons to regenerate. One approach to promote axon growth is by enhancing the intrinsic growth capacity of the neuron. We aimed to promote axon

regeneration *in vitro* by targeting two separate pathways: microtubule stabilization and the mTOR pathway. Taxol has both chemotherapeutic and neuroregenerative properties and has been shown to increase axon outgrowth. In addition, constitutively active Rheb (cRheb) has been shown to enhance axonal regeneration by upregulating the mTOR pathway. We hypothesized that by activating two different pathways in the cell, the combinatorial treatment of applying Taxol and transfecting cRheb would lead to further enhanced axon outgrowth than either single treatment alone. We used two cell lines: mouse/rat hybrid sensory neuronal cell line F11 and neuroblastoma cell line Neuro2a (N2a). The neurons were differentiated by switching to a serum-free media and applying forskolin. The neurons were grown on either a growth-promoting substrate of low levels of laminin or an inhibitory substrate of low levels of laminin plus inhibitory aggrecan to simulate the high chondroitin sulfate proteoglycan (CSPG) environment of the glial scar. Neurons were transfected with pcRheb-GFP, treated with a continuous or discontinuous application Taxol, or a combination of transfection and Taxol treatment. Transfection without DNA and DMSO were used as controls. After 3 days *in vitro*, neurons were immunostained and imaged. Neurites were traced using NeuronJ/ImageJ (NIH). For N2a-derived neurons, the continuous application of Taxol produced significantly longer neurites than the discontinuous application on both substrates. The combination treatment with discontinuous Taxol resulted in significantly longer neurites than either single treatment alone on the inhibitory substrate. cRheb transfection did not provide an added benefit to the continuous application of Taxol, however. It is possible that the neurons were already at their maximal growth state. For F11 neurons, cRheb alone had significantly longer neurites than the combination treatments on either substrate. The combination treatment did provide an added benefit to the continuous Taxol condition on aggrecan and laminin and to the discontinuous Taxol condition on laminin. Further experiments will compare differing behavior of the two cell types and the possibility of favoring different levels of Taxol. By testing combinations of treatments, we may find an optimal therapy for axon regeneration *in vivo*.

Title: A gutsy move for Parkinson’s disease: Targeting the gut microbiome with human umbilical cord blood plasma to arrest neuroinflammation and gut motility deficits

Authors: J.-Y. LEE[1], J. P. TUAZON[2], J. EHRHART[2], P. R. SANBERG[3], ***C. V. BORLONGAN**[4];
[1]Neurosurg. Brain Repair, [2]Neurosurg., [3]Dept. of Neurosurg. & Brain Repair, [4]Univ. of South Florida, Tampa, FL

Abstract: Current therapies for Parkinson's disease (PD) have generated mixed results with the eventual induction of dyskinesia during chronic treatment. Cell therapy has been introduced as an experimental treatment for PD. Despite lack or minimal capacity to differentiate into mature dopaminergic neurons, transplantation of human umbilical cord blood (hUCB) stem/progenitor cells has been shown to significantly attenuate parkinsonian symptoms likely via bystander effects, specifically stem cell graft-mediated secretion of growth and anti-inflammatory factors, altogether promoting brain repair. Recognizing this non-cell replacement mechanism, we examined here the effects of intravenously delivered hUCB-derived plasma into the 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP)-induced rodent model of PD. Animals received repeated dosing of either hUCB-derived plasma or vehicle at 3, 5, and 10 days after induction of MPTP lesion, then behaviorally and immunohistochemically evaluated over 56 days post-lesion. Compared to vehicle treatment, transplantation with hUCB-derived plasma significantly improved gut motility and nigral dopaminergic neuronal survival, which coincided with reduced pro-inflammatory cytokines in both the SNpc and the intestinal mucosa and dampened inflammation-associated gut microbiota. These novel findings implicate a key pathological crosstalk between gut and brain harnessing a new therapy that targets the gut microbiome with hUCB-derived plasma to retard PD-associated gut motility dysfunction and dopaminergic depletion.

Title: Characterizing astrocytes as a cell source for reprogramming and transplantation to repair the brain

Authors: *A. R. STEEVENS[1], S. RADHA[1], E. F. MARRON[2], W. C. LOW[1];
[1]Neurosurg., Univ. of Minnesota Twin Cities, Minneapolis, MN; [2]Pharmacol., Univ. of Minnesota, Minneapolis, MN

Abstract: The human brain is an exquisite example of nature's engineering; however, its major design flaw is the inability of self-repair. Increasing evidence suggests the potential of using glial cells as a therapy for brain injury and neurodegenerative diseases. For instance, using viruses to reprogram endogenous astrocytes to neurons is a method with demonstrated functional benefit in a variety of neurological disease models. Additionally, transplantation of astrocyte progenitor cells has demonstrated improvements in models of brain disease such as Huntington's disease. While both of these approaches hold great therapeutic promise, they have not been extensively characterized. We set out to establish a baseline for astrocyte reprogramming and transplantation in non-diseased *in vitro* and *in vivo* models. To do this, we developed an *in vitro* culture system derived from mouse primary cortical astrocytes to test reprogramming by adeno-associated viral vectors (AAVs) and to generate cells for transplantation. Astrocytes were harvested from post-natal day 1 mouse pups, expanded in culture, and their purity was characterized using immunocytochemistry (ICC). Our culture system efficiently generated astrocytes that expressed glial fibrillary acidic protein (GFAP) and excitatory amino acid transporter 1 (EAAT1) astrocyte markers and displayed characteristic astrocyte-like morphology. *In vitro* reprogramming experiments were performed in astrocytes transduced with the following AAV9-based system: an astrocyte specific Cre recombinase (GFAP::Cre-WPRE) co-administered with either a reporter (CAG::DIO-mRUBY) or reprogramming virus (CAG::DIO-Neurod1-P2A-mRuby). Upon analysis we discovered that, in some cases, astrocytes transduced with the reprogramming AAV migrated to assemble into neuronal-like arrangements on a global level and formed large aggregates that were organized to have the appearance of a soma and multiple extending processes. Moreover, cells in these arrangements expressed the neuronal marker TUJ1, indicating that they were being reprogrammed, but still also expressed the astrocyte marker GFAP, indicating that they were in an intermediate reprogramming state. Next, the reprogramming viruses were tested *in vivo* as was astrocyte transplantation. Stereotactic

injections were made into mouse striata using a Hamilton syringe containing either reprogramming or control AAV viral constructs or astrocytes. Our study makes great strides in characterizing novel glial cell based approaches in non-disease models both *in vitro* and *in vivo*.

Title: Successful zebrafish optic nerve regeneration is dependent upon dynamic regulation of protein-DNA and protein-protein interactions

Authors: *A. J. UDVADIA[1], **S. P. DHARA**[1], H. L. LESKINEN[1], A. RAU[3], P. L. AUER[2]; [1]Biol. Sci., [2]Joseph J Zilber Sch. of Publ. Hlth., Univ. of Wisconsin Milwaukee, Milwaukee, WI; [3]Animal Genet. and Integrative Biol., Inst. Natl. de la Recherche Agronomique, Jouy-en-Josas, France

Abstract: Injuries or diseases that damage CNS axons typically result in permanent loss of function in human patients. The functional loss is due, in part, to an inability of adult CNS neurons to undergo regenerative axon growth. A major challenge to mammalian CNS axon regeneration lies in initiating and sustaining gene expression programming that promotes axon growth and guidance to re-establish functional connections with appropriate targets after injury. Unlike mammals, zebrafish respond to optic nerve injury by reinitiating programs of axon growth and guidance, leading to restoration of the visual circuitry. We have recently completed a comprehensive analysis of gene expression changes (RNA-seq) and DNA regulatory element accessibility (ATAC-seq) that accompany distinct stages of optic nerve regeneration in zebrafish (see figure). We find over 7,000 genes that are temporally regulated over the course of optic nerve regeneration, from which we identified distinct signaling pathways that characterize each phase of the regenerative process. We also identified over 40,000 potential DNA regulatory elements, many of which are found within 100 kb of differentially expressed genes and are enriched in binding sites for regeneration-associated transcription factors. Surprisingly, of the over 40,000 accessible elements, we discovered only 233 whose accessibility changed in response to optic nerve injury. Furthermore, we found that the accessibility changes were mostly restricted to two timepoints corresponding to re-initiation of axon growth and re-establishment of connections with brain targets. We hypothesize that differentially accessible elements may play roles in (1) higher order chromatin organization, and (2) regulating the expression of key

transcription factors responsible for triggering a regeneration-associated gene regulatory cascade. Our long-term goal is to identify DNA and protein interactions essential for successful CNS axon regeneration that may serve as targets for therapeutic design.

Title: Integrin facilitates optimal growth of primary rat cortical endothelial cells *in vitro*

Authors: R. KUWAR, X. WEN, N. ZHANG, *D. SUN;
Virginia Commonwealth Univ., Richmond, VA

Abstract: Neovascularization and angiogenesis in the Central Nerve System (CNS) are important physiological processes for CNS normal development and tissue repair/regeneration following insults. Integrins are tissue adhesion molecules that play important roles in survival, growth and development of cells during tissue organization, differentiation and organogenesis. In this study we examined the effect of different integrins in the growth and development of primary brain microvascular endothelial cells (ECs). The primary microvascular endothelial cells were isolated from rat brain at post-natal day 7. Cells were seeded in a custom-designed integrin array, an integrin-coated 48-well plate containing 16 types of integrins. BrdU was added into the culture at 48 hrs prior to fixation to assess cell proliferation. After 7 days culture, the cells were fixed and processed for immunostaining with endothelial markers including VWF and PECAM-1. Among 16 integrins tested, we found that $\alpha_5\beta_1$, $\alpha_v\beta_5$ and $\alpha_v\beta_8$ greatly promoted proliferation of the culture ECs. To examine the effect of integrins in promoting neovascularization and angiogenesis, these three integrins were selected for 3-D cultures using our tailored hydrogel with addition of VEGF. Following a 7-day 3-D culturing, the culture was fixed and processed for double labeling of phalloidin with VWF or PECAM-1. The staining pattern particularly the blood vessel formation was assessed using confocal microscopy. We found that EC cell rearrangement forming clumps and the capillary like network structures with lumens inside were clearly identifiable with the 3-D reconstructed imaging in the 3-D hydrogel system. Our study optimized the growth condition of ECs in the 3-D culture system using the most appropriate integrin in hydrogel system that are ideal for primary brain EC cell tubule formation in vitro. This information is important for designing organoids cultures and for in vivo cell transplantation study for the injured brain following neurological insults.

Abstract: Unlike mammals, some non-mammalian vertebrate species are able to spontaneously regenerate and achieve functional recovery after traumatic spinal cord injury (SCI). Comparing physiological responses across organisms can provide important insights into the conserved mechanisms of successful recovery from SCI. Here, we compared the molecular responses after SCI in regenerative and non-regenerative species in order to begin identifying the molecular profiles that are shared between highly regenerative species. We compared published functional transcriptomic data (RNA-Seq, microarray) from spinal cord of two regenerative species, lamprey and zebrafish, (Herman et al., 2018; Hui et al. 2014) and two non-regenerative species, rat and mouse (Chamankhah et al., 2013; Wu et al., 2013) after SCI. We found that 432 transcripts were differentially expressed exclusively in both rat and mouse at 3 days post injury (dpi) compared to uninjured animals. As expected, gene ontology analysis revealed that immune pathways were enriched among genes that were upregulated in rodents. At 3dpi in lampreys and zebrafish, 36 transcripts were identified as differentially expressed in both highly regenerative species. These included transcripts for regeneration-associated genes: Plexin D (downregulated), SLIT3 and activating transcription factor 3 (ATF3) (upregulated). Of these, ATF3 was one of the most highly induced genes after SCI (3.57 and 5.11 Log2 Fold Change in zebrafish and lamprey, respectively). A protein BLAST analysis revealed that lamprey ATF3 is 51% identical and 67% similar to human ATF3, with even greater homology in the DNA binding domain (62% identical and 83% similar). Immunofluorescence labeling of lamprey spinal cord sections revealed that ATF3 protein levels were increased in both motor and sensory neurons at 3wpi and returned to control levels by 11wpi, when functional recovery is typically achieved. This expression profile and comparative species analysis is consistent with the hypothesis that ATF3 promotes regeneration in the lamprey. Moving forward, we will determine the role for ATF3 in regeneration in lampreys by manipulating its expression and examining the impact on neuronal regeneration and functional recovery after SCI.

Title: Cellular reprogramming in experimental Parkinson's disease

Authors: *S. RADHA[1], A. R. STEEVENS[2], E. MARRON[3], A. CRANE[4], A. W. GRANDE[5], W. C. LOW[5];
[1]Dept. of Neurosurg., Univ. of Minnesota Twin Cities Campus, Minneapolis, MN; [2]Dept. of Neurosurg., Univ. of Minnesota Twin Cities, Minneapolis, MN; [3]Pharmacol., [4]Stem Cell Inst., [5]Dept. of Neurosurg., Univ. of Minnesota, Minneapolis, MN

Abstract: Direct cellular reprogramming to drive lineage switching from one differentiated cell type to another can be exploited to develop cell-based therapies for neurodegenerative diseases. *In-vivo* reprogramming provides an attractive therapeutic strategy to circumvent the hurdles of immune rejection and ethical constraints associated with transplant-based therapy. Supporting cells of the CNS can be reprogrammed to neurons by targeted viral delivery of transcription factors and small molecules. Previous studies have demonstrated the effectiveness of a single proneural transcription factor NeuroD1 to drive reprogramming in the reactive glial lesions of Alzheimer's and stroke. However, the ability of NeuroD1 to promote a similar benefit in models of Parkinson's disease has yet to be demonstrated. Here we tested the hypothesis that NeuroD1 delivered via an Adeno-Associated Virus (AAV) can promote reprogramming in striatal astrocytes to neurons in an *in vivo* PD model. To do this, we designed a dual plasmid approach: one expressing the Cre recombinase, driven by an astrocyte-specific GFAP promoter and the second reporter construct with CAG::DIO-mRuby2 as control or a CAG::DIO-NeuroD1-P2A-mRuby2 reprogramming virus. Aiming to transduce non-dividing cells with minimal off-target effects, our approach employs an AAV9 delivery system, which is FDA approved for human clinical trials. To gain mechanistic insight into the process, we additionally set out to characterize NeuroD1-mediated reprogramming in an *in vitro* model. Cortical astrocytes isolated from P0 mice were cultured and characterized for astrocyte maturity, culture purity. Reprogramming was examined in homeostatic and reactive glial conditions, induced by transforming growth factor-β (TGF-β) treatment. IHC analysis of the NeuroD1-transduced astrocytes revealed neuronal marker expressions and intriguing patterns of aggregated $mRuby^+$ cell clusters connected by multiple processes. The dynamics and trajectory of the fate conversion was traced using IHC and time-lapse imaging. Collectively the *in vitro* results demonstrate the ability of NeuroD1 to reprogram astrocytes. To evaluate NeuroD1-mediated reprogramming in a murine Parkinson's model, glial lesions were induced by unilateral intracranial injections of 6-OHDA into the striatum, followed by the transduction of dual viral vectors. IHC was performed to assess the

efficiency of viral transduction and reprogramming. Our study establishes a novel AAV9-based approach to NeuroD1-mediated astrocyte reprogramming in the context of Parkinson's disease.

Title: Spinal cord injury in lampreys induces microglia/macrophage interactions with regenerating axons

Authors: *E. GUADARRAMA, J. R. MORGAN;
Eugene Bell Ctr. for Regenerative Biol. and Tissue Engin., Marine Biol. Lab., Woods Hole, MA

Abstract: A growing number of neuro-immune interactions have been observed after spinal cord injury (SCI) in both mammals and non-mammalian vertebrates, but the full impacts remain unclear. Both positive and negative immune responses have been reported in commonly used SCI models, including in highly regenerative animals like lampreys, fishes and amphibians, as well as mammals with limited regeneration. The post-SCI immune response often involves infiltration and/or proliferation of microglia/macrophages in and around the lesioned area, leading to an interest in understanding how microglial responses influence central nervous system (CNS) regeneration. Here, we address this question in sea lampreys (*Petromyzon marinus*), which are basally diverging vertebrates that undergo functional recovery after SCI supported by robust axon and synapse regeneration. We previously showed that elevated cAMP increased microglia/macrophage density in the regenerating lamprey spinal cord, correlating with enhanced lesion repair and axon regeneration. This raises the possibility that microglia/macrophages in lampreys promote axon regeneration after SCI. To test this, we examined the distribution of microglia/macrophages in relation to regenerating axons. After spinal cord transection, lampreys were allowed to recover for 3-11 weeks before harvesting the spinal cords for sectioning and immunofluorescence. Microglia/macrophages within control and transected spinal cords were labeled with fluorescein-conjugated Isolectin B4, and axons were labeled with a lamprey-specific NF-180 antibody. As expected, SCI significantly increased microglia/macrophage density, compared to uninjured controls. Isolectin-labeled cells exhibited both amoeboid and stellate morphologies and were in similar density 500 μm rostral and caudal

to the lesion site. Furthermore, the microglia/macrophages made physical contacts with regenerating axons and extended elongated projections along or around them. These microglia-axon contacts were observed within the immediate vicinity of the lesion site within transected spinal cords, but were rarely, if ever, observed within control spinal cords. Preliminary data suggest these contacts may occur at newly-formed synapses within regenerated axons. Thus, the working hypothesis is that microglia/macrophages facilitate axon regeneration by remodeling axons and synapses. Future experiments will test this hypothesis through ablation of microglia/macrophages. Understanding the importance of these neuro-immune interactions could lend insight into cellular and molecular mechanisms that promote regeneration in the CNS.

Title: Role of Per3, a circadian clock gene, in corticogenesis

Authors: *K.-I. NAGATA, M. NODA, I. IWAMOTO, H. TABATA, H. ITO;
Inst. for Developmental Research, Aichi Developmental Disability Ctr., Kasugai, Japan

Abstract: Per3 is one of the primary components of circadian clock system. While circadian dysregulation is known to be involved in the pathogenesis of several neuropsychiatric diseases. It remains largely unknown whether they participate in embryonic brain development. Here, we examined the role of clock gene *Per3* in the development of mouse cerebral cortex. *In situ* hybridization analysis revealed that *Per3* is expressed in the developing mouse cortex. Acute knockdown of *Per3* with *in utero* electroporation caused abnormal positioning of cortical neurons, which was rescued by RNAi-resistant Per3. Per3-deficient cells showed abnormal migration phenotypes, impaired axon extension and dendritic arbor formation. Taken together, Per3 was found to play a pivotal role in corticogenesis via regulation of excitatory neuron migration and synaptic network formation.

Title: PlexinA1 is crucial for the midline crossing of cingulate axons in the developing corpus callosum under BALB/cAJ genetic background

Authors: *M. HOSSAIN[1,2,3], T. TSUZUKI[1], K. SAKAKIBARA[1], F. IMAIZUMI[1], A. IKEGAYA[1], M. INAGAKI[1], I. TAKAHASHI[1], T. ITO[2], H. TAKAMATSU[3], A. KUMANOGOH[3], T. NEGISHI[1], K. YUKAWA[1];
[1]Grad. Sch. of Pharm., Meijo Univ., Nagoya, Japan; [2]Dept. of Neurol., Aichi Med. Univ., Nagakute, Japan; [3]Dept. of Immunopathology, Osaka Univ., Suita, Japan

Abstract: The corpus callosum (CC) is the biggest commissure that links cerebral hemispheres. In the cortical midline during CC development, the guidepost structures emerge and express axon guidance molecules to instruct neurons about the proper direction of axonal elongation toward and across the midline. Neuropilin-1 (Npn1), a high-affinity receptor for class 3 semaphorins (Sema3s), localized on the cingulate pioneering axons has a crucial role for the axon guidance to the midline through the interactions with Sema3s. However, it remains unclear which type of Plexin acts as a component of Sema3 holoreceptors with Npn1 during the axon guidance of the cingulate pioneering axons. To address the role of PlexinA1 in CC development, we examined the localization of PlexinA1, Npn1 and Sema3s by immunohistochemistry (IHC) with embryonic brains from wild-type (WT) and the PlexinA1-deficinet (PlexinA1 KO) mice under BALB/cAJ background. The IHC confirmed the expression of PlexinA1 in callosal axons derived from cingulate and neocortex of WT mice at embryonic day 17.5 (E17.5) but not in PlexinA1 KO mice. To examine the role of PlexinA1 in the navigation of callosal axons, the extension of callosal axons toward and across the midline was traced in WT and PlexinA1 KO brains at E17.5. In the absence of any misguidance of callosal axons to ectopic areas other than the midline, callosal axons of PlexinA1 KO brains at E17.5 showed significantly lower incidence in the midline crossing of callosal axons as compared with WT. To examine further the role of PlexinA1 in CC development, CC phenotype was examined in PlexinA1 KO mice at postnatal day 0.5 (P0.5). Agenesis of corpus callosum in the anterior half of CC was observed in 76.9% of the PlexinA1 KO mice at P0.5. These results indicate the crucial involvement of PlexinA1 in the midline crossing of callosal axons during the CC development under BALB/cAJ background.

Title: Phosphorylation of FE65 serine 459 by protein kinase C zeta potentiates neurite outgrowth

Authors: ***W. LI**[1,2], D. CHAU[2], K. LAU[2];
[1]Shenzhen Inst. of Advanced Technol., Shenzhen, China; [2]The Chinese Univ. of Hong Kong, Hong Kong, Hong Kong

Abstract: Neurite outgrowth is an essential process for establishing connections between developing neurons. FE65 is a brain-enriched phosphor-adaptor protein that has been shown to stimulate neurite extension by recruiting and activating the small GTPase ARF6. However, the mechanism(s) that regulates FE65-ARF6 interaction is still not known. In this study, we show that phosphorylation of FE65 Serine 495 (S459) enhances FE65-ARF6 interaction and FE65-mediated ARF6 activation. Moreover, the synergistic effect of FE65 and ARF6 on neurite outgrowth is further potentiated by FE65 S459 phosphorylation. Additionally, we demonstrate that FE65 S459 is phosphorylated by protein kinase C zeta (PKCζ). Knockdown of PKCζ suppresses the stimulatory effects of FE65 on ARF6 activation. Furthermore, overexpression of PKCζ promotes whereas siRNA knockdown or pharmacological inhibition of PKCζ attenuates FE65 stimulation of neurite outgrowth. Hence, we reveal a novel mechanism that FE65 is phosphorylated by PKCζ at S459 to potentiate the stimulatory effect of FE65 on ARF6 activation and in turn neurite outgrowth.

Title: Exploring the unexpected - How a glycan biosynthesis inhibitor changes cell morphology and mitochondria

Authors: *C. MENCIO[1], S. TILVE[1], H. KATAGIRI[1], H. M. GELLER[2];
[1]NIH, Bethesda, MD; [2]Office of Educ., Natl. Heart, Lung, and Blood Institute, NIH, Bethesda, MD

Abstract: Proteoglycans (PGs) are important to a variety of neurological functions. From neural development to memory to regeneration and disease, both heparan sulfate (HS) and chondroitin sulfate proteoglycans (CSPGs) play several promoting and inhibitory roles. While research is clear that these macromolecules are involved in neural development and repair, their actual role of action is difficult to understand. This is in part due to the lack of available research tools and a limited understanding of existing tools, such as xylosides. Consisting of an aglycone attached to a xylose residue, xylosides are known to affect glycosaminoglycan (GAG) biosynthesis both *in vitro* and *in vivo.* Used in high concentrations (≥1mM) in research since the 1970s, treatment has been shown to lead to the inhibition of endogenous PGs and the production of primed GAGs, or GAG chains built on the xyloside and as such lack a core protein. Primed GAGs are pushed out of the cell and can be found in the extracellular space. However, it is only recently that application of lower, more therapeutically relevant concentrations has been explored. The presented research offers evidence that acute exposure with nanomolar, but not millimolar, concentrations of xyloside leads to altered cytoskeleton *in vitro* evidenced by enlarged growth cones and lamellipodia. Both microtubules (MTs) and actin are misregulated and their dynamics altered after xyloside treatment. Examining two of the major players in actin turnover and MT stabilization, we found changes in phosphorylation in both cofilin and GSK3β signaling pathways. The speed of MT, measured by EB3 comets, is significantly increased and lamellipodia appear to show increased formation and persistence. Additionally, assessment of mitochondria has shown increased capacity and altered trafficking in xyloside treated neurons indicating xyloside treatment may play a role in energy production. Both the changes in cytoskeleton and mitochondria may factor into the morphological changes observed in neurites and could lead to an improved ability of xyloside-treated neurons to overcome injury and degenerative stress. This research indicates that xylosides may serve as more than just GAG biosynthesis inhibitors. Exploring nanomolar xyloside treatment may provide new insights into these other functions, and provide novel insights into neuron development, survival and repair.

Title: Ca^{2+} -activated non-selective cation channel (TRPM4) modulates neurite growth in cortical neurons

Authors: N. JUANCHUTO-VIERTEL, C. ALAMOS, E. LEIVA-SALCEDO, *D. RIQUELME;
Dept. of Biol., Univ. de Santiago, Santiago, Chile

Abstract: Neurite growth and extension is a critical process to determine neuronal function; changes in the actin cytoskeleton and Ca^{2+}_i dynamics underlie this process. In this regard, filopodia formation experiments performed in absence of Ca^{2+}_i showed that neurite progression is arrested at initial stages. Moreover, it has been demonstrated that neurite elongation and neuronal development is affected by the activation of ion channels that regulates Ca^{2+}_i levels. Among the channels which participate in Ca^{2+}_i dynamics, TRPM4, a non-selective monovalent cation conducting channel activated by Ca^{2+}_i, could be having a role in this process by promoting changes in the cytoskeleton dynamics through the modulation of intracellular levels of Ca^{2+} as it has been described in other cellular models. In this work, we assess the participation of TRPM4 in the neuritogenesis and Ca^{2+}_i dynamics during early stages of neurite development. Using a combination of pharmacological modulation and genetic suppression of TRPM4 in a model of cortical neurons in culture, we performed multiplex immunofluorescence using cytoskeleton markers such as MAP2 (microtubules), phalloidin (actin) and then, we characterized the neurite initiation and measure the neurite number and length during neuritogenesis. Additionally, we assessed the Ca^{2+} dynamics during the first stages of neuritogenesis using Fura-2 and Fluo-4 calcium probes. We found that pharmacological inhibition of TRPM4 change neurite length and number, thus affecting the stage progression. These results were similar to the effects observed with TRPM4 silencing using an shRNA. Furthermore, experiments using electrical stimulation and K^+ induce-depolarization showed that TRPM4 inhibition affects Ca^{2+} dynamics during neurite growth. Our current efforts are focused in the understanding of the actin dynamics and its relationship with changes in Ca^{2+}_i. These results bring insight in the role of TRPM4 as an

indirect modulator of the cytoskeleton dynamics through the regulation of the intracellular calcium.

Title: Dysregulation of adhesion dynamics in TSC2 deficient human forebrain neurons

Authors: *M. M. ONESTO, T. S. CATLETT, T. M. GOMEZ;
Dept. of Neurosci., Univ. of Wisconsin-Madison, Madison, WI

Abstract: Growing evidence suggest that patients with Tuberous Sclerosis Complex (TSC), like other neurodevelopmental disorders, have mis-wiring of neuronal connections that form during development. These defects in neuronal connectivity likely contribute to symptoms of TSC, such as cognitive deficits, autism and epilepsy. Precise connectivity depends on proper regulation of growth cone motility downstream of axon guidance cues. Directed leading edge protrusion/retraction and adhesion is mediated in part through coordinated F-actin polymerization the coupling of the F-actin cytoskeleton to nascent focal adhesions, or “point contacts”. This process slows retrograde flow to support actin polymerization at the leading edge of growth cones. Chemorepulsive factors slow axon extension or induce retraction by activating signaling pathways that result in endocytosis, adhesion destabilization and rapid actin depolymerization. To examine whether these processes also function in human neurons and test if they are defective in TSC2 mutant neurons, we used induced pluripotent stem cells to generate neurons from corrected control and TSC2+/- mutant forebrain neurons. Utilizing this human model system we have demonstrated that TSC2+/- mutant forebrain neurons exhibit increased axon outgrowth and have reduced sensitivity to several chemorepellants known to signal through RhoA. Further, our data show that TSC2+/- neurites have lower basal active RhoA and fail to activate RhoA normally in response to inhibitory cues. Here I show using live cell fluorescence imaging that TSC2+/- growth cones also have reduced focal adhesions, but lower retraction of new protrusions. I hypothesize that TSC2+/- neurons have reduced myosin II-mediated contractility and heightened adhesion turnover rate, which is due to dysregulated RhoA activity leading to rapid axon extension rates. Further, I hypothesize that inability to TSC2+/- neurons to

activate RhoA prevents adhesion site destabilization and F-actin contraction, making these mutant neurons less sensitive to chemorepellants. This research will further our basic understanding of the role of F-actin and adhesion dynamics downstream of chemorepulsion in human neurons with autism spectrum disorder mutation.

Title: Serotonergic fibers as random walks - A spatial analysis

Authors: *K. C. MAYS, K. L. THOMAS, C. A. LOUIE, A. ZHANG, J. H. HAIMAN, S. JANUSONIS;
Psychological and Brain Sci., Univ. of California, Santa Barbara, Santa Barbara, CA

Abstract: Serotonergic densities in brain regions may form as a result of random walks performed by individual serotonergic axons (fibers). We have recently shown that these walks can be described by the directional von Mises-Fisher (vMF) distribution, parametrized by the "concentration parameter" κ (Janusonis, Mays, Hingorani (2019) *ACS Chemical Neuroscience*, in press). This parameter controls the rigidity of the walk, which can potentially affect the equilibrium density of fibers in the adult brain.
In the present study, we visualized individual serotonergic fibers in the adult mouse brain using three methods: immunohistochemistry with confocal microscopy, (ii) tissue clearing (CUBIC) with immunohistochemistry and high-resolution light sheet fluorescence microscopy, and (iii) imaging in an inducible Brainbow transgenic model (with the Cre-recombinase under the promoter of tryptophan hydroxylase 2). The trajectories of serotonergic fibers were converted into numerical arrays using semi-manual and automated tracing algorithms, and the optimal step-length of the random walk was determined based on modeling and data analysis. Estimates of κ values were obtained in a number of forebrain regions (cortical and subcortical) using published methods. Our results indicate that the vMF-random walk can closely approximate the behavior of individual serotonergic fibers. The analysis shows that κ can be used as a robust parameter to assess the regional tortuosity of serotonergic fibers in health and disease, and that this approach

may support studies of Autism Spectrum Disorder, Major Depressive Disorder, and other mental disorders.

Title: GTP-bound ran regulates non-centrosomal microtubule formation and is transported by actin waves towards the neurite tip

Authors: C.-H. HSU[1], Y.-A. HUANG[2], H.-C. CHIU[1], C. T. HO[1], W.-L. LO[2], ***E. HWANG**[1,2,3]; [1]Inst. of Mol. Med. and Bioengineering, [2]Dept. of Biol. Sci. and Technol., [3]Inst. of Bioinformatics and Systems Biol., Natl. Chiao Tung Univ., Hsinchu, Taiwan

Abstract: Microtubule is the most abundant and arguably the most important cytoskeleton in neurons. While the organizing center of microtubules in mitotic cells is typically located at the centrosome, microtubule nucleation in post-mitotic neurons switch to non-centrosomal sites. A handful of proteins and organelle have been shown to promote non-centrosomal microtubule formation in neurons, yet the regulation mechanism remains unknown. Here we demonstrate that the small GTPase Ran is a key regulator of non-centrosomal microtubule nucleation in neurons. The GTP-bound Ran (RanGTP) localizes to the neurite tips and around the soma. Using the RanGTP- and RanGDP-mimic mutants, we show that RanGTP promotes microtubule nucleation at the tip of the neurite. To demonstrate that RanGTP can promote microtubule nucleation in region along the neurite other than the tip, an optogenetic reagent (RanTRAP) was constructed to enable local production RanGTP in the neuronal cytoplasm. An increase of non-centrosomal microtubule nucleation can be observed by elevating the RanGTP level along the neurite using RanTRAP, establishing a new role for Ran in regulating neuronal microtubules. Additionally, the mechanism of RanGTP localization at the neurite tip was examined. We discovered that the actin wave drives the anterograde movement of RanGTP to the neurite tip. Pharmacological disruption of the actin wave abolishes the localization of RanGTP and reduces the non-centrosomal microtubule nucleation at the neurite tip. These observations provide a novel indirect connection between the actin and microtubule cytoskeletons in neurons.

Title: Interrogating functional interactions between Cadherin 8 and Cadherin 11

Authors: *C. R. MERCEDES, R. E. MESIAS, Y. ZAKI, G. W. HUNTLEY, D. L. BENSON; Nash Family Dept. of Neurosci. and Friedman Brain Inst., Grad. Sch. of Biomed. Sciences, Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract: Genome wide association studies highlight involvement of cadherin adhesion proteins in many neuropsychiatric and neurobehavioral disorders. In particular, rare microdeletions in Cadherin 8 (Cdh8), a type II classic cadherin, are associated with Autism Spectrum Disorders (ASD), while another type II classic cadherin, Cadherin 11 (Cdh11), is associated with non-syndromic ASD. Classical cadherins are cell adhesion molecules involved in synaptic plasticity, cell to cell communication, and circuit formation. Cadherins have selective binding preferences and specific expression patterns enabling them to work in a combinatorial, complementary or collaborative fashion to delineate cortical regions and circuits. For example, in retina, several type II cadherins, including Cdh8, act both collaboratively and independently to generate appropriate functional circuits (Duan et al., 2014; 2018). In cell-based adhesion assays, Cdh8 and Cdh11 can bind heterophilically (Brasch et al., 2018; Shimaoyama et al. Biochem. J. 2000), suggesting these two cadherins may work together. The distribution of Cdh8 and Cdh11 mRNAs is partially overlapping. For example, both are expressed in medial prefrontal cortex, but in striatum, Cdh8 mRNA expression shows a dorsal-to-ventral gradient, while Cadh11 mRNA expression shows the reverse (Friedman et al., 2015; Suzuki et al., 1997). Despite these patterns, it is not known if these two cadherins functionally interact in vivo, nor is it clear where Cdh11 protein is localized. By western blot, our data show that Cdh11 is expressed in different regions of the brain with significant levels detectable by postnatal day 10, during the peak period of synaptogenesis. By immunofluorescence, we find that Cdh11 is localized to discrete puncta along postsynaptic dendrites similar to Cdh8. In addition, both Cdh8 and Cdh11 are found in sub-populations of cortical cells where they form clusters on postsynaptic membranes. Functional interactions between these two cadherins are being tested using target selection and

cell-substrate based assays. Together these patterns may reveal combinatorial interactions important for the establishment of corticostriatal circuits that are impaired in autism.

Title: Human stem cell-derived photoreceptors generate processes by non-cell autonomous pulling

Authors: *S. K. REMPEL[1], Y. KANCHERLA[1], D. J. ZACK[3], D. M. GAMM[2], T. M. GOMEZ[1];

[3]Ophthalmology, Johns Hopkins Univ., Baltimore, MD

Abstract: Photoreceptors (PR) are our primary visual sensory cells, and their loss causes irreversible vision loss. Cell replacement therapy provides a potential treatment approach to those who have lost PRs through damage or disease. While PR transplant research is ongoing in animal models, success is hindered by our limited understanding of PR axonogenesis and synaptogenesis in both developing and regenerating conditions. Using a human pluripotent stem cell line that labels PRs ($Crx^{+/tdTomato}$), we generated PRs within retinal optic vesicles to study their development within this human organoid system and address the mechanisms of process extension of these potential transplant candidate neurons *in vitro*. We made the unexpected finding that while PRs do form terminal specializations that resemble classical growth cones *in vitro*, they do not extend axons by cell autonomous terminal extension. Instead, we observed that, on a variety of substrata tested, PR neurite extension is primarily achieved through interactions with motile non-PR cells in these mixed neuroretinal cultures. Close examination of PR terminals by high-resolution live cell imaging and super-resolution microscopy showed that PR terminals are highly adherent and have a disorganized actin cytoskeleton. Our observation that human PR axons elongate primarily in association with motile support cells *in vitro* suggests

that PR axon development and regeneration may also occur through interactions with motile neuroretinal support cells *in vivo*. To begin to test this possibility, we are imaging PR axon elongation within organoids using 2-photon microscopy and find that PRs undergo apical-basal migration that may be related to their axon development. These findings will be vital for understanding human PR development and for informing our methods to promote PR connectivity in cell replacement therapies to cure blindness.

Title: Decreasing geranylgeranylation of RhoA and Rac1 increases cortical actin content by increasing activation of WAVE/ARP and JNK pathways

Authors: *N. G. R. RAUT[1], J. M. REDDY[2], D. L. HYNDS[1];
[2]Biol., [1]Texas Woman's Univ., Denton, TX

Abstract: Abnormal cytoskeletal organization of actin is one of the common features of many neurodegenerative diseases like Alzheimer’s disease (AD), Parkinson diseases (PD) and Huntington’s disease (HD). Actin polymerization and depolymerization are controlled in large part by Rho guanosine triphosphatases (GTPases). These proteins are active when bound to guanosine triphosphate (GTP) and inactive when bound to guanosine diphosphate (GDP). Rho GTPases are targeted to the plasma membrane by the addition of a 20-carbon lipophilic geranylgeranyl isoprene. It is not known how Rho and RhoA geranylgeranylation affects the location and activity of downstream effectors to facilitate either polymerization or depolymerization of actin. We used non-geranygeranylatable RhoA and Rac1 constructs to test how inhibiting geranygeranylation affects morphology, localization of activation of RhoA and Rac1 cell signaling pathways. Western blotting, Co-immunoprecipitation and confocal microscopy analyses show that expressing non-geranylgeranylatable constructs increases cortical

actin filament content in growth cones, but have differential effects on process outgrowth from neuroblastoma cells and rat primary cortical neurons. Expressing non-geranylgeranylatable Rac1 decreased neurite initiation and elongation, while expressing non- geranylgeranylatable RhoA increased neurite elongation. Furthermore, expressing non-geranylgeranylatable RhoA or Rac1 significantly altered formation of the actin nucleation complex of WAVE with the Arp2/3 complex and activation of some mitogen activated protein MAP kinase pathways, including JNK. Elucidating the signaling cascades of the aberrantly-localized active Rho GTPases and the effect on actin may also identify the distinct functions of these GTPases or their downstream effectors, which may identify novel targets to facilitate axon regeneration in traumatic or degenerative neurological conditions.

Title: LIM and SH3 protein 1 promotes actin-based axon development

Authors: *S. L. POLLITT[1], K. R. MYERS[1], J. YOO[2], G. ARORA[3], J. Q. ZHENG[1];
[1]Cell Biol., Emory Univ. Dept. of Cell Biol., Atlanta, GA; [2]Emory Col., Emory Univ., Atlanta, GA; [3]Univ. of Georgia, Athens, GA

Abstract: During brain development, neurons extend axons rapidly and precisely towards their specific targets to form synaptic connections. Axonal growth is primarily driven by a highly motile, actin-rich structure found at the tips of axons, called the axon growth cone. LIM and SH3 Protein 1 (LASP1) is a unique member of the nebulin family of actin binding proteins and contains several protein interaction motifs for mediating signal transduction and actin regulation, and thus may facilitate complex signaling pathways to regulate actin dynamics. *LASP1* has been implicated in autism and schizophrenia, but its role in neuronal development is unknown. We

found that LASP1 is highly expressed in both developing and mature rat brains. Interestingly, the LASP1 protein is concentrated at the leading edge of motile growth cones where actin-based membrane protrusion occurs. Using live microscopy of motile CAD neuroblastoma cells, we found that LASP1 accumulates at the leading edge specifically during membrane protrusion, but is then lost or diminished from the cell edge during membrane retraction. Furthermore, we found that the leading edge enrichment of LASP1 depends upon its LIM and nebulin domains. Finally, our work shows that the loss of LASP1 in mammalian hippocampal neurons reduces axonal growth. Together these data identify LASP1 as a novel actin-binding protein that regulates membrane protrusion and growth cone motility. The modular structure of LASP1 may enable it to link multiple signaling cascades to the actin-based events underlying brain development.

Title: TNFR2 activation enhances neurite outgrowth in cortical neurons

Authors: M. GERALD[1], *J. RICARD[1], ***V. BRACCHI-RICARD**[1], R. FISCHER[1], R. KONTERMANN[2], K. PFIZENMAIER[2], D. RICCI[3], Y. ARGON[3], J. BETHEA[1]; [1]Drexel Univ., Philadelphia, PA; [2]Univ. of Stuttgart, Stuttgart, Germany; [3]Univ. of Pennsylvania, Philadelphia, PA

Abstract: Promoting axonal regeneration or neuroplasticity have long been pursued to improve functionality after spinal cord injury. In a previous study we have shown that continuous infusion in the spinal cord of EHD2-sc-mTNF$_{R2}$, an agonist of tumor necrosis factor receptor 2 (TNFR2) improved recovery after contusion and enhanced cortical response following hindlimb stimulation (Gerald *et al.*, 2019) leading us to examine the effect of TNFR2 activation on neurite outgrowth. We report that treatment of cortical neurons *in vitro* with the TNFR2 agonist EHD2-sc-mTNF$_{R2}$ enhanced the growth and branching of neurites. The outgrowth correlated with increased BDNF release and JNK activation that led to the phosphorylation of Superior Cervical Ganglion-10 protein (SCG10), a microtubule destabilizing factor. The actin-binding protein filamin A was also up-regulated as a result of TNFR2 engagement. Futhermore, we showed that inhibiting the RNase activity of IRE1α abrogated the TNFR2-mediated neurite outgrowth. Our

study identifies a new role for the TNFR2 receptor on neurite outgrowth that could be harnessed to enhance regeneration following spinal cord injury.

Title: Growth cone invadosome formation and function in developing spinal axon growth and guidance

Authors: ***C. A. SHORT**[1], G. D. FRANCIS, Jr.[2], T. M. GOMEZ[3];
[1]Neurosci. Dept., Univ. of Wisconsin, Madison, WI; [2]Univ. of Wisconsin, Madison, Madison, WI; [3]Dept of Neurosci., Univ. of Wisconsin Madison Sch. of Med. and Publ. Hlth., Madison, WI

Abstract: Invadosomes are specialized F-actin rich adhesions, which protrude from cells to promote remodeling of the extracellular matrix through the targeted release of matrix metalloproteases (MMPs). Invadosomes are formed by many types of migrating cells including metastatsic cancer and immune cells, where they have been extensively studied. Recent work from our lab suggests that developing nerve growth cones also form invadosome-like protrusions and that disruption of invadosome formation significantly inhibits motor neuron (MN) exit from the spinal cord into the periphery in *Xenopus laevis* embryos. We hypothesize that pioneering sensory Rohon-Beard (RB) and MN axon growth cones utilize invadosomes to breech the dense ECM basement membrane around the spinal cord to facilitate exit from the central nervous system and that the formation of these protrusions is regulated by signaling proteins in the local environment. Preliminary data suggests that growth factors, including epidermal growth factor (EGF), promote the formation of invadosome precursors in developing neurons *in vitro*. EGF is expressed in the muscle and skin of developing embryos around the time RB and MN axons exit to the periphery. EGF is known to promote invadosome formation in other cell types through the activation of Src and PI3K and we determined that inhibition of either of these kinases disrupts invadosome formation in nerve growth cones. Kinase activity is also increased in response to EGF in nerve growth cones. Local EGF receptor activation, downstream actin assembly, and targeted MMP delivery are being examined in response to EGF in growth cones with a combination of immunochemical and molecular biosensors. In addition, the targeting of MMPs

in invadosome-like protrusions is being examined *in vivo*. Future work will continue to elucidate the signaling mechanisms controlling the formation of invadosomes and downstream delivery of MMPs in developing nerve growth cones *in vivo*.

Title: Systematic analysis of effects of glucose in CNS neurons-implications to diabetes related neurodegeneration

Authors: *V. DEVANATHAN[1], H. CHAKRAVARTHY[2], G. SURESH[2], S. SHARMA[2], A. MARIMUTHU[1];

Abstract: Neurodegeneration due to diabetes is gaining importance as our understanding towards this complex phenomenon is increasing. Diabetes is a complex, heterogeneous metabolic disorder that affects millions of population worldwide. India ranks highest in harbouring diabetes patients leading to multiple organ dysfunctions including brain damage. Diabetes in CNS results in neuronal dysfunction, neurodegeneration both in neurons of the brain and eye (retinal neurons). Altered signalling mechanisms that regulate neuronal differentiation are one of the main causes of neuronal dysfunction and degeneration. Neuronal proteins abundantly expressed in the brain, eye and spinal cord are crucial players in orchestrating signalling for neuritogenesis which is essential for regeneration of neurons. Secondary signalling pathways required to maintain cellular homeostasis, such as signalling mediated by Gai proteins are key regulators of diabetes. Previously G proteins has been hypothesised to be involved in neuritogenesis and "may be" neuronal regeneration. Role of G protein signalling pathway along with neuronal transmembrane proteins in neuronal regeneration after the onset of diabetes is unexplored. Our research focusses in understanding the role of neuronal transmembrane proteins and also other molecules such as Neuronal cell adhesion molecule (NCAM), Prion and L1 that might be involved in neuritogenesis. Our preliminary data towards this strongly shows that modulating glucose concentrations regulate expression of an abundantly expressed neuronal protein. Currently we are understanding this observation further and hope to have an interesting science finding to share in SfN, Chicago. From our findings it is also interesting to see the same protein is differentially expressed in retinal neurons treated with different concentrations of glucose. Such systematic studies will allow us to explore other modes of managing diabetes associated neuronal complications in CNS (brain and eye).

Abstract: Reactive oxygen species (ROS) are derivatives of oxygen molecule, often highly reactive due to the free electrons. Excess production of ROS is associated with oxidative stress in several pathologies including cancer, Alzheimer's disease, Parkinson's disease, multiple sclerosis, and amyotrophic lateral sclerosis. In homeostatic conditions, optimal ROS levels are required for cellular signaling. In the nervous system, physiological levels of ROS mediate neural progenitor cell maintenance and differentiation, cerebellar development, axon growth, neuronal polarity, and axon regeneration. NADPH oxidases (Nox enzymes) are transmembrane proteins, catalyzing electron transfer from NADPH to O_2 to generate superoxide and hydrogen peroxide (H_2O_2). Based on previous observations, we hypothesized that Nox-derived ROS mediate axonal growth and guidance. To test this, we adopted CRISPR-Cas9 genome editing strategy to establish *nox* mutants in zebrafish embryos. We found that *nox2*$^{-/-}$ mutants exhibit defects in ganglion cell layer (GCL) formation in embryonic zebrafish retina and misguided axons of retinal ganglion cells (RGCs) in the optic tecta. Besides retinal development, anterior commissure in the forebrain and longitudinal spinal cord axons exhibited aberrant projections, suggesting a role for Nox-derived ROS in axonal growth and guidance. The general brain development was not affected, since well-established CNS markers *pax6a* (forebrain), *otx2* (midbrain), and *fgf8* (midbrain hindbrain boundary) showed normal expressions in *nox2*$^{-/-}$ mutants. *In vitro*, cultured RGC neurons from *nox2*$^{-/-}$ mutants exhibited loss of proper response to guidance cues slit-2 and netrin-1, implying a cell-autonomous relationship between Nox2 and cues. To test this, we are now mutating *nox2* specifically in RGCs, along with cell transplantation experiments between mutant and wildtype embryos.

Title: Regulation of axonal length and 4EBP1, independent of mTORC1 activity, by a farnesylation-defective Rheb in embryonic primary neurons

Authors: S. CHOI[1], A. SADRA[1], J.-E. KANG[1], J. RYU[2], J. KIM[2], W. SUN[2], ***S.-O. HUH**[1]; [1]Hallym Univ. Med. Sch., Chuncheon, Korea, Republic of; [2]Brain Korea 21, Korea Univ., Seoul, Korea, Republic of

Abstract: Rheb (Ras homolog enriched in the brain) is a small GTPase protein that plays an important role in cell signaling for development of the neocortex through modulation of mTORC1 (mammalian-target-of-rapamycin-complex-1) activity. mTORC1 is known to control various biological processes including axonal growth in forming complexes at the lysosomal membrane compartment. As such, anchoring of Rheb on the lysosomal membrane via the farnesylation of Rheb at its cysteine residue (C180) is required for its promotion of mTOR activity. To test the significance of Rheb farnesylation, we overexpressed a farnesylation mutant form of Rheb, Rheb C180S, in primary rat hippocampal neurons and also in mouse embryonic neurons using *in utero* electroporation. Interestingly, we found that Rheb C180S maintained promotional effect of axonal elongation similar to the wild-type Rheb in both test systems. On the other hand, Rheb C180S failed to exhibit the multiple axon-promoting effect which is found in wild-type Rheb. The levels of phospho-4EBP1, a downstream target of mTORC1, were surprisingly increased in Rheb C180S transfected neurons, despite the levels of phosphorylated mTOR being significantly decreased compared to control vector transfectants. A specific mTORC1 inhibitor, rapamycin, also could not completely abolish axon elongation characteristics of Rheb C180S in transfected cells. Our data suggests that Rheb in a non-membrane compartment can promote the axonal elongation via phosphorylation of 4EBP1 and through an mTORC1-independent pathway

Title: Distribution regularity of mitochondria and en passant presynaptic sites along axon in the cerebellar granule neurons

Authors: *I. HORI[1], N. MATSUMOTO[1], S. MIYAKE[2,3], Y. KONISHI[1,3];
[1]Fac. of Engineering, Univ. of Fukui, Fukui, Japan; [2]Fac. of Med. Sciences, Univ. of Fukui, Fukui, Japan; [3]Life Sci. Innovation Center, Univ. of Fukui, Fukui, Japan

Abstract: In axons, mitochondria are transported via microtubules and motor proteins. On the other hand, stationary mitochondria stopping movement are also widely distributed and are considered to be involved in axon branching and elongation. The systems regulating the distribution of stationary mitochondria remain to be elucidated. In this study, we investigated the distribution patterns of stationary mitochondria. The probability distribution did not follow the Poisson distribution, suggesting that it is not a random distribution. Furthermore, by calculating the distribution concentration index called $I\delta$ index, it was suggested that there is a tendency of equal distribution. Next, in order to investigate the relevance of the distribution of stationary mitochondria and presynaptic factors, we analyzed the distribution of presynaptic factors using a same method. We found that there is a tendency of random distribution at the early stage of development, and it became close to equal distribution as maturation progresses. From the above, we performed time lapse imaging to test the possibility that the distribution of mitochondria controls the distribution of presynaptic factors. Notably, we observed that part of presynaptic factors and mitochondria were cotransported. These results suggested that mitochondria could regulate the distribution of presynapses.

Title: Sara protein participation as a negative regulator of the transforming growth factor β signaling pathway during neuronal development

Authors: *V. ROZES-SALVADOR[1,2], S. SIRI[1], C. GONZALEZ-BILLAULT[3], C. B. CONDE[4];
[1]Neurobio., INIMEC-CONICET-UNC, Cordoba, Argentina; [2]Natl. Univ. of Villa María UNVM, Cordoba, Argentina; [3]Dept Biology, Fac of Sci., Santiago, Chile; [4]Inst. Mercedes Y Martin Ferreyra (INIMEC-CONICET), Cordoba, Argentina

Abstract: Several events are necessary for proper neuronal development, such as differential protein expression, cytoskeletal dynamics, and endosomal trafficking. Smad Anchor for Receptor Activation (SARA) is a protein that binds to early endosomes; carrying out specific functions related to traffic but also participating in signaling such as in Transforming Growth Factor β (TGFβ) pathway. In this regard, it has been described that SARA recruits Smad2/3 and, therefore, favors the activation of this pathway but also can modulate the TβRI dephosphorylation by PP1c, and inactivate the pathway both in epithelial cells and cell lines. Moreover, it has been shown that TGFβ signaling specifies axon during neuronal development; however, SARA participation in this signaling pathway during the developmental process remains unknown. For this reason, we proposed to analyze the participation of SARA in TGFβ signaling during neuronal development. Results obtained in cultures of hippocampal neurons, through FRET Acceptor Photobleaching showed physical interaction between SARA and the TGFβ receptor I (TβRI). Also, performing loss and gain of function experiments, we found that SARA suppression (through shRNA expression) generates both greater axonal growth and loss of axonal specification since neurons have more than one axon compared with the control condition. In addition, the transition of polarity stage is accelerated in these neurons. Interestingly, this same phenotype is repeated when we use a mutant form of SARA (SARA-F728A) that alters its binding to PP1c protein (involved in TGFβ inactivation) and therefore, the TβRI remains hyperphosphorylated, keeping the pathway activated. Also, by FRET we found that SARA-F728A has more interaction with PP1c than control conditions, suggesting that SARA arrests to PP1c. Taking together; these results suggest that SARA participates in the TGFβ pathway in neurons through the negative regulation, which seems to be a necessary requirement for the correct neuronal development.

Title: Precise removal of Calm1 long 3′UTR isoform by CRISPR-Cas9 genome editing impairs dorsal root ganglion development in mice

Authors: H. N. GRUNER[1], ***B. BAE**[1], M. LYNCH[1], D. OLIVER[2], K. SO[1], G. S. MASTICK[1], W. YAN[2], P. MIURA[1];
[1]Dept. of Biol., Univ. of Nevada Reno, Reno, NV; [2]Dept. of Physiol. and Cell Biol., Univ. of Nevada Reno Sch. of Med., Reno, NV

Abstract: Alternative polyadenylation often produces different length 3′UTR isoforms with the same protein-coding sequences. In mice and humans, thousands of alternative long 3′UTR isoforms are preferentially expressed in neural tissues. However, few studies have evaluated the function of alternative 3′UTR isoforms *in vivo*. In mice, the Calmodulin1 gene (*Calm1*) transcribes two mRNA isoforms, *Calm1-S* (0.9 kb 3′UTR) and *Calm1-L* (2.5 kb 3′UTR) in the nervous system. *Calm1* is one of three genes that encode calmodulin (CaM), a calcium signaling modulator important for the proper development of precerebellar and dorsal root ganglia (DRG) neurons. Our characterization of the expression patterns of *Calm1-S* and *Calm1-L* showed neural-enriched expression of *Calm1-L*, with particularly strong expression in DRG. To understand the functional impact of the *Calm1-L* loss in vivo, we performed CRISPR-mediated long 3′UTR-specific deletions. Our novel approach successfully abolished the expression of the *Calm1-L* specifically without impairing the expression of the short 3'UTR isoform and allowed us to directly assess the long 3′UTR isoform-specific phenotypes. Mice embryos lacking *Calm1-L* displayed abnormal positioning of cell bodies and aberrant axon extension of DRG neurons. Furthermore, *ex vivo* explant culture of mutant DRG showed abnormal axon fasciculation. We performed low-input capillary western of dissected DRGs and found that overall CaM protein levels were not changed between wild-type and mutants. Fluorescence *in situ* hybridization (FISH) and RNA-seq analysis of DRG revealed that *Calm1-S* but not *Calm1-L* was localized to axons. Consistent with this finding, 3′UTR isoform-specific stability assays showed that *Calm1-L* is less stable than *Calm1-S*. FISH analysis using 3′UTR-specific probes suggested that the *Calm1* 3′UTR is cleaved to generate isolated 3′UTR fragments. Further investigation is required

to determine the mechanism by which these isolated *Calm1* 3′UTR fragments are produced, and whether they contribute to the DRG phenotypes observed upon *Calm1-L* loss.

Title: Subcellular regulation of protein synthesis in dopaminergic neurons

Authors: *B. D. HOBSON[1,2], L. KONG[1], O. LIEBERMAN[2], D. SULZER[2], P. A. SIMS[1];
[1]Dept. of Systems Biol., [2]Dept. of Psychiatry, Columbia Univ. Med. Ctr., New York, NY

Abstract: Subcellular localization and translation of mRNA is involved in neuronal development and synaptic plasticity, but most studies of local translation have focused on excitatory and inhibitory neurons. Midbrain dopaminergic neurons provide critical input to circuits involved in reward processing, movement control, and cognitive function. Dopamine neurons produce extensive, unmyelinated axons that travel via the medial forebrain bundle to innervate basal ganglia and cortical targets. In addition to axonal release in the forebrain, dopamine neurons also exhibit somatodendritic dopamine release in the midbrain, including from dendrites projecting ventrally into the substantia nigra pars reticulata. The molecular mechanisms by which dopamine neurons regulate neurotransmission across expansive subcellular compartments remain unclear. Therefore, detailed studies of subcellular translation in DA neurons may shed light on molecular mechanisms of dopaminergic function in health and disease.

Given the dynamic regulation of dopamine release across an elaborate cytoarchitecture, we suspected that dopamine neurons might employ local protein synthesis to enable rapid changes in the dendritic and axonal proteome. Here, we employed a combination of metabolic labeling, fluorescence *in situ* hybridization, and dopamine neuron-specific ribosome-bound RNA-sequencing to investigate local protein synthesis in midbrain dopamine neurons. In DA neuronal cultures, protein synthesis is particularly prominent in migrating DA axons (growth cones). We identified localization of mRNAs encoding for dopamine transmission machinery in both axons and dendrites of dopamine neurons *in vitro*. Fluorescence *in situ* hybridization revealed extensive mRNA in dopaminergic dendrites *in vivo*. Finally, ribosome-bound RNA sequencing revealed translating mRNAs in striatal axons and dendrites of the substantia nigra pars reticulata. These

results demonstrate that similar to excitatory and inhibitory neurons, dopamine neurons employ local translation in both axons and dendrites. Ongoing studies will address the relationship between local translation, regulation of dopamine release, and exposure to drugs of abuse.

Title: Molecular, cellular, electrophysiological and behavioral correlates of neuronal dysfunction in KSRP knockout mice

Authors: *M. DELL'ORCO[1], P. PATEL[3], S. L. OLGUIN[1], A. S. GARDINER[2], R. D. COLE[5], P. I. ORTINSKI[4], A. M. ALLAN[1], J. L. BRIGMAN[1], J. L. TWISS[3], N. I. PERRONE-BIZZOZERO[1];

Abstract: The KH-type splicing regulatory protein (KSRP) is an RNA-binding protein (RBP) associated with the decay of short-lived mRNAs containing AU-rich elements in the 3' untranslated region. Our previous studies demonstrated that KSRP is expressed in neurons during late stages of differentiation, where it destabilizes GAP-43 and other growth-associated mRNAs, halting axonal outgrowth. In contrast, loss of KSRP results in increased GAP-43 mRNA stability and axonal outgrowth in hippocampal neurons (Bird et al, PLoS One 2013). To understand the role of KSRP in neuronal differentiation and function in vivo, we first analyzed gene expression in adult mice that were either heterozygous (Het) or knockout (KO) to the *Khsrp* gene, along wild type (WT) littermates. Using microarrays, we found upregulation of 1902 transcripts in the neocortex, 532 of which are high affinity KSRP interacting mRNAs. This set was further compared to a set of neuron-specific mRNAs to identify neuronal targets of this RBP. Biological pathway analyses revealed that these targets are involved in dendritic and axonal formation and neurotransmission. Supporting these results, we found that neurons in the neocortex of *Khsrp* Het and KO mice exhibit increased dendritic spine density and axon growth. *Khsrp* KO mice also show increased frequency of miniature excitatory postsynaptic currents (mEPSC) in the hippocampus, while prefrontal cortex mEPSC frequency is increased in both KO

and Het mice. Primary neuron cultures from these mice point to a neuron-intrinsic alteration in axonal and dendritic growth. *Khsrp* KO mice showed significant trace conditioning deficits compared to age- and sex-matched WT, indicating impaired hippocampal-dependent learning. *Khsrp* KO mice also had significant deficits in behavioral flexibility as shown by their impaired performance in the reversal and set-shifting of species-specific stimulus domains, which require intact working memory. In addition, *Khsrp* KO mice display novelty-induced hyperactivity that was observed in several tests including open field and zero maze. Overall, our results indicate that prenatal deletion of KSRP impairs neuronal differentiation resulting in alterations in neuronal morphology and activity as well as prefrontal- and hippocampal-dependent behavior.

Title: A CLN6-CRMP2-KLC4 complex regulates anterograde, ER-derived vesicle trafficking in cortical neurites

Authors: *K. A. WHITE[1], J. T. CAIN[1], S. KOH[1], T. B. JOHNSON[1], D. TIMM[1], D. STURDEVANT[1], K. HENSLEY[2], J. M. WEIMER[1];

Abstract: As neurons establish vast connections throughout the central nervous system, the transport of cargo along the microtubule network of the axon is a crucial step in neuronal differentiation, maintenance, and health. Specifically, building blocks such as membrane components, organelles, transmembrane receptors, adhesion molecules, and neurotransmitters all require proper transport to the distal end of the axon. Here, we identify a novel complex regulating anterograde vesicular transport in axons, composed of CLN6: an ER-associated protein of unknown function implicated in Batten disease, CRMP2: a tubulin binding protein important in regulating neurite microtubule dynamics, and KLC4: a classic transport motor protein. We find that this CCK complex allows ER-tagged vesicles to properly migrate to the distal end of the axon, aiding in proper neurite outgrowth and arborization. In the absence of CLN6, the CCK complex is unable to form, leading to deficits in CRMP2 binding to a host of

other protein partners, as well as reduced vesicular transport and stunted neurite outgrowth. Interestingly, treatment with a CRMP2 modulating compound, lanthionine ketamine ester, partially restored these deficits in a mouse model of CLN6 deficiency, indicating that stabilization of CRMP2 interacting partners may prove beneficial in lieu of restoring the CCK complex. Taken together, these findings boast a novel mechanism of ER vesicle transport in the axon, and provide new insights into therapeutic targets for neurodegenerative disease.

Title: Selective axonal translation of prenylated Cdc42 mRNA isoform supports axon growth

Authors: *M. D. ZDRADZINSKI, S. J. LEE, P. PATEL, A. N. KAR, P. SAHOO, K. D. LANTZ, J. L. TWISS;
Univ. of South Carolina, Columbia, SC

Abstract: Cdc42 is a member of the Rho family of GTPases that plays a key regulatory role in actin dynamics. Actin polymerization is integral to neuronal growth, regeneration, axon pathfinding and circuit formation. The *CDC42* gene gives rise to two splice variants that have mRNAs with different 3'UTRs and encode proteins with distinct C-termini containing a CCAX motif for palmitoylation and a CAAX motif for prenylation (Palm-Cdc42 and Prenyl-Cdc42, respectively). Palm-Cdc42 has been shown to regulate dendritic spine maturation, while Prenyl-Cdc42 acts in axon specification (Yap et al, 2016). We show that knockdown of the Prenyl-Cdc42 and not Palm-Cdc42 reduces axon length in cultured Dorsal Root Ganglion (DRG) neurons. Despite that both proteins are seen in axons, Prenyl-Cdc42 mRNA and not Palm-Cdc42 mRNA localizes into axons. The 3'UTR of Prenyl-Cdc42 mRNA drives its localization into axons of both PNS and CNS neurons in culture. Full axon growth promotion by Prenyl-Cdc42 requires that both the mRNA localize into axons and the encoded protein has an intact CAAX motif for post-translational modification in axons. Interestingly, the axonally translated Prenyl-Cdc42 protein localizes to the distal membrane of axonal growth cones, which is distinct from

the patterns seen for Palm-Cdc42 when its mRNA is targeted into axons with a heterologous 3'UTR and for cell body-translated Prenyl-Cdc42 protein. On the other hand, the Palm-Cdc42 mRNA localizes into dendrites raising the possibility that localized translation of Prenyl-Cdc42 is needed for dendrite growth. Taken together, these data show that alternative splicing of the CDC42 gene product generates unique subcellular localizing mRNAs that likely underlie its role in neuronal growth and maturation.

Title: Investigating the role of Miro 1-dependent mitochondrial trafficking in GABAergic interneurons

Authors: *K. NDOCI[1], P. PELZER[1], V. SAKTHIVELU[1], G. WANI[1], J. M. SHAW[2], M. BERGAMI[1,3];
[1]Cologne Excellence Cluster on Cell. Stress Responses in Aging-Associated Dis. (CECAD), Cologne, Germany; [2]Dept. of Biochem., Univ. of Utah Sch. of Med., Salt Lake City, UT; [3]Ctr. for Mol. Med. (CMMC), Cologne, Germany

Abstract: GABAergic interneurons are generally characterized by fast firing rates and a higher energetic demand as compared to most excitatory neurons. By supplying ATP and several biosynthetic precursors, mitochondria critically contribute to energy metabolism in neurons, particularly at synaptic sites, suggesting a key role for mitochondrial trafficking in interneurons. Recent evidence indicates that interfering with mitochondrial ATP supply at early stages of neuronal development specifically impairs the migration of interneurons, but not excitatory neurons, through the neocortex. However, whether and to which extent mitochondrial motility per se is required for interneuronal migration during development or for synaptic transmission and circuit activity later on is incompletely understood. Mitochondrial transport relies on microtubule-based motors: kinesin proteins carry the organelles toward the plus end of the microtubules, whereas dynein proteins move them in the opposite direction. The attachment of mitochondria to these motors is mediated by an adaptor complex which comprises the Ca^{2+}-dependent mitochondrial GTPases Miro1 and 2 as well as their binding partners (Traks). Here, we examined the role of Miro1 in GABAergic interneurons *in vivo* and tested the hypothesis that

mitochondrial trafficking is important to sculpt the connectivity of these cells. We conditionally deleted Miro1 from the two most represented interneuronal subtypes, i.e. parvalbumin-positive (PV+) and somatostatin-positive (SST+) interneurons. Loss of Miro1 disrupted mitochondrial trafficking in both classes of interneurons, leading to altered mitochondrial distribution and morphology along neurites, despite negligible neuronal death. Intriguingly, we found that mice lacking Miro1 in SST+ neurons, but not in PV+ neurons, developed epileptic seizures during their first months of life, indicating a key role of Miro1 in maintaining the inhibitory tone of specifically this class of interneurons. Our finding suggests that a differential susceptibility of distinct classes of GABAergic interneurons to defective mitochondrial dynamics may underlie the emergence of pro-epileptogenic symptoms.

Abstract: Neurons are highly polarized cells continuously relying on intracellular transport, which allows them to send information outside trough the axon and receive them through the dendrites. Movement along different regions is a key feature of neuronal transport, allowing many proteins with different roles in neuron homeostasis to reach long distances. Several neurodegenerative diseases, such as Alzheimer's, Parkinson's or Amyotrophic Lateral Sclerosis, exhibit significant axonal pathology, where transport impairment can have a crucial influence. However, the mechanism underlying the disruption of neuronal transport remains unclear. In this study we aim to characterize neuronal transport dynamics of specific proteins and the molecular machinery that is regulating this complex process. Human Neural Stem Cells derived neurons were terminally differentiated in a multichannel device (Ibidi) for 30 DIV. Plasmids encoding for

different GFP coupled proteins were designed to express those who are involved in important neuronal functions (development, synaptic activity, disease signaling) and transfected in neurons. Time-lapse movies of the cargos were acquired to detect possible changes in movement. Data analysis was performed in Imaris software, using specific object segmentation and tracking algorithms. Raw data from automated analysis were processed to describe the main motion parameters: velocity, directionality, track length, and others. Post-imaging Immunocytochemistry experiments were performed to assess the localization of our cargos, and discriminate between axonal or dendritic transport. Preliminary results showed different cargo's behavior during movement: Amyloid Precursor Protein (APP) cargos with higher velocity in anterograde movement were observed compared with the retrograde one; meanwhile for Synaptophysin a major population of stationary particles was found. Moreover, sorted data for axonal and dendritic transport description shown faster APP particles in axonal anterograde movement. Relying on the description of movement dynamics in neurons, we decided to screen for protein-protein interactions of our cargos, using GFP trap and CoIP approaches followed by Mass Spectrometry analysis, which will shed light on possible partners involved in the regulation of transport. Our work describes an *in vitro* model for neuronal transport study to highlight the different behavior of proteins involved in crucial physiological processes. The complete view will elucidate details about neuronal transport regulation and will open a way to understand the role of this process in the pathophysiology of neurodegenerative diseases.

Title: Cooperation of MAP7 and tau controls regional regulation of axonal transport in sensory neurons

Authors: *S. TYMANSKYJ, L. MA;
Thomas Jefferson Univ., Philadelphia, PA

Abstract: Different regions of a neuron have varying functional needs that require differential regulation of axonal transport driven by microtubule motors, but the underlying mechanisms of motor regulation remains unclear. *In vitro* studies have shown that binding of motors to microtubules can be regulated by microtubule associated proteins (MAPs). For example, tau inhibits the binding of the conventional kinesin (kinesin-1) to microtubules, whereas MAP7

recruits kinesin-1 to microtubules. Here, we examined the function and regulation of these two MAPs in sensory neurons from the dorsal root ganglion (DRG). We show that MAP7 is enriched at branch junctions, whereas tau has an opposing localization, concentrated distally towards the growth cone. Interestingly, transport of mitochondria in these regions is correlated with MAP7 and tau localization, with increased anterograde transport at branch junctions but reduced anterograde transport in the distal axons. We further examined the mechanisms mediating MAP7 and tau localization. In COS cells where single microtubules can be resolved, we show MAP7 and tau occupy different regions along individual microtubules, with MAP7 preferring stable regions and tau binding to more dynamic regions. This binding property of MAP7 creates a boundary that prevents microtubule depolymerization and rescues microtubule polymerization. In DRG neurons, this property allows MAP7 to promote branching by reducing branch retraction. Further domain analysis shows that this MAP7 function is mediated by the middle 'P'-domain, which is responsible for competing against tau for microtubule binding. In addition to harboring a second microtubule binding site, the P-domain also contains multiple phosphorylation sites that influences the microtubule binding kinetics of MAP7 and hence impacts microtubule stability and kinesin-mediated transport. Taken together, our studies demonstrate that a cooperative mechanism mediated by differential microtubule binding by MAP7 and tau that impacts kinesin mediated delivery of cargos into different compartments of the neuron.

Title: Growth cone molecular machinery locally implements the development of subtype-specific neocortical circuitry

Authors: *J. HATCH[1], A. POULOPOULOS[2], A. ENGMANN[1], J. MACKLIS[1];
[1]Stem Cell & Regenerative Biology, Ctr. for Brain Sci., Harvard Univ., Cambridge, MA;
[2]Pharmacol., Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract: During development, growth cones (GCs) of diverse projection neuron (PN) subtypes navigate complex extracellular environments to reach distant, subtype-specific targets. These axon-terminal structures must respond to substrate-bound and diffusible signals in a subtype- and context-specific fashion to construct functional circuitry. Recent studies strongly indicate that subcellular localization of specific molecular machinery to GCs might underlie the precise behaviors of these structures during circuit "wiring." While great progress has been made toward identifying diffusible and substrate-bound signals that guide axon growth, it is becoming increasingly clear that intracellular, local growth cone biology underlies the distinct behaviors of specific neuronal subtypes at specific developmental stages. Molecular determinants of these critical processes remain largely unstudied with respect to distinct neuronal subtypes under physiological conditions. Because most current knowledge of growth cone biology was identified *in vitro,* often with heterogeneous populations, access to subtype-specific growth cones in their native environments during normal development will substantially elucidate molecular bases of cortical and other neural circuit formation.
Our laboratory has recently developed an integrated approach that enables high-throughput, high-depth proteomic and transcriptomic investigation of purified GCs from fluorescently labeled subtype-specific cortical projection neurons. This approach has already revealed unanticipated depth of GC molecular machinery, subtype-specificity, and GC enrichment of hundreds of transcripts and proteins. Building on this foundational work, GCs have been isolated from closely-related PN subtypes with distinct axonal trajectories at critical developmental stages to investigate whether and how subtype-specific GC molecular machinery might functionally enable specific subtypes to build and maintain specific circuitry. In particular, we investigate dynamic regulation of GC transcriptomes before and after midline crossing in interhemispheric callosal PN (CPN), and investigate whether and how local molecular machinery might implement a subcortical vs. intracortical trajectory in closely related subtypes, including CPN, corticospinal neurons (CSN), and corticothalamic PN (CThPN). Together, this work has revealed a number of exciting new candidate regulators of cell-autonomous, subtype-specific axon guidance, as well as generated conceptually novel hypotheses about how regulation of growth cone transcriptomes might contribute to the formation of specific circuitry.

Title: Defects in transport of SFPQ RNA granules by KIF5A/KLC1 motors contribute to axon degeneration in CMT

Authors: *Y. FUKUDA, M. F. PAZYRA-MURPHY, O. E. TASDEMIR-YILMAZ, H.-S. SEO, S. DHE-PAGANON, *R. A. SEGAL;
Dana-Farber Cancer Inst., Boston, MA

Abstract: Neuronal axons and dendrites can span enormous distances, and so rapid intracellular transport is needed for sustained activity of these extensive projections. RNA binding proteins (RBPs) are needed for transport of RNA granules and local translation, and thus are critical regulators of the axonal transcriptome. Multiple mutations that disturb functions of RBPs can cause neurological disorders. However, whether disrupted axonal transport of RBPs directly compromises axon integrity in neurological diseases is not yet known. Splicing factor proline-glutamine rich (SFPQ) is a RBP that packages NGF-regulated transcripts, such as *Bclw*, into RNA granules and enables axonal translation of these transcripts to prevent axonal degeneration. To identify the mechanisms that transport SFPQ to axons**,** we first asked which kinesins can interact with SFPQ using co-precipitation studies. In lysates of primary rat dorsal root ganglion neurons (DRG), SFPQ selectively binds to KIF5A, one of the three conventional kinesins, and not to the other, highly related conventional kinesins, KIF5B and KIF5C, or to other KIF motors. Further specificity was evident as SFPQ selectively interacts with tetrameric motors, containing KIF5A motors and the cargo adaptor KLC1, and not those containing KIF5A and KLC2. To define the mechanism for this dual specificity, we identified the domains responsible for the interactions. We find that the highly divergent carboxy-terminal regions of KIF5A and KLC1 are required for binding to SFPQ. Recently, a Y-acidic motif residing in the cargos of kinesin-1 motor has been demonstrated to provide specificity for binding to KLC1 over KLC2. Interestingly, SFPQ contains the Y-acidic motif within its coiled coil domain. Using Isothermal titration calorimetry, we demonstrate that the peptide region spanning the Y-acidic motif of SFPQ is sufficient to directly bind to KLC1. Mutations in KIF5A are a frequent cause of axon degeneration and neuropathy in patients with CMT2 We find that expression of human, CMT2-associated mutations of KIF5A in DRGs lead to degeneration of axons. Similarly, specific disruption of kinesin-driven transport of SFPQ by expression of the Y-acidic mutant of SFPQ , which does not bind to KIF5A/KLC1 motor complex, also causes axon degeneration. Together these data demonstrate that disrupted transport of a KIF5A/KLC1-specific cargo, SFPQ, may be one of the key mechanisms underlying axon degeneration in patients harbouring KIF5A CMT2 mutations.

Title: 3'Utr RNA sequence motifs that direct subtype-specific axonal RNA trafficking during development of cerebral cortex projection neurons: Identification and functional analysis via computationally-enabled, massively parallel reporter assay (mprau) *in vivo*

Authors: *P. VEERARAGHAVAN, J. J. HATCH, J. D. MACKLIS;
Dept. of Stem Cell and Regenerative Biol. & Ctr. for Brain Sci., Harvard Univ., Cambridge, MA

Abstract: Neurons are by far the most polarized cell type, and they need to isolate cellular functions from their dendrites at one end to their distal axons at the other, with cell body functions in between. Projection neurons (PN) of the cerebral cortex, in particular, are among the longest of any neuron classes, and I focus on these. Cortical PN exemplify the extreme of spatially distributed functionality; they underlie sensory-motor integration, cognition, and behavior, and are thus critically important to understand. Advances in molecular understanding of their subtype-specific development enables their functional molecular interrogation. During development, PN extend axons led by semi-autonomous growth cones (GCs) over great distances (10^3 -10^5 soma diameters), through varied extracellular environments, to reach defined, circuit-appropriate targets. The mechanisms by which GCs sense and respond to the many environments through which they move are not fully understood, nor is the extent to which the nucleus communicates or controls the transcriptomic and proteomic makeup of subtype-specific GCs *in vivo*. RNA trafficking and stability are major determinants of GC transcriptomic makeup; while these general mechanisms have been well studied in other cell types, subtype-specific RNA trafficking and stability in PN are not deeply understood.
Our lab has recently developed an approach that enables deep transcriptomic and proteomic investigation of purified GCs from fluorescently-labeled subtype-specific projection neurons. Our lab has already identified an early GC-localized motif, but this alone is insufficient to explain the hundreds of transcripts we find localized to GCs. I extend this work through a combined computational and experimental approach to identify (potentially minimal) *cis*-acting sequence elements within the GC-localized transcriptome that might direct axonal RNA trafficking, and therefore control circuit development and later synaptic function. In particular, I adapt novel tools, notably a massively parallel reporter assay (MPRA), to perform a screen of *cis*-acting RNA sequences that drive axonal localization in PN *in vivo,* computationally informed by our existing subcellular transcriptomic data. I functionally test perturbations of RNA

sequences that drive GC localization, in order to discover minimal, potentially combinatorial, subelements responsible for GC localization. These investigations aim to reveal novel *in vivo* biology that underlies the spatial distribution of function in developing neurons, and to provide new knowledge about the mechanisms by which neurons generate precise, subtype-specific circuitry.

Abstract: Maintenance methyltransferase, DNA methyltransferase 1 (DNMT1) is essential to copy the methylation pattern on newly replicated genomic DNA in proliferating cells. Although the abundant expression of DNMT1 in post-mitotic neurons at developmental stage and in the adult mammalian brain has been observed, its function in these cells still remains elusive. To investigate the function of DNMT1 in post-mitotic neurons, we induced DNMT1 deficiency in these cells and examined the phenotype in vitro and in vivo using neuron-specific Dnmt1 conditional knock-out (cKO) mice. We found that the dendritic complexity in DNMT1-deficient cultured neurons and in dentate gyrus (DG) neurons of Dnmt1 cKO mice was increased compared to that in control neurons. Moreover, Dnmt1 cKO mice exhibited a symptom of hyperactivity in behavioral analysis, especially the open field test and light/dark transition test. DNA methylome analysis shows preferential hypomethylation of neuron-specific enhancers together with the slight genome-wide hypomethylation in DNMT1-deficient neurons directly

isolated from DG of Dnmt1 cKO mice. Correlating with this result, the upregulated expression of neuronal genes that are controlled by these enhancers was observed in DNMT1-deficient cultured neuron. Collectively, these results suggest that DNMT1 in post-mitotic neuron play a crucial role in proper neuronal development and function via DNA methylation on neuronal enhancers. Further analysis of the DNMT1 function in post-mitotic neurons is currently underway.

Title: LKE maintains tubulin polymerization and CRMP2 function in cortical neurons and oligodendrocyte precursor cells during inflammation *in vitro*

Authors: *V. L. SAVCHENKO, D. L. FEINSTEIN;
Anesthesiol., Univ. of Illinois at Chicago, Chicago, IL

Abstract: Neuroinflammation includes the release of pro-inflammatory cytokines from astrocytes, microglia or other immune cells and it may trigger axonal degeneration. Collapsin response mediator protein-2 (CRMP2), a tubulin-binding protein, has been shown to be cleaved by calpain1 during neurodegeneration and considered as a potential target for therapeutic approaches. Lanthionine ketimine ester (LKE) binds to CRMP2 and prevents its cleavage during protease activation. The effect of LKE was examined in cortical cultured neurons at 12 days in vitro (DIV) in normal and under inflammatory conditions induced by glutamate, interferon gamma (IFNγ) or conditioned medium from microglial cells treated with IFN (mIFNγ). The same effects were assessed in purified cultured oligodendrocytes (OLGs) and their precursor cells (OPCs) *in vitro.* The morphological features of neurons and glia and the distribution of cytoskeletal proteins were analyzed by immunofluorescent method and image analysis. CRMP2 and β3 tubulin were distributed in neuronal soma and neurites uniformly under normal conditions. LKE increased CRMP2 expression in cortical neurons and their neurites become thicker and longer. The overexcitation of cortical neurons induced by glutamate evoked reduction of β3 tubulin expression and the neurites became swollen and shortened, whereas LKE partially maintained the expression of β3 tubulin and CRMP2. IFNγ induced down-regulation of β3 tubulin in CRMP2 expressed neurons. However, mIFNγ was found to be most harmful and induced damage in cortical neurons. Quantitative analysis shows that CRMP2 expression was

increased by incubation with LKE, or glutamate. The expression of β3 tubulin was increased by LKE and decreased by glutamate, IFNγ or mIFNγ. The ratio of CRMP2 and β3 tubulin expression was increased due to LKE, but decreased during inflammation. The highly branched OPCs expressed PDGFRα and were regulated by PDGF and glutamate. The purified cultured OPCs were less branched and CRMP2 was expressed in the growth cones and protrusions connected to ECMs; CRMP2 was highly expressed in branched OLGs that were labeled with myelin basic protein. The purified OPCs were vulnerable and CRMP2 expression was suppressed during inflammation. The response of purified cultured microglia to the cytokines was stronger than in the mixed cultured neuronal cells suggesting the contribution with factors released from neurons and astrocytes. The results suggest that cleaved CRMP2 protein does not stabilize microtubules during neuroinflammation and LKE maintains CRMP2-mediated microtubule polymerization in neurons and the differentiation of OPCs into OLGs.

Title: Dysregulation and restoration of homeostatic network plasticity in fragile X syndrome mice

Authors: *D. E. EAGLEMAN[1], K. A. JEWETT[1], K. LEE[1], S. SORIANO[2], D.-C. LIU[2], N.-P. TSAI[1,2];

Abstract: Chronic activity perturbations in neurons induce homeostatic plasticity through modulation of synaptic strength or other intrinsic properties to maintain the correct physiological range of excitability. Although similar plasticity can also occur at the population level, what molecular mechanisms are involved remain unclear. In the current study, we utilized a

multielectrode array (MEA) recording system to evaluate homeostatic neural network activity of primary mouse cortical neuron cultures. We demonstrated that chronic elevation of neuronal activity through the inhibition of GABA(A) receptors elicits synchronization of neural network activity and homeostatic reduction of the amplitude of spontaneous neural network spikes. We subsequently showed that this phenomenon is mediated by the ubiquitination of tumor suppressor p53, which is triggered by murine double minute-2 (Mdm2). Using a mouse model of fragile X syndrome, in which fragile X mental retardation protein (FMRP) is absent (*Fmr1* knockout), we found that Mdm2-p53 signaling, network synchronization, and the reduction of network spike amplitude upon chronic activity stimulation were all impaired. Pharmacologically inhibiting p53 with Pifithrin-α or genetically employing *p53* heterozygous mice to enforce the inactivation of p53 in *Fmr1* knockout cultures restored the synchronization of neural network activity after chronic activity stimulation and partially corrects the homeostatic reduction of neural network spike amplitude. Together, our findings reveal the roles of both *Fmr1*and Mdm2-p53 signaling in the homeostatic regulation of neural network activity and provide insight into the deficits of excitability homeostasis seen when *Fmr1* is compromised, such as occurs with fragile X syndrome.

Title: Impaired reliability and precision of spiking in adults but not juveniles in a mouse model of Fragile X syndrome

Authors: *D. DWIVEDI[1], S. CHATTARJI[2,3,4], U. S. BHALLA[1,3];
[1]Natl. Ctr. For Biol. Sci., Bangalore, India; [2]Natl. Ctr. for Biol. Sci., Bangalore, India; [3]Ctr. for Brain Develop. and Repair, Inst. for Stem Cell Biol. and Regenerative Med., Bangalore, India; [4]Ctr. for Discovery Brain Sciences, Deanery of Biomed. Sciences, Univ. of Edinburgh, Hugh Robson Building, 15 George Square, Edinburgh, United Kingdom

Abstract: Fragile X Syndrome (FXS) is the most common source of intellectual disability, affecting 1 in 100 people. Previous studies have implicated altered functioning of ion channels in

multiple symptoms manifested in FXS. Our knowledge about intrinsic conductance changes, at the cellular level in disease models is still limited, despite extensive network level studies in mouse models. Studies in the past few years have shown reduced synchrony of spike discharge in CA1 hippocampus in FXS, which might be due to alterations in synaptic connections between neurons or changes in intrinsic conductances of the neuron. The present study examines intrinsic conductances which might underlie synchrony changes in neurons of FXS mice. The objective of the study was to see if one can establish single-cell correlates of the network incoherence observed in vivo. Firing variability at the single cell level was measured using whole cell patch clamp in CA1 pyramidal cells of hippocampal slices in FXS mice, in both juvenile and adult animals. We used a step current pulse protocol repeated over multiple trials and probed for variability in spike number and spike timing precision across different trials. We found that both spike numbers and spike timing were more variable for adult KO animals as compared to their WT littermates, but the same phenotype was not observed in juveniles. Spike number variability was increased at both within and between cell levels across multiple trials, in FXS neurons. Increased variability had a high correlation with reduced spike number, only for adult but not for juvenile CA1 cells. In contrast, juvenile CA3 cells were found to be hyperexcitable in FXS mice, indicating differential effects of FMRP KO in different regions. The reduction in spike numbers in CA1 was due to increased mAHP which we attributed to elevated SK currents. Blocking the SK current led to a partial rescue of the phenotypes of cell variability. We did not find differences in levels of I_h current and M currents between WT and KO, which were other putative candidates affecting mAHPs. We probed levels of SK channels at the soma and dendrites using immunfluorescence experiments. In agreement with previously published results we did not observe a significant change in the levels of SK channel at either soma or dendrites. We interpret this to mean that FMRP has an alternate mechanism, such as some previous studies have shown that it can interact via protein - protein interaction and modulate ion channels functioning. Thus, the present study has established a single cell level correlate of increased spike incoherence observed in FXS mice where SK currents are found to be partially responsible for the observed phenotype.

Title: Mitochondrial deficits contribute to impaired dendritic maturation in FXS human and mouse neurons

Authors: *M. SHEN, X. ZHAO;
UW-Madison, Madison, WI

Abstract: Fragile X syndrome results from a loss of the RNA-binding protein fragile X mental retardation protein (FMRP). How FMRP regulates neuronal development and function remains unclear. During embryonic development, mitochondria are important for neural progenitor proliferation and neuronal survival. Alterations in mitochondrial morphology and function directly impact morphological development of neurons. Here, we report that FMRP has a critical role in dendritic maturation of adult new neurons, neonatal hippocampal neurons, and human neurons developed in transplanted mouse brains. We discover that FMRP-deficient immature neurons exhibited altered expression of mitochondrial genes, fragmented mitochondria, impaired mitochondrial function, and increased oxidative stress. Enhancing mitochondria fusion by either a chemical activator or exogenous expression of mitochondrial fusion genes rescued both mitochondrial morphology and dendritic maturation deficits of FMRP-deficient neurons. We discovered that FMRP deficient neurons had reduced HTT levels and acute knockdown of HTT recapitulates both mitochondrial fusion and neuronal maturation deficits seen in Fmr1 KO neurons. We used guide RNAs to target modified CRISPR/Cas9 (dCas9VP64-SAM) to selectively activate the endogenous Htt gene in neurons and show that increased Htt transcription rescued both mitochondrial fusion and dendritic maturation deficits of Fmr1 KO neurons. Finally, we show that mice with HTT knockdown in the hippocampus exhibit several behavioral deficits similar to Fmr1 mutant mice and treatment with a mitochondrial fusion compound rescued behavioral deficits of both Fmr1 KO mice and mice with hippocampal knockdown of HTT. Our data demonstrate that mitochondrial dysfunction contributes to the impaired maturation of FMRP-deficient developing neurons and present a crosstalk between FMRP and HTT in pathogenesis of human diseases.

Title: Loss of fragile x protein fmrp impairs homeostatic synaptic downscaling through tumor suppressor p53 and ubiquitin E3 ligase Nedd4-2

Authors: *K. LEE[1], K. A. JEWETT[1], H. CHUNG[1,2], N.-P. TSAI[1,2];
[1]Dept. of Mol. and Integrative Physiol., [2]Neurosci. Program, Univ. of Illinois at Urbana-Champaign, Urbana, IL

Abstract: Synaptic scaling allows neurons to homeostatically readjust synaptic strength upon chronic neural activity perturbations. Although altered synaptic scaling has been implicated to underlie imbalanced brain excitability in neurological disorders such as autism spectrum disorders and epilepsy, the molecular dysregulation and restoration of synaptic scaling in those diseases have not been demonstrated. Here, we showed that the homeostatic synaptic downscaling is absent in the hippocampal neurons of Fmr1 KO mice, the mouse model of the most common inherited autism, fragile X syndrome (FXS). We found that the impaired homeostatic synaptic downscaling in Fmr1 KO neurons is caused by loss-of-function dephosphorylation of an epilepsy-associated ubiquitin E3 ligase, neural precursor cell expressed developmentally down-regulated gene 4-2, Nedd4-2. Such dephosphorylation of Nedd4-2 is surprisingly caused by abnormally stable tumor suppressor p53 and subsequently destabilized kinase Akt. Dephosphorylated Nedd4-2 fails to elicit 14-3-3-dependent ubiquitination and down-regulation of the GluA1 subunit of AMPA receptor, and therefore impairs synaptic downscaling. Most importantly, using a pharmacological inhibitor of p53, Nedd4-2 phosphorylation, GluA1 ubiquitination and synaptic downscaling are all restored in Fmr1 KO neurons. Together, our results discover a novel cellular mechanism underlying synaptic downscaling, and demonstrate the dysregulation and successful restoration of this mechanism in the FXS mouse model.

Title: FMRP deficiency up-regulates miR-128 and contributes to GLT1 dysregulation in Fmr1 KO astrocytes

Authors: *Y. MEN, V. PROMES, R. JARVIS, J. YELICK, E. BROWN, Y. YANG;
Tufts Univ., Boston, MA

Abstract: Fragile X syndrome (FXS) is a neurodevelopmental disorder which is caused by the loss-of-function of fragile X mental retardation protein (FMRP). We previously showed that astroglial glutamate transporter subtype GLT1 is significantly reduced, resulting from the decreased mGluR5 signaling in cortical astrocytes of Fmr1 KO mice. The downregulation of GLT1 contributes to dysregulated extracellular glutamate homeostasis and enhanced neuronal excitability in Fmr1 KO mice. In our current study, we investigated the miRNA (miR)-mediated mechanisms for mGluR5 and GLT1 dysregulation in Fmr1 KO astrocytes. We first compared miR expression levels from both wild type (WT) and Fmr1 KO primary astrocytes and neurons using miR microarrays. The loss of FMRP has little effect on the overall miR expression in neurons. In contrast, a large percentage (29.1%) of miRs are found up- (but not down-) regulated in Fmr1 KO astrocytes compared to WT astrocytes, implicating a primarily inhibitory role of FMRP in regulating miR expression in astrocytes, but not in neurons. Re-expression of FMRP in Fmr1 KO astrocytes sufficiently reverses increased miR expression. Consistently to the elevated miR levels in Fmr1 KO astrocytes, the primary transcripts of representative miRs (pri-miRs) are also increased in Fmr1 KO astrocytes, implicating that FMRP likely suppress the transcription of miRs in astrocytes. We further analyzed up-regulated miRs and found that one such miR, miR-128 (15-fold increase in Fmr1 KO vs. WT astrocytes) has a predicted binding site on mGluR5 3'UTR. Subsequent transfection of miR-128 abolished 36% mGluR5 protein level by directly binding to mGluR5 mRNA transcript in astrocytes. MiR-128 transfection also reduces 33% of neuron-induced GLT1 in neuron and astrocyte co-cultures. Our results suggest that miR-128 has an inhibitory effect on GLT1 by directly inhibiting mGluR5 expression through binding to its 3'UTR in astrocytes. Thus, the substantial upregulation of miR-128 reveal a potential new role of miR-mediated pathological mechanisms in mGluR5 and GLT1 dysregulation in mouse models of FXS, providing potential new targets to modulate FXS symptoms.

Title: Altered ionotropic receptor maturation underlies network dysregulation and impaired auditory critical periods of Fragile X knockout mice

Authors: *Y. J. SONG, F. E. JENSEN;
Neurol., Univ. of Pennsylvania, Perelman Sch. of Med., Philadelphia, PA

Abstract: Fragile X syndrome (FXS) is the leading genetic cause of intellectual disability and autism. Patients have deficits in auditory processing, communication and language development, making the auditory cortex of interest. *Fmr1* KO mice exhibit impaired tonotopic plasticity during the auditory critical period (CP) (Kim et al, 2013), impaired parvalbumin cell development in auditory cortex (Wen et al, 2017), and altered auditory processing (Rotschafer et al, 2013). Such plasticity and excitatory-inhibitory (E-I) imbalance phenotypes suggest a dysregulated auditory circuitry that causes FXS symptoms.
AMPA subunits of the glutamate receptor and $GABA_A$ receptor subunits undergo dynamic regulation during development to mediate E-I levels and optimize plasticity. We hypothesized that altered maturation of AMPA and $GABA_A$ receptor subunits in the auditory cortex contributes to the impaired CP in *Fmr1* KOs. Compared to WTs, *Fmr1* KOs exhibit an earlier developmental switch in AMPAR subunits with the relative GluA2:GluA1 expression significantly increased in KOs at P9 ($p=0.011$; prior to ear canal opening) and P12 ($p=0.015$; onset of WT auditory CP) that normalizes at older ages, as measured by Western blot. $GABA_A$ $\alpha3$ and $\alpha1$ subunits also have an accelerated developmental switch: $\alpha3$ is reduced at P12 ($p=0.021$) (trends at P9, $p=0.0695$), and $\alpha1$ is increased at P24 ($p=0.0056$) (pattern appears at P15, closure of CP). Consistent with the pattern of precocious maturation of AMPAR and $GABA_A$Rs, extracellular recordings in L2/3 of auditory cortex slices with L4 stimulation revealed that KOs are significantly more excitable at P12-13 ($p<0.0001$) and less excitable at P21-25 ($p<0.0001$) compared to WT. Furthermore, *Fmr1* KOs further exhibit an earlier and enhanced age-dependent sensitivity to $GABA_A$ antagonist picrotoxin. In P12-13 KOs I-O curves are significantly attenuated after picrotoxin ($p=0.0009$), indicating depolarizing GABA, and increased at P21-25 ($p=0.0005$), indicating hyperpolarizing GABA. However, WTs do not exhibit such responses until P15-16 and P40-45, respectively. Additionally, preliminary patch-clamp electrophysiology experiments are suggestive of functional differences in $GABA_A$R kinetics and zolpidem sensitivity in KOs across development. Our results highlight dysregulation of normal maturation patterns, a phenomenon where a precocious functional maturation of such receptors precedes ear canal opening to limit CP plasticity and contribute to functional deficits.

Title: The role of potassium channels as pharmacological targets for Fragile X syndrome

Authors: *W. E. CRUSIO[1], S. MIDDEI[2], J. GAUDISSARD[1], M. PREMOLI[1,3], V. LEMAIRE-MAYO[1], S. PIETROPAOLO[1];
[1]INCIA, CNRS and Univ. of Bordeaux, Pessac, France; [2]Inst. of Cell. Biol. and Neurobio., Italian Natl. Res. Council, Rome, Italy; [3]Dept. of Mol. and Translational Med., Univ. of Brescia, Brescia, Italy

Abstract: Fragile X Syndrome (FXS) is a pervasive developmental disorder caused by expansion of a CGG repeat in the promoter region of the *Fmr1* gene, located on the X chromosome, resulting in hypermethylation of a CpG island, silencing of the gene transcription, and subsequent deficiency of the encoded protein known as FMRP (fragile X mental retardation protein). In the last decade, several pharmacological therapies for FXS have been proposed targeting specific synaptic components, but none of the tested therapeutic agents demonstrated a full effect on FXS symptoms. Recent studies have highlighted the implication of potassium channels in FXS pathology, and on large-conductance Ca2+-activated K+ channels (BKCa channels) in particular, as a reduced expression and functionality of these channels have been observed in FX patients and mice. Hence, we have investigated the role of BKCa channel as a new pharmacological target in FXS therapy. Here we evaluated the neurobehavioral therapeutic effects of a BKCa channel opener molecule (BMS-204352) in the *Fmr1*-KO mouse model of FXS. The focus of our work was on the long-term effects of BMS and on their age-dependency. We demonstrated that BMS chronic administration during a critical period of neurobehavioral development (i.e., at adolescence), but not later at adulthood, was able to correct FXS-like behavioral deficits, an effect that was accompanied by the rescue of the dendritic spine morphological abnormalities.

Sci. and Biochem., Rush Univ. Med. Ctr., Chicago, IL

Abstract: Aberrant translation and disrupted signaling are molecular defects common to several neurodevelopmental disorders, including Fragile X syndrome (FXS), the most common monogenic cause of autism and inherited intellectual disability. Studies in animal models of FXS have shown that in the absence of the RNA-binding protein FMRP, there is an increase in global translation and dysregulation of key signaling pathways. However, the molecular pathogenesis of FXS in humans has remained understudied. Here we use induced pluripotent stem cell (iPSC)-derived neural precursor cells (NPCs) from multiple control and FXS patients to characterize molecular defects in a human disease-relevant model. We found that a major subset of FXS patient derived NPCs show increased protein synthesis, increased cell proliferation and altered differentiation profiles. FXS patient derived cerebral organoids also express more KI67+/SOX2+ proliferating cells. Furthermore, genome-wide splicing analysis of patient cerebral organoids revealed alternative splicing of a key cell-cycle regulated kinase in FXS. We developed a multi-parametric flow cytometry based assay to quantify protein synthesis and proliferation within specific neural subpopulations in our patient cells. Our results suggest that increased cell proliferation is a core molecular phenotype in FXS, and that this may be the result of dysregulated protein synthesis. The loss of FMRP also affects the differentiation of neural progenitor cells during development and results in increased protein synthesis in specific neural subtypes. We anticipate that this study using a human disease-relevant cellular model will shed new light on phenotypes in FXS, as well as provide a platform to be used in the development of therapeutic strategies. Our results provide strong support for an approach that involves patient

stratification based on cellular and molecular phenotypes, facilitating pre-clinical testing of potential treatments for precision medicine.

Title: Hypoactivity and increased variability of neural dynamics in fragile X circuits

Authors: ***H. MOTANIS**[1], D. V. BUONOMANO[2];
[1]Dept. of Neurobio., [2]Dept Neurobiol, UCLA, Los Angeles, CA

Abstract: A variety of network-level alterations have been reported in *Fmr1* knockout (*Fmr1*-KO) mice. One of the most well-studied network-level properties within cortical circuits are Up-states, which reflect transitions from a quiescent state to a stable network-wide increases in depolarization and firing rates. Up-states are network-level emergent phenomenon, and require the tuning of many cellular and synaptic properties. Here we examined whether spontaneous and evoked neural dynamics in isolated Fmr1-KO circuits exhibit developmental abnormalities. We used two-photon Ca^{2+} imaging to examine spontaneous network activity in $Fmr1^{-/y}$ KO slices. The mean $\Delta F/F$ of $Fmr1^{-/y}$ circuits (0.04 ± 0.004, n=10) was significantly reduced compared to $Fmr1^{+/y}$ circuits (0.11 ± 0.019, n=9; $p < 0.001$) at 11-16 days in vitro (DIV). Quantification of Up-state frequency revealed that $Fmr1^{-/y}$ circuits also exhibited a significant decrease in Up-state frequency (0.006 ± 0.004 Hz) compared to $Fmr1^{+/y}$ circuits (0.034 ± 0.009 Hz; p=0.01). Interestingly, at DIV 25-30 there was no difference in mean $\Delta F/F$ and Up-state frequency between $Fmr1^{+/y}$ and $Fmr1^{-/y}$ circuits. While Up-state frequency normalized over the course of *in vitro* development, it is important to determine whether the spatiotemporal patterns of Up-states is equivalent. Therefore, we calculated the mean pairwise correlation of the spatiotemporal patterns of activity during Up-states. Group analysis revealed that $Fmr1^{-/y}$ circuits exhibited significantly reduced correlation coefficient of Up-states (0.68 ± 0.01; n=7) compared to WT circuits (0.83 ± 0.03; n=6; $p<0.001$), indicating that the variability of the Up-states in KO circuits was higher. Thus, even though the levels of spontaneous activity in KO and WT circuits were similar at DIV 25-30, the stability of this activity was different. Since we observed a sharp decrease in Up-states in $Fmr1^{-/y}$ circuits at 11-16 DIV, we asked whether this delay might reflect

weaker excitatory connections. To characterize the net excitatory drive, input-output (IO) curves were derived using evoked electrical stimulation (40-140 μA). Surprisingly, even though KO circuits exhibited fewer Up-states at DIV 11-16, the excitatory drive between WT and KO circuits was not different. At DIV 25-30, however, EPSPs were significantly weaker in $Fmr1^{-/y}$ circuits as measured by the asymptote magnitude (5.78 + 0.54, n= 13) compared to WT circuits (8.55 + 0.86, n=16; $p<0.01$). Our results establish a sequence of in vitro developmental delays, and importantly show that even when overall activity is equivalent between WT and FX circuits, the spatiotemporal structure of this underlying activity is increased.

Title: Alteration in the intracellular cross-talk between mitochondria and exosome in the developmental disorder

Authors: *B. HA, J. HEO, Y.-J. JANG, T.-S. PARK, K.-H. LIM, S.-J. JEONG;
Korea Brain Res. Inst., DAEGU, Korea, Republic of

Abstract: Extracellular vesicles (EV) including exosomes are considered as emerging tools for biomarkers screening and drug/gene delivery in diagnostic and therapeutic strategies, respectively, because they include tissue-specific and disease-related molecules such as lipids, proteins and RNAs. *Exosomes,* 50-150 nm nano-sized vesicles, are secreted by cells and important mediators of intercellular communications. In central nervous system, various evidences show that exosomes can transfer pathogens such as prion protein (PrP), α-synuclein, amyloid β (Aβ) and phosphorylated tau. Recent findings reveal that mitochondrial component including mtDNA can be packaged in exosome and thus be horizontally transferred between cells. It has been observed that intact mitochondria or their components can be transferred between cells in disease conditions such as cancer, stroke, and lung injury. However, until now, it is not elucidated the intracellular transferring mechanism between mitochondria and exosome in the developmental disorders yet. In this study, we performed the protein profiling in exosome derived from either the brain or primary neuron/astrocyte of the developmental disorders. Various mitochondrial components were detected in exosomes isolated from the brain and primary neuron/astrocyte prepared from the mouse model. Our findings show that mitochondrial

proteins were remarkably decreased in disease mouse models which was confirmed by analysis with mitotracker and qRT-PCR for mtDNA/nDNA ratio as well as gene expression related to mitochondrial biogenesis. In conclusion, these results suggest that the intracellular trafficking system between mitochondria and exosome is altered under the developmental dysfunction and exosomes-derived mitochondrial components have a possibility as potential diagnostic/prognostic/therapeutic targets.

Title: Cell type-specific deletion of FMR1 in somatostatin and parvalbumin interneurons results in distinct behavioral phenotypes

Authors: *M. KALINOWSKA, M. VAN DER LEI, E. KLANN;
Ctr. for Neural Sci., New York Univ., New York, NY

Abstract: Fragile X syndrome (FXS) is the most common genetic cause of autism spectrum disorder (ASD) and intellectual disability that results from abnormal trinucleotide CGG repeat expansion in the *FMR1* gene, which encodes fragile X mental retardation protein (FMRP), leading to its silencing and lack of FMRP expression. FMRP is an mRNA binding protein with roles in mRNA transport, localization and translation. Thus, mRNA translation is dysregulated, which has been linked to pathophysiology, including abnormal synaptic function and dendritic morphology, and autistic-like behavioral phenotypes in mice lacking *Fmr1*. The role of FMRP in excitatory neuronal morphology and function has been well studied in *Fmr1* KO mice; however, the impact of on inhibitory synapses remains less characterized. Altered expression of GABA synthesizing enzymes and receptor subunits have been observed previously in multiple brain regions of *Fmr1* KO mice, indicating both pre- and post-synaptic dysregulation of the GABAergic system. Further, inhibitory neurotransmission is altered in a number of brain regions in *Fmr1* KO mice including amygdala, hippocampus and neocortex. However, the contribution of deleting *Fmr1* in specific subtypes of interneurons to the behavioral deficits observed in *Fmr1* KO mice has yet to be explored. Using Cre -lox recombinase technology, we generated mice with cell type-specific deletion of *Fmr1* in either parvalbumin (PV) or somatostatin (SOM) expressing interneurons, two of the major interneuron subtypes in the central nervous system. To

elucidate the complex interaction between GABAergic dysfunction and behavioral phenotypes in FXS, we assessed anxiety-like behaviors, motor function, memory, repetitive, and social behaviors in *PV-Fmr1*$^{-/y}$ and *SOM-Fmr1*$^{-/y}$ mice. Our findings indicate a cell type-specific role for FMRP in regulating distinct behavioral features associated with FXS.

Abstract: Loss of function of the gene (Fmr1) encoding Fragile X mental retardation protein (FMRP) results in unregulated, elevated mRNA translation and aberrant synaptic morphology. We find that mitochondria in neurons of the Fmr1-/y mouse have an inner membrane leak that undermines ATP synthesis and contributes to a metabolic phenotype similar to that of certain immature cells. Previous work in cardiomyocytes showed that developmental maturation is dependent on closure of a mitochondrial membrane leak. We now find that mild depletion of ATP synthase c-subunit or inhibition of the c-subunit leak with ATP synthase interacting agents decreases mRNA translation in Fmr1-/y mouse neurons and fibroblasts from Fragile X patients. Leak inhibition during synaptic stimulation alters metabolism in favor of oxidative phosphorylation over glycolysis, in part by encouraging the translation of components of the ATP synthase. In addition, the stimulus-induced, ATP-dependent, phosphorylation of translation elongation factor EF2, a crucial stimulus-response mechanism for synaptic plasticity, is lacking in Fmr1-/y synapses, and is rescued by closing the c-subunit leak. This suggests that synaptic stimulation leads to a switch in mitochondrial metabolism and phenotype that accompanies, and may be required for, the change in subsets of synaptic proteins synthesized. In keeping with this, exaggerated repetitive behaviors in Fmr1-/y mice are ameliorated by mitochondrial membrane

leak closure. We therefore suggest that FMRP regulates a stimulus-dependent change in mitochondrial metabolism required for synaptic development.

Title: Maternal stress and prenatal fluoxetine exposure on offspring of fragile X knockout mice

Authors: *A. L. ARZUAGA[1], M. PATEL[1], J. MROCZEK[2], J. LARSON[1,3,4,5], M. E. RAGOZZINO[2,4];

Abstract: Fragile X Syndrome (FXS) is a genetic disorder that results in mild to moderate intellectual disability. FXS is caused by transcriptional silencing of Fmr1, a gene encoding an RNA-binding protein that plays a crucial role in typical synapse development. FXS is the most common monogenic syndrome of Autism Spectrum Disorders (ASD), although only about one-third of individuals meet criteria for an ASD diagnosis. The increased prevalence of ASD in recent decades and the heterogeneity of symptom severity may arise from a complex interaction of environmental and genetic risk factors that induce alterations in synaptic function. The present study investigated whether exposure to restraint stress in pregnant female Fmr1 knockout (KO) and wildtype (WT) mice affects repetitive behaviors, anxiety and/or hippocampal synaptic plasticity in male and female offspring. Pregnant female mice were subjected to either a no restraint condition or a restraint condition that consisted of chronic restraint stress from gestational days 4-18 (three daily 30-minute sessions). Offspring were tested as young adults (7 weeks of age) on self-grooming behavior, anxiety behavior in elevated plus maze and for spatial learning and reversal learning with probabilistic reinforcement. Subsequently, hippocampal slices from offspring were tested for alterations in long-term potentiation (LTP) induced by theta burst stimulation (TBS) at Schaffer-commissural synapses in field CA1. Restraint stress, used to model depression, did not affect anxiety in either Fmr1 KO or WT mice. Maternal restraint stress selectively increased grooming behavior in male WT offspring. All groups were comparable on

learning a spatial discrimination task. However, male and female Fmr1 KO mice in both restraint and no - restraint conditions were impaired on spatial reversal learning compared to WT mice. Ongoing experiments are determining whether there is a relationship between impaired spatial reversal learning and hippocampal LTP in Fmr1 KO mice. Initial findings suggest that maternal stress during pregnancy in Fmr1 KO mice does not affect anxiety, self-grooming behavior, or alter the behavioral flexibility deficit in male and female offspring. Additional studies are examining whether maternal stress and antidepressant (SSRI) exposure during pregnancy affect the phenotype in Fmr1 KO offspring that can build a greater understanding of how early life experiences interact with genetics to affect synaptic plasticity and behavior in offspring.

Title: Norbinaltorphimine, a kappa opioid receptor antagonist influences behavioral phenotypes in a fragile X mouse model

Authors: *D. M. M. MCCARTHY, M. X. TRUPIANO, L. ZHANG, P. G. BHIDE;
Florida State Univ. Col. of Med., Tallahassee, FL

Abstract: Fragile X syndrome (FXS) is a genetic condition characterized by a spectrum of neuro-behavioral symptoms including attention deficit, hyperactivity, anxiety, unstable mood, autistic behavior, acoustic hypersensitivity, delayed speech and seizures. It is caused by inactivation of the X-linked fragile-X mental retardation -1 (*FMR1*) gene and it is the number one inherited cause of intellectual disabilities, and the most common known cause of autism worldwide. Using the *B6.129P2-Fmr1tm1Cgr*/J strain of *Fmr1* KO mouse we confirmed that both male and female *Fmr*1 KO mice display hyperactivity, poor nest construction, motor-impulsivity and impaired social interaction. These phenotypes are consistent with impaired dopamine and/or noradrenaline signaling in the brain. Kappa opioid receptor antagonists, such as norbinaltorphimine (norBNI) increase dopamine and noradrenaline content in the brain by increasing synaptic release of the neurotransmitters. Therefore, norBNI has the potential to influence behavioral phenotypes in the *Fmr1* KO mouse via dopamine and noradrenaline signaling mechanisms. We found that a single administration of nor-BNI (20mg/kg; ip)

significantly reduced hyperactivity in male but not female *Fmr1* KO mice, and reduced motor-impulsivity in female but not male *Fmr*1 KO mice. The effects lasted 24 hours. However, a single oral administration of nor-BNI (20mg/kg; oral gavage) reduced hyperactivity significantly in both male and female *Fmr1* KO mice, and the effects lasted up to 48 hours. Moreover, a lower dose of norBNI (1 mg/kg) administered daily for 5 days via oral gavage improved nest construction in the *Fmr1* KO mouse. Thus, norBNI produced significant effects on multiple behavioral phenotypes in the *Fmr1* KO mouse, and some of the effects were dependent on sex and the route of administration.

Title: Uncovering the role of mTORC2 in fragile X syndrome

Authors: *S. ROUDABUSH[1], J. YAN[1], R. ZUKIN[2];
[1]Albert Einstein Col. of Med., Bronx, NY; [2]Dept Neurosci, Albert Einstein Col. Med., Bronx, NY

Abstract: Fragile X syndrome (FXS) is one of the most common heritable forms of intellectual disability and the leading genetic cause of autism in humans. The neuroanatomical hallmark of Fragile X is an increased density of immature spines, a factor thought to underlie synaptic dysfunction and impaired cognition in Fragile X mice. While a role for mTORC1 in FXS and autism spectrums disorders is well established, little is known about the role of mTORC2, which is thought to mediate actin polymerization. Moreover, mTORC2 is thought to be upstream of Rac/cofilin signaling and actin polymerization. Our laboratory previously identified cofilin, an actin depolymerizing agent that regulates spine structure, and its upstream effector Rac1, a Rho GTPase, to be dysregulated in Fragile X mice (Fmr1 KO) and casually related to dendritic spine abnormalities. Specifically, delivery of constutively active cofilin into juvenile Fmr1 KO mice was sufficient in rescuing the immature dendritic phenotype and aberrant spine density in the somatosensory cortex of Fmr1 KO mice. We hypothesized that genetic reduction of Rictor, a defining component of mTORC2 and binding partner critical to mTOR function and stability, might rescue synaptic defects in Fragile X mice. Since Rictor-null mice are embryonically-lethal,

we generated Fmr1 KO mice in which Rictor could be conditionally knocked out, Fmr1 KO Rictor conditional knockout (cKO), by means of CRISPR/Cas9 and the Lox-Cre systems. In preliminary experiments, we showed that delivery of lentivirus synapsin-Cre into the somatosensory cortex of neonatal Rictor cKO mice successfully knocked out Rictor protein and is sufficient to return phosphorylated (overactive) cofilin and components of the Rac/PAK pathway to wildtype levels. Preliminary findings indicate that cKO of *Rictor* in layer V of the somatosensory cortex of juvenile/neonatal Fmr1 KO mice is sufficient to rescue aberrant dendritic spine morphology. Ongoing studies will determine if cKO of Rictor in layer V of the somatosensory cortex of neonatal Fmr1 KO mice is sufficient to rescue aberrant dendritic spine morphology and density. Future studies will determine whether cKO of Rictor can rescue aberrant synaptic plasticity and somatosensory-mediated behavioral phenotypes in Fmr1 KO mice.

Title: Cortical morphology in children with the FMR1 premutation

Authors: *J. Y. WANG[1], M. DANIAL[2], C. SOLEYMANZADEH[2], B. KIM[2], Y. XIA[2], K. KIM[2], F. TASSONE[2], T. J. SIMON[3], R. J. HAGERMAN[2], S. M. RIVERA[4];

Abstract: Premutation alleles (55-200 CGG repeats) of the fragile X mental retardation 1 (*FMR1*) gene are associated with developmental problems, such as cognitive impairment in specific domains and autism-like symptoms. *FMR1* protein is widely expressed in precursors of neurons and oligodendrocytes during brain maturation, stressing the importance of the gene in neurodevelopment. Consistently, defects of neuronal migration and altered expression of neuronal lineage markers have been revealed in knock-in mouse models of the premutation. Such deficits likely affect cortical folding (*i.e.*, gyrification). We performed a retrospective study of cortical morphology in 33 children with the *FMR1* premutation (19 boys, age 8-12 years) and 25 age-matched controls (12 boys). CGG repeat length (N = 55), *FMR1* mRNA level (N = 50), and

IQ scores (N = 47) were also available. Local gyrification indices (LGI) were acquired semi-automatically to quantify folding complexity in 68 cortical regions. Multiple linear regression was used to examine the effect of age, group, and sex on LGI. To identify individuals with hyper- and hypo-gyrification, percentiles were determined based on Z scores of the age- and sex-adjusted LGI relative to controls. Bartlett's test of homogeneity of variances was conducted to compare variances in LGI Z scores between the groups. Pearson's correlation analysis was used to examine the correlations between abnormal LGI and *FMR1* markers and IQ scores. After adjusting for multiple comparisons using the false discovery rate method, we detected significant effects of age and/or sex in 29 regions among which bilateral posterior cingulate and right pars obritalis showed significant sex by group interaction (p = 0.012-0.045) driven by less sex effect in the premutation groups compared with the control groups. High variances of LGI Z scores were also revealed in the right isthmus in the premutation boys, and in the left entorhinal, right rostral anterior cingulate, and right caudal anterior frontal cortices in the premutation girls (p <0.001-0.007). Using Z = ±2.58 (upper and lower 1 percentile) as the cutoff, 17/19 of the premutation boys displayed hyper- and/or hypo-gyrification in 1-10 regions and 11/15 premutation girls showed such scores in 1-14 regions. In contrast, only 1 boy and 1 girl in the control groups showed hypergyrification in two different regions. Importantly, strong associations between the LGI Z scores and molecular and IQ measures were demonstrated in some of the regions showing hyper- or hypo-gyrification. These findings suggest a presence of abnormal cortical folding in children with the *FMR1* premutation, which may underlie cognitive problems.

Title: Glutamate and GABA in fragile-X syndrome and neurofibromatosis type 1

Authors: M. MABIKA, A. LACROIX, M. PROTEAU-LEMIEUX, P. MAURICE, F. CORBIN, *J.-F. LEPAGE;
Sherbrooke Univ., Sherbrooke, QC, Canada

Abstract: Fragile-X syndrome (FXS) and Neurofibromatosis type 1 (NF1) are two genetic conditions with overlapping symptoms, including seizures and a high risk of neurodevelopmental disorders, namely autism spectrum disorder (ASD). Moreover, previous work suggests that a dysbalance between inhibitory and excitatory mechanisms may be central to the neuropathophysiology of both disorders. Because aberrant excitation/inhibition ratio is a common feature of several animal models of ASD, we sought to assess the level of Glutamate+glutamine (Glx) and GABA in the brain of patients with FXS and NF1 in relationship with ASD symptomatology. So far, magnetic resonance spectroscopy (MRS) was acquired in 35 participants (11 FXS; 14 NF1; 10 Controls; expected N=45) using the MEGA-PRESS sequence (Voxel 3X3X2 cm placed in the occipital lobe) and symptoms severity was assessed using the Aberrant Behavior Checklist (ABC-C) and the Social Communication Questionnaire. Preliminary analyses conducted on MRS data show a marked reduction of GABA concentration in NF1 patients, who differ from controls ($p<0.001$), and also tend to differ from FXS patients ($p=0.055$). GABA level in FXS tend to be lower than controls ($p=0.055$), but show a high inter-individual variability. Reduced level of Glx was noted in FXS compared to NF1 ($p=0.019$), but they did not differed from controls. Correlational analyses with behavioural measures with be conducted once the sample is complete (N=45). This study will be the first to compare genetic conditions at high risk of ASD with regards to the excitation/inhibition hypothesis, and clarify the potential links between an imbalance in neurotransmitter concentration and ASD symptomatology.

Title: Understanding and overcoming pharmacological tolerance in the treatment of fragile-X syndrome

Authors: *P. K. MCCAMPHILL[1], R. K. SENTER[1], H. J. DE JESÚS-CORTÉS[1], M. F. BEAR[2];
[1]Picower Inst. for Learning and Memory, [2]MIT, Cambridge, MA

Abstract: Recent clinical trials investigating the efficacy of metabotropic glutamate receptor 5 (mGluR5) inhibitors to treat Fragile-X syndrome (FXS) have had mixed results, with several studies reporting a lack of efficacy in patient populations. Specifically, negative allosteric modulators (NAMs) of mGluR5 were found to work well in treating several disease markers in animal studies, but did not show the same results in human trials. One potential explanation for the failure of these trials is that tolerance rapidly develops to the drugs, and indeed caregiver reports have suggested some early improvement did not continue for the length of treatment. In this study we show that animals also develop tolerance to mGluR5 NAMs, similar to patient populations. Specifically, we demonstrate that a single acute dose of the mGluR5 NAM CTEP reduces 1) the incidence of audiogenic seizures (AGS), 2) the aberrant increase in hippocampal protein synthesis and 3) cortical hyperexcitability of *Fmr1* KO animals; however these effects are lost after repeat administrations. To test whether the development of tolerance is due to a compensatory upregulation of mGluR5 we chronically treated wild type and *Fmr1* KO animals with CTEP for 5 days and then harvested both hippocampal and visual cortical tissue 4 hours after the final dose. There was no significant enhancement of mGluR5 receptor expression in tissue homogenates, however whether membrane or synaptic levels of the receptor are specifically changed following chronic treatment remains to be tested. The viability of pharmacologically targeting intracellular signaling hubs rather than surface receptors to better circumvent tolerance from prolonged dosing was also tested. We have previously used a novel GSK3α specific inhibitor BRD0705 to reverse many core FXS pathophysiologies, however whether chronic administration of BRD0705 could maintain durable efficacy was unknown. We now show that the ameliorative effect of BRD0705 on AGS incidence, seen after a single acute dose, was maintained after chronic administration. This lack of tolerance to BRD0705 in the AGS assay is of considerable interest and suggestive of durable efficacy of chronic GSK3α inhibition for the treatment of other FXS-related pathophysiologies. These findings will be essential to the future development of effective treatments for FXS, therefore it is of critical importance to understand when and how tolerance occurs and explore approaches to circumvent it.

Title: Astrocyte purinergic signaling and thrombospondin-1 expression are dysregulated within the Fragile X Syndrome mouse cortex

Authors: *K. E. REYNOLDS[1], C. R. WONG[2], L. C. DOERING[3], A. L. SCOTT[3];
[1]Neurosci. Grad. Program, [3]Dept. of Pathology and Mol. Med., [2]McMaster Univ., Hamilton, ON, Canada

Abstract: The neurological symptoms of Fragile X Syndrome (FXS), the leading genetic cause of Autism Spectrum Disorder (ASD), largely arise due to dysregulations in glial-neuronal communication. While these glial-neuronal interactions may be mediated through various signaling pathways, an integral form of intercellular communication both in the brain and throughout the body is purinergic signaling. Purinergic signaling is broadly defined as the use of ATP, UTP, and their metabolites as excitatory signaling molecules, and is extensively used by astrocytes to facilitate reciprocal glial-neuronal and glial-glial crosstalk. We therefore sought to identify alterations in this signaling pathway within the FXS cortex, using an *Fmr1* knockout (*Fmr1-/-*) mouse model of FXS. In *Fmr1-/-* primary astrocyte cultures, treatment with exogenous UTP evoked a sustained intracellular calcium response compared to wildtype (*Fmr1+/+*) levels. This response was silenced following co-treatment with the general P2 receptor antagonist suramin, suggesting a role for UTP-sensitive P2Y receptors. We then quantified P2Y receptor expression in *Fmr1-/-* vs. wildtype astrocytes, and found elevated expression of P2Y2 and P2Y6 receptors in *Fmr1-/-* primary astrocyte culture, as well as in *Fmr1-/-* magnetically sorted astrocytes obtained from postnatal cortex. Focusing on potential downstream effects, the astrocyte protein thrombospondin-1 (TSP-1) is known to be regulated through UTP-induced activation of P2Y receptors and acts to establish immature excitatory synapses in the cortex. In *Fmr1-/-* early postnatal cortex, we observed transiently elevated TSP-1 expression compared to wildtype levels. *Fmr1-/-* astrocytes also demonstrated proportionally greater TSP-1 production than wildtypes in response to low levels of exogenous UTP, along with dysregulated TSP-1 secretion. Ongoing studies seek to quantify levels of purinergic signaling molecules using liquid chromatography-mass spectrometry, and to identify the effects of heightened astrocyte purinergic signaling on FXS versus wildtype neurons. Together, our results suggest that purinergic signaling is differentially regulated in *Fmr1-/-* astrocytes, and through its regulatory action on TSP-1, may have therapeutic relevance to the excitatory-inhibitory imbalances seen in FXS.

Title: Investigations of oxidative stress in astrocytes of the Fragile X syndrome cortex

Authors: G. VANDENBERG[1], N. DAWSON[2], A. HEAD[1], *A. L. SCOTT[1];
[1]Pathology and Mol. Med., [2]Biol., McMaster Univ., Hamilton, ON, Canada

Abstract: Fragile X Syndrome (FXS) is caused by the instability of a CGG-repeated tract at the 5' end of the Fmr1 transcript. This instability causes silencing of the gene coding for FMRP. Higher levels of reactive oxygen species, lipid peroxidation, and protein oxidation within brain tissue have been found to be associated with the disease. These imbalances, along with altered levels of components of the glutathione system, provide evidence for increased oxidative stress. Astrocytes, glial cells within the brain, have many functions within neurodevelopment. Specifically, they regulate growth and synaptic contacts of neurons, regulate the level of excitability of synapses, and protect neurons at high levels of activity. To protect neurons from oxidative stress, astrocytes maintain oxidative homeostasis through their mitochondrial electron transport and antioxidant systems. This study examines the relationship between oxidative stress and FXS by assessing mitochondrial function and the antioxidant system of astrocytes. Using the Fmr1 knockout (KO) mouse model, astrocytes collected from male and female mice were grown in either normoxic or hypoxic conditions. After collection of the cultured cortical astrocytes, mitochondrial respiration and reactive oxygen species (ROS) production was analyzed. In addition, western blots were conducted on both cortical tissue and cultured cortical astrocytes to determine potential differences in enzyme expression. Lastly, enzyme assays were conducted on cultured cortical astrocytes to determine potential differences in enzyme activity. Preliminary results indicate sex differences in the oxidative capacity of KO cultured cortical astrocytes. Future steps involve assessing mitochondrial function and the antioxidant system of astrocytes while in the presence on neurons, with the intent to provide greater insight into the relationship between FXS and oxidative stress. Characterization of mitochondrial function and the antioxidant system of astrocytes will be highly valuable to the understanding of glial roles during brain development and could provide future insight to direct clinically relevant studies of FXS and other neurodevelopment disorders.

Title: Mitochondrial bioenergetic impairment in the cerebral cortex of the Fmr1 knockout mouse model of Fragile X syndrome

Authors: S. D'ANTONI[1], L. DE BARI[2], D. VALENTI[2], C. M. BONACCORSO[3], R. VACCA[2], ***M. CATANIA**[1,3];
[1]Inst. of Neurolog. Sciences, Natl. Res. Council (CNR), Catania, Italy; [2]Inst. of Biomembranes, Bioenergetics and Mol. Biotechnologies, CNR, Bari, Italy; [3]IRCCS Oasi Res. Inst., Troina (EN), Italy

Abstract: Fragile X syndrome (FXS) is the most common form of inherited intellectual disability and a leading genetic cause of autism. In most cases, FXS is caused by mutations in the FMR1 gene ultimately leading to the absence of the Fragile X mental retardation protein (FMRP), a pleiotropic RNA binding protein involved in multiple aspects of RNA metabolism. A growing body of evidence supports a role for mitochondrial dysfunction and defective oxidative phosphorylation (OXPHOS) in autism spectrum disorders; likewise, the involvement of mitochondrial alterations in the FXS pathogenesis has been suggested. While changes in brain metabolism, such as an increased rate of glucose metabolism, altered levels of energy metabolites and increased oxidative stress markers, have been described in the Fmr1 knock out (KO) mouse model of FXS, the effect of FMRP deficiency on mitochondrial energy metabolism remains to be investigated. To disclose whether and how mitochondrial bioenergetics is affected in *Fmr1* KO mouse brain, we monitored the ATP production via OXPHOS, which represents the major source of ATP in the central nervous system, particularly during development, and investigated some aspects of cell bioenergetics, namely the activity of key glycolytic enzymes, glycerol-3-phosphate shuttle and mitochondrial respiratory chain (MRC) complexes, in the cerebral cortex of the *Fmr1* KO mice. We found that, despite a hyper-activation of MRC complexes, ATP production OXPHOS is compromised, resulting in brain energy impairment in juvenile and late-adult Fmr1 knockout mice. Furthermore, we detected an increased activity of mitochondrial glycerol-3-phosphate dehydrogenase (mG3P-DH) in the cortex of young and late adult Fmr1 KO mice compared to age-matched wild type mice, whereas no change occurred in the activity of cytoplasmic glycerol-3-phosphate dehydrogenase and key glycolytic enzymes.

Our findings provide the first evidence of a compromised and inefficient mitochondrial bioenergetics in brain cortex of Fmr1 KO mice, which is present in young animals and persists into adulthood, and further support the idea that mitochondrial dysfunctions may contribute to neurological impairment in FXS.

Title: Audiogenic seizures in the Fmr1 knockout mouse are induced by Fmr1 deletion in subcortical, vGlut2-expressing excitatory neurons and require deletion in the inferior colliculus

Authors: D. GONZALEZ[1], M. TOMASEK[1], S. A. HAYS[3], V. SRIDHAR[1], S. AMMANUEL[1], C.-W. CHANG[1], K. PAWLOWSKI[2], ***J. R. GIBSON**[1], K. HUBER[1];

[3]Bioengineering, Univ. of Texas At Dallas, Richardson, TX

Abstract: Fragile X syndrome (FXS) is the most common form of inherited intellectual disability and the leading monogenetic cause of autism. One symptom of FXS and autism is sensory hypersensitivity (also called sensory over-responsivity). Perhaps related to this, the audiogenic seizure (AGS) is arguably the most robust behavioral phenotype in the FXS mouse model - the *Fmr1* knockout (KO) mouse. Therefore, the AGS may be considered a mouse model of sensory hypersensitivity. Hyperactive circuits are hypothesized to underlie dysfunction in a number of brain regions in FXS patients and *Fmr1* KO mice, and the AGS may be a result of this. But the specific cell-types and brain regions underlying AGSs in the *Fmr1* KO are unknown. We used conditional deletion or expression of *Fmr1* in different cell populations to determine whether *Fmr1* deletion in those cells was sufficient or necessary, respectively, for the AGS phenotype. Our data indicate that *Fmr1* deletion in glutamatergic neurons that express vesicular glutamate transporter 2 (vGlut2) and located in subcortical brain regions is sufficient and necessary to cause AGSs in the *Fmr1* KO. Furthermore, deletion of *Fmr1* in glutamatergic neurons of the inferior colliculus is necessary for AGSs. When we demonstrate necessity, we show that *Fmr1* expression in either the larger population of vGlut2-expressing glutamatergic neurons or the smaller population of inferior collicular glutamatergic neurons - in an otherwise

Fmr1 KO mouse - eliminates AGSs. Therefore, targeting these neuronal populations in FXS and autism may be part of a therapeutic strategy to alleviate sensory hypersensitivity.

Title: Adiponectin can rescue hippocampal synaptic plasticity in a mouse model of fragile X syndrome

Authors: *L. BETTIO[1], J. THACKER[1], E. BROCKMAN[2], S. YAU[3], B. R. CHRISTIE[1]; [1]Div. of Med. Sci., [2]Univ. of Victoria, Victoria, BC, Canada; [3]Rehabil. Sci., Hong Kong Polytechnic Univ., Hong Kong, Hong Kong

Abstract: Fragile X Syndrome (FXS) is the most common form of inherited intellectual disability and a leading cause of autism. This neurological condition is caused by the transcriptional silencing of the *Fmr1* gene, which codes for fragile X mental retardation protein (FMRP, a negative regulator of protein translation). The lack of FMRP is associated with an overactivation of mTOR signaling in the brain, which in turn leads to the excessive translation of several proteins that regulate spine structure and function. Treatments that increase AMPK activity hold promise for rescuing some of the deficits in synaptic plasticity seen in FXS. AMPK is a highly conserved protein that acts as an energy sensor and regulates several processes impaired in FXS such as mTOR activity, autophagy, insulin signaling and mitochondrial function. In the present study, we investigated the influence of adiponectin (APN, an adipocyte-derived hormone that stimulates AMPK activity) on deficits in synaptic plasticity induced by the lack of FMRP in mice. Short-term incubation with APN (10 min, 50 nM) was able to reverse deficits in both long-term potentiation (LTP) and long-term depression (LTD) induced by the lack of FMRP. Conversely, we found that prolonged incubation with APN (1.5-3 h, 50 nM) exacerbated deficits in LTP. Our findings indicate that APN may be a promising treatment for the management of FXS, but further studies are necessary to elucidate the optimal mode for delivery and timing of treatment.

Abstract: Social isolation during developmental critical windows could be highly detrimental to proper functioning of mature prefrontal cortex (PFC) and establishment of appropriate adult behaviors. However, the specific circuits that undergo social experience-dependent maturation to regulate social behavior development are poorly understood. *In vivo* imaging of mPFC-PVI activity by fiber photometry demonstrated that mPFC-PVI activity immediately preceded active social exploration in adult male mice, and short activation of mPFC-PVIs in a 3-chamber test led to increased social, but not object, approach. Selective chemogenetic suppression of mPFC-PVI activity during the 3-chamber test showed mPFC-PVI activity is required for normal levels of social interaction. Disrupted social experience during a juvenile window resulted in reduced intrinsic excitability and input drives of mPFC-PVIs, with absent mPFC-PVI activity prior to a social encounter. Chemogenetic restoration of mPFC-PVI activity in the adult animal selectively rescued juvenile isolation-induced social deficits. Therefore, PVI development in the juvenile mPFC is critically linked to long-term impacts on social behavior.

Abstract: Attention is a goal-directed cognitive process that facilitates the detection of task-relevant sensory stimuli from our dynamic environment. Attention deficits are frequently observed in several psychiatric disorders; including autism spectrum disorders, schizophrenia, and depression, yet the underlying neural circuits that regulate attentional behavior are not well understood. Across species, previous studies have demonstrated that the frontal cortex—particularly the anterior cingulate cortex (ACC) — contributes to "top-down" control of sensory processing in the visual cortex (VIS). Here, we aim to investigate the contribution of these evolutionarily conserved, long-range ACC to VIS projecting neurons in top-down control of visual attention behavior. We achieve this by integrating circuit-based techniques to monitor and manipulate selective top-down neural activity in mice performing freely moving attention behavior with a translational automated touchscreen system. Our study has shown that selective chemogenetic suppression of ACC to VIS projections impairs attentional performance in the 5-choice serial reaction time task without disrupting additional detectable readouts of decision-making capacity, motivational state, motor activation, impulsivity, and compulsivity. *In vivo* calcium imaging of projection-specific top-down neurons using fiber photometry imaging in behaving mice revealed their preferential activation during correct trials of attentionally demanding task conditions. Optogenetic modulation of top-down projection neuron during a period of sustained attention, but not during visual cue presentation, improved attentional performance selectively at low gamma frequency (30Hz) stimulation. Conversely, direct optogenetic inactivation of top-down projection terminals at visual cortex during the later period of sustained attention disrupts attentional behavior selectively in high attentionally demanding conditions. Collectively, our data demonstrate that rhythmic recruitment of long-range prefrontal-sensory projections right before the appearance of task relevant stimuli is essential for successful task performance in attentionally demanding conditions. Our findings may provide circuit-based insight into the pathophysiology and neuromodulation intervention strategies for impaired visual attention in neuropsychiatric disorders.

Abstract: Juvenile social isolation causes long-lasting dysfunction in the medial prefrontal cortex (mPFC) and disruption of adult sociability. However, the neural circuit mechanisms underlying these phenomena are poorly understood. Among various subcortical targets, we identified the limbic thalamus, which relays signals to various components of the classical reward circuitry, as the most prominent projection target from the mPFC that is preferentially recruited by social interaction. Chemogenetic or optogenetic suppression of this projection was sufficient to induce sociability deficits without affecting motor activity or anxiety-related behaviors, showing that this circuit is necessary for normal social preference. Importantly, transient juvenile social isolation (p21-35) leads to a failure to activate adult mPFC->limbic thalamus projection neurons in response to a social encounter, due to their reduced intrinsic excitability and aberrantly increased inhibitory drive from low-threshold spiking inhibitory neurons in deep layers of the mPFC. Sociability deficits caused by juvenile social isolation are rescued by an acute chemogenetic or optogenetic activation of mPFC->limbic thalamus projection neurons. Our study identifies a novel pair of mPFC excitatory and inhibitory circuits whose maturation is profoundly affected by social experience during the juvenile period and points toward potential targets for the amelioration of social processing deficits shared across a range of disorders.

Title: Social isolation during development reduces excitability of a subtype of pyramidal cell in mouse prefrontal cortex which projects to subcortical areas

Authors: *Y. NISHIHATA[1], H. YOSHINO[1], Y. OGAWA[2], T. SUGIMURA[2], K. OKAMURA[1], K. YAMAMURO[1], M. MAKINODAN[1], M. TORITSUKA[1], T. KOMORI[1], T. KANEDA[1], Y. SAITO[2], T. KISHIMOTO[1];

Abstract: Social Isolation during development is crucial for the functional development of forebrain regions, especially the prefrontal cortex (PFC). Social isolation during development causes severe PFC dysfunction in humans, but their neural bases remain poorly understood. Our previous studies of 'social isolation' animal model showed that isolate-housing mouse (for 2 weeks after weaning) had autistic-like behavior, PFC dysfunction and hypomyelination in medial PFC (mPFC). Especially because hypomyelination due to social isolation is prominent in deep-layer of mPFC, we focused on layer-5 pyramidal cells in the mPFC and classified them into 2 types depending on the magnitude of h-current: prominent h-current (PH) cells and nonprominent h-current (non-PH) cells. We found that 2-week social isolation after weaning leads a reduction in excitatory synaptic inputs in PH cells. According to other previous studies, this subtype of pyramidal cells could have axonal projection to subcortical areas as mediodorsal thalamus (MD), striatum or pontine nuclei. However, it is unknown which subcortical area the pyramidal cells affected by social isolation project axons to. To identify which the pyramidal cells of mPFC project axons to, we performed intracranial stereotaxic surgery for mouse and injected the retrograde neural tracer into three subcortical areas (MD, Striatum and Pontine Nuclei) by coordinate and performed whole-cell patch-clamp recordings on the labeled neurons to find the change of electrical activity of pyramidal neuron. We analyzed the electrophysiological data and found that social isolation during development affects excitability of a subtype of pyramidal cell in mouse prefrontal cortex which projects to subcortical areas.

[2]Psychology & Neurosci., Univ. of North Carolina, Chapel Hill, NC

Abstract: Underage alcohol binge drinking in humans is associated with altered behavior and cognition in adulthood. Rodent studies have linked binge-like adolescent intermittent ethanol (AIE) to adult deficits in inhibitory control, behavioral flexibility, and memory encoding, along with changes in neuroimmune signaling, synaptic plasticity and neurogenesis. AIE exposure reduces choline acetyltransferase (ChAT)-expressing neurons in the basal forebrain, and the loss of ascending cholinergic projections may lead to behavioral and cognitive deficits. However, it is unknown if AIE basal forebrain reductions in ChAT+ neurons are exclusive or extend to cholinergic interneurons (ChI) or parvalbumin-expressing interneurons (PVI). These interneurons are key regulators of network function by modulation of local circuits and are important in motor and cognitive function. We hypothesized that AIE exposure decreases ChI and PVI in the PFC, striatum and amygdala relative to controls. We exposed rats to ethanol or water during adolescence (5g/kg, 2-days-on/2-days-off, P25-55). When rats reached adulthood, brains were removed and processed for immunohistochemical visualization of ChAT+ or PV+ cells. ChAT+ interneurons were counted in PFC (orbitofrontal and medial) and striatum (dorsomedial, dorsolateral and ventral). However, we found no difference in cell counts from AIE-exposed and control rats in any of these regions (unpaired t-tests, all p's>0.15). PV+ cell counts are ongoing. Thus, forebrain ChAT+ cholinergic projection neurons are sensitive to AIE, however frontal cortical and striatal ChI are not reduced by AIE. These results highlight the potential relevance of projection neurons in the cognitive and behavioral deficits observed after AIE. Additional ongoing studies on mechanisms underlying AIE behavioral deficits will be presented.

Title: The effect of adolescent phthalate exposure on cognitive behavior in rats

Authors: *E. P. SELLINGER[1], J. WILLING[2], J. STANLAND[3], L. MAHLOCH[3], J. M. JURASKA[4];
[1]Neurosci., Univ. of Illinois Urbana-Champaign, Champaign, IL; [2]Psychology, Bowling Green State Univ., Bowling Green, OH; [3]Univ. of Illinois at Champaign-Urbana, Champaign, IL; [4]Psychology, Univ. of Illinois, Champaign, IL

Abstract: Adolescence is a unique period of development associated with the onset of puberty and rising gonadal hormone levels that restructure neural areas, especially the prefrontal cortex, leading to changes in associated cognitive behaviors. Critically, this period of neurodevelopment may allow for greater susceptibility to environmental factors. Phthalates are a class of endocrine-disrupting chemicals widely used as plasticizers, solvents, fixatives, and emulsifiers in plastics, food processing, and a variety of personal care products. Phthalates are primarily antiandrogenic but have also been shown to influence estrogen signaling (Takeuchi et al., 2005). Our lab has shown that exposure to an environmentally relevant phthalate mixture during perinatal development, a time when gonadal hormones are also playing a role in neurodevelopment, leads to a lasting reduction in synapse and neuron number in the mPFC as well as impaired cognitive flexibility in adulthood (Kougias et al., 2018). The current study aims to understand if exposure to phthalates during adolescence impacts cognitive behaviors.
Male and female Long Evans rats were fed the same environmentally relevant mixture of phthalates mentioned above from postnatal day (P) 27 through P50 at a dose of 0, 0.20, or 1 mg/kg bodyweight. A battery of behavioral tests were run beginning on P85 with an N= 10-11 of each sex per group. The elevated plus maze measures anxiety-like behavior where a higher number of open arm entries indicates lower levels of anxiety. In females, we observed a significant effect of dose in number of trips to the end of the open arm ($p = 0.02$) where the 1mg/kg exposure group had significantly more trips to the end than controls ($p = 0.05$). In males, there was a significant effect of dose in number of closed arm entries during the first five minutes ($p = 0.02$), providing more of an index of locomotor activity than anxiety-like behavior, where the 1mg/kg group had significantly fewer closed arm entries than controls ($p = 0.02$). We

observed no effects of phthalates on performance in the attentional set shift task, which measures cognitive flexibility. The final behavioral paradigm, pre-pulse inhibition, measures sensorimotor gating, and there was no effect of phthalate exposure. However, in analyzing habituation of startle reactivity, we saw a trend of dose ($p = 0.052$) in females only, but post hoc comparisons revealed no significant differences between phthalate and control groups. These results indicate adolescent phthalate exposure does not greatly impact cognitive behaviors including those associated with the mPFC.

Title: Age-dependent α7nAChR modulation of prefrontal inputs and associated fear memory behavior

Authors: *A. M. M. MIGUELEZ FERNÁNDEZ, H. M. MOLLA, D. R. THOMASES, K. Y. TSENG;
Univ. of Illinois at Chicago - Col. of Med., Chicago, IL

Abstract: Increased brain concentrations of the tryptophan metabolite kynurenic acid (as found in schizophrenia) disrupt the balance of excitatory and inhibitory transmission in cortical circuits through an α7nAChR-dependent mechanism. In the present study, we conducted local field potential recordings along with local administration of the α7nAChR antagonist MLA to determine to what extent α7nAChR signaling regulates prefrontal processing of afferent drive *in vivo*. We found blocking α7nAChR signaling in the prefrontal cortex markedly attenuated the potentiation of local field potential responses elicited from the basolateral amygdala both in adult and adolescent rats. However, prefrontal infusion of MLA failed to disrupt the potentiation of local field potential responses elicited from the ventral hippocampus. Instead, blocking α7nAChR signaling diminished the inhibitory component of the hippocampal drive such that a shift from suppression of local field potential responses to facilitation emerges. Interestingly, this effect of MLA on ventral hippocampal transmission does not arise in the prefrontal cortex after P45, indicating an age-dependent recruitment of α7nAChR signaling by the ventral hippocampus that is input-specific. To examine the behavioral impact of prefrontal α7nAChR signaling, MLA

was locally infused and changes in fear conditioning behavior were assessed. A trace fear conditioning task was selected because it contains a delay period between the conditioned tone and the delivery of a foot shock, which requires normal prefrontal integration of inputs from both the amygdala and the ventral hippocampus. We found that blocking α7nAChR signaling in the prefrontal cortex diminished the acquisition of fear induced freezing behavior and disrupted the normal extinction pattern in adult rats. Such behavioral modulation by α7nAChR was absent in adolescent rats, indicating that prefrontal α7nAChR signaling emerges to control trace fear behavior only in adulthood. Collectively, these results point towards an age-dependent α7nAChR modulation of fear memory likely through a developmental mechanism in which the emergence of an α7nAChR component shapes the appropriate balance between amygdalar and hippocampal inputs to the prefrontal cortex. Title: Sex differences and influences of puberty on the trajectory of perineuronal net development in the rat medial prefrontal cortex

Authors: *C. DRZEWIECKI[1], J. WILLING[3], E. P. SELLINGER[4], J. M. JURASKA[2]; [2]Psychology, [1]Univ. of Illinois, Champaign, IL; [3]Psychology, Bowling Green State Univ., Bowling Green, OH; [4]Neurosci. Program, Univ. of Illinois Urbana-Champaign, Champaign, IL

Abstract: Perineuronal nets (PNNs) are specialized components of the extracellular matrix that surround the soma, dendrites, and axon segments of neurons. Within the prefrontal cortex (PFC), they play a critical role in maintaining proper inhibitory/excitatory balance and have been implicated in learning and cognitive flexibility. The development of PNNs is thought to coincide with brain maturation, and several studies have found that male rodents reach adult levels of PNN density in the PFC in mid to late adolescence. Consequently, aberrant PNN development may be associated with psychological disorders that commonly emerge during adolescence. However, previous work from our laboratory has shown that the medial prefrontal cortex

(mPFC) decreases in volume across adolescence, and because density is confounded by changes in volume, a more thorough approach for PNN quantification is necessary. The goal of this study is to stereologically quantify the total number of PNNs by collecting the mPFC from male and female hooded rats at various ages between P30 and P60. Additionally, because puberty coincides with broad behavioral and neuroanatomical changes, we included pubertal status as a factor by collecting tissue from age-matched pre- and post- pubertal siblings within a litter. This design allows us to track longitudinal changes in the number of PNNs as well as study the influence of pubertal onset on the overall number of PNNs. Preliminary data analysis (N = 52) replicates previous findings that PNN density increases between P30 and P60 in both males and females ($p < 0.001$). However, when comparing post-pubertal females to their age-matched, pre-pubertal sisters, there is a significant decrease in PNNs at puberty in the infralimbic cortex (IL) ($p = 0.02$, N = 5/group). A similar decrease is observed in the prelimbic cortex (PL), though not significant ($p = 0.4$, N = 5/group). In males, this effect is reversed, such that pubertal onset seems to increase in PNN density in the PL and IL, though a larger sample is needed before making broad conclusions (N = 3/group). Whether these findings are influenced or amplified by changes in cortical volume has yet to be determined. Nonetheless, alterations to PNNs could provide a mechanism by which the mPFC matures during pubertal onset.

Title: Postnatal prefrontal myelination and associated maturation of social behaviors are regulated by Npas4 in mice

Authors: E. LEMANSKI[1], **C. PAGE**[2], *L. COUTELLIER[3];
[1]Psychology, [2]Neurosci., [3]The Ohio State Univ., Columbus, OH

Abstract: The juvenile prefrontal cortex (PFC) undergoes several maturational processes including myelination. Studies indicate that experience and neuronal activity drive myelin formation in the brain, which contributes to the acquisition of adult social functions. The molecular mechanisms underlying experience-dependent prefrontal myelination remain to be fully elucidated. We previously showed that the transcription factor Npas4 is highly expressed in the juvenile PFC of mice and regulates aspects of prefrontal adolescent maturation. Furthermore, the activity-dependent expression of Npas4 is highly sensitive to experience. These previous findings led us to hypothesize that Npas4 could contribute to juvenile prefrontal myelination. We

first exposed Npas4 conventional wild-type (WT) and heterozygote (HET) mice to juvenile chronic stress (previously shown to decrease Npas4 expression in the PFC) to determine whether Npas4 deficiency modulates the effects of developmental stress on markers of myelination (MBP and PLP/DM20). In WT mice, juvenile stress did not impact MBP mRNA levels and reduced PLP/DM20 by 25% ($p=0.051$ vs. WT non-stressed mice). The effects of juvenile stress were more pronounced in HET mice: MBP and PLP/DM20 were both decreased vs. HET mice not exposed to stress (MBP: 40% reduction $p=0.003$; PLP/DM20: 57% reduction $p=0.007$). We then tested juvenile and adult Npas4 WT and knock-out (KO) mice for their social performances, as well as related prefrontal mRNA levels of MBP and PLP/DM20. Our preliminary data indicate that while sociability tends to mature in WT mice from the juvenile period to adulthood, the same maturation of social behaviors is not observed in KO mice. Interestingly, we also observed that reducing Npas4 expression in the adult brain decreases sociability to juvenile levels ($p=0.03$). RT-PCR analysis of mRNA expression of myelination markers indicate that juvenile, but not adult, Npas4 KO mice have lower MBP mRNA expression. Altogether, this first set of data is suggestive of a potential role of Npas4 in prefrontal myelination during postnatal development. Our on-going experiments assessing markers of myelination and social behaviors throughout the postnatal development of Npas4 deficient mice will further confirm these results.

Title: Early chronic noise exposure can induce aminoacidergic neurotransmission changes and reactive gliosis in the hippocampus of adolescent rats. Influence of enriched environment housing

Authors: S. J. MOLINA[1], L. D. UDOVIN[2], C. F. KUSNIER[2], G. E. BUJÁN[3], F. CAPANI[2], *L. R. GUELMAN[3,1];

Abstract: We have previously shown that exposure of immature rats to moderate noise can induce hippocampus (HC)-related behavioral, molecular and histological alterations, including oxidative imbalance and neural damage, during the peri-adolescence period. In addition, housing

animals in an enriched environment (EE) has shown to be effective in the reversal of most of these alterations. As the involvement of excitotoxicity has been proposed in different brain injuries, the aim of the present work was to test the effects of early noise exposure on aminoacidergic neurotransmission. In addition, considering that glial cells might influence neuronal environment and integrity, hippocampal histology was also evaluated. Finally, the possibility that EE could prevent these changes was further considered. Male Wistar rats of 7 and 15 postnatal days (PND) were exposed to noise (95-97 dB, 2h) for one (N1) or five (N5) consecutive days. After weaning, rats were transferred to an EE, consisting of toys, a wheel, plastic tunnels and ramps, whereas others were placed in standard cages. One week later, western blot experiments were performed to evaluate the levels of GAD 65/67 (a marker of GABAergic neurotransmission) and EAAT-1 (glutamate transporter, a marker of glutamatergic neurotransmission). GFAP reactive area was studied through immunohistochemical procedures to evaluate the presence of reactive gliosis. Results showed that although an increase in EAAT-1 levels and GFAP reactive area was induced only in rats exposed to N5 at PND 7 when compared with non-exposed rats, housing these animals in an EE was effective in restoring these differences. In contrast, no significant changes were observed in GAD 65/67 levels in neither group. These findings suggest that early noise exposure might differentially affect rats by inducing excitotoxicity, demonstrating a high vulnerability of repeated exposures (N5) at earlier ages (PND7). Furthermore, the associated increase of the GFAP reactive area might suggest reactive gliosis as a mechanism aimed to protect HC against excitotoxicity. In consequence, it could be proposed that this defensive response could have been produced in reaction to a previous excitotoxic extra-cellular challenge in order to prevent neuronal damage. Finally, EE has shown to be an effective strategy to reverse all the alterations found, suggesting that visual, social and physical stimulation during the peri-adolescence period could be an effective strategy to prevent HC-related molecular and histological changes.

Title: The differential impact of periodic and acute enrichment on evoked activity in the adolescent rat amygdala

Authors: C. A. PEGGS, C. E. GAILLARD, C. T. FENNELL, M. P. CARD, A. W. CARPENTER, ***M. C. ZRULL**;
Appalachian State Univ., Boone, NC

Abstract: Adolescence is a stressful time often marked by emotion-driven decision making that can lead to increased risk-taking behavior during both novel and familiar experiences. Environmental enrichment (EE) can provide sensory and motor stimulation, opportunity to interact with same-sex conspecifics, and can evoke behavioral responses to an emotionally arousing situation. Given the relative importance of the amygdala in learned and unlearned emotional response as well as the evaluation of social cues, we examined how periodic and/or acute EE might evoke neural activity across lateral (LA), basolateral (BLA), and central amygdala (CeA). Eleven Long-Evans rats were enriched between postnatal days (pnd) 25 and 48, and 10 controls were not. The daily, 90 min EE sessions allowed same-sex enriched rats to interact in enclosures with ramps, platforms, and objects, which were changed each day. Control rats were handled each day, and all rats lived in same-sized, same-sex groups. Prior to sacrifice on pnd 49, 6 enriched (EE+EE) and 5 control (No+EE) rats experienced a final, acute EE session and other rats did not (EE+No, No+No, n=5 each). Floating section immunohistochemistry was used to process tissue and visualize the neural activity marker c-FOS, and alternate sections were processed for cell body staining using thionin. Neuron densities were quantified in LA, BLA, and CeA using digital microscopy and stereological technique. We observed 25% more neurons in LA of rats with periodic EE than in controls ($p<.019$, $eta^2=0.30$) but no difference in other amygdala subdivisions. However, only the No+EE group exhibited enhanced evoked activity in LA (+95%, $p<.015$, $eta^2=0.14$) relative to controls not experiencing a final EE session. In contrast, both EE+EE and No+EE rats exhibited a greater proportion of c-FOS+ neurons than EE+No and No+No rats in BLA (+64%, $p<.001$, $eta^2=0.43$) and CeA (+71%, $p<.001$, $eta^2=0.41$). Our data suggest a history of enrichment may increase capacity for rapid emotional responses and memory by sparing LA neurons, but that only a first EE experience seems to boost activation of those neurons, which may indicate greater emotional response is elicited only by the novelty of a situation. The enhancement of neural activity in both BLA and CeA of all groups experiencing an acute EE session suggests current information, whether extremely novel or not, is integrated with contextual information to appropriately influence behavior and inform other neural circuits. This interpretation suggests the possibility of emotion-driven assessment prior to response in these adolescent rats.

Title: Post-weaning social isolation-induced social deficits and disrupted network activity across prefrontal subregions

Authors: *L. BIRO[1], C. MISKOLCZI[1], B. BRUZSIK[1], H. SZEBIK[1], Z. K. VARGA[1], L. SZENTE[1], O. HORVATH[1], J. HALASZ[1,2], M. TOTH[1], E. MIKICS[1];

Abstract: Early childhood and the periadolescent period represent time windows during which brain regions modulating social behavior undergo major network reorganization. Aversive social experience during these sensitive periods can lead to disrupted development. Here we aimed to investigate social behavioral changes induced by post-weaning social isolation (a model of childhood neglect) in mice and characterize underlying network disturbances in distinct subregions of the prefrontal cortex (PFC), a crucial regulator of social behavior. After weaning at P21, mice were housed either socially or isolated (alone) until reaching adulthood, and social interaction and resident-intruder (RI) tests were used to investigate social and aggressive behaviors. We demonstrate that mice subjected to post-weaning social isolation display social disturbances, shown by increased defensive and abnormal aggressive behavior that disregards species-specific rules. We characterize how these behavioral changes are reflected at the neuronal activity level within infralimbic (IL), prelimbic (PrL), anterior cingulate (Cg1) cortices in socially-reared and isolated animals under resting conditions and following RI test. To study RI test induced co-activation patterns across prefrontal subregions, we generated matrices from correlation coefficients of c-Fos activation. Quadratic assignment procedure correlations revealed that social experience exerts differential c-Fos co-activation patterns in isolated animals. Parvalbumin-positive interneurons enwrapped by perineuronal nets (PV+PNN+) are implicated in network organization and closure of critical periods of plasticity but little is known about their activity during social encounters. We found that aggressive social encounter increased the activity of PV+PNN+ neurons within Cg1 and PrL cortices of socially-reared and isolated animals. In contrast, in the IL social encounter decreased the activity of PV+PNN+ neurons in socially-reared mice, an effect absent in isolated animals. Social isolation leads to social behavioral abnormalities and impaired PV-PNN activity following a social encounter. Our results contribute to understanding how disruption of neuronal network organization during development translates into social abnormalities in adulthood.

Title: Clock∆19 mutation leads to increased oxidative damage and altered adolescent development of parvalbumin interneurons in mouse frontal cortex

Authors: *J. BURNS[1], Z. KARANIKOS[2], K. N. FISH[3], J. F. ENWRIGHT, III[3], C. A. MCCLUNG[3];
[1]Psychiatry, [2]Neurosci., Univ. of Pittsburgh, Pittsburgh, PA; [3]Psychiatry, Univ. of Pittsburgh Med. Sch., Pittsburgh, PA

Abstract: Adolescence represents a critical period of heightened plasticity in the prefrontal cortex (PFC) and is a time in which individuals are at an increased risk for mental illness. The development of parvalbumin (PV) cells is thought play an important role in critical period timing, as their maturation is thought to underlie the initiation of the critical period, and perineuronal nets (PNNs), which form around PV cells at the end of the critical period, act to restrict plasticity. Given that alterations in PV cells and PNNs have been observed in multiple psychiatric diseases, this suggests that a developmental deficit in PV cells may play a role in psychiatric disease pathophysiology. Additionally, PV cells are particularly vulnerable to oxidative stress and studies have shown increased levels of oxidative stress in the brains of patients with psychiatric diseases. As genes in the endogenous antioxidant system (EAS) are thought to be under the control of the molecular clock, we used *Clock*∆19 mice to investigate the relationship between the molecular clock, oxidative stress, and PV cell maturation in frontal cortical regions across adolescence in order to gain insight into how this process may be perturbed in disease. Quantitative fluorescence microscopy was used to measure oxidative stress, PV expression, and PNN formation in the anterior cingulate cortex (ACC) and prelimbic region (PL) of wildtype and *Clock*∆19 mice at postnatal days 20, 40, and 90 (n=4-5/group). qRT-PCR was performed on micropunches from the ACC and PL of wildtype and *Clock*∆19 mice (n=4-5/group) to investigate changes in the expression of genes in the EAS, as well as genes related to PV cell development and PNN formation. We find that adult *Clock*∆19 mice display a cell-type specific increase in oxidative stress in PV cells in adulthood. Furthermore, *Clock*∆19 mice show decreased PV expression at postnatal day 40 and into adulthood and decreased staining for PNNs in adulthood. *Clock*∆19 mice also show reduced expression of genes in the EAS and altered expression of genes involved in PV cell maturation. Given that *Clock*∆19 mice display increased oxidative stress in PV cells only in adulthood, we hypothesize that the increase in oxidative

stress, due to an impairment in the EAS, may negatively affect PV cell development. Furthermore, the decreased expression of PV and decreased PNN formation in adult *Clock*Δ19 mice suggests impaired critical period timing in these mice. Given that PV cells are crucial for the proper adolescent development of the PFC, by understanding the effect of oxidative stress on PV cell maturation we may gain insight into the development of PFC dysfunction in psychiatric disease.

Title: Endocannabinoid modulation of prefrontal afferent transmission and associated extinction of fear memory

Authors: *H. M. MOLLA[1], A. M. M. MIGUELEZ FERNANDEZ[2], K. Y. TSENG[2];
[1]Rosalind Franklin Univ., North Chicago, IL; [2]Anat. and Cell Biol., Univ. of Illinois at Chicago, Chicago, IL

Abstract: Prefrontal cortex (PFC) maturation during adolescence involves remodeling of glutamatergic and GABAergic transmission in the PFC, and is partly dependent upon proper modulation of afferent drive. Previous studies have also implicated changes in signaling components of the endocannabinoid system (CB1 receptor and endocannabinoids such as 2-AG and anandamide) in the PFC during adolescence. However, the manner by which endocannabinoid signaling impacts PFC synaptic transmission during the transition to adulthood remains unknown. Here we conducted in vivo local field potential recordings in rats and examined how pharmacological manipulations of prefrontal endocannabinoid signaling affects transmission originating from the basolateral amygdala (BLA) and ventral hippocampus (vHIP). We found the recruitment of endocannabinoid-CB1R signaling in the PFC is developmentally regulated, which emerges to exert a powerful inhibitory control of BLA and vHIP inputs after P45. Our data indicate both 2-AG and anandamide contribute to limit vHIP-to-PFC transmission, yet only 2-AG was recruited to modulate BLA inputs. At the behavioral level, PFC elevation of endocannabinoids delays the extinction of fear memory, an effect that cannot be mimicked by prefrontal activation of CB1Rs. Together, these results show that endocannabinoid-CB1R

signaling in the PFC emerges to control the gain of afferent transmission in an age-dependent and input-specific manner.

Title: Systemic administration of the cannabinoid CB1 receptor agonist WIN during adolescence disrupts the maturation of trace fear extinction behavior

Authors: *A. Y. OROZCO[1], H. M. MOLLA[2], A. M. MIGUELEZ FERNÁNDEZ[1], A. CABALLERO[1], K.-Y. TSENG[1];
[1]Dept. of Anat. & Cell Biol., Univ. of Illinois At Chicago - Col. of Med., Chicago, IL; [2]Dept. of Cell. and Mol. Pharmacol., Rosalind Franklin Univ., North Chicago, IL

Abstract: During the transition from adolescence to adulthood, the prefrontal cortex (PFC) undergoes marked development accompanied by increased risk for developing psychiatric disorders which display prefrontal dysfunction. In preclinical studies, administration of synthetic cannabinoids during adolescence has been shown to disrupt the functional connectivity between the ventral hippocampus and PFC when tested in adulthood (Cass et al., *Molecular Psychiatry* 2014). Accordingly, a disruption of PFC-mediated extinction of trace fear memory emerged. What remains unknown is whether the effect of adolescent cannabinoid exposure on the PFC can be observed immediately or it is manifested only when reaching adulthood. To fill this gap in knowledge, i.p. injection of the synthetic CB1 receptor agonist WIN was delivered once daily for 5 days to adolescent (postnatal days P35-40) rats at 2 mg/kg. Behavioral assessment of ventral hippocampal-PFC function was determined using the trace fear conditioning and extinction paradigm at 24 hours or 10 days post-last injection of WIN or vehicle. Results show that the rate of extinction was significantly decreased in WIN-treated rats when compared to vehicle controls. Moreover, rats exposed to WIN had extinction rates equivalent to those observed in P30-35 juveniles. Collectively, the results show that exposure to CB1 receptor cannabinoids during adolescence is sufficient to elicit behavioral deficits which can be detected shortly after administration. However, the disruption endures and becomes more apparent in adulthood as ventral hippocampal-PFC functional connectivity is recruited to regulate behavior.

Title: Effects of hippocampal dysregulation on the hyper-dopaminergic state induced by chronic adolescent THC exposure

Authors: *M. DE FELICE[1], T. VINE[1], R. M. HUDSON[1], M. RODRÍGUEZ-RUIZ[1], C. CHEN[2], M. LAM[2], S. N. WHITEHEAD[3], K. K. C. YEUNG[2], W. J. RUSHLOW[4], S. R. LAVIOLETTE[1];
[1]Anat. and Cell Biol., [2]Chem., Univ. of Western Ontario, London, ON, Canada; [3]Anat. and Cell Biol., Western Univ., London, ON, Canada; [4]Dept of Anat. and Cell Biol., UWO, London, ON, Canada

Abstract: Clinical and preclinical studies have associated adolescent cannabis exposure with a higher risk to develop neuropsychiatric disorders later in life. It is widely accepted that glutamate and dopamine (DA) dysfunctions are critical to the pathophysiology of schizophrenia. Moreover, aberrant mesolimbic DAergic signaling is associated with dysregulation of hippocampal activity, as shown in both human and rodent studies.
We have demonstrated in a neurodevelopmental rodent model that adolescent administration of delta-9-tetrahydrocanabinol (THC), the primary psychoactive component of marijuana, induces a schizophrenia-like phenotype, characterized by a hyper-DAergic state in the VTA (Renard J. et al, 2016; 2017), and linked to a loss of inhibitory control in the prefrontal cortex. However, given the established role of hippocampal dysregulation in schizophrenia-related DA dysfunction, we hypothesized that adolescent THC exposure may similarly induce DAergic dysregulation through functional, polysynaptic connections between the hippocampus and VTA. In this study we examined whether neuronal and molecular dysregulation of the hippocampal dorsal subiculum (DS) might disinhibit dopamine neural activity, through direct modulation of the nucleus accumbens (NAc), following adolescent THC exposure.
Adolescent rats were treated from postnatal day (PND) 35 to 45 with increasing doses of THC (days 1-3 2.5mg/kg, days 4-7, 5mg/kg, days 8-11, 10mg/kg i.p., twice a day) or vehicle. At adulthood (PND 75), we used Matrix-assisted laser desorption ionization Imaging Mass Spectrometry (MALDI-MS) to investigate neuroanatomical distributions of GABA and

glutamate levels in both, DS and NAc. Moreover, we quantified receptor levels using Western Blot technique.
We report that chronic adolescent THC exposure enhances NMDA2B and NMDA1 glutamate receptor expression in the nucleus accumbens (NAc) as well as altering DA receptor expression levels, inducing an increase in D1R expression and a reduction in D2R. Moreover, MALDI-MS neurotransmitter quantification revealed a significant reduction of GABA and dopamine in DS as well as a decrease in GABA and glutamate in both, NAc shell and core.
Overall, our findings provide evidence that adolescent THC exposure induces a persistent glutamatergic/DAergic imbalance in DS-NAc-VTA circuitry. We are currently performing *in vivo* electrophysiology experiments to investigate the neural activity in DS and NAc.
Results from these studies will improve our knowledge of the neurobiological mechanisms underlying the pathophysiology of THC-induced neuropsychiatric disorders.

Title: Acute ethanol challenge differentially regulates the expression of growth factors in the dorsal hippocampus: A comparison of adolescent and adult rats of both sexes

Authors: *T. M. BARNEY[1], A. S. VORE[2], T. DEAK[3];
[1]SUNY Binghamton, Binghamton, NY; [2]Binghamton Univ., Binghamton, NY; [3]Behavioral Neurosci. Program, Dept. of Psychology, Binghamton University-SUNY, Binghamton, NY

Abstract: Acute ethanol exposure produces rapid alterations in neuroimmune gene expression that are both time- and cytokine-dependent. For instance, IL-6 increased rapidly in the CNS after ethanol challenge, peaking at about 3 hr post-injection, whereas IL-1β and TNFα increased during acute ethanol withdrawal (Doremus-Fitzwater et al., 2014; Gano et al., 2017). Interestingly, adolescent rats, who often consume binge-like quantities of alcohol, displayed reduced neuroimmune responses to acute ethanol challenge (Doremus-Fitzwater et al., 2015). The mechanisms underlying reduced neuroimmune reactivity in adolescents remains unclear. Since growth factors and their signaling pathways are intimately intertwined with

cytokine/inflammatory signaling, we hypothesized that age-related differences in growth factor expression and their response to acute ethanol exposure may shed important light on these mechanisms. To investigate this, adolescent (P29-P34) and adult (P70-P80) Sprague Dawley rats of both sexes were injected with either ethanol (3.5 g/kg) or saline, and brains were harvested at 3 hr post-injection for assessment of growth factor expression using RT-PCR. Initial analyses examined the dorsal hippocampus with a panel of growth factors. As expected, acute ethanol challenge significantly increased IL-6 expression, replicating our prior findings. When growth factors were examined, acute ethanol significantly decreased BDNF and increased FGF2. In contrast, GDNF and PDGF were unresponsive to ethanol, but displayed tendencies toward heightened expression among adolescents. NGF and VEGF did not vary as a function of ethanol, age or sex. Overall, these findings indicate selective regulation of growth factors by acute ethanol challenge, yet little evidence emerged to support the hypothesis that high expression of growth factors during adolescence might contribute to reduced neuroimmune reactivity among adolescents, though future follow-up studies are necessary to test this causally. Furthermore, no significant sex differences were observed in any of the factors examined. These findings may have implications for understanding unique features of the adolescent brain that confer unique sensitivity to, and proclivity for, binge-like ethanol exposure.

Title: Adolescent ethanol exposure alters frontolimbic neuronal firing patterns to a reward predictive cue in adult female rats

Authors: *J. A. POCHAPSKI[1], S. J. STRINGFIELD[2], A. GOMEZ-A[3], C. A. DANNENHOFFER[3], H. D. JAGGERS[3], C. DA CUNHA[1], C. A. BOETTIGER[3], D. L. ROBINSON[3];

Abstract: Adolescent ethanol exposure has been associated with long-term adverse outcomes, including cognitive deficits and neurochemical changes, due to effects of ethanol on adolescent brain development. Many consequences of adolescent ethanol consumption and exposure in male rodents are described in the literature, but the behavioral and neuronal changes promoted by adolescent intermittent ethanol (AIE) exposure in females are less well described. As we previously found that AIE-exposed rats showed reduced conditioned approach to a reward receptacle, we hypothesized that AIE would alter neuronal firing patterns in brain regions involved in reward conditioning. Thus, the present study examined the effect of AIE on reward learning and underlying neurocircuits by measuring activity of neurons in orbitofrontal cortex (OFC) and nucleus accumbens (NAc) during Pavlovian conditioned approach (PCA). Sprague-Dawley female rats received AIE (5g/Kg intragastric ethanol, 2-day-on/2-days-off) or water through adolescence (P25-54). At ~P70 rats began PCA training, where a 30-second conditioned stimulus (CS), presented as a cue light and lever extension, predicted delivery of a 20% sucrose reward. After training, electrode arrays were implanted in the OFC and NAc and electrophysiological recordings were performed during PCA sessions. Neuronal firing in both the OFC and NAc exhibited phasic excitation at CS onset. Control rats had larger population-level excitation in the NAc (~85% increase in firing within 500 ms after CS onset) than the OFC (~20%). In contrast, AIE-exposed rats presented a more similar magnitude of CS-induced population-level excitation in both regions (~60% in NAc and ~45% in OFC). Moreover, at the first receptacle entry after the CS onset, 35% of NAc neurons exhibited phasic excitations and 21% exhibited inhibitions in control rats. In contrast, only 17% of NAc neurons exhibited phasic excitations and 10% exhibited inhibitions in AIE-exposed rats. Additional analyses on the neuronal firing patterns during specific conditioned responses are in progress. Taken together, these preliminary data suggest altered fronto-limbic participation in neuronal processing of reward-motivated behavior.

Title: Anxiety and sociability in adult rats after adolescentcannabinoid exposure

Authors: *R. D. LUNDY, C. E. YULE, H. M. PARRISH, L. M. PACK, L. M. BUYNACK, G. D. MEDLEY, D. M. HAYES, P. A. JACKSON;
Psychology, Radford Univ., Radford, VA

Abstract: During adolescence, the brain undergoes developmental stages that are necessary for a healthy cognitive state. Studies have found that rats exposed to a cannabinoid during these key developmental stages exhibit learning deficits as well as potentially negative effects on levels of anxiety and sociability (Biscaia et al., 2003; O'Shea & McGregor, 2006; Schneider, 2009). This may be attributable to the cannabinoid, however, another possible explanation for these deficits is a lack of nutrients and healthy weight gain during the injection period (Biscaia et al., 2003; Schneider, 2009). For this study, Long-Evans male rats were semi-randomly assigned to one of ten conditions on post-natal day (PND) 34. These conditions determined the amount of nutritional supplement and food that the rats received throughout the injection period (PND 35-48), in addition to whether they received a synthetic cannabinoid (CP55, 940) injection, or the vehicle, at a dose of 0.35 mg/kg. The animals were subjected to an extensive series of behavioral measures including the Elevated Plus Maze (EPM), Open Field (OF), and Social Interaction (SI) engagement with a conspecific rat. On PND 78, the animals performed their first task on the EPM, and were observed for anxiety levels via time spent in open or enclosed arms and locomotor activity. Results suggested that drug animals not receiving nutritional supplement exhibited greater anxiety. In addition, the groups that received drug but no supplement were significantly less active than supplemented animals or vehicle controls. Following this, on PND 83 the animals performed an OF task where they were placed on the apparatus for ten minutes to explore and habituate while researchers observed thigmotaxis and rear count in relation to anxiety, as well as locomotor activity. Results seem to indicate that the groups which received higher amounts of additional nutrition were less active than the untreated control group while groups that received no additional supplement during their injection period showed lower levels of anxiety. On PND 84 the rats performed a social interaction task on the open field along with an unfamiliar conspecific rat located inside a circular wire cage. The results suggest that the vehicle groups which received lower supplementation were significantly more likely to seek out social interaction. In conclusion, nutritional supplementation during adolescent cannabinoid exposure alters behavior and could explain some of the long-term changes observed.

Title: Perineuronal net development during adolescence is critical for optimal decision-making in adulthood

Authors: *E. JACOBS-BRICHFORD[1], J. D. ROITMAN[2];
[2]Psyc, [1]Univ. of Illinois at Chicago, Chicago, IL

Abstract: A hallmark of adolescent brain development is the establishment of a finely-tuned excitatory-inhibitory (E-I) balance in the prefrontal cortex (PFC). This balance, which comes online as inhibitory signaling is refined, helps regulate neuron activity and is essential for the acquisition of higher cognitive function, such as decision-making, in adulthood. It is widely accepted that the maturation of parvalbumin-containing (PV^+) interneurons is critical for developing E-I balance, as PV^+ interneurons are known to regulate excitability of other cells. Approximately 70% of PV^+ interneurons in PFC are surrounded by perineuronal nets (PNNs), a lattice-like structure that wraps around them and regulates their plasticity. Extensive research has established that the emergence of PNNs around PV+ cells is associated with the closing of critical periods of development and a reduction in the neural placticity typical of these periods, but the functional relevance of PNN development remains unclear.
To address this gap in our knowledge, we assessed whether PNN development in prelimbic cortex (PrL) and orbitofrontal cortex (OFC) is essential for optimal decision-making in adulthood in rats. We used chondroitinaseABC (chABC) to digest PNNs in PrL or OFC during adolescence (P35) or adulthood (P75). In adulthood, animals were trained on a probabilistic choice task, where one lever pays a small, certain reward (1 sucrose pellet at 100%) and the other pays a larger, risky reward (3 sucrose pellets at 16, 33 or 67%). After animals completed the task, they were sacrificed, and we use immunohistochemistry to assess any long-lasting changes in parvalbumin-PNN colocalization or in the number or fluorescence intensity of PNNs using *Wisteria floribunda* agglutinin (WFA), a plant lectin that often colocalizes with PNNs.
All groups (P35-control, P35-chABC, P75-control, P75-chABC) showed increasing preference for the larger, risky reward with increasing probability of reward delivery. Degradation of PrL PNNs during adolescence, but not adulthood, led to increased preference for risky rewards in adulthood, even when selecting the risky option was suboptimal. Findings in OFC are forthcoming, but the results from PrL indicate that higher cortical functions are disrupted when PNNs are not present during PV cell maturation, suggesting a mechanism of adolescent vulnerability.

Title: Effects of THC on schizophrenia-related gene DNA methylation and expression in mouse primary neuron culture and adolescent mice

Authors: G. P. VALLERINI[1,2], M. KAZMI[1], S. KAZMI[1], *D. P. GAVIN[1,2];
[1]Univ. of Illinois at Chicago, Chicago, IL; [2]Jesse Brown VA Med. Ctr., Chicago, IL

Abstract: Tetrahydrocannabinol (THC) is the main psychoactive component of marijuana and exerts its pharmacological actions through activation of specific receptors highly expressed in the brain, namely cannabinoid receptors 1 (CB1) and 2 (CB2). Increasing evidence suggests a link between cannabis use during adolescence and a higher risk of developing psychosis later in life. Increased expression of DNA methylating enzymes, such as DNMT1 and DNMT3A, and increased BDNF promoter methylation associated with reduced BDNF expression have been reported in postmortem brain samples in schizophrenia. A decrease in *Bdnf* levels is reported in rodent studies as a result of THC treatment. To date, there have been few studies that have examined whether enduring gene expression changes observed in schizophrenia may be the result of THC-induced changes in DNA methylation. In the current study, we examined whether THC affects *Dnmt* expression and genes associated with schizophrenia using mouse primary neuron culture and *in vivo.* We tested the effects of cannabinoid 1 and 2 receptor agonists, and THC with and without cannabinoid 1 and 2 receptor antagonists on mouse E18 primary cortical neuron cultures. Using mice, we also examined the effects of a single dose of THC 10 mg/kg and adolescent chronic THC exposure on gene expression changes in the prefrontal cortex. In mouse primary cortical neuron cultures we found concentration-dependent increased levels of the DNA-methylating enzymes *Dnmt1* and *Dnmt3a* following THC or cannabinoid agonists application. Interestingly, the observed increase in *Dnmts* mRNA expression was abolished or reversed by co-treatment with either a CB1 antagonist or a CB2 inverse agonist, indicating a causal role for THC through interaction with both its main brain pharmacological targets. Further, schizophrenia-related genes *Gad1*, *Reln*, and *Bdnf* were all down-regulated in the presence of THC, and the effect was reversed by cannabinoid antagonists and the DNMT inhibitor RG-108. In adult male mice treated with THC 10 mg/kg and in adolescent mice treated with IP injections of THC twice a day for 10 days *Dnmt3a* mRNA expression was significantly increased. In the adolescent mice there was also a significant reduction in *Gad1*, *Reln*, and *Bdnf* mRNA expression. These early studies suggest that THC produces robust changes in expression of epigenetic pathways that may contribute to gene expression changes observed in schizophrenia.

Title: Developmental nicotine exposure elicits multigenerational neurotrophic, neuroendocrine, and neuroepigenetic alterations in the frontal cortices, striata, and hippocampi of adolescent mice

Authors: *J. M. BUCK[1], H. C. O'NEILL[3], J. A. STITZEL[2];
[2]Inst. Behav Genet., [1]Univ. of Colorado Boulder, Boulder, CO; [3]Univ. of Colorado Boulder Inst. for Behavioral Genet., Boulder, CO

Abstract: Maternal smoking during pregnancy, a form of developmental nicotine (NIC) exposure (DNE), is associated with neurodevelopmental disorders such as ADHD in children. Modeling the transmissible impacts of smoking during pregnancy in the first- (F1) and second- (F2) generation adolescent offspring of NIC-exposed female C57BL/6J mice, we have previously reported that DNE elicits multigenerational nicotine preference, hyperactivity and risk-taking behaviors, aberrant rhythmicity of activity, altered nicotinic acetylcholine receptor expression and function, impaired dopamine transporter function, and global DNA hypomethylation in the frontal cortices and striata. This ensemble of multigenerational behavioral, neuropharmacological, and DNA methylomic anomalies recapitulates multiple domains of ADHD pathosymptomatology. Further characterizing this mouse model via an array of immunoblot experiments, the present study reveals multigenerational DNE-induced disruptions of both BDNF processing and glucocorticoid receptor (GR) activation in the frontal cortices (n = 8-12), striata (n = 9-11), and hippocampi (n = 9-12) of male and female adolescent mice compared to saccharin (vehicle)-exposed controls. These findings are consistent with the BDNF deficits and HPA axis hypoactivity reported in both ADHD patients and the children of maternal smokers. Moreover, as BDNF is a quintessential mediator of neurodevelopment, our findings of multigenerational DNE-induced ADHD-like behavioral and neuropharmacological anomalies may stem from neurodevelopmental insults conferred by the aberrant BDNF and pro-BDNF signaling observed in DNE mice. In addition, our findings of multigenerational GR hypoactivity may contribute to the increased risk-taking behaviors displayed by F1 and F2 DNE mice. Given that BDNF and GR signaling are epigenetically regulated, and in light of our prior findings of corticostriatal global DNA hypomethylation in F1 and F2 DNE mice, the current study next probed for alterations in the expression and phosphorylation of key epigenetic factors via immunoblotting. The resulting data indicate multigenerational downregulation and aberrant phosphorylation of methyl-CpG-binding protein 2 (MeCP2), DNA methyltransferase 3A

(DNMT3A), and histone deacetylase 2 (HDAC2) in the frontal cortices (n = 8-12), striata (n = 9-11), and hippocampi (n = 9-12) of male and female adolescent DNE mice. Given the extensive regulatory roles of MeCP2, DNMT3A, and HDAC2, these findings suggest that neuroepigenetic abnormalities may constitute a mechanistic hub for the multigenerational transmission of DNE-induced ADHD-like phenotypes.

Title: Phytocannabinoids strongly modulate BDNF/TrkB expression in the dorsal hippocampus of adolescent female mice

Authors: J. WINSTONE, H. S. SHAFIQUE, K. MACKIE, ***J. WAGER-MILLER**;
Indiana Univ., Bloomington, IN

Abstract: The increasing acceptance and use of marijuana in the US and abroad require a better understanding of the effects its constituents may have on the developing brain. In this exploratory study, adolescent female *CD1* mice (n=7, each group) were exposed to delta9-tetrahydrocannabinol (THC) and/or cannabidiol (CBD) (each at 3mg/kg, IP), two major phytocannabinoids in cannabis, from P28 to P49. Mice were sacrificed at P50 and mRNA prepared from the dorsal hippocampi. Levels of four brain derived neurotrophic factor (BDNF) variants and the TrkB receptor were analyzed. While treatment with THC or CBD alone did not significantly affect BDNF transcript levels, there was a significant increase in BDNF4 mRNA when both THC and CBD were present. Furthermore, combining THC and CBD led to a large decrease in BDNF6 mRNA. Treatment with either THC or CBD, but not the combination, significantly decreased TrkB transcript levels. These results suggest that different combinations of phytocannabinoids have distinct effects on the BDNF/TrkB system, a finding that could be related to some of the transient and enduring consequences of adolescent cannabis use. [KM1]CD1, C57 etc. [KM2]Say how many (or which ones) were analyzed.

Title: Growing up hamster: Analysis of social behavior across adolescence in the Syrian hamster

Authors: K. C. DE LORME[1], **A. M. BAUMANN**[2], I. R. GORE[2], *B. M. ARSZNOV[2]; [1]Psychological Sci., Gustavus Adolphus Col., Saint Peter, MN; [2]Minnesota State Univ. Mankato, Mankato, MN

Abstract: Syrian hamsters must appropriately display complex agonistic behaviors used to communicate social status, ensure successful reproduction, and defend territory and resources. These behaviors include aggression, submission, and flank marking, which are all essential to survival and develop across adolescence. Most research investigating agonistic behavior has focused on male hamsters; however, female hamsters display aggression earlier than male hamsters do and are as aggressive as males. Additionally, agonistic behavior has been studied extensively using the resident/intruder paradigm, but few studies have investigated how hamsters interact in a neutral territory. Thus, we are interested in exploring how prepubescent, adolescent, and adult female hamsters differ in their display of agonistic behavior using the neutral arena paradigm.Twenty-four female Syrian hamsters were divided into three groups of eight: prepubertal, adolescent, and adult. All females were age and weight-matched with another experimental female for behavior testing. During their dark cycle, all pairs were placed in a neutral arena, that neither female had occupied prior to testing, for 10 minutes in dim red light. Behavior was recorded using a digital camera and later quantified using Behavioral Observation Research Interactive Software (BORIS). Preliminary analyses revealed significant main effects of age for both attacks ($p = 0.023$) and flank marking ($p < 0.000$). Post-hoc analysis revealed prepubertal hamsters engaged in significantly greater number of attacks compared to both adolescent ($p= 0.001$) and adult hamsters ($p = 0.002$) with adolescents and adult not differing from each other. Furthermore, adults displayed a significantly greater amount of flank marking compared to prepubertal hamsters ($p= 0.027$), but not compared to adolescent hamsters. These data are in line with previous studies on the adolescent development of agonistic behavior in Syrian hamsters using the resident/intruder paradigm. However, the mean number of attacks is lower and mean number of flank marks is higher when using the neutral arena paradigm compared to previous studies using the resident/intruder paradigm. Taken together, these data suggest that the patterns of agonistic behavior are similar across adolescent development when establishing (neutral arena) and maintaining (resident/intruder) territory, but the behavioral strategies differ between the establishment and maintenance of territory.

Title: Development of memory for conspecifics and caregivers

Authors: *B. J. LAHAM, E. C. COPE, E. DIETHORN, E. GOULD;
Princeton Univ., Princeton, NJ

Abstract: Social recognition, or memories of familiar individuals, is imperative for the development and stability of large social groups consisting of unrelated individuals. Recent investigation has pinpointed the CA2 region of the hippocampus as necessary for the memory of adult conspecifics in mice, with silencing of CA2 pyramidal neurons resulting in a temporary loss of memory for familiar conspecifics (Hitti and Siegelbaum, 2014; Dudek et al., 2016; Smith et al., 2016). While previous research has elucidated the role of the CA2 in social memories formed by adult mice, little is known about the development of social memory. Using a direct social investigation test, we found evidence of social recognition memory as early as P14 in mouse pups. This behavior is qualitatively similar to that observed in adulthood, with increased investigation times associated with novel, compared to familiar, conspecifics. Shortly after weaning, mice display social recognition memory that is quantitatively similar to that observed in adulthood in terms of investigation times. We also explored the earliest form of social memory, the memory a mouse pup has for its caregiver. Using a modified social test, we observed that genetically related, as well as cross-fostered, mouse pups exhibit a preference for their caregiver over a novel lactating female as early as P3. After separation from the caregiver at the time of weaning, mice retain the memory of the caregiver but exhibit a transition in preference for a novel female over the caregiver. The memory of the caregiver persists long into adulthood, for up to at least 150 days. Ongoing studies will explore the role of the CA2 and other hippocampal subregions in the development and maintenance of social memory, for age-matched conspecifics as well as for the caregiver.

Title: Reflexological and physical developmental impairment of male rats offspring induced by maternal stress through the nesting material reduction

Authors: *P. S. RODRIGUES, T. MENDES-LIMA, A. C. S. SAMPAIO, L. S. MEDEIROS, M. C. GALVÃO, K. E. KIATAQUI, T. M. REIS-SILVA, N. MOREIRA, T. B. KIRSTEN, M. M. BERNARDI;
Envrn. and Exptl. Pathology, Paulista Univ., São Paulo, Brazil

Abstract: Reductions in maternal care during the development of young rats may contribute to different impairments such as predisposition to depressive and anxiety-like behaviors, cognition deficits such as learning and memory deficits, and changes in the immune system. Considering that these behavioral changes may lead to a different behavioral pattern in the adulthood, the objective of this study was to analyze the effects of maternal neglect induced by the reduction of the nesting material during lactation in the physical and reflexological development of male offspring. For this, lactating rats were divided into two groups: control group (CG), in which the amount of nesting material was preserved and an experimental group (EG) where the amount of nesting material was reduced in 50% from post natal day 2 to 21 (PND). General activity and maternal behavior were analyzed in the mothers on PND 5-7 while the puppies were evaluated for their physical and reflexological development. The parameters with two groups were determinate with a student t test. Two-way ANOVA was used considering weight and time period as variables when pertinent, and finally, a Fisher exact test was performed to analyze the survival percentage. Regarding the results in the mother, despite no differences in general activity or maternal behavior being observed, the EG displayed increased frequency ($p = 0.02$), time ($p = 0.002$) and maximal duration ($p = 0.04$) of self-grooming compared to CG. In the pups, the maternal neglect decreased the survival percentage ($p = 0.01$), the body weight at 31 days of age [$F(1,84) = 3.37$, $p = 0.07$] as well as the delay in the average day of hair appearance (t test, $p = 0.04$), descent of the testicles ($p = 0.0007$) and reflex of palmar grasp ($p = 0.03$). Thus, it was possible to conclude that the maternal neglect direct affect the physical and reflexological development of the male offspring despite maternal behavior has been preserved in the mothers. These results may be attributed to maternal stress expressed by increased self-grooming of the mother at this first moment. This study was financed in part by the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior - Brasil (CAPES/PROSUP) - Finance Code 001.

Title: Combination of exercise and pharmacological neuromodulation targeting $GABA_A$ receptors promotes motor recovery and BDNF protein expression in the M1 after focal brain ischemia in rats

Authors: *T. INOUE[1,3], M. KITAHARA[1], M. OKAMURA[1], Y. TAKAMATSU[2], H. MAEJIMA[2];
[1]Grad. Sch. of Hlth. Sci., [2]Dept. of Rehabil. Science, Fac. of Hlth. Sci., Hokkaido Univ., Sapporo, Japan; [3]Res. Fellow of Japan Society for the Promotion of Sci., Tokyo, Japan

Abstract: It has been well recognized that aerobic exercise increases the expression of brain-derived neurotrophic factor (BDNF), a member of neurotrophins, which has a crucial role for neuroplasticity in the central nervous system. Recently, neuromodulation has attracted attention as a tool for promoting the recovery in stroke rehabilitation. Specifically, studies showed that pharmacological neuromodulation reducing GABAergic inhibition enhanced motor functional recovery after stroke. Thus, it was expected that both exercise and pharmacological neuromodulation beneficially contribute to the recovery after stroke. However, there is a dearth of research on the interactive effect of exercise and pharmacological neuromodulation targeting GABA in stroke rehabilitation. The objective of this study was to examine the interactive effects of exercise and low-level inhibition of $GABA_A$ receptors on the recovery of motor function and BDNF expression in the primary motor cortex (M1) using stroke model rats. Thirty-seven male Sprague-Dawley rats were divided into 5 groups: a sham group (SHAM, n=8), a control group (CON, n=7), an exercise group (EX, n=7), a bicuculline group (BIC, n=7), and a bicuculline and exercise group (BICEX, n=8). Animals except the SHAM group received the middle cerebral artery occlusion (MCAO) surgery to induce an ischemic stroke. We administered the $GABA_A$ receptor antagonist bicuculline intraperitoneally to the BIC and BICEX groups at a non-epileptic dose of 0.25 mg/kg. The EX and BICEX groups received treadmill exercise for 30 min a day. Following 2-week intervention after MCAO surgery, mRNA expression and protein level of BDNF in the ipsilateral and contralateral M1 were assayed using RT-PCR and ELISA. All study procedures were approved by the ethics committee for animal research of Hokkaido University

in Japan. Slight recovery was found in the EX and BIC groups, whereas exercise in the presence of bicuculline administration significantly enhanced the recovery of motor function in the BICEX group. Furthermore, BDNF protein level in the ipsilateral M1 was significantly greater in the BICEX group compared with those of other groups, whereas no significant difference among the groups was found in BDNF protein level in the contralateral M1. These findings suggested that the enhancement of BDNF protein level in the ipsilateral M1 could contribute to the specific recovery in the BICEX group more than that in the contralateral. Altogether, it was expected that exercise combined with low-level inhibition of $GABA_A$ receptors would promote the recovery of motor function after stroke accompanying the upregulation of BDNF expression in the ipsilateral M1.

Title: BDNF V66M variant exhibits reduced functional compliance in mediating neuronal survival

Authors: *C. JOSEPH, A. MANGANI, V. GUPTA, S. GRAHAM;
Macquarie Univ., Sydney, Australia

Abstract: Brain Derived Neurotrophic factor (BDNF) dysregulation is attributed to progressive cell loss leading to pre-disposition to neurodegenerative disorders. A common single nucleotide polymorphism associated with BDNF, BDNF V66M has been reported in conjunction with pathological features found in several neuronal diseases, however the precise mechanism underlying the regulation of BDNFV66M on downstream survival kinases is not well known. Here we compared the effects of BDNF and BDNF V66M molecules on different neuronal types to understand BDNF V66M specific effects on downstream receptors. Differentiated SHSY5Y cells (sensory neurons) and NSC34 cells (motor neurons) were treated with 1uM Cyclotraxin-B (TrkB inhibitor) and 1uM TAT-Pep5 (p75NTR inhibitor) overnight. (n=3) Cells were then subjected to either 50ng/ml BDNF or BDNF V66M treatment for 10 minutes. Cells were then immediately washed with ice-cold PBS, lysed and quantified using BCA assay. Western blotting

was performed with respective antibodies and analyzed using ImageJ software. BDNF treatment induced phosphorylation of survival kinases ERK and AKT in both cell types. TrkB inhibition rendered a loss in protein phosphorylation and BDNF treatment could restore the effects only partially. However, BDNF V66M induced effects were less significant compared to BDNF (pTrkB 3.6±0.16, pAkt 6.2±0.2, pERK 1.8±0.12) and, TrkB inhibition significantly ablated the BDNF V66M biochemical effects (pTrkB 1.6±0.21, pAkt 2.5±0.2, pERK 1.5±0.26). p75NTR inhibition compromised BDNF induced effects much more than TrkB inhibition and it was irrecoverable with BDNF V66M treatment (pTrkB 0.6±0.02, pAkt 1.6±0.13, pERK 0.4±0.08). Also, a differential activation pattern of kinases was observed in different neuronal cells. Together these results demonstrate that BDNF V66M lacks the usual neuroprotective effect of BDNF in inducing survival pathways and has a cell type-specific phosphorylation pattern in distinct neuronal cells. Survival pathways are more severely compromised with Cyclotraxin-B treatment than TAT-Pep5 treatment reiterating the role of TrkB in BDNF signaling essential for neuronal development and survival.

Title: Voluntary exercise combined with repetitive inhibition of GABAergic synapses modulates the expression of BDNF in the motor cortex

Authors: *H. MAEJIMA[1], M. HAYASHI[2], T. INOUE[2], M. KITAHARA[2];
[1]Dept. of Rehabil. Science, Fac. of Hlth. Sci., [2]Grad. Sch. of Hlth. Sci., Hokkaido Univ., Sapporo, Japan

Abstract: Recent researches focus on pharmacological treatments using $GABA_A$ receptor antagonists or inverse-agonist to inhibit GABAergic synapses and enhance excitability of cortical neurons in patients with CNS disorders, like the treatment using transcranial direct current stimulation (tDCS). Neurotrophins play crucial roles in neuroplasticity, neurogenesis, and neuroprotection in the central nervous system. Specifically, aerobic exercise increases the expression of brain-derived neurotrophic factor (BDNF) in the brain. In our previous studies, exercise combined with low-level $GABA_A$ receptor inhibition increased the expression of BDNF in the brain, i.e., low-level $GABA_A$ receptor inhibition with intraperitoneal administration of 0.25

mg/kg bicuculline, an antagonist for $GABA_A$ receptor, potentiated exercise-induced expression of BDNF in the motor cortex and the cerebellar cortex. Meanwhile, it was reported that bicuculline administration improved the scores of behavioal tests in a dose-dependent manner. Therefore, we assessed the interactive effects of exercise and higher inhibition of $GABA_A$ receptors with the intraperitoneal administration of 1.00mg/kg bicuculline for two weeks on the expression of BDNF in the motor cortex. The objective of this study was to consider the clinical treatment of GABAergic inhibition for neurorehabilitation in the patients with CNS disorders such as cerebrovascular accident (CVA). ICR mice were randomly divided into 4 groups based on the factors of exercise and $GABA_A$ receptor inhibition. We administered bicuculline intraperitoneally (1.00 mg/kg) every day and mice exercised on a running wheel for 2 weeks. Protein expression and mRNA expression of BDNF and its receptors (TrkB and p75) in the motor cortex were assayed using ELISA and real time PCR. Bicuculline administration enhanced daily running distance. However, repetitive administration of 1.00 mg/kg bicuculline reduced protein BDNF and increased transcriptional expression of p75, a receptor for BDNF related to neuronal death, whereas exercise tended to attenuate the exacerbation caused by bicuculline administration. Therefore, the present study suggested that exercise combined with low-level $GABA_A$ receptor inhibition could beneficially adjust the excitability of cortical neurons and modulate the expression of BDNF in the motor cortex as demonstrated in our previous studies using 0.25 mg/kg bicuculline in neurorehabilitation for the patients with CNS disorders.

Abstract: The present study examines the expression of the Tropomyosin-related kinase B (TrkB) receptor and the electrophysiological consequences of its activation on GABAergic interneurons of hippocampal area CA3. Triple immunolabeling for glutamate decarboxylase 67, the calcium-binding proteins parvalbumin, calbindin or calretenin, and the TrkB, shows that TrkB is widely expressed in horizontally-oriented bipolar and rounded-multipolar Stratum Oriens interneurons, bipolar and multipolar Stratum Lucidum interneurons and rounded-

multipolar GABAergic cells somatically located in the Stratum Radiatum/Stratum Lacunosum-Moleculare of area CA3. Electrophysiological characterization showed that Stratum Oriens interneurons exhibited a fast-spiking pattern of firing output, whereas Stratum Lucidum cells exhibited either fast-spiking or regular spiking output. In the Stratum Radiatum/Lacunosum-Moleculare, interneurons fired slow regular spiking trains of action potentials. Activation of the TrkB receptor with the perfusion of the specific agonist 7-8, dihydroxyflavone, modulated the amplitude and frequency of spontaneous excitatory events recorded in acute hippocampal slices. On Stratum Oriens interneurons, both amplitude and frequency of events increased significantly. On Stratum Lucidum, fast-spiking interneurons also exhibited increased amplitude and frequency of the spontaneous events. In contrast, regular spiking interneurons exhibited a significant reduction in the amplitude of the spontaneous events accompanied by increased spontaneous events frequency. The rounded-multipolar interneurons of the Stratum radiatum/Lacunosum-Moleculare exhibited increased amplitude and frequency of spontaneous excitatory events. The increased excitability of the inhibitory transmission was mirrored in the GABAergic inputs impinging on CA3 pyramidal cells, as the spontaneous inhibitory activity was dramatically increased on CA3 pyramidal cells during the perfusion of 7,8-DHF. Our data show that activation of TrkB receptors via Brain-Derived Neurotrophic Factor modulates the strength of synaptic transmission of area CA3 and restrain the excitability of CA3 pyramidal neurons.

Abstract: Brain-Derived Neurotrophic Factor (BDNF), an endogenous ligand for the Tropomyosin-related kinase B (TrkB) receptor, mediates multiple neural functions including synaptic transmission and plasticity. In this work, we are exploring the expression of TrkB receptors on anatomically identified CA3 interneurons and the physiological consequences of TrkB activation on the synaptic transmission of CA3 interneurons. Confocal analysis revealed

TrkB immunoreactivity in GAD-67 positive neurons that are also immunopositive to the calcium-binding proteins parvalbumin, calbindin or calretinin. TrkB is abundantly expressed in interneurons somatically located in the strata Oriens, Lucidum, Radiatum, and Lacunosum-Moleculare. Whole cell recordings in acute hippocampal slices showed that stimulation of TrkB receptor with the specific agonist 7, 8-dihydroxyflavone, differentially modulates amplitude and frequency of spontaneous excitatory postsynaptic currents (sEPSCs) of CA3 interneurons. In S. Oriens interneurons, both amplitude and frequency of sEPSCs increased significantly. In S. Lucidum, depending on its firing pattern, stimulation of TrkB increased amplitude and frequency of sEPSCs (fast-spiking interneurons) or decreased the sEPSCs amplitude without changes in the frequency (regular spiking interneurons). For interneurons located at the S. Radiatum and S. Lacunosum-Moleculare stimulation of TrkB consistently increased amplitude and frequency of sEPSCs. As expected, the increase in the glutamatergic transmission on CA3 interneurons was accompanied by an increase in the spontaneous inhibitory postsynaptic currents (sIPSCs) recorded on CA3 pyramidal neurons. Our results provide experimental evidence that activation of the TrkB receptor modulates the synaptic transmission of GABAergic interneuron and restrain the excitability of CA3 pyramidal cells.

Title: Visualizing activity-dependent BDNF expression in living mouse brain

Authors: *M. FUKUCHI[1], R. SAITO[2], S. MAKI[2], N. HAGIWARA[1], S. MITAZAKI[1], H. MORI[3];

Abstract: BDNF (Brain-derived neurotrophic factor), a member of neurotrophin family, plays a crucial role in expressing a variety of neural functions such as memory consolidation. In addition, alterations in BDNF level has been reported in psychiatric and neurodegenerative diseases including depression and Alzheimer's disease, suggesting that BDNF could be a biomarker and drug target for these diseases. We previously generated a novel transgenic mouse strain, termed *Bdnf-Luciferase* transgenic (*BDNF-Luc*) mouse, to visualize changes in *Bdnf* expression in living mice, using a luciferase as an imaging probe. We successfully detected bioluminescence signals from *BDNF-Luc* mice after the administration of D-luciferin, a substrate for luciferase. However, it was quite difficult to visualize changes in *Bdnf* expression in the brain region of the Tg mice, because the bioluminescence light producing D-luciferin and luciferase poorly penetrates biological tissues. We here used a novel substrate for luciferase, TokeOni, water-soluble substrate producing highly penetrable near-infrared bioluminescence light. Comparing with D-luciferin, we clearly detected the bioluminescence signal from the brain region of *BDNF-Luc* mice after the administration of TokeOni. Using TokeOni, we could also visualize kainic acid- or light stimulation-induced *Bdnf* expression in the brain region of the Tg mice. Taken together, TokeOni would be a beneficial substrate for luciferase to visualize changes in BDNF expression in the brain region, and this could be a powerful tool for clarification of the role of BDNF expression in pathophysiological and physiological conditions.

Title: Neuregulin-3 promotes excitatory synapse formation on hippocampal interneurons in a Bace1 dependent manner

Authors: *T. MULLER[1], R. JÜTTNER[1], B. C. VOIGT[1], S. BRAUD[2], F. RATHJEN[1], J. GEIGER[2], J. F. A. POULET[1], C. BIRCHMEIER[1];

Abstract: NRG3 and ERBB4 were implicated by human genetics in schizophrenia and other neuropsychiatric diseases. Nrg3 is a ligand of the Neuregulin gene family. Fast spiking

GABAergic interneurons are crucial for cortical network function and have been implicated in psychiatric disorders. They express high levels of the molecular interaction partner of Nrg3, the ErbB4 tyrosine kinase receptor. We found that Nrg3 is a functionally important and even the dominant interaction partner of ErbB4 in parvalbumin-positive (PV) GABAergic interneurons. Nrg3 and ErbB4 are located pre- and postsynaptically, respectively, in excitatory synapses on PV interneurons *in-vivo* and in-*vitro.* Ablation of Nrg3 results in a similar phenotype as the one described for ErbB4 ablation, i.e. reduced numbers of excitatory synapses on PV interneurons, altered short-term plasticity, and a disinhibition of the hippocampal network. In culture, presynaptic Nrg3 increases excitatory synapse numbers on ErbB4+ interneurons. Conversely, Nrg3 mutant neurons were poor donors of presynaptic terminals, which was particularly evident in the presence of competing neurons that produce recombinant Nrg3. Furthermore, we found that when presented by non-neuronal cells, Nrg3 induced postsynaptic membrane specialization. ErbB4, the tyrosine kinase receptor that binds Nrg3, is mainly known for its signaling function. However, we show that Nrg3 is a poor signaling molecule and instead provides adhesive cues in neuronal culture. These cues facilitate excitatory neurons to synapse onto ErbB4+ interneurons. Furthermore, we show that the synaptogenic activity of Nrg3 requires processing by the protease Bace1. Our work revealed the molecular mechanisms underlying the synaptic function of Nrg3, and provides insight into the role of Nrg3/ErbB4 functions in psychiatric disease.

Title: PI3K and AKT signaling pathway activated by prolactin in the rat hippocampus

Authors: *G. MOLINA SALINAS[1], V. RODRIGUEZ CHAVEZ[2], M. CERBON CERVANTES[2];
[1]UNIVERSIDAD NACIONAL Autónoma DE México, Mexico City, Mexico; [2]Biol., Univ. Nacional Autonoma de Mexico, Mexico City, Mexico

Abstract: Prolactin (PRL) is a peptide hormone, produced primarily by lactotrophs of the adeno-hypophysis and belongs to group I of cytokines family, together with growth hormone (GH) and placental lactogen (LP). PRL has been reported that it is synthesized in extra pituitary tissues, such as mammary gland, ovaries, decidua, also in cells of the immune system as well as

endothelial cells and more recently it has been suggested its synthesis in the brain. PRL It is associated with functions such as: neuronal plasticity, stimulation of neurogenesis in the olfactory bulb, induction of maternal behavior, reduction of anxiety, activation of glia and remyelination of oligodendrocytes and in recent reports as a neuroprotective against excitotoxicity produced by glutamate (Glu) or kainic acid (KA). The signaling pathways associated with its effects are JAK2/SATA5, ERK1/2 and PI3K/AKT. However, the signaling pathway by which PRL exerts its effects in the hippocampus, a region of the brain related to memory and learning, is not known in detail. The aim of this work is to determine, whether the PI3K/AKT pathway is responsible in part for the PRL-activated molecular mechanisms in the rat hippocampus. The animal model to answer this issue was ovariectomized wistar rats which were administered PRL via intraperitoneal (500µg/kg). The time course assay was done at 15, 30 and 60 minutes. mRNA and proteins were obtained from dissection of hippocampus. Analysis of the expression of AKT, pAKT CREB, pCREB, BDNF and NFkB proteins which are located downstream of the PI3K/AKT pathway and RT qPCR to evaluate some genes such as Bcl2 and PRLR that are activated by PRL were performed. Results show differential expression in the phosphorylated proteins from 30 min of PRL administration as well as increased expression of both genes. This suggests that PI3K/AKT pathway is early activated by PRL treatment and it would be responsible in part for the molecular actions induced by prolactin in the hippocampus of rats.

Title: Quantification of urinary neurotrophins by ELISA assay in prostate cancer patients

Authors: B. MARCH[1], ***L. M. FOSTER**[2], S. FAULKNER[3], M. SMOLNY[2], R. A. RUSH[2], H. HONDERMARCK[3];
[1]Dept. of Surgery, John Hunter Hosp., New Lambton Heights, NSW, Australia; [2]BIOSENSIS PTY LTD, Thebarton, Australia; [3]Sch. of Biomed. Sci. and Pharmacy, Fac. of Hlth. and Med., Univ. of Newcastle, Callaghan, NSW, Australia

Abstract: Background: The autonomic nervous system regulates the development and progression of prostate cancer. Prostate cancer-derived neurotrophins promote nerve infiltration

into the tumour microenvironment, whereby the local release of neurotransmitters stimulates cancer cell progression, growth, and invasion. Immunohistochemical studies have shown an association between prostatic neurotrophins (in particular BDNF, proNGF, NGF, GDNF)[1-3] and tumour aggressiveness, therefore we hypothesised that urinary neurotrophins may be candidate biomarkers for prostate cancer detection and prognosis.
Method: We used and validated the Biosensis *Rapid*™ ELISA kits for the quantification of neurotrophins in human urine (ELISA kits for NGF, BDNF, NT3, NT4/5, proNGF, proBDNF and GDNF). Reproducibility, spike recovery, parallelism and selectivity tests were performed for each kit. Thereafter, urine specimens were tested from a prospectively collected cohort of men with suspected or established prostate cancer (n=60). Control urine specimens were collected in healthy volunteers of similar age (n=15). All samples were undiluted and tested in duplicate. Total protein and creatinine were measured in each sample to normalise urinary neurotrophin concentration. Assay reliability was analysed by several criteria including potential interference by sample matrices and heterophilic antibodies.
Results: Neurotrophins were detected in both cancer and healthy urine, but there was no significant difference in the mean concentration between groups in any of the tested neurotrophins. Normalising the neurotrophin concentration to urinary creatinine or total protein concentration did not affect the outcome.
Conclusion: Neurotrophins are detectable in human urine samples and at this stage we have not evidenced any significant difference between prostate cancer patients and healthy controls.

Title: Increased accumulation of Rab7 and nerve growth factor receptor TrkA and $p75^{NTR}$ in rat sciatic nerve during peripheral inflammation

Authors: *V. GUJAR, K. E. MILLER;
Anat. and Cell Biol., Oklahoma State University, CHS, Tulsa, OK

Abstract: In addition to modulating the synthesis of neuropeptides like substance P (SP), calcitonin gene-related peptide (CGRP) and neurotransmitter glutamate (GLU), nerve growth factor (NGF) signaling is crucial for the regulation of growth and survival of sympathetic and sensory neurons. A small GTPase Rab7 has been shown to mediate the trafficking of NGF/TrkA signaling endosomes in sympathetic neurons. To determine whether Rab7 performs the similar function in primary afferents during the inflammatory state, we examined the immunoreactivity of Rab7 along with NGF and its receptors TrkA and p75NTR in rat sciatic nerve during adjuvant-induced arthritis (AIA). AIA was induced by a single unilateral subcutaneous injection of 150 µl of 1:1 of saline/CFA emulsion (complete Freund's adjuvant, 150 µg/150 µl) in the hind paw plantar surface. AIA was allowed to develop for 6hr prior to sciatic nerve ligation surgery and then after 24hr the distal end to the ligature is collected and processed for determining immunoreactivity. We found that the immunoreactivity of Rab7 was elevated in the distal side of a ligated peripheral nerve. NGF, pTrkA, and p75NTR also showed elevated immunoreactivity in sciatic nerve during peripheral inflammation. These results indicate the enhanced axoplasmic trafficking of Rab7 and NGF signaling molecules in the sciatic nerve during the process of peripheral inflammation. Further, these results suggest a possible association between NGF signaling and Rab7 GTPase in primary afferents during AIA.

Abstract: Genetic variants of Neuregulins (NRGs), and their cognate neuronal receptor ErbB4 have been associated with a risk for schizophrenia. Null ErbB4 knock-out (KO) mice exhibit neurodevelopmental impairments and behavioral deficits relevant to psychiatric disorders. ErbB4 transcripts are alternatively spliced at two locations: alternative splicing of JMa or JMb exons

encoding the extracellular juxtamembrane region renders the receptor susceptible or resistant to metalloprotease-mediated cleavage, respectively. In the cytoplasmic domain, inclusion of the Cyt-1 exon 26 confers upon the receptor the ability to signal via the PI3K pathway, in contrast to Cyt-2 variants lacking this exon. The ErbB4 Cyt-1 isoform comprises approximately 40% of ErbB4 in most brain areas, and independent studies have reported that ErbB4 transcripts including the Cyt-1 exon are increased in postmortem brains of schizophrenia patients. To investigate the functional role of ErbB4 Cyt-1, we targeted exon 26 by site-directed recombination. Ablation of the Cyt-1 exon was confirmed by the absence of Cyt-1 transcripts in brain sections using a novel *in situ*hybridization approach that detects single-exon boundaries (BaseScope), and by quantitative real-time PCR using TaqMan probes. Importantly, absence of the Cyt-1 exon did not alter overall expression levels of ErbB4, the JMa/JMb isoform ratios or the related NRG receptor ErbB3 in mutant mice. We then addressed phenotypes reported in ErbB4 KO mice. While GABAergic interneurons are reduced in the adult cortex and hippocampus of ErbB4 KO mice, we found no changes in density or distribution of interneurons in Cyt-1 KO mice. Unexpectedly, Cyt-1 KO mice performed normally in a series of behavioral assays: open field, elevated plus maze, sensorimotor gating and cognitive behaviors; all affected in ErbB4 KO mice. Lastly, our expression analyses in the hippocampus and the mesencephalon revealed only few changes in the transcriptome of Cyt-1 mutant mice. Taken together, we conclude that ErbB4 Cyt-1 receptors are largely dispensable for CNS development and function *in vivo*. *This work was kindly supported by the Eunice Kennedy Shriver NICHD Intramural Research Program, NIH.*

Title: NMDA receptors regulate both neuregulin 2 accumulation at ER-PM junctions and ectodomain shedding by ADAM10

Authors: *D. VULLHORST[1], A. L. BUONANNO[2];
[1]NICHD, NIH, Bethesda, MD; [2]Head of Cell Biol. Affinity Group, NICHD, Chief of Sect Mol Neurobiol (SMN), NICHD, NIH, Bethesda, MD

Abstract: Unprocessed pro-Neuregulin 2 (pro-NRG2) and the voltage-gated potassium channel Kv2.1 co-localize on neuronal cell bodies at junctions between the endoplasmic reticulum and plasma membrane (ER-PM junctions). NMDA receptors (NMDARs) trigger NRG2 ectodomain shedding from these sites followed by activation of ErbB4 receptor tyrosine kinases, and ErbB4 signaling cell-autonomously downregulates intrinsic excitability of GABAergic interneurons by reducing voltage-gated sodium channel currents. NMDARs also promote dispersal of Kv2.1 clusters from ER-PM junctions and cause a hyperpolarizing shift in its voltage-dependent channel activation, suggesting that NRG2/ErbB4 and Kv2.1 act in concert to regulate intrinsic interneuron excitability in an activity-dependent manner. Here we explored the cellular processes underlying NMDAR-dependent NRG2 shedding in cultured rat hippocampal neurons. We report that NMDARs control shedding by two separate but converging mechanisms. First, NMDA treatment disrupts pro-NRG2 clusters at ER-PM junctions by post-translationally modifying conserved Ser/Thr residues in its intracellular domain, remarkably similar to the molecular mechanisms underlying NMDAR-dependent downregulation of Kv2.1 clusters. Second, using a mutant NRG2 that cannot be modified at these residues and that fails to accumulate at ER-PM junctions, we demonstrate that NMDARs directly promote NRG2 shedding by ADAM-type matrix metalloproteinases. Using pharmacological and shRNA-mediated knock-down, and metalloproteinase overexpression, we unexpectedly find that ADAM10, but not ADAM17/TACE, is the major NRG2 sheddase acting downstream of NMDAR activation. Together, these findings reveal how NMDARs exert tight control over the NRG2/ErbB4 signaling pathway in GABAergic interneurons, and strengthen the notion that NRG2 and Kv2.1 are co-regulated components of a pathway that homeostatically regulates intrinsic excitability.

Abstract: The leptomeninges referring to arachnoid and pia mater and their projections into the perivascular compartments in the central nervous system actively participate in diverse biological processes including fluid homeostasis, immune cell infiltrations, and neurogenesis, yet their detailed cellular and molecular identities remain elusive. The present study provides the first comprehensive characterization of platelet-derived growth factor beta (PDGFR-β)-expressing cells in the leptomeninges in the adult rat brain using light and electron microscopy. PDGFR-β^+ cells comprised the inner arachnoid, arachnoid trabeculae, and pia mater as well as the leptomeningeal sheath of the subarachnoid vessels, thereby forming a cellular network throughout the leptomeninges. Leptomeningeal PDGFR-β^+ cells were commonly characterized by large euchromatic nuclei, thin branching processes forming web-like networks, and expression of intermediate filaments nestin and vimentin. They were typical of active fibroblasts showing well-developed rough endoplasmic reticulum and close spatial correlation with collagen fibrils. Leptomeningeal PDGFR-β^+ cells ensheathing the vasculature in the subarachnoid space joined with pial PDGFR-β^+ cells upon entering the cortical parenchyma, yet perivascular PDGFR-β^+ cells in these penetrating vessels showed an abrupt changes in their morphological and molecular characteristics: they became more flattened with loss of immunoreactivity for nestin and vimentin and deficient collagen deposition, indicative of inactive fibroblasts termed fibrocytes. In cortical parenchyma, PDGFR-β immunoreactivity was almost exclusively localized to larger caliber vessels, and significantly decreased in capillary-like microvessels. Collectively, our data identify PDGFR-β as a novel cellular marker for leptomeningeal fibroblasts comprising the leptomeninges and perivascular adventitial cells of the subarachnoid and penetrating large-sized cortical vasculatures. Title: Synapse population distributions reveal synaptome architecture including regional differentiation

Authors: *E. A. FRANSÉN[1], M. REHN[1], Z. QIU[2], M. J. CIZERON[2,3], B. KONIARIS[2], S. G. N. GRANT[2];
[1]Computat. Sci. and Technol., KTH Royal Inst. of Technol., Stockholm, Sweden; [2]Ctr. for Clin. Brain Sci., Univ. of Edinburgh, Edinburgh, United Kingdom; [3]Inst. NeuroMyoGène, Université de Lyon, Univ. Claude Bernard Lyon 1, France

Abstract: Synaptic properties have been studied extensively, temporally over a range of time scales, and spatially either at high resolution in small volumes, or at low resolution across the brain, however systematic characterization of types and subtypes of individual synapses within and across brain regions remains poorly understood.
We have produced the first synaptome atlas of the vertebrate brain by examining the expression of fluorescently labelled MAGUK proteins in individual excitatory synapses in mice (Zhu et al., 2018). Results show large diversity of synaptic types as well as regional specific composition and perturbations of these maps in disease-relevant mutations. Previous studies on the distribution of excitatory postsynaptic potential (EPSP) amplitudes or spine sizes show skewed distributions with heavy tails, but interpretations are limited by the small number of synapses and regions studied. As these distributions constitute fingerprints of learning as well as development, theoretical work on learning rules has nevertheless been informed by these findings.
To further analyze the synaptic organization from single synapses to brain-wide scale we have developed and used statistical methods. Using very large datasets obtained from the mouse synaptome atlas (+100 million synapses), we have evaluated the population (frequency) distributions of PSD95 positive excitatory synapses as described by protein numbers, morphology of postsynaptic density protein expression and associated subtype features. We observed skewed heavy-tailed distributions, consistent with previous electrophysiological and morphological findings. We further find differences between brain regions with regard to both the locations of the distribution peaks (constituting the most common synapses) and the width of the distributions (constituting the diversity) and support for spatial patterning and gradients. Previous studies have shown correlations between PSD95 expression, spine morphology and EPSP amplitude, allowing our results to be interpreted also in functional terms and to address hypothesis based on theoretical work. These analyses and other approaches are being developed to understand the remarkably complex architecture of the mouse synaptome.

Abstract: We previously generated a mouse synaptome atlas that reveals high diversity of synapse types distributed into an architecture across the brain (Zhu, Cizeron & Qui, *et al*, Neuron 2018). This atlas is based on the static levels of expression of synaptic proteins. Here we introduce a novel method to visualize and systematically analyse endogenous synaptic protein turnover at single synapse resolution across the living brain. We created a line of genetically modified mice in which the endogenous PSD95 was fused to the HaloTag domain. These mice were injected intravenously with silicone-rhodamine (SiR) HaloTag ligand, which covalently binds the HaloTag domain, enabling the visualization of excitatory synapses with confocal and super-resolution microscopes. The turnover of PSD95 can be measured by the loss of fluorescence observed in brain tissue sections. Furthermore, the newly synthesised PSD95 can be detected by labelling with a second ligand (TMR-Halo) applied post-fixation. Combining this labelling method with synaptome mapping technology enabled us to quantify the changes in synapses in many brain regions. Strikingly, the vast majority (>90%) of excitatory synapses in the brain had replaced all detectable PSD95 within two weeks. However, there were residual populations of “long-lived” synapses in the cortex, hippocampus and amygdala showing discrete anatomical localisations. In addition to creating a dynamic synaptome atlas, this versatile technology enables us to study the mechanisms governing synapse diversity and its relevance to behaviour and disease.

Title: Climbing fiber-mediated spillover transmission to interneurons is regulated by EAAT4

Authors: *S. MALHOTRA[1], G. BANUMURTHY[2], J. H. VADEN[2], L. S. OVERSTREET-WADICHE[2], J. I. WADICHE[2];

Abstract: A single cerebellar climbing fiber (CF) makes hundreds of individual contacts with one Purkinje cell (PC) and releases multiple vesicles at each synapse, a process termed multivesicular release (MVR)[1]. The high synaptic glutamate concentration resulting from MVR is mostly limited to the synaptic cleft by Excitatory Amino Acid Transporters (EAATs) on Bergmann glia that express EAAT1/2 and on PCs that express EAAT4. Nevertheless, sufficient glutamate spills over to activate glutamate receptors on nearby molecular layer interneurons (MLIs) despite the absence of anatomically-defined synaptic specializations. The expression of EAAT4 follows a parasagittal banding pattern and may limit CF-MLI glutamate spillover,

similar to its regulation of extrasynaptic neuroglial signaling[2,3]. Here, we use mice expressing Venus under the Aldolase C promoter to visualize EAAT4 expression[4] to test the idea that cerebellar regions are endowed with distinct spillover properties. We made patch-clamp recordings from MLIs and electrically isolated CFs in microzones with both high and low EAAT4 expression. Consistent with our hypothesis, spillover responses are smaller in areas where EAAT4 is expression is high, and larger where EAAT4 expression is low. Because many proteins have patterned expression that matches that of EAAT4, we used the pan-EAAT inhibitor TBOA to block glutamate transporters. The amplitudes of CF-mediated spillover EPSCs onto MLIs were similar between microzones in the presence of TBOA, confirming that these differences resulted from glutamate transport. This suggests that a lower concentration of glutamate escapes from CF-PC synapses when EAAT4 is prevalent. Since spillover signaling to MLIs triggers feedforward inhibition and disinhibition of PCs[5], these results suggest that non-synaptic circuity generates distinct patterns of inhibition in EAAT4 microzones.

Title: NSG2 confers unique postsynaptic properties via AMPAR surface expression in a discrete subset of hippocampal synapses

Authors: *P. CHANDER, G. M. ELIASON, J. P. WEICK;
Neurosciences, Univ. of New Mexico, Albuquerque, NM

Abstract: Previous studies demonstrate that members of the Neuron-Specific Gene family (NSG1 and NSG2) are actively transported in multiple endo-lysosomal vesicles throughout dendritic arbors, and regulate secretory trafficking of postsynaptic AMPARs. Interestingly, we

recently demonstrated that NSG2 resides in a subset (~30%) of excitatory postsynaptic densities (PSDs) in hippocampal cultures, yet robustly affects postsynaptic efficacy. Thus, we hypothesized that either: 1) NSG2 is targeted to a unique subset of hippocampal synapses, or 2) NSG2 transiently visits all or most excitatory synapses over time, but occupies an average of 30% at any given timepoint. Using timelapse imaging we now demonstrate that postsynaptic NSG2 is stable during prolonged imaging periods (>3hr), supporting its preferential targeting to a subset of excitatory PSDs. Further, a proportion of synaptic NSG2 co-localizes with PSDs that contain large, multi-headed spines that resemble dentate gyrus-CA3 Mossy fiber synapses. To determine the function of NSG2 within PSDs we analyzed surface GluA1 and GluA2, and found that NSG2-containing PSDs displayed increased surface expression of AMPARs compared to PSDs that lacked NSG2. Furthermore, evoked excitatory postsynaptic currents (EPSCs) were significantly greater at NSG2-containing synapses, consistent with a role for NSG2 in promoting surface AMPAR expression. In order to determine the molecular determinants of NSG2 localization we deleted the entire amino (ΔN) or carboxy (ΔC) termini of NSG2. We found that the ΔN-NSG2 localized to significantly fewer synapses, while ΔC-NSG2 was trafficked to PSDs to a similar extent as wild-type NSG2. However, we found that compared to wild-type NSG2, neither ΔN-NSG2 nor ΔC-NSG2 mutants were able to cause increases in the amplitude of miniature EPSCs. This suggests that the N-terminus regulates PSD localization while the C-terminus is important for promoting AMPAR surface expression. Together, these and other data suggest that NSG2 promotes AMPAR surface expression at a subset of excitatory synapses and utilizes unique targeting and functional domains within the N- and C-termini, respectively.

Abstract: Variants in the *ANK3* gene encoding ankyrin-G are associated with neurodevelopmental disorders, including intellectual disability, autism, schizophrenia, and bipolar disease. However, no upstream regulators of ankyrin-G at synapses are known. Through an unbiased screen, we show that ankyrin-G interacts with Usp9x, a neurodevelopmental disorder-associated deubiquitinase (DUB). Usp9x phosphorylation enhances their interaction, decreases ankyrin-G polyubiquitination, and stabilizes ankyrin-G to maintain dendritic spine development. In forebrain-specific Usp9X knockout mice ($Usp9X^{-/Y}$), ankyrin-G as well as multiple ankyrin-repeat domain (ANKRD)-containing proteins are transiently reduced at two, but recovered at 12-weeks, postnatally. However, reduced cortical spine density in knockouts persists into adulthood. $Usp9X^{-/Y}$ mice display ankyrin-G aggregates, increased anxiety, and novelty-induced hyperactivity. *USP9X* mutations in patients with intellectual disability and autism ablate its catalytic activity or ankyrin-G interaction. Our data reveal a DUB-dependent mechanism of ANKRD protein homeostasis, impairment of which only transiently affects ANKRD protein levels, but leads to persistent neuronal, behavioral, and clinical abnormalities.

Title: The spinophilin, SAPAP3, and mGlu5 complex as a potential regulatory node of obsessive-compulsive disorder-like behavior

Authors: *C. W. MORRIS[1], D. S. WATKINS[1], A. J. BAUCUM II[2];
[1]Stark Neurosciences Res. Inst., Indianapolis, IN; [2]Biol., Indiana University-Purdue Univ. Indianapolis, Indianapolis, IN

Abstract: Scaffolding proteins enriched in dendritic spines are poised to organize protein complexes and facilitate downstream signaling in response to neuronal activation. Genetic loss of scaffolding proteins that are highly expressed in the striatum lead to altered behavioral outputs. For example, loss of spinophilin, the major dendritic spine protein phosphatase 1-targetting protein, induces striatal motor deficits. Specifically, these mice have deficits in rotarod learning and do not sensitize to the hyperlocomotive effects of amphetamine. Biochemically, spinophilin has been implicated in regulating the surface expression of the metabotropic

glutamate receptor 5 (mGlu5). Interestingly, we have reported that spinophilin interacts with SAPAP3 in the striatum. SAPAP3 is also a scaffolding protein enriched in dendritic spines, where loss of this protein yields an excessive grooming phenotype, making it a validated mouse model of obsessive-compulsive disorder (OCD). Work investigating SAPAP3 KO mice has revealed this excessive grooming phenotype is largely due to exacerbated mGlu5 signaling. However, the role spinophilin plays in regulating this mGlu5-driven excessive grooming phenotype is largely unknown. The present study explores this knowledge gap by utilizing biochemical and behavior approaches to address the physiological importance of the spinophilin/SAPAP3/mGlu5 complex. Elucidating the mechanisms and consequences of this interaction in the striatum can lead to novel druggable targets capable of rescuing OCD-like phenotypes.

Title: Mesophasic organization of $GABA_A$ receptors in hippocampal inhibitory synapse

Authors: Y.-T. LIU[1], ***C.-L. TAO**[1], X. ZHANG[2], L. QI[1], R. SUN[1], P.-M. LAU[1], Z. H. ZHOU[3], G.-Q. BI[1];

Abstract: Neurotransmitter receptors play pivotal roles in synaptic functions. However, the structure and organization of individual receptor molecules has not been observed *in situ*. Here, we identified and determined the structure of $GABA_A$ receptor ($GABA_AR$) in the inhibitory synapses of cultured hippocampal neurons by cryo electron tomography. The $GABA_ARs$ form super-complexes with a fixed 11nm inter-receptor distance but variable relative angles. These

super-complexes then form receptor networks with reduced Voronoi entropy than randomly distributed receptors. The receptor networks further organize into a mesophasic assembly with a ~18nm phase boundary. The assembly correlates with condensates of postsynaptic scaffolding proteins, as well as presynaptic neurotransmitter release sites. This hierarchical self-organization maintains both regularity and flexibility, thus could serve for balanced reliability and plasticity in synaptic information processing.

Title: Gephyrin phosphorylation regulates sex-dependent inhibitory connectivity in the mouse brain

Authors: *B. F. N. CAMPBELL[1], M. HLEIHIL[1], S. K. TYAGARAJAN[2];
[1]Inst. of Pharmacol. and Toxicology, Univ. of Zurich, Zuerich, Switzerland; [2]Inst. of Pharmacol. and Toxicology, Univ. of Zurich, Zurich, Switzerland

Abstract: Recent characterisation of sex differences in inhibitory neurotransmission has revealed both developmental and regulatory dimorphisms, although underlying mechanisms are poorly understood. Fast GABAergic synaptic transmission is enacted via the pre-synaptic output of inhibitory interneurons and the post-synaptic activation of $GABA_A$ receptors ($GABA_ARs$) which in turn are organised by the scaffolding protein gephyrin. Gephyrin is the substrate for a plethora of post-translational modifications which affect the clustering and interactions of gephyrin molecules. Our group has reported that phosphorylation of gephyrin at serines 268 (by ERK1/2) and 270 (by GSK3β) negatively controls gephyrin cluster size and inhibitory synaptic transmission. Consequently, blocking the phosphorylation of these residues leads to increased density and size of gephyrin clusters, enhancing the amplitude and frequency of GABAergic input. We have recently found evidence that gephyrin is differentially phosphorylated between males and females in the brain. To understand how gephyrin phosphorylation may be a substrate for control of GABAergic transmission between the sexes, we developed a mutant mouse model in which serines 268 and 270 are mutated to alanines to constitutively prevent phosphorylation at these residues. Characterisation of behavioural phenotypes in these mutant mice has revealed deficits in learning, with altered inhibitory connectivity in the hippocampal CA1 formation

leading to functional changes in inhibitory synaptic input. This phenotype presents as sexually dimorphic, with opposing changes between male and female mice due to regulation of interneuron number. Taken together, this research reveals the unexpected involvement of a synaptic scaffold protein controlling inhibitory connectivity in a sexual dimorphic manner.

Title: Latrophilin adhesion GPCRs direct synapse specificity by coincident binding of FLRTs and Teneurins

Authors: *R. SANDO, X. JIANG, T. C. SUDHOF;
Mol. and Cell. Physiol., Stanford Univ., Stanford, CA

Abstract: Emerging evidence supports that bidirectional signaling by cell-adhesion molecules mediates synapse formation, but the mechanisms involved remain elusive. The adhesion-G-protein coupled receptor (GPCR) Latrophilins are large cell-adhesion molecules with extensive extracellular sequences, as well as putative intracellular signal transduction capabilities. We found that the adhesion-GPCRs latrophilin-2 and latrophilin-3 are postsynaptic molecules that selectively direct formation of perforant path and Schaffer-collateral synapses, respectively, in hippocampal CA1-region neurons. Latrophilin-3 binds to at least two trans-cellular ligands, fibronectin leucine-rich-repeat transmembrane proteins (FLRTs) and teneurins. Binding to both ligands *in vivo* was required for input-specific synapse formation, suggesting that coincident binding of both ligands is necessary for synapse specificity. *In vitro*, co-expression of FLRT and teneurin was required to induce excitatory synapse formation. Thus, postsynaptic latrophilins promote excitatory synapse formation by simultaneous binding of two unrelated presynaptic ligands, which is required for the formation of distinct synaptic inputs at specific dendritic localizations. These results suggest a coincident binding and signal integration mechanism for input-specific excitatory synapse formation.

Title: The nanoscale organization of glutamate receptor subtypes is optimized for synaptic function and plasticity

Authors: *M. HRUSKA[1], R. CAIN[1], M. B. DALVA[2];
[2]Neurosci., [1]Thomas Jefferson Univ., Philadelphia, PA

Abstract: At many synapses in the brain, action potential (AP) evoked synaptic transmission consists of a synchronous and asynchronous phase. The synchronous and asynchronous release at individual synapses underlie diverse computational outcomes that modulate synaptic transmission and plasticity. The synchronous release is dependent on the presence of fast calcium sensor Synaptotagmin-1 (SYT1), whereas Synaptotagmin-7 (SYT7) functions as a sensor for asynchronous release. Despite their importance for regulating the kinetics of release, how the nanosynaptic architecture of SYT1 and SYT7 is related to the functional organization of the synapse is unknown. Using multi-color Stimulated Emission Depletion (STED) nanoscopy, we find a precise relationship between the organization of glutamate receptors and sites of synchronous and asynchronous release at spine synapses. Using cultured cortical neurons, we find that 20% of spines are "silent" consisting of only NMDAR containing nanomodules. As spines increase in size the number, but not the size, of NMDAR nanomodules increases. In AMPAR containing spines, the number of GluA2 nanomodules scales with spine size, but the number of GluA1 nanomodules does not. At most synapses, GluA1 clusters co-localize only with one PSD-95 nanomodule regardless of PSD-95 nanomodule numbers. We find SYT1 and SYT7 localize to most spines containing NMDARs and AMPARs. Similar to GluN1 and GluA2 clusters, the number of both SYT1 and SYT7 nanomodules scales with the number of PSD-95 nanomodules and the spine size. To begin to understand how synaptic release sites are organized with relation to glutamate receptors, we analyzed the distances between pre- and postsynaptic modules. NMDAR modules localize closer to the center of PSD-95 and SYT7 nanomodules. In contrast, GluA1 and GluA2 clusters are found at the edges of PSD-95 nanomodules and are located closer to SYT1 than to SYT7. These findings indicate a remarkably precise organization of the nanostructure of the synapse and suggest that distinct sub-synaptic domains may define regions responsible for synaptic function and plasticity.

Title: Proteomics and functions of the synaptic proteins circulating in the CSF in schizophrenia

Authors: *M. DOS SANTOS[1,2], E. K. BOMBA-WARCZAK[3], E. L. PARNELL[1,2], D. D. LOIZZO[2], R. GAO[1], M. D. MARTIN-DE-SAAVEDRA[1,2], J. N. SAVAS[3], P. PENZES[1,2]; [1]Physiol., [2]Ctr. for Autism and Neurodevelopment, [3]Neurol., Northwestern Univ., Chicago, IL

Abstract: Schizophrenia (SZ) is a chronic debilitating psychiatric disorder involving complex interactions between genes and environment. At the neuronal level, this disorder is characterized by a decrease in synapses number in postmortem brain tissues. Due to this large heterogeneity of factors coupled with the lack of specific animal models, the molecular and neuronal bases of the synaptopathies in SZ are still poorly known. In order to develop better therapeutic strategies, it becomes crucial to find new biomarkers of the disease. Our study aims to identify novel synaptic markers of schizophrenia circulating in the cerebrospinal fluid (CSF) and study their physiological functions. The CSF is one of the bodily fluid most in contact with neurons and contains many synaptic proteins due to ectodomain shedding and extracellular vesicles release. Therefore, the CSF can mirror the synaptic proteome environment and requires only a mildly invasive extraction procedure. CSF proteins levels were measured in 5 controls and 5 individuals with schizophrenia using an unbiased tandem mass tag labeling followed by liquid chromatography/Mass spectrometry. We detected 140 proteins with dysregulated levels in the CSF in SZ individuals when compared to controls. Among these proteins, we focused our attention on proteins localized in the postsynaptic density for their fundamental roles in neuronal network development. Interestingly, we found a high proportion of cell adhesion molecules as well as ion channels regulators in this fraction, some of them are already known to be implicated in psychiatric disorders. The second part of the project consists in studying the neuronal functions of these circulating dysregulated proteins by using single cell 2photon calcium imaging on mouse brain slices exposed to recombinant forms of the candidates. This approach shows us the impact of these proteins at the neuronal network level such as the synchrony of the calcium events, their frequency and amplitudes. Ultimately, these results can pave the way to new therapeutic strategies using CSF peptides infusion based on observed dysregulated proteins in SZ.

Title: Patch clamp recordings in adult mouse thoracic paravertebral ganglia show changes in spontaneous event frequency and amplitude after spinal cord injury

Authors: D. B. STOCKTON[1], ***M. L. MCKINNON**[2], Y. LI[2], S. HOCHMAN[2], A. A. PRINZ[1]; [1]Dept. of Biol., Emory Univ., Atlanta, GA; [2]Dept Physiol, Emory Univ. Sch. Med., Atlanta, GA

Abstract: Thoracic intraspinal preganglionic neurons project to sympathetic postganglionic neurons (SPNs) within paravertebral ganglia. Major functions of the signals processed or relayed by these neurons include control of vasomotor tone, brown adipose tissue, sweat glands, and piloerector muscles. Spinal cord injury (SCI) can disrupt proper signal transmission and have profound effects, including the onset of autonomic dysreflexia, episodes of extreme hypertension that can lead to seizures, strokes, or death.

In a recently published paper, we developed an *in vitro* approach for whole-cell recordings in intact murine thoracic ganglia (T3-T12) to characterize cellular and synaptic properties. In the present abstract, we describe exploratory efforts to characterize the effects on synaptic properties due to SCI.

Our control group consisted of 3 male and 2 female C57Bl/6J mice and the treatment group of 1 male and four female C57Bl/6J mice. In the treatment group, we transected the spinal cord above the T2 vertebra three weeks or six weeks before sacrificial surgery. In both groups, we dissected the spinal column to perform *ex vivo* whole cell patch clamp electrophysiological recordings. We analyzed the recordings to characterize differences between groups. We found that spontaneous excitatory post-synaptic current (sEPSC) events approximately doubled in frequency post-SCI, while amplitude showed a trend to increase. In addition, amplitude statistical characteristics showed greater variability after SCI.

In summary, thoracic SPNs show marked changes in sEPSC event characteristics after spinal cord injury. This may suggest a compensatory reorganization of synaptic input to regain loss of function after SCI. These data highlight the potential role of spontaneous event mechanisms in understanding and treating spinal cord injuries.

Title: Neuroligin4 regulates excitatory synaptic transmission in human neurons

Authors: *S. G. MARRO[1], S. CHANDA[2], T. C. SUDHOF[1], M. WERNIG[3];
[2]MCP, ISCBRM, [3]Werning Lab, Stem Cell Inst., [1]Stanford Univ., Stanford, CA

Abstract: The autism-associated synaptic-adhesion gene Neuroligin-4 (NLGN4) is poorly conserved evolutionarily, limiting conclusions from Nlgn4 mouse models for human cells. Here, we show that the cellular and subcellular expression of human and murine Neuroligin-4 differ, with human Neuroligin-4 primarily expressed in cerebral cortex and localized to excitatory synapses. Overexpression of NLGN4 in human neurons resulted in an increase in excitatory synapse numbers but a remarkable decrease in synaptic strength. Human neurons carrying the syndromic autism mutation NLGN4-R704C also formed more excitatory synapses but with increased functional synaptic transmission due to a postsynaptic mechanism, while genetic loss of NLGN4 did not significantly affect synapses in the human neurons analyzed. Thus, the NLGN4-R704C mutation represents a change of function mutation. Our work reveals contrasting roles of NLGN4 in human and mouse neurons, suggesting human evolution has impacted even fundamental cell biological processes generally assumed to be highly conserved.

Title: DKK2 regulates neuronal development and synaptic transmission in hippocampal CA1 neurons

Authors: *W. SONG, S. H. YOON, M.-H. KIM;
Seoul Natl. Univ. Col. of Med., Seoul, Korea, Republic of

Abstract: DKK2 (Dickkopf-related protein 2) is a member of the DKK family (DKK1-4) proteins which modulate the Wnt signaling pathway through the interaction with Wnt co-receptors LRP5/6. Previous studies have suggested that DKK2 can modulate the Wnt signaling pathway either positively or negatively, depending on the cellular or tissue context. However, the role of DKK2 in the nervous system, especially in brain neurons, has not been investigated. Here we show that the deficiency of DKK2 in mice promotes neuronal development of hippocampal CA1 pyramidal neurons. DKK2 knockout (KO) mice displayed increased dendritic arborization and spine density in CA1 neurons. These morphological changes were accompanied by an increased frequency of miniature excitatory postsynaptic currents (mEPSCs). Furthermore, DKK2 KO mice showed enhanced long-term potentiation (LTP) at the Schaffer collateral-CA1 synapse, while basal synaptic transmission and the paired-pulse ratios were comparable to wild-type littermates. These results suggest that DKK2-mediated signaling is critical for normal neuronal development and synaptic function.

Title: Lack of interaction between gephyrin and tubulin at the inhibitory post-synapse

Authors: *I. ARIOZ[1], A. BECKER[1], D. DIETRICH[2], S. SCHOCH[1];
[1]Inst. of Neuropathology, Bonn, Germany; [2]Univ. Clin. Bonn, Bonn, Germany

Abstract: Disruption of excitation/inhibition balance of neuronal circuits contributes to various brain pathologies. Despite the importance of inhibitory synaptic transmission, our understanding of the structural organization of the inhibitory postsynaptic scaffold and how it is maintained, stabilized and dynamically modulated lacks far behind our knowledge of excitatory synapses. It is well established that Gephyrin a multifunctional protein that plays role in clustering of glycine and GABAA receptors is a major scaffold specific to inhibitory post-synapses. Interestingly, in contrast to excitatory postsynapses a direct link of the postsynaptic scaffold to microtubules has been reported. This was based on biochemical studies, which showed a direct interaction of polymerized tubulin with gephyrin. However, other studies suggest that postsynaptic and

extracted gephyrin was not affected by the depolymerization of microtubules or actin in cultured mature hippocampal neurons. To date, the nanoscale architecture of cytoskeletal elements has not been resolved in inhibitory post-synapses. To visualize the underlying structure, we have used super resolution microscopy (dSTORM) of microtubules and the inhibitory post-synapse scaffold protein gephyrin in cultured neurons. We found that the frequency of clustered gephyrin significantly increased with the number of dendritic microtubule filaments and that single filament-containing dendrites were devoid of gephyrin punctae. However, we did not collect evidence for a direct contact of tubulin with postsynaptically clustered dendritic gephyrin. These results may suggest that tubulin-gephyrin interaction is important for transport and/or initiation of an inhibitory synapse but not for the maintenance of the gephyrin postsynaptic scaffold.

Title: Insights into spinule dynamics, regulation, and function uncovered by 3D enhanced resolution microscopy

Authors: *C. R. ZACCARD[1], L. P. SHAPIRO[1], C. P. PRATT[2], K. MYCZEK[1], M. D. MARTIN-DE-SAAVEDRA[2], P. PENZES[3];

Abstract: Dendritic spinules are thin, membranous protrusions formed by neuronal dendritic spines that are not adequately resolved by diffraction-limited light microscopy. Our understanding of their structure and function is largely inferred from fixed-tissue electron microscopy, but recently developed enhanced-resolution modalities have enabled live-cell nanoscopic imaging of transient, sub-spine structures. Herein, we utilized rapid structured illumination microscopy (SIM) and enhanced resolution confocal microscopy to study spatiotemporal spinule dynamics in live cultured cortical pyramidal neurons. Spinules typically formed on large mushroom spines at the same topographical locations. Most were short-lived, originating near simple post-synaptic densities (PSDs), while a subset was long-lived and elongated, emerging from complex PSDs. We observed calcium transients within spinules

synchronized with spine head transients and a drastic decrease in spinule number following calcium depletion, while providing evidence of differential calcium-mediated regulation of spinule classes. We next investigated the role of Kalirin in spinule formation, a guanine nucleotide exchange factor for Rho GTPases that is a major regulator of actin dynamics in spines. Finally, we utilized live FM dye staining to assess short- and long-lived spinule interactions with presynaptic terminals. In summary, we identified unique spinule classes divergent in lifespan, dynamics, morphology, relationship to the PSD, and mode of regulation. These data together suggest distinct synaptic functions of short-lived and long-lived spinules, informing future studies, and demonstrating a new application for enhanced resolution microscopy to study sub-spine membrane projections.

Title: Ion channel dysfunction and seizure susceptibility in the 16p11.2 duplication mouse model is mediated by epilepsy gene PRRT2

Authors: *M. P. FORREST[1], N. H. PIGUEL[1], Y.-Z. WANG[2], D. SIMKIN[3], L. E. DIONISIO[1], N. HAWKINS[3], V. BAGCHI[1], M. DOS SANTOS[1], A. L. GEORGE, Jr.[3], J. KEARNEY[3], J. N. SAVAS[2], P. PENZES[1];
[1]Physiol., [2]Neurol., [3]Pharmacol., Northwestern Univ., Chicago, IL

Abstract: The 16p11.2 microduplication is a rare copy number variant (CNV) that confers risk of multiple neuropsychiatric conditions including, schizophrenia, autism, and epilepsy. The 16p11.2 chromosomal region contains 27 protein-coding genes however, the mechanisms by which altered gene dosage in this region increases disease susceptibility is still unknown. To uncover novel disease-relevant pathways, we undertook a quantitative proteomic profiling in the 16p11.2 microduplication mouse model (dp/+) and discovered a large set of upregulated synaptic and ion channel proteins, which converged on known epilepsy risk factors. Using electrophysiology and calcium imaging we demonstrate that cortical neurons *in vitro* are hyperexcitable and have hypersynchronous calcium oscillations suggesting abnormal cortical activity in dp/+ mice. Moreover, we show that dp/+ mice are more susceptible to kainate-induced seizures. We searched for a potential driver gene of these excitability-related phenotypes within

the CNV region and show that *Prrt2,* a monogenic epilepsy gene, has a leading role. To illuminate the function of PRRT2, we performed immunoaffinity purification combined with mass spectrometry, and identified a PRRT2 protein-interaction network that is highly disrupted in dp/+ mice. Lastly, we show that genetic correction of *Prrt2* gene dosage in dp/+ mice delays the onset of kainate-induced seizures, functionally validating its role in seizure susceptibility. Our study reveals that the 16p11.2 microduplication disrupts an epilepsy risk network causing seizure-related endophenotypes due to increased *Prrt2* gene dosage. This work improves our understanding of CNV pathogenesis, and outlines novel strategies for identifying causal genes in CNVs.

Title: Computational modeling of crosstalk between different calcium stores in dendritic spines

Authors: *D. OHADI, P. RANGAMANI;
UCSD, La Jolla, CA

Abstract: Neurons critically rely on spatially and temporally regulated Ca^{2+} dynamics in subcellular compartments. This exquisite level of Ca^{2+} compartmentalization is achieved through storage and release of Ca^{2+} from various intracellular organelles. Mitochondria and endoplasmic reticulum (ER) are well-known as storage organelles in controlling Ca^{2+} dynamics in neurons. IP_3-induced Ca^{2+} release from ER through Ca^{2+}-induced Ca^{2+} release (CICR) controls long-term potentiation (LTP) and long-term depression (LTD). On the other hand, Ca^{2+} influx in dendritic mitochondria can regulate ATP synthesis and Ca^{2+} homeostasis. The ability of ER to store Ca^{2+} and exchange it with mitochondria at an inter-organelle distance of less than 30 nm, can potentially develop complex spatiotemporal interactions between the organelles. This type of crosstalk may result in diverse synaptic functions including presynaptic short-term plasticity, and postsynaptic long-term plasticity.
Ca^{2+} signal specificity is encoded in the temporal, spatial, frequency, and amplitude of Ca^{2+} transients. Globally, the Ca^{2+} signal is regulated by the close interconnection between plasma membrane channels and intracellular organelles. However, little is known about how Ca^{2+}

signals are regulated locally. This can be specifically critical for efficient Ca^{2+} signaling in small subcompartments such as dendritic spines in neurons. In this study, we propose a 3D computational reaction-diffusion model that investigates the role of dendritic mitochondria and ER-dependent Ca^{2+} dynamics in dendritic spines. This spatiotemporal model accounts for Ca^{2+} oscillations initiated by glutamate stimulation of metabotropic glutamate receptors and Ca^{2+} changes in three different compartments: cytosol, ER, and mitochondrion. Simulations predict that the organization of these organelles and differential distribution of key Ca^{2+} channels such as IP_3 receptor and ryanodine receptor can change Ca^{2+} dynamics. Our findings shed light on the involvement of calcium stores in the generation and maintenance of long-term potentiation.

Title: Stimulation induces gradual increases in the thickness and curvature of the postsynaptic density

Authors: *J.-H. TAO-CHENG;
NINDS, NIH, Bethesda, MD

Abstract: Activity can induce structural changes in glutamatergic excitatory synapses, including increase in thickness and curvature of the postsynaptic density (PSD); these structural changes can only be documented by electron microscopy. Here in rat organotypic hippocampal slice cultures where experimental conditions can be easily manipulated, increases in thickness and curvature of PSDs were noticeable within 30 seconds of stimulation (depolarization with high K^+ at 90 mM or NMDA treatment at 50 μM) and progressed with time up to 3 min. These structural changes were reversible upon returning the samples to control medium for 5-10 min. The gradual increase in thickness of PSD could result from a gradual translocation of some PSD proteins to the PSD. The most likely major contributor is CaMKII because of its great abundance and its substantial translocation to the PSD under excitatory conditions. Under basal conditions, label for CaMKII is typically evenly distributed within the spine. Upon stimulation, CaMKII molecules could initially translocate to the cytoplasmic edge of the PSD core (the proximal layer of the PSD, up to 30-40 nm from the postsynaptic membrane) to bind to NR2B. As stimulation progresses, additional CaMKII molecules could continue to pile into thicker layers that extend into the PSD pallium (the deeper layer of the PSD, ~ 40-120 nm from the postsynaptic

membrane). Alternatively, the additional CaMKII at the PSD brought on by stimulation might initially distribute evenly in the PSD pallium and bind to other scaffold proteins like Shank that exist there. Eventually, after 2 min of stimulation, label for CaMKII became concentrated and confined within the border of the PSD pallium, and the laminar distribution of CaMKII at the PSD became very similar to that of Shank. These additional CaMKII and shank molecules in the PSD pallium may account for the appearance of PSD thickening. The change in curvature of PSD (from "concave" to "convex") upon depolarization by high K^+ could be due to an increase of presynaptic membrane caused by massive release of synaptic vesicles, forcing the presynaptic terminal to wrap around the PSD and bend the PSD to arch into the presynaptic terminal. Alternatively, a postsynaptic mechanism might be involved. Upon stimulation, a change in actin configuration or interaction with PSD proteins could exert a pull toward the interior of the spine and result in a curvature change in the PSD. The present data support a postsynaptic mechanism, since NMDA treatment does not induce synaptic vesicle release, and yet it still increases the curvature of the PSD.

Title: Towards quantification of plasticity-related protein turnover at central synapses

Authors: *M. KUWAJIMA[1], N. T. N. PHAN[2], J. M. MENDENHALL[1], G. KNOTT[3], S. O. RIZZOLI[2], K. M. HARRIS[1];

Abstract: Long-term potentiation (LTP) has been widely used as a model to elucidate cellular and molecular mechanisms of learning. Using 3D reconstruction from serial section electron microscopy (3DEM) we previously found changes in synapse structure that manifest after the initial saturation of LTP at CA3→CA1 synapses in the hippocampus: Many of these synapses

contained nascent zones, dynamic edge regions that have a postsynaptic density (PSD) but lack the presynaptic vesicles normally found at active zones. By 30 min following LTP induction, the nascent zones were converted to active zones (i.e., presynaptic vesicles were acquired). By 2 hr, both nascent and active zones were enlarged, with the greatest synapse enlargement occurring on dendritic spines that contained polyribosomes or smooth endoplasmic reticulum (Bell et al., 2014. J Comp Neurol 522: 3861-84; Chirillo et al., 2019, Sci Reports 9: 3861). Thus, we hypothesized that nascent zones may exhibit an increased turnover of proteins to support dynamic regulation of PSD structure and molecular composition during synaptic plasticity. To address this hypothesis, we are developing a correlative imaging approach combining 3DEM and secondary-ion beam mass spectrometry (SIMS). We aim to map protein turnover at a subsynaptic resolution from the brain tissue of animals that underwent metabolic labeling with stable isotopes. As a proof of concept, low-resolution EM imaging followed by SIMS was performed on sections (~70 nm) of resin-embedded neocortical tissue from a perfusion-fixed Wistar rat (6 wk old male) fed with ^{13}C-labeled glucose (10% solution for 24 hr). SIMS analysis showed overall ^{13}C abundance ratio of 2.2% in the analyzed sections, which was higher than the ratio of naturally occurring ^{13}C (~1.1%). When correlated with EM images, areas of ^{13}C enrichment were non-uniformly distributed across the tissue sections, demonstrating the feasibility of our approach. Thus, further analysis at a higher spatial resolution will be done with animals fed with isotope-labeled amino acids to examine which subsynaptic compartments show enrichment of newly synthesized proteins *in vivo*.

Title: Partial segregation of spontaneous and evoked neurotransmission at inhibitory synapses

Authors: *P. M. HORVATH[1], L. M. MONTEGGIA[3], E. T. KAVALALI[2];
[2]Vanderbilt Brain Inst., [1]Vanderbilt Univ., Nashville, TN; [3]Vanderbilt Brain Inst., Nashville, TN

Abstract: Neurotransmission can be classified into two broad types: spontaneous and evoked. Much of the work examining these types of neurotransmission and their properties has been done in excitatory synapses. Previous work has shown a segregation of AMPA receptors which respond to spontaneous and evoked neurotransmission at excitatory synapses in both the central

nervous system as well as the *Drosophila* neuromuscular junction. Additionally, central nervous system NMDA receptors also show a near complete segregation of spontaneous and evoked neurotransmission. Although inhibitory synapses also transmit both spontaneous and evoked neurotransmission, they differ from excitatory synapses in both structure and function. Therefore, it has been unclear if the same principle of segregation holds true at inhibitory synapses. We have addressed this question by utilizing the use-dependent properties of picrotoxin, a $GABA_A$ receptor antagonist. By selectively blocking $GABA_A$ receptors activated by spontaneous neurotransmission we can examine the $GABA_A$ receptors specifically activated by evoked neurotransmission. Through these studies we show that there is partial, but not full, segregation of spontaneous and evoked neurotransmission at inhibitory synapses. These data indicate that while the principle of segregation of spontaneous and evoked neurotransmission still applies at inhibitory synapses, it is not as complete as at excitatory synapses.

Title: Wnt5a modulates dendritic spines morphology through the small Rho GTPases and their downstream target Cofilin

Authors: *D. VALLEJO[1], C. B. LINDSAY[1], C. GONZALEZ-BILLAULT[2], N. C. INESTROSA[1,3];
[1]Cell. and Mol. Biol., Ctr. for Aging and Regeneration (CARE), P. Catholic Univ. of Chile, Santiago, Chile; [2]Dept Biology, Fac of Sci., Univ. of Chile, Santiago, Chile; [3]Ctr. of Excellence of Biomedicine of Magallanes (CEBIMA), Univ. of Magallanes, Punta Arenas, Chile

Abstract: Introduction: Dendritic spines are actin-rich small protrusions that act as receiving sites of most excitatory inputs in the central nervous system. Actin cytoskeleton remodeling is required for the formation and consolidation of functional spines, a process regulated by the small Rho GTPases family. Wnt5a is a synaptogenic factor that promotes the formation of new dendritic spines and induces synaptic transmission in hippocampal and cortical neurons. Our main goal is to elucidate the mechanism by which Wnt5a promotes dendritic spine density and controls their morphology. **Methodology:** We employed primary culture of rat cortical and

hippocampal neurons DIV14 and HT22 cell line to analyze by pull-down activation assays, western blot and immunofluorescence the effects of Wnt5a in actin dynamics. **Results:** Wnt5a induces an increase in the number of dendritic spines and promotes their maturation. Moreover, Wnt5a controls the activation of the small Rho GTPases Rac1, Cdc42, and RhoA. Wnt5a also regulates the phosphorylation of LIMK1 and Cofilin in a time-dependent manner. Specifically, Wnt5a regulates Cofilin phosphorylation through Cdc42 and Rac1 by two different mechanisms. **Discussion:** Wnt5a is a synaptogenic factor whose expression increases during development. Synaptogenic factors have been described as inductors of plastic changes through the activation of different signaling pathways. Wnt5a was shown to activate the non-canonical planar cell polarity pathway, essential for neuronal morphogenesis in which the small Rho GTPases are included. Additionally, Wnt5a has been described as a promoter of dendritic spines formation in hippocampal neurons. In the present study we evaluated the hypothesis that treatment with Wnt5a regulates small Rho GTPases, as controls the dendritic spines morphology through the actin cytoskeleton remodeling. Our results suggest that Wnt5a controls actin cytoskeleton dynamics at synaptic level through the modulation of the small Rho GTPases as a part of the underlying mechanism of the postsynaptic function of Wnt5a.

Title: Thalamo cortical synaptic network in motor cortex analyzed with large volume electron microscopy

Authors: *Y. KUBOTA[1,2], J. SOHN[1,3], E. KURAMOTO[4], Y. KAWAGUCHI[1,2];
[1]Natl. Inst. Physiol Sci. (NIPS), Okazaki, Japan; [2]Sokendai, Okazaki, Japan; [3]JSPS Res. Fellow, Tokyo, Japan; [4]Dept. of Oral Anat. and Cell Biol., Kagoshima Univ., Kagoshima, Japan

Abstract: It is well known that the cortex receives signals from the basal ganglia and cerebellum via thalamo-cortical afferents. About 4 - 16% of the thalamo-cortical excitatory afferents make synaptic contacts on spines each of which is also postsynaptic to an inhibitory terminal, dually innervated spine (DiS) (J Neurosci, 2007, 27, 1139-1150). Our previous morphological and physiological analyses (eLife, 2015, elife 4) as well as optogenetic methods demonstrated that the inhibitory synapse to the DiS can effectively veto the local excitatory synaptic inputs. Furthermore, the inhibitory synapses on the DiS display more dynamic properties than the inhibitory synapses on the dendritic shaft (Neuron, 2016, 90: 662-664). One of the important functions of the thalamo-cortical system is to provide feedforward inhibition. We showed that FS basket cells receive thalamo-cortical innervation on their soma, and believe that this link is likely involved in feedforward inhibition (Cereb Cor, 2016, 26: 2689-2704).
To understand this intriguing cortical microcircuit architecture further, we investigated how the thalamo-cortical axon terminals participate in the cortical microcircuit in rat frontal cortex. The axon arborization pattern across cortical layers varies significantly among thalamocortical afferents from three motor-related thalamic nuclei: the ventral medial nucleus (VM), the ventral anterior (VA) and the ventral lateral (VL) thalamic complex, which relay motor information from the basal ganglia (VM/VA) and the cerebellum (VL), respectively (2015, *Cereb Cor* 25: 221-235). We hypothesized that the synaptic connections of VM/VA and VL afferents in the cortical microcircuits are different. A viral vector (AAV pal-GFP) was injected into each of three motor-related thalamic nuclei. Their target structures in the motor cortex was investigated using a correlated light and electron microscopy (CLEM) with a laser confocal microscopy and automated tape-collecting ultramicrotomy (ATUM) with scanning electron microscopy (SEM). To identify the GFP labeled axonal fibers subsequently at the electron microscopy, we stained blood vessels with lectin, and cellular nuclei with DAPI, and used them as landmarks in cortical tissue sections. Firstly, images were taken with a laser confocal microscopy. Then the tissue sections were embedded in plastic and sectioned with ATUM for SEM observation. GFP-labeled thalamo-cortical fibers and their target structures were identified in serial electron micrographs, and reconstructed three-dimensionally. Our preliminary results indicated that the VA fibers mainly targeted dendritic spines of the layer 5 pyramidal cell.

Sch. of Med., Philadelphia, PA

Abstract: The *ANK3* gene, encoding the protein ankyrin-G (AnkG), is associated with a variety of neuropsychiatric and cognitive disorders including bipolar disorder, autism spectrum disorder, and schizophrenia. These diseases are characterized by abnormal dendritic and synaptic architecture. AnkG is a multifunctional scaffold protein with several isoforms: The 480 kDa and 270 kDa isoforms have roles at the axon initial segment and node of Ranvier, but the function of the 190 kDa isoform (AnkG-190) is less well understood. Moreover, these isoforms are regulated by palmitoylation, but palmitoylation of AnkG-190 has not been investigated in neurons. Here we show that AnkG is required for normal dendrite and spine architecture in vivo and that AnkG-190 stabilizes pyramidal neuron dendrites. We found that Cys70 palmitoylation stabilizes AnkG-190 in spine heads and at dendritic plasma membrane nanodomains, and is necessary for the maintenance of normal spine density, dendrite arborization, and for correct microtubule dynamics. Lithium, a commonly used mood stabilizer, reverses spine and dendrite deficits induced by AnkG knockdown in a manner that is dependent of palmitoylation. Finally, we found that lithium reduces AnkG-190 palmitoylation and increases its mobility in spines. Taken together, our data reveal a novel mechanism regulating dendritic architecture and mood stabilizer action on palmitoylation of an important psychiatric disorder risk factor.

Title: Neuroligins maintain clustering of AMPA receptors at a central synapse

Authors: *Y. HAN[1], L. Y. CHEN[2], T. C. SUDHOF[3], B. ZHANG[4];
[1]Southern Univ. of Sci. and Technol., Shenzhen, China; [2]Univ. of California, Irvine, CA; [3]Stanford Univ., Stanford, CA; [4]Dept. of Mol. & Cell. Physiol., Stanford Univ. Sch. of Med., Stanford, CA

Abstract: The efficiency of synaptic transmission is largely determined by the composition of postsynaptic neurotransmitter receptors and its distribution. Accumulating evidence suggests that neuroligins (Nlgns) are critical for alpha-amino-3-hydroxy-5-methyl-4 isoxazolepropionic acid receptors (AMPARs) mediated synaptic transmission *in vivo*. However, how Nlgns regulate postsynaptic AMPA receptors *in vivo* is still not fully understood. Electrophysiological recording from the principal neurons in the medial nucleus of the trapezoid body (MNTB) slice of the parvalbumin-specific conditional knockout Nlgn1 and Nlgn3 (Nlgn1/3) mice showed slower kinetic and smaller amplitude of AMPARs-mediated miniature excitatory postsynaptic current (mEPSC) from postnatal day (P) 12-13 MNTB neurons compared to control while viral-mediated Nlgn1/3 knockout reduced amplitude without altering the kinetics of mEPSC from P8-9 MNTB neurons. Furthermore, Nlgn1/3 knockout did not alter the level of postsynaptic scaffold protein Homer-1. Our computational modeling suggested that increasing the inter-GluAs distance at the postsynaptic site and reducing GluAs content caused the slower kinetics and smaller amplitude of mEPSC. Thus, our results suggest that Nlgn1/3 maintain high synaptic transmission efficiency via controlling the content and clustering of postsynaptic AMPARs at a central synapse.

Abstract: Gene *pyridox(am)ine 5'-phosphate oxidase* (*PNPO*) encodes a rate-limiting enzyme in the synthesis of pyridoxal 5'-phosphate (PLP), which is the biologically active form of vitamin B6 and a co-factor required for the synthesis of several neurotransmitters including GABA. Mutations in *PNPO* were initially identified in neonatal epileptic encephalopathy patients and recently also in early-onset epilepsy. *PNPO* is also regarded as one of the sixteen epilepsy genes involved in the common epilepsies. In contrast to the increasingly recognized significance of PNPO deficiency in epilepsy, our understanding of the neurobiological mechanisms of PNPO deficiency is limited, and PNPO mutations have never been studied systematically due to the lack of animal models. Based on a nutritional conditional lethal phenotype, we have previously identified a *Drosophila PNPO* gene (*sugarlethal*, *sgll*) and a hypomorphic *sgll* allele ($sgll^{95}$). Here we report that PNPO deficiency causes seizures in flies as it does in humans, and that seizure patterns in these flies resemble that in wild-type flies caused by GABA blockade. Moreover, seizures are correlated with low internal PLP levels and can be rescued by ubiquitous expression of wild-type human PNPO, demonstrating that human and *Drosophila* PNPOs are functionally conserved. Based on that, we further generated four knock-in (KI) fly strains using CRISPR/Cas9. In each strain, *Drosophila sgll* gene was replaced by human WT *PNPO* cDNA or one of three mutant *PNPO* cDNAs: D33V, R116Q, and R95H. We have found that severe hPNPO deficiency leads to lethality in early development, intermediate hPNPO deficiency results in conditional lethality and seizures, whereas mild hPNPO deficiency shortens lifespan. At the molecular and cellular level, different hPNPO mutations reduce its protein stability, change its protein cellular localization, or affect its transcription. Lastly, we report a dominant-negative effect of R95H mutant hPNPO on WT hPNPO protein. Our fly models can be used to study PNPO biology and treatment options for PNPO deficiency. These studies also indicate that *Drosophila* can be used as a diagnostic tool to examine the functional consequences of newly identified *hPNPO* mutations.

Title: Alterations of an evolutionarily conserved electroconvulsive seizure-flight motor sequence by two classes of hyperexcitable *Drosophila* mutations

Authors: *A. IYENGAR, C.-F. WU;
Univ. of Iowa, Iowa City, IA

Abstract: Studies of hyperexcitable behaviors in *Drosophila* mutants have yielded insights into the role of epilepsy genes in nervous system function. In flies, high frequency stimulation across the brain triggers a stereotypic sequence of electroconvulsive seizure (ECS) discharges, consisting of an initial seizure discharge (ID), period of paralysis, a delayed seizure discharge (DD), followed by eventual recovery of the fly. These seizure discharge episodes manifest across the nervous system and can be assessed through spiking activity (peak firing rate > 30 Hz) in the large, indirect flight muscles, the Dorsal Longitudinal Muscles (DLMs), in conjunction with microphone recordings of wing beats. During flight, the DLM motor neuron spikes (~5 Hz) provide Ca^{2+} influx for stretch-activated myogenic contractions which power wing beats (~200 Hz).

Unexpectedly, in tethered wild-type (WT) flies with a strictly isolated stimulation configuration, we found that WT flies would reliably display sustained flight activity following DD, with DLM spiking (~ 5 – 10 Hz) and wing beats (~170 Hz). Indeed, this motor sequence was present across a number of *Drosophila* species including *melanogaster*, *robusta*, and *virilis*, divergent by ~60 million years. Ordinary air-puff triggered flight requires intact antennal and haltere sensory inputs. However, DD-evoked flight was present after surgical removal of these organs, suggesting a mode of flight pattern generator activity independent of sensory feedback.

Using Poincaré plots of adjacent inter-spike intervals and related non-linear dynamical systems analyses to produce a spike pattern 'signature', we examined DLM spiking during ECS discharges in two classes of hyperexcitable mutants: 'shakers' (e.g. *Sh*, *qvr*) whose legs twitch under ether anesthesia, and 'bang-sensitives' (e.g. *eas*, *sda*) which display mechanical shock-induced seizures. In 'shaker' mutants, with disrupted I_A K^+ currents, the DD-evoked flight sequence was largely intact, but with a reduced and dwindling wing beat frequency, presumably reflecting alterations direct flight muscle motor programs. In contrast, bang-sensitive mutants

which display distinctive mutant-specific DLM ECS discharge patterns, with varying duration, firing frequency and regularity. Strikingly, a common feature across the bang-sensitive mutants was the complete absence of DD-evoked flight.
Together, these findings highlight the range of mutations-specific vulnerabilities in motor circuits which could be quantitatively characterized to provide signatures of their alterations of nervous system function.

Title: Novel cellular and zebrafish model system of DNM1 epileptic encephalopathy

Authors: *L. LLACI, G. C. MILLS, R. PANDEY, R. GUPTA, E. FRANKEL, C. BILAGODY, R. C4RCD, V. NARAYANAN, S. RANGASAMY;
Translational Genomics Res. Inst. (TGen), Phoenix, AZ

Abstract: Next generation sequencing (NGS) has led to the identification of several causal genes in individuals with epileptic encephalopathies (EE), and the list has expanded dramatically. Recently, mutations in the DNM1 gene, encoding Dynamin 1 (OMIM: 602377) have been recognized to cause early infantile epileptic encephalopathy-31 (OMIM: 616346). At the Center for Rare Childhood Disorders (C4RCD), we have assembled a cohort of EE patients with de novo heterozygous mutations in dynamin 1 (DNM1) and established patient-derived (skin biopsy) fibroblast cultures to understand the cell biology of DNM1 EE. Patient-derived DNM1 mutant fibroblast cells demonstrate altered phosphorylation levels of the Dynamin 1 protein, and an impaired clathrin mediated endocytosis (CME), showing that DNM1 mutations cause a functional deficit. Surprisingly, mitochondrial dysfunction (complex I or IV deficiency) was the primary finding in two of the patients in our cohort. Muscle biopsy from these patients confirmed mitochondrial dysfunction, and this remained the neurological diagnosis for over ten years, until the discovery of the primary DNM1 mutation. We observed a significant decrease in the ATP generation and mitochondrial spare capacity in DNM1 mutant patient cells compared to control cells. Collectively, our results demonstrate mitochondrial involvement in the DNM1 EE. Interestingly, the dynamin superfamily members share a conserved GTPase domain, which plays a critical role in mitochondrial fission and fusion. However, mammalian Dynamin 1 has never been linked to mitochondrial function, and our results suggest a mechanistic link between mitochondrial function and DNM1. We also created a zebrafish model of epilepsy by inhibiting DNM1 via a chemical inhibitor. Further, through microinjection of human mutant DNM1

(p.Gly43Asp) mRNA at 72-hr post-fertilized embryos, we also recapitulated the seizure-like activity observed in patients. Screening of FDA approved anti-epileptic drugs (AEDs) led to the identification of a new compound (C4RCD-1) as a potential therapy for DNM1 induced seizures. In summary, we identified a novel association of DNM1 EE with mitochondrial dysfunction using a patient derived cell model. Furthermore, we developed a genetic DNM1 model of zebrafish which will advance epilepsy treatment through development of personalized therapy.

Title: Sestrin3 and seizures after traumatic brain injury

Authors: *Q. ZHOU[1], Z. LEI[2], L. ZHOU[4], X. DONG[3], Z. C. XU[5];
[1]Stark Neurosciences Res. Inst., indianapolis, IN; [2]Anat. & Cell Biol., Indiana Univ. Sch. of Med., Indianapolis, IN; [3]Dept. of Biochem. and Mol. Biol., Indiana Univ. Sch. of Med., indianapolis, IN; [4]GHM Inst. of CNS Regeneration, Jinan Univ., Guangzhou, China; [5]Anat. & Cell Biol., Indiana Univ. Med. Ctr., Indianapolis, IN

Abstract: Traumatic brain injury (TBI) is one of the major causes of epilepsy. However, no effective treatment of post traumatic epilepsy (PTE) is currently available. The mechanisms underlying PTE are under active investigation. Recent studies indicate that Sestrin 3 (Sesn3), a highly conserved protein encoded by the Sesn3 gene whose expression is upregulated in cells exposed to environmental stresses, Sesn3 has been recently identified as a regulator of a pro-convulsant gene network. It is conceivable that the Sestrin3 might be involved in seizure generation following TBI. The present study attempts to reveal the role of Sestrin 3 in PTE and the potential mechanisms. TBI was produced in WT and Sesn3 KO mice using controlled cortical impact method. Seven days after TBI, seizures were induced with Pentylenetetrazole (PTZ, 40mg/kg. i.p). One day after seizure induction, the animals were sacrificed and brain slices were prepared for electrophysiological studies. Whole cell patch-clamp recording was performed on granule cells in hippocampus. Passive membrane properties and miniature excitatory postsynaptic current (mEPSC) were compared in different experimental groups. The seizure rate increases from 60% in naïve animals to 71% after TBI and further increases to 100% in Sesn3

KO mice after TBI, suggesting that Sesn3 has negative impacts on seizure generation after TBI. The spike threshold, the amplitude of afterhyperpolarization and rheobase in granule cells significantly increases in KO mice after TBI as compared with the naïve ones, suggesting the excitability of granule cells in Sesn3 KO mice is reduced after TBI. The frequency of mEPSCs in granule cells increases after TBI as compared with the naïve animals but return to control levels in Sesn3 KO mice. These results suggest that Sesn3 might reduce seizure generation by increase of granule cell excitability after TBI. However, depletion of Sesn3 reduces the mEPSC frequency after TBI.

Title: Genetic modifiers influence survival in a mouse model of Dravet syndrome

Authors: N. A. HAWKINS[1], L. D. COPELAND-HARDIN[2], S. E. DUARTE[1], *J. A. KEARNEY[1];
[1]Pharmacol., [2]Driskill Grad. Program in Life Sci., Northwestern Univ. Feinberg Sch. of Med., Chicago, IL

Abstract: Epilepsy is a common neurological disorder that affects 1% of the worldwide population. Pathogenic variants in voltage-gated sodium channel genes are the most common cause of monogenic epilepsies. More than 1,600 pathogenic variants in *SCN1A* have been reported in individuals with several epilepsy syndromes. The clinical phenotype most frequently associated with *SCN1A* is Dravet syndrome, which often results from *SCN1A* haploinsufficiency. Mice with heterozygous deletion of *Scn1a* (*Scn1a*$^{+/-}$) recapitulate core features of Dravet syndrome, including spontaneous seizures, seizures provoked by hyperthermia, and sudden unexpected death. These phenotypes have prominent strain-dependence that is reminiscent of variable expressivity observed in patients with monogenic epilepsies. *Scn1a*$^{+/-}$ mice on the [129S6/SvEvTac x C57BL/6J]F1 strain exhibit spontaneous seizures and high mortality, whereas these phenotypes are masked on the 129S6/SvEvTac (129) strain. This suggests that 129 contributes protective alleles, while C57BL/6J (B6) contributes risk alleles. Previously, we identified modifier loci on chromosomes 5, 7, 8 and 11 that influence strain-dependent severity of the *Scn1a*$^{+/-}$ Dravet phenotype. The objective of the current study was to refine the map interval and perform candidate gene analysis for the *Dsm5* (Dravet survival modifier) locus on

mouse chromosome 11.
A series of B6.129-Chr11 interval-specific congenic (ISC) strains were generated and crossed with 129.*Scn1a*$^{+/-}$ mice. Resulting offspring were homozygous 129/129 or heterozygous 129/B6 in the interval of interest. Survival to 8 weeks of age was monitored in male and female *Scn1a*$^{+/-}$ offspring and compared between ISC genotypes. Analysis of six ISC strains with overlapping intervals narrowed the modifier locus to a <14 Mb region ($p<0.03$, LogRank). This interval contains ~600 genes, of which 115 are expressed in brain. RNA-seq analysis identified 7 genes with differential brain expression between the 129 and B6 strains. In addition, the region contains 22 genes with moderate-high impact coding sequence variants. Among the protein coding genes with strain-dependent differences, 13 have a prior association with epilepsy or seizures. Furthermore, this interval contains 5 miRNA genes with seed matches in the *Scn1a* 3'UTR, suggesting potential regulation of *Scn1a* transcript. Strain-dependent expression differences were recently reported for some of these miRNAs, and several have been shown to be upregulated by seizures. Identification of modifier genes that influence severity of Dravet syndrome may advance our understanding of disease pathogenesis and suggest novel therapeutic approaches.

Title: A CRISPRi screen in human iPSC-derived iNeurons to discover novel focal cortical dysplasia genes

Authors: *A. M. TIDBALL[1], J. L. MARGOLIS[1], T. W. GLENN[1], G. L. CARVILL[2], J. M. PARENT[1];
[1]Neurol., Univ. of Michigan, Ann Arbor, MI; [2]Neurol., Northwestern Univ., Chicago, IL

Abstract: Focal cortical dysplasia (FCD) is a common cause of focal epilepsy and often results from somatic, mosaic mutations. The sparse nature of mutated cells (1-6% of cells in surgically resected tissue) presents many experimental barriers to FCD gene discovery, and only a small number of FCD genes have been identified based upon hypothesis-driven targeted sequencing. Therefore, we have developed an unbiased screening platform for identifying novel FCD genes ***in vitro*** using a genome-wide CRISPR interference library. We first reprogrammed human iPSC

lines stably expressing both KRAB-dCAS9 and Neurogenin (*NGN*) 1,2 genes under control of a doxycycline (DOX)-inducible promoter. The inducible expression of NGN1,2 allows for the efficient, uniform differentiation of human excitatory cortical neurons. The KRAB-dCAS9 inhibits the expression of genes targeted by a guide RNA (gRNA) sequence introduced via lentivirus, with 80-95% knockdown of mRNA and protein after DOX treatment in prior studies. We are using phosphorylated S6 ribosomal protein (pS6), a biomarker for FCD type II, as the selection assay in our screen. Using a pS6 antibody and FACS sorting, we were able to obtain genomic DNA from pS6-high and -low cell populations. To validate our screen, we constructed a test library of 12 genes that were expected to be positive, negative, or neutral regulators of pS6. The pS6-sorted neuronal genomic DNA samples were amplified using primers flanking the gRNA portion of the lentiviral insertion. The abundance of each gRNA sequence was then assessed using NGS. As expected, the gRNAs for FCD genes were significantly enriched in the pS6-high sample while gRNAs for genes necessary for S6 phosphorylation were significantly enriched in the pS6-low sample. A genome-wide gRNA library containing 5 unique sequences for each human gene (>100,000 total gRNAs) is now being applied to identify novel genes. Validated FCD gene candidates will offer additional targets for sequencing from patient tissues and the potential for new therapeutic strategies for FCD-associated epilepsies.

Title: Genomic dissection of the 5p15-q12 locus implicates the CDC20B gene in a juvenile myoclonic epilepsy family

Authors: *P. BARAK[1], A. ANAND[1], M. KAUR[1], S. SINHA[2], P. SATISHCHANDRA[2], G. KURUTTUKULAM[3];
[1]Jawaharlal Nehru Ctr. For Advanced Scientific Res., Bengaluru, India; [2]NIMHANS, Bengaluru, India; [3]Lourdes Hosp., Kochi, India

Abstract: Juvenile Myoclonic Epilepsy (JME) is a common genetic generalized epilepsy characterized by frequent myoclonic jerks which are accompanied by generalized tonic-clonic seizures and absence seizures. Linkage studies have identified about 30 sub-genomic locations which may harbor genes underlying JME. Here, we present, whole genome-wide linkage analysis of a multi-affected JME family which led to the identification of a novel locus that maps to chromosome 5p15-q12. Whole exome-based sequencing study for affected members of this family helped identify a potentially causative gene, *CDC20B* (Cell Division Cycle 20B). In addition, four rare (MAF<0.005), missense *CDC20B* variants present almost exclusively among a cohort of over 500 JME patients were found. *CDC20B* encompasses 60 kilobase of the genome and encodes a 591 amino acid protein. It has 7 WD repeat domains at its C-terminus. *CDC20B* is paralogous to the *CDC20* gene, which is known to interact with anaphase promoting complex and has a major role in cell cycle progression. Cellular and molecular roles of CDC20B are beginning to be examined. Cellular expression and localization of CDC20B protein has been studied in mammalian cultured cells. While during late telophase and cytokinesis, the protein localizes to the midbody, during other cell cycle stages, it is present in the cytoplasm. CDC20B co-immunoprecipitates with gamma tubulin, a protein present abundantly at midbody during cytokinesis. The missense mutations identified in the JME patients do not seem to alter expression and localization of the CDC20B proteins in mammalian cells. Over-expression of the mutants in HeLa cells led to the accumulation of cells at the cytokinesis stage, suggesting cell cycle associated roles for the protein.

Informatics (DBHi), Children's Hosp. of Philadelphia, Philadelphia, PA; [4]Dept. of Neuropediatrics, Christian-Albrechts-University of Kiel, Kiel, Germany; [5]Dept. of Neurology, Univ. of Pennsylvania, Perelman Sch. of Med., Philadelphia, PA; [6]Dept. of Neurosurgery, Univ. of Tuebingen, Tuebingen, Germany

Abstract: Voltage-gated sodium channels (Navs) are crucial players of neuronal function, and mutations in genes encoding CNS Navs (Nav1.1 [*SCN1A*], Nav1.2 [*SCN2A*], Nav1.3 [*SCN3A*], and Nav1.6 [*SCN8A*]) are a cause of some of the most common and severe genetic epilepsies and developmental and epileptic encephalopathies (DEE). Fibroblast-growth-factor homologous factors (FHFs) compose a family of 4 proteins that interact with the C-terminal tails of Navs and enhances the kinetics of channel inactivation. Even though mutations have been identified in FGF13, to date only one recurrent mutation in FGF12 p.R52H was reported as a cause for early-onset DEE inducing a strong gain-of-function due to an interaction with the cytoplasmic tail of Nav1.6 (*SCN8A*). We performed an exome sequencing study in 395 patient-parent trios with DEE and could detect a novel *de novo* variant in FGF12 (p.G50S). This variant is located two amino acids upstream of the already known variant. We actually characterize the effect of variant by co-transfecting ND7/23 cells together with Nav1.6. Another aim of this study is to identify potential precision medicine e.g. sodium channel blockers to compensate the effect of the mutation. Additionally, there is a *FGF12* duplication case reported with early-onset DEE. If it is possible, we will extend our study to understand the functional consequence of the FGF12 duplication on the Nav1.6 channel, and to find a precise therapeutic intervention.

Title: lncRNAs modulate MAPK signaling in human neocortical epilepsy

Authors: *A. KIRCHNER[1], S. ZARINEBEF[1], F. DACHET[1], L. LIPOVICH[2], J. A. LOEB[1]; [1]Univ. of Illinois at Chicago Col. of Med., Chicago, IL; [2]Wayne State Univ., Detroit, MI

Abstract: BACKGROUND: One third of all epileptic patients are resistant to current drug treatments. To develop improved therapeutics, the molecular basis of epilepsy needs to be better understood. Previous studies from our group have compared high versus low spiking from human epileptic neocortical regions as an unbiased approach to identify new molecular targets. We previously identified the Mitogen Activated Protein Kinase (MAPK) pathway as highly upregulated in epileptic brain and showed in parallel rodent studies that MAPK inhibition prevented the development of epileptic spiking.Given the ubiquitous presence of MAPK signaling, a brain specific regulator of MAPK signaling could be a useful therapeutic avenue that would limit peripheral side effects. In addition to looking at genes that code for proteins, we examined both the differential expression and potential regulatory roles of non-protein coding, long non-coding RNAs (lncRNAs) in the human brain. **OBJECTIVE**: To identify lncRNAs that are either regulated by or regulate MAPK signaling in human epilepsy and could be translated into targeted epilepsy therapeutics by reducing MAPK selectively in the brain. **METHODS**:Differentially expressed MAPK genes and lncRNA genes were identified using genome-wide protein coding as well as customized lncRNA microarrays by comparing high versus low spiking regions of human neocortex from 8 epilepsy patients studied with long-term intracranial recordings. Clustering of the differentially expressed genes was used to identify lncRNAs that demonstrated the same expression patterns as the differentially expressed MAPK genes. Mechanistic studies were performed using Sh-SY5Y cells following depolarization and using specific MAPK signaling modulators. Human epileptic tissues were used to localize lncRNAs in the neocortex. **RESULTS**: Clustering of the transcriptomic data comparing the differentially expressed lncRNA and MAPK genes showed that 4 lncRNAs were significantly co-expressed with MAPK genes. Expression of 2 of these lncRNAs were activity dependent and induced with depolarization of the Sh-SY5Y cells that could then be blocked with MAPK inhibitors, suggesting these lncRNAs are regulated by activity and MAPK signaling. lncRNAs were spatially located nearby MAPK genes, suggesting that they may regulate the expression of MAPK genes at the transcriptional level and dependent on their relative genomic positions.

CONCLUSION: lncRNAs spatially positioned near MAPK genes could play an important regulatory role of MAPK induced synaptic plasticity needed to promote epileptic circuits in the epileptic brain and could have potential uses as targets to combat epilepsy.

Title: Dynamics sustaining focal seizures: A dual function of inhibition and interaction across scales

Authors: *W. VAN DRONGELEN[1], A. K. TRYBA[2], T. PHAM[3], E. M. MERRICKS[4], A. BHANSALI[5], L. PESCE[3], S. CHO[3], S. LEE[3], T. EISSA[6], D. R. NORDLI, Jr.[3], C. A. SCHEVON[7];
[1]Univ. Chicago, Chicago, IL; [2]Pediatric Neurol., The Univ. of Chicago, Chicago, IL; [3]Univ. of Chicago, Chicago, IL; [4]Dept. of Neurol., Columbia Univ. Med. Ctr., New York, NY; [5]North Texas Neurosurgical & Spine Ctr., Forth Worth, TX; [6]Applied Math, Univ. of Colorado Boulder, Boulder, CO; [7]Columbia Univ., New York, NY

Abstract: Multi-electrode array recordings of human focal seizures showed distinct territories in a mm-sized cortical area: a core and penumbra, separated by a slowly propagating ictal wave(1. Correlation between spiking in this small area of hyperexcitation and the surrounding network's electrical activity was shown to be significant over a surprisingly extended, cm-sized area(2. Furthermore, while inhibition fails at the mesoscale, inhibitory function is crucial for the hypersynchronous oscillatory signal in the macroscopic recordings of brain electrical activity (2. Paroxysmal depolarization (PD) in the setting of inhibitory failure is a critical factor in sustaining focal seizures, and we describe supporting experimental, clinical, and modeling evidence. We present dual patch recordings in cortical cultures showing a reduction of synaptic transmission at presynaptic occurrence of PD (n=5). We find that PD is a cell-size related phenomenon causing smaller inhibitory cells to be more susceptible than larger excitatory ones (n=8). We further find that optically-evoked PD activity in parvalbumine neurons promotes propagation of activity in cortical networks. At the mesoscopic level, spike sorting results from microelectrode array measurements around ictal wave propagation in three patients with epilepsy demonstrate a strong

increase in putative inhibitory firing, followed by a sudden reduction of firing at wavefront passage. At the macroscopic level we summarize evidence that the excitatory ictal wave activity acts as a perturbator evoking oscillatory activity across a cm-sized cortical network, and that inhibitory function is a crucial modulator. Macroscopic oscillations are time-locked with the ictal wave's spikes but not necessarily with associated PDs. The above findings motivated us to simulate a network with neurons governed by a reduced version of the Hodgkin-Huxley formalism, to show how feed forward, feedback and local failure of inhibition contribute to the dynamics across network scales.
We conclude that the multidisciplinary data on the role of PD supports our hypothesis that it is not only a cellular marker of epileptiform activity, but actively contributes to the emergent seizure.

Title: Permanent functional silencing of hippocampal parvalbumin- or somatostatin-interneurons induces epilepsy

Authors: *M. DREXEL, A. BUKOVAC, R. O. TASAN, G. SPERK;
Dept. of Pharmacol., Med. Univ. of Innsbruck, Innsbruck, Austria

Abstract: Signal transduction in the hippocampus is based on excitatory neuronal pathways (trisynaptic circuitry of the hippocampus). Excitatory transmission is under the tight control of inhibitory interneurons. More than 20 subtypes of such interneurons have been characterized by their anatomy, neurochemical markers, and functional properties. Among these, (1) parvalbumin expressing basket cells exerting potent *feed-forward* inhibition upon pyramidal cell somata and (2) somatostatin-containing interneurons projecting from the stratum oriens to pyramidal cell dendrites in the stratum lacunosum moleculare (O-LM cells) and exerting potent *feed-back* inhibition are functionally especially prominent. Malfunctioning of either of these neurons has been proposed to cause epilepsy. In our experiments, we functionally silenced both subtypes of

interneurons and investigated the development of epileptic seizures. We used transgenic male mice expressing the enzyme Cre-recombinase either on the parvalbumin or somatostatin promoter. We locally injected a viral vector into the subiculum/CA1 of the mice expressing tetanus toxin light chain/GFP in a Cre-recombinase dependent manner. This treatment resulted in a selective functional silencing (inhibition of GABA release) of these neurons without damaging them. Control mice were injected with a viral vector expressing GFP only. We characterized the selectivity of tetanus toxin expression in the respective neurons and the functional impairment of GABA release by immunohistochemical and electrophysiological experiments. Both, silencing of parvalbumin-containing and somatostatin-containing GABA neurons resulted in epileptic discharges and spontaneous motor seizures in the mice and were monitored for up to three months by continuous telemetric EEG and video monitoring. The seizure threshold was already reduced before the first motor seizure (after about one week) was observed. Spontaneous seizures developed only after permanent silencing of parvalbumin or somatostatin interneurons but not after their selective transient inhibition. Furthermore, the frequency of spontaneous seizures declined after 4 to 6 weeks. At the same time, neuropeptide Y (NPY) expression increased and that of the cannabinoid receptor CB1 declined, indicating possible development of endogenous protective mechanisms.

Title: Presynaptic GABA-B receptor modulation of hippocampal dentate network excitability during cortical UP states in an experimental model of epilepsy

Authors: *D. SUBRAMANIAN[1], S. RATNADURAI-GIRIDHARAN[2], V. SANTHAKUMAR[1];
[1]Univ. of California, Riverside, CA; [2]Burke Neurolog. Inst., White Plains, NY

Abstract: Cortical UP/Down states (UDS) represent periods of highly synchronized epochs of excitability, followed by periods of neuronal quiescence occurring physiologically during NREM sleep and deep anesthesia (Steriade, 1993). While functionally UDS are thought to be critical for memory consolidation, the hippocampal subfields are barely influenced by UDS, most likely due to the strong gating function of the Dentate gyrus (DG) (Ouedraogo, 2016). However, this gating function of DG is severely compromised following status epilepticus (SE) mediated cell loss and

network reorganization leading to DG granule cell firing during UP states which could impact hippocampal information processing and development/propagation of seizure activity (Ouedraogo, 2016, Flynn 2015). GABA-B auto-receptors, known to augment DG-granule cell firing through disinhibition (Foster, 2014), are upregulated in epileptic animals (Straessele, 2003). Since disinhibition has the potential to compromise the dentate gate, we evaluated the role of presynaptic GABA-B receptors in modulating DG network excitability during cortical UDS. Evoked and spontaneous local field potentials (LFP) were recorded in the dentate and cortex of urethane anesthetized male Wistar rats 1 week, 4-8 weeks and 8-24 weeks after pilocarpine induced SE. Age matched, saline injected rats were used as controls. Labchart and custom Matlab codes were used for analysis. On stimulation of perforant path inputs, post-SE rats displayed enhanced population spike/slope ratio and reduced paired pulse ratio (to stimuli 20 ms apart) compared to controls ($p=<0.05$) indicating greater network excitability and robust feedback inhibition after SE. DG-LFP periodically switched between epochs of large-irregular activity and high amplitude slow wave oscillations with distinct UP/Down states during which dentate spikes were frequently observed during UP states. Evaluating the total number of dentate spikes within a 10 min period revealed a significant increase in post-SE rats compared to controls animals in all time points examined ($p= <0.001$). Selectively blocking presynaptic GABA-B receptors increased the total number of dentate spikes in controls ($p=0.011$), but failed to do so in post-SE rats ($p=0.851$). These data suggest changes in presynaptic GABA-B receptor mediated regulation of dentate network excitability after SE. Further understanding the cell and synapse specific effects of presynaptic GABA-B in dentate circuit would help resolve the role of GABA-B modulation of inhibition in DG network excitability in physiological and pathological conditions such as Epilepsy.

Title: Interneuron-driven interictal spikes in an *in vitro* model of post-traumatic epilepsy

Authors: *K. P. LILLIS, L. A. LAU, K. J. STALEY;
Neurol., Massachusetts Gen. Hosp., Boston, MA

Abstract: Interictal spikes are a diagnostic feature of EEG recordings from epileptic patients, but their role in ictogenesis and epileptogenesis remains elusive. Understanding the basic circuit and molecular mechanisms underlying interictal spikes will offer new insight into how the epileptic brain can transition to pathological activity but isolating key elements responsible for the generation of network rhythms is technically challenging. Mounting evidence from *in vivo* recordings, as well as chronic and acute brain slice recordings, suggest that interictal spikes may be *generated* primarily by synchronous interneuron activity. In this work, we imaged the earliest emergence of interictal spikes in an *in vitro* model of post-traumatic epileptogenesis: the organotypic hippocampal slice culture. Slices were prepared from P7 DLX-cre mice that were transduced intracerebroventricularly on P0 with two AAV vectors: FLEX-tdTomato and syn-GCaMP7f, producing pan-neuronal expression of a green calcium sensor and interneuron-specific expression of a red fluorescent protein. We then used a novel imaging system constructed inside of a tissue culture incubator, to image slices continuously beginning shortly after the injury and continuing through the onset of spontaneous recurrent seizures (after ~7 days *in vitro*). Every 4 hours during this latent period, a movie of calcium dynamics with ***cellular resolution*** and a ***field of view spanning the entire epileptic network*** was acquired. For each detected interictal spike, all imaged neurons (typically n~=1000) were quantified by onset time and amplitude of calcium transient (ΔF/F). Preliminary data suggest that there is a bimodal distribution of onset times and peak ΔF/F amplitude, with the earliest firing and highest amplitude activity occurring in interneurons. Next, we sought to test the hypothesis that synchronous interneuron activation is sufficient to trigger interictal spikes. We co-transfected DLX-cre animals with FLEX-CoChR and syn-jRCaMP1a, producing pan-neuronal expression of a red calcium indicator and interneuron-specific expression of a high-current channelrhodopsin variant. We then used a digital micromirror device to pattern light to selectively stimulate a selected groups of interneurons. Preliminary data indicate that the number of interneurons stimulated is directly proportional to the amplitude of the network-wide calcium response. Together, these results suggest that the earliest synchronous activity in post-traumatic epileptogenesis is interneuron-driven interictal spiking.

Title: Direct evidence for excitatory GABAergic transmission in acute and chronic mouse models of epilepsy *in vivo*

Authors: *A. FERREIRA GOMES DA SILVA[1], O. DUBANET[1], A. FRICK[1], H. HIRASE[2], A. BEYELER[1], X. LEINEKUGEL[1];

Abstract: Numerous in vitro studies have reported high intracellular chloride levels, depolarizing and potentially excitatory actions of GABA in various pathological conditions such as epilepsy, autism spectrum disorders, or schizophrenia. It has therefore been recently proposed that drugs restoring low [Cl^-]i may provide novel therapies for a wide range of brain disorders. However, the relevance of this hypothesis in vivo remains largely speculative because of the technical difficulty to evaluate the polarity of GABAergic transmission in vivo. Combining non-invasive extracellular detection of unitary perisomatic inhibitory postsynaptic field-potentials (fIPSPs) with silicon probe recording of the firing activity of multiple individual neurons, we were able to probe the polarity of GABAergic transmission at the population and individual cell level in the hippocampal circuit in vivo. We now provide direct evidence for depolarizing actions of perisomatic GABAergic transmission and time-locked excitation of CA3 pyramidal neurons in acute and chronic mouse models of epilepsy. This approach will also prove useful to investigate alterations in the interplay between excitation and time-locked perisomatic inhibition in pathological conditions such as neurodegenerative and neurodevelopmental disorders.

Title: Sex and inhibition: Role of sex hormones during the development of hippocampal GABAergic network

Authors: *D. C. WOLF[1,2], N. T. SANON[1], A. O. CUNHA[3], T. SHAKER[1,2], A.-R. ELHASSAN[1], S. A. F. NASCIMENTO[1], L. CARMANT[1], G. DI CRISTO[1,2], A. G. WEIL[1,2];

Abstract: Sexual differentiation of the brain is influenced by testosterone (T) and its metabolites during the perinatal period in males (♂) and females (♀). This period is also critical for GABAergic network maturation and may be involved in T♀ susceptibility to seizures. Similar happens to ♂ but it is unlikely in ♀, according to our epilepsy model. Since T (endo-or-exogenous) might be involved in brain excitability, we aim to understand the development of the GABAergic network in non-epileptic rats, not only in ♂ and ♀ rats, but also in T♀ and T-insensitive ♂ rats. Sexual morphological and hormonal parameters were accessed during development. Protein expression of the chloride co-transporter KCC2 was evaluated in the hippocampus at postnatal days (P) 3, 7 and 40, whereas its membrane protein fraction was analyzed at P7 and P40. Gene expression of GABA signaling components (chloride co-transporters, glutamic acid decarboxylase (GAD), GABAA receptor (GABAAR) subunits, and GABA transporter (GAT)) were analyzed by RT-qPCR at P40. Functional aspects were determined by spontaneous inhibitory postsynaptic currents (sIPSCs) recorded in CA1 pyramidal cells at P40. We found strong effects of circulating T levels on sexual phenotypes (absence of nipples and anogenital distance). Levels of T were significantly lower in ♀($P<0.0001$, n=15/group), whereas estradiol levels were similar between sexes. Total KCC2 protein expression was not significantly different between sexes, however ♀ have higher membrane KCC2 levels compared to ♂ ($P=0.0007$, n=8) and T♀ ($P=0.0071$, n=8) at P7. At P40, membrane KCC2 levels were similar between sexes. GABAergic spontaneous currents in CA1 pyramidal cells of the hippocampus were smaller ($P=0.0313$) and less frequent in ♂ ($P<0.0001$). Kinetic parameters of sIPSCs, such as rise-time, were different between ♂ and T-insensitive ♂ rats ($P= 0.0072$, n=5-7 cells/4 animals per group). However, no differences were found in the components of GABA signaling, such as GAD65/67, GABAAR subunits (α1, α5, β2, γ2), GAT-1, NKCC1 and KCC2 at P40. Thus far, phenotypical and physiological differences between sexes are observed, namely in KCC2 expression in a specific developmental time point and in the amplitude and frequency of GABAergic spontaneous currents in the hippocampus of adult animals, suggesting possible involvement of sex hormones in cell excitability. Further analysis of the GABAergic network in these sex conditions will help to understand the sex-specificity of epileptogenesis.

Title: Spontaneous seizures can cross a transection by electric field coupling *in-vitro* and *in-vivo*

Authors: *C.-C. CHIANG[1], R. SHIVACHARAN[2], N. H. COUTURIER[3], M. SUBRAMANIAN[1], D. M. DURAND[4];
[2]Dept. of Biomed. Engin., [3]Biomed. Engin., [1]Case Western Reserve Univ., Cleveland, OH; [4]Dept Biomed. Eng, Case Western Res. Univ., Cleveland, OH

Abstract: In epilepsy, surgical transections are performed to isolate the epileptogenic zone while keeping brain function intact. However, this technique has a poor success-rate (30-40%) and the mechanism of how seizures in the epileptogenic zone expands beyond the transection is unclear. Several experimental results have shown that 4-AP-induced epileptiform activity in rodent hippocampi propagating at a speed of ~0.1 m/s independently of synaptic transmission and gap junctions is best explained by electric field coupling. Additional studies show that electric fields can activate neighboring neurons, thereby generating a self-propagating wave that could cross a transection. Using both *in-vitro* and *in-vivo* electrophysiology, we studied the mechanism driving activity through a physical cut or transection. We provide evidence that electric fields self-generate and recruit neighboring neurons to create a self-propagating wave through a transection/cut in the hippocampus. This self-generating seizure like activity can propagate through the cut ~0.11 m/sec, which was not significantly different if there was no cut present. We further show that these endogenous fields are self-sustaining through a cut with no significant difference in the field amplitude proximal to the cut, in the cut, and distal to the cut. Moreover, we show that in *in-vivo* 4-AP acute model seizures with larger amplitude and power have higher probability to cross a complete transection of the hippocampus. These results indicate that electric fields are sufficient for driving *in-vitro* and *in-vivo* epileptiform activity and could explain the low success rate of surgical transections.

Title: Fetal medial ganglionic eminence-derived GABAergic progenitors transplanted into the dentate gyrus of mice with temporal lobe epilepsy regulate adult neurogenesis

Authors: *M. N. ARSHAD[1], J. JEONG[1], B. BUYUKDEMIRTAS[1], M. ADLER-WACHTER[1], F. WICKHAM[1], S. MARRA[1], S. FOX[1], J. R. NAEGELE[2];

Abstract: In the dentate gyrus of adult hippocampus, heterogeneous populations of GABAergic interneurons or their axons localize in the vicinity of the stem cell niche and both local and long-range GABAergic neurons regulate this niche as well as the maturation of adult-born hippocampal granule cells (GCs) (Wang et al., 2005; Masiulis et al., 2011; Bao et al., 2017). Partial loss and axonal sprouting of hippocampal GABAergic interneurons are two characteristic features of the pilocarpine (PILO) model of temporal lobe epilepsy (TLE) in rodents (Choi et al., 2007; Peng et al., 2013) and these changes may be linked to aberrant neurogenesis and seizure development in temporal lobe epilepsy (TLE) (Hester & Danzer, 2014). Hippocampal transplants of GABAergic progenitors from human PSCs or fetal medial ganglionic eminence (MGE) suppress seizures in rodents with PILO-induced TLE (Henderson et al., 2014; Hunt et al., 2013; Cunningham et al., 2014; Upadhya et al., 2019 but see Anderson et al., 2018). MGE-derived GABAergic interneuron transplants migrate in the adult brain and innervate host brain neurons, including adult-born GCs (Hsieh and Baraban 2017; Upadhya et al., 2019; Cunningham et al., 2014; Henderson et al., 2014; Gupta et al., 2019). Recent work shows that transplanted MGE-derived GABAergic progenitors not only innervate adult-born GCs in TLE mice but also restrict the growth of their dendritic arbors (Gupta et al., 2019). However, the effects of MGE transplants on adult-neurogenesis have not been directly examined. We investigated the neurogenic effects of transplanting MGE progenitors harvested from ChR2 -EYFP transgenic mouse embryos (embryonic day 13.5) into the dentate gyrus of epileptic adult C57Bl/6N mice (Envigo, males 6-8 weeks of age). The number of adult-born doublecortin (DCX) neurons was quantified in the hilus, subgranular zone (SGZ), and granule cell layer (GCL). We found significant reductions in DCX-positive cells in mice with MGE transplants, consistent with the hypothesis that maturation of adult-born GCs may be inhibited by MGE transplants. To determine whether MGE transplantation impacts earlier stages of adult neurogenesis, we made systemic injections of either BrdU or EdU, thymidine analogues incorporated into DNA during S-phase of the cell cycle (Mandyam et al., 2007). In agreement with previous studies, mice with TLE show increased numbers of BrdU-labeled cells (Parent et al., 1997). However, MGE transplantation resulted in further increases in BrdU-labeling. Together, these findings suggest that MGE progenitors increase the proliferation of neural stem cells but diminish the survival or maturation of post-mitotic granule cells.

Title: Development of electrophysiological properties and dendritic morphologies in human pluripotent stem cell-derived GABAergic interneurons transplanted into the hippocampus of adult mice with pilocarpine-induced temporal lobe epilepsy

Authors: *S. SHRESTHA, N. ANDERSON, J. NAEGELE, L. GRABEL, G. AARON; Wesleyan Univ., Middletown, CT

Abstract: Human embryonic stem cell (hESC)-derived GABAergic interneurons are being studied for cell replacement therapies directed toward replacing damaged GABAergic interneurons in neurological disorders. Human neurons show protracted differentiation over periods of months (Cunningham *et al.,* 2014, Anderson *et al.,* 2018 Upadhya et al., 2019), but little is known about how their dendritic development is linked to electrophysiological maturation. To examine this question, we derived GABAergic progenitors from the hES3 NKX2.1: GFP/Ubi:mCherry cell line and transplanted them into the hippocampus of NOD-SCID immunodeficient mice (JAX labs) with pilocarpine-induced temporal lobe epilepsy. Four months after post-transplantation, *ex vivo* whole-cell patch clamp recordings were performed in hippocampal slices and the recorded cells were filled with biocytin for morphological analyses. Dendritic morphology was studied with IMARIS 9.2 (Bitplane) by making 3-dimensional (3D) computer-based reconstructions of 75 biocytin-filled neurons that were characterized by electrophysiology. Of these, 32 were completely reconstructed and morphological features were quantified including: soma volume, primary dendrites, total dendritic length, dendritic terminal points and dendritic complexity. We performed hierarchical clustering analyses and identified four morphologically unique clusters (Type A-D). Based on electrophysiological firing responses to current injections, five functional groups were identified (Type I-V, Anderson *et al.,* 2018). We found significant differences in action potential (AP) firing rates between groups: type I cells had immature firing patterns and type V cells had more mature firing patterns. Interestingly, 75% of the type I cells were also categorized as type C (simple morphologies) cells. Likewise, 40% of type V cells fell into the type D cluster, with complex dendritic morphologies. Six neurons had spinous dendrites and 4 of these were type D cells, consistent with this group's more mature electrophysiological and morphological properties. These findings suggest that hESC-derived interneuron progenitors differentiate at different rates following transplantation and by 4 months, some have developed complex dendritic morphology and mature firing patterns. Our

classification scheme linking different structural and functional maturation of hESC-derived GABAergic neurons provides a foundation for work aimed at identifying how neural activity, genetic programs, and neurological disorders regulate interneuron development.

Title: Patterns of limbic seizures induced by chemogenetic silencing of GABAergic neurons in the adult mouse hippocampus and entorhinal cortex

Authors: *N. H. CIMINO, M. N. ARSHAD, M. A. VAN ZANDT, D. B. LAWRENCE, K. T. COBBOL, A. R. HOOKER, J. R. NAEGELE;
Dept. of Biol., Wesleyan Univ., Middletown, CT

Abstract: Functionally diverse types of γ-aminobutyric acid-releasing (GABAergic) interneurons in the hippocampus and entorhinal cortex regulate patterns of neuronal activity and play key roles in learning and memory. Dysfunction within these populations is implicated in some neurological disorders including epilepsy, schizophrenia, and autism. Experimentally manipulating GABAergic circuits in these brain regions by means of optogenetics and chemogenetics is providing new insights into the functional roles of limbic GABAergic interneurons. We expressed a floxed ivermectin-gated glycine receptor (iGlyR3-GFP) (kindly provided by Anthony van den Pol, Yale Univ. Sch. of Med. New Haven, CT) in a cell-type and region-specific manner to examine the role of silencing hippocampal and entorhinal cortical GABAergic neurons in limbic seizures. Adult male and female mice expressing Cre-recombinase under control of the vesicular GABA transporter (VGAT-ires-Cre; B6J.129S6(FVB)-Slc32a1$^{tm2(cre)Lowl/}$MwarJ) received stereotaxic injections of an AAV-DJ vector containing the iGlyR3-GFP construct. Hippocampal GABAergic interneuron expression occurred 2-5 weeks following stereotaxic delivery of this AAV-DJ vector. Video-electroencephalographic recordings (V-EEGs) were carried out for ~12 hours to obtain baseline EEGs prior to injecting ivermectin (5mg/kg, i.p.) or vehicle (i.p.) into the mice. V-EEGs were continued for ~7 hours post-injection. In ivermectin-treated mice, we observed bursts of high amplitude activity that typically

developed into non-convulsive and convulsive seizures with corresponding hypersynchronous waveforms. On average, iGlyR-expressing mice injected with ivermectin developed ~8 seizures within 7 hours (durations ~20-60 sec), whereas none of the vehicle-injected mice showed abnormal EEGs. These experiments demonstrate that acute silencing of hippocampal GABAergic circuits promotes seizure activity. In mice with longer periods of AAV-DJ-mediated iGlyR expression, the expression spread to GABAergic cells in the entorhinal cortex, including some parvalbumin-positive neurons. We are examining whether the expression is specific to the long-range GABAergic neurons that comprise bidirectional hippocampal-entorhinal inhibitory connections and preferentially target GABAergic interneurons of the hippocampus, and how expression of iGlyR in these pathways influences seizure phenotypes. Additional studies are underway in brain slices and in parvalbumin (PV)-expressing GABAergic interneurons in PV-ires-Cre transgenic mice to study the effects of silencing distinct types of GABAergic neurons on seizure activity.

Title: *In vitro* anticonvulsant activity of pterolobium stellatum extracts

Authors: *S. S. SALILE[1,2], T. ABULA[1], J. H. LEE[2], J. V. RAIMONDO[2];
[1]Addis Ababa University, Sch. of Pharm., Addis Ababa, Ethiopia; [2]Univ. of Cape Town, Cape Town, South Africa

Abstract: Though there are conventional antiepileptic drugs in use ,one third of cases are refractory to treatment which underscores the need for new anticonvulsant agent. While four-fifths of the potential market for antiepileptic drugs is in the developing world, up to 90% of people with epilepsy in developing countries receive no treatment at all. In Ethiopia, many diseases are treated using traditional medicines. Pterolobium stellatum is often used to treat epilepsy. The whole plant juice is given orally for one month. The aim of this study is to investigate the anticonvulsant activity of P. stellatum extracts using the *in vitro* 0 Mg2+ model of seizures in mouse hippocampal brain slices. Methods Plant material was collected and extracted using standard methods. The crude hydroalcholic extracts of P. stelatum: petether, chloroform, butanol and water extracts with 0.7 mg/ml concentration were tested for anticonvulsant activity. Extracellular field potential recordings were performed in coronal hippocampal slices from P14-P21 of C57BL16 mice.The 0Mg2+model of seizures was utilized. Baseline recordings were

made for 600s with normal artificial cerebrospinal fluid(aCSF) before 0Mg2+aCSF was washed in for 3000s in order to induce seizure-like activity. The 0 Mg2+ solution either contained plant extract or solvent as a control. The presence of seizure-like events was compared in treated versus untreated control. The Chi square test with $P<0.05$ was used to determine statistical difference between groups. Results The crude extract had a statistically significant anticonvulsant activity compared to control($P=0.0153$). The chloroform and water extracts were also shown to have significant anticonvulsant activity as compared to control ($P=0.0008$ and $P= 0.0001$ respectively). The petether and buthanol extract activity was not statistically significant compared to control ($P=0.4760$ and $P=0.4637$ respectively). A positive control using the known anticonvulsant diazepam(3µM), showed significant anticonvulsant activity ($P= 0.0118$). Discussion and recommendations Our results demonstrate that P. stellatum has anticonvulsant activity. Active compounds are likely in both the water fraction and the chloroform fraction of the extracts as these both demonstrated good anticonvulsant activity. Further chemical studies are required to isolate the active compounds from these fractions. The mechanism of action of the active compounds in terms of their targets will also require further elucidation. This work demonstrates the utility of harnessing Africa's indigenous knowledge and rich biodiversity to identify novel anticonvulsant therapies based on natural compounds.

Title: Effects of hippocampal temporally irregular deep brain stimulation over PTZ-induced seizures in rats

Authors: *D. MARTINEZ-VARGAS[1], E. URBINA-TREJO[1], F. SANTOS-VALENCIA[1], S. ALMAZÁN-ALVARADO[2], A. RUBIO-LUVIANO[1];
[1]Lab. de Neurofisiología del Control y la Regulación, [2]Lab. de Bioelectrónica, Inst. Nacional de Psiquiatria, Mexico City, Mexico

Abstract: Deep brain electrical stimulation (DBS) is an alternative therapy used to treat pharmacoresistant epilepsy; however, the optimal parameters of stimulation are undetermined. The variation of temporal patterns of electrical pulses in stimulation trains is an emerging proposal that has opened a wide new field of opportunity to improve the effectiveness of the stimulation and minimize its side effects. It has been described that temporally irregular DBS (TiDBS) applied to amygdala reduces the severity and number of seizures induced by pentylenetetrazole (PTZ) and pilocarpine in rats. Thus, TiDBS could be an alternative approach

against epilepsy in other therapeutic targets involved in the generation of seizures like the hippocampus. The aim of this work was to analyze the effects of unilateral responsive TiDBS in hippocampus over PTZ-induced seizures and compare their efficacy with low-frequency stimulation (LFS) and high-frequency stimulation (HFS) in rats. Twenty-four adult male rats were implanted in the right dentate gyrus (DG) (AP -4 mm; ML 2.4 mm; V -3.6 mm from bregma) and both motor cortices for EEG recording. The implanted electrode in DG was used for stimulation and recording. Rats were randomly assigned to 4 groups; control, stimulation at 4 Hz (LFS), 130 Hz (HFS) or TiDBS (pseudo-random intervals inter-stimulus). The convulsive agent PTZ (60 mg/kg, i.p.) was applied to induce generalized tonic-clonic seizures (GTCS). LFS, HFS or TiDBS was applied for 30 min with a continuous train of biphasic square-wave pulses, onset immediately after of PTZ-injection. The latency to neck jerks (NJ), GTCS number, seizure score, and survival percent were analyzed. In addition, the effects over EEG seizures were evaluated. Obtained results showed a decrease of GTCS number [$F(3,20)=6.667$, $p=0.003$] with LFS ($p=0.013$), HFS ($p=0.013$) and TiDBS ($p=0.005$) compared to control. On the other hand, the seizure score decrease [$H=0.007$] with HFS ($p=0.05$) and TiDBS ($P=0.025$) compared to control. The latency to NJ increase [$F(3,23)=6.151$, $p=0.004$] with TiDBS ($p=0.004$) compared to control. The percent of survival after the PTZ administration was increased in rats treated with LFS (50%), HFS (83.3 %) and TiDBS (83.3 %), which were superior to the control group (0%). The EEG analyses showed a stronger effect of TiDBS in comparison with LFS and HFS. The animals treated with TiDBS only showed spike-wave discharges while animals treated with LFS or HFS showed a great number of spikes or recurrent electrographic seizures. The data suggest that TiDBS in DG can be an effective anticonvulsant method and could be lead an alternative treatment against the progress and the pathophysiology of epilepsy.

Title: Combined neural stem cell grafting and ganaxolone therapy greatly eases spontaneous seizures and co-morbidities in a model of chronic TLE

Authors: *R. UPADHYA[1,2], M. KODALI[1,2], B. SHUAI[1], J. XU[1,2], D. UPADHYA[1], A. K. SHETTY[1,2];

[1]Inst. For Regen Med, Texas A&M Univ. Coll Med., College Station, TX; [2]Olin E. Teague Veterans Med. Center, CTVHCS, Temple, TX

Abstract: Epilepsy, typified by spontaneous recurrent seizures (SRS), affects ~60 million people worldwide. Temporal lobe epilepsy (TLE), seen in ~30% of epilepsy patients, is a condition where seizures originate from the hippocampus. Memory and mood impairments are co-morbidities of chronic TLE. Since >35% of TLE patients acquire intractable epilepsy, alternative approaches such as cell therapy, either alone or in combination with drugs, have received much interest. We tested the hypothesis that combined intrahippocampal grafting of neural stem cells (NSCs) with short-term oral administration of ganaxolone (GAN, a synthetic analog of the neurosteroid allopregnanolone), facilitates better seizure control and improved cognitive and mood function than NSC grafting alone in rats afflicted with chronic TLE. We induced status epilepticus (SE) in young adult F344 rats via graded intraperitoneal injections of Kainic acid. After 2 hours of SE, the seizures were terminated through a dose of diazepam, and the frequency of behavioral SRS was quantified at 2-4 months after SE. Chronically epileptic rats (CERs) exhibiting comparable frequency of SRS were next randomly assigned to one of the five groups: CERs receiving sham surgery, CERs receiving oral GAN treatment for 14 days, CERs receiving intrahippocampal NSC grafting, and CERs receiving NSC grafting plus two-weeks of GAN. The donor NSCs were expanded from the subventricular zone of postnatal F344 rats expressing the green fluorescent protein in all cells. The frequency of SRS or Stage V-SRS, measured through continuous video-EEG recordings for 14-21 days at 4-5 months after treatment, was reduced in all treated groups. Furthermore, grafting of NSCs with or without GAN treatment reduced neuroinflammation, enhanced neurogenesis, and improved cognitive function. However, the overall efficacy for suppressing SRS was much higher in CERs receiving combined NSC and GAN treatment (63-65% reduction), than CERs receiving GAN (20-29% reduction) or NSC grafts alone (37-38% reduction). Besides, unlike with NSC or GAN treatment alone, combined NSC and GAN therapy improved pattern separation function and reversed anhedonia. Combined therapy also mediated superior enhancement of hippocampal neurogenesis and repression of activated microglia without altering the survival and differentiation of graft-derived cells. The results underscore that combined NSC and GAN therapy is superior to NSC or GAN treatment alone for alleviating seizures and easing the co-morbidities of TLE.

Title: Deep brain stimulation in the parahippocampus as an alternative target for the treatment of mesial temporal lobe epilepsy in patients with hippocampal sclerosis

Authors: *P. E. SAUCEDO-ALVARADO[1], F. J. VELASCO[2], A. VELASCO[2], M. A. AVILA-RODRIGUEZ[1], A. AVENDAÑO-ESTRADA[1], M. CUELLAR-HERRERA[2], R. MARQUEZ-FRANCO[3];

Abstract: Objectives:Evaluate the response of seizure control in drug-resistant Mesial Temporal Lobe Epilepsy (MTLE) patients with Hippocampal Sclerosis (HS) after neuromodulation in the parahippocampal cortex (PH-DBS). Methods:A group of 6 MLTE-HS patients were implanted in the parahippocampal cortex and neuromodulated with High-Frequency Stimulation (HFS). Stimulation parameters were the same in all patients (2.5 V, 130 Hz, 450 μs, Open Loop 1 min ON/4min OFF), and they were kept in anticonvulsive medication that had worked best in pre-operative evaluation. The evaluation included: number of seizures measured as percentage decrement from the previous 3 months baseline (BL), neuropsychological performance and 18FDG interictal PET-CT before and at the end of one-year follow-up.Results:Plotting the active contacts of DBS electrodes in post-operative MRI confirmed the correct placement of electrodes in all cases. The number of seizures decreased significantly since the second month ON stimulation to reach decrements from 50% to 80% in subsequent months. Secondary tonic-clonic seizures and Focal seizures with impairment awareness decreased significantly but not focal seizures. Neuropsychological performance remained unchanged for the two groups with an improvement in those patients that had best seizure control. 18FDG interictal PET-CT values increased after twelve months of therapy of those hypometabolic regions before PH-DBS. The obtained data were compared with two more targets results, Hippocampal and Subiculum neuromodulation, from previous studies. In contrast with these two other targets, in patients with HS, PH-DBS has better results than the previous studies.Conclusions:PH-DBS is a great alternative on seizure control in MTLE-HS, this could be related to changes in the metabolism of the epileptogenic zone as a result of DBS therapy.

Title: Changes of the electrical activity of the thalamic reticular nucleus by the electric stimulation

Authors: *V. M. MAGDALENO-MADRIGAL[1], J. VALERIO-MUÑOZ[2], M. I. ORTIZ-ZARATE[2], G. CONTRERAS-MURILLO[1], S. ALMAZÁN-ALVARADO[1];

Abstract: The high-frequency deep brain stimulation (DBS) is used for the control of refractory epilepsy. In our laboratory, we have reported that DBS in the thalamic reticular nucleus (TRN) protects against generalized seizures provoked by Pentylenetetrazol (PTZ). The TRN contains inhibitory neurons that release GABA and is involved in the generation and control of spike-wave discharges (SWD) and tonic-clonic generalized seizures (TCGS). To explore the mechanism underlying TRN-DBS we recorded the multiunit activity of TRN in response to DBS-TRN and PTZ. In the acute protocol, under deep anesthesia induced by intraperitoneal injection of urethane (1.5 g/1000 g) the rats were prepared with a stainless-steel bipolar electrode directed to TRN and standard extracellular recordings were performed using glass microelectrodes (4–8 MΩ) filled with 3M KCl solution. Two nail-shaped were implanted in the frontal bone to EEG recording and a jewelry screw as a reference was implanted in the occipital bone. TRN recording tracks were aimed vertically at the stereotaxic coordinates. The PTZ caused a significant decrease in the firing rate of TRN cells, in 15 neurons their firing from tonic mode to burst mode was modified, while in five neurons an increase in the firing rate was induced. The DBS-TRN decreased the firing rate compared to the baseline and the second dose of PTZ, and changes in the type of firing in three neurons did not observe. The results suggest that the NRT participates in the maintenance of the SWD characteristics of the absence seizures, and the DBS in the NRT may induce the inhibition of the oscillatory activity synchronization.

Title: Focal suppression of epileptiform activity in the hippocampus by a time-varying magnetic field

Authors: H. YE, V. CHEN, J. HELON, N. APOSTOLOPOULOS;
Loyola Univ. Chicago, Chicago, IL

Abstract: Electric current has been used to suppress seizure activity clinically by targeting specific neural circuity. When electric current is delivered by implanted electrodes, the direct

contact between electrodes and tissue causes many side effects such as pain, inflammation, and other adverse biological reactions. An alternative method to generate electric current inside the brain, is via electromagnetic induction through a magnetic coil. In comparison to electrical stimulation, magnetic stimulation offers several advantages in biocompatibility and operational feasibility. However, further development of this technology for clinical practice is hindered by the lack of complete understanding of the cellular mechanism of magnetic stimulation, particularly, in the context of hyperexcitable neural activity (seizure) in epilepsy. In this paper, we report that epileptiform activity in the CA3 area of the hippocampus could be locally suppressed by a mini size coil in an *in vitro* low-Mg^{2+} /high K^{+} model. The inhibition effect is dependent on the magnitude, frequency, and duration of the magnetic field delivered by the coil. This work provides a platform for further investigation of cellular/molecular mechanisms underlying seizure inhibition by time varying magnetic field, and insights on the clinical TMS treatment for epilepsy.

Title: Closed-loop implementation of intersectional short-pulse (ISP) stimulation to stop temporal lobe seizures

Authors: M. HARANGOZO, **T. FOLDI**, G. KOZAK, A. J. NAGY, T. GYURKOVICS, M. VOROSLAKOS, *A. BERENYI;
Univ. of Szeged, Szeged, Hungary

Abstract: Transcutaneous electric stimulation (TES) using weak currents has been used extensively in attempts to influence brain activity. *In vitro* and *in vivo* experiments in rodents and computational modeling suggest that the magnitude of voltage gradient of the induced electric field should exceed 1 mV/mm to instantaneously and reproducibly alter neuronal spiking and consequent brain network patterns. Evidence for immediate and unconditional neuronal effects of TES in the human brain is still lacking, mainly due to the saturation of the recording amplifiers by the large induced electromagnetic fields. For many therapeutic applications, it is desirable to affect neurons in a regionally constrained manner to reach maximum on-target effects and reduce side effects on unintended brain networks.
Here, we determine the needed TES currents in human cadavers to achieve 1 mV/mm fields.

Scalp stimulation greatly reduced the generated intracerebral electric fields (>50% in cadavers) and these measurements predicted that ~5 mA is needed to achieve 1mV/mm electric field gradient via scalp stimulation. To reach the desired intracerebral field strength without the adverse peripheral effects of >5 mA currents, we introduce a spatially focused multiple site, Intersectional Short-Pulse (ISP) stimulation. We demonstrate the instantaneous entraining effect of ISP on EEG waves in human subjects and on neuronal spiking in rats. Immediate effects of TES can be best utilized in disorders with sudden, major electrographic changes such as epileptic seizures. We showed earlier that thalamocortical seizures can be quickly terminated by temporally targeted, diffuse transcranial stimulation, however secondarily generalized temporal lobe seizures are more resistant to these diffuse interference interventions.
ISP also has the capacity to spatially focus its effect, thus it is capable to overcome the unwanted mirror effect (anodal vs cathodal) of the traditional TES protocols. We report here a novel stimulation pattern, that can simultaneously entrain both hippocampi. To evaluate its utility, temporal lobe seizures were induced in rats by electrical kindling, and each electrically kindled seizures were automatically detected and silenced by a closed loop ISP stimulation. By comparing to closed-loop diffuse TES, we found that ISP with bilateral foci is more effective in early seizure termination.
Lastly, we introduce our prototyping efforts to implement an implantable, minimal-invasive, transcranial closed-loop seizure termination device, aiming for human clinical applications.

Title: Dynamic volume changes of the brain’s extracellular space as a target for eliminating epileptiform seizure activity

Authors: R. COLBOURN[1,2], J. H. GOODMAN[3,4], *S. HRABETOVA[2];
[1]Sch. of Grad. Studies, SUNY Downstate Med. Ctr., Brooklyn, NY; [2]Dept. of Cell Biology, SUNY Downstate Med. Ctr., Brooklyn, NY; [3]Inst. for Basic Res. in Developmental Disabilities, Staten Island, NY; [4]Dept. of Physiol. and Pharmacol. SUNY Downstate Med. Ctr., Brooklyn, NY

Abstract: Chronic seizure syndromes are notoriously difficult to treat, with between 20-40% of cases being refractory to anti-seizure medications. The identification of therapeutic targets that promote seizure generation are critical in the development of new treatments for these patients. The volume of the brain's extracellular space (ECS) has long been recognized as having an important role in seizure generation, but how it exerts its influence is still up for debate. The brain's ECS represents a large, interconnected compartment that is a reservoir of ions and a communication channel for neurotransmitters, which allows any changes in volume of the ECS to modulate the effects those functions might have on net neuronal excitability and synchrony. To investigate how ECS volume changes during epileptiform activity, we utilized a technique called relative volume monitoring (RVM), which continuously tracks the concentration of an ECS probe to calculate changes in its volume. By using RVM in the neocortex of brain slices from C57BL/6 mice undergoing 4-aminopyridine (4AP, 100 μM) induced epileptiform activity (n = 40 slices), we have discovered that the ECS transiently shrinks up to 13% during each synchronous epileptiform discharge. Because ECS shrinkage is an important pro-excitatory force in the brain, these dynamic volume changes (DVCs) of the ECS may represent a therapeutic target for inhibiting seizures. To determine this, we decided to pharmacologically block channels and transporters that were likely necessary to allow for these DVCs to occur. Blockade of sodium-bicarbonate cotransporter 1 (NBCe1) with 4,4'-Diisothiocyano-2,2'-stilbenedisulfonic acid (DIDS, 300 μM) led to the elimination of both DVCs and epileptiform activity (n = 5 slices). Based on the effect of blockade, we argue that it was because of the elimination of DVCs that the epileptiform activity was halted. In summary, we conclude that DVCs represent a mechanism that helps promote excitability and synchrony and therefore may serve as a possible target for seizure treatment.

Title: Transcriptomic alterations following early life hypoxia-induced seizures and anti-seizure drug exposure

Authors: *S. M. M. QUINLAN, P. A. FORCELLI;
Georgetown Univ., Washington DC, DC

Abstract: Hypoxic-ischemic encephalopathy (HIE) is the main precipitator of neonatal seizures and a leading cause of long-term disabilities in infants (Soul, 2018). Survivors are at increased risk of autism, epilepsy, cognitive and learning difficulties and psychiatric conditions (Glass et al., 2016; Soul, 2018). Common clinical practice is to suppress neonatal seizures using pharmacotherapies such as phenobarbital [PB] or levetiracetam [LEV]. However, treatment of neonatal seizures poses a particular challenge: both seizures and anti-seizure drugs (ASDs) can result in long-term adverse effects on brain development. While there is growing evidence for the adverse impact of both seizures and medication alone, very little is known about how these insults interact. Identifying early mechanistic targets triggered by seizures and ASDs will be crucial for understanding how HS and ASDs affect the developing brain, and how we can improve the long-term negative neurological outcomes.
Postnatal day (P)7 Sprague-Dawley rat pups were exposed to graded global hypoxia-induced seizures (HS) with or without anti-seizure drug treatment (PB 75 mg/kg; LEV 200 mg/kg). Hippocampal transcriptome was assessed 72 h post-HS by RNAseq. Animals subjected to HS had 280 significantly dysregulated transcripts, including a cluster involved in glutamate transmission. Using 4-channel multiplex qPCR we validated the changes seen with RNAseq, using pre-designed primers. We observed a 25% decreased expression of genes coding for ionotropic glutamate receptor subunits when compared to control animals. Levels of transcripts coding for AMPA receptor subunits *GRIA1, GRIA2, and GRIA3* were all significantly decreased by HS and LEV alone, but not by PB, however levels of *GRIA4* were significantly decreased by PB. *GRIN1, GRIN2A, GRIN2B,* and *GRIN3A* transcripts, which code for NMDA receptor subunits, were all significantly decreased by treatments HS, LEV, and combinations, apart from PB treatment alone. Validation of other transcripts is ongoing, as is validation at the level of protein. While alterations in glutamatergic transmission have previously been reported after HS, these data raise the possibility that ASDs, when given during a critical developmental period, may also dysregulate glutamatergic transmission.

Title: Deciphering the neuroprotective mechanism of ayurvedic formulations using mouse model of epilepsy

Authors: *B. VERMA, P. SINHA, S. GANESH;
Biol. Sci. and Bioengineering, Indian Inst. of Technol. Kanpur, Kalyanpur, Kanpur, India

Abstract: Epilepsy affects approximately 50 million people worldwide and continues to remain as one of the leading causes of disability. Much progress has been made in understanding the etiology and pathogenesis of epilepsy, and several anti-epileptic drugs (AED) have been developed. Nonetheless, the AEDs are often associated with adverse effects, and over one-third of the patients with epilepsy fail to respond to the AEDs after prolonged usage. Therefore, the use of AEDs is often considered as a symptomatic treatment, and there is a genuine need to explore the alternative therapeutic approaches with fewer side effects when administered for the long term. *Ayurveda*, the traditional Indian medicinal system, describes complex formulations that aim to bring about healthy aging and thereby prevent and/or delay the neurological dysfunctions with no/minimal adverse effects. However, their mode of action and physiological basis have not yet been well characterized. The current study aimed at investigating the physiological basis of neuroprotection conferred two formulations, namely the *Amalaki Rasayana* and *Rasa sindoor*. For this is we used a mouse of Lafora disease - a progressive and fatal form of epilepsy in humans - known to show increased susceptibility to induced seizure, neurodegeneration, and deficit in neurocognitive functions. The animals were fed with the formulations for a period for six months, and at the end of the treatment, the animals were tested for their susceptibility to pentylenetetrazole-induced seizure, neuroinflammation, and cognitive functions. We found a significant reduction in the seizure susceptibility in the groups that received *Ayurvedic* formulations as compared to the controls, and this correlated with a significant reduction in the neuroinflammation in the treated group. In addition, the treated animals showed a significant improvement in learning & memory, anxiety and depression. These findings indicate that the *Ayurvedic* formulations confer neuroprotection and are attractive alternative modes of treatment for some of the epileptic disorders.

Abstract: Roughly 30% of epileptic patients do not respond to available anti-epileptic drugs, often leading to surgeries which can be dangerous and costly. Finding novel drugs for these patients is costly and time-consuming. Therefore, repurposing compounds approved by the FDA to treat other diseases is appealing for use in treating epilepsy. To identify candidate compounds for this effort, we harvested seizing and non-seizing brain tissue that had been clinically resected from patients suffering intractable epilepsy. We generated RNA expression profiles of both tissues, and identified a list of differentially expressed genes, i.e., an epileptic gene signature. We compared this list to previously-published expression profiles of cells exposed to various FDA-approved compounds. Those that induced changes in gene expression that were anti-correlated with the epileptic gene signature were candidate therapeutics for epilepsy. Next, we screened a subset of such candidates in an animal model of epilepsy: zebrafish larvae treated with the GABAergic inhibitor, PTZ. We found that metformin, nifedipine, and pyrantel tartrate were able to partially suppress convulsions in PTZ-treated larvae. Currently, we are testing these drugs in zebrafish *scn1a* mutants, which are a model of genetic epilepsy. These findings illustrate a pipeline for identifying drugs that are candidates for re-purposing to anti-epileptic therapy.

Title: Evaluating in-hospital care for the treatment of nerve agent-induced status epilepticus in rats

Authors: J. E. MORGAN, S. C. WILSON, J. M. COPPOLA, C. JACKSON PIERCY, H. M. BELSKI, K. A. HUNDERTMARK, S. T. MILLS, M. R. EISEN, D. L. NGUYEN, *H. S. MCCARREN;
US Army Med. Res. Inst. of Chem. Def., Aberdeen Proving Ground, MD

Abstract: Nerve agent (NA) poisoning initiates a catastrophic cholinergic crisis that can induce *status epilepticus* (SE) if left untreated. Survivors of NA exposure will likely require treatment in a hospital intensive care setting. Guidelines currently exist for pre-hospital management of NA-induced SE, which includes up to two doses of a benzodiazepine. However, previous research in rodent models has indicated that doses of diazepam equivalent to 3-12 convulsive antidote for nerve agent (CANA) auto-injectors are insufficient to stop SE. There is currently no standard therapy regimen for definitive termination of NA-induced SE. Our goal is to determine a treatment strategy to completely resolve NA-induced SE in a hospital setting using benzodiazepines as a first-line therapy, followed by antiepileptic drugs and anesthetic agents as second- and third-line therapies respectively, if benzodiazepines prove insufficient. Male Sprague Dawley rats were surgically implanted with jugular vein catheters and tethered EEG headpieces. Twenty minutes after soman (GD) exposure they received human equivalent doses of standard pre-hospital countermeasures for NA exposure, followed ten minutes later by initiation of in-hospital treatments. When compared head-to-head as first-line treatments, midazolam and lorazepam were equally ineffective at terminating SE ($p = 0.56$), with respective seizure termination rates of 7% ($n = 15$) and 18% ($n = 11$). The second-line treatments valproic acid and phenobarbital also showed equivalent efficacy ($p = 0.68$), with respective seizure termination rates of 43% ($n = 14$) and 60% ($n = 10$). The third-line treatments ketamine ($n = 6$) and propofol ($n = 8$) were dosed until SE terminated in all subjects, but 24-hour survival rates in animals that required these drugs were very low (14%). Still, animals that were successfully treated in the ICU and returned to their home cages after 24 hours of seizure freedom showed a

return to baseline body weight by 6 days post-exposure, while animals that only received pre-hospital treatment and did not demonstrate SE termination never recovered to baseline before the end of the study (10 days post-exposure). Work to identify impacts of treatment regimen on behavioral task performance, as well as neuropathology analysis, is ongoing.

Title: The direct contact of astrocytes to neuron is critical for lowering excitatory synaptic transmission after the exposure of amyloid β-protein 25-35 onto astrocytes

Authors: *K. OYABU[1], H. KIYOTA[1], K. KUBOTA[1,2], T. WATANABE[1,2], S. KATSURABAYASHI[1], K. IWASAKI[1,2];
[1]Fukuoka Univ., Fukuoka, Japan; [2]Collaborative Res. Inst. for Aging and Brain Sci., Fukuoka, Japan

Abstract: Alzheimer's disease is a progressive neurodegenerative disease that presents with cognitive and behavioral disorders. Because Aβ25-35 cause synaptic dysfunction and synapses loss, Aβ25-35 are regarded as an initiator of the pathogenesis of AD. Giving that astrocytes play important roles, such as modulation of neurotransmission, synaptogenesis, in information processing of the central nervous system, the close relationship between astrocytes and synapses suggests that astrocyte dysfunction by Aβ25-35 affects synaptic abnormalities in AD. However, their relationship is not well understood so far. In this study, the synaptic transmission and synaptic number were assessed in single neuron cultures, where the neuron was co-cultured with astrocytes exposed Aβ25-35 3 days beforehand, namely, the neuron had not undergone the exposure of Aβ25-35. Neurons in direct contact with astrocytes showed a significant decrease in excitatory postsynaptic current together with a significant decrease in the number of glutamatergic synapses. However, the vesicular release probability was unchanged. On the other hand, the number of synapses was not changed in neurons that did not contact astrocytes that exposed Aβ25-35. Taken together, the direct contact of astrocytes to neurons is important for the synaptic abnormality by the astrocyte-mediated exposure of Aβ25-35. This study further implies that not only the direct neuronal effect of Aβ25-35 but also the astrocyte-mediated effect is severe in the pathogenesis of AD.

Title: Neuron-derived estrogen is critical for neuroprotective astrocyte activation after ischemic injury to the brain

Authors: ***Y. LU**[1], G. R. SAREDDY[2], J. WANG[1], Q. ZHANG[1], F.-L. TANG[1], U. PRATAP[2], R. K. VADLAMUDI[2], D. W. BRANN[1];

Abstract: 17β-estradiol (E2) is produced from androgens via the action of the enzyme aromatase. E2 is known to be made in neurons in the brain, but its precise functions in the brain are unclear. Here, we used a forebrain-neuron-specific aromatase knockout (FBN-ARO-KO) mouse model to deplete neuron-derived E2 in the forebrain of adult female ovariectomized mice and determine its roles in the hippocampus after global cerebral ischemia (GCI). The results revealed that FBN-ARO-KO mice had significantly reduced hippocampal E2 levels, as well as a significant attenuation of astrocyte activation and increased neuronal damage after GCI. Behavioral tests demonstrated that FBN-ARO-KO mice had worse cognitive outcome compared to control mice, and *in vivo* E2 replacement was able to rescue the cognitive deficits. RNA-seq analysis revealed alterations in pathways and genes associated with astrocyte activation, neuroinflammation and oxidative stress in FBN-ARO-KO mice. Double immunohistochemistry analysis revealed that the compromised astrocyte activation in FBN-ARO-KO mice was associated with robust downregulation of the astrocyte-derived neurotrophic factors, like BDNF and IGF-1, as well as glutamate transporter levels in astrocytes. Moreover, neuronal FGF2 that acts in a paracrine manner to suppress astrocyte activation, was found to be dramatically increased in FBN-ARO-KO neurons. Interestingly, blocking FGF2 signaling in astrocytes by central injection of an FGFR3 antibody was able to reverse the decrease in neuroprotective astrocyte reactivity, as well as attenuate neuronal damage in FBN-ARO-KO mice. Collectively, our data provides novel genetic evidence for an essential role of neuron-derived E2 in neuroprotection and cognitive preservation by maintaining a beneficial neuroprotective astrocyte reactive status following ischemic injury to the brain.

Title: Disruption in the formation of tripartite synapses by reactive astrocytes is responsible for the learning and memory impairments in Alzheimer's disease

Authors: ***M. CHOI**[1], H. KIM[2], E. YANG[1], H.-S. KIM[3];
[1]Seoul Natl. Univ., Seoul, Korea, Republic of; [2]Seoul Natl. Univ., Yeongeon-Dong, Jongno-Gu, Seoul, Korea, Republic of; [3]Seoul Natl. Univ. Col. Med., Seoul, Korea, Republic of

Abstract: Astrocytes are the most abundant cell type in the central nervous system, and various roles of the astrocytes have been well known from the formation of blood brain barrier to the involvement in the memory formation. These cells have a potential of dynamic morphological changes according to the status of the cells. Astrocytes closely interact with neurons, making structures called as tripartite synapses. However, the pattern of dynamic morphological changes in memory induction status of astrocytes and/or tripartite synapses in Alzheimer's disease (AD) have been not clarified yet. In the present study, we investigated the changes in morphology of astrocytes and the number of tripartite synapses during learning and memory processes using AD model, 5XFAD mouse. The hippocampus dependent long-term spatial memory was induced with the contextual fear conditioning test . 1 hour after the induction of memory formation, the number of processes of astrocytes was increased in both wild type (WT) and 5XFAD mice group. 24 hour after memory induction, the number of processes of astrocytes was increased in WT but not in 5XFAD mice group. In addition, the number of tripartite synapses was increased in both WT and 5XFAD group after 1 hour after the induction of memory formation. Taken together, our results suggest that disruption in the formation of tripartite synapses is responsible for the learning and memory impairments in AD.

Title: Phosphatidylserine recognition and rac activation link proliferation, gliosis and phagocytic activity of muller glia in the rat retinal injury model

Authors: *K. NOMURA-KOMOIKE, F. SAITOH, H. FUJIEDA;
Dept. of Anat., Tokyo Women's Med. Univ., Tokyo, Japan

Abstract: Müller glia, the principal glial cell type in the retina, have the potential to reenter the cell cycle after retinal damage. In mammals, proliferation of Müller glia is followed by gliosis, but not neuronal regeneration. Retinal damage is also followed by phagocytic removal of degenerated cells. Here we investigated the possibility that proliferation of Müller glia, gliosis, and phagocytosis of degenerated cells may be regulated by the same molecular pathways. N-methyl-N–nitrosourea was intraperitoneally injected into five-week-old male Wistar rats (MNU, 70mg/kg BW) to induce photoreceptor damage, and the retinas were subjected to immunohistochemistry for cell cycle and cell type-specific markers. Retinas were also cultured as explants after MNU treatment. All experiments were repeated at least 3 times and at least 3 animals were used per stage or condition. Degeneration of photoreceptors was observed by day 1 after MNU treatment, followed by cell cycle reentry of Müller glia by day 2. Notably, most degenerated photoreceptors were eliminated by day 2.5 prior to the infiltration of microglia/macrophages into the outer nuclear layer and inhibition of microglia/macrophages by minocycline did not affect the elimination of degenerated photoreceptors. Besides, accumulation of lysosomes and rhodopsin-positive photoreceptor debris were found within the cytoplasm of Müller glia. These data indicate that Müller glia, rather than microglia/macrophages, play a major role in the phagocytic clearance of degenerated photoreceptors. We treated retinal explants with *O*-phospho-L-serine (L-SOP), which inhibits the recognition of phosphatidylserine (PS), the key “eat me” signal exposed by apoptotic cells. Cell cycle reentry, GFAP upregulation, and phagocytic activity of Müller glia were significantly inhibited by L-SOP treatment, while all these responses were observed in the control explants. We also tested the involvement of Rac, a member of the Rho family small GTPases, known to promote phagocytic engulfment by regulating cytoskeletal rearrangement and found that Rac1 expression was upregulated in Müller glia after MNU treatment. Treatment of retinal explants with NSC23766, a specific inhibitor of Rac1 activation, significantly inhibited the proliferative, gliotic, and phagocytic responses of Müller glia. These data provide evidence that Müller glia play a major role in phagocytic

clearance of degenerated photoreceptors and that PS recognition and Rac1 activation are required not only for phagocytic activity but also for proliferation and gliosis of Müller glia in the mammalian retina.

Title: Synaptic and glial cell responses to neuroinflammation in spinal organotypic slices

Authors: *G. PANATTONI[1], V. GIACCO[3], C. BALLERINI[4], L. BALLERINI[2];
[2]Neurosci., [1]SISSA-ISAS, Trieste, Italy; [3]SISSA-ISAS Trieste, Trieste, Italy; [4]Univ. di Firenze, Firenze, Italy

Abstract: Neuroinflammation is a characterizing trait of various central nervous system (CNS) pathologies, from neurodegenerative diseases to neuropsychiatric disorders.In the effort of dissecting the impact of immune status alterations on neural circuit function, we focused our study on the effects of local inflammation in a controlled micro-environment where neurons and neuroglial cells maintain their appropriate organization: the organotypic spinal cord slices. These cultures, developed from the spinal cord of mouse embryos, represent a complex in vitro model where sensory-motor cytoarchitecture, synaptic properties and spinal cord resident cells, encompassing heterogeneous neuronal phenotypes and neuroglia, are retained in a 3D fashion.Organotypic spinal cord slices are cultured for two weeks in vitro. Then, they are exposed for 4 and 6 hours to a cocktail of cytokines (CKs, 10 ng/mL), composed by tumor necrosis factor alpha (TNF alpha), interleukin-1 beta (IL-1 beta) and granulocyte macrophage-colony stimulating factor (GM-CSF), or to lipopolysaccharide (LPS, 1 µg/mL). We use single cell electrophysiology, live cell calcium imaging, immunocytochemistry and confocal microscopy to investigate and compare the spinal tissue responses to neuroinflammation induced by CKs and LPS. We focus first on the synaptic level, describing the shortening of GABAergic current due to CKs incubations, absent in LPS treated ones, despite the overall increased network activity. We further explore by immunofluorescence and confocal microscopy, resident neuroglia reactivity and by calcium live imaging we document an increase in the occurrence of calcium waves displayed by the glial cells located in the ventral horn, differently tuned by the diverse threats.

Title: Calcitonin gene-related peptide (CGRP) influences cortical spreading depolarization (CSD) in adult rats - Could this be important in brain pathophysiology?

Authors: F. GIMENO-FERRER[1], F. RICHTER[1], R. BAUER[2], *A. LEHMENKUHLER[3], H.-G. SCHAIBLE[1];
[1]Inst. of Physiol. I, [2]Inst. of Mol. Cell Biology, CMB-Center for Mol. Biomedicine, Univ. Hosp. Jena, Jena, Germany; [3]Pain Inst., Duesseldorf, Germany

Abstract: It is known from the literature that CGRP plays an important role in migraine, and antagonizing CGRP is an effective treatment against migraine pain. CSD, the correlate of the migraine aura, is able to release CGRP in rat neocortical slices. CGRP may increase neuronal excitability, but a possible interference with CSD has not been investigated yet. To test this, we applied CGRP at different concentrations topically to a restricted part of the cortical surface and compared the electrocorticogram and CSD there with the untreated brain area. In spontaneously breathing anesthetized adult rats (sodium thiopentone, 100 mg/kg, i.p.) CSDs were recorded in cerebral cortex with two pairs of glass micropipettes (distance 5-6 mm) at depths of 400 and 1200 µm in two areas of the cortex, separated by a wall. In the untreated area, CSD was elicited by a microinjection of 1 M KCl (100 kPa, 300 ms up to 1 s) into the grey matter at intervals of 30 min. In the remote area 100 µl of CGRP at concentrations from 10^{-8} M to 10^{-5} M were applied topically and left there for three hours. In the treated area additionally changes in extracellular potassium concentration and in both areas regional cortical blood flow were measured. In all rats tested, a pulse of KCl elicited a single propagating CSD. The topical application of CGRP to the brain surface reduced the amplitudes of CSD in the treated area (10^{-5} M to 60 % of controls; 10^{-8} M to 70 % of controls; untreated to 85-90 % of controls) and slowed the propagation velocity (10^{-5} M from 3.0 to 2.6 cm/s; 10^{-8} M from 2.4 to 2.2 cm/s). Rarely spontaneous CSDs were observed originating from the CGRP treated area. In another few rats CGRP induced focal ictal activity after 2-3 hours of application that did not spread into the untreated cortex. This activity was accompanied by increases in extracellular potassium concentration and occurred at intervals of 8-10 min. Our results identify the neuropeptide CGRP as a candidate that could interfere with CSD by changing neuronal excitability. In contrast to other previously investigated

neuropeptides, the capability of CGRP to ignite CSD at the same concentrations varies markedly between the animals. This has to be taken into account when using CGRP as a model for neuroinflammation or disturbed brain homeostasis.

Title: The effect of a high fat diet on endocannabinoid-mediated astrocyte-neuron signaling in the arcuate nucleus

Authors: *A. K. SCOTT[1], C. D. MURAT[2], P. KOFUJI[1], A. ARAQUE[1];
[1]Neurosci., Univ. of Minnesota, Minneapolis, MN; [2]Physiol., Univ. of São Paulo, Ribeirão Preto, Brazil

Abstract: Astrocyte-neuron interactions in the arcuate nucleus (ARC) of the hypothalamus are emerging as important elements of regulating energy homeostasis. The dysregulation of this astrocyte-neuron interaction may contribute to the imbalance in energy homeostasis that leads to obesity. An acute high fat diet (HFD) is known to induce astrogliosis in the ARC. However, the functional effect of this astrogliosis has seldom been explored. Here we examined the effects of HFD on astrocyte-neuron signaling in the ARC of adult, male and female mice. Using calcium indicators in acute coronal brain slices, we found that spontaneous calcium activity in ARC astrocytes was increased in mice fed with HFD compared to animals fed with normal diet. Using whole-cell patch clamp electrophysiology, we also found an increase in the frequency of slow inward currents (SICs), which are known to be mediated by astrocytic glutamate release and consequential activation of neuronal extrasynaptic NMDA receptors, in ARC neurons from animals fed a HFD. No HFD-induced changes in astrocyte calcium or SICs were observed in $IP_3R2^{-/-}$ mice. Due to the increased levels of endocannabinoids (eCBs) within the arcuate of obese mice and patients, we investigated the effects of a HFD on eCB-mediated astrocyte-neuron signaling. Using transgenic and pharmacological tools, we found that eCBs regulate the frequency of basal astrocyte calcium oscillations and SICs in control and HFD animals. These findings indicate the existence of astrocyte-neuron communication in the ARC, its regulation by eCB signaling, and its dysregulation in HFD.

Title: Glial cells induced restructuring of corpus callosum and pattern of constancy in fractional anisotropy in high-grade glioma

Authors: *V. PAREEK[1], P. K. ROY[2];
[1]Natl. Brain Res. Ctr., Manesar, India; [2]Natl. Brain Res. Ctr., Manesar (NCR Delhi), India

Abstract: Introduction High-Grade Gliomas (HGG) with poor prognosis is the fatal gliomata condition. In the current study, we endeavor to explore the restructuring/remodeling induced in the corpus callosum (CC) structure evaluated using diffusion tensor imaging (DTI) application. **Materials and Methods** The unilateral HGG subjects are exclusively recruited for this study having normal appearing CC in the T1 weighted structural image and the FA map of the subject's diffusion space. The total of 8 glioma and control subjects are scanned for T1-weighted images and DTI acquisitions using 3 Tesla magnetic resonance scanner. Turbo field echo (TFE SENSE) sequence and pulse sequence with 32 gradient directions with a gradient of 1000s/mm2 are used for TI-weighted and DTI acquisitions respectively. FDT (FMRIB's Diffusion Toolbox) a software tool from FSL (FMRIB's Software Library) is used for the analysis of diffusion-weighted images evaluating Fiber density, Radial Diffusivity (RD), Mean Diffusivity (MD), Fractional Anisotropy (FA), and Lattice Index (LI). **Results** No differences ($p>0.05$) observed for Fiber density, RD, FA, and LI. Mild Significant Difference ($p=0.028$) for MD is observed. **Discussion** With the glioma cell infiltration in the CC, the axonal loss is evident because of malignant glioma-induced neuronal cell death because of glutamate excitotoxicity primarily, the increased cellular count of glioma cells may induce the CC to undergo remodeling whereby the fiber density does not change, even though the CC dystrophies. The constancy of FA and LI are representative of in-variant fiber density. The mild increase in MD and no difference in RD represents slight edema and myelin intactness respectively in the glioma condition.

Fiber Density and Diffusivity Indices/	t	df	*p*-Value	*p*-Value Summary	R squared (eta squared)	Glioma Effect ($p < 0.05$)

Title: Excitatory amino acid transporters (EAATs) and presynaptic afferent metabotropic glutamate Receptors (mGluRs) differentially limit synaptic currents via control of presynaptic calcium and extracellular glutamate kinetics in normoxia and chronic intermittent hypoxia (CIH)

Authors: *D. MARTINEZ[1], G. E. HERMANN[2], E. M. HASSER[3], R. C. ROGERS[2], D. D. KLINE[4];
[1]Univ. of Missouri, Columbia, MO; [2]Pennington Biomed. Res. Ctr., Baton Rouge, LA; [3]Univ. Missouri-Columbia, Columbia, MO; [4]Biomed. Sciences/Dalton CRC, Univ. Missouri, Columbia, MO

Abstract: The nucleus tractus solitarii (nTS) is the first central integration site for visceral reflexes including the chemoreflex. Sensory afferent signals are transmitted to the nTS via release of glutamate (Glu). Extracellular Glu is removed from the synaptic cleft via EAATs, limiting Glu receptor activation. We have shown that general EAAT block with DL-TBOA reduced the amplitude of afferent (TS)-evoked EPSC (TS-EPSC). Interestingly, both activation of Group II/III mGluRs and CIH, a model of obstructive sleep apnea, decrease TS-EPSC amplitude. Here we sought to identify the contribution of presynaptic mGluR-II/III receptors, which attenuate TS-EPSCs in naïve rats, to the decrease in TS-EPSC amplitude following EAAT

block and CIH. We used a combination of electrophysiology, live cell imaging with the fluorescent Glu reporter (iGluSnFR), and presynaptic afferent Ca^{2+} imaging. Male Sprague-Dawley 3-8 week old rats underwent 10 day normoxia (Norm, 21% O_2) or CIH (alternating 21% O_2 and 6% O_2, 8h/day) followed by brain slice generation. Prior to slice generation, a subset of rats received either nTS microinjection of AAV-hSyn-iGluSnFR followed by 4 weeks of expression, or injection into the nodose ganglia of the Ca^{2+} tracer Cal-520 Dextran and allowed 5 days for anterograde nTS transport. TS-EPSC amplitude in monosynaptic nTS neurons, extracellular Glu concentration $[Glu]_e$, or presynaptic Ca^{2+} [(ΔF/F)%] was monitored during 20 Hz stimulation in aCSF, EAAT block (TFB-TBOA, 500 nM) alone, and during block of EAAT and mGluR-II/III receptors (eGlu & MSOP 200 μM). In Norm, EAAT block reduced TS-EPSC amplitude, and mGluR-II/III block limited the EAAT-induced depression. To confirm a presynaptic mechanism, presynaptic Ca^{2+} was measured; Ca^{2+} entry decreased after EAAT block but was restored to control after EAAT-mGluR-II/III block. To examine the consequence of reduced afferent Ca^{2+}, which is responsible for attenuated TS-EPSCs, we examined $[Glu]_e$. EAAT block increased $[Glu]_e$ relative to aCSF; additional mGluR-II/III block further enhanced $[Glu]_e$ and dramatically slowed its decay. In CIH-exposed rats, TS-EPSC amplitude was smaller compared to Norm. However, in CIH EAAT block increased TS-EPSC amplitude differing from the decrease seen in Norm. Following CIH, in aCSF $[Glu]_e$ during 20 Hz stimulation was reduced relative to Norm. EAAT block produced only a modest increase in $[Glu]_e$, further mGluR-II/III block dramatically enhanced $[Glu]_e$. These data suggest that EAATs regulate $[Glu]_e$, Glu kinetics and the amplitude of TS-EPSCs through mGluR Group II/III. CIH reduces EAAT influence on synaptic activity and mGluRs contribute to the reduced TS-EPSC.

Title: Impact of a TREM2 variant on neuronal pathology in a mouse model of tauopathy

Authors: *V. JADHAV[1], G. XU[3], S. PUNTAMBEKAR[3], S. BISSEL[3], P. LIN[4], S. PHILTJENS[5], M. MOUTINHO[3], A. OBLAK[2], B. T. LAMB[3];
[2]STARK Neurosci. Res. Inst., [1]Indiana Univ. Sch. of Med., Indianapolis, IN; [3]Stark Neurosciences Res. Inst., Indianapolis, IN; [5]Stark Neurosciences Res. Inst., [4]Indiana Univ. Sch. of M, Indianapolis, IN

Abstract: Genome-Wide Association Studies have identified variants of Triggering Receptor Expressed on Myeloid cells-2 (TREM2) as risk factors for different types of dementia. The TREM2-R47H variant confers increased risk for developing Alzheimer's disease, while the TREM2-Y38C mutation is associated with a Frontotemporal Dementia-like phenotype. Hyperphosphorylated tau (pTau) is the key similarity in these diseases, however, the impact of microglial TREM2 on tau pathology remains understudied. We hypothesized that TREM2 mutations will change microglial homeostasis early in the disease, leading to altered tau pathology and neuronal functions.
To test this, we generated mice expressing human tau (htau) with the TREM2-Y38C mutation (htau;Trem2$^{Y38C/+}$). We found that 6-month-old htau;TREM2$^{Y38C/+}$ mice showed reduced intraneuronal pTau as compared to controls. There was a nonsignificant trend of reduced cortical neuronal counts in htau;TREM2$^{Y38C/+}$ mice, suggesting neuronal death did not significantly account for the reduced tau pTau. Next, we analyzed protein levels of PSD95 and synaptophysin in cortical brain lysates and found a reduction in PSD95, but not in synaptophysin, suggesting a loss of post-synaptic elements. These results suggest that reduced intraneuronal tau is not protective. For an unbiased look at pathology, we performed gene expression analysis, using the mouse Neuroinflammatory panel from NanoString Technologies on cortical lysates. Endothelial cells showed the most gene changes in htau;TREM2$^{Y38C/+}$ mice, therefore, we quantified cortical cytokines using Meso Scale Discovery to recognize the factors that impact endothelial cells. Increased IL12, IL6 and decreased IL2 in htau;TREM2$^{Y38C/+}$ mice were observed. These cytokines have been reported to reduce vascular permeability.
Vascular permeability alters neuronal functions and excitability which potentially explains the significant alterations observed in neuronal genes in our Nanostring analysis. We plan to study the underlying mechanisms of reduced intraneuronal pTau and altered neuronal functions elicited by TREM2-Y38C mutation by deciphering the molecular links between microglial TREM2 and endothelial cell hemostasis.

Title: Signaling through the C3a receptor modulates peri-infarct reactive gliosis after ischemic stroke

Authors: A. STOKOWSKA[1], Y. LI[1], J. MORAN SUAREZ[1], M. PEKNY[2], *M. PEKNA[1]; [1]Lab. of Regenerative Neuroimmunology, Dept. of Clin. Neurosci., [2]Lab. of Astrocyte Biol. and CNS Regeneration, Dept. of Clin. Neurosci., Sahlgrenska Acad. at the Univ. of Gothenburg, Gothenburg, Sweden

Abstract: Ischemic brain injury is a powerful inducer of reactive gliosis that serves to demarcate the lesion and restore tissue homeostasis. Prolonged reactive gliosis, can, however, inhibit ischemia-induced plasticity and functional recovery. Complement is a component of the innate immune system that has emerged as a regulator of multiple neural processes such as developmental neuronal migration, synaptic pruning and neuroprotection.
We previously showed that signaling through the receptor for complement-derived peptide C3a (C3aR) stimulates neural plasticity and intranasal treatment with C3a facilitates recovery of motor function after ischemic stroke (Stokowska et al., Brain, 2017). In an *in vitro* ischemia model, C3a increased the survival of astrocytes and reduced their expression of GFAP (Shinjyo et al, Mol Neurobiol, 2016). Here we used the photothrombotic stroke model in mice to investigate the role of C3a-C3aR axis in the regulation of glial responses to brain ischemia. We observed that transgenic overexpression of C3a in reactive astrocytes reduced the immunoreactivity of GFAP in the peri-infarct cortex 3 weeks after ischemic stroke; the absence of C3aR had the opposite effect. Overexpression of C3a increased whereas the absence of C3aR reduced the density of microglia and infiltrating blood-derived monocytes / macrophages (Iba-1 positive cells). Daily intranasal treatment of wild-type mice with C3a for 2-3 weeks starting 7 days after stroke induction reduced the expression of GFAP but did not affect the density of Iba-1 positive cells in the peri-infarct cortex assessed 3 and 8 weeks after ischemic stroke. Together these results show that the C3a-C3aR axis regulates reactive gliosis in the peri-infarct region exerting opposite effects on astrocytes and microglia / macrophages. Modulation of peri-infarct reactive astrogliosis may contribute to the positive effect of intranasal treatment with C3a on neural plasticity and functional recovery.

Title: Actomyosin inhibition in astrocytes leads to cytoskeleton remodeling and to an enhanced neuronal regenerative profile

Authors: *S. C. LEITE[1], R. SANTOS[2], A. MEI[3], M. C. MARCHETTO[3], F. H. GAGE[3], Z. LENKEI[2];
[1]Inst. of Psychiatry and Neurosci. of Paris, Inserm U1266, Paris, France; [2]Inst. of Psychiatry and Neurosciences of Paris, Inserm U1266, Paris, France; [3]Lab. of Genet., The Salk Inst. of Biol. Studies, La Jolla, CA

Abstract: Cytoskeleton remodeling is fundamental for neuronal development and function and its impairments often featured in neurodegenerative diseases. A major key regulator of actin cytoskeleton is the RhoA/ROCK pathway. RhoA/ROCK pathway is a negative regulator of axonal regeneration and its role has been confirmed in *in vivo* models of central nervous system (CNS) injury. However, transition to clinics has been hindered by many systemic side effects of inhibitors of the RhoA/ROCK pathway. An interesting alternative is the targeted inhibition of a key individual downstream effector that would ideally result in a similar effect with decreased side effects. Here, we present actomyosin inhibition as an alternative to target to RhoA/ROCK pathway.
Actomyosin is a negative regulator of axonal growth by direct reorganization of the axonal growth cones. However, it's *in vivo* use has been limited because blebbistatin, the commonly used inhibitor, has low aqueous solubility and high toxicity. Recently, new blebbistatin-derived molecules such as para-amino-blebbistatin and para-nitro-blebbistatinhave been developed, conjugating decreased toxicity with increase solubility and photo-stability, while conserving the growth-enhancing effect of blebbistatin in neurons. Importantly, actomyosin inhibition by these new tools in astrocytes leads to a fast morphological reorganization, leading to the reactive astrocyte stellate shape. According to recent literature, stellate reactive astrocytes can either be of a protective or of a pro-inflammatory subtype. Our data suggests that actomyosin-inhibited astrocytes are not pro-inflammatory, as shown by their interleukin secretion profile. Moreover, the secretome of actomyosin inhibited astrocytes has a pro-regenerative effect in neurons, further suggesting that actomyosin inhibition drives astrocyte maturation into a protective subtype.
Our data suggests that the regulation of the CNS into a more permissive environment through actomyosin inhibition opens new solutions to enhance CNS regeneration in neurodegenerative conditions.

Title: Lipolysaccharide attenuates NMDAR dependent LTD in the nucleus accumbens

Authors: *B. C. COLEMAN, D. KASHIMA, B. GRUETER;
Vanderbilt Univ., Nashville, TN

Abstract: The nucleus accumbens (NAc) is a key node within the mesolimbic reward network implicated in maladaptive motivational states including addiction. Adaptations at glutamatergic synapses in the NAc critically contribute to behavioral states associated with drugs of abuse. Recent work from our lab and others suggests a contribution from the innate immune system in synaptic function. Particularly, toll-like receptor 4 (TLR4), a pattern recognition receptor known to activate the innate immune response, has been implicated in NAc circuit development and synaptic plasticity. While synaptic plasticity mechanisms in the NAc are increasingly well-characterized, little is known about how the innate immune system regulates synaptic strength. We hypothesized that microglia, the brain's resident macrophage which express TLR4, modulate synaptic plasticity within the NAc. Utilizing *ex vivo* slice electrophysiology and D1 dopamine receptor reporter mice, we report that lipopolysaccharide, an immunogenic TLR4 agonist, attenuates NMDAR-dependent long-term depression in the NAc core. Further studies are ongoing to elucidate the mechanisms by which activated microglia can alter synaptic function in the NAc, and may ultimately contribute to maladaptive motivational states.

Title: The role of axons in glioblastoma migration

Authors: *G. VELEZMORO JAUREGUI, V. M. POZO DEVOTO, M. NOVAKOVÁ, M. FEOLE, V. LACOVICH, G. B. STOKIN;
Translational Neurosci. and Aging Program (TAP), FNUSA-ICRC, Brno, Czech Republic

Abstract: Derived from glial cells, glioblastoma (GBM) is the most common and highly aggressive malignant brain tumors affecting adults. Currently, the standard treatment combines surgery with chemo- and radio-therapy. Despite enormous advances on the therapeutic field, the median overall survival is of only 12-18 months mainly because the GBM property to infiltrate

over a significant distance in the brain parenchyma; commonly along nerve fiber tracts followed by extracellular matrices of blood vessels according to clinic-pathological observations. Studies on GBM migration are hindered by the lack of efficient *in vitro* or *in vivo* migration models that describe their real-time interaction with axons. In this study, we postulate that glioblastoma cells exploit axons as physical tracks for their migration. We plan to test this hypothesis by co-culturing neurons and glioblastoma cell lines on microfluidic devices. In order to achieve this goal, a well characterized neuronal culture differentiated from human Inducible Pluripotent Stem Cells (iPSC) was used to be co-cultured with Glioblastoma line A172 (ATCC® CRL1620™) in compartmentalized microfluidic devices that allow specific interaction between GBM and isolated axons. The number of GBM able to migrate through the channels in presence and absence of axons was recorded every 24 hours using time lapse imaging. Our preliminary data show out an interesting close interaction between GBM and axonal structures in terms of migration.Further experiments already planned will shed light on understanding the genes and molecular pathways involved in the migration of GBM on axonal fibers.

Title: The reduction of astrocytic Epm2a induces GLT1 process withdrawal accompanied by neuronal damage in a neuron-glia mixed culture system

Authors: *C.-C. HUNG[1], S.-P. HSU[1], Y.-H. LEE[1,2];
[1]Physiol., Natl. Yang-Ming Univ., Taipai, Taiwan; [2]Natl. Yang-Ming Univ., Brain Research Center, Taiwan

Abstract: Laforin, encoded by the *Epm2a* (epilepsy of progressive myoclonus type 2 A), is a dual specificity phosphatase with a carbohydrate-binding module that prevents glycogen hyperphosphorylation leading excessive glycogen deposition, and maintains normal glycogen metabolism through forming a complex with an E3 ligase, malin. Astrocytes are the main glycogen storage cells that provide energy to neurons in the brain for survival and function. *Epm2a* deficiency increases the abnormal glycogen inclusions knowns as Lafora bodies, and recently reported to decrease the expression of surface glutamate transporter 1 (GLT1) in

astrocytes. In this study, we investigated the effects of specific knockdown of *Epm2a* in astrocytes on glutamate homeostasis, neuronal survival, and neuron-astrocyte interaction in a neuron-glia culture system. We used GFAP promoter-driven shRNA to specific knockdown *Epm2a* expression in astrocytes. On immunostaining with GLT1 and MAP2, we found that astrocytic *Epm2a* knockdown significantly caused GLT1 process withdrawal and decreased the number of neuronal dendrites in this mixed cultured cell; moreover, western blot analysis showed the induction of GLT1 protein expression in the neuron-glia culture. Further, the survival pathway of AKT phosphorylation was decreased after astrocytic *Epm2a* knockdown. We also found that *Epm2a* knockdown in pure astrocytes with stellate-like morphology revealed shorter GLT1-labeled process and decreased GAP43 phosphorylation, which mediates astrocyte plasticity. Thus, astrocytic *Epm2a* may mediate astrocyte plasticity and GLT1 function to support neuronal survival. Importantly, *Epm2a* increases GLT1 expression on the astrocytic process to maintain glutamate homeostasis and prevent excitotoxicity leading to neuron damage.

Title: Repeated morphine or fentanyl administration in rats induces glial and neuronal NLRP3 inflammasome activation on the dorsal raphe nucleus

Authors: *C. J. CARRANZA-AGUILAR, C. GONZÁLEZ-ESPINOSA, S. L. CRUZ; Dept. de Farmacobiología, Ctr. de Investigación y de Estudios Avanzados del IPN, Mexico City, Mexico

Abstract: Morphine and fentanyl are effective μ-opioid receptor (MOR) agonists, but tolerance to their analgesic effects develops after repeated use. Several opioids induce neuroinflammation by nuclear transcription factor (NF)-κB-dependent pro-inflammatory cytokine release, but the participation of intracellular innate immune receptors in the phenomenon remains as an important question to be solved. Here, we studied the effects of repeated administration of morphine or fentanyl on NOD-like receptor protein 3 (NLRP3) activation in glial and neuronal cells in the dorsal raphe nucleus (DRN), which exerts a regulatory role in pain. Male Wistar rats (250 g) were i.p. injected with morphine (10 mg/kg) or fentanyl (0.1 mg/kg) three times daily, for 6 days. Antinociception was measured by the tail-flick test after the 1st, 7th, and 19th

administration. Activation of caspase-1 and NLRP3 was analyzed by immunofluorescence. For specific cell staining, the following antibodies were used: anti CD11b (microglia), anti-Glial Fibrillary Acidic Protein (GFAP) for astrocytes and anti-NeuN for neurons. As expected, repeated morphine or fentanyl administration produced analgesic tolerance to different extents. Rats develop hyperalgesia two hours after the 19th fentanyl (but not morphine) administration. Co-treatment with any of the used opioids and the NF-κB inhibitor minocycline delayed tolerance development. Both morphine and fentanyl increased the immunoreactivity to NLRP3 and caspase-1 in astrocytes and neurons (but not in microglia), whereas fentanyl produced greater effects. NLRP3 activation was mediated by opioid receptors because naloxone co-treatment prevented it. Differences between both opioids were also observed in their ability to induce NLRP3 activation in the DRN. In conclusion, repeated morphine and fentanyl induces NLRP3 activation in DRN and drugs targeting NF-kB or NLRP3 could be used as adjuvant therapy to prevent opioid tolerance.

Title: Crosstalk between stressed brain-cells: Direct and indirect effects of ischemia and aglycemia in microglia

Authors: *M. RABENSTEIN[1], S. U. VAY[1], S. BLASCHKE[2,3], H. L. WALTER[1], A. LADWIG[1], G. R. FINK[1,3], M. SCHROETER[1,3], M. A. RUEGER[1,3];
[1]Neurol., Univ. of Cologne, Cologne, Germany; [2]Dept. of Neurol., Univ. of Cologne, Koeln, Germany; [3]Res. Ctr. Jülich, Jülich, Germany

Abstract: *Background:* In cerebral ischemia, microglia have a dichotomous role in keeping the balance between pro- and anti-inflammatory mediators to avoid deleterious chronic inflammation and to leverage repair processes. *Methods:* We examined functional and inflammatory markers in primary rat microglia *in vitro* after oxygen-glucose-deprivation (OGD) or glucose-deprivation (aglycemia). We then investigated the preconditioning effect of OGD or aglycemic preconditioning to a subsequent strong inflammatory stimulus, namely lipopolysaccharides (LPS). Moreover, an "*in vitro* brain model" of neurons and glia, differentiated from primary rat neural stem cells, was exposed to OGD or aglycemia. Conditioned medium (CM) of this neuronal/glial co-culture was then used to pre-condition microglia, followed by LPS as a "second

hit". *Results:* OGD or aglycemia at sublethal doses did not significantly affect microglia function including the expression of inflammatory markers. However, preconditioning with either OGD or aglycemia led to a decreased pro-inflammatory response to a subsequent stimulus with LPS. Interestingly, the anti-inflammatory markers IGF-1 and IL-10 were additionally reduced after such preconditioning, while expression of CD206 remained unaffected. Treatment with CM from the neuronal/glial co-culture alone did not affect the expression of inflammatory markers. In contrast, preconditioning with CM increased the expression of both pro- and anti-inflammatory markers from microglia upon a second hit with LPS. *Conclusions:* Data suggest specific and distinct microglia signatures in response to metabolic stress: While metabolic stress directly applied to microglia mitigated their subsequent response to inflammation, indirect metabolic stress experienced by neighboring cells such as neurons and astroglia induced microglia alertness, with subsequent increase of both pro- and inflammatory microglia markers.

Title: The effects of adolescent intermittent ethanol exposure on astrocyte-synaptic coupling and contact mediated signaling

Authors: *C. D. WALKER[1], H. G. SEXTON[1,2], M.-L. RISHER[1,3,2];
[1]Joan C. Edwards Sch. of Medicine, Marshall Univ., Huntington, WV; [2]Huntington Veteran Affairs Med. Ctr., Huntington, WV; [3]Duke Univ. Med. Ctr., Durham, NC

Abstract: INTRODUCTION: Adolescence is a critical time of brain development, characterized by neuronal maturation and refinement of synaptic circuitry. During this period, increased independence is at odds with delayed development of inhibitory control, contributing to impulsive, risky behavior including binge drinking. Animal models of binge drinking have shown that ethanol (EtOH) engenders long-term deficits in cognition associated with changes in neuron structure and function, but the mechanisms underlying these changes are not well understood. While progress has been made to understand the consequences of binge drinking on neuronal function, little is known about the effects of EtOH on glia. Astrocytes couple with synapses and through secreted and contact mediated signaling, play a critical role in regulating

synaptic structure and function. Therefore, we hypothesize that adolescent EtOH exposure disrupts astrocyte-synapse coupling to drive changes in neuronal circuitry that persist into adulthood.
METHODS: Male Sprague Dawley rats received intracranial injections of an astrocyte-specific adeno-associated GFP virus in medial prefrontal cortex (mPFC) and dorsal hippocampus (dHIPP). Beginning at PND30, animals received intermittent EtOH (5g/kg i.g.) or water for 16 days. Brains were collected 24 hours after the 10^{th} dose and 26 days later (PND70). Co-localization of postsynaptic marker PSD95 with fine astrocyte processes was quantified from 3D reconstructions generated via IMARIS analysis of confocal microscopy-imaged astrocytes. Western blotting was performed to investigate the expression of proteins involved in astrocyte-synaptic contact mediated signaling.
RESULTS: 24 hours after the 10^{th} dose of EtOH there was a significant decrease in the co-localization of astrocytic processes with PSD95 in dHIPP, indicative of astrocyte-synaptic decoupling. Data from mPFC will also be presented. At PND70 there is a significant decrease in astrocyte volume and a decrease in astrocyte-synaptic coupling following EtOH in both the dHIPP and mPFC. Changes in protein expression will also be presented.
CONCLUSION: Appropriate communication between astrocytes and neurons via secreted and contact mediated signaling require astrocytes to be in close proximity to synapses. The decoupling of astrocyte-synaptic partners may play a critical role in the disruption of normal synaptic structure and function that we have previously observed following adolescent intermittent EtOH exposure.

Title: An analysis of hippocampal microglia and astrocytes in a rat model with features of delirium reveals possible mechanisms behind memory dysfunction

Authors: *L. G. RODRIGUES[1], N. SALLA[2], A. S. ARNOLD[1], J. WEIR[3], S. L. PATTERSON[1];
[1]Biol., [2]Dept. of Biol., [3]Temple Univ., Philadelphia, PA

Abstract: Older individuals are more likely to experience an abrupt decline in mental function, termed delirium, after events (e.g. infection, injury, or surgery) that trigger activation of the

peripheral immune system. Although the decline is often temporary, it is associated with increased risk for dementia and can exacerbate existing neurocognitive dysfunction. Little is known about the underlying mechanisms of this decline, but a rodent model may provide some clues. Aging (24 month old) F344xBN rats are generally healthy with no major physical or cognitive deficits. However, after a peripheral immune challenge (i.p. injection of *E. coli*), the brains of aged rats mount an exaggerated inflammatory response (producing more pro-inflammatory cytokines, e.g. IL-1β) compared to those of younger (3 month old) counterparts. The aberrantly elevated levels of these cytokines are associated with deficits in memory and synaptic plasticity.
Memory-related plasticity is dependent on complex, highly regulated interactions between neurons, astrocytes, and microglia. Microglia phagocytize foreign invaders and clear debris from damaged CNS cells; they also interact with neurons by removing synapses marked by "eat-me" signals (C1q and C3). We have shown that microglia display a more amoeboid morphology, consistent with a more activated state in aged vs young, and *E. coli*- vs saline-injected. The combination of age and *E. coli*-injection exacerbated these differences. Similarly, we are investigating the distribution and morphological profiles of astrocytes to better understand their role in the immune response in the aging brain. Astrocytes may interact with microglia to regulate neuroinflammation and maintain neuronal health and integrity.
During development, astrocytes and microglia contribute to the elimination of inappropriate synapses and integration of new neurons into existing circuits, essential processes for establishing appropriate connectivity in a healthy brain. Increasing evidence suggests that adult neurogenesis is regulated by similar neuron-glia interactions involved in memory formation. We will investigate how glial responses to acute immune challenge may impact the process of neurogenesis. Immunohistochemistry (IBA1, GFAP, DCX) will be used to examine differences in microglia, astrocytes, and newly differentiated neurons between young and aged rats. A more complete understanding of interactions between these cells following an immune challenge could provide insights into the etiology of delirium.

Abstract: Chronic inflammation in the hypothalamus has been proposed as a key pathological factor that alters feeding behaviors and energy homeostasis associated with obesity and diabetes. Emerging evidence suggests that metabolic shift from oxidative phosphorylation to glycolysis contributes to neuroinflammatory responses and pathophysiology of diverse neurological disorders. We report that streptozotocin- or high fat diet-induced diabetes enhanced hypothalamic expression and activity of pyruvate dehydrogenase kinase (PDK), a key regulatory enzyme in mitochondria, that caused glycolytic metabolic shift along with substantial inflammatory activation in the hypothalamus. Genetic ablation or inhibition of hypothalamic PDK attenuated diabetes/obesity-induced neuroinflammatory hallmarks in the hypothalamus and food/calorie intake. Moreover, dysregulation of hypothalamic neuropeptidergic circuitry involved in the regulation of feeding behavior was improved by deficiency or inhibition of hypothalamic PDK. Studies using primary astrocytes revealed that PDK plays a critical role in altered glycolytic metabolism and inflammatory activation of glial cells, which favor hypothalamic inflammation *in vivo*. Collectively, these findings unveil a novel role of PDK in regulating metabolic and inflammatory pathways that contribute to hypothalamic manifestations of diabetes and obesity.

Title: Are astrocytes the stars controlling orofacial cortical neuroplasticity?

Authors: *L. AVIVI-ARBER;
Univ. of Toronto Dent., Toronto, ON, Canada

Abstract: In the healthy brain, star-shape astroglial cells (i.e., astrocytes) play an important role in driving, mediating and modulating neuronal function and neuroplasticity. Similar to neurons, astroglial cells have a remarkable capacity for structural as well a functional plasticity that underlies their diverse functions. Little is known of their structural characteristics within the orofacial sensorimotor cortex and their involvement and roles in orofacial sensorimotor functions in health and after injury or disease. In this presentation, findings from our recent studies will be presented. We have shown that: **(1)** extraction of 3 maxillary molar teeth produces sex-dependent changes in peri-oral mechanosensitivity of BXA24 mice; **(2)** extraction of 3 maxillary molar teeth induces, 1-8 weeks later, **(a)** functional neuroplasticity in Sprague-Dawley rats and C57BL/6J male mice manifested as decreased jaw and tongue motor representations and sensorimotor cortex excitability; **(b)** structural plasticity in BXA24 female mice manifested as decreased volume of MRI-defined gray and white matter of the sensorimotor cortex; **(c)** sex-dependent structural plasticity in BXA24 mice manifested in differential morphological changes in astroglial processes; **(3)** acute noxious stimulation of the tooth pulp in Sprague-Dawley male rats produces decreased sensorimotor cortex neuroplasticity manifested as decreased excitability that can be modulated by inhibition of the astroglial enzyme glutamine synthetase (GS) within the sensorimotor cortex. GS is a specific astroglial enzyme that converts the astroglial glutamate to glutamine which is a major precursor for the excitatory (glutamate) and inhibitory (gamma aminobutyric acid, GABA) neurotransmitters in neurons; **(4)** tooth extraction in Sprague-Dawley rats and BXA24 mice can produce sex-dependent plasticity in the morphological features of astroglial cells. Acute tooth stimulation can also produce astroglial plasticity in Sprague-Dawley male rats. Better understanding of neuro-astroglial processes within the sensorimotor cortex is an important step towards the development of improved prevention and management of impaired oral sensorimotor functions.

Title: Human astrocytoma line 1321N1 spontaneously drives SH-SY5Y neuronal differentiation in the absence of traditional differentiation factors in coculture

Authors: A. F. HOFFMAN, P. NUTHULAGANTI, A. S. GOETZ, ***J. C. CLEMENS**; GlaxoSmithKline, Collegeville, PA

Abstract: As the incidence of neurodegenerative diseases continues to rise, it is becoming increasingly clear that these diseases will represent the top unmet medical and public health needs in the coming decades. We are developing neuron-based 384 well assay platforms for target and phenotypic based drug discovery approaches. The platform utilizes the SH-SY5Y neuroblastoma cell line that can be differentiated into a dopaminergic neuron phenotype. Traditionally, SH-SY5Y differentiation protocols utilized retinoic acid, dibutyryl cyclic AMP, and brain derived neurotrophic factor to achieve differentiation and support cell survival. We have found that these factors could be removed from the differentiation protocol if the SH-SY5Y cells were grown in coculture with the human astrocytoma line called 1321N1 in the presence of Laminin 521. SH-SY5Y cells elaborate robust neurite processes in the coculture by day ten, which is similar to what we typically see in SH-SY5Y monoculture with differentiation factors at three weeks. Once differentiation has occurred, the elaborated neuron networks can be maintained in culture for several weeks allowing for the analysis of both short and long-term assay modalities. Coculture of SH-SY5Y cells not only reduces reagent costs and time to produce the assay platform, it also is more representative of the *in vivo* environment and a better experimental system for drug discovery. Combined with high content image analysis and a battery of cellular and mitochondrial health reporters, we anticipate that this platform will better enable and accelerate drug discovery and our understanding of the etiology of neurodegenerative diseases.

Title: Inhibition of IDO1 metabolically reprograms the neuronal milieu to rescue energetic and cognitive deficits in Alzheimer's disease

Authors: *P. S. MINHAS[1], A. L. HERNANDEZ[1], M. MCREYNOLDS[2], L. LIU[2], E. GAUBA[1], S. D. MHATRE[3], J. RABINOWITZ[2], F. LONGO[1], K. ANDREASSON[1];
[1]Dept. of Neurol. and Neurolog. Sci., Stanford Univ., Stanford, CA; [2]Lewis-Sigler Inst. for Integrative Genomics, Princeton Univ., Princeton, NJ; [3]AMES Res. Ctr., NASA, Mountain View, CA

Abstract: Background: Metabolic dysfunction is a well characterized feature of Alzheimer's disease (AD) that often precedes symptomatic AD. Indoleamine-2,3-dioxygenase 1 (Ido1) is the rate-limiting step of de novo nicotinamide adenine dinucleotide (NAD+) synthesis from tryptophan, an enzymatic cascade that is expressed in the glia of the brain. In this study, we sought to determine whether glial de novo NAD+ synthesis through Ido1 impacts cognition in AD. Method: APP PS1;IDO1-/- mice were subject to electrophysiologic, metabolomic, and behavioral studies. Genetics studies were complemented with pharmacological administration via oral gavage of Ido1 inhibitor EOS200271/PF-0684003 (15mg/kg) in APP-PS1 and 5xFAD mice for 10d. Metabolomics was performed using a Q-trap LC-MS/MS. Result: IDO1 inhibition increased the glial NADH/NAD+ ratio within the hippocampus of transgenic or treated mice, favoring the production of lactate. *In vivo* isotope metabolite tracing revealed a decrease in lactate shuttling from the astrocyte to the neuron through the monocarboxylate transporter 4 (MCT) in AD mice. Specifically, decreased U-13C-Glucose incorporation into the TCA cycle and oxidative phosphorylation resulted in decreased LTP and spatial memory deficits. APP-PS1;IDO1-/- mice as well as AD mice treated with the IDO1 inhibitor exhibited a rescue in metabolomic, LTP, and cognitive deficits. Blockage of MCT4, the transporter responsible for translocation of lactate from the astrocyte to the neuron, recapitulated cognitive deficits seen in AD even when the Ido1 enzyme was inhibited. Conclusion: Ido1 plays a pivotal role in the bioenergetic phenotype of glia and glial production of lactate may serve as a novel therapeutic target for normalization of bioenergetic and cognitive phenotypes associated with AD.

Title: Xenotransplantation of human PSC derived microglia creates a chimeric mouse brian model that recapitulates features of human adult microglia

Authors: *R. XU, P. JIANG;
Rutger Univ., Piscataway, NJ

Abstract: Microglia, the brain-resident macrophages, exhibit highly dynamic functions in neurodevelopment and neurodegeneration. Human microglia possess unique features as compared to mouse microglia, but our understanding of human microglial functions is largely limited by an inability to obtain human microglia under resting, homeostatic states. We developed a human pluripotent stem cell (hPSC)-based microglial chimeric mouse brain model by transplanting hPSC-derived primitive macrophage precursors into neonatal mouse brains. The engrafted human microglia widely disperse in the brain and replace mouse microglia in corpus callosum at 6 months post-transplantation. Single-cell RNA-sequencing of the hPSC microglial chimeric mouse brains reveals that xenografted hPSC-derived microglia largely retain human microglial identity, as they exhibit signature gene expression patterns consistent with physiological human microglia and recapitulate heterogeneity of adult human microglia. Importantly, the chimeric mouse brain also models species-specific transcriptomic differences in the expression of neurological disease-risk genes in microglia. This model will serve as a novel tool to study the role of human microglia in brain development and degeneration.

Title: P2X7 receptor-mediated reactivation of retinal microglia in a mouse chronic ocular hypertension model

Authors: *X. HU, G.-L. ZHAO, N. YIN, F. LI, Y. MIAO, X.-L. YANG, Z. WANG;
Inst. of Brain Science, State Key Lab. of Med. Neurobio. and MOE Frontiers Ctr. for Brain Science, Fudan Univ., Shanghai, China

Abstract: In the present study, we investigated the mechanisms underlying retinal microglia reactivation in a mouse chronic ocular hypertension (COH) model. Our results showed that the

branched microglia in normal retina was changed to the ramified and amoeboid-like one and further agminated during 4 day to 4 weeks (G4d to G4w) after the elevation of intraocular pressure (IOP). The rod-like microglia in morphology was observed during G4w to G6w. Meanwhile, microglia was translocated from the inner/outer plexiform layer to the ganglion cell layer in COH retina. The expression of translocator protein (TSPO), a marker of the reactivated microglia, was increased in COH retinas, which could be reversed by intravitreal/intraperitoneal injections of the P2X7 receptor (P2X7R) inhibitor brilliant blue G (BBG), suggestive of P2X7R-mediated reactivation of microglia. Calcium imaging showed that the P2X7R agonist BzATP-induced elevation in intracellular Ca2+ level was quicker and higher in acutely isolated microglia from COH retinas, as compared with control. Moreover, in primary cultured mouse microglia, BzATP treatment increased the TSPO protein level, and induced the release of inflammatory factors (IL-6 and TNF-α). These results suggest that P2X7R mediates retinal microglia reactivation in experimental glaucoma model.

Title: Gene-wide screen and validation of micriglia pro-inflammatory mediators in stroke

Authors: *Y. YI[1], **Y. LU**[2];
[1]The Inst. for Brain Research, Collaborative in, Wuhan, China; [2]Sch. of Basic Med., Huazhong Univ. of Sci. and Technol., Hubei, China

Abstract: Stroke activates microglia pro-inflammatory response that not only induces the early neuronal injuries but also causes the secondary brain infarction. Yet, the underlying mechanisms for how microglia becomes activated in stroke are still unknown. Here, using the next-generation of RNA sequencing we find a total of 778 genes increasingly expressed in brain of stroke mice. Of these, Hmgb2 is validated as a microglia activator and pro-inflammatory mediator. Hmgb2 binds to a promoter region of Ctss and activates Ctss transcription. Inhibition of either Hmgb2 or Ctss blocks microglia pro-inflammatory response and protects against brain damages and improves the neurological functions of stroke mice. The same neuronal protective effects against stroke injuries are achieved by knocking down C3ar1 gene, a complement 3a receptor 1 that modulates cytotoxic neuronal immune reactions in stroke. This study uncovers Hmgb2, Ctss and C3ar1 as the major microglia inflammatory and immune response mediators in stroke and hence warrants the promising targets for stroke therapies.

Title: Microglial networks in response to exogenously delivered particles in the brain

Authors: *A. OGAKI, Y. IKEGAYA, R. KOYAMA;
Grad. Sch. of Pharmaceut. Sciences, The Univ. of Tokyo, Tokyo, Japan, Tokyo, Japan

Abstract: Immune response mechanisms to exogenously delivered factors in the brain remain unclear. Accumulating evidence suggests that exogenous particles such as PM2.5 in the environment, especially those particles with a diameter less than a micron, i.e., nanoparticles, have been found in the human brain. Further, it has been suggested that the early-life exposure to nanoparticles can be a cause of the development of psychiatric disorders such as cognitive dysfunction, attention-deficit hyperactivity disorder (ADHD), or depression. However, cellular and molecular mechanisms how nanoparticles affect the structure and function of brain remain unknown. Here we examined the possible involvement of microglia, the resident major immune cells in the brain, in nanoparticle-mediated brain malfunction. We administered silica nanoparticles, major components of yellow dust in the atmosphere, to postnatal mice. Three days after the administration, we found the invasion of silica nanoparticles in the brain parenchyma. The nanoparticles were frequently found around the brain vessels and were surrounded and engulfed by gathering microglia. Further, the process of microglia that engulfed the nanoparticles often interacted each other. Real-time imaging of microglia in vitro revealed that silica nanoparticles engulfed by one microglia were frequently passed to another microglia in a form incorporated in microglia-associated vesicles. Finally, the nanoparticle-injected mouse pups exhibited aggressive and anxiety-like behaviors and these behavioral abnormalities were correlated to the activation of microglia around silica nanoparticles. Thus, it is possible that activated microglia configure microglial networks in response to silica nanoparticles for the protection of brain structure and function.

University, Sch. of Med., Shimotsuke, Japan; [4]Sch. of Med. Sci., UNSW Australia, Sydney, Australia

Abstract: Microglia are sole immune cells in the central nervous system (CNS). Microglia are activated in neurological diseases such as multiple sclerosis, Alzheimer's disease and epilepsy, and release cytokines and neuro-trophic factors, which act on neurons and vessels to affect disease pathologies. The inflammatory cytokines released from the activated microglia enhance the permeability of the blood-brain barrier (BBB), which causes infiltration of immune cells and worsens intracerebral inflammation. On the other hand, microglia are also activated even during systemic inflammation such as severe infections or auto-immune diseases (e.g., systemic lupus erythematosus: SLE) that increase BBB permeability. However, it is not clear how systemic inflammation causes microglia activation and brain pathologies. Since microglia are highly motile cells and frequently contact vessels, this study focused on microglia, and investigated their dynamics and change of BBB permeability during systemic inflammation. Toward this goal, this study used SLE model mice and systemic inflammation induced by lipopolysaccharide (LPS) intraperitoneal injection. Using two-photon *in vivo* imaging, we showed that microglia migrated to the vessel in response to systemic inflammation which was associated with increased BBB permeability. Following genetic ablation of microglia, BBB permeability was increased in the early phase and reduced in the late phase of systemic inflammation. Those results indicated that microglia prevent BBB leakage in the early phase of inflammation, but exacerbate the leakage under prolonged inflammation. Further details shown by immunostaining revealed that vessel-associated microglia expressed Cldn5, a tight junction-related molecule, in the early phase and a phagocytosis marker, CD68, in the late phase. The CD68 immunoreactivity co-localized with that of a BBB component, aquaporin-4, suggesting that microglial phagocytosis of BBB component impairs BBB functions. In addition, inhibition of microglial activation with minocycline suppressed the increase of BBB permeability in the late phase. In summary, these

results showed that microglia have a dual function onto the BBB, and suggest that microglia can be the therapeutic target for the brain pathologies induced by systemic inflammation.

Title: Dreadded microglia in ethanol-induced neuroimmune signaling and epigenetic modification

Authors: *J. Y. ZOU, L. G. COLEMAN, F. T. CREWS;
Ctr. for Alcohol Studies, Univ. North Carolina, Chapel Hill, Chapel Hill, NC

Abstract: Microglia play a critical role in ethanol-induced persistent brain neuroimmune signaling. To dissect the role of microglia in neuroimmune signaling during ethanol exposure, the present study used a novel Designer Receptor Exclusively Activated by Designer Drugs (DREADD) to selectively inhibit microglia in an organotypic hippocampal-entorhinal cortex (HEC) slice culture model. DREADDs under a CD68 (microglia/macrophage) promoter were transfected via an AAV9 vector. HEC slices were transfected with inhibitory Gi-coupled DREADDs for 24hrs and then treated with ethanol (100mM) for 4 days in the absence or presence of the DREADD-selective ligand clozapine-N-oxide (CNO). RT-PCR analysis indicates that ethanol-treated Gi-DREADD slices without CNO stimulation had significant higher levels of proinflammatory mediator mRNAs such as IL-1β, TNFα, MCP-1 and Trail comparing those activated by CNO stimulation. Similarly, activation of Gi-DREADD slices with CNO significantly reduced proinflammatory cytokine induction stimulated by TLR4/7 agonist LPS (100ng/ml) and Imiquimod (5ug/ml) respectively. These data suggest an essential role of microglia in neuroimmune signaling in response to ethanol and TLR activation. Furthermore, intracellular epigenetic molecules including G9a, KMD6B, DNMT1, DNMT3a and 3b were monitored. Our data indicate that ethanol exposure of Gi-DREADD slices significantly increased G9a, KMD6B and DNMT3a mRNA levels, which were further potentiated by CNO activation of Gi-DREADD slices. However, CNO activation of Gi-DREADD slices resulted in significant

reduction of DNMT1 and DNMT3b mRNA expression altered by ethanol exposure. We also tested the effects of CNO-alone on the expression of neuroimmune genes and epigenetic molecules in this model. Treatments of HEC slices with CNO alone for 4 days dose-dependently increased proinflammatory cytokine gene expression but significantly down-regulated epigenetic molecules, for example: TNFα.(Control:100±1; CNO-500nM:70±6; CNO-1uM:215±11; CNO-10uM:1346±19); G9a (Control:101±12; CNO-500nM:68±7; CNO-1uM:59±2; CNO-10uM:44±7). Together, these results reveal the important role of microglia in ethanol-induced neuroimmune signaling and epigenetic modification. Our results also suggest that cell type-specific DREADD-based approach may be a unique tool to selectively explore the physiological and pathological role of neurons or glia during ethanol exposure. Title: Microglia collect maternally delivered exogenous nanoparticles in the postnatal brain

Authors: *R. KONO, Y. IKEGAYA, R. KOYAMA;
The Univ. of Tokyo, Tokyo, Japan

Abstract: Growing attentions have been paid to the influence of exogenous nanoparticles, including $PM_{2.5}$ in air pollution, on the brain. Particularly, embryonic brains are considered to be fragile to the invasion of exogenous nanoparticles because of the immaturity of blood-brain barrier. In addition, epidemiological studies have suggested that the exposure to concentrated exogenous nanoparticles during prenatal life correlates with the increased possibility to exhibit attention-deficit hyperactivity disorder (ADHD) later in life, but the underlying cellular mechanisms left undiscovered. Here, we examined the possible involvement of the brain resident immune cell microglia in the regulation of exogenously delivered nanoparticles during pregnancy in the brain of offspring. Silica nanoparticles, major components of yellow dust in atmosphere, were intranasally administered to pregnant mice. The brains of offspring during postnatal days were subjected to immunohistochemical analysis to examine the localization of fluorescently-labeled silica nanoparticles. We often encountered localized silica nanoparticles in cerebral cortex and meninges. Further, we found that localized nanoparticles were engulfed by

accumulating microglia. Because the processes of microglia that incorporated nanoparticles were extended toward the brain surface, it is possible that microglia play a role to remove maternally delivered nanoparticles from the postnatal brain.

Title: Chemokine production by microglia mediates blood derived-monocytes trafficking in neuroinflammation

Authors: M. HUANG[1,2], J. KIM[1], J. PARK[1,2], W. LEE[1], *J. LEE[1,2,3];
[1]Dept. of Anatomy, Yonsei Univ. Col. of Med., Seoul, Korea, Republic of; [2]BK21 Plus Project for Med. Science, Yonsei Univ. Col. of Med., Seoul, Korea, Republic of; [3]Brain Res. Institute, Yonsei Univ. Col. of Med., Seoul, Korea, Republic of

Abstract: Microglia and recruited macrophages play major roles in neuroinflammation. We explored how these cells affect counterpart's polarization and infiltration and revealed some chemokines and receptors can be important modulators of the interaction. We set up a undirect co-culture system of BV2 (microglia cell line) and THP-1 (monocyte cell line). BV2 or THP-1 cultured in M1, M2 conditioned media. Transwell migration was used for assessment of THP-1 infiltration and BV2 migration. M1/M2 conditioned media of BV2 and THP-1 were assessed by proteome profiler array to find target cytokine and chemokine. The expression of chemokine receptors in THP-1 was confirmed by western blotting. 8 weeks old male, CCR2::RFP C57BL/6J mice were obtained from Jackson Laboratories (Bar Harbor, ME) and followed by LPS injection (i.c.v). All animal procedures were following National Institutes of Health guidelines. Mice were anesthetized with an intraperitoneal (i.p.) injection of a mixture of zoletil (100 mg/kg) and xylazine (rompun, 10 mg/kg). THP-1 expressed CD206 when cultured in M2 conditioned media of BV2, and also got increased the infiltratory ability. Several chemokines such as CCL2, CCL3, CCL4 and CCL5 were significantly increased in conditioned media of BV2 while their receptor CCR4, CCR5 shows high expression in THP-1. Antagonists of CCR2, CCR4 and CCR5 significantly reduced the infiltration ability of THP-1 to BV2 M2 conditioned media. CCR2 positive cells in mouse cortex were significantly increased after LPS injection, when CCR4, CCR5 antagonist co-injection can reduce the number of infiltrated CCR2 positive cells.

Chemokine receptors CCR4, CCR5 can be strong candidates of target protein in new therapeutic strategies to acute brain inflammation by modulating the functions of microglia and monocytes.

Title: Targeting neuregulin-mediated microglial activation in Alzheimer's disease

Authors: *F. SONG, J. LIU, S. SCHRAM, S. MARTIN, J. A. LOEB;
Univ. of Illinois at Chicago, Chicago, IL

Abstract: The gliotrophic factor neuregulin1 (NRG1) is a key neuronal communication signal critical for normal peripheral and central nervous system development. However, in the mature nervous system NRG1 is reactivated in response to injury and leads to abnormal, pathogenic microglial activation. This occurs in the spinal cord after peripheral nerve injury in a model of chronic pain and in the SOD1 model of amyotrophic lateral sclerosis (ALS) where NRG1 promotes disease progression through microglial activation and neuronal death. We have developed a novel way to block NRG1 signaling using a humanized fusion protein that targets heparin-rich surfaces using NRG1's heparin-binding domain fused to a decoy NRG1 receptor called HBD-S-H4. We have previously shown that HBD-S-H4 effectively blocks microglia-induced inflammation after nerve injury preventing chronic pain and slows ALS disease onset and progression by blocking inflammatory microglia and preventing motor neuron loss in SOD1 mice.

In Alzheimer's Disease (AD), microglia have mixed roles in disease progression by both clearing Aβ deposits and releasing cytotoxic mediators. Aβ has been shown to activate microglia through innate immune receptors. Here, we hypothesize that NRG1 signaling from neurons to surrounding microglia promotes the local spread of AD pathology through microglial activation that could lead to synaptic loss and neurodegeneration. We found that intraventricular NRG1 augments microglial activation and Aβ plaque formation in early-stage 5XFAD mice. Blocking endogenous NRG1 activity with HBD-S-H4 prevents microglial activation and Aβ plaque formation in early-stage and reduces microglial activation and Aβ plaque formation in later stage disease. Mechanistically, NRG1 induces pro-inflammatory cytokine expression in cultured microglia and decreases $A\beta_{42}$ and the $A\beta_{42}/A\beta_{40}$ ratio in 5XFAD mice. Consistently, we have previously found that human cerebrospinal fluid from AD patients has increased NRG1 activity compared to normal controls or patients with other neurodegenerative diseases. Our results

suggest that blocking NRG1 signaling prevents and reduces AD pathology and supports the future use of our targeted therapeutic to slow disease progression in AD.

Title: Optogenetic manipulation of microglia inhibits fundamental response properties

Authors: *L. LAPRELL, T. G. OERTNER;
Ctr. for Mol. Neurobio., Hamburg, Germany

Abstract: Microglia are the only resident immune cells in the brain. Under physiological conditions microglia are highly ramified; with their thin processes they surveil the surrounding area and detect changes in the extracellular space, such as dying neurons, invading organisms, or alterations in neuronal activity. Under physiological conditions microglia exhibit a hyperpolarized membrane potential around -40 mV. Hyperpolarization together with low cAMP levels result in high microglial ramification and baseline surveillance. However, hyperpolarization has also been linked to pathophysiological microglia activation states, such as ageing and local tissue damage. Surprisingly, this damage-induced hyperpolarization could not be directly linked to the chemotactic response of microglia. In contrast, depolarization of microglia by pharmacological blockade or genetic deletion of potassium channels as well as raising extracellular K^+ leads to retraction of processes and decrease in microglia surveillance activity, also inducing an activated microglia phenotype. As pharmacological manipulations may affect glia, microglia and neurons, a direct causal link between microglia membrane potential, chemotaxis and activation state has been difficult to establish. By selectively manipulating microglia membrane potential using optogenetic tools we are able to gain a better understanding of the relationship between membrane potential and microglia activation state. Activation of channelrhodopsin with blue light allows us to depolarize microglia robustly. Repetitive light stimulation at 1 Hz can be applied for at least 45-60 minutes without adverse effects. In our experiments, we tested whether optogenetic depolarization before and during the local tissue damage affects the chemotactic response towards the damaged area. Activation of channelrhodopsin reduced the amplitude of damage-induced hyperpolarization and more importantly, increased the response time towards the damaged site. This attenuation in

chemotactic motility establishes neuronal damage-induced membrane hyperpolarization as a causal factor in microglia motility. We hypothesize that optogenetic depolarization reduces the driving force for Ca^{2+}, a very tightly controlled second messenger in microglia which has been shown to play a role in the induction of chemotaxis. In future experiments, we would like to use optogenetic microglia manipulation not only to investigate intracellular signaling pathways, but also to study the role of microglia in synaptic physiology with high temporal and spatial precision.

Title: Restraint stress suppresses microglia activation and production of pro-inflammatory cytokines

Authors: *Z. YU[1], M. SAKAI[4], Y. TAKAHASHI[2], C. ONO[3], H. TOMITA[3];
[1]Disaster of Psychiatry, Tohoku Univ., Sendai, Japan; [2]Dept. of Disaster Psychiatry, Tohoku Univ., Sendai-Shi, Japan; [3]Tohoku Univ., Sendai, Japan; [4]Dept. of Disaster Psychiatry, Grad. Sch. of Med. ,tohoku Univ., Sendai, Japan

Abstract: Altered inflammatory cytokine profiles are observed in the peripheral blood of patients with major depression and the brain of depression mice models, which suggest that depression is accompanied by immune dysregulation and activation of the inflammatory response system. Microglia are the primary immune cells of the central nervous system, which form a major component of the brain immune system and release pro- and anti-inflammatory cytokines in neurodegenerative diseases. However, microglial activation response to chronic stress such as chronic restraint stress had not been extensively explored. In this study, we subjected mice to 3 weeks restraint stress and allowed to recover for 3 weeks to investigate the stress and recovery impact on microglia activation. We found that restraint stress induced depression-like behaviors that were maintained 2 weeks after cessation of restraint stress. Following the restraint stress, microglia activation was significantly suppressed with decreased *Tnf, Il1b, Il10* and *Tgfb1* mRNA expression compared with controls. During the first week or two of recovery period, microglia activation and its M2 phenotype marker *Cd86* mRNA expression displayed a significant up-regulation along with significantly increased *Tnf, Il1b,Il10* and *Tgfb1* mRNA expression. Furthermore, *Il10* and *Tgfb1* mRNA expression were significantly increased throughout the 3 weeks after cessation of chronic restraint stress. These findings demonstrated that a chronic stressful event could produce delayed immune response in the brain,

may help us understand the microglia reversibility of the effects of chronic stress, which could also be used for further studies on anti-depression drug development.

Abstract: The role of microglia/macrophages after ischemic stroke is poorly understood. This study is to examine the function of microglia/macrophages in the focal infarct area after transient middle cerebral artery occlusion (MCAO) in rhesus monkeys. We evaluated infarct volume with MRI and neurological function to assess subsequent temporal changes. The post-mortem brains (n = 8) were harvested and analyzed immunohistochemically including two controls and at 3 and 24 hours; 2 and 4 weeks; 4, and 20 months respectively after MCAO by examining activated phagocytic microglia/macrophages. We found that the infarct volume progressively decreased from 1 to 4 weeks after MCAO, along with the neurological recovery. Cluster of differentiation (CD) 68-expressing microglia/macrophages in the infarct lesion were identified more in the chronic stage (2 weeks-20 months) than in the acute stage (3-24 hours). Surprisingly, 96-99 % of transforming growth factor beta (TGFβ) was co-localized in CD68-expressing cells. In addition, Ki67 was found in neurons and microglia in the infarct area. Collectively, microglia/ macrophages in the chronic stage, may exert anti-inflammatory effects by expressing TGFβ, which can promote neurogenesis and functional recovery after ischemic stroke.

Title: Effects of α7 nicotinic receptor positive allosteric modulator PNU120596 on expression of PPAR-α and NF-κB following LPS-induced depressive-like behavior in mice

Authors: *S. RAHMAN[1], S. ALZAREA[2];
[2]Pharmaceut. Sci., [1]South Dakota State Univ., Brookings, SD

Abstract: Previous evidence indicates that brain α7 nicotinic acetylcholine receptor (α7 nAChR) has a critical role in regulating neuroinflammation implicated in the pathophysiology of major depressive disorder (MDD). The α7 nAChR stimulation was found to modulate the anti-inflammatory activity of nuclear peroxisome proliferator-activated receptor-α (PPAR-α) via its endogenous ligands in the brain. The objective of the present study was to determine the effects of PNU120596 on expressions of PPAR-α and nuclear factor-κB (NF-κB) in the hippocampus and prefrontal cortex, MDD-relevant brain regions in an inflammatory mouse model of MDD. We also examined the combination effects of PNU120596 and GW6471, a PPAR-α antagonist, against lipopolysaccharide (LPS)-induced depressive or cognitive deficit-like behavior using tail suspension test (TST), forced swim test (FST) and Y-maze test. Systemic administration of LPS (1 mg/kg, i.p.) resulted in downregulation of PPAR-α and upregulation of phosphorylated-NF-κB p^{65} in the dentate gyrus and CA1 regions of the hippocampus, and prefrontal cortex. The PNU120596 pretreatment (4 mg/kg, i.p.) significantly prevented LPS-induced dysregulation of PPAR-α and p-NF-κB p^{65} in these specific brain regions. The PNU120596 showed antidepressant-like activity against LPS-induced depressive-like behavior by decreasing immobility time during TST and FST. LPS-induced cognitive deficit-like behavior was also attenuated by the effects of PNU120596 due to increasing spontaneous alternations during Y-maze test. Coadministration of PNU120596 and GW6471(2 mg/kg) resulted in the disappearance of antidepressant and pro-cognitive-like effects of PNU120596. Overall, these results suggest that PPAR-α plays a key role in regulating antidepressant-like effects of PNU involving α7 nAChR signaling pathway in MDD. (*Supported in part by grant from SACM*)

Abstract: Microglia play critical roles in maturation and refinement of neural networks during postnatal brain development. Although microglia have been shown to arise from the yolk sac and colonize the CNS during early embryogenesis and undergo expansion during the first two postnatal weeks, it remains unclear what intrinsic signals regulate early postnatal microglia and how disruption of microglia at this stage affects brain function. Here we report that signal transducer and activator of transcription 3 (Stat3) regulates microglial survival and activation in the developing brain and that neonatal disruption of Stat3 signaling in microglia results in impaired hippocampal synapse plasticity in adult mice. *Cx3cr1*$^{CreERT2/+}$*:Stat3*^{loxP} mice were generated to achieve inducible deletion of exon 22 of the *Stat3* gene in microglia, which results in truncated Stat3 protein incapable of nuclear translocation. Neonatal *Stat3* ablation caused spontaneous microglial over-activation and transient loss of microglial cell population at postnatal day 10 (P10) that was recovered by P28. The transient decrease of microglial density was due to increased DNA damage and cell cycle arrest, and was associated with increased immune responses including type I interferon signaling, complement pathways and cytokine/chemokine production as determined by transcriptome analysis of acutely isolated microglia. Although adult microglia were morphologically indistinguishable between Stat3 mutant and littermate controls, hippocampal long-term potentiation was significantly impaired in the mutant mice. Similarly, the mutant mice exhibited spatial and social memory deficits. Together, our data demonstrate that Stat3 signaling plays a critical role in normal postnatal microglial development, and highlight that early-life events disrupting microglial regulatory networks at critical developmental stages could have long-term neurological consequences.

Title: Acute effects of α7nAChR agonists on pro-inflammatory cytokine release in primary microglia

Authors: *M. E. HAMMARLUND, S. HUA, F. ALBABILY, M. E. JOHANSSON;
Dept. of Neurosci. and Physiol., Univ. of Gothenburg, Gothenburg, Sweden

Abstract: Background: Inflammation is a key mediator in ischemic brain injury, and microglia, the "macrophage of the brain" plays a central role in providing immunosurveillance. The alpha 7 acetylcholine nicotinic receptor (α7nAChR), present on peripheral macrophages are involved in the cholinergic anti-inflammatory pathway. The α7nAChRs are also expressed in the brain were they contribute to regulation of neuronal plasticity and neuroprotection. The aim of this project was to investigate the effect of two different agonists specific for the α7nAChR on pro-inflammatory cytokine release in microglia. **Methods:** Primary microglia was isolated from C57BL6Jrj mice pups, 0-3 days old. Microglia was stimulated for 4 hours with LPS (10ng/ml) with or without AR-R17779 (1-15 μM) or for 24 hours with LPS (10ng/ml) with or without PHA 568487 (0.5 μM). Cytokine release was measured in the supernatants using TNFα and IL-6 ELISA. **Results:** Stimulation with the specific α7nAChR agonist AR-R17779 at 5, 10 and 15 μM significantly decreased the release of TNFα after 4 hours incubation with LPS ($p < 0.05$). There was no significant difference in TNFα or IL-6 release between cells stimulated with PHA or LPS + PHA for 24 hours. **Conclusion:** The specific α7nAChR agonist AR-R17779 exhibits anti-inflammatory effects in microglia after 4 hour activation with LPS, while no statistical difference was seen after stimulation with PHA 568487 for 24 hours. However, it is possible that a higher concentration and different time point would result in a different outcome.

Title: Increased number and altered morphology of hippocampal microglia in a female rat model of alcohol use disorder

Authors: *J. K. MELBOURNE[1], H. PENG[2], C. ANASOOYA SHAJI[3], K. NIXON[3]; [1]Pharmacol. & Toxicology, Univ. of Texas at Austin, Austin, TX; [2]Pharmaceut. Sci., Univ. of Kentucky, Lexington, KY; [3]Pharmacol. & Toxicology, The Univ. of Texas at Austin, Austin, TX

Abstract: Neuroimmune activation is a common feature of neurodegeneration, including in alcohol use disorders (AUDs). Microglia are one of the main drivers of a neuroimmune response in male rat models of AUDs; however, very little is known about microglial alterations following ethanol exposure in female rats. Microglia exhibit a range of contextually sensitive morphologies. They are highly ramified at “rest” and upon activation undergo cytoskeletal rearrangements spanning from hyper-ramification to a “fully activated” ameboid morphology. Therefore, we examined microglial morphology and number in a female rat model of an AUD. Rats were gavaged with 25% (w/v) ethanol (n=8) or isocaloric control diet (n=8) every 8 h for 4 days (modified Majchrowicz model), which resulted in 10.2 ± 0.9 g/kg/d ethanol and yielded 384.2 ± 19.4 mg/dl blood ethanol concentrations. Rats were perfused transcardially 7 days post alcohol, a time when glial activation remains high in male rats. Brains were harvested, sectioned on a vibrating microtome, and immunohistochemistry was performed for microglial marker, Iba-1. Pre-processing and quantification of microglial morphology was carried out on hippocampal (dentate gyrus) sections using ImageJ (FIJI). Intensity threshold and size filter parameters were adjusted to create two images displaying; 1) the entire cell body and processes, and 2) the cell body only. The ‘analyze particles’ function was used to quantify total cell size, cell body size and cell number for each image. Individual cells were selected for further analysis. Sholl analysis and fractal analysis (FracLac for FIJI) was carried out to determine the number of intersections per radius and to quantify the complexity (fractal dimension) and heterogeneity (lacunarity) for each cell. Binge ethanol increased microglia number ($p=.0001$) and average cell body to cell size ratio ($p<.0001$) in the female rat hippocampus compared to controls. Conversely, the average cell size ($p<.0001$), cell body size ($p=.02$) and cell process size ($p<.0001$) were decreased in ethanol animals. Sholl analysis of individual cells showed an overall decrease in the number of intersections ($p<.0001$) in microglia in ethanol rats. Further, the fractal dimension of the microglia was decreased ($p<.0001$), whereas lacunarity was increased ($p=.01$). These data

demonstrate that microglia in female rat hippocampus proliferate and decrease in size, primarily due to a decrease in ramification, which suggests a retraction of processes consistent with activation. Thus, we have demonstrated three complementary methodologies to quantify microglia morphological complexity at the multi- and individual-cell level.

Title: Single prolonged stress increases hippocampal inflammation and produces PTSD-related behaviors in rats

Authors: *O. I. TORRES-RODRÍGUEZ, Y. RIVERA-ESCOBALES, M. COLÓN-ROMERO, B. VELAZQUEZ-PEREZ, A. HERNANDEZ, J. T. PORTER;
Ponce Hlth. Sci. Univ., Ponce, Puerto Rico

Abstract: Post-traumatic stress disorder (PTSD) is a neuropsychiatric disorder often characterized by impaired discrimination between safe and harmful signals from the environment and increased peripheral inflammation. In addition, patients with PTSD may exhibit exaggerated anxiety and difficulty extinguishing fear-related memories. Although stress and inflammation are closely associated with PTSD, it is not well understood whether exposure to stress alters inflammatory signaling in the brain to cause the cognitive impairments seen in PTSD. We hypothesized that exposure to stress would impair cue discrimination, impair fear extinction and increase anxiety by increasing inflammatory microglial activity in the ventral hippocampus (vHPC). To test this, we exposed adult male and female rats to single prolonged stress (SPS) and then differential cue fear conditioning, extinction, and open field test 7 days later. Three days after SPS, we found increased expression of the pro-inflammatory genes high mobility group box 1 (HMGB1) and IL1b in the vHPC suggesting increased inflammation prior to behavioral treatment. Our behavioral results showed that both non-stressed (NS) and SPS-exposed animals were able to discriminate between auditory cues. However, SPS animals showed impaired fear extinction and increased anxiety. After behavioral analysis, we evaluated microglia activity in

the vHPC. Immunofluorescence staining showed increased Iba-1 expression in SPS-exposed animals, suggesting increased microglial activity. To further characterize vHPC microglial activity, we examined isolated hippocampal microglia with fluorescence-activated cell sorting (FACS) and found no differences in the expression of the pro-inflammatory marker, CD86. Our results suggest that exposure to SPS increases inflammatory processes and hippocampal microglia activity to impair fear extinction and increase anxiety.

Title: Increased amperage in electroconvulsive shock decreases microglia branch order

Authors: *E. A. AQUINO, R. M. HINES, D. J. HINES;
Univ. of Nevada Las Vegas, Las Vegas, NV

Abstract: Damage to the central nervous system activates a series of structural and functional changes to microglia, collectively known as reactive microgliosis. Reactive microgliosis is implicated in both the symptomology and treatment of many neuropsychiatric disorders. Electroconvulsive therapy is an effective treatment for neuropsychiatric disorders, however, its typically only used on those who are treatment resistant. Although beneficial for treatment resistant, it has a potential to cause damage to the CNS due to the electroconvulsive shock itself. Weak stimulation paradigms with low amperage have low potential for damage but also reduced therapeutic potential. There is a need for an optimal stimulation paradigm that has a high therapeutic potential but also minimizes the potential for damage. This paradigm is possible but a better understanding of the mechanisms behind ECT is necessary. In addition to helping optimize optimal stimulation, examination of how ECT affects microglia may also provide insight into the therapeutic mechanism behind ECT. To determine the effects of ECT on microglia, transcranial ECT was administered at different amperages, followed by an immunohistochemical analysis of microglia and their structure. Results show that different amperages cause a differential extent of microglia cell activation and increased amperage causes a decrease in microglia branch order. Developing a better understanding of the mechanism behind ECT and how it affects glia cells will lead to the production of an optimal stimulation paradigm, and further refinement of the procedure to optimize beneficial aspects of microgliosis.

Title: Persistent markers of neuroinflammation in Zika virus post infection stage of adult rhesus macaque

Authors: *K. M. SMITH[1], M. JACKSON[2], C. FONTENOT[3], E. L. V. SILVEIRA[4], K. A. ROGERS[5], M. M. TEIXEIRA[6], F. VILLINGER[7];

Sciences, Univ. of Sao Pablo, Sao Pablo, Brazil; [5]NIRC, New Iberia Res. Center, Univ. of Louisiana at Lafayette, New Iberia, LA; [6]Federal Univ. of Minas Gerais, Belo Horizonte, Brazil; [7]New Iberia Res. Center, UL Lafayette, New Iberia, LA

Abstract: Zika virus is a member of the flavivirus family that gained world-wide notoriety as a central nervous system teratogen after an outbreak in Brazil was linked to an increased prevalence of microcephaly in infants exposed *in utero*. Zika virus has also been linked to both autoimmune destruction of myelin proteins and Guillain-Barré syndrome, as well as macular atrophy. Zika is primarily a mosquito borne disease, and pandemic outbreaks of Zika stand to infect a large portion of the population where the Aedes aegypti and Aedes albopictus mosquitos are prevalent. Transmission via sexual intercourse has also been reported. The long-term consequences infection in adults are not well understood. We have investigated neuroinflammation of the post-infected adult brain of 3 rhesus macaque monkeys compared to 5 control monkeys. We examined astrocytes (GFAP) and microglia (Iba1) in the hippocampus and lateral geniculate nucleus via immunohistochemistry. All three monkeys had been infected with a Brazilian isolate of the Zika virus (10\7 PFUs of a Brazilian viral strain HS-2015-BA-01), intravenously, with detectable viral loads in plasma up to 7 days and mucosal secretions up to 42 days post infection. No evidence of virus persistence was obtained thereafter and the monkeys were euthanized on day 142 after infection. We therefore examined whether persistent changes in astrocyte and microglial numbers were present in the brains of infected animals at necropsy. Results: Here, we show that the number of GFAP+ cells in the lateral geniculate nucleus was increased in monkeys infected with Zika virus ($p=0.017$). We also found an increased number of Iba1+ cells in the subgranular zone and hilus regions ($p=0.03$) of the hippocampus. We conclude that in spite of the resolution of viral replication *in vivo*, increases in astrocyte and microglia

populations indicate a potential for a sustained state of neuroinflammation not previously reported. Our results raise questions to the long-term effects of Zika virus and accompanying detrimental sequelae of infection.

Title: Modeling neuroinflammation using iPSC-derived engineered microglia

Authors: *B. C. FREITAS, M. MCLACHLAN, S. J. DICKERSON, C. A. MUNN, S. A. BURTON, A. MUSINSKY, M. GOEDLAND, D. RAJESH, S. HILCOVE, E. JONES; FUJIFILM Cell. Dynamics, Inc., Madison, WI

Abstract: Neurodegenerative and neurodevelopmental disorders can display neuroinflammation settings, having microglial cells as crucial players during this detrimental stage. Microglia, the resident immune cells of the central nervous system, is a necessary cell type for neuronal homeostasis also responsible for synaptic pruning and brain development. Human iPSC-derived microglia can serve as an authentic preclinical tool for understanding the pathobiology of neurodegenerative, neurodevelopmental diseases. The present study involves the generation and characterization of genome engineered iPSC-derived iCell Microglia to facilitate disease modeling for both neurodevelopmental (Rett Syndrome) and neurodegenerative disorder (Alzheimer's and Parkinson's disease). iCell Microglia generated from both the engineered and non-engineered clones offering a unique isogenic pair for research applications. Microglia-derived by differentiating cryopreserved and purified hematopoietic progenitor cells (HPCs) and further differentiating the HPCs to microglia using technology developed by the Blurton-Jones laboratory (Abud et al. Neuron 2017.) for which FujiFilm Cellular Dynamics Inc. has an exclusive license from the University of California-Irvine. End-stage Microglia were characterized by morphology, quantification of TREM2, P2RY12, CX3CR1, IBA1, CD33 and CD45 levels by flow cytometry, quantification of a phagocytic function using pHrodo BioParticles and aggregated amyloid beta, quantification of neuroinflammatory molecules by multiplex Luminex and quantification of soluble TREM levels and finally RNAseq analysis. Cryopreserved Microglia retained purity and function comparable to pre-cryopreserved end-stage Microglia. The results identified critical differences in survival, the kinetics of phagocytosis, and levels of molecules involved in neural inflammation between healthy control lines (Ctrl) and engineered microglia. Thus, iPSC-derived isogenic controls and engineered

microglia could serve as a powerful tool to gain insight into various physiological and pathological conditions associated with neurological disorders.

Title: Microglia specific knockout of TLR4-mediated resiliency to chronic stress induced vulnerability to depression and anxiety phenotype

Authors: *U. H. IQBAL, T. FROLINGER, S. WESTFALL, G. PASINETTI;
Ichan Sch. of Med. At Mount Sinai, New York, NY

Abstract: Chronic stress-induced inflammatory responses occur in part via danger-associated molecular pattern (DAMP) molecules, such as high mobility group box 1 protein (HMGB1), but the receptor(s) underlying DAMP signaling have not been identified. Our recent findings suggested a major role for HMGB1/TLR4/NF-kB danger signaling in the microglia in stress-induced susceptibility to depression and anxiety phenotypes. Microglia morphology and DAMP signaling in enriched amygdala microglia were examined in a mouse model of microglial specific CRE-LOX knockout of TLR4 (TLR4$^{tm1.1Karp}$ Cx3cr1) during the development and expression of chronic unpredictable stress (CUS)-induced behavioral deficits, including long-term, persistent changes after CUS. Behavior and FACS enriched microglia were collected from vehicle or stressed mice exposed to CUS (CUS), followed by post-stress rest (post stress), followed by subsequent exposure to short term unpredictable stress (CUS+US), or from stressed mice exposed to short term unpredictable stress only (US) and compared to age matched non-

stressed, vehicle treated mice (Ctrl). The results show that microglial specific knockout of TLR4 prevents CUS-induced depression and anxiety phenotypes following CUS and CUS+US together with significant attenuation of CUS-induced microglia morphological changes and diminution of CUS-induced robust upregulation of cortical IL-1β protein expression. Our results provide further evidence for persistent DAMP signaling via microglia TLR4 that increases vulnerability to depressive-like behaviors long after chronic stress exposure.

Title: *Ex vivo* examination of microglial proliferation patterns following a direct lesion to the olfactory bulb of the adult zebrafish brain

Authors: *S. R. VAR, C. A. BYRD-JACOBS;
Biol. Sci., Western Michigan Univ., Kalamazoo, MI

Abstract: Plasticity of the zebrafish olfactory system makes it an ideal model for regeneration studies and for examining the immune cell response following injury. Microglia are the resident mononuclear phagocytes in the brain, with the potential to contribute to regeneration. Previously, we demonstrated the microglial response to a direct lesion to the olfactory bulb (OB), but it is unclear whether this is a contribution from local proliferation or peripheral migration. We hypothesize that, after damage, there will be a gradual increase in resident microglia, followed by an influx of macrophages from the periphery, rather than localized cellular proliferation. We compared a direct lesion injury to the right OB in the whole fish to direct lesion injury to the right OB in the ex vivo brain with afferent input removed. 4C4 antibody was used to label microglia. Proliferating cell nuclear antigen (PCNA) antibody was used to label cellular proliferation. Direct lesion injury in the whole fish showed at 1h after damage labeled microglia were scattered and ramified with few proliferating microglial profiles, comparable to controls. At 4h, there was a noticeable increase in transitioning and amoeboid microglia in both bulbs but a decrease in dividing microglial profiles compared to control. At 12h, there was an accumulation of transitioning microglia around the presumptive site of the wound in the right OB, with a noticeable increase in dividing microglia compared to controls. At 24h, there were fewer microglia compared to the previous time point but an additional increase in dividing microglia. A

direct lesion injury in the ex vivo brain showed that at 1h after damage both labeled microglia and proliferating microglia were similar to controls. At 4h, there was an increase in transitioning and amoeboid microglia around the periphery of both bulbs and a noticeable increase in dividing microglia compared to control. At 12h, there was a small decrease in amoeboid microglia around the periphery of both bulbs compared to the previous time point but levels of dividing microglia remained the same. At 24h, there was a slight decrease in transitioning microglia around the periphery and few to no dividing microglia. These results suggest that microglia can respond to damage effectively without afferent input or peripheral influence, with similar microglial response patterns as an intact brain. Comparisons between the intact and isolated brains demonstrate that further proliferation and potential contribution from peripheral leukocytes occurs at 12h and increases at 24h. Further work is required to explore the potential role of proliferating microglia in recovery and regeneration after injury.

Title: Examination of the injury response to chemical ablation in the zebrafish olfactory epithelium

Authors: *M. M. ALI, C. A. BYRD-JACOBS;
Biol. Sci., Western Michigan Univ., Kalamazoo, MI

Abstract: The ability of lower vertebrates to regenerate entire organs is an intriguing phenomenon with various beneficial implications for improving human health. Zebrafish have shared and conserved features with mammals, making them an ideal model to study regeneration. Intranasal irrigation with Triton X-100 produces severe degeneration of the olfactory epithelium, followed by rapid regeneration. We hypothesized that following chemical lesioning of the olfactory epithelium, there will be increased phagocytic activity by macrophages that leads to recovery of the epithelium. The right olfactory epithelium of adult zebrafish was damaged with infusion of 0.7% Triton X-100 into the olfactory cavity, and some fish also received an intraperitoneal injection of 50ug/ml body weight of 20mM bromodeoxyuridine (BrdU). Immunocytochemistry for anti-4C4 allowed identification of macrophages/microglia and anti-BrdU revealed cell proliferation. We determined infiltration of macrophages/microglia

into the olfactory organ and nerve at various survival times following damage.In control organs, scattered 4C4+ profiles were observed in the lamina propria of the lamellae, consistent with their role in surveying the epithelium for debris. Four hours after Triton X-100 treatment, there was obvious thinning of the olfactory epithelium from loss of olfactory sensory neurons, and numerous 4C4+ profiles were observed in the olfactory nerve and in the lamina propria beneath the olfactory epithelium of the troughs at the base of the lamellae, showing a macrophage/microglial response to the damage. At one day, enlarged oval ameboid 4C4+ profiles were present in the regions of thinned olfactory epithelium, possibly correlating with their role in phagocytizing injured neurons. At this time point, there was increased cell proliferation in the basal region of the olfactory epithelium. Additional studies will focus on determining if this degradation of damaged neurons via phagocytosis by 4C4+ cells is signaling basal cells to divide and replenish the olfactory epithelium. Further investigation will focus on understanding the mechanisms involved in the interaction between the phagocytic cells and regenerating neurons after damage, with an overall goal of facilitating recovery from neurodegenerative diseases and traumatic brain injuries.

Abstract: Abstract
Microglia are known to be important for neuropathic pain, however, a causal relationship between microglia and development of neuropathic pain has yet to be directly tested in vivo. To address this question, we have developed CX3CR1^{creER}:LSL-hM4Di transgenic mice to enable selective expression of Gi DREADD and employed microglia-based chemogenetic techniques in a mouse model of neuropathic pain. We found that microglial Gi DREADD activation inhibited

spinal nerve transection (SNT)-induced microglial activation, chronic pain initiation and maintenance. Gi DREADD activation downregulated the transcription factor interferon regulatory factor 8 (IRF8) and its downstream proinflammatory cytokines including interleukin 1 beta (IL-1β). These findings deepen our understanding the causal role of microglia in neuropathic pain pathogenesis and suggest the potential therapeutic approach of targeting microglial Gi DREADD for neuropathic pain treatment.

Title: TREM2 regulate microglia response to TDP43 pathology related neurodegeneration

Authors: *M. XIE[1], Y. LIU[1], M. P. MATTSON[2], L.-J. WU[1];
[1]Mayo Clin., Rochester, MN; [2]Lab. of Neurosciences, Natl. Inst. on Aging Intramural Res. Program, Baltimore, MD

Abstract: Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disease, which is characterized by the progressive loss of both upper and lower motor neurons in the brain and spinal cord, leading to muscle weakness and paralysis. Although it is generally believed that the disease onset is initially derived from selective motor neuron degeneration, the non-cell-autonomous nature of this disease emphasizes the contribution of glia cells in disease progression. The TAR-DNA binding protein 43 kDa (TDP-43) is an RNA binding protein which was discovered to be the main component of intracellular, insoluble protein aggregates found within motor neurons in ALS pathology. Studies from rodent models of ALS demonstrate dynamic states of microglial morphology across different stages of ALS pathology, including a neuroprotective state in the early disease stage. However the underlying molecular mechanisms are still largely unknown. Triggering receptor expressed on myeloid cell 2 *(TREM2)* is a surface receptor that is exclusively expressed on microglia in the brain and plays a crucial role in microglial proliferation, migration and phagocytosis. Heterozygous expression of *TREM2* variants has been linked to increased risk for neurodegenerative diseases, including ALS. We recently generated an ALS-like motor neurodegenerative mouse model using viral

overexpression of hTDP-43 protein in neurons (AAV9-CAG-hTDP43) or control vector (AAV9-CAG-GFP). We found overexpression of hTDP-43 in WT mice resulted in progressive microglia activation characterized by larger soma size and shorter process. In TREM2 KO mice, the microglia exhibited less reactive phenotype. We further found that CD68 expression was significantly lower in TREM2 KO mice compared with WT mice, which indicated the microglia phagocytic function deficiency in TREM2 KO mice. To test this hypothesis, we did immunostaining for phosphorylated TDP43 and found that reactive microglia cleared pathology related phosphorylated TDP-43 only in WT mice. We further compared the TDP43 proteinopathy and found that at later stage, total hTDP-43 and phosphorylated TDP43 level were significant higher in TREM2KO mice compared with WT mice. Overall our results reveal a TREM2-mediated neuroprotective role for microglia in the hTDP-43 overexpression model of ALS-like motor neuron degeneration.

Title: Microglia-astrocyte interaction drives neuromyelitis optica evolution

Authors: *T. C. CHEN, L. VANDA, Y. LIU, B. DALE, Y. LI, M.-H. YI, J. ZHU, L. WU; Neurol., Mayo Clin., Rochester, MN

Abstract: Neuromyelitis optica (NMO) is an inflammatory autoimmune CNS disorder triggered by binding of an IgG autoantibody to its antigen, the aquaporin 4 (AQP4) water channel on astrocytes. Microglia, as CNS sentinels, would be first responders to astrocytes being attacked by IgG. However, the role of microglia in the evolution of NMO is unknown. We developed an informative murine model in which NMO patient-derived IgGs are infused continuously into the spinal subarachnoid space. The outcome was that NMO-IgG induced motor impairment and classic NMO pathology in wild-type mice but not in AQP4-null mice. In vivo spinal cord imaging revealed that NMO-IgG induced microglia-astrocyte physical interaction. In mice depleted of microglia, both motor impairment and characteristic NMO immunohistopathology were significantly reduced. We further discovered that early microglial-astrocyte interaction requires astrocytic secretion of complement C3. Mice genetically lacking C3 or C3a receptor lacked motor deficits and NMO pathology after NMO-IgG infusion. Our study revealed that

early-activated complement components mediate astrocyte-microglia signaling in NMO initiation, and identifies microglia as a new target for NMO therapeutic interception.

Title: Neuronal network activity controls microglial process surveillance in awake mice via norepinephrine signaling

Authors: *Y. LIU, Y. LI, U. B. EYO, T. CHEN, A. D. UMPIERRE, J. ZHU, D. B. BOSCO, L.-J. WU;
Neurol., Mayo Clin., Rochester, MN

Abstract: Microglia are resident immune cells that dynamically survey the brain parenchyma. Microglial processes interact with neuronal elements, however, the role that neuronal network activity plays in regulating microglial dynamics is not entirely clear. Most studies of microglial dynamics have either utilized slice preparations or in vivo imaging in anesthetized mice. Here we demonstrate that microglia in awake mice have relatively reduced process area and surveillance territory. By contrast, reduced neuronal activity under general anesthesia increases microglial process velocity, extension and territory surveillance. Similarly, reductions in local neuronal activity via sensory deprivation or optogenetic inhibition increases microglial process surveillance. Using pharmacological and chemogenetic approaches, we demonstrate that reduced norepinephrine signaling is necessary for the observed increases in microglial process surveillance. Thus, we reveal that noradrenergic tone in awake mice normally suppresses microglial process surveillance under basal physiological conditions. Our results therefore unveil a novel mechanism for regulation of resting microglia dynamics.

Title: Microglial modulation of hippocampal neurogenesis after global cerebral ischemia

Authors: *A. ISAKHAROV, C. BUTLER, W. ZHU, E. SCHNELL, I. KOERNER;
OHSU Dept of Anesthesiol. and Perioperative Medi, Portland, OR

Abstract: Hippocampal neurogenesis continues into adulthood and is modulated by numerous environmental factors, including neuronal injury. However, much remains unknown regarding the factors that influence proliferation, maturation, and integration of adult-born granule cells into the hippocampal circuit after injury. As prior studies have suggested that brain inflammation modulates neurogenesis after brain injury, we are investigating the role of microglia in sculpting hippocampal neurogenesis after global brain ischemia. We use a mouse model that allows selective ablation of microglia to determine how microglia modulate neurogenesis after cardiac arrest and resuscitation. In mice with intact microglia, this model of global ischemia robustly increases cell proliferation in the dentate gyrus granule cell layer, coincident with an increase in markers expressed in immature neurons. In the absence of microglia, our preliminary data suggest dramatic alterations in the early stages of post-ischemic neurogenesis. We are currently replicating and expanding these preliminary studies, with the hope of elucidating the rapidly expanding roles of microglia in the brain and the mechanisms underlying microglial modulation of post-injury neurogenesis.

Title: Insulin and brain aging: Increasing signaling without the ligand to offset cognitive decline with aging

Authors: *K. L. ANDERSON[1], H. N. FRAZIER[1], R.-L. LIN[1], A. O. GHOWERI[1], G. J. POPA[2], M. D. MENDENHALL[2], O. THIBAULT[1];

Abstract: Acute or short term intranasal delivery of different insulin formulations has been shown to enhance insulin signaling, alter cerebral blood flow, and enhance memory recall. Other approaches that do not increase ligand availability in the brain, but instead use molecular techniques to knockout the insulin receptor (IR), introduce an IR antisense sequence via a lentivirus, or introduce an inhibitory IR binding peptide have been employed to illustrate the impact of a loss-of-function of the IR on brain function. However, it has yet to be determined whether increasing IR activity without introducing the ligand can offset cognitive decline with age. Here, we tested whether increasing insulin signaling through *in vivo* expression of a constitutively active human insulin receptor beta subunit (IRβ) in the hippocampus of young and aged rats improves spatial memory and recall. We also studied the impact of IRβ manipulation on long-term potentiation induction and maintenance, and on key markers of the insulin signaling pathway.
Preliminary studies in primary hippocampal cell cultures optimized the construct of an IRβ based on prior work from Lebwohl et al. 1991, and subsequently confirmed the expression and constitutive activity of this receptor in neurons using lentiviral delivery. Following this work, we constructed an AAV for *in vivo* delivery of HA-tagged IRβ. The AAV was bilaterally injected into the hippocampus of young (2 mo) and aged (18 mo) F344 rats. Following three months of expression, animals were tested for learning and memory recall using the Morris water maze. The animals were then divided into two groups for analysis. The first group was used for electrophysiology measures (excitability, long-term potentiation), while the other was perfused with ice-cold saline. Hippocampal dorsal and ventral extremities, thalamus, and cortex were extracted from the electrophysiology group and frozen for later use in Western blots. Saline

perfused brains were split so that one hemisphere was post-fixed for immunohistochemistry against the HA tag on IRβ, while the other was divided into hippocampus, thalamus, and cortex sections and immediately frozen for Western blots against pAkt and Akt. Results from the Morris water maze were then analyzed in the animals showing successful HA-IRβ expression. These results provide new insights and test the efficacy of this ligand-less approach for offsetting cognitive decline with aging.

Title: *In vivo* measurements of cerebral blood flow and neuronal calcium in the F344 model of aging treated acutely with intranasal insulin

Authors: *R.-L. LIN, H. N. FRAZIER, A. O. GHOWERI, K. L. ANDERSON, O. THIBAULT; Dept. of Pharmacol. and Nutritional Sci., Univ. of Kentucky Med. Ctr., Lexington, KY

Abstract: Multiphoton calcium imaging techniques are quickly becoming favored approaches for investigations into cellular mechanisms of neurodegeneration as seen in aging and Alzheimer's disease. It is also well documented that intranasal insulin (IN) improves age-related cognitive deficits and can reverse some calcium electrophysiological correlates of brain aging. Previous work from our lab has also shown that IN can increase cerebral blood flow in aged animals, providing a novel mechanism for the role of insulin in improving memory function. Given the impact of insulin on neuronal calcium processes and on cerebral blood flow, we tested whether these processes we co-dependent in the brain and in response to IN *in vivo*.
We delivered calcium sensors to the somatosensory cortex of young and aged rats to characterized neuronal calcium changes, and also acutely injected rhodamine dextran to monitor hemodynamic changes in response to peripheral hind and fore limb activation prior to, and shortly after IN delivery. Bilateral acute cranial windows were created on the day of the experiment and two-photon microscopy was used to perform line scans and frame scans across different vascular beds and neuronal layers (depth) in anesthetized animals.
As previously reported, we show here a positive correlation between vessel diameter and velocity. We did note a significant reduction in velocity across all vessel sizes imaged in the aged, compared to the young group. Hindpaw and forepaw stimulation triggered neuronal

activation in the somatosensory cortex and also elicited rapid increases in vessel diameter in both young and aged groups, particularly in larger vessels (>30 μm). An interaction term was identified where IN did not alter velocity over a 30-minute period in the young group while an increase in velocity was seen across time in the aged animals. This result highlights greater insulin sensitivity may be present in the aged, compare to the young animals.
Our results align well with few studies that have used multiphoton imaging in the aged anesthetized animal and also reported decreases in blood flow. Here we provide evidence that IN increases vessel plasticity more in the aged compared to the young animal. This could highlight a potential mechanism of action for IN enhancing memory in clinical settings.

Title: Increasing insulin receptor signaling enhances glucose metabolism and elevates glucose-transporter 3 expression in primary hippocampal neurons

Authors: *H. N. FRAZIER[1], A. O. GHOWERI[1], K. L. ANDERSON[1], R.-L. LIN[1], G. J. POPA[2], M. D. MENDENHALL[2], R. J. CRAVEN[1], O. THIBAULT[1];

Abstract: Recent studies have reported that insulin signaling diminishes with aging, evidenced by decreased signaling markers, reduced insulin mRNA, and lower insulin receptor (IR) density. Similarly, many reports have also highlighted the role of insulin in normal brain function, with early stage clinical trials reporting a positive impact of intranasal insulin administration on memory recall in patients with mild cognitive decline or Alzheimer's disease. However, the specific pathways targeted by insulin signaling in the brain remain unclear. To address this, we conducted a series of experiments exploring the relationship between insulin signaling, glucose

metabolism and binding, and glucose transporter (GLUT) expression in hippocampal neurons. Using a lentiviral delivery system, we infected mixed, primary hippocampal cultures with either a control plasmid encoding only a red fluorescent marker (mCherry), or one encoding both mCherry as well as a constitutively active human IR (IRβ). A synapsin promoter was included in both plasmids to limit expression to neurons. 2-NBDG imaging was performed to assess the effect of increased IR signaling on glucose metabolism. Glucose uptake was obtained by measuring initial 2-NBDG fluorescence at the start of recording. The rate of fluorescent signal decay over time was calculated as an indirect measure of glucose utilization. Results were further corroborated using radiolabeled glucose uptake assays. To test if changes in glucose metabolism were related to GLUT density, immunocytochemistry and Western immunoblots against the neuron-specific GLUT3 and the insulin-sensitive GLUT4 were performed.
Visual observations suggested that expression of IRβ had no detrimental effects on neuronal survival, morphology, or density. 2-NBDG imaging revealed that IRβ-expressing neurons had elevated levels of glucose uptake and faster rates of glucose utilization compared to controls. No detectable differences in GLUT4 protein levels were noted between the two groups. However, Western immunoblots indicated that IRβ was associated with a significant increase in overall GLUT3 expression, as well as with alterations in this transporter's localization within the cell. The results presented here highlight the validity of using molecular approaches to study the effects of sustained IR activation without administration of exogenous insulin, and suggest that neuronal glucose metabolism, specifically GLUT3, may be an important downstream target of IR signaling in the hippocampus.

Title: Activated integrated stress response in obese diabetic mice may cause impairment of adult hippocampal neurogenesis and episodic-like memory

Authors: K. NAKAGAWA[1], S. ISLAM[2], M. UEDA[3], ***T. NAKAGAWA**[1];
[1]Gifu Univ. Grad Sch. of Med., Gifu, Japan; [2]BCSIR Labs. Chittagong, Chittagong, Bangladesh; [3]1nst. for Developmental Res., Aichi, Japan

Abstract: The integrated stress response, eIF2α phosphorylation-ATF4 signaling, is activated in the brain of obese diabetic mice, leading to impairment of memory and adult hippocampal neurogenesis.
The eIF2α is phosphorylated at residue Ser51 by four protein kinases: general control nonderepressible-2 (GCN2) kinase, double-stranded RNA-activated protein kinase (PKR), PKR-endoplasmic reticulum (ER)-related kinase (PERK), and heme-regulated inhibitor kinase (HRI). These kinases are activated by amino acid starvation, viral infection, ER stress, and heme deficiency, respectively. The signaling cascade initiated by these kinases is known as the integrated stress response (ISR). In the ISR signaling, general protein synthesis is reduced, and the activating transcription factor 4 (ATF4) is paradoxically translated. Several studies, including ours, indicated that the levels of eIF2α phosphorylation and ATF4 expression are important for memory formation. Diabetes affects adult hippocampal neurogenesis through the increased levels of glucocorticoids and the hyperglycemia. However, whether the ISR affects adult hippocampal neurogenesis remains obscure. Therefore, this study aimed to determine whether ISR activation in the brain of mice with diabetes and obesity affects memory and neurogenesis. We used high fat diet (HFD)-induced diabetic C57BL/6, obese and diabetic *db/db*, and APP23 mouse model of Alzheimer's disease (AD) crossed with *db/db* (AD;*db/db*) mice. Bromodeoxyuridine (BrdU) at a dose of 150 mg/kg was administered intraperitoneally twice a day for three consecutive days. The eIF2α phosphorylation and ATF4 expression were increased in the brain of AD;*db/db* and *db/db* mice, indicating activation of the ISR signaling. The impairment of novel object localization, novel object recognition, and radial arm maze was exacerbated in obese mice with diabetes. Immunohistochemical analysis revealed a reduction in the number of bromodeoxyuridine-labeled cells expressing the neuronal migration protein doublecortin in *db/db* mice. In the hypothalamus of 45-week old *db/db* mice, brain-derived neurotrophic factor (BDNF) was increased during aging. These results suggested that the ISR may affect BDNF expression in the brain of mice with diabetes and obesity, impairing neurogenesis and memory.

Title: Long-term high-fat diet changes DNA methylation resulting in pro-neurodegenerative gene changes in the dorsal hippocampus

Authors: *D. M. OSBORNE[1], J. W. VANDER VELDEN[2];
[1]Legacy Res. Inst., Portland, OR; [2]Georgia State Univ., Atlanta, GA

Abstract: Obesity and Type 2 Diabetes (T2D) are leading predisposing environmental factors for the development of neurodegenerative diseases. Prior research has established the hippocampus as particularly vulnerable to obesogenic lifestyles; as such, we investigated whether a long-term high-fat/high-sugar diet (HFD) would affect methylation and subsequent gene expression changes within the dorsal hippocampus of male mice. Male mice received either standard chow or a 60% HFD supplemented with 10% sucrose water beginning at six weeks of age and maintained until either six (young) or 14 months (old) of age when tissues were taken, following confirmation of T2D status. Bilateral hippocampi were submitted for Reduced Representation Bisulfite Sequencing (RRBS) to determine genome-wide methylation profiles at areas with high CpG content, while rt-PCR and Western blots were used to determine expression levels. Comparisons were made to determine effects of Chow vs HFD on both young and old mice. RRBS indicated 107 genes that were differentially methylated between the four groups. Several of these gene targets, with major roles in neuroprotection/neurodegeneration, had significantly altered methylation levels across multiple conditions. Both calsyntenin-1, an amyloid precursor protein transporter, and zinc finger homeobox-3 (related to neuroprotection and Alzheimer's Disease) had significantly increased methylation in old HFD mice, relative to young HFD and old Chow conditions. Young HFD mice also had significantly increased methylation of histone deacetylase-5 and the mitochondrial solute carrier Slc25a15, relative to young Chow, while methylation was further significantly increased in old HFD mice. Additionally, significant methylation changes were found in several genes related fibroblast growth factor signaling due to HFD. The net result of HFD exposure, in regard to methylation, is a pro-neurodegenerative state, with the potential "shutting off" of several different genes vital for neuroprotection.

Title: Human plasma fractions as therapeutics to enhance cognitive function in aging by multiple modes of action

Authors: *D. D. LUU, I. GALLAGER, E. CZIRR, M. K. CAMPBELL, S. MINAMI, V. KHEIFETS, S. P. BRAITHWAITE, N. HUBER;
Alkahest, San Carlos, CA

Abstract: Cognitive impairment associated with neurodegenerative diseases of aging is a major unmet medical need. Multiple processes contribute to these medical conditions, such as decreased number of neuronal stem cells, reduced neurogenesis, decreased neuronal cell survival, and increased neuroinflammation. To combat these diseases and their symptoms, novel multimodal therapeutic strategies are urgently needed. Heterochronic parabiosis and the infusion of young plasma have demonstrated that age-related decline in neurogenesis and increase in neuroinflammation can be reversed, providing initial proof of concept for an approach to restore age-related impairment of processes in the CNS and to enhance cognition. To build on this concept and develop potential human therapeutics, we have characterized human plasma fractions with enhanced safety, tolerability and regenerative effects compared to whole human plasma. Administration of an active plasma fraction to neuronal cells promotes neurite outgrowth as well as neuronal activity and network formation in vitro. Infusion of this plasma fraction into aged mice improves cognitive behavior, which correlates with increased neurogenesis, neuronal survival, number of functional synapses and neuronal activity. These findings are deepening our mechanistic understanding of the multifactorial, regenerative properties mediated by circulating proteins in the blood. They also provide a rationale for the development of novel plasma fractions to enhance cognitive function in neurodegenerative diseases, which we are currently testing in clinical trials for Alzheimer's and Parkinson's diseases.

Authors: *A. L. NGUYEN, N. HUBER, D. LUU, S. LOHR, V. KHEIFETS, S. BRAITHWAITE, D. P. LEONE;
Alkahest, San Carlos, CA

Abstract: Adult neurogenesis, the process of continuous generation of new neurons in discrete areas of the brain, decreases during aging and in neurodegenerative diseases. Modulation of

neurogenesis in rodent models is associated with changes in learning and memory leading to improvements in cognitive function. We have characterized a human plasma fraction that improves cognitive function when infused into aged mice. This observed regenerative effect correlates with increased neurogenesis and neuronal survival in the hippocampal region. Here we utilized RNAseq analysis of human neural progenitor cells as an in vitro model system to study the functional effect of transcriptional changes induced by this human plasma fraction. Gene ontology enrichment analysis reveals modulation of multiple pathways after plasma fraction treatment. Understanding the molecular response of neural progenitor cells to this therapeutically relevant plasma fraction will enable us to better understand molecular and cellular mechanisms that regulate adult neurogenesis during both healthy aging and in neurodegenerative diseases. These findings are deepening our mechanistic understanding of the multifactorial, regenerative properties mediated by circulating proteins in the blood. They also provide a rationale for the development of this novel plasma fraction as therapy for neurodegenerative diseases, currently being tested in clinical trials for Alzheimer's and Parkinson's diseases.

Title: Estrogen regulation of miR-9-5p subcellular localization in neurons

Authors: *C. K. KIM[1], T. R. PAK[2];
[1]Loyola Univ. Chicago, Maywood, IL; [2]Dept Cell and Mol. Physiol., Loyola Univ. Chicago Stritch Sch. of Med., Maywood, IL

Abstract: Estrogens are a class of pleotropic steroid hormones crucial for the maintenance of normal physiology, especially in the central nervous system. Levels of estrogens fluctuate across the lifespan suggesting that they target intracellular mediators, such as microRNAs, to fine-tune homeostatic cellular processes. However, it is still relatively unknown how estrogens can regulate endogenous miRNAs, particularly in the context of the central nervous system. Previous work in our lab demonstrated that 17β-estradiol (E_2), the predominant circulating estrogen,

upregulated the total cellular expression of miR-9-5p, a brain-enriched miRNA that is necessary for neuronal differentiation; however, cytoplasmic levels of miR-9-5p remained unchanged with E_2 treatment. These results led to the hypothesis that E_2 might alter the subcellular localization of mature miRNA by increasing the nuclear levels of miR-9-5p. While the E_2-mediated nuclear import of miRNA is a novel phenomenon that has not been previously characterized, E_2 is a well-known regulator for the nuclear transport of estrogen receptors (ERs), raising the intriguing possibility of a nuclear import mechanism involving a direct ER-to-miRNA interaction. To test this hypothesis, IVB cells, derived from rat hypothalamus, were incubated with either E_2 or vehicle treatment for 2 HRs or 15 HRs. After E_2 treatment, nuclear and cytoplasmic compartments were separated using differential centrifugation. The purified RNA was reverse transcribed, and RT-qPCR was performed to measure levels of mature miR-9-5p in each fraction. Our results indicate that miR-9-5p subcellular localization could be altered with E_2, not only to the nucleus, but to other subcellular compartments such as polysomes. These data suggest a novel mechanism for hormonal regulation of miRNA stabilization in the brain, and future research will investigate the downstream cellular consequences of altered nuclear to cytosolic miR-9-5p localization.

Title: Phosphorylation and functional implications of estrogen receptor beta in the aging female brain

Authors: M. ZHANG, C. K. KIM, S. FLURY, ***T. R. PAK**;
Cell and Mol. Physiol., Loyola Univ. Chicago Stritch Sch. of Med., Chicago, IL

Abstract: Circulating estrogens dynamically fluctuate across the lifespan; they rapidly rise at puberty, peak during the reproductively competent years, and then sharply decline at menopause. The estrogen receptors (ERα/β) must adapt to this changing hormonal milieu to efficiently modulate the target genes of estrogens. We propose that there is a biological switch in ER action that occurs coincident with age and length of time after ovarian hormone depletion (i.e. menopause). Our data support the idea that phosphorylation of ERβ is a potential molecular mechanism mediating a menopausal “switch” in ER function. Phosphorylation of ERβ alters its protein conformation and interaction with other coregulatory proteins, thereby changing its

ability to transactivate target genes. In this study, we used a rat model of surgically-induced menopause to test the hypothesis that ERβ phosphorylation is differentially altered in the hippocampus dependent on length of time following deprivation of endogenous estrogens, and that these changes in phosphorylation dictate the functionality of the receptor on estrogen response element (ERE)-mediated target genes. We used a targeted quantitative mass spectrometry approach (absolute quantification (AQUA)) to precisely determine the phosphorylation status of multiple predicted serine and tyrosine residues on ERβ. In addition, we used ERE reporter gene assays to show that phosphorylation status of these sites altered ERE-mediated promoter activity. Together, our data revealed a novel molecular mechanism that could partly explain the discrepant clinical observations showing estrogens actions are different in recent (<5 yrs) compared to late (>10 yrs) post-menopausal women.

Abstract: Vitamin B1 (Thiamine) deficiency causes Wernicke-Korsakoff's syndrome in human that displays severe deficits in learning and memory. However, mechanism of Vitamin B1 deficiency-induced memory impairments remain unclear. Here we show that Vitamin B1 deficiency impairs hippocampus-dependent memory by degenerating hippocampus and imparting CREB-signaling pathway through neural inflammation. We showed that pyrithiamine-induced thiamine deficiency (PTD)-treated mice (PTD-recovery mice) that recovered from PTD display impairments of hippocampus-dependent memory. Importantly, we observed that PTD-recovery mice showed significant decreases in the number of NeuN positive cells in dentate gyrus (DG), CA1 and CA3 areas of the hippocampus and decreases in spine density in DG of the hippocampus. To further understand mechanisms of memory impairments and hippocampal

degeneration by PTD at the molecular level, we performed RNA-sequencing of hippocampus just (PTD mice) and 3 weeks (PTD-recovery mice) after PTD treatment. Interestingly, PTD mice showed significant increases in mRNA expressions of inflammatory related genes and decreases in mRNA expressions of synaptic signaling associated genes, whereas PTD-recovery mice showed decreases in mRNA expressions of immediate-early genes (IEGs). Since activity dependent expression of IEGs are regulated by CREB, we examined CREB mRNA level and found that PTD recovery mice show a significant decrease in expression of CREB mRNA in the hippocampus. This observation suggests that memory impairments observed in PTD-recovery mice is caused by dysfunction of CREB signaling pathway in the hippocampus. From these observations, we finally examined effects of PTD on transgenic mice expressing a constitutively active CREB mutant in the forebrain (DIEDML mice, Suzuki et al 2011) and found that PTD treatment failed to induce hippocampal degeneration and memory impairments in DIEDML mice. These observations suggest that PTD treatment causes strong inflammation, thereby leading to hippocampal degeneration and impairing CREB signaling pathway followed by impairments in hippocampus-dependent memory formation.

Title: The role of gut microbiome in age associated cognitive impairment

Authors: J. BEHERA, J. ISON, K. KELLY, *N. TYAGI;
Physiol., Univ. of Louisville, Louisville, KY

Abstract: Alzheimer's disease (AD) remains a major clinical problem in older individuals. However, the pathophysiology of aging-associated AD remains unresolved. Interestingly, recent findings suggest that the gut microbiota may also play an important role in restraining immune responses in the brain via the brain-gut axis during AD. Through, it is unknown, whether age-related disruption of the gut-barrier integrity or dysbiosis, causes impaired cognitive function. Allyl sulfide (AS), an organosulfur compound from garlic. It has many health benefits and is known for its H_2S production. Therefore, we proposed, that administration of allyl sulfide (AS) can mitigate the gut dysbiosis and cognitive function by regulating the non-coding RNA, in part, by histone acetylation regulatory mechanism during aging.To test the hypothesis, we used (1): 5-

months age-matched mice as a control group (Young),(2): 24-months old age-matched mice as an aging group (AG),(3): 21-months (AG)+ allyl sulfide (AS) at the dosage of 2mg/kg/b.wt/per day through oral gavage (AG+AS). We found that, compared to young and AG+AS mice, AG mice had significantly increased levels of inflammation and AD biomarkers. The results also showed impaired blood-brain barrier (BBB) function and reduced cerebral blood flow as well as compromised learning and memory in aging mice. The gut microbiota is significantly altered as assessed by the denaturing gradient gel electrophoresis (DGGE) analysis in AG group as compared to Young and AG+AS group. Mechanistic study shows that AG mice display an increased plasma level of circulating non-coding RNA-Hotair (lncRNA-Hotair), as assessed by RT2 lncRNA qPCR Assay, This lncRNA-Hotair can cause a specific deregulation of histone H3 lysine 27 (H3K27) acetylation (ac) at the neuronal derived natriuretic factor (NDNF) promoter, and fail to initiate hippocampal activity associated with memory consolidation. However, administration of AS in the AG group was shown to ameliorate gut dysbiosis and memory functions. Furthermore, restoration of NDNF using recombinant NDNF-therapy promotes the recovery of cognitive abilities. In conclusion, our study suggests that the aging process involves deleterious changes in brain metabolic, vascular and cognitive functions, and gut microbiome structure and diversity, all of which may lead to inflammation and thus increase the risk for AD. Also, AS could serve as potential anti-aging therapeutics in treating aging individuals. Funding Information: This work is financially supported by the National Institute of Health grant AR-067667-NT, is greatly appreciated.

Title: Adipocyte-derived exosomal microRNAs from cerebrospinal fluid are associated with downregulation of IL-8 and IL-6 pathways in aged animals

Authors: *L. R. CECHINEL[1], M. GOLDBERG[2], B. HARMON[2], R. FREISHTAT[2], I. SIQUEIRA[1];
[1]Univ. Federal Do Rio Grande Do Sul, Porto Alegre, Brazil; [2]Children's Natl. Hlth. Syst., Washington, DC

Abstract: It is well established that aging is associated with adipose tissue dysfunction, which is characterized by redistribution of fat depots and changes in the profile of cytokines released. Moreover, this age-related dysfunction is related to shortened lifespan and increased age- related diseases, including dementia. In this context, studies have proposed that adipocyte- derived exosomes might play a central role in the mechanisms by which adipose tissue dysfunction impact other tissues during aging. Exosomes can transfer several molecules such as microRNAs and they are able to cross the blood-brain barrier, releasing their cargo in the central nervous system (CNS). However, the effect of adipocyte-derived exosomal cargo, specifically microRNA, on the CNS needs to be better studied. Our aim was to investigate the microRNA profile of adipocyte-derived exosomes during aging process and their impact on central nervous system. The Local Ethics Committee (CEUA - Comissão de Ética no Uso de Animais - UFRGS; #29818) approved all animal procedures and experimental conditions. Male Wistar rats of 3- and 21-month-old were used and cerebrospinal fluid (CSF) was obtained from the cisterna magna. Exosomes were isolated and then the adipocyte-derived were selected (Fatty Acid Binding Protein 4 positive). microRNA was isolated from exosomes and profiled on Affymetrix GeneChip miRNA 4.0. Ingenuity Pathway Analysis (IPA) was used to identify pathways regulated by significantly altered miRNAs. The analysis of global microRNA expression revealed 47 differentially expressed ($p<0.05$; fold change of 1.1) between aged and young-adult animals of which 20 miRNAs were significantly up-regulated and 27 were down-regulated in aged animals compared to young-adult. A conservative filter was applied on IPA and only experimentally validated and highly conserved predicted mRNA targets for each microRNA was used. IPA analysis showed that IL-8 and IL-6 pathways are ranked as highly predicted targets for these differentially expressed microRNAs ($p<0.0001$). Moreover, IPA demonstrated that those canonical pathways are downregulated in aged animals when compared to young-adult. Interestingly lower levels of IL-8 and IL-6 were reported in subjects with dementia. Considering that, our results indicate that CSF adipocyte-derived exosomal miRNAs are predicted to influence neuroinflammatory pathways involved in neurodegenerative disorders.

Title: Chronic short sleep initiates gender-dependent limbic system neurodegeneration

Authors: *J. E. OWEN, Y. ZHU, P. FENIK, K. SHULMAN, S. VEASEY;
Dept Med., Univ. of Pennsylvania, Philadelphia, PA

Abstract: Introduction: Chronic short sleep (CSS) is prevalent in society and evidence is accumulating for the role of sleep loss in neurodegenerative processes, including Alzheimer's disease (AD). Sleep loss can accelerate AD pathology in transgenic animals that overexpress either Abeta42 or tau. However, it is not known whether sleep loss can initiate AD like pathology in non-transgenic mice. The present study tested the hypothesis that CSS in early adulthood would lead to neurodegenerative changes in old age that resemble the beginning stages of AD.
Methods: The present study subjected male and female C57B6 mice to 12 weeks of CSS (8hrs lights-on sleep loss for 3d/wk) as young adults. Spatial memory tests were performed at 18 months of age on CSS mice and rested control littermates. Subsequently, brain tissue was collected and analyzed for neurodegeneration including hippocampal (HC) and entorhinal cortex (EC) atrophy (stereological Cavalieri's volumes) and AD-suggestive immunopathology.
Results: Control mice had intact spatial memory ($p<0.05$), while CSS mice did not ($p>0.05$). CSS mice showed increased volume of the lateral ventricles (51%, $p<0.05$) and decreased total HC volume (-5%, $p<0.05$) as well as specific loss in the CA1 (-5%, $p<0.05$), CA2 (-19%, $p<0.05$) and EC (-5%, $p<0.05$). When analyzed separately, CSS exposed males had increased lateral ventricle volume (83%, $p<0.05$) and decreased total HC volume (-6%, $p<0.05$) as well as specific loss in CA2 (-26%, $p<0.05$). Female CSS versus control mice did not show any significant volume changes. Overall, CSS mice had increased AT8, a marker of phosphorylated tau, in the HC ($p<0.01$) and EC ($p<0.01$); increased punctate Ab42 ($p<0.05$) and LAMP2 ($p<0.01$), an autolysosomal marker in the HC and increased CD68, a marker of microglial activation, in the HC ($p<0.05$) and EC ($p<0.01$). When analyzed separately, female CSS mice had increased AT8 ($p<0.05$) and CD68 ($p<0.05$) in the EC only, not in HC, whereas male CSS mice had increased AT8 in the EC ($p<0.05$) and HC ($p<0.05$) and increased LAMP2 in the HC ($p<0.05$).
Conclusion: These results suggest chronic short sleep early in life in wild type mice can initiate a neurodegenerative process, which appears more significant in males than in females.

Title: Aging of the blood-CNS barriers

Authors: *M. J. CUMMINS[1,2], E. T. CRESSWELL[1,2], D. W. SMITH[1,2];
[1]Ctr. for Brain and Mental Hlth. Research, Sch. of Biomed. Sci. and Pharmacy, Fac. of Hlth. and Medicine, Univ. of Newcastle, Callaghan, Australia; [2]Hunter Med. Res. Inst., Newcastle, Australia

Abstract: Background: The blood-brain and blood-spinal cord barriers maintain the neural environment and protect it from ionic variations and potential toxins in the systemic circulation. Aging is thought to alter barrier permeability, resulting in neuronal dysfunction, but the literature is conflicted. We used molecular and functional assays to assess the effects of aging on blood-CNS barriers. The research contains both confirmatory and exploratory components.
Methods: Animals: Young (2-4 mo) and old (≥24 mo) C57Bl6 male mice were used for all studies.
RNA seq: RNA-seq was carried out on the frontal cortex (CTX) and spinal cord (SC), and differential gene expression (DEG) between young (n=4) and old (n=4) groups determined using cuffdiff, deseq2, and edgeR. DEGs were compared to cell-specific gene lists for endothelial (EC), pericyte, and astrocyte cells, as well as other barrier related genes.
CNS Regions: A subset of 29 barrier genes were investigated by qPCR across 5 regions (frontal cortex (CTX), corpus callosum (CC), hippocampus (HIP), spinal cord grey matter (SCGM), and spinal cord white matter (SCWM)) in young (n=8) and old (n=8) mice.
Time course of barrier changes: 12 genes were investigated by qPCR across 5 ages (2.5, 4, 8, 14, 26 months, n=6/group) in SC.
Microvessel-specific effects: Microvessels containing ECs and pericytes were microdissected from young (n=6) and old (n=6) CTX and SCGM and expression of 12 genes was determined by qPCR.
Barrier permeability: The effects of aging on permeability were assessed by CNS water content (n=6/group), and sodium-fluorescein (NaFl) permeability (n=10-12/group).
Statistics: For 2 group comparisons, the Mann-Whitney U Test was used. For the time course, the Kruskal-Wallis Test with the Games Howell post-hoc was used. p-value <0.05 was set for significance.
Results: RNA seq: A number of EC (CTX 19%, SC 19%), pericyte (20%, 40%), astrocyte (23%, 27%), and barrier (18%, 32%) specific genes were changed in old CNS. In general the SC was more affected than CTX.
CNS Regions: Of 29 genes investigated, 4 CTX, 7 HIP, 9 CC, 12 SCGM, and 14 SCWM were significantly changed in old CNS.
Time course of barrier changes: 4 barrier genes were significantly altered with aging and changes generally occurred at older ages.
Microvessel-specific effects: Only 1 gene was changed, in the SCGM.
Barrier permeability: Water weight was unchanged in whole brain and increased in whole SC.

NaFl permeability was significantly reduced in HIP, and SC, but not in CTX and CC (combined).
Conclusion: Overall, our data indicate barrier function in the SC may be affected by aging, but other regions remain intact. Barrier changes appear to occur later in the lifespan.

Title: Endothelial senescence mediated by $p16^{INK4a}$ leads to cerebrovascular dysfunction in mouse brains

Authors: *T. AIKAWA[1], Y. CHEN[2], I.-A. VETELENAU[1], H. OUE[1], M.-L. HOLM[1], B. Y. S. KIM[2], T. KANEKIYO[1];

Abstract: As the cerebrovascular system plays a critical role in maintaining brain homeostasis, disturbances of this pathway can lead to cognitive impairment and dementia during aging. Interestingly, population-based epidemiologic studies have revealed that cerebrovascular damage due to hypertension, diabetes or smoking is also associated with the increased risk for Alzheimer's disease (AD). While AD and vascular cognitive impairment and dementia (VCID) are major causes of dementia, the prevalence and the incidence of both diseases remarkably increase in an age-dependent manner. Although the process of aging is complex, current evidence indicates that aging is caused by the accumulation of senescent cells, where the increase of $p16^{INK4a}$ is the major hallmark. Thus, we investigated how the forced expression of $p16^{INK4a}$ in vascular endothelial cells impacts cerebrovascular function, using an in vivo gene delivery system through a unique recombinant adeno-associated virus 2 (rAAV2) with a modified capsid. We confirmed that intraperitoneal injection of the rAAV2, harboring an enhanced green fluorescent protein (EGFP) reporter gene under the control of the CAG promoter, successfully induced the specific expression of EGFP in cerebrovascular endothelial cells in mice. When $p16^{INK4a}$ or EGFP was expressed in cerebrovascular endothelial cells in wild-type mice at 3 months of age, results showed an increase in IgG leakage into the brain parenchyma in the $p16^{INK4a}$-expressed mice in comparison with the control EGFP-expressed mice, 4 weeks after the rAAV2 injection. Whereas we also examined the coverage of endothelial cells with pericytes and major tight junction proteins, there were no significant differences between two mouse groups. When cerebral blood flow was measured by in vivo 2-photon

imaging 10 weeks after the rAAV2 injection in the mice, we found that cerebrovascular endothelial $p16^{INK4a}$ overexpression substantially reduced blood flow in arterioles and capillaries in the cortex. Together, our results indicate that $p16^{INK4a}$-induced endothelial senescence disturbs cerebral blood supply as well as blood-brain barrier integrity, which may contribute to the pathogenesis of AD and VCID.

Sci., [5]Sch. of Life Sciences, Fac. of Sci., The Chinese Univ. of Hong Kong, Sha Tin, Hong Kong

Abstract: Ageing is the strongest risk factor for neurodegenerative diseases. With advances in single-cell transcriptomics, molecular signatures of cells constituting the neurovascular units (NVUs) are revealed in unprecedented details. We performed high-throughput single-cell RNA sequencing (scRNA-seq) and RNA fluorescence *in situ* hybridization (RNA-FISH) of endothelial and mural cells in young adult and aged mice brains to characterize ageing-associated gene expression changes that concur with compromised blood brain-barrier (BBB) integrity. We identified shared and divergent transcriptomic changes in endothelial and mural cell subtypes along the arterio-venous axis, implicating altered energy metabolism pathways in multiple endothelial cell (EC) subtypes. Among the distinct NVU-constituting cell subtypes, capillary ECs exhibit the most gene expression changes with strong neurodegenerative disease-implicated gene enrichment. Furthermore, we demonstrated that exendin-4 (Ex4) treatment normalizes many gene expression level changes capillary ECs and highly reduces BBB leakage in aged brain, pointing to a novel neurovascular mechanism of action underlying the therapeutic efficacies of glucagon-like peptide11 receptor (GLP-1R) agonists in neurodegenerative diseases widely reported in pre-clinical and clinical studies.

Abstract: The hypothalamus is the most important integrator of the autonomic and endocrine regulation and is responsible for growth, development, reproductive function and metabolism. In recent years, evidence has been obtained that the hypothalamus also controls aging. The ventromedial (VMH) and dorsomedial (DMH) hypothalamic nuclei are important hypothalamic nuclei critical for regulating feeding and maintaining whole body energy homeostasis.
The aim of the study was to analyze the expression of neuronal nitric oxide synthase (nNOS), calbindin (CB), sirtuin 1 (Sir1), neuropeptide Y and steroid factor 1 (SF1) in the VMH and DMH hypothalamic nuclei using immunohistochemistry and western blotting in young (3-month-old) and aged (2-years-old) rats during aging.
The results have shown that in DMH, the percentage of CB-immunoreactive (IR) neurons was significantly reduced, and the percentage of CR-IR neurons increased in DMH and VMH during aging ($p<0.05$). The expression of SF1 significantly declined in the VMH during ageing ($p<0.05$). In old rats, there was an increase in the density of NPY-IR fibers in the VMH and a decrease in the DMH ($p<0.05$). The number of NPY-IR neurons in DMH of young and aged rats did not change significantly ($p>0.05$). The number of Sir1-immunoreactive (IR) neurons decreased in both VMH and DMH in old rats when compared to young animals ($p<0.05$). In young rats, nNOS-IR neurons had low intensity of fluorescence in the VMH and DMH. In old animals, the number of nNOS-IR neurons and the degree of immunofluorescence to nNOS significantly increased in all studied nuclei ($p<0.001$).
Thus, neurochemical properties of the hypothalamic neurons change during ageing. There are differences of age-dependent changes between VMH and DMH.

Title: Elucidating the cell specific roles of apolipoprotein E in Alzheimer's disease

Authors: *R. J. JACKSON[1], J. C. MELTZER[1], H. N. NGUYEN[1], B. T. HYMAN[2], E. HUDRY[3];
[1]Massachusetts Gen. Hosp. Inst. for Neurodegenerative Dis., Charlestown, MA; [2]Massachusetts Gen. Hosp., Charlestown, MA; [3]Dept. of Neurol. Alzheimer Res. Unit, MGH, Charlestown, MA

Abstract: **Background:** Late-onset sporadic Alzheimer's disease (LOAD) represents about 95% of all Alzheimer's disease cases and has become a global health crisis with more than 3 million cases of AD in the US alone. More than two decades ago, apolipoprotein E (apoE) was identified as the strongest genetic modulator of LOAD, with the apoE4 isoform increasing the risk of developing LOAD by a factor of 3 (heterozygote) to 12 (homozygote) and apoE2 decreasing this risk by half as compared with the most common apoE3 isoform. Despite those compelling genetic findings and numerous experimental studies that have established apoE as a multifaceted player in AD, the field remains largely conflicted about the best way to target apoE for clinical improvement. In our recent work, we have demonstrated that the complete absence of apoE in a model of amyloidosis (APP/PS-APOEnull) reduces the overall amount of neuritic plaques in the brain, the density of reactive astrocytes and microglia, and more importantly preserves synaptic integrity and rescues Aß-dependent neuronal dysfunction (assessed by array tomography and in vivo multiphoton calcium imaging in awake animals, respectively). The present follow-up study aims at unraveling the cell-autonomous role of APOE in the brain, with an emphasis on the distinct effects of astrocyte- or microglia-derived APOE. **Approach:** Using healthy and diseased human brain samples, we will establish the topology of APOE expression in astrocytes and microglia by RNAscope in situ hybridation and determine whether APOE genotype or the disease course modulate APOE mRNA profile in each glial cell types. In addition, we have established novel humanized mouse models in which the expression of APOE3 or APOE4 can be conditionally switched off in astrocytes and microglia upon recombination to determine the contribution of astrocyte- and microglia-derived apoE in wild-type mice or in the context of amyloidosis. **Results:** We have successfully established the detection of apoE messengers in

fresh frozen brain tissue using RNAscope, and a large stereological analysis is ongoing. In addition, we have generated cx3cr1-Cre^{ERT2}xAPOE (microglial knockdown) and Aldh1l1-Cre^{ERT2}xAPOE mouse lines (on a wild-type or AD mouse model backgrounds) and observed that, at baseline, the microglial contribution for apoE messengers is minimal as compared to astrocytes. Whether or not the ratio between microglia- and astrocyte-derived apoE will change upon amyloid deposition and whether the genetic knockdown of apoE in either cell type will impact their phenotype as neuroinflammation progresses is under evaluation.

Title: Neuroinflammatory effects of apolipoprotein E4 in the brain

Authors: *J. M. IANNUCCI[1,2], A. SEN[1], M. MAJCHRZAK[1], W. RENEHAN[1], P. GRAMMAS[1];
[1]George & Anne Ryan Inst. for Neurosci., [2]Interdisciplinary Neurosci. Program, Univ. of Rhode Island, Kingston, RI

Abstract: Mutations to the cholesterol transport protein apolipoprotein E (ApoE) have been identified as a major genetic risk factor for the development of sporadic or late onset Alzheimer’s disease (AD), with the E4 allele representing an increased risk and the rare E2 allele having a reduced risk compared to the primary E3 form. The reasons behind the differences in risk are not entirely understood, though ApoE4 has been connected to inflammation-related changes in both the brain and the periphery. It is our hypothesis that markers of both inflammation and oxidative stress are increased in response to apolipoprotein E4. We tested this hypothesis using both *in vivo* and *in vitro* models. Brains of mice with the human E4 gene were collected at 10 months of age along with age-matched wild-type controls. Western blot was used to assess whole-brain protein expression. Human astrocytes, human brain microvessel endothelial cells (HBMVECs), and a human immortalized microglia cell line (HMC3), were grown *in vitro*. Cells were treated for 24 hours with cholesterol (100 µM) with or without ApoE2/3/4 (20 nM). Following treatment, supernatant and lysate were collected, and western blot was used to assess protein expression. Our results indicate changes in expression of inflammation- and oxidative stress-related proteins both *in vivo* and *in vitro. In vivo,* mice

expressing the E4 allele exhibited changes in expression of inflammation-related proteins (GFAP, cd11b, Iba1, TNFalpha, IL-6, IL-1beta), and oxidative stress-related proteins (iNOS, eNOS, and NOX4). Similar results were seen *in vitro*, with astrocytes and microglia showing increased expression of pro-inflammatory cytokines including IL1beta, TNFalpha, and IL-6 in response to ApoE4. Similarly, HBMVECs *in vitro* showed altered expression of oxidative stress-related proteins, particularly NOX4 in the presence of ApoE4. Overall, results indicate that ApoE isoform affects the expression of inflammation-related proteins both *in vivo* and *in vitro*, with ApoE4 favoring a pro-inflammatory phenotype. Further studies are needed to better understand the mechanism by which different ApoE isoforms may drive inflammatory processes in the brain.

Abstract: The combination of two neuropathological hallmarks distinguish Alzheimer’s Disease (AD) from other dementias: amyloid plaques, composed of amyloid-beta peptide, and neurofibrillary tangles. Additionally, the brain experiences a robust inflammatory response to these amyloid plaques, which induces the activation and proliferation of microglia. Researchers have identified multiple genetic risk factors for developing AD. One of the most significant genetic risk factors is Apolipoprotein E (ApoE), a cholesterol transport lipoprotein in the brain. Of the three identified ApoE alleles, ApoE3 is believed to be the “control” phenotype, ApoE4 confers an increased risk of AD, and the ApoE2 allele may be protective for AD. Interestingly, ApoE binds to a surface receptor on microglia, triggering receptor expressed on myeloid cells 2 (TREM2). Evidence suggests that, amyloid plaques interact with ApoE, which then bind to

microglial TREM2. This activates a neuroinflammatory cascade and leads to microglial phagocytosis of the amyloid plaque, suggesting a role for ApoE in the inflammatory response seen in AD. While differences are evident, the field knows very little about how each ApoE allele affects the activation of the neuroinflammatory cascade. To test the impact of each ApoE allele, we used the Human Neuroinflammation NanoString panel to assess the inflammatory profile in the superior medial temporal gyrus (SMTG) and cerebellar regions of age and sex matched cases with the following pathology: ApoE3/3 Braak V/VI (ApoE3/3-AD; N=9), ApoE4/4 Braak V/VI (ApoE4/4-AD; N=10), and ApoE3/3 Braak I/II (ApoE3/3 without AD; N=5). Total RNA was extracted from frozen SMTG and frozen cerebellum. NanoString results were analyzed with NanoStringDiff. Furthermore, qPCR was performed to verify RNA trends from NanoString. We found significant differences in expression of a number of inflammatory genes expressed between the ApoE3/3-AD and ApoE4/4-AD brains. Additionally, the data suggests the ApoE3/3-AD cases exhibited an altered neuroinflammatory response from those ApoE3/3 without AD patients suggesting that ApoE3 may also react to the amyloid plaques. ApoE4/4-AD patients tend, instead, to be in a state of neuroinflammation similar to that found in ApoE3/3 patients without AD, suggesting they cannot respond to the amyloid plaques. These results suggest differences in neuroinflammation between ApoE3/3 and E4/4 patients and may be implicated in the progression of the disease.

Abstract: To date, the greatest genetic risk factor for sporadic Alzheimer’s disease (AD) is the possession of the apolipoprotein E4 (*APOE4*) variant. Yet the mechanism by which *APOE4* increases AD susceptibility is unclear. Our lab has revealed that *APOE4* may have unique effects on the regulation of important biological processes in the entorhinal cortex (EC), which is one of

the first regions of the brain to be affected by AD pathology. Using aged *APOE4* targeted replacement mice, we investigated the effects of *APOE4* expression in the EC using a combination of omics analysis, immunohistochemistry, and biochemical assays. Our data revealed *APOE4*-associated alteration in genes, lipids, and metabolites in the EC related to neuronal activity and bioenergetics. Follow up studies have elucidated the ways in which *APOE4* expression causes dysregulation of these vital biological pathways in the EC, and further studies are currently underway to understand how these pathways dysregulations are related to one another and whether they are instrumental in the AD pathology that accumulates early on in the EC. These findings provide novel insights into the ways in which *APOE4* expression may increase AD disease risk by revealing region-specific alterations in vital biological pathways such as neuronal activity and bioenergetics in AD-specific brain regions. We believe that these results will point to novel ways in which AD can be slowed or prevented, especially among *APOE4* carriers.

Title: The effects of high fat diet on metabolism and cognition in APOE mice

Authors: *N. JONES[1], G. W. REBECK[2];
[2]Neurosci., [1]Georgetown Univ., Washington, DC

Abstract: Obesity is a strong physiological risk factor for AD and *APOE4* is the strongest genetic risk factor for AD. Since these factors are present in high percentages of the population, it is imperative that the combined effects of a high fat (western) diet (HFD) and the *APOE4* allele be defined. Male and female human *APOE3* and *APOE4* knock-in mice were fed either a HFD (45% kcal fat) or a low fat diet (LFD) (10% kcal fat) for 3 months (from 6 to 9 months of age). At 9 months, metabolic measurements were determined: weight, baseline glucose levels, glucose tolerance, and visceral adipose tissue (VAT) accumulation. For behavioral or cognitive effects, we tested the mice on the Open Field, Elevated Zero, and Barnes Maze (BM). HFD had similar effects on *APOE4* and *APOE3* mice in terms of weight gain (22% vs 14%) and baseline glucose levels (15% vs 14%). HFD had greater effects in *APOE4* mice compared to *APOE3* mice

in a measure of glucose intolerance (34% higher), and in VAT accumulation (33% higher). Weight gain was positively correlated with glucose intolerance in *APOE3* mice, but not *APOE4* mice indicating *APOE4* mice have deficits in glucose metabolism independent of weight gain. On the BM, *APOE4* mice performed significantly worse than *APOE3* mice, but HFD did not impair spatial learning in either genotype. There were no significant differences in the other behavioral tasks. In summary HFD caused increased weight and metabolic disturbances in both *APOE3* and *APOE4* mice, with *APOE4* mice more affected. Given the highly inflammatory nature of VAT, the higher VAT accumulation in *APOE4* mice could cause higher levels of peripheral and CNS inflammation. Current research is addressing measures inflammation, as well as neuronal complexity, in order to test the effects of HFD on central mechanisms.

Title: Western diet affects the level of brain exosomes in an APOE-genotype dependent manner in mice

Authors: *L. RACHMANY[1,5], S. F. NEWBURY[2], S. BHAMDEO[2], B. S. EAST[3], G. M. FLEMING[3], K. Y. PENG[2,6], D. A. WILSON[3,4,7], E. LEVY[8], P. M. MATHEWS[2,5]; [2]Ctr. for Dementia Res., [3]Emotional Brain Inst., [4]Dept. of Child & Adolescent Psychiatry, [1]Nathan S. Kline Inst., Orangeburg, NY; [5]Dept. of Psychiatry, [6]Dept. of Neurol., [7]Dept. of Neurosci. & Physiol., New York Univ. Langone Hlth., New York, NY; [8]Nathan S Kline Inst., Orangeburg, NY

Abstract: Apolipoprotein E (APOE) transports cholesterol from astrocytes to neurons, contributing to the lipid composition of neuronal membranes. The three human alleles APOE2 (E2), APOE3 (E3), and APOE4 (E4) are linked epidemiologically to Alzheimer’s disease (AD). In a dose-dependent manner, expression of the APOE4 allele is the greatest genetic risk factor for Alzheimer’s disease. The common APOE3 allele is considered to be a neutral-risk factor for AD, while the less common APOE2 allele is protective. Prior findings have shown that expression of the APOE4 compared to APOE3 allele affects the neuronal endosomal-lysosomal system, including brain exosomes levels. Exosomes are phospholipid bilayer enclosed vesicles that are secreted into the tissue extracellular space following their formation by the invagination of the membrane of late endosome/multivesicular body (MVB) around cytoplasmic materials. In

humanized APOE2, APOE3, and APOE4 mice, we compared olfactory behavior and exosome biology in mice fed a standard diet to those fed a “Western diet” that contains increased cholesterol and fat. Initial cohorts of mice were fed the Western diet for one month, beginning at 12 months of age, and assessed behaviorally using an olfactory odor habituation test, previously shown to be affected by APOE genotype in mice of this age. Brain exosomes were then isolated by centrifugation through a differential-density gradient. One month of Western diet altered odor habituation only in APOE3 mice, while this behavior was unchanged in APOE2 and APOE4 mice following one month of the diet. Additionally, the Western diet resulted in changes in brain exosomes levels in an APOE-genotype dependent manner, with APOE3 mice appearing to be the most sensitive to diet-induced changes. Additional cohorts of mice assessed at the same age but fed the Western diet for 6 months are being examined. Thus, the APOE-genotype may modify the response to a diet high in cholesterol and fat, with our current findings suggesting APOE genotype-dependent responses to the diet in both behavior and brain exosomes.

Title: Cholesterol regulates exosome release in cultured astrocytes

Authors: *M. ABDULLAH, T. FERDOUS, M. MICHIKAWA*;
Dept. of Biochemistry-I, Nagoya City Univ., Nagoya, Japan

Abstract: Extracellular vesicles (EVs), particularly exosomes, have emerged in the last 10 years as a new player in the progression of Alzheimer’s disease (AD) with high potential for being useful as a diagnostic and treatment tool. Apolipoprotein E (ApoE), secreted from astrocytes plays an essential role in high-density lipoprotein (HDL) generation by removing cholesterol from the cells. Aβ is known to binds ApoE-HDL, taken up by the cells, and degraded. Recent studies have demonstrated that exosome release is mediated by SM and ceramide in the cells. Flotillin, a marker for exosome, exists in lipids raft, which is rich in cholesterol and SM, suggesting that cholesterol may regulate exosome release from astrocytes. In this study, we performed experiments to determine whether cholesterol regulates exosome release in cultured

astrocytes.
Initially we found that exosome release demonstrated by flotillin and HSP90 levels in the conditioned media is significantly reduced in cultured astrocytes prepared from ApoE-KO mouse, compared with that in astrocytes prepared from WT, ApoE3- knock-in (KI), and ApoE4-KI mice. The reduced level of flotillin and HSP90 were accompanied by the elevation of cholesterol levels. PI3K/Akt phosphorylation was enhanced in ApoE-deficient astrocytes. Addition of cholesterol to the astrocytes significantly reduced exosome release demonstrated by flotillin and HSP90 levels. Whereas, depletion of cholesterol by the treatment with β-cyclodextrin recovered the secretion levels of exosome in ApoE-deficient astrocytes to a similar level of WT astrocytes. In addition, reduced levels of exosome release by the addition of cholesterol were recovered by the treatment of PI3K inhibitor (LY294002). These results suggests that, exosome release is regulated by cholesterol via stimulation of PI3K/Akt signal pathway.

Title: Investigating the contribution of astrocytic cholesterol transport in neuronal amyloid beta generation using human-induced pluripotent stem cells

Authors: *W. JEONG, H. LEE, J. SEO;
Brain and Cognitive Sci., DGIST, Daegu, Korea, Republic of

Abstract: Alzheimer's disease (AD) is the most common form of irreversible dementia characterized by progressive neurodegeneration and accumulation of Aβ plaques. In brain, neurons are the major source of Aβ, and cholesterol-rich membrane domains, lipid rafts are thought to offer a structural platform for Aβ generation and aggregation. Previous study showed increased cholesterol levels in human induced pluripotent stem cell (iPSC)-derived astrocytes carrying *APOE4* variant compared to its APOE3 astrocytes. We aimed to address the role of hiPSC-derived astrocytes with *APOE4* alleles on the formation of lipid rafts and Aβ production in neurons. By performing lipidomic analysis, we first examined differentially secreted lipid metabolites by APOE isoforms. We found that cholesterol is the one of the up-regulated metabolites by *APOE4* variant in astrocytes. To investigate the effect of astrocytic cholesterol

transport to neurons, we applied cholesterol or inhibitor of cholesterol synthesis (*MβCD*) to rat primary neurons and measured the area and intensity of lipid rafts on plasma membrane. Cholesterol-treated neurons displayed increased area and intensity compared to non-treated neurons, whereas inhibition of cholesterol synthesis showed opposite phenotypes. We further observed that lipid rafts in rat primary neurons were indeed regulated by APOE isoform when they were co-culture with hiPSC-derived astrocytes carrying either *APOE3* or *APOE4* alleles. We are currently investigating whether cholesterol dysregulation in APOE4 astrocytes is sufficient to alter neuronal Aβ production, which will be presented at the meeting.

Title: Differential effects of astrocyte and microglia apolipoprotein E production on the development of amyloid-beta pathology

Authors: *T. E. MAHAN[1], J. D. ULRICH[1], T.-P. V. HUYNH[1], N. SCOTT[1], J. REMOLINA SERRANO[1], R. E. TANZI[2], D. M. HOLTZMAN[1];

Abstract: The ε4 allele of apolipoprotein E (apoE) is the strongest genetic risk factor for developing late-onset Alzheimer disease (AD). One of the key characteristic pathologies of AD is the formation of extracellular amyloid-β (Aβ) plaques. Previous studies have shown that both the level of apoE and the extent of lipidation of apoE-containing lipoprotein particles dramatically influence the development of Aβ pathology. While astrocytes are the primary producer of apoE in the CNS, studies have shown that microglia also produce apoE and upregulate their apoE mRNA levels as Aβ pathology develops. To address whether apoE produced by astrocytes vs. microglia might be playing specific roles in the development of Aβ plaque pathology, we first compared apoE-containing lipoprotein particles from microglia to those produced by astrocytes. We found that microglia produce smaller, likely much less lipidated apoE particles than astrocytes. Additionally, we found that microglia expressing the human apoE4 isoform produce greater amounts of smaller apoE particles relative to apoE2 and apoE3 expressing microglia. Next, we looked *in vivo* to investigate how removal of apoE from

astrocytes would affect the development of Aβ plaque pathology in APPPS1-21 mice expressing human apoE3 or human apoE4 and compared the results to previous work with global apoE KO in APPPS1-21 mice. We found that the loss of astrocytic apoE resulted in changes to Aβ plaque size and morphology, similar to what was seen in the global apoE KO. Plaques were larger and less compact in the absence of astrocyte-produced apoE. However, the loss of astrocytic apoE did not dramatically reduce the levels of fibrillar Aβ plaques, which is contrary to what was seen with global apoE KO's. Global apoE KO's had previously been shown to have a significant decrease in microgliosis around fibrillar amyloid plaques. The astrocyte-specific-apoE knockouts, however, did not display a similar decrease in microgliosis. Additionally, we found isoform dependent differences on Aβ plaque development between the apoE3 and apoE4 expressing mice. These results suggest that astrocyte-apoE plays an important role in regulating amyloid plaque morphology. The results also suggest that apoE produced by cells other than astrocytes, including microglia, or apoE produced by astrocytes, microglia, and other cells in the brain may be critical in facilitating fibrillization of Aβ and its local consequences in brain parenchyma. These results also suggest that the presence of microglial apoE and/or apoE produced by other CNS cell types is sufficient for microgliosis to occur around Aβ plaques.

Title: The plasma lipoprotein profile in a novel transgenic mouse model is modulated by Alzheimer's disease (AD) risk factors: Potential as an AD biomarker

Authors: B. XIANG[1], K. PANCHAPAKESAN[1], Y. SALEH[1], S. CORONEL[1], N. FAULK[1], J. E. MALDONADO WENG[1], J. M. YORK[1], A. C. VALENCIA[1], *M. LADU[1], A. J. KARSTENS[2,1];
[1]Anat. and Cell. Biol., [2]Psychology, Univ. of Illinois, Chicago, Chicago, IL

Abstract: Alzheimer's disease (AD) is the 6th leading cause of death in the United States with no cure, few palliative treatments and no prognostic biomarker. While age is the greatest risk factor for AD, the greatest genetic risk factor is *APOE4*, increasing risk 4- to 12-fold compared to the common *APOE3*, while the rare *APOE2* reduces risk. Female (♀) *APOE4* carriers have greater lifetime risk and rate of cognitive decline compared male (♂) *APOE4* carriers. *APOE* encodes apolipoprotein E (apoE), a protein component of plasma lipoproteins and the primary apolipoprotein in the brain, expressed by glial cells. In the brain, apoE plays a major role in lipid transport and clearance of soluble, oligomeric amyloid-β (oAβ), likely the proximal AD neurotoxin. Separate from the brain, plasma lipoproteins in the blood are heterogenous, including very low density lipoproteins (VLDL), low density lipoproteins (LDL) and high density lipoproteins (HDL). Blood lipid panels typically report total lipid levels and lipid levels associated with isolated lipoproteins, with an emphasis on HDL/LDL cholesterol. In contrast, plasma lipoprotein profiles (PLP) generated via fast liquid protein chromatography (FPLC) are the age- and *APOE*-dependent signature of peripheral lipid transport. FPLC elutes lipoproteins from largest to smallest (chylomicrons/VLDL, LDL, HDL-2, HDL-3, and free proteins) and resulting fractions can be further analyzed for lipid/protein content (e.g., cholesterol, oAβ). Thus, the PLP could be a physiologically relevant biomarker for AD, and the current study determines the effects of age, *APOE* and sex on the lipoprotein profiles of the EFAD transgenic mouse model. The EFAD mice overexpress human Aβ42 and express human *APOE3* (E3FAD) or *APOE4* (E4FAD), allowing for analysis of the synergistic effects of age, *APOE* and sex on the PLP. We hypothesize a leftward dyslipidemic shift (>VLDL/LDL; <HDL) in the PLP with age, *APOE4*, and ♀ sex. Further, oAβ will preferentially distribute to the larger particles. PLP fractions from EFAD mice ages 8- and 18-months (M) were analyzed for lipids and oAβ. With age, lipid transport appeared compromised, diminishing the *APOE* and sex effects on PLPs. Across age and sex, dyslipidemic PLPs were E4FADs > E3FADs, an effect driven by ♀E4FADs. Lipidation of VLDL was ♀E4FADs > ♀E3FADs = ♂EFADs, while HDL was ♀EFADs < ♂EFADs. The distribution of oAβ showed similar age, *APOE,* and sex effects. In conclusion, EFAD dyslipidemic PLPs correspond with AD pathology in EFAD mice and AD risk in humans. Thus, future studies will use human samples to validate the PLP as a surrogate biomarker for cognition in AD.

Title: Phosphorylation and cytoplasmic translocation of TDP-43 in response to a neurotoxic fragment of apolipoprotein E4 (ApoE4): A mechanism that may underlie loss of cognition in Alzheimer's disease and Alzheimer's disease related dementias (ADRD)

Authors: *P. MCDONOUGH[1], K. L. GORDON[1], R. C. B. BASA[1], S. RAMESH[1], C. HANDLEY[1], T. T. ROHN[2], A. WARD[3], J. WANG[3,4], J. H. PRICE[1,4];
[1]Vala Sci. Inc, SAN DIEGO, CA; [2]Boise State Univ., Boise, ID; [3]Allele Biotech., San Diego, CA; [4]Scintillon Inst., San Diego, CA

Abstract: Elevated phosphorylation and cytoplasmic localization of TDP-43 (transactive response DNA-binding protein of 43kDA), is found in brain sections from patients that develop dementia due to Alzheimer's Disease (AD), Parkinson's Disease (PD), Dementia with Lewy Bodies (DLB), Frontotemporal Dementia (FTD), Amyotrophic Lateral Sclerosis (ALS), Frontotemporal Dementia (FTD), stroke (Vascular contributions to cognitive impairment and dementia [VCID]) and traumatic brain injury (TBI) (collectively referred to as Alzheimer's Disease Related Dementias, ADRD). The presence of the *APOE-ε4* gene variant, which encodes apolipoprotein E4 (ApoE4), increases the tendency for dementia to develop for patients with these afflictions, but the mechanisms responsible for this effect remain to be elucidated. In experiments utilizing glutamatergic neurons representing excitatory cortical neurons derived from human induced pluripotent stem cells (hiPSC-Gluts) we have found that a fragment of ApoE4 (aa1-151) is neurotoxic and induces phosphorylation and translocation of TDP-43 from the nucleus to cytoplasmic puncta (likely corresponding to stress granules) consistent with TDP-43 proteinopathy observed in AD and ADRD. In ongoing research, the assay system will be modified to include cocultured hiPSC-microglia, and hiPSC-astrocytes, cell types that may also be affected by ApoE4 fragments. HiPSC-neurons representing different CNS types (e.g., inhibitory or dopaminergic) will also be tested, as will neurons, microglia, and astrocytes derived from hiPSCs featuring mutations that predispose subjects to AD and ADRD. The assay system features cells cultured in 384-well dishes, in which TDP-43 phosphorylation and translocation are quantified via automated digital microscopy and image analysis, enabling high throughput testing of chemicals, biologics, and genomic constructs to elucidate the mechanisms of ApoE4 and TDP-43 neurotoxicity and to identify agents that may provide therapeutic benefit against dementia.

Title: Lipid peroxidation product 4-hydroxynonenal alters tertiary conformation and fold of apolipoprotein E in an isoform dependent manner

Authors: *M. ABEER, S. CRUZ, V. TRAN, V. NARAYANASWAMI;
Chem. and Biochem., California State Univ. Long Beach, Long Beach, CA

Abstract: Problem statement: Post mortem tissues from brains of Alzheimer's disease (AD) patients show higher levels of 4-hydroxynonenal (HNE)-modified proteins, with HNE arising as a result of oxidative stress and lipid peroxidation. The overall goal of our study is to understand the effect of HNE modification on the structure and function of apolipoprotein E3 (apoE3) and apoE4, which play a critical role in brain cholesterol homeostasis. Individuals carrying the *APOE* ε4 allele are at a higher risk of developing AD. In the present study, we report the biophysical analysis of HNE modification of apoE3 and apoE4 in terms of protein fold and conformation. **Methods:** Recombinant apoE3 and apoE4 were modified by HNE followed by Western blot with HNE specific antibody to confirm modification. The modified samples were subjected to circular dichroism (CD), fluorescence (intrinsic and 1-anilinonaphthalene-8-sulfonic acid (ANS) fluorescence) spectroscopic and guanidine hydrochloride (GdnHCl)-induced unfolding analyses. Cellular uptake studies of lipid-associated HNE modified apoE isoforms were performed with brain endothelial cells and monitored by confocal microscopy. **Results:** Western blot analysis of apoE3 and apoE4 that were treated with 20-200 μM HNE confirmed modification, with a major band appearing at ~36 kDa. HNE-modified apoE3 and apoE4 were highly helical (60.5 ± 3.1 and 61.0 ± 2.7 %, respectively, n=3) comparable to that of unmodified proteins (56.4 ± 1.5 and 57.9 ± 3.3 %, respectively, n=3) as revealed by far UV CD spectroscopy. A significant decrease in the intrinsic fluorescence emission was noted for both HNE-apoE3 and HNE-apoE4, compared to the corresponding unmodified proteins. GdnHCl-induced denaturation monitored by changes in intrinsic fluorescence revealed a notable difference in terms of increased susceptibility to unfolding for HNE-apoE4, but not HNE-apoE3. Further, ANS fluorescence emission spectra revealed a 10 nm red shift in the wavelength of maximal fluorescence emission for HNE-apoE4 (but not for HNE-apoE3) compared to unmodified protein. Incubation of HNE-apoE3 or -apoE4

with endothelial cells revealed punctate, perinuclear vesicles suggesting cellular uptake via the lipoprotein receptor family of proteins and/or scavenger receptors. **Conclusions:** Taken together, our data indicate that there are isoform-specific differences in protein conformation and tertiary fold as a consequence of modification of apoE by HNE. Further studies are needed to understand the mechanism of cellular clearance of HNE modified apoE at the neurovascular junction and the role of oxidatively modified apoE4 as a risk factor for AD and amyloid pathology.

Title: The role of pericytes and blood-brain barrier in regulation of soluble tau clearance from brain

Authors: *A. P. SAGARE, A. ARMENDARIZ, E. J. LAWSON, A. NELSON, B. V. ZLOKOVIC;
USC, Los Angeles, CA

Abstract: Recent studies suggest that pericyte loss and cerebrovascular dysfunction contributes to pathology and cognitive decline in Alzheimer’s disease (AD). In addition to Aβ deposition, accumulation of tau may also play a significant role in neurodegeneration. We have shown that brain vascular pericytes internalize and clear Aβ by low density lipoprotein receptor-related protein 1 (LRP1) in an apoE isoform-specific mechanism. However, the role of pericytes and blood-brain barrier (BBB) in the clearance of tau is still not completely elucidated. Here, we studied the ability of primary mouse brain microvascular pericytes to internalize and clear Cy3-labeled human recombinant tau (Cy3-tau), and the role of LRP1 in iodinated labeled human recombinant monomeric tau (^{125}I-tau) clearance across the BBB. Our results show that pericytes from *Apoe*$^{+/+}$ mice cultured on coverslips internalize Cy3-tau and that silencing *Lrp1* or *Apoe* by siRNA inhibits Cy3-tau uptake, whereas silencing of other lipoprotein receptors such as *Lrp2*, *Ldlr*, *Vldlr*, and *Apoer2* or scrambled siRNA (si*Ctr*), did not affect Cy3-tau clearance. Pericytes from *Apoe*$^{-/-}$ mice did not clear Cy3-tau; however, the addition of human lipidated apoE3, but not apoE4, reversed Cy3-tau clearance by *Apoe*$^{-/-}$ pericytes. We used an *in vivo* brain clearance technique to study tau clearance across the BBB in *Apoe*$^{+/+}$ and *Lrp1*$^{lox/lox}$; *Tie2-Cre* transgenic mice. After intracerebral microinjection of ^{125}I-tau (20 nM) and ^{14}C-inulin (an inert reference

molecule), we analyzed the brain at 30 minutes. Our data show that ^{125}I-tau is cleared rapidly compared to ^{14}C-inulin in *Apoe*$^{+/+}$ mice via transport across the BBB, but poorly cleared from *Lrp1*$^{lox/lox}$*; Tie2-Cre* mice with endothelial-specific *Lrp1* deletion. These results indicate that tau is cleared by pericytes and across murine BBB *in vivo* in an LRP1-apoE-isoform-dependent manner. Collectively these results suggest that improving vascular clearance may reduce brain accumulation and spread of tau pathology thereby minimizing neuronal injury in AD.

Title: Vascular specific expression of apoE4 enhances CAA pathology and promotes cerebrovascular damages

Authors: *C.-C. LIU, Y. YAMAZAKI, Y. A. MARTENS, A. YAMAZAKI, Y. CHEN, L. JIA, C. M. LINARES, J. KNIGHT, B. KIM, G. BU;
Mayo Clin., Jacksonville, FL

Abstract: Alzheimer’s disease (AD) is the leading cause of dementia in the elderly. Accumulating evidence has shown that risk factors for vascular diseases such as hypertension, diabetes, and hypercholesterolemia are associated with increased risk for AD. The ε4 allele of the apolipoprotein E (*APOE*) gene is the strongest genetic risk factor for late-onset AD and cerebral amyloid angiopathy (CAA) compared to the common ε3 allele. ApoE4 promotes the aggregation and deposition of amyloid-β (Aβ), principal component of both parenchymal amyloid plaques and CAA. Thus, understanding the effects of apoE isoforms on CAA formation represents a great opportunity to both uncover pathogenic mechanisms underlying AD and also explore new strategies for AD therapy.
ApoE is expressed in the brain mostly by astrocytes. Vascular mural cells (VMCs), the major cell types in the cerebrovasculature including smooth muscle cells and pericytes, also express abundant apoE. However, how vascular apoE isoforms modulate parenchymal plaques and CAA is unknown due to the lack of appropriate model systems to distinguish cell autonomous versus non-autonomous effects. Towards this, we have developed novel mouse models expressing human apoE3 or apoE4 in an inducible, cell type-specific manner. After breeding to *SM22α*-Cre, we generated VMC-specific human apoE3 and apoE4 mouse models in the murine *Apoe*-

knockout background. Upon breeding to amyloid model mice, we found that expression of apoE exclusively in VMCs exacerbated CAA pathology with apoE4 exhibited stronger effect compared to apoE3. Differential effects on blood-brain barrier integrity, amyloid deposition in the brain parenchyma, neuroinflammation and cerebrovascular transcriptomic signatures are also observed between vascular apoE4 and apoE3 mice. Together, our findings provide novel mechanistic insights into the specific role of vascular apoE in AD pathology and cerebrovascular integrity, and have implications in designing new therapeutic strategies targeting apoE.

Title: Preventing cerebrovascular decline in $APOE^{E4}$ mice

Authors: *K. FOLEY[1,2], L. GRAHAM[1], S. YANG[1], G. HOWELL[1,2];
[1]The Jackson Lab., Bar Harbor, ME; [2]Sackler Sch. of Biomed. Sci., Tufts Univ., Boston, MA

Abstract: The primary burden of dementia cases worldwide is attributed to Alzheimer's disease (AD) and Vascular dementia (VaD). Recent evidence suggests there is significant pathological overlap between these two diagnoses, implicating some form of cerebrovascular damage as a contributor to more than 90% of dementia cases. Therefore, preserving cerebrovascular integrity throughout aging is an underexplored therapeutic option for dementia. Importantly, mice carrying the humanized *APOE*$^{\varepsilon 4}$ gene, the greatest genetic risk factor for dementia, show cerebrovascular leakage by 2wks of age. We hypothesize that these early cerebrovascular deficits increase risk for dementia in later life. We propose that exercise can overcome cerebrovascular dysfunction, reducing risk for dementia. However, the interactions between genetic risk and environmental factors (such as exercise) are not well understood.
To evaluate exercise as an intervention to improve cerebrovascular health, young (1-2mos) and midlife (12mos) B6 mice were provided a running wheel for 12wks. Midlife runners showed a natural variation in running distance, which allowed us to determine the impact of various amounts of running on brain health during aging. Transcriptional profiling of the hippocampus and cortex revealed significantly enriched vascular remodeling terms such as extracellular matrix organization and angiogenesis in the young running mice but not in the midlife running mice. This suggests a reduction in cerebrovascular plasticity with age, and that interventions should be considered during youth.

We next examined whether the benefits of running at a young age will have similar effects on mice carrying human *APOE* $^{\varepsilon 4}$. Male and female B6.*APOE*$^{\varepsilon 3/\varepsilon 3}$, B6.*APOE*$^{\varepsilon 3/\varepsilon 4}$, and B6.*APOE*$^{\varepsilon 4/\varepsilon 4}$ were provided access to a running wheel at 1-2 months of age for 12 weeks. Lipid profiling revealed a sex by activity interaction for HDL levels, indicating running may alter serum lipids differently between the sexes. Although there was no difference in running distances between genotypes, there was similar variation in distance ran and running intensity between genotypes. This allows for interrogation into running intensity for each sex and genotype and ultimately, its effects on angiogenesis and vascular integrity. Transcriptional profiling by RNA-sequencing of the cortex and hippocampus from mice from all groups, as well as assessment of vascular density and blood brain barrier integrity by immunofluorescence is underway. Ultimately, our work aims to assess running as a prevention/intervention to strengthen cerebrovascular integrity for those with a genetic predisposition for dementia.

Title: APOE4 predisposes to cancer chemotherapy-induced cognitive impairment in a mouse model

Authors: *G. W. REBECK[1], T. C. DEMBY[2], O. C. RODRIGUEZ[3], Y. LEE[3], C. ALBANESE[3], J. S. MANDELBLATT[4];
[1]Neurosci., [2]Tumor Biol., [3]Mol. Oncology, [4]Oncology, Georgetown Univ., Washington, DC

Abstract: The E4 allele of Apolipoprotein E (APOE) is the strongest genetic risk factor for cognitive impairment in late-onset Alzheimer’s disease (AD). Human genetic studies of breast cancer survivors have shown that *APOE4* carriers also have a significantly higher risk for cognitive impairments after cancer chemotherapy. Cognitive impairments to attention, executive function, and learning and memory are prevalent and debilitating side effects of many cancer chemotherapies. To test the association of chemotherapy-induced cognitive impairment with *APOE4*, we used human *APOE* targeted replacement mice, a model lacking the most overt

neuropathological signs of AD. We treated one year old female *APOE3* and *APOE4* mice by intraperitoneal injection with the common cancer chemotherapeutic agent doxorubicin or with saline (n=14-15 per group). We treated mice with 10 mg/kg doxorubicin, in two doses separated by one week, which caused a small (less than 5%), and temporary, reduction in body weight but no overt signs of toxicity. Five weeks following treatment, mice were tested for spatial learning and memory by the Barnes Maze. As expected, under control conditions *APOE4* mice were mildly impaired in their ability to identify and escape through the target hole compared to *APOE3* mice. Doxorubicin treatment had no effect on this behavior in *APOE3* mice. In contrast, doxorubicin caused a strong and significant impairment in *APOE4* mice over several training days ($p<0.01$). Other behaviors, including movement in an Open Field maze, exploration in an Elevated Plus maze, demonstration of Pre-Pulse Inhibition, and Fear Conditioning, were not significantly affected by doxorubicin in either the *APOE3* or *APOE4* mice. Mice were euthanized at 21 months of age, and their brains are being analyzed by voxel based morphometry, immunohistochemistry, and biochemical assays to explore possible long-term morphological and molecular mechanisms for this *APOE*-related impairment by doxorubicin. These findings extend our earlier published work in younger (six month old) *APOE* mice, which also demonstrated an effect of doxorubicin on spatial learning specifically in the *APOE4* mice. Together, these studies support the human studies that *APOE4* positive individuals undergoing cancer chemotherapy are at higher risk of adverse cognitive side effects, knowledge of which may affect their treatment decisions. Furthermore, the work supports the important hypothesis that *APOE4* predisposes to cognitive impairment via mechanisms beyond those specific to AD pathogenesis.

Title: Oxidative stress responsive kinase signaling and its accompanied insulin resistance precede overt AD pathology

Authors: *W.-B. SHEN, S. CAO, W. LUO, P. YANG;
Univ. Maryland Sch. Med., Baltimore, MD

Abstract: Alzheimer’s disease (AD) is a progressive neurodegenerative disorder and the most common form of dementia in the elderly. AD manifests the deposit of extracellular amyloid plaques and intra-cellular neurofibrillary tangles containing hyper-phosphorylated tau. However,

the exact mechanism underlying AD pathogenesis remains obscure. Studies in the past few years have revealed metabolic dysregulation and insulin resistance in the AD brain. We hypothesize that oxidative stress responsive kinase-induced insulin resistance is involved in AD pathogenesis. To test this hypothesis, we analyzed kinases and insulin receptor signaling in the cortical tissues of non-AD controls (*APOEε3* carriers) and non-AD experimental group (*APOEε4* carriers) at age of around 50 years. *APOEε4* is associated with significantly increased AD frequency. We found no β-amyloid plaques and neurofibrillary tangles in the brain tissues of both groups. However, thioredoxin 1, an endogenous inhibitor to the oxidative stress responsive kinase ASK1 (Apoptosis signal-regulating kinase 1), was significantly downregulated in the *APOEε4* carriers with concurrently increased levels of phospho-ASK1, and phospho-JNK1/2 (c-Jun N-terminal kinases 1 and 2) and phospho-p38 MAPK (mitogen-activated protein kinase), two kinases downstream of ASK1. Furthermore, we found that in *APOEε4* carriers expression of the insulin receptor (IR) were downregulated, whereas phospho-IRS1 (insulin receptor substrate 1) at Serine 636/639, an inhibitory index of IR signaling, was upregulated and phospho-AKT1, a collective output of the IR signaling, was downregulated. We further verified these findings in an AD mouse model, the APP-PSEN1 Transgenic mouse. β-amyloid deposits were manifested in the cortex at 5.5 months in this AD model. At the age of 3.5 months or earlier, there was no β-amyloid deposit formed but levels of phospho-ASK1, phospho-p38MAPK and phospho-IRS1 at Serine 636/639 were significantly upregulated. However, insulin receptor expression was not affected at this age. Because studies in other systems have demonstrated that activation of the ASK1-JNK1/2/p38MAPK signaling contributes to insulin resistance, our studies implicate that oxidative stress responsive kinase signaling and its accompanied insulin resistance precede overt AD pathology.

Title: Understanding Alzheimer’s disease risk: Early behavioral changes and physiological biomarkers associated with the human APOE4 allele in a knock-in rat model

Authors: L. BLACKMER-RAYNOLDS, L. AUGUSTIN, J.-Y. PARK, A. DOAK, *M. J. GLENN;
Psychology, Colby Col., Waterville, ME

Abstract: The human apolipoprotein E e4 (hAPOE4) allele is the greatest known genetic risk factor for Alzheimer's disease (AD) and is associated with numerous aspects of its symptomatology. Despite the importance of the hAPOE4 allele in one's risk of developing AD, the early life changes associated with it are not well understood. There is some evidence, derived from mouse models with a hAPOE4 knock-in, of memory impairments and elevated anxiety behavior, but only as early as 6 months of age; little is known about whether the hAPOE4 allele may affect features of cognitive and emotional functioning earlier in the lifespan. Furthermore, there exists no published research thus far using a hAPOE4 knock-in rat model. Significant insights are possible with rats given their long-standing use as behavioral models over the last century. Thus, the goals of the present study were to 1) carefully study behavior using a hAPOE4 knock-in rat model, and 2) begin these assessments early in life. To address these goals, 20 hAPOE4 knock-in and 20 wildtype Sprague Dawley rats (10 females and 10 males of each genotype) were acquired at 4 weeks of age. After a short period of acclimation to the facility, a series of behavioral tasks were conducted over a 3-month period, followed by an examination of rats' corticosterone reactivity to an acute stressor. Cognitive tests included assays of object, place, and context memory along with object-in-place scene memory. Emotion-based tests included the open field and elevated plus maze to assess rats' hesitation to explore and extent of exploration of novel, anxiety-provoking spaces. Overall, the results revealed subtle, sex-dependent effects of the hAPOE4 knock-in: hAPOE4 females displayed deficits in remembering the location of objects and decreased inhibition in both the open field and the elevated plus maze tests. Consistent with decreases in anxiety-like behavior, hAPOE4 females, compared to wildtype females, also showed significantly faster declines in serum corticosterone after 20 min of acute restraint stress. A similar, smaller, result was found in male rats' corticosterone reactivity, though few differences in their behavior as a function of genotype were evident. Taken together, the results of the present study demonstrate that the hAPOE4 allele has measureable impacts on behavior and physiology, particularly in female rats, during late adolescence and early adulthood. Continued monitoring of these rats across their lifespan is planned and may offer important indices of how early patterns of cognitive and emotional functioning map onto deficiencies that emerge later in life because of the hAPOE4 risk allele for AD.

Title: Lentiviral vectors for expressing human amyloid precursor protein or apolipoprotein E gene variants associated with increased risk of Alzheimer's disease

Authors: A. MORRIS[1], P. ZALAMEA[2], M. R. SWERDEL[2], ***R. P. HART**[2];
[1]Joint Program in Toxicology, [2]Cell Biol. & Neurosci., Rutgers Univ., Piscataway, NJ

Abstract: Variants of two human genes are associated with the greatest risk of Alzheimer's disease (AD)—the E4 allele of apolipoprotein E (APOE) and the Swedish mutation of amyloid precursor protein (APP). Studies suggest that risk is related to dosage, in that APOE E4/E4 has higher risk than E4/E3 or other APOE genotypes, and overexpression of APP, either Swedish or wild-type, leads to enhanced AD markers. Therefore, we constructed a library of lentiviruses designed to express selected variants of each gene. One group of plasmids is based on the pTet-O backbone so that expression is induced by doxycycline (dox), when co-transduced with rtTA, the required regulatory factor. Another version provides constitutive expression under control of the UBC promoter and is based on FUGW. The plasmids co-express either the expression marker mCherry or a drug-selectable resistance gene, each separated by a "self-cleaving" T2A peptide sequence. The 17-aa C-terminal T2A peptide can also be used as an epitope tag for specific detection of the exogenous protein. The APP plasmids include the wild-type sequence (NM_201414), the Swedish mutation (KM670/671NL), or the protective Icelandic mutation (A673T). The APOE (NM_000014) plasmids express E2, E3, or E4 variants. To demonstrate expression, we transduced cells and detected expression by mCherry fluorescence in live cells, by Western blotting, or using immunocytochemistry. Results indicate that expression from the dox-inducible promoter is responsive to dose of dox and that the UbC promoter expresses protein levels similar to normal expression. Imaging with mCherry is consistent with immunocytochemical detection of co-expressed protein. Transduced glial cells provide a source of extracellular APOE suitable for co-culture with neurons or preparation of conditioned media. Transduction of neurons with APP alters AD pathways. Transduction of APOE-null induced pluripotent stem (iPS) cells with the dox-inducible APOE provides a convenient starting material to study human neurons with controlled expression of individual APOE alleles. These lentiviruses provide effective tools for studying AD mechanisms in cultured cells or *in vivo.*

Title: The role of apoE isoforms in Alzheimer's disease-related neuropathology in isogenic human neuronal cells

Authors: S. O. ADEOSUN[1], X. CHEN[3], R. ALKAWAS[3], L. SHI[3], E. WICKS[3], B. ZHENG[3], T. MOSLEY[3], Y.-Y. MO[3], ***J. WANG**[2];

Abstract: Studies indicate that the prevalence of Alzheimer's disease (AD) differs among subjects with different APOE isoforms (E3, E4, or E2), with E4 being higher and E2 lower versus E3. The pathogenic mechanism of APOE isoforms in AD progression is not completely clear. One of the hurdles is that the analyses are often performed in cells derived from resources with different genetic backgrounds. In this work, we sought to generate isogenic apoE neuronal cell lines in a human immortalized cell line with adrenergic and dopaminergic phenotype -the SH-SY5Y cell. gRNAs were constructed in EF1α-hspCas9 all-in one Cas9 SmartNuclease plasmid; the homologous right and left arm (with ApoE2, E3, E4, or ApoE null exon4) were constructed in pHR2 plasmids with a GFP-T2A-Puro-polyA reporter on the 3-prime end of Exon4. We delivered the respective donor constructs and dual gRNA plasmids to replace, or remove the whole exon 4 in the genome of SH-SY5Y cells, respectively, using electroporation. After selection with puromycin, the phenotype of GFP positive cells were confirmed by sequencing the PCR products of the genomic DNA and RT-PCR products of the transcripts. In addition to evaluate the effects of ApoE isoforms on the expression of neuro-pathological markers and cell behaviors. We have successfully generated isogenic APOE4/3/2 and APOE knockout SH-SY5Y neuronal cell lines. These cells are used to compare the specific roles of individual apoE isoforms in the expression of known and new AD neuro-pathologic markers, including coding and non-coding genes, in response to neurotoxin (e.g. alcohol, rotenone, etc.) exposure. We are currently using a similar protocol to generate isogenic AD patient-derived fibroblasts and monocytes in our laboratory.

Title: Epigenetic regulation of apolipoprotein E by sphingosine-1-phosphate signaling

Authors: *N. TAKASUGI, M. KOMAI, N. KANESHIRO, T. UEHARA;
Dept. of Medicinal Pharmacol., Okayama University, Grad. Sch. of Medicine, Dentistry, and Pharmaceut. Sci., Okayama-ken, Japan

Abstract: Background: Sphingosine-1-phosphate (S1P) is a pluripotent lipophilic mediator working as a ligand for G-protein coupled S1P receptors (S1PR). Previously, we reported that sphingosine kinase (SphK2), which phosphorylate sphingosine to produce S1P, is upregulated in Alzheimer disease (AD) brains. And we also found that S1P signaling regulates the production of Amyloid-β peptide (Aβ) which is a pathogenic molecule for AD. However, the effect of S1P signaling on glial function remains unclear. Because S1P is reported as an epigenetic modulator, we examined the effect of this signaling on the one of the AD therapeutic target, nuclear receptors RXR/LXR agonists, which upregulate the Apolipoprotein E (ApoE) and ABCA1 expression. Method: Using specific inhibitor or RNA interference methodology, we analyzed the effect of SphK2/S1P signaling on a human astrocytoma cell line or primary astrocyte. Results: We identified that SphK2/S1P signaling specifically inhibited the induction of ApoE transcription, meanwhile, genetical and chemical inhibition of SphK2 activity enhanced ApoE induction by RXR/LXR agonists. Interestingly, the upregulation of ABCA1 by RXR/LXR agonists is not altered. By screening with RNA interference, we identified the candidate S1P receptor which may epigenetically regulate ApoE expression. Conclusion: Our results indicate that SphK2/S1P signaling is the key epigenetic regulator for ApoE, and the sensitivity of RXR/LXR agonists are changed by this lipid mediator. We will report the significance of this mechanism on AD pathogenesis.

Title: Endosomal pH drop ameliorates ApoE4-mediated synaptic impairments and reduces amyloid plaque load *in vivo*

Authors: *T. POHLKAMP, X. XIAN, M. DURAKOGLUGIL, C. H. WONG, F. PLATTNER, J. HERZ;
Univ. of Texas Southwestern Med. Ctr., Dallas, TX

Abstract: The pathological hallmarks of Alzheimer's disease (AD) are extracellular aggregates of the Amyloid β (Aβ) peptide, called plaques, and neurofibrillary tangles of hyperphosphorylated Tau. Processing of the Aβ precursor protein (APP) at the β- and γ-sites leads to Aβ production. Aβ forms neurotoxic oligomers and accumulates in plaques. Apolipoprotein E (ApoE) isoform ε4 is the highest genetic risk factor for AD and is thought to be involved in plaque deposition. ApoE is a cholesterol transporter in the brain and delivers its cargo by receptor-mediated endocytosis. The three main ApoE isoforms seen in humans are ApoE2 (ε2), ApoE3 (ε3), and ApoE4 (ε4). Due to two single nucleotide polymorphisms in the ApoE gene the amount of positively charged residues differs between the isoforms. The least common isoform ApoE2 has one positive charge less than the most common isoform ApoE3. ApoE4 has one positive charge more than ApoE3. Each allele of ApoE4 reduces the age of AD onset by approximately three years, whereas ApoE2 has protective effects, when compared to ApoE3. The difference in the quantity of positively charged residues alters the net charge and the isoelectric point (IEP) of ApoE. Importantly, the IEP of ApoE4 matches the pH 6.4 present in early endosomes. **We hypothesize that the match of the ApoE4 IEP with the early endosomal pH prevents ligand-receptor dissociation resulting in a trafficking defect.** In neurons ApoE, its receptor Apoer2, and glutamate receptors traffic through the same endosomal compartments. The neuronal stimulator Reelin is an alternative ligand of Apoer2 and can stimulate the increase of glutamate receptor expression on the neuronal surface resulting in enhanced long-term potentiation. Importantly, the AD risk factor ApoE4 impairs the surface expression of glutamate receptors upon Reelin stimulation. **Our recent data show that endosomal acidification, achieved by chemical or genetic depletion of the endosomal proton leakage channel Na/H Exchanger 6 (NHE6), prevents this ApoE4-mediated recycling deficit. Conditional NHE6 knockout alleviates ApoE4-mediated deficits in synaptic plasticity *in vivo*.** Moreover **NHE6 knockout in an Aβ producing AD mouse model led to a reduction in plaque load by approximately 80%. Fewer plaques were accompanied by increased activation of microglia and astrocytes in the NHE6 knockout brains.** There was no change in β-site cleavage by NHE6-ablation, which indicates that phagocytosis of Aβ deposits might be the underlying mechanism. Together these data suggest endosomal acidification as a promising drug target to prevent AD.

Abstract: Apolipoprotein E is a 299-residue lipid carrier protein produced in both the liver and the brain. The protein has three major isoforms denoted apoE2, apoE3, and apoE4 which differ at positions 112 and 158 and which occur at different frequencies in the human population. Genome-wide association studies (GWAS) indicate that the possession of two E4 alleles is a strong genetic risk factor for late-onset Alzheimer’s disease (LOAD). We have found that apoe4 is less stable to thermal denaturation than either aope2 or apoe3 and our hypothesis is that this decreased stability of apoe4 may lead either to some toxic loss of function, or, to some toxic gain of function for apoE4 compared to apoE2 and apoE3 and thereby be a contributing factor to the greater risk of developing Alzheimer’s disease for apoe4 carriers. In an attempt to identify a small molecule stabilizer of apoE4 that may have utility as a therapy for Alzheimer’s disease, we initially carried out an NMR-based fragment screen on the N-terminal domain of apoE4 and identified a benzyl amidine core that exhibited robust binding to the protein. Binding of the core was also characterized by thermal shift analysis, surface plasmon resonance, and its effect in a liposome breakdown assay. A crystal structure of the fragment bound to the apoE4 N-terminal domain was used to guide synthetic chemistry which yielded a ligand exhibiting single-digit micromolar affinity for apoE4. The resulting compound was also evaluated for mouse pharmacokinetics and in a cell-based functional assay and found to be efficacious in ameliorating readout of the inflammatory cytokines IL-6 and IL-8.

Abstract: A number of risk factors for late-onset sporadic Alzheimer’s disease (AD) have been identified, with apolipoprotein E4 (APOE4) being the largest genetic risk factor and driving greater disease risk in females. Though there are a number of mechanisms through which APOE4 may be acting to drive increased risk of AD, there is substantial evidence that neuroinflammation and glial function are key pathways in its effects. APOE4 has been shown to alter microglia, which are one of the major immune cells of the brain and are known to have a role in AD. Specifically, microglia are more pro-inflammatory both at baseline and after being

stimulated, when in the presence of APOE4. Recent reports have demonstrated that microglia have unique transcriptional profiles in the context of AD and other neurodegenerative conditions. Whether these signatures are exaggerated in the context of APOE4 or if APOE4 microglia have their own unique transcriptional phenotype is unknown. Thus, we used RNAseq to profile APOE4 microglia, both from a mouse model of AD as well as from patient induced pluripotent stem cell (iPSC)-derived microglia. CD11b+ microglia were isolated from male and female EFAD mice, which carry either human APOE3 or APOE4 and the 5xFAD transgenes. Additionally, iPSCs from healthy, non-demented APOE3 and APOE4 carriers were differentiated into microglia and treated with various inflammatory stimuli. RNAseq performed on both mouse and human iPSC-derived microglia uncovered that APOE4 and sex are associated with altered transcriptional phenotypes in microglia. Determining how APOE4 affects microglial transcription will be critical in understanding how this AD risk factor alters the function of microglia and contributes to disease. We have identified microglial networks that are altered in the context of APOE4 and sex, enabling us to now examine how these pathways may be impacting AD risk and progression.

Title: APOE genotype and sex affect TREM2-dependent microglial interactions with amyloid plaques in EFAD mice

Authors: T. STEPHEN[1], M. CACCIOTTOLO[1], D. BALU[2], T. E. MORGAN[1], M. LADU[2], C. E. FINCH[1], ***C. J. PIKE**[1];

Abstract: Microglia affect the pathogenesis of Alzheimer’s disease (AD), by protecting against amyloid accumulation in early phases of the disease and promoting neuropathology in advanced stages. Recent research has identified that specific microglial interactions with amyloid plaques exert important protective functions including attenuation of early pathology. It is unknown how these microglial interactions with plaques are affected by apolipoprotein E (*APOE*) genotype and

sex, two well-established AD risk factors that modulate microglial function. We investigated this question using high-resolution confocal microscopy to compare microglial interactions with amyloid plaques in EFAD mice (AD model that is hemizygous for the 5xFAD transgenes and homozygous for human *APOE3* or *APOE4*). In male and female E3FAD (*APOE3)* and E4FAD (*APOE4)* mice at 6 months of age, we observed that microglial coverage of plaques is highest in male E3FAD mice with significant reductions in coverage observed in female E3FAD and E4FAD mice. Plaque compaction, a beneficial consequence of microglial interactions with plaques, showed a similar pattern in which female E3FAD and E4FAD mice were associated with significantly lower values. Within the plaque environment, microglial expression of triggering receptor expressed on myeloid cells 2 (TREM2), a known regulator of microglial plaque coverage, was highest in male E3FAD mice and reduced in female E3FAD and E4FAD. These differences in plaque interactions were unrelated to the number of microglial processes in the plaque environment across groups. Interestingly, the pattern of amyloid burden across groups was opposite to that of microglial plaque coverage, with female E3FAD and E4FAD mice showing the highest amyloid levels. Alongside this, a similar pattern in the levels of dystrophic neurites, within the plaque environment, was observed. Together, these findings suggest a possible mechanism by which microglia may contribute to the increased AD risk associated with *APOE4* genotype and female sex.

Title: Interaction among sex, APOE genotypes and TREM2 on primary mouse microglial functions

Authors: *T. IIDA[1], C. J. PIKE[2];
[1]Leonard Davis Sch. of Gerontology, Los Angeles, CA; [2]USC Leonard Davis Sch. of Gerontology, USC, Los Angeles, CA

Abstract: Microglia are significant modulators of Alzheimer’s disease (AD) risk and pathogenesis. An important but understudied issue is how AD-related microglia actions are

affected by individual and interactive effects of AD risk factors. Three important factors are sex, apolipoprotein E (APOE) genotype, and triggering receptor expressed on myeloid cells 2 (TREM2). First, AD is characterized by numerous sex differences. One important sex difference is that the predominant genetic risk factor for late-onset of AD, the ε4 allele of APOE (APOE4), enhances AD risk more in women than men. Sex also affects microglial phenotypes and functions, including those implicated in AD. Interestingly, APOE4 carriers show enhanced microglial activation, which is thought to contribute to pronounced neuroinflammation. Third, a TREM2 mutation that results in partial loss of function strongly increases AD risk. In brain, TREM2 is mainly expressed in microglia and signals with APOE protein to regulate several microglial functions. The extent to which microglial actions are modulated by interactions among sex, APOE genotype, TREM2 expression is not known. To investigate this issue, we utilized primary mixed glial cultures generated from young adult (age 3-3.5 months) male and female mice homozygous for human APOE3 or APOE4. To model TREM2 partial loss of function, we used TREM2 knockdown. Transfection of TREM2 siRNA decreased protein and mRNA levels of TREM2 compared to scrambled siRNA. Inflammatory cytokines secreted from microglia in response to various stimuli contribute to progression of AD. Thus, we examined mRNA expression of inflammatory cytokines (e.g., IL-1β, IL-6 and TNFα) under basal conditions and following stimulation with lipopolysaccharide or oligomeric amyloid-β (Aβ). Furthermore, microglia clear Aβ from brain, decreasing accumulation of neurotoxic Aβ. To assess microglial clearance, we evaluated (1) microglial phagocytosis of fluorescent beads, and (2) phagocytosis and digestion of fluorescence-labeled Aβ. A range of individual and interactive outcomes were observed among TREM2 expression, APOE genotypes and sex. These findings provide new insight into the role of AD risk factors in modulating microglial actions relevant to development of late-onset AD.

Title: Sex- and APOE genotype-associated differences in cortical thickness in healthy, middle-aged adults

Authors: *K. N. LECLAIRE, J. K. BLUJUS, I. DRISCOLL;
Psychology, Univ. of Wisconsin-Milwaukee, Milwaukee, WI

Abstract: The Apolipoprotein E (APOE) ε4 allele is the best-established genetic risk for late-onset Alzheimer's disease (AD). Moreover, APOE ε4 allele confers even greater risk for AD in females than males. Extant literature has largely focused on characterizing sex-APOE interactions on structural brain integrity in older adults (aged 65+). It is important to better characterize these relationships in middle-aged adults, well prior to the onset of overt clinical symptoms and already substantial structural damage that accompanies this stage, in order to aid in early prevention or intervention efforts. We investigated the relationships between sex, APOE status, and cortical thickness in healthy, non-demented, middle-aged adults (ages 40-60, *M*=49.97, *SD*=6.04, N=128; 77 females). All participants underwent structural MR imaging, were genotyped and classified as ε4 carriers (i.e., ε4/ε4, ε3/ε4, ε2/ε4; n=38) or noncarriers (i.e., ε3/ε3, ε2/ε3, ε2/ε2; n=90). Main effects of both sex and APOE status were significant, even after controlling for multiple comparisons. Females had greater cortical thickness bilaterally in the superior frontal gyrus ($p<0.01$), the left pars triangularis ($p<0.03$) and middle temporal gyrus ($p<0.03$) compared to males. Thinner cortices were observed in the left rostral middle frontal gyrus ($p<0.02$) in ε4 allele carriers compared to noncarriers. Furthermore, there was a significant sex-APOE interaction. Female ε4 noncarriers had thicker cortices in the left caudal anterior cingulate cortex, banks of the superior temporal sulcus, superior frontal gyrus, and superior parietal cortex, as well as the right precentral gyrus ($p's<0.01$), compared to male ε4 noncarriers. Female ε4 allele carriers had thicker cortices bilaterally in the superior frontal gyrus ($p<0.01$) compared to male ε4 allele carriers. Female ε4 carriers also had thinner cortices in the left rostral anterior cingulate cortex compared to female noncarriers ($p<0.03$). No differences in cortical thickness were observed in males regardless of APOE status. Overall, our findings suggest that the associations between APOE risk and cortical thickness may be more pronounced in females and can be observed in middle age, well before the onset of overt symptoms associated with pathological aging.

Title: Effects of APOE genotype and estrogen status on systemic and neural effects of acute immune challenge in female mice

Authors: *J. LIU, C. SAMPLE, C. J. PIKE;
USC, Los Angeles, CA

Abstract: Alzheimer's disease (AD) is an age-related neurodegenerative disease with multiple risk factors. An accumulating literature provides evidence that the innate immune system is an important regulator of both the initiation and progression of the disease. The predominant genetic risk factor for late-onset AD is the ε4 allele of apolipoprotein E (APOE4), which is implicated in contributing to AD risk in part by increasing susceptibility to inflammation. Consistent with a regulatory role in innate immune responses, acute challenge with the endotoxin lipopolysaccharide (LPS) is reported to yield higher inflammation in both human carriers of APOE4 and mice with knock-in of human APOE4. Another AD risk factor is age-related depletion of the estrogens in women. Estradiol, the primary bioactive estrogen, is also a regulator of inflammation. Low estradiol level is associated with changes in the peripheral immune response that can be partially reversed by hormone therapy. Uncertain are the extent to which APOE genotype may modulate innate immune responses in females and whether this relationship is affected by estradiol levels. To study these questions, we studied the peripheral, neural, and behavioral effects of acute LPS challenge on adult female mice homozygous for human APOE3 or APOE4 in the presence or absence of estradiol. Peripheral LPS administration was associated with hypothermia and sickness behaviors - likely to be important defense responses to severe systemic inflammation - that were more pronounced in APOE4 mice, particularly under low estradiol. LPS induced robust increases in cytokine expression, which was assessed in liver, brain, and plasma. Overall, patterns of cytokine levels were similar across APOE genotype and estrogen status though there was an unexpected general trend for APOE3 genotype to exhibit higher cytokine expression under basal and challenge conditions. Whereas prior evidence suggests APOE4 can increase vulnerability to immune challenges, the current findings indicate that APOE4 also can exert relatively protective outcomes in acute inflammatory response.

Title: Metabolic and cognitive effects of obesity: Regulation by estradiol in female APOE3, APOE3/4 and APOE4 mice at early middle age

Authors: *A. CHRISTENSEN, C. J. PIKE;
USC Leonard Davis Sch. of Gerontology, USC, Los Angeles, CA

Abstract: The predominant genetic risk factor for late onset Alzheimer's disease (AD) is the apolipoprotein E ε4 allele (*APOE4*). AD risk associated with *APOE4* disproportionately affects women. Further, human and rodent studies indicate that the cognitive deficits associated with *APOE4* are greater in females. Several modifiable lifestyle factors also affect AD risk. One such factor is obesity during middle-age. Given that ~65% of US adults are overweight, it is important to understand how obesity affects AD risk, how it interacts with *APOE4*, and the extent to which its detrimental effects can be mitigated with therapeutics. One intervention often considered for women is estrogen-based hormone therapy, which can exert wide-ranging health benefits when administered in early middle-age but may be harmful in late middle-age. No experimental studies have explored the interactions among *APOE4*, obesity, and hormone therapy in aging females. To look at these issues, we considered how obesity outcomes are affected by treatment with estradiol at the onset of middle-age in female mice with human *APOE3* and *APOE4*. Transgenic mice with targeted replacement of mouse *APOE* with human *APOE3* or *APOE4* (called EFAD non-carriers, EFAD-NC) were generated from breeding of EFAD-Tg mice, which are homozygous for human *APOE* against a hemizygous background of 5xFAD-Tg mice. In addition to studying *APOE3* and *APOE4* mice, we also explored how gene dosage would be affected by obesity and estradiol treatment, so we also generated mice hemizygous for *APOE4* (*APOE3/4)*. Female EFAD-NC mice were examined over a four-month period that spans the transition into reproductive senescence, which models many aspects of human perimenopause. Beginning at 5 months of age, mice were maintained on a control diet (10% fat) or high-fat diet (HFD; 60% fat). After 8 weeks, by which time obesity was present in all HFD groups, mice were implanted with an estradiol or vehicle capsule that was maintained for the final 8 weeks of the experiment. Animals were assessed on a wide range of metabolic and neural measures. Three general patterns emerged: (1) Under normal diet, *APOE4* was associated with poorer metabolic function and cognitive performance; (2) With HFD, *APOE3* showed greater obesity-induced impairments in metabolic function and cognitive performance; (3) Estradiol treatment improved metabolic and cognitive outcomes across all groups, with *APOE4* generally exhibiting the greatest benefit. Together, these findings highlight the importance of *APOE* genotype as a modulator of not only consequences induced by the AD risk factor obesity, but also beneficial outcomes of estradiol, a putative AD preventive intervention.

Universitario de la Princesa, Madrid, Spain

Abstract: Alterations in autophagy are increasingly being recognized in the pathogenesis of different neurodegenerative diseases such as tauopathies. Therefore, regulation of this process in the early stages could be a promising disease modifying strategy. Melatonin is a neurohormone that has shown a good neuroprotective profile in Alzheimer related models. The aim of this study was to evaluate if melatonin treatment, before cognitive decline, could restore the autophagic flux and prevent dementia. We have used as tauopathy model the injection of AAV-hTau^{P301L}/GFP viral vectors (under the promotor of synapsin) and treatment/injection with okadaic acid in *ex vivo*, human brain slices and *in vivo* models. In the *in vivo* studies, intracerebroventricular injection of AAV-hTau^{P301L} increased oxidative stress, neuroinflammation and tau hyperphosphorylation in the hippocampus 7 days after the injection, without inducing cognitive impairment; however, 28 days later, animals presented cognitive decline in the NOR test. Administration of melatonin (10 mg/Kg) in the drinking water, from day 7 to day 28, reduced oxidative stress, neuroinflammation, tau hyperphosphorylation and caspase-3 activation; these observations correlated with restoration of the autophagy flux and memory improvement. This study highlights the importance of autophagic dysregulation in tauopathy and how melatonin treatment in the early phases of the disease can restore the autophagy flux, and thereby, prevent cognitive decline. Therefore, the development of drugs that improve the autophagy flux such as melatonin or melatonin derivatives could be useful for the treatment of proteinopathies like AD.

Title: CDPPB prevents neurotoxic effects induced by amyloid-beta 1-42 and improve neuropathological changes in app transgenic mice

Authors: *P. M. Q. BELLOZI[1], M. C. M. DA SILVA[1], G. F. GOMES[1], I. V. A. LIMA[1], C. R. A. BATISTA[1], W. O. C. JUNIOR[1], J. G. DORIA[1], T. WYSS-CORAY[2], F. M. RIBEIRO[1], A. C. P. DE OLIVEIRA[1];
[1]Univ. Federal de Minas Gerais, Belo Horizonte, Brazil; [2]Stanford Univ., Palo Alto, CA

Abstract: Alzheimer’s disease (AD) is the most incident neurodegenerative disorder. Despite the advances in the understanding of its pathophysiology, none of the available therapies prevents its progress. Glutamate-induced excitotoxicity plays an important role AD. However, the role of metabotropic glutamate receptors (mGluR) in neuronal cell death is not completely understood. Recent data indicates that CDPPB, a positive allosteric modulator of mGluR5, has neuroprotective effects. Thus, we investigated the effects of CDPPB in Aβ-induced pathological alterations and in a mouse overexpressing APP. Hippocampal neuronal cultures prepared from newborn C57Bl/6 mice were treated with CDPPB (1 μM), followed by Aβ, to assess the neuronal death. Male C57Bl/6 mice submitted to Aβ 1-42 intra-hippocampal injection were treated for 8 days with CDPPB (1 or 5 mg/Kg, i.p.) or its vehicle and then submitted to object recognition task or contextual conditioned fear test. Subsequently, animals were euthanized and their hippocampal brain slices were stained with FluoroJade C (FJC), NeuN, Iba-1, CD68 and GFAP. APP41 (T41) transgenic mice, 14 months old, received CDPPB (5 mg/Kg, i.p.) or its vehicle for 28 days and were submitted to the same behavioral tasks. After euthanized, their hippocampal slices were stained with NeuN, Iba-1, CD68 and GFAP; the hippocampal Aβ content was measured; and serum levels of hepatic enzymes were assessed. CDPPB prevented *in vitro* Aβ-induced neuronal death. Despite not preventing memory deficits in T41 mice, the drug recoveried Aβ-induced memory impairment. CDPPB ameriorated neuronal viability both after

Aβ injection and in T41 mice and partially reversed gliosis in CA1 region of T41 mice. The mGluR5 modulator, however, did not change Aβ levels and, importantly, seric hepatic enzymes content, in T41 mice. Therefore, CDPPB has a potential neuroprotective effect in AD, especially associated with the prevention of neuronal loss. Thus, there should be considered additional evaluations of the drug, either with earlier interventions in AD models or with longer treatments.

Title: Discovery of novel small molecule therapeutics for Alzhiemer's disease by targeting steric zippers involved in tau aggregation

Authors: *M. APOSTOL[1], M. GRAF[1], A. LAY[1], M. SCHULTZE[1], J. SCHERRER[1], G. NAUMANN[1], A. P. WRIGHT[1], I. HERNANDEZ[2], G. LUNA[2], K. S. KOSIK[2], J. J. TREANOR[1];
[1]Adrx, Inc., Thousand Oaks, CA; [2]Neurosci. Res. Inst., Univ. of California Santa Barbara, Santa Barbara, CA

Abstract: Frontotemporal dementia and Alzheimer's disease (AD) are progressive neurodegenerative diseases characterized in part by aggregation of the tau protein. At the molecular and cellular levels the aggregation of tau leads to the formation of neurofibrillary tangles (NFTs) that cause a loss of neuronal connectivity, initiates neurodegeneration, and result in the cognitive decline that is the hallmark of the disease. Tau aggregation is dependent on two highly aggregation-prone hexapeptide segments or "steric zippers"--VQIVYK and VQIINK--that are located in the repeat domains in the tau protein. ADRx has used a structure-based approach to design and optimize novel peptidic Tau Aggregation Inhibitors (pTAI) that bind to these segments in their aggregation-competent conformation. Here we show that pTAIs are potent inhibitors of Tau aggregation both *in vitro*biochemical and cellular assays and *in vivo*into transgenic rTg4510 mice using a novel viral delivery approach. Based on the ability of pTAIs to specifically bind to Tau in its aggregated state, we have designed a competition assay to enable high throughput screening to find small molecules that elicit the same effects in the developed suite of assays. We show here that by screening a library of over 200,000 compounds we were able to identify a series of small molecule TAIs that block aggregation of Tau *in vitro*biochemical and cellular assays. Because of the nature of the unique competition assay used

for screening, the discovered molecules promise a level of specificity and potency superior to previously offered aggregation inhibitors. Results from these studies enhance our understanding of aggregation-prone segments of tau as a therapeutic target and of targeted small molecule TAIs as a potential therapy for AD and other tauopathies.

Title: Role of plasminogen activator inhibitor-1 (PAI-1) in cerebrovascular morphometry and cognition in a mouse model of Alzheimer's disease

Authors: ***T. K. STEVENSON**[1], R. C. STEVENSON[2], E. J. SU[3], D. A. LAWRENCE[5], G. G. MURPHY[4];
[1]Mol. and Behavioral Neurosci. Inst., [2]Mol. and Integrative Physiol., [3]Dept. of Intrnl. Medicine, Div. of Cardiovasc. Med., [4]MBNI/Physiology, Univ. of Michigan, Ann Arbor, MI; [5]Intrnl. Med., Univ. Michigan, Ann Arbor, MI

Abstract: BACKGROUND: There is accumulating evidence which suggest that cerebrovascular pathologies are associated with cognitive decline and neurodegeneration in Alzheimer’s disease (AD) patients. Indeed, risk factors known to promote vascular dysfunction in cardiovascular disease (CVD) are also risk factors for the development of AD. Of particular interest is the serine protease inhibitor, PAI-1, plasminogen activator inhibitor-1, which is a well-established, independent CVD risk factor that increases with age. Recently, PAI-1, which is known to regulate angiogenesis, was found to be significantly upregulated in the tauopathy AD mouse model Tg4510; importantly, Tg4510 mice were shown to have severe cerebrovascular-patterning abnormalities. OBJECTIVE: It is unclear what role PAI-1 is playing in vascular remodeling and if similar changes in vascular remodeling are present in an amyloidogenic AD mouse model (5xFAD). In addition, it is unclear what effect these changes on the vasculature have on cognition, cerebrovascular physiology, and AD pathology. To address these questions, 5xFAD mice and littermate controls were given a novel PAI-1 inhibitor, and cognition, vascular

morphometry, and amyloid-beta (Aβ) plaque load were assessed. METHODS: The Morris water maze was used to assess cognition in 8-month old 5xFAD (n = 9) and littermate controls (n = 5) treated with the PAI-1 inhibitor. Following completion of the Morris water maze, the cerebrovasculature was double-labeled with a tail-vein injection of DyLight 594 tomato-lectin and a TRITC-Dextran gelatin solution. Brains were sectioned (500µm) and treated with the Pittsburgh compound B (6-OH-BTA-1) to visualize Aβ plaques. SeeDeepBrain technology was then used to optically clear the sectioned tissue and a ~0.1mm^3 volume of tissue was imaged using confocal microscopy. Hippocampal vascular morphometry statistics, including vessel diameter and length and vascular density, were gathered using custom Matlab and Mathematica software programs. RESULTS: Cognitive assessment of learning and memory from the Morris water maze suggests that inhibition of PAI-1 improves cognition in 8 month old 5xFAD mice. Moreover, preliminary analysis of hippocampal vascular morphometry indicates that the 5xFAD mouse model has differences in vessel branch density, and vessel diameter and length. Treatment with the PAI-1 inhibitor appears to ameliorate these changes in the 5xFAD mouse model. CONCLUSIONS: This data will provide important insights into AD pathology; specifically, how changes in the vasculature architecture can affect cerebrovascular physiology and AD progression.

Title: Targeting the Alzheimer’s disease-associated risk gene, TREM2, with antisense oligonucleotides

Authors: *K. M. SCHOCH[1], R. N. BANNON[1], L. EZERSKIY[1], P. JAFAR-NEJAD[2], F. RIGO[2], T. M. MILLER[1];
[1]Neurol., Washington Univ. in St. Louis, Saint Louis, MO; [2]Ionis Pharmaceuticals, Carlsbad, CA

Abstract: Genetic variants within the *TREM2* gene show strong association with increased Alzheimer's disease (AD) risk. To enhance understanding of TREM2 loss, mice haploinsufficient or null for *TREM2* have been crossed with amyloid beta-depositing mouse models, yielding both positive and negative effects of TREM2 reduction on amyloid beta deposition. While these ongoing studies have identified important relationships between TREM2, microglia, and AD pathology, they are challenging to interpret in the context of varying microglial phenotypes and disease progression. We hypothesized that short-term *TREM2* reduction in the adult mouse may alter amyloid pathology and microglial pathology, thereby helping to guide *TREM2*-targeted therapeutic strategies for patients. We developed antisense oligonucleotides (ASOs) that potently lower *TREM2* mRNA throughout the brain. ASOs were administered to the lateral ventricle via a single bolus injection in male APP/PS1 mice at 10 months of age. One month later, mice were assessed for plaque deposition and microglial responses. *TREM2*-targeted ASO treatment in APP/PS1 mice substantially decreased *TREM2* mRNA compared to control ASO treatment across multiple brain regions. When evaluated for amyloid plaques, brains from ASO-mediated *TREM2* knockdown treated mice exhibited significantly reduced plaque deposition and less microglial association around plaque deposits. Results obtained from cultured microglia suggest phagocytosis activity may be increased with *TREM2* reduction, consistent with the decreased plaque load identified *in vivo*. These results confirm a role for TREM2 in mediating increased plaque deposition and suggest that *TREM2* lowering may reduce pathological markers of neuroinflammation. While these data are seemingly contradictory to the presumption that *TREM2* genetic variants confer a loss of function, an ASO approach allows for greater understanding of TREM2 interventions throughout disease progression, which may depend on the timing and location of TREM2 signalling. Overall, ASOs that target *TREM2* will be highly informative on *TREM2*-mediated AD pathogenesis and may be effective at modulating disease.

Title: Design and assessment of antiepileptic drug nanocarriers as a therapeutic strategy for pharmacoresistant seizures control

Authors: *A. ROSILLO-DE LA TORRE, F. ROMERO-ARGOTE, I. A. QUINTERO-ORTEGA, L. E. CASTELLANO-TORRES, J. DELGADO-GARCÍA;
Chemical,Electronic and Biomed. Engin. Dept., Univ. of Guanajuato, León, Mexico

Abstract: Nanocarriers represent a novel strategy for the transport and delivery of drugs in several pathologic conditions, which are characterized by the overexpression of efflux proteins, such as, P-glycoprotein (P-gp). The aim of the present study was to synthesize and physicochemically characterize phenytoin (PHT) loaded silica nanocarriers (SnC) and, evaluate their effect in an animal model of refractory seizures with P-gp overexpression. SnC were synthetized by the Stober method and PHT was loaded by absorption. The PHT *in vitro* release evaluation was performed simulating physiological conditions. P-gp overexpression was induced in male Wistar rats by repeated administration of 3-mercaptopropionic acid (3MP, 37.5 mg/kg i.p.), every 12 hours for 5 days. Microscopy analysis verified the sphere-shaped morphology with a mean diameter of 69.51 ± 7.63 nm and 3.62 mg of PHT were loaded in each 100 mg SnC. The infrared analysis revealed characteristic bands (3276 and 3212 cm^{-1}) attributed to the functional groups of the AE drug. The drug release kinetics from the SnC presented a two-phase behavior: first an initial burst discharge (308.31 ± 19.86 μg/mL) followed by a sustained release (618.44 ± 86.81 μg/mL) throughout 48 h. For in vivo evaluation, Pgp-PHT-SnC group (n=5) were administered with PHT loaded SnC (210 mg/kg, i.p.) one hour before a new (11^{th}) 3MP injection. Other experimental groups also were evaluated: a) Pgp-SnC group (n=5), rats were manipulated as Pgp-PHT-SnC group, but injected with SnC not loaded with the AE drug; b) Pgp-PHT group (n=5), animals were handled as Pgp-PHT-SnC group, but administered with PHT not loaded in SnC; c) 3MP group (n=5) that only received repetitive 3MP administration and d) PHT group (n=5), rats were manipulated as the Pgp-PHT group, except that the animals do not received repetitive 3MP injections. Incidence to tonic-clonic seizures were assessed during 30 min immediately after the last 3MP injection. All the rats (100%) from the 3MP presented tonic-clonic seizures while none of the subjects of the Pgp-PHT group presented seizures. Pgp-SnC and Pgp-PHT groups presented similar incidence for tonic-clonic seizures (80 and 70%, respectively), when compared with 3MP group. In contrast, PHT loaded in SnC protected all the animals of the Pgp-PHT-SnC group (0%, $p<0.05$), to present tonic-clonic seizures. These findings show that the SnC could be a therapeutic tool for the transport of AE drugs in refractory disorders with overexpression of efflux proteins, as P-gp. Nevertheless, more studies should be done for evaluating the positive or negative bearings of SnC in experimental models of refractory epilepsy.

Title: Characterization of an HDAC corepressor complex inhibitor for the treatment of FTD-GRN

Authors: *M. IVARSSON, B. A. LYNCH, A. PIRONE, N. O. FULLER;
Rodin Therapeut., Cambridge, MA

Abstract: The familial form of progranulin-associated progressive frontotemporal dementia (FTD-GRN) is caused by haploinsufficiency at the progranulin gene (*GRN*); FTD-GRN has no significant treatments at this time. Upregulation of progranulin expression from the remaining normal *GRN* allele in patients is a potential therapeutic strategy that is being explored. The HDAC inhibitor (HDACi) Vorinostat, or SAHA, an approved cancer drug, was first reported as upregulating *GRN* expression in *in vitro* cell systems. Vorinostat is a broad spectrum HDACi, which inhibits multiple members of the multi-class HDAC family. Broad spectrum HDACi such as Vorinostat generally have significant toxicity, especially hematological toxicity, and combined with low brain exposure creates an impediment to using HDACis as a therapy for FTD-GRN treatment. We are developing more selective HDACis to treat FTD-GRN. Evidence supports that some, but not all, Class I selective HDACi can upregulate progranulin expression; furthermore, most known Class I selective HDACis still exhibit significant toxicity. We've previously screened a collection of proprietary, complex-selective HDACi, with much-improved safety profiles relative to Vorinostat and other known Class I HDACi, in an *in vitro* neuroblastoma cell line assay (SH-SY5Y), and we have identified compounds, including representative compound R8, that upregulate progranulin *in vitro*. We have also tested R8 effects on gene expression in an *in vitro*, differentiated SH-SY5Y cells, which were treated with the compound under various conditions. Extracted RNA was analyzed by the Nanostring neuropathology probe set, and changes in levels of mRNA were compared across treatments. We report the effects of treatment with R8 on gene expression, noting specific effects on neuronal, and learning and memory-related genes and pathways. Additionally, sub-chronic oral administration of R8 in WT mice resulted in increased expression of progranulin in brain. Interestingly, this result correlates with a significantly increased spine density in the CA1 region of the dorsal hippocampus of WT mice after sub-chronic *in vivo* treatment with R8. Together, our results describe the properties of a new, selective and safe HDACi (R8) which upregulates

progranulin levels as well as synaptic formation, representing a new potential therapeutic intervention in FTD-GRN.

Title: Carbachol-induced phosphorylation of glycogen synthase kinase 3 beta (GSK3beta) and extracellular signal-regulated kinase (ERK 1/2) in the telencephalon of adult zebrafish is mediated by muscarinic acetylcholine receptors

Authors: *R. A. MANS, G. POWERS;
Georgia Southern University-Armstrong Campus, Savannah, GA

Abstract: The zebrafish (*Danio rerio*) represents a widely used model organism for the study of vertebrate development, and it has recently gained in prominence for the study of brain function and disease. While it is known that zebrafish share approximately 70% genetic similarity with humans, the physiology of the zebrafish brain remains largely uncharacterized. In mammals, the proteins glycogen synthase kinase 3 beta (GSK3beta) and extracellular-signal regulated kinase (ERK1/2) are integral for normal and pathogenic brain processes including cell survival, synaptic plasticity, and inflammation, and the activity of mammalian GSK3beta and ERK1/2 are regulated by muscarinic acetylcholine receptors (mAChRs). Recently, we demonstrated that cholinergic stimulation of the adult zebrafish brain using the non-specific cholinergic agonist carbachol (CCh) induces phosphorylation of GSK3beta and ERK1/2 in the zebrafish

telencephalon, a structure with functional homology to the human hippocampus and striatum. The current study was conducted to investigate the AChR subtypes mediating CCh-induced phosphorylation of GSK3beta and ERK1/2. To this end, male and female adult zebrafish brains were isolated and maintained *ex vivo* in oxygenated artificial cerebrospinal fluid (aCSF) before being subjected to pharmacology and Western blot analysis. It was demonstrated that blockade of mAChRs using scopolamine attenuated CCh-induced increases in GSK3beta (N=16) and ERK1/2 (N=9) relative to vehicle-treated controls, indicating mAChRs contributed to the increased phosphorylation observed in CCh treatments. Additionally, selective stimulation of mAChRs with oxotremorine-M increased the phosphorylation of GSK3beta (N=11) and ERK1/2 (N=9) relative to vehicle-treated controls. These results provide evidence for the coupling of GSK3beta and ERK phosphorylation to mAChRs in the adult zebrafish telencephalon, which indicates functional conservation between the cholinergic systems of zebrafish and mammals (no sex differences were detected). Future experiments investigating the roles of GSK3beta and ERK1/2 in AChR dependent processes will further elucidate the degree by which zebrafish may be used to model mammalian brain function and disease.

Title: Novel synthetic BDNF derived peptides protects dental pulp mesenchymal stem cells (DPSCs) against oxidative stress through the TrkB receptor

Authors: *M. SILVA-LUCERO[1], G. LOPEZ-TOLEDO[2], T. PADILLA[1], V. TORRES-ROJAS[3], L. ZHANG[1], M. CARDENAS-AGUAYO[1];
[1]Physiol., UNAM, Med. Sch., Mexico, Mexico; [2]Physiol. Biophysics and Neurosci., CINVESTAV, Mexico, Mexico; [3]Ingenieria en Biotecnologia, UnADM, Mexico, Mexico

Abstract: Dental Pulp Stem Cells (DPSCs) are adult mesenchymal stem cells, with a great capacity for differentiation towards different lineages. The *in vitro* differentiation of DPSCs depends mainly on the presence of growth factors and cytokines. Currently the goal of cell therapy is to promote the regeneration of lost or damaged tissue by means of the implantation of cells, undifferentiated or differentiated into the damage tissue, for this purpose it is necessary to establish the appropriate conditions to culture the DPSCs and differentiate them into the required

cell type. There is great interest in using DPSCs in the treatment of neurodegenerative diseases such as Alzheimer's, Parkinson's and Huntington's, since they share similarities with the stem cells of the neural crest and can be differentiated into neuronal and glial cells *in vitro*, in the presence of growth factors. Neurotrophic factors are of great importance in the development, differentiation, maintenance and regeneration of neurons. Although it has been demonstrated that BDNF favors the survival and differentiation of neural precursors, it does not have appropriate pharmacological properties, due to its high molecular weight, and its low permeability in the blood-brain barrier, thus our gold is to evaluate the effect of small synthetic peptides derived from the active site of BDNF that mimic the functions of BDNF, but are more permeable through the blood-brain barrier and stable in the plasma. Therefore, we evaluated the trophic role of two hexa- (B3E and B5E) derived from the active site of BDNF, on the proliferation, survival and differentiation of normal female (46 years old) DPSCs, in order to find peptides with possible therapeutic applications for neurodegenerative diseases, we challenge the cells culturing them in stress conditions, such as oxidative stress in the presence or absence of the peptides. We evaluate the effect of the peptides on the viability (by WST-1), proliferation and differentiation of DPSCS, through the detection of stem cell and neuronal markers by Western blot and immunofluorescence techniques, as well as by RT-PCR. We conclude that BDNF synthetic peptides activate TrkB receptor and promote survival of DPSCs, therefore these small molecules have therapeutic potential.

Title: Alendronate, an antiresorptive drug, confers neuroprotective effect against Alzheimer's disease like pathological changes in mice induced by high fat diet and aluminium trichloride plus D-galactose

Authors: *S. ZAMEER[1], D. VOHORA[2], J. ALI[2], M. AKHTAR[2];
[1]Pharmaceut. Med., [2]Jamia Hamdard, New Delhi, India

Abstract: In the present scenario, millions of people throughout the world are affected by various age-linked neurological disorders such as neurodegenerative diseases. Alzheimer’s

disease (AD) is a most prevalent and complex neurodegenerative disorder which is manifested by progressive cognitive depletion, senile plaques, neurofibrillary tangles, neuronal and synaptic death. The elusive etiopathology and constant clinical trial failure directed the researchers to explore therapeutic target for AD. Neurodegenerative disorders and osteoporosis were observed to have some similar risk factors such as increasing age, altered isoprenoids and their downstream components. Supporting this notion, bisphosphonates (BPs), recommended for treatment of bone disorders were demonstrated to be beneficial in attenuation of dementia in osteoporotic patients.
Alendronate, a nitrogen-containing BPs, acts by blocking farnesyl pyrophosphate synthase (FPPS) enzyme in Mevalonate pathway and modulate isoprenoids and also cited to inhibit acetylcholinesterase enzyme and cholesterol in brain. Thus the present hypothesis was designed to explore the effect of alendronate against high fat diet (HFD) induced pathologies resembling AD in mice. It was observed that oral administration of alendronate for 15 days in mice exposed to HFD for 14 weeks and AlCl3+D-galactose for 6 weeks showed improvement in neurobehavior, reduction in hippocampal neuroinflammatory cytokine (IL-1β, TNF-α), cholinesterases, Aβ, APP processing, and oxidative stress markers and isoprenoids serum cholesterol (in HFD model). These neuroprotective findings of alendronate were supported by histopathological analysis done by Congo red staining. Our current outcomes suggest the prominent role of alendronate against AD like pathologies by targeting Mevalonate pathway, supporting this NBPs a potential target for AD treatment.
Key words: Alzheimer’s disease, alendronate, isoprenoids, amyloid beta, APP processing, GSK-3β

Title: An automated microliter-scale high-throughput screening system (MSHTS) using quantum-dot nanoprobes for amyloid aggregation inhibitors

Authors: *R. SASAKI[1], R. TAINAKA[1], Y. ANDO[1], M. KURAGANO[1], K. OTA[2], K. MONDE[3], K. UWAI[1], K. TOKURAKU[1];
[1]Muroran Inst. of Technol., Muroran, Japan; [2]Showa Univ., Tokyo, Japan; [3]Hokkaido Univ., Sapporo, Japan

Abstract: Alzheimer's disease (AD) is the most popular disease in dementia. Recent studies have shown that aggregation and accumulation of amyloid β (Aβ) and tau are involved in the pathogenesis of AD. Therefore, substances inhibiting the aggregation and accumulation of Aβ and tau have great potential as a lead compounds of prophylactic and therapeutic drugs for AD. In this study, we tried to develop an automated real-time microliter-scale high throughput screening (MSHTS) system for Aβ and tau aggregation inhibitors using quantum-dot (QD) nanoprobes. We also analyzed 504 crude extracts from plants and 134 low molecular weight aromatic compounds using this automated system. To automate the MSHTS system, first, we tried to optimize the sample dilution and the mixing steps by JANUS G3 automated workstation (Perkin Elmer). The results demonstrated that the mixing process of $A\beta_{42}$and inhibitor significantly affected the evaluation of inhibitory activity. Therefore, we examined optimal pipetting conditions (number of times, speed, volume) in the mixing process of Aβ and inhibitor. Next, we examined the type of QDs to visualized aggregates. In previous reports, we used QD655 which emits fluorescence at 655 nm. Since chlorophyll-derived absorption of plant extracts at 650-700 nm may affect to the fluorescence intensity of QD655, we used QD605, which does not overlap with the absorption of chlorophylls. In addition, for rapid analysis, we also examined automatic imaging conditions using a fluorescence microscope system (ECLIPSE Ti-E, Nikon).With these trials, we were able to capture all 1536 wells within 1 hour, and it became possible to correctly analyze the amount of aggregates without depending on the brightness and darkness of the samples. Screening 504 plant crude extracts revealed the relationship of Aβ aggregation inhibitory activities of plant extracts using a plant-based classification. Within the eudicots, rosids, Geraniales and Myrtales showed higher activity. Screening of low molecular weight aromatic compounds demonstrated that the structure of tropolone endows it with potential Aβ aggregation inhibitory activity. The activity of the most active tropolone derivative was higher than that of rosmarinic acid that we previously identified from summer savory. MSHTS also identified three chaperone molecules as tau aggregation inhibitors. These results demonstrate that our automated MSHTS system is a novel and robust tool that can be adapted to a wide range of compounds and aggregation-prone polypeptides.

Abstract: Recent focus has been given to natural dietary compounds (so-called ‘nutraceuticals’) as Alzheimer’s disease (AD) modifying therapies. Plant-derived phenolics make ideal nutraceuticals, because they are well-tolerated and have drug-like properties including anti-inflammatory and anti-oxidant activities. Here, we investigated the therapeutic potential of gallic acid (GA) using the pre-clinical mutant human amyloid β-protein precursor and presenilin 1 (APP/PS1) transgenic mouse model of AD. Beginning at 12 months of age, we orally administered GA (20 mg/kg) or vehicle once daily for 6 months to APP/PS1 mice that have accelerated cerebral amyloidosis. At 18 months of age, GA treatment reversed transgene-related learning and memory impairment by most outcome measures but did not alter behavior in nontransgenic littermates. GA-treated APP/PS1 mice had mitigated cerebral amyloidosis, including brain parenchymal and cerebral vascular β-amyloid deposits as well as decreased cerebral abundance of amyloid β-protein species *versus* vehicle-treated APP/PS1 mice. These beneficial effects co-occurred with a shift toward nonamyloidogenic APP processing. In support, α-secretase candidate and nonamyloidogenic soluble APP-α protein expression were increased, whereas β-secretase protein expression together with amyloidogenic soluble APP-β and amyloidogenic β-C-terminal APP fragments were decreased. Additional significant benefits included alleviation of neuroinflammation and oxidative stress. Collectively, these results demonstrate that six months of GA treatment exerts disease-modifying effects by tandemly impacting α- and β-cleavage of APP in parallel with stabilizing neuroinflammation and oxidative stress. We propose dietary supplementation with GA as a promising prophylaxis for AD.

Title: Effects of fluoxetine on the neurons and synapses in the hippocampus of early APP/PS1 transgenic AD mice

Authors: *Y. TANG, C. N. ZHOU, Y. ZHANG, L. JIANG, F. L. CHAO, L. ZHANG, J. MA; Dept. of Histology and Embryology, Chongqing Med. Univ., Chongqing, China

Abstract: It has recently reported that fluoxetine (FLX) shows positive effects on the AD patients who have depression and anxiety. It is unclear, however, whether FLX can affect the pathogenesis of early AD. To address this issue, we designed the present study. The present study is the first study to investigate the effects of FLX on the neurons and synapses in the hippocampus of early APP/PS1 transgenic AD mice using the unbiased stereological techniques and other techniques. 8-month-old male APP/PS1 mice were randomly divided into an APP/PS1+NS group and an APP/PS1 + FLX group. 8-month-old male wild-type (WT) littermates were randomly divided into a WT+NS group and a WT + FLX group. The mice in the WT + FLX group and APP/PS1 + FLX group were intraperitoneally injected daily with FLX (10 mg/kg i.p. dissolved in 0.9% NS) regime for 10 weeks. The mice in the WT+NS group and APP/PS1+NS group were intraperitoneally injected daily with NS (equivalent 0.9% NS i.p.) for 10 weeks. At last two weeks injection, the spatial learning and memory ability of the mice was detected with Moriss water maze. After 10 weeks, 6 mice were randomly selected from each group. The total numbers of the neurons, immature neurons and synapses were estimated with the unbiased stereological methods. The newborn neurons and $5HT4R^{+}/NeuN^{+}$ cells in the hippocampal subregions were counted with immunofluorescence technique. Immunofluorescence was used to detect the changes of amyloid plaques, 5HT1A receptor and the density of PSD95 in the hippocampus of each group mice. The changes of phosphorylated Tau protein, the levels of GSK3β and p-ser9-GSK3β and the levels of SYP and BDNF in the hippocampus of each group mice were detected with ELISA technique. The present results indicated that FLX treatment could protect the neurons and synapses in the hippocampus of early AD through 5-HT system, which might be the important structural bases for the FLX-induced improvement of the spatial learning and memory ability of early AD. Moreover, our results suggested that the FLX may be a safe and effective drug for delaying the progress of AD, which might provide a starting point for further research into the new preventative measures and treatments of AD.

Title: ACAT inhibition in the cns as a therapeutic target for APOE4-induced Alzheimer's disease risk

Authors: *A. C. VALENCIA, N. FAULK, D. BALU, E. LOUKENAS, J. M. YORK, M. LADU;
Anat. and Cell. Biol., Univ. of Illinois, Chicago, Chicago, IL

Abstract: *APOE4*, the gene encoding apolipoprotein E4 (apoE4), is the greatest genetic risk factor for Alzheimer's disease (AD), compared to common *APOE3*, and *APOE2*, which is protective but rare. While the mechanism underlying *APOE*-modulated AD risk remains unclear, *APOE4* is associated with accelerated amyloid-beta (Aβ) accumulation, both as amyloid plaques and soluble oligomeric forms of Aβ (oAβ), the latter considered a proximal neurotoxin. In addition, apoE4 levels in the brains of humans and transgenic mice (Tg) expressing human *APOE* are lower compared to apoE3, suggesting that the poorly lipidated apoE4 particles are unstable. Thus, one possible therapeutic target for *APOE4* carriers is increasing the intracellular free cholesterol pool in neurons and glial cells to allow greater lipidation of apoE4 particles, with a parallel reduction in Aβ. This was tested using an Acyl-CoA: cholesterol-acyltransferase (ACAT) inhibitor avasimibe (AVAS). ACAT esterifies intracellular free cholesterol to produce cholesteryl ester droplets and reduce the free cholesterol pool. Therefore, our therapeutic target for *APOE4* carriers is increasing intracellular cholesterol via inhibition of ACAT, thus increasing extracellular transport of cholesterol to lipidate the apoE4 particles in the parenchyma. In this study, we treated male E4FAD-Tg mice, which specifically over-express human Aβ42and express human *APOE4,* with AVAS in a prevention paradigm (6-8M). AVAS treatment prevented memory loss and a reduction in synaptic proteins, reduced soluble and insoluble Aβ levels, Aβ deposition, amyloid deposition, and neuroinflammation. However, there was no evidence of indirect target engagement as measured by an increase in apoE4 lipidation. Thus, in the absence of indirect target engagement, AVAS demonstrates efficacy and produced significant changes in mechanistic pharmacodynamics readouts for both neuroinflammation and Aβ solubility/deposition, two critical components of AD-related pathology. Further investigation is ongoing to understand the mechanisms underlying ACAT inhibition and apoE4 lipidation as a therapeutic target for AD.

Title: Neuroprotective role of Myo/Nog cells in a rat model of Alzheimer's disease

Authors: *A. PAYNE[1], S. JOSEPH-PAULINE[1], M. BRACCIA[1], G. GORSKI[1], R. BRAHMBHATT[1], S. YOUNG[1], J. GERHART[1], M. GEORGE-WEINSTEIN[1], J. STONE[2], S. PURUSHOTHUMAN[2], A. BRAVO-NUEVO[1];
[1]PCOM, Philadelphia, PA; [2]Univ. of Sydney, Sydney, Australia

Abstract: Introduction: Alzheimer’s disease (AD) is a degenerative disorder of the central nervous system in which plaques of misfolded beta amyloid proteins accumulate in brain tissue over time, impeding cognitive function and causing memory loss.
Previous studies by our colleagues suggest the beta amyloid accumulation is due to spontaneous, clinically silent micro-hemorrhages (“tiny bleeds”) in the brain tissue that lead to plaque formation.
Recently, Myo/Nog cells, identified by their expression of the MyoD transcription factor and an inhibitor of bone morphogenetic proteins called noggin, have been discovered to have neuroprotective effects in nervous tissue in the retina. They migrate to sites of injury to mitigate subsequent damage.
The established needle-stick injury model was used to introduce micro-hemorrhages and plaque formation in the rat brain, and to explore the amount of Myo/Nog cells in the affected areas and their effects on neuronal cell death.
Methods: Sprague Dawley rats were injected with either Myo/Nog cells purified from the mouse brain by labeling them with the G8 monoclonal antibody and isolating labeled cells by magnetic cell sorting. Myo/Nog cells were depleted in the area of the needlestick by injecting the G8 mAb and complement. Additional experimental groups included rats that only received a needlestick, animals injected with complement alone following needlestick, and rats that were not subjected to needlestick injury. These treatment groups served to modify the number of Myo/Nog cells at the site of injury.

Tissue sections of the brain from all groups were then stained using double labeled with the G8 mAb and antibodies to NeuN to localize neurons, glial fibrillary acidic protein (GFAP) that is expressed in glial cells , and oligomeric amyloid-beta. Cell death was measured by the terminal deoxynucleotidyl transferase dUTP nick end labeling (TUNEL) technique.
Results: Our preliminary data show a negative correlation between Myo/Nog cells and stress induced by the needlestick in the brain. While depletion of endogenous Myo/Nog cells in the area of injury did not affect neuronal cell death, addition of brain-derived Myo/Nog cells did reduce cell death.
Conclusion: Myo/Nog cells appear in areas of injury. Addition of Myo/Nog cells is neuroprotective following brain injury. Further analysis is needed to confirm our results.

Title: Role of protein prenylation in the pathogenesis of Alzheimer’s disease

Authors: *A. JEONG[1], S. CHENG[1], W. QU[2], M. DISTEFANO[3], D. A. BENNETT[4,5], M. BERGÖ[6], L. LI[1];
[1]Exptl. and Clin. Pharmacol., [2]Neurosci., [3]Chem., Univ. of Minnesota-Twin Cities, Minneapolis, MN; [4]Rush Alzheimer's Dis. Ctr., Chicago, IL; [5]Neurolog. Sci., Rush Univ. Med. Ctr., Chicago, IL; [6]Biosci. and Nutr., Karolinska Institutet, Huddinge, Sweden

Abstract: Alzheimer’s disease (AD) is the leading cause of age-related dementia, but its pathogenesis is not fully understood. Protein prenylation, a posttranslational lipid modification of proteins, is dysregulated in aging and might contribute to AD pathogenesis. Many proteins, including the Ras superfamily of small GTPases, undergo prenylation by farnesyltransferase (FTase) and geranylgeranyltransferases (GGTase-I, GGTase-II). Small GTPases serve as molecular switches in signal transduction pathways that regulate diverse cellular processes and functions. We showed previously that systemic heterozygous deletion of FTase reduces amyloid

pathology and neuroinflammation, and rescues learning and memory in the APP/PS1 mouse model of AD. To further investigate the role of protein prenylation in AD pathogenesis, this study was undertaken to compare farnesylated or geranylgeranylated protein levels in human postmortem brain samples from individuals with a range of clinical diagnosis from no cognitive impairment (NCI), mild cognitive impairment (MCI), to AD. We found that the levels of farnesylated H-Ras and its downstream effector protein phosphorylated ERK were higher in MCI and AD brains compared to control. Moreover, farnesylated H-Ras levels correlated positively with tau tangle pathology, whereas levels of geranylgeranylated Rho GTPases did not correlated with either amyloid or tau pathology. To define the impact of inhibiting FTase in forebrain neurons on AD pathology, we generated neuronal-specific FTase knockout mice and bred them with APP/PS1 mice. Preliminary results revealed that FTase deletion ameliorates the neuropathology and memory deficits in APP/PS1 mice. Thus, these preliminary studies suggest that protein prenylation is dysregulated in AD pathogenesis and that protein farnesylation could be a potential therapeutic target for AD. Further analyses are underway to unravel the molecular mechanisms underlying the effects of FTase inhibition in forebrain neurons on multiple aspects of AD pathology.

Title: Naringenin produces neuroameliorative effects and counteracts genotoxicity induced by $AlCl_3$ and D-gal in rat model of AD

Authors: ***S. HAIDER**[1], L. LIAQUAT[1], Z. BATOOL[2];
[1]Univ. of Karachi, Karachi, Pakistan; [2]Panjwani Ctr. for Mol. Med. and Drug Research, Univ. of Karachi, Karachi, Pakistan

Abstract: Currently available medication for the treatment of Alzheimer’s disease (AD) such as acetylcholinesterase inhibitors can only offer symptomatic relief. Such medications only work on intact neurons, but cannot stop the ongoing neurodegeneration. So, there is an intense need for the development of therapeutic strategy that can not only improve brain functions but can also prevent neurodegeneration. Since oxidative stress is one of the main causative factors of AD, various antioxidants are under investigations to prevent neurodegenerative mechanism of AD.

The present study was intended to investigate the neuroprotective effects of naringenin (NAR) against $AlCl_3$+D-gal induced AD-like animal model. For this purpose rats were orally pre-treated with NAR (50 mg/kg) for two weeks. Rats were then exposed to $AlCl_3$+D-gal (150 mg/kg+300 mg/kg) intraperitoneally for one week to develop AD-like animal model. On the basis of the cholinergic hypothesis of AD, scopolamine (SCO) and donepezil (DPZ) were used as standard drugs in present investigation. Results showed that NAR pre-treatment significantly protected behavioral disturbances in rats. Observed effects might be due to improved neurotransmission, prevention against histopathological alteration, DNA fragmentation and antioxidant defense system. In DPZ group, rats showed improved cognitive and cholinergic functions but neuropsychiatric functions were highly impaired and marked histopathological alterations were observed. NAR not only prevented $AlCl_3$+D-gal induced AD-like symptoms but also significantly prevented SCO induced cholinergic dysfunctions in rats. Results of present study strongly suggest neuroprotective and cognition enhancing functions of NAR. NAR may be considered as a neuroprotective compound in the future for therapeutic management of AD.

Med., Taipei, Taiwan

Abstract: Amyloid-beta (Aβ) plaque is known for pathological evidence in Alzheimer’s disease (AD) which is a progressive neurodegenerative disorder in the brain over the age of 65. AD causes cognitive impair and behavioral dysfunction over time that affect daily activities. Neuroinflammation is characterized by reactive astrocytes and activated microglia in brain and also involved in AD. One of the role, astrocytes, are the most abundant cell type in the central nervous system which are essential for homeostasis and support to neuron. Here, we elucidate the potential mechanism in Aβ-induced inflammatory response in astrocytes. Aβ uptook by astrocytes which occurs after inflammatory response may not be entirely beneficial in AD. It would cause the accumulation and deposition of Aβ plaque leading to accelerate AD progression. Therefore, our strategy is to find a potential protein which is responsible for regulating

inflammatory response. Soluble Epoxide Hydrolase (sEH) is well-known for metabolism of epoxyeicosatrienoic acids (EETs). It exhibits two functional domains activities - C-terminus with epoxides hydrolase activity and N-terminus with phosphatase activity. Once sEH eliminates the effect of EETs, it results in inflammatory response. Thus, limited reports indicated that sEH inhibitor could be as the approach to against the response. In this study, we hypothesize that sEH may induce reactive astrocytes to increase Aβ uptake ability and neuroinflammation leading to exacerbate neuronal impairments in AD. We used primary mouse astrocytes and 4 months of AD mouse model (5xFAD) separately treated with different terminal-sEH inhibitors (AFC compound for inactive N-terminus and ADUA compound for inactive C-terminus). We examined phagocytosis ability, inflammatory level, brain tissue staining and animal behaviors test to verify our hypothesis. Our evidence showed that Aβ uptake and inflammatory level in astrocytes were decreased with inactivation of sEH treatment. Besides, immunohistochemistry data indicated Aβ/ GFAP were decreased in cortex and hippocampus. Furthermore, we found the learn/ memory, position balance, grip strength and motor coordination were also improved. It indicates that sEH has a potential role for neuroinflammation and Aβ aggregation which developing AD progression. In conclusion, sEH inhibition may be as a therapeutic potential approach for providing neuroprotective effect to against AD.

Title: Enhancing blood circulation to facilitate the efflux of amyloid β from the brain to peripheral blood circulation by xuefu zhuyu decoction

Authors: *L. CHAO[1], C.-W. YEH[1], Y. SKYE HSIN-HSIEN[2], H.-K. LIU[3], F.-S. SHIE[4], H.-J. TSAY[1], Y.-J. SHIAO[3];

Abstract: The burden of amyloidosis and senile plaques in the brain of Alzheimer’s Diseases (AD) patients are determined by the production and the clearance of cerebral Aβ. The predominant mechanism is vascular-mediated efflux of Aβ from the brain into the circulation, and this mechanism is actively mediated by low-density lipoprotein receptor-related protein 1 at the brain blood barrier.

Xuefu Zhuyu Decoction is a traditional Chinese herbal formula and it is well-knownfor improving blood circulation and anti-inflammation. Also, XZD is used for the treatment of metabolic syndrome through removing blood stasis.Recently, we have reported that XZD ameliorating obesity, hepatic steatosis, neuroinflammation, amyloid deposition and cognition impairments in metabolically stressed APPswe/PS1dE9 mice. We have identified that the increase of serum Aβ42 induced by high fat diet (HFD) streptozotocin (STZ) is attenuated by XZD. However, the mechanism mediating the reduce of cerebral Aβ42 remains unclear. The therapeutic potential of XZD is based on multiple beneficial aspects including the enhancement of blood circulation and anti-inflammation.
The glycemic homeostasis and the plasma Aβ level of HFDSTZ AD mice with and without Chinese medicines be monitored weekly. The glucose usage acquired by positron emission tomography/computer tomography (PET/CT) was performed to evaluate the neuronal activity of HFD with and without Chinese medicines. Whole brain static PET images were acquired, reconstructed, and then corrected for attenuation based on CT imaging data. Regional radioactivity concentration (kBq/mL) of [^{18}F]flu-deoxyglucose ([^{18}F]FDG) was estimated from the maximum pixel. Furthermore, the effect of blood circulation improved by XZD in the brain of HFDSTZ AD is going to be done by using small animal PET/MRI. The efflux of Aβ of HFDSTZ AD mice brain by using XZD will be more complete.
For the measurement of Aβ, mice were sacrificed and the brain was removed. After processing the brain, we acquired SDS-soluble and SDS-insoluble Aβ samples. Both Aβ samples underwent enzyme-linked immunosorbent assay (ELISA) using Aβ40 and Aβ42 ELISA kits (Life Technologies, Carlsbad, CA, USA). The absorbance was measured at 450 nm using a TECAN plate reader (Sunrise, UK).

Title: Mechanism of gamma-secretase modulators

Authors: ***J. E. LUO**[1,2], C. W. ENDE[3], K. D. RYNEARSON[4], S. L. WAGNER[4], Y.-M. LI[1,2]; [1]Dept. of Pharmacol., Weill Grad. Sch. of Med. Sci. of Cornell Univ., New York, NY; [2]Chem.

Biol. Program, Mem. Sloan Kettering Cancer Ctr., New York, NY; [3]Neurosci. Medicinal Chem., Pfizer Worldwide Res. and Develop., Groton, CT; [4]Dept. of Neurosciences, Univ. of California San Diego, La Jolla, CA

Abstract: Amyloid-beta (Aβ) plaques are believed to be integral to Alzheimer's disease (AD) pathogenesis through their role in the "amyloid cascade hypothesis," in which the accumulation of Aβ peptides initiates a cascade of pathological events leading to neurodegeneration and AD. γ-Secretase is a transmembrane aspartyl protease which cleaves amyloid precursor protein in the final step of proteolysis to generate Aβ peptides, making γ-secretase an attractive drug target. However, γ-secretase inhibitors failed in clinical trials due to their unwanted side effects on other γ-secretase substrates such as Notch. ɣ-Secretase modulators (GSMs) selectively reduce levels of the pathogenic Aβ species without affecting Notch and overall APP processing. However, the precise mechanism of action of GSMs is still unclear. Using photoaffinity labeling in cross-competition studies, active site-directed inhibitor L-686, 458 (L458) enhances the labeling of GSM photoprobe E2012-BPyne to presenilin-1 (PS1), the catalytic subunit of γ-secretase, suggesting cooperative action between the active and allosteric GSM binding sites on γ-secretase. We aim to determine their exact peptide interactions and elucidate the mechanism of action for GSMs. We have demonstrated that L505, a probe developed to profile the active site, increases E2012-BPyne labeling of PS1-NTF. Furthermore, we have shown that an active site-directed probe containing a cleavable Dde linker also enhances PS1-NTF labeling of E2012-BPyne and are in the process of optimizing elution conditions. We have also characterized the labeling of other GSM photoprobes which can be enhanced by L458. Together these results will allow us to pull down the photolabeled targets and analyze them with LC-MS/MS to map the binding sites on γ-secretase. Identification of these sites will define the molecular mechanism of GSMs, leading to a better understanding of their modulation for AD drug development.

Title: Oral immunization with soybean storage protein ontaining Aß4-10

Authors: *T. KAWARABAYASHI[1], M. AMARI[2], M. TAKATAMA[2], M. SHOJI[2];
[1]Geriatrics Res. Inst. Hosp., Meabashi, Japan; [2]Geriatrics Res. Inst. Hosp., Maebashi, Japan

Abstract: Amyloid ß peptide (Aß) plays a central role in the pathogenesis of Alzheimer's disease (AD). Immunotherapies for Aß amyloidosis have therefore been developed as putative disease-modifying therapies (DMTs) of AD. Because AD pathologies begin two decades before the onset of dementia, prevention of Aß amyloidosis has been proposed as a means to block the pathological cascade leading to cognitive devastation. For this reason, safe and non-invasive interventions are necessary. Here, we generate a transgenic plant-based vaccine, a soybean storage protein containing Aß4-10, named Aß+, for oral Aß immunization. One mg of Aß+ or control protein (Aß-) was administered to TgCRND8 mice once a week from 9 weeks up to 58 weeks. Aß+ immunization raised both anti-Aß antibodies and cellular immune responses. Morris water maze test revealed significant prevention of spatial memory deterioration in escape latency and path-length in Aß+ immunized animals compared with littermates in the Aß- treatment group from 21 to 57 weeks. Quantitative ELISA for Aß40 and Aß42 in Tris phosphate buffered saline (TBS), sodium dodecyl sulfate (SDS), and formic acid (FA) serial extractions from brains showed that large amounts of Aß40 and Aß42 were recovered in SDS and FA fractions from both Aß+ and Aß- groups, with no significant differences between the groups, except for an increase of Aß40 in the FA fraction of the Aß+ group. In contrast, the levels of soluble Aß oligomers (AßOs) in the TBS soluble fraction were significantly decreased in the Aß+ treated group. Western blot analyses showed all sets of Aß species to have different solubility in 3 step extractions from Aß monomer, low to high molecular weight (LMW and HMW) AßOs, and Aß smears in TgCRND8 brains. These were increased with aging, and C-terminal ends of HMW AßOs were blocked. Decreased Aß oligomers in TBS fractions, a corresponding increase in HMW AßOs in SDS fractions, and Aß smears in FA fractions were observed in the Aß+ treated group. Processing of amyloid precursor protein, and tau levels were not different between Aß+ and Aß- groups. There was significant inhibition of histological Aß burden, especially in diffuse plaques and suppression of microglial inflammation. No evidence of amyloid-related inflammatory angiopathy was observed. These findings suggest that Aß+ oral immunization reduces toxic soluble AßOs and sequestrates them to form aggregated Aß amyloidosis. Thus, Aß+ oral immunization could be a promising, cheap, and safe DMT to prevent AD pathological process leading to cognitive impairment.

Title: BACE1 inhibitions affect on astrocytic amyloid beta clearance

Authors: *J. ZHOU[1], R. YAN[2];
[1]Mol. Med., Cleveland Clin., Cleveland, OH; [2]Neurosci., Univ. of Connecticut Hlth. Ctr., Farmington, CT

Abstract: Abnormal accumulation of amyloid beta peptide (Aβ) in the brain is regarded as the possible causative agent of Alzheimer's disease (AD). Increased production of Aβ or impaired clearance of Aβ results in the accumulation and aggregation of Aβ into insoluble, toxic plaques, which are surrounded by glia cells. BACE1 is the rate-limiting secretase required for production of Aβ through its initial cleavage of amyloid precursor protein (APP). Because of this, inhibiting BACE1 as a means to reduce Aβ production is being tested for treating Alzheimer's disease. A recent study using conditional deletion of BACE1 in an AD mouse during adulthood showed a reversal of previously formed plaques and rescues Aβ-associated behavioral deficits. One intriguing question is whether plaque reversal requires an action from reactive astrocytes surrounding plaques. In this study, we aimed to test our hypothesis that BACE1 inhibition likely facilitates astrocytic Aβ clearance. Using *in vitro* primary astrocyte cultures, we found that BACE1 inhibition enhances both astrocytic Aβ uptake and degradation. Furthermore, using single cell RNA sequencing, we found that BACE1 knockout mice had an increased number of reactive astrocytes and these reactive astrocytes from BACE1 knockout mice have transcriptomes distinct from reactive astrocytes from wild-type mice. Some of the gene signatures upregulated in BACE1 knockout astrocytes likely play a role in clearing Aβ. Our preliminary results identified a unique signature that could enhance Aβ clearance based on our *in vitro* characterization. Together, our study suggests a novel function of BACE1 in astrocytes.

Abstract: In the aging brain, reduction in the pulsation of cerebral vasculature and fluid circulation cause impairment in fluid exchange between different compartments that pave a foundation for neuroinflammation that results in Alzheimer’s disease (AD). The knowledge on central nervous system lymphatic vessels in clearance of brain derived metabolic waste products opens an unprecedented capability to increase the clearance of macromolecules such as amyloid beta (Aβ) proteins. However, currently there is no pharmacological mechanism available to increase fluid circulation in the aging brain. In the present study, we demonstrate the influence of cranial osteopathic manipulative medicine (COM) therapy on spatial memory and changes in substrates associated with CNS metabolic waste clearance mechanisms using the naturally aged and transgenic (TgF344-AD) rat model of AD. The results obtained from Morris water maze assay indicate an improvement in spatial memory after seven days of COM therapy. Live animal positron emission tomography (PET) imaging and immunoassays reveal that COM treatment reduces Aβ levels, activates astrocytes and increases expression of their water channels, and improves neurotransmission. These findings demonstrate molecular mechanisms of COM treatment currently used in clinical practice. Further investigation in this direction will help clinicians practice COM as an evidence based adjunct treatment strategy for AD.

Abstract: The gut microbiome (GM), the collective genome of microbiota residing within the gut, is emerging as an important component in neurological disorders such as Alzheimer's disease (AD), a fatal neurodegenerative disease diagnosed post mortem by the presence of amyloid plaques and neurofibrillary tangles. The brain is in constant bidirectional communication with the gut, allowing the brain to modulate the bacterial composition and metabolic function of the GM. With dysbiosis, the GM becomes a source of endotoxins rather than essential metabolites. To understand if dysbiosis plays a significant role in the GM of AD patients, the effects of the known AD risk factors must first be determined. Although rare, familial AD (FAD) is caused by autosomal dominant mutations that increase amyloid-β peptide (Aβ). Age is the greatest risk factor for AD and *APOE4*, the ε4 allele of *APOE*, is the greatest genetic risk factor for AD, increasing risk up to 15-fold compared to the common *APOE3*. *APOE4* is associated with increased Aβ, resulting in increased levels of both amyloid plaques and soluble neurotoxic oligomeric Aβ (oAβ). Importantly, female (♀) *APOE4* carriers have a greater risk for developing AD, an increased rate of cognitive decline and an accelerated accumulation of Aβ compared to male (♂) *APOE4* carriers. To study the interactions among these AD risk factors, we use the EFAD mice, transgenic mice that overexpress human Aβ42 and express human *APOE3* (E3FAD) or *APOE4* (E4FAD). **Our specific hypothesis is that *APOE* genotype and sex interact to modulate the GM composition in young EFAD mice.** Microbial analysis of fecal samples from 4-month (M) EFAD mice demonstrate that *APOE* genotype has a significant effect on the GM at various taxonomic levels. Additionally, there are significant differences in the GM of ♂E4FAD vs ♀E4FAD, manifested at the operational taxonomic unit (OTU) level. The synergistic effect of *APOE4* and female sex on the GM was further validated

visually by a bootstrap resampling plot. In addition, ♀E4FAD and ♂E4FAD samples cluster together with heatmap analysis based on the abundance of 29 specific bacterial OTU identified by a machine learning algorithm, again suggesting that *APOE* genotype and sex interact to alter the EFAD GM. Future work will include defining the interactive effect of age with *APOE* genotype and sex, with the goal of producing a distinct compositional and functional GM profile that distinguishes ♂E3FAD, ♀E3FAD, ♂E4FAD and ♀E4FAD. These data will be used to inform GM remodeling, for example, from ♀E4FAD to ♂E3FAD, producing a potential AD therapeutic that corrects the GM, particularly in the at risk ♀*APOE4* carriers.

Title: Reduction of amyloid pathology by probiotic supplementation in a mouse model of Alzheimer's disease

Authors: *E. LEE, J. LEE, J. JUNG, H. KIM, H. PARK, T. KIM;
Gwang-Ju Inst. of Sci. and Technol., Gwang-ju, Korea, Republic of

Abstract: Alzheimer’s disease (AD) is one of the most common neurodegenerative disorders, which associates with impaired cognition. In the past decade, the understandings of the commensal microbiota in human have been expanded rapidly and their roles in neuropsychiatric disorders such as AD have been investigated. Studies in germ-free animals and animals exposed to pathogenic microbial infections, antibiotics, probiotics, or fecal microbiota transplantation propose a role of the gut microbiota in AD pathogenesis. However, there is a lack of studies that confirmed the effects of specific strains of probiotics on the brain of Alzheimer's disease. Therefore, we examined the effects of selected probiotics on the neuropathologic progression in the brain of Alzheimer’s disease. We used the 5XFAD mouse model of Alzheimer’s disease from the age of five weeks (N=95 males). Six strains of probiotics were selected, and the mice were grouped based on the strains (n=13 for each group). Additionally, groups of wild type (n=9) and sham administration (n=8) were treated with phosphate-buffered saline (PBS). Probiotics or PBS were administered daily per os for four months. At the age of 5 months, we sacrificed the mice and harvested the brain followed by the dissection of two brain regions (cortex, hippocampus). Soluble/insoluble amyloid-β 42 (Aβ42), and tau/p-tau proteins were quantified with enzyme-linked immunosorbent assay. Among the six probiotic groups, three groups showed

a decreased level of soluble Aβ42 in the cortex compared with the sham control group ($P<0.05$ by the two-sample t-test). Furthermore, the levels of soluble Aβ42 of the three strain groups were similar to that of the wild type group. In contrast, the levels of soluble Aβ42 in the hippocampi did not differ among all six strain groups and sham group, whereas insoluble Aβ42 in the hippocampi even increased in four strain groups, including two groups that showed decreased soluble Aβ42. These data suggest that certain strains of probiotic supplementation may induce the changes of soluble and insoluble Aβ42 in different regions of the brain. Given that soluble Aβ42, but not insoluble one has a significant association with the severity and progression of AD, it is highly likely that the reduction of soluble Aβ42 through probiotic supplementation may have therapeutic effects in AD. Further investigation in this novel approach as a therapeutic and/or preventive intervention for AD is warranted.

Title: Enriching enrichment: A novel 'enrichment track' protocol produces controllable and persistent cognitive enhancement in mice

Authors: ***H. A. COLLETT**[1], S. GATTAS[3], E. A. HUFF[1], S. D. CREIGHTON[1], S. E. WEBER[1], S. BUCKHALTER[2], S. A. MANNING[1], B. L. MCNAUGHTON[4], B. D. WINTERS[1]; [1]Psychology, [2]Biomed. Sci., Univ. of Guelph, Guelph, ON, Canada; [3]Electrical Engin. and Computer Sci., Univ. of California, Irvine, Irvine, CA; [4]Dept. of Neurosci., The Univ. of Lethbridge, Lethbridge, AB, Canada

Abstract: Cognitive reserve (CR) is a conceptual construct reflecting rich life experience, such as higher education, intellectual activity, travel, and multilingualism. It is the best predictor of preservation of cognitive function in humans with trauma, neurodegenerative or age-related brain changes. CR can be modeled in rodents using environmental enrichment (EE). In standard EE protocols, however, it is difficult to measure or control individual animal enrichment, making it difficult to compare treatment effects (such as drugs, lesions, age, or sex) on EE induced brain or behavioral changes. We developed a novel EE protocol, using reward-motivated running on tracks with built-in obstacles of progressive complexity, to enable quantification and control of enrichment experience and effects. 28 day-old male C57/BL6 mice were divided into 4 different

groups (n = 10/group): home cage enrichment (EE) using conventional EE procedures; enrichment track (ET); exercise control track (CT); or standard ("impoverished") housing control (SH). All but the EE group were housed in standard cages containing only simple nesting supplies. After 2 mo (with 1 h/d x 6 d/wk for the ET and CT groups), a 'difficult' version of the object recognition task with reduced sample exploration time was used to assess memory performance. Cognitive enhancement was evident for both the EE and ET groups with a 20-min retention delay, but only ET mice discriminated between familiar and novel objects with a 24-h delay. We also assessed ET effects on other object recognition tasks including category, view-invariant and cross-modal object recognition. The ET group demonstrated superior performance on the more difficult versions of these tasks, with longer retention delays, indicating that ET mice can use object representations with greater flexibility. Enhanced memory performance on such tasks was observed up to 4 mo post discontinuation of ET. The ET is thus an advancement over typical enrichment protocols, enabling more direct and measurable individual enrichment, and conferring sustained cognitive enhancement. The ET protocol may enable further characterization of experience-dependent mechanisms that contribute to the development of CR in mouse models of Alzheimer's disease or other brain disorders.

Title: Beneficial effects of resistance exercise in improving cognitive functions and reducing neuropathology in postoperative cognitive dysfunctions and Alzheimer's transgenic mice

Authors: *R. C. C. CHANG[1,2], Y. LIU[1,3], J. M. T. CHU[1,3], C. HUANG[1,3], G. T. C. WONG[3]; [1]Lab. of Neurodegenerative Diseases, Sch. of Biomed. Sciences, LKS Fac. of Medicine, The Univ. of Hong Kong, Hong Kong, China; [2]State Key Lab. Abstract: Exercise is well-known to have great beneficial effects to the whole body. While majority of research demonstrates neuroprotective effects of aerobic exercise, a certain large population of patients who are too old or suffer from motor problem cannot gain the benefits of aerobic exercise. Some Alzheimer's disease (AD) patients cannot even perform proper aerobic exercise. Therefore, investigating the effects of resistance exercise is important for patients lying

on the bed and for some AD patients. We hypothesize that resistance exercise can improve cognitive functions. We proved the correction of cognitive functions by two experimental models. One model was the risk factor for developing dementia, namely postoperative cognitive dysfunctions (POCD), using C57BL/6 mice. Another model was to use AD transgenic mice bearing three types of mutations (3xTg mice). Resistance training was accomplished by a ladder-climbing protocol for 5 weeks with 3-4 training sessions per week. For each session, mice were forced to climb up a 1-meter ladder with progressively larger weight attached to tail for 15 times with 2 minutes rest during each trail. Effects of resistance training on cognition and muscle strength were checked by Y-maze and weight lifting test, respectively. For 3xTg mice, we used 9-month-old mice. For POCD, laparotomy was performed using aseptic procedures under sevoflurane (3-4%) as anesthesia (~20 min). Cognitive functions were assessed by Y-maze test and novel object recognition (NOR) test 2 weeks afterwards. Levels of synaptic proteins in the hippocampus were detected by western blot. Cytokines levels were measured by their expression of mRNA and proteins. Our results showed that resistance exercise could revert the cognitive dysfunctions induced by laparotomy and attenuate progressive cognitive loss in 3xTg mice in Y-maze test. Furthermore, western-blot analysis showed that it could ameliorate loss of synaptic proteins, tau protein phosphorylation, and inflammatory cytokines. Our studies demonstrate that resistance exercise can be an alternative way of exercise that can provide to patients who have motor deficit or difficulty in working out for aerobic exercise.

Title: Exercise mitigates cognitive dysfunction resulting from a graduate loss of ovarian function in an Alzheimer’s disease mouse model

Authors: J. R. WILLIAMS[1], C. GRANT[1], S. S. VASHISTH[1], I. KOC[1], S. A. AHMAD[1], S. V. MAURER[1], C. A. COLTON[2], E. A. FINCH[3], ***C. L. WILLIAMS**[1];

Abstract: Over two-thirds of individuals with Alzheimer's disease (AD) are female, with the gradual loss of ovarian hormones during the perimenopausal transition thought to be a major factor contributing to greater female risk. A sedentary lifestyle also increases the risk for AD, and accumulating evidence suggests that physical activity may provide a therapeutic intervention to slow or mitigate AD progression. Here we investigated whether a graduate loss of ovarian function exacerbates AD neuropathogenesis and exercise might mitigate these effects. We induced transitional menopause (TM) in AD and control mice by injecting the ovotoxin 4-vinylcyclohexene diepoxide for 16 days, beginning at 9 wks of age; and exercise-trained mice for 12 wks at various stages of AD-like disease and TM using both voluntary (wheel running 5 days/wk) and enforced (treadmill running 2X/wk) exercise. We used the APPSwDI/mNos2$^{-/-}$ AD (CVN-AD) mouse model, which mimics familial AD by expression of mutated APP and a human-like immune environment through lowered NOS2 expression; and both C57BL/6 and mNos2$^{-/-}$ mice as controls. CVN-AD mice exhibit many neuropathological features of AD, and exacerbated AD-like neuropathogenesis and resistance to therapeutic intervention in females. TM mice had lower uterine weights than oil-treated control mice in each mouse line, confirming lower cycling estrogen levels following TM. Increased time-to-exhaustion on a treadmill test and lower body weights confirmed significant physiological benefits of exercise training in CVN-AD mice. When trained on a Novel Object Recognition task with a short retention interval, sedentary and exercised cycling mice showed intact short-term recognition memory. In contrast, the short-term memory of sedentary TM mice was impaired. However, as hypothesized, exercise-trained TM mice had no difficulty recalling the familiar object, indicating that exercise can mitigate the detrimental effects of menopause on short-term memory. Preliminary analysis of microglia suggests that exercise also prevents enhanced neuroinflammation caused by AD and TM. Our findings support previous reports that CVN-AD mice show progressive, age-related cognitive impairment and provide strong evidence that a gradual, menopause-like loss of ovarian hormones exacerbates AD-like cognitive decline and neuropathogenesis which can be mitigated by exercise training around the menopause transition. Ongoing studies are investigating the consequences of TM on other aspects of AD-like disease progression, and the response of females to therapeutic interventions with exercise at various stages of the menopausal transition.

Title: Altered dopamine neuron activity in the FAB rodent model of Alzheimer's disease

Authors: *S. M. PEREZ[1], A. M. BOLEY[1], D. J. LODGE[2];
[1]Pharmacol., UT Hlth. San Antonio, San Antonio, TX; [2]Pharmacol., UTHSCSA, San Antonio, TX

Abstract: Individuals affected by Alzheimer’s disease (AD) often experience comorbid psychosis, which severely diminishes the quality of life for the patient and their family. Because of the potential risk antipsychotic medications present to the elderly, there is an immediate need to establish novel alternative therapies. Psychosis (including hallucinations and delusions) has been demonstrated to be associated with a dysregulation of the dopamine system. We have previously demonstrated that psychosis observed in schizophrenia, may be attributed to aberrant regulation of dopamine neuron activity by the hippocampus. Because the hippocampus has been identified as a site of pathology in AD, we posit that it may also be a key region contributing to comorbid psychosis in AD. Thus, we used the ferrous amyloid buthionine (FAB) rodent model of AD to model a sporadic form of the disease and examine alterations in dopamine system function. FAB rats display structural and functional alterations in the hippocampus, which is accompanied by a decrease in spontaneous low frequency oscillatory activity. Additionally, FAB rats exhibit robust increases in dopamine neuron population activity, consistent with what is observed in other models of psychosis. These data suggest that aberrant hippocampal activity in AD may contribute to dopamine dependent psychosis. We believe that understanding the pathophysiology leading to comorbid psychosis in AD, will lead to novel targets for the treatment of this disease.

Title: Mild uncoupling of astrocyte mitochondria as a strategy to alleviate spatial memory deficits in Alzheimer's disease

Authors: N. ROSENBERG[1], A.-B. ROCHER[1], L. RESTIVO[1], M. BRIQUET[1], Y. BERNARDINELLI[2], *J.-Y. CHATTON[1];

[1]Dept. Fundamental Neurosciences, Univ. of Lausanne, Lausanne, Switzerland; [2]Neonomia, Geneva, Switzerland

Abstract: Hypometabolism and oxidative stress, along with neuronal death are often associated with the cognitive symptoms of Alzheimer's disease (AD). It has been shown in neuron-astrocyte co-cultures that uncoupling proteins 4 (UCP4) expressed by mitochondria of astrocytes decrease peroxide production, increase their glycolysis and lactate release, and enhance the survival rate of neurons. In parallel, lactate is known to exert beneficial effects in cerebral ischemia and has a non-metabolic effects modulating neural activity. In neurons, lactate has been shown to promote plasticity gene expression and is a key player for memory formation. We pose the hypothesis that in vivo overexpression of astrocytic mitochondrial UCP4 will provide support to neurons facing AD-associated injuries. Adeno-associated viruses (AAV) containing mCherry, as a fluorescent reporter, or UCP4 in combination with mCherry under the GFAP promoter, were stereotaxically injected in the CA1-subiculum of the dorsal hippocampus of wild-type (WT) and 3xTg-AD triple-transgenic mice. We assessed the cognitive status in a first cohort of 3- and 7-month-old mice. We found that the viral construct had no effect on the exploratory behavior in both either groups. While 3- and 7-month-old WT mice reacted to the spatial change, 3xTg-AD mice failed to selectively explore displaced objects. Uncoupling astrocyte mitochondria appeared to rescue spatial memory deficits in 7-month-old mice. The electrophysiological properties of CA1-subiculum pyramidal cells of 7-month-old 3xTg-AD mice showed alterations that were reversed by UCP4 treatment. They are possibly linked to abnormal calcium responses. Overall, astrocytic UCP4 overexpression appears to positively influence AD symptoms both at behavioral and cellular levels.

Abstract: Patients suffering from Alzheimer's disease (AD) demonstrate both cognitive symptoms (including deficits of learning, memory, attention and executive function) and emotional symptoms (including irritability and low mood). Depressive symptoms and behaviors are very common comorbidities observed in AD patients and generally precede the onset of AD. However, the vast majority of AD research has focused on the neurobiological mechanisms underlying the cognitive symptoms, whilst the mechanisms underlying depression associated symptoms have been grossly neglected and are poorly understood. In current study, we investigated the emotional phenotypes in a typical Alzheimer Disease (AD) animal model and discovered that the depression-like symptoms occurred before the onset of brain pathological changes and cognitive impairments. Further we showed that an improvement in emotional state either by anti-depression drugs or enriched environment can delay the initial deposition of Aβ.This work has important implications for future strategy for AD detection and treatment.

Title: How to stimulate: Basal forebrain DBS parameters to restore the attentional performance of rats with cholinergic losses

Authors: *M. NAZMUDDIN[1], H. A. RAO[2], T. VAN LAAR[1], M. F. SARTER[2];
[1]Univ. Med. Ctr. Groningen, Univ. of Groningen, Groningen, Netherlands; [2]Psychology, Univ. of Michigan, Ann Arbor, MI

Abstract: The degeneration of basal forebrain (BF) cholinergic neurons is an index of the severity of cognitive impairment in Alzheimer disease (AD) and Parkinson's disease (PD). Moreover, in PD patients, gait and balancing deficits, and an increased propensity for falls have been attributed to cholinergic losses. Thus, Deep Brain Stimulation (DBS) of the BF has been considered a potential therapeutic intervention to improve cognition and movement control in these patients. However, efficacy of BF DBS in clinical populations has yet to be conclusively demonstrated. Likewise, the demonstration of beneficial effects of BF DBS in rodent models has

been hampered by uncertainties about useful animal models and behavioral tasks and, importantly, a lack of consensus concerning DBS parameters (duration, frequency, current, intermittent versus continuous, prior and/or during task, etc.). Here we assessed various DBS parameters in rats with a partial loss of the cortical cholinergic input system. In rats, such cholinergic losses have been frequently demonstrated to impair the detection of cues during the performance of a Sustained Attention Task (SAT) and to attenuate performance recovery following a distractor challenge (dSAT). In PD patients with cholinergic losses, attentional impairments were also attributed to cortical and thalamic cholinergic losses (Kim et al., 2017). The attribution of SAT impairments to cholinergic losses is consistent with evidence showing that the detection of cues and associated attentional control parameters depend on cortical cholinergic signaling (e.g., Howe et al., 2017). Here, rats acquired the SAT, received infusions of the cholino-specific neurotoxin 192-IgG-saporin into the BF, and were implanted bilaterally with BF unipolar stimulation electrodes. Initial DBS parameters consisted of continuous high (130 Hz) versus low (20 Hz) frequency stimulation, intermittent (20-s ON at 80 Hz and 40-s OFF) stimulation, with pulse width and amplitude kept constant at 100 µs and 100 µA, respectively. We first assessed the effects of these DBS parameters on the behavior of rats in an open field space and then when administered during, or only prior to (for 1 hr), SAT and dSAT performance. Ongoing experiments indicate that these stimulation parameters are well tolerated as indicated by the absence of effects on locomotor and exploratory activity. We predict that BF DBS will be particularly effective in restoring attentional performance in the dSAT condition. If confirmed, this finding will suggest that demonstration of efficacy in patients will require measures indicating their attentional capacities in response to taxing performance challenges.

Title: Modulation of Alzheimer’s neuropathology through peripheral circulation

Authors: W. LIU[1], D. A. HOTTMAN[1], A. GRAM[1], V. D. KRISHNA[2], M. C.-J. CHEERAN[2], W. C. LOW[3], ***L. LI**[1];

Abstract: To date there is no effective treatment for Alzheimer's disease (AD), the most common form of dementia. Pathological hallmarks of AD include the deposition of amyloid-β peptide (Aβ) in the brain parenchyma (senile plaques) and in the cerebral blood vessels (cerebral amyloid angiography or CAA) and associated neuroinflammation, as well as neurofibrillary tangles. Previous studies have shown that administration of young blood/plasma or circulatory exchange by parabiosis ameliorates age-related changes and facilitates clearance of Aβ in mouse models. To further understand the role of peripheral circulation in the pathogenic process of AD, we performed parabiotic surgeries between C57BL/6 (B6) congenic APP/PS1 transgenic (Tg) mice and sex/age matched B6 congenic green-fluorescent-protein (GFP) Tg mice at 3 to 6 months of age (before or at the onset of Aβ deposition in the brain). The mice remained parabiosed until 7 to 10 months of age (n=7 pairs). The age/sex-matched APP/PS1 mice (n=7) without parabiosis served as controls. Success of the parabiotic surgery/circulatory exchange was confirmed two weeks after the surgery by the presence of GFP-expressing cells in the blood of paired APP/PS1 mice by flow cytometry analyses. At the end of the experiments, blood and brain tissue samples were collected for further analyses. Compared with age/sex matched non-parabiotic APP/PS1 mice, Aβ40 and Aβ42 levels in the plasma of parabiosed APP/PS1 mice were significantly decreased. Immunohistochemical analyses showed that Aβ deposition and associated neuroinflammation, represented by immunoreactivity to activated microglial marker Iba-1 and astrocytic marker GFAP, in the cortex and hippocampus were reduced significantly in the parabiosed APP/PS1 mice. In addition, CAA, quantified by Congo red staining, was also attenuated in the brain of the parabiosed APP/PS1 mice. Intriguingly, while substantial numbers of GFP-expressing cells circulated in the blood of parabiosed APP/PS1 mice, no or negligible GFP-expressing cells were found in the brain of parabiosed APP/PS1 mice, indicating that there was no or minimal recruitment of circulating cells from the parabiosed donor into the Aβ-bearing brain, despite evidence of GFP-chimerism in lymphoid organs. Taken together, these findings suggest that modulation of peripheral circulation could be a potential therapeutic approach against AD.

Title: Learning the game of chess reduces age related cortical thinning in patients with mild cognitive impairment

Authors: *J. STOUT[1], T. MALONE[2], J. HEFFERNAN[1], T. MALMSTROM[2], P. RUPPERT[2], S. BROWN[2], R. BUCHOLZ[3], R. TAIT[2], G. HEADY[2], L. SCHWARZ[2];

Abstract: Introduction: Patients with mild cognitive impairment (MCI) have memory and mental processing changes that are greater than expected within the normal aging process. Approximately 10-20% of adults ages 60 or older have MCI. The rate of progression to Alzheimer's disease is 12% per year for patients diagnosed with MCI, significantly higher than the 1-2% for older adults. Previous studies have shown cognitive training improves immediate and delayed recall in MCI patients. This study examines the effectiveness of a complex activity, learning and playing chess, on memory and mental function among older adults with MCI. The subset of data reported here examine the effects of learning and playing chess on longitudinal cortical thickness among MCI patients. **Methods:** This study is a 2-year, prospective, randomized, single-blinded, controlled trial to investigate the effects of learning and playing chess among older adults with MCI. Participants with MCI are randomized to either a chess intervention group or a non-chess control group. The MCI chess group (CG) is taught how to play chess by chess grand masters using a computer tablet and standard chess board, and the non-chess MCI group (Ctrl) is be instructed to continue to engage in their typical cognitive activities. This study is on-going. This analysis comprises patients with follow-up at 12 months, CG(N=11) and Ctrl(N=11). Data was acquired on a 3T Siemens Skyra scanner at St. Louis University Medical Center. MRI acquisition was performed at 0, 6, 12, and 18 month time points. T1 and T2 MRIs, were acquired using Human Connectome Project (HCP) acquisition sequences. Images were processed through the HCP anatomical pipeline for surface segmentation, parcellation, and cortical thickness evaluation. Longitudinal volume and surface processing was performed using Freesurfer. Connectome workbench was used to extract parcellated cortical thickness assessments using the Glasser parcellation. A T-test between CG and Ctrl patients was calculated on all parcels for 12 month vs baseline. **Results**: The ROIs with the most significant changes between CG and Ctrl patients are the following areas: Left peri entorhinal cortex, area TF, orbitofrontal cortex with p-values of .007, .008, .008 respectively. **Conclusions:** In this preliminary analysis we found a positive effect of chess training and gameplay on cortical thickness over time. The regions identified as most significant also correspond to regions that have previously been identified in MCI research. Future analysis will include additional subjects and neuropsych findings.

Title: The effects of deep brain stimulation of the cholinergic forebrain on markers of nerve growth factor and beta-amyloid

Authors: *J. S. KUMRO[1], J. SWORD[1], S. A. KIROV[1], A. PILLAI[2], D. T. BLAKE[1]; [1]Neurosci. and Regenerative Med., [2]Psychiatry and Hlth. Behavior, Med. Col. of Georgia at Augusta Univ., Augusta, GA

Abstract: The cholinergic forebrain or nucleus basalis of Meynert (NBM) degenerates earlier and more rapidly than other brain regions during Alzheimer's disease (AD). The current frontline therapy for AD is cholinesterase inhibitors which improve cognition and slow structural degeneration, particularly of the basal forebrain, over the first three to four months prior to decline restarting. Our previous research demonstrated that intermittent electrical stimulation of the NBM improves working memory in a young adult primate model. Anticholinergic pharmacology suggested ACh release to be the responsible mechanism. In states of beta-amyloid (Aβ) plaque accumulation like AD, Aβ binds and antagonizes α7-nAChR, a nicotinic ACh receptor densely populated in the cholinergic forebrain, resulting in cholinergic neuronal degeneration. We hypothesize that intermittent NBM stimulation can treat this AD pathogenesis by stimulating α7-nAChR and promoting its role in increased expression of nerve growth factor (NGF) and its receptor TrkA, which has been shown to modify amyloid precursor protein (APP) cleavage reducing Aβ and maintain cholinergic axons respectively. Here we show that stimulation in mouse NBM significantly improves cerebral blood flow, measured using laser speckle imaging, and ACh synaptic release, measured using a fluorescent protein coupled acetylcholine receptor sensor in confocal imaging. This stimulation pattern in middle-aged adult rats prevented performance decline observed in sham controls. Additionally, unilateral stimulation for multiple weeks, in either APP/PS1 mice or old rats, increased markers indicating improved vitality of the basal forebrain neurons and reduction in Aβ production in the stimulated hemisphere.

Title: Feasibility of dynamic sleep enhancement in a mouse model of Alzheimer's disease

Authors: D. HUFFMAN[1], A. A. AJWAD[2], J. WANG[1], M. P. MURPHY[3], B. F. O'HARA[1], M. J. DUNCAN[4], ***S. SUNDERAM**[1];

Abstract: Alzheimer’s disease (AD) is a degenerative condition that is marked by memory impairment, cognitive deficits, and changes in personality. Neurofibrillary tangles and amyloid plaque buildup in the brain are believed to play an integral role in AD pathology, and are therefore active topics of research. However, disruptions or alterations in sleep commonly seen in this condition are less understood. There is growing evidence that disordered sleep is not merely a consequence of AD, but that it may also accelerate pathology. Therapeutic strategies for improving sleep quality may slow disease progression and are therefore desirable. To this end, we have developed a system to accomplish sleep enhancement through simple closed-loop control of ambient temperature (*Ta*), which is known to influence sleep through thermoregulation. We first applied this technique to wildtype mice to evaluate feasibility. With institutional approval, five adult C57/BL6 mice (3 female, 2 male) were instrumented for electroencephalogram (EEG) and electromyogram (EMG) recording in individual cages. After complete recovery, each mouse was subjected to a closed-loop protocol in which *Ta* was adjusted at regular intervals to promote EEG slow wave activity in the delta band (0.5-4 Hz), a recognized marker of deep sleep, for five hours during the light period, every other day over four days. The recordings were supplemented by motion signals from a noninvasive floor-mounted piezoelectric sensor (Signal Solutions, LLC), to better discriminate sleep and behavior. A comparison of sleep metrics from these experiments showed that the mice experienced significantly longer bouts of NREM and REM sleep as well as greater amounts of deep NREM sleep under the experimental protocol compared to the sham reference period in which *Ta* remained constant. Having thus established the feasibility of sleep enhancement in controls, we applied a similar protocol to an AD model. Six 5xFAD mice (6-8 months old; 3 male, 3 female) were instrumented for EEG/EMG recording and subjected to two weeks of *Ta* manipulation in the light period directed at sleep depth enhancement. For each animal, an age- and sex-matched sham-treated control was monitored in an adjacent cage that remained at room temperature.

These experimental recordings have been completed and data analysis is ongoing. Future work will investigate the effects of sleep enhancement on molecular and cognitive disease markers in this and other experimental models of AD.

Title: Assessment of the mechanisms of action of ethanolic extracts of bacopa floribunda and angraecum eichlerianum on amyloid beta (1-42) model of Alzheimer's disease in male Wistar rats

Authors: *M. OMOTOLA OYELEKE[1,2], O. L. AROKOYO[1], H. T. ONI[1], B. V. OWOYELE[2]; [1]Physiol., Afe Babalola Univ., Ado-Ekiti, Nigeria; [2]Physiol. Dept., Univ. of Ilorin, Ilorin, Nigeria

Abstract: This study investigated the effects of crude extracts obtained from *Bacopa floribunda* and *Angraecum eicherianum.* A total number of 48 (n=6) male wistar rats were used for this study. AE and BF extracts were given at a dose of 200mg/kg/day and Alzheimer's disease was induced by a single bi-lateral intra-cerebroventricular (ICV) injection of Amyloid beta protein (4µg/µl/site) using a stereotaxic apparatus. Pre-treatment and post-treatment models with BF and AE were employed for 21 days. Rats were grouped as follows; Group 1 (Normal saline), Group 2 (Amyloid beta without treatment), Group 3 (BF alone), Group 4 (AE alone), Group 5 (pre-treated with BF), Group 6 (pre-treated with AE), Group 7 (post-treated with BF) and Group 8 (post-treated with AE). Novel Object Recognition (NOR) and Y maze task were carried out on different days during the course of the study. Twenty-four hours after the last administration, rats were sacrificed and brain tissues excised using appropriate forceps. The hippocampus was isolated on cold surface and assayed for the levels of glutamate, acetylcholinesterase (AChE), Na^+ - k^+ ATPase activities and Amyloid beta deposition using ELISA kits. Data were analyzed using One-way ANOVA followed by a post-hoc test and expressed as Mean ± SEM. A significant increase was observed in the activities of AChE in group 6 when compared with every other group, likewise, a significant decrease was observed between groups 5 and 7 when compared with groups 1, 2, 3, 4 and 8. Results also showed that group 3 alone had the highest level of significance of Na^+- k^+ ATPase activities when compared with every other group. Groups 6, 7 and 8 revealed some levels of significance when compared with groups 1, 2, 4 and 5. Neurobehavioural scores were observed to be better in BF and AE groups compared to Aβ and normal saline groups. Glutamate excitotoxicity was equally observed in hippocampal

homogenates of rats in group 2 and this was suppressed by our extracts. In conclusion, Amyloid beta (1-42) caused an increase in the level of AChE and a decrease in Na^+ - k^+ ATPase level, while BF elicited its protective action by increasing the levels of Na^+ - k^+ ATPase and the mechanism of action of AE was by reducing the activities of acetylcholinesterase in Amyloid beta induced Alzheimer's disease. Therefore, our study suggests that these extracts possess cognitive enhancement properties and as such can relieve dementia to a great extent.

Title: Development of NeuroD1-mediated *in vivo* neuroregeneration therapy in an Alzheimer's disease mouse model

Authors: *X. HOU, Y. WANG, Z. WU, F. ZHANG, Z. PEI, Y. BAI, G. CHEN; Pennsylvania State Univ., University Park, PA

Abstract: Alzheimer's disease (AD) is a chronic neurodegenerative disorder with a plethora of pathological changes such as amyloid-β accumulation, intracellular tau tangles, synaptic dysfunction, reactive gliosis, and ultimately neuronal loss. AD is the most prevalent dementia among elderly people and ranked as the sixth leading cause of death in the United States. Currently available drugs are targeting cholinergic and glutamatergic neurotransmission and can only alleviate certain disease symptoms. So far, there is no disease-modifying therapy to prevent or reverse AD progression, largely because of the lack of a technology to prevent neuronal loss or to replenish the lost neurons after degeneration. In this study, we employed our AAV NeuroD1-based gene therapy to achieve high efficiency astrocyte-to-neuron conversion in the 5xFAD mouse model for AD. We found that after AAV NeuroD1-mediated conversion, the number of cortical neurons increased while the number of reactive astrocytes decreased, leading to a rebalanced neuron to astrocyte ratio in the cortex. Moreover, we observed a reduction of intracellular amyloid-β level accompanied with a reduction of inflammatory microglia. The NeuroD1-converted neurons showed long-term survival of more than 8 months in old AD mice,

and the NeuroD1-converted areas showed higher synaptic density and improved blood vessel integrity. In summary, our NeuroD1-based gene therapy not only regenerates a large number of functional new neurons through high efficiency astrocyte-to-neuron conversion but also changes the previously degenerative landscape into a neural regenerative environment.

Title: Altered heme metabolism in Alzheimer's disease pathogenesis

Authors: *L. ZHANG[1], C. VIDAL[1], K. DAESCU[1], K. E. FITZGERALD[1], A. STAROKADOMSKA[2], I. BEZPROZVANNY[3];

Abstract: Heme is a central molecule for mitochondrial respiration and for all processes involved in oxygen utilization. Multiple subunits in the mitochondrial respiration complexes also require heme in order to function. Particularly, neurons have an increased demand for cellular energy and are known to enhance heme biosynthesis and uptake. Therefore, it is not surprising that heme has been implicated with the progression of Alzheimer's disease. Heme has been shown to colocalize with Aβ in AD tissue. This Aβ heme complex has been shown to generate ROS, which can generate an array of neurotoxic products. Despite this evidence of the involvement of heme in AD pathogenesis it is not clear what heme-related events play a causative role in AD pathogenesis. To elucidate the role of heme in AD we identified heme-related proteins whose expression is altered in AD patients and APPPS1 mice. We found that the rate-limiting heme synthetic enzyme ALAS1 and heme degradation enzyme HO-2 are selectively reduced in AD brain hippocampi. Further, to identify the potentially early events in Aβ action, we employed the SH-SY5Y cell line to study the AD pathogenesis. Using the SH-SY5Y cell line, we monitored heme synthesis, uptake, and degradation, as well as heme-related proteins and

enzymes as neuronal differentiation progresses. Using fully differentiated SH-SY5Y cells we found that Aβ selectively reduces the levels of HO-2 and heme degradation which are elevated to support neuronal function. Our data show that heme degradation should also lead to lowered levels of biliverdin and bilirubin in neuronal cells, which would likely lead to oxidative stress in early stages of AD pathogenesis. Further experiments are underway to illuminate the roles of altered heme metabolism in AD pathogenesis.

Title: Propagation of neurodegenerative protein in human aging

Authors: *S. MURAYAMA[1], Z. TANEI[1], T. MATSUBARA[1], R. SENGOKU[1], Y. SAITO[2]; [1]Neurol and Neuropathology (the Brain Bank for Aging Research), Tokyo Metropolitan Geriatric Hosp. and Inst. of Gerontology, Tokyo, Japan; [2]Natl. Ctr. Hosp. Neurol. & Psy., Tokyo, Japan

Abstract: Introduction: Age- related neurodegenerative pathology presents relatively high incidence and extent, with certain symptomatic threshold for each pathogenic protein. The aim of this study is to provide full profile of Alzheimer pathology and Lewy body- related alpha synucleinopathy (LBAS) in human aging population in addition to other neurodegenerative proteins including four repeat tau and TDP43.
Method: The Brain Bank for Aging Research (BBAR) consists of consecutive autopsy cases of a general geriatric hospital, which supports an aging cohort of Tokyo Metropolitan suburban area. The registration to BBAR was based on the first kin of relatives' informed consent with or without patients' living will. The tissues were processed following BBAR method which was uploaded to www.mci.gr.jp/BrainBank/. We have screened not only the brain and spinal cord, but also the peripheral nervous system (PNS) of all the registered cases to BBAR immunohistochemically. The antibodies employed include antibodies against Abeta, phosphorylated (p) tau, p- synuclein (psyn), p- TDP43 and ubiquitin.
Results: Among the 534 cases registered to BBAR from 1995 to 2018, 181 cases (34%) contained LBAS either in the PNS and/ or the central nervous system (CNS). 46 out of the 181

cases fulfilled diagnostic criteria of Parkinson disease (PD) with (PDD) or without dementia, dementia with Lewy bodies (DLB) or pure autonomic failure (PAF). The most predilection site of LBAS was sympathetic ganglia in PNS and olfactory bulbs in CNS. In the earliest stage of Lewy body disease, these two sites were independent as we previously reported. PNS had strong connection with brain stem, while olfactory bulbs with limbic system. We classified incidental LB disease (LBD) to preclinical and prodromal stage either with or without loss of pigmentation in substantia nigra. Preclinical and prodromal PD, DLB and PAF could be recognized of lesser frequency than preclinical, prodromal and clinical AD, which roughly represents 20%, 10% and !0% of all the registered cases.
Conclusion: This data provides basic information about the propagation of AD pathology, LBAS and their combination in human aging. Our brain bank could provide resource for mechanistic research of multiple proteinopathy in human aging.

Title: *In vivo* redox regulation of ΔFosB's structure-function relationship in Alzheimer's

Authors: *H. LYNCH[1], C. MCCORNACK[2], V. BALI[1], G. RUDENKO[4], E. J. NESTLER[5], A. ROBISON[3];
[1]Physiol., [3]Neurosci., [2]Michigan State Univ., East Lansing, MI; [4]Pharmacology/Toxicology and Sealy Ctr. for Structural Biol., Univ. of Texas Med. Br., Galveston, TX; [5]Icahn Sch. Med. At Mount Sinai, New York, NY

Abstract: Many neurodegenerative diseases, including Alzheimer’s disease (AD), are driven by altered reduction/oxidation (redox) balance in the brain. Moreover, cognitive decline in AD is caused by neuronal dysfunction that precedes cell death, and this dysfunction is in part produced by altered gene expression. However, the mechanisms by which redox state controls gene expression in neurons are not well understood. ΔFosB is a neuronally enriched transcription factor critical for orchestrating gene expression underlying memory, mood, and motivated behaviors and is dysregulated in Alzheimer’s Disease (AD). ΔFosB regulates gene expression by dimerizing with JunD to form activator protein 1 (AP-1) which binds the promoter regions of

target genes to control transcription. In controlled *in vitro* conditions, AP-1 complex formation and DNA binding are modulated by redox-sensitive disulfide bonds, and by redox-sensitive conformational changes in ΔFosB. Here, we show that the redox-dependence of the structure-function relationship of fos-family proteins found *in vitro* is also conserved in ΔFosB *in vivo*; a characteristic that we find across the brain. Under non-reducing (oxidizing), fully denatured conditions, immunoprecipitation followed by Western blot reveals a shift in the molecular weight of ΔFosB from 37kDa to ~75kDa and ~150 kDa; potentially representing the binding of ΔFosB to other proteins through disulfide bridge formation between cysteine residues that has been demonstrated *in vitro*. We also demonstrate that JunD is part of this oxidation-dependent complex. In contrast, under reducing conditions, denatured ΔFosB remains at 37kDa, indicative of no oxidation-dependent covalent complex formation. Additionally, we delve into the ability of ΔFosB to form both heterodimers and homodimers under various redox conditions and the role of specific cysteine residues in these complexes in cultured Neuro2a cells. Taken together, these data suggest that ΔFosB complex formation in the brain is directly regulated by redox state through disulfide bonds. Better understanding of how the structure-function relationship of ΔFosB is regulated by cysteine oxidation may ultimately allow us to use ΔFosB as a therapeutic target for diseases associated with an altered redox state, like AD.

Title: Differential expression of PICALM in the cortex and hippocampus of Alzheimer’s disease (AD)

Authors: *S. SARKAR[1], Q. GU[2], J. RAYMICK[3], E. CUEVAS[3], H. ROSAS-HERNANDEZ[4]; [1]Div. of Neurotoxicology, Natl. Ctr. For Toxicological Research/Us FDA, Jefferson, AR; [2]Div. of Neurotoxicology, FDA Natl. Ctr. for Toxicological Res., Jefferson, AR; [3]Div. of Neurotoxicology, Natl. Ctr. for Toxicological Res., Jefferson, AR; [4]Div. of Neurotoxicology, Natl. Ctr. For Toxicological Res., Jefferson, AR

Abstract: Phosphatidylinositol-binding clathrin assembly protein or PICALM is a genetic risk factor for AD based on recent genome wide association studies (GWAS). The preponderance of PICALM in the brain capillary endothelium makes it an ideal candidate for regulation of blood brain barrier function in vivo due to its ability to clear Aβ from the brain into circulation. Additional evidence also suggests that PICALM’s involvement in receptor mediated clearance

such as low-density lipoprotein receptor related protein (LRP1), which eventually binds to Aβ. By using a highly specific antibody, we studied the localization of PICALM in the temporal cortex (BA21), prefrontal cortex (BA10) and hippocampus across different stages of AD. Although recent studies suggest the downregulation of PICALM in AD disease progression, localization of PICALM in the present study does not support the earlier observations. At Braak stage I, most PICALM positive endothelial cells are present in the surface layer of the cortex and terminals were seen in the meningeal membrane; however, most of the axonal varicosities as well terminals were seen in the polymorphic layer of the hippocampus. At Braak stage III, a moderate number of PICALM positive terminals were still present in the cortex and, at Braak stage VI, very few PICALM positive terminals were seen in the cortex and hippocampus. PICALM positive endothelial cells are present in early Braak stages (I-III); however, this level increased across higher Braak stages. PICALM positive pre-tangles started to appear in Braak stages III-IV, but they are limited in the BA21 and BA10. However, most of the ghost tangles and flamed tangles that are PICALM can only be seen in the hippocampus at Braak stages V-VI. PICALM colocalized with phospho-Tau that were specific for either paired helical factor of phosphorylated Tau. Western-blot data also revealed that there is significant upregulation of PICALM expression in the hippocampus of AD patients compared to control. Additional studies correlating the expression of PICALM in the endothelium and brains and genotype of patients from control and AD patients would be useful to determine how genotypes such as APOE and other vascular risk factors can influence the progression of AD.

Title: Linking gamma-secretase and glutamate homeostasis: Presenilin-1 and glutamate transporter GLT-1 interaction

Authors: *L. C. ANDERSON[1], M. MAESAKO[1], N. SEKULA[1], C. ZHANG[1], S. L. WAGNER[2,3], R. E. TANZI[1], O. BEREZOVSKA[1];
[1]MassGeneral Inst. for Neurodegenerative Dis., MGH-Harvard Med. Sch., Charlestown, MA; [2]Univ. of California San Diego, La Jolla, CA; [3]VA San Diego Healthcare Syst., La Jolla, CA

Abstract: We recently discovered an unknown interaction between Presenilin 1 (PS1), a catalytic subunit of γ-secretase responsible for the generation of amyloid-β (Aβ) peptides, and GLT-1, a major glutamate transporter in the brain (a.k.a. EAAT2). This PS1/GLT-1 interaction may be the critical link between two major pathological aspects of Alzheimer's disease (AD): abnormal Aβ occurrence and neuronal network hyperactivity. We previously verified that PS1 and GLT-1 interact both *in vitro* and *in vivo* and that the interaction is not impacted by treatment with γ-secretase inhibitors. Here, we investigate the effect of PS1 conformation and familial AD mutations on the PS1/GLT-1 interaction. First, we employ a FRET-based assay, fluorescence lifetime imaging microscopy (FLIM), to characterize the PS1/GLT-1 interaction in the brain tissue of sporadic AD patients and control individuals (Experiment 1). Next, to identify possible modulators of the PS1/GLT-1 interaction, we use FLIM to explore the effect of gamma-secretase modulators (GSMs; Experiment 2) and of familial AD PS1 mutations (Experiment 3) in transiently transfected CHO and HEK PS1 and PS12 double knockout cells. Our findings indicate that there is significantly less interaction between PS1 and GLT-1 in sporadic AD brains, as measured by a decrease in FRET efficiency, compared to tissue of non-demented controls and Frontotemporal dementia (FTD) controls. Interestingly, treatment with PS1 conformation modulators (sGSM15606 and sGSM36), increase the PS1/GLT-1 interaction, as measured by an increase in FRET efficiency. Furthermore, pathological familial AD mutations in the PS1 protein, specifically Δ9, L166P and G384A, reduce PS1's binding to GLT-1. Of note, non-pathogenic mutation E318G had similar FRET efficiency levels as the wildtype PS1 protein. The current results suggest the PS1/GLT-1 interaction is disrupted in sporadic AD and is affected by PS1 conformational changes.

Title: Effect in weight, cogntion and serum glucose after the administration of intracerebroventricular streptozotocin injections during a 60 days period in CD1 mice. A model for sporadic Alzheimer's disease

Authors: *C. G. ESTRADA-GOMEZ, P. C. BELLO-MEDINA, S. DIAZ-CINTRA; Neurobiologia del Desarrollo y Neurofisiologia, Inst. De Neurobiologia. UNAM, Queretaro, Mexico

Abstract: Since diabetes has a factor which duplicates the risk of appearance of Alzheimer's disease (AD), however this mechanism remains unknown. In addition, the theory called "diabetes type 3" refers to an insulin resistance confined to the brain and that can be induced with the administration of intracerebroventricular (icv) streptozotocin (STZ). The aim of this study is to contribute to the characterization of the sporadic model of AD in male mice CD-1 of 8 weeks old. In order to evaluate it, we measured the changes in weigh, spatial memory and serum glucose during a 60 days period after an icv injection of STZ. These mice were housed randomly in an inverted cycle room, followed by a stereotaxic surgery. We injected (icv) 5 µl of artificial cerebrospinal fluid (vehicle group (VEH), n=30) or added STZ at a dose of 3 mg/kg (experimental group, n=30). The animals were let grow until 15, 30 and 60 days of age. During these times, all mice were weighed two times per week. When the time was fulfilled, all the animals were tested in the Morris Water Maze (filled with water at 22 ±1 °C) with a non-visible escape platform. In acquisition phase (8 trials/1 day), mice were given up to 60s per trial to find the platform, remained on the platform for 20s and then were placed in a holding cage for 20s until the next trial. Twenty-four hours later, retention test was conducted with one trial in the pool without the platform and starting in the first liberation point. On the next day, animals were sacrificed by cervical dislocation and its serum glucose was measured with a glucometer. We found in the animals that received STZ in three periods (15, 30 and 60 days) a decreased in their weights compared to the VEH groups. The STZ group showed a learning deficit in the Morris Water Maze task compared to the VEH groups. We didn't find significant differences between the serum glucose of VEH and STZ groups at the end of each period (15, 30 and 60 days), this finding is similar with other reports in which an icv injection of STZ did not pass the blood brain barrier because it does not alter the systemic metabolism. Thus, we found a model that resembles the cognitive deficit found in the AD. Also, the changes in weight as well as serum glucose help to understand that the insulin resistance effect by STZ occurs every time this drug is administrated directly in the brain due to it does not cross the blood-brain barrier. We thank to Azucena Aguilar Vazquez for her technical assistance. The present work was supported by PAPIIT (IN203616) and CONACyt (CB-255399)

Abstract: Mounting evidence indicates type 2 diabetes mellitus (T2DM) as a risk factor for Alzheimer's disease (AD), the most common form of dementia syndromes. Consistently, multiple lines of studies suggest that T2DM and AD may share several pathophysiological mechanisms at the cellular/molecular level. It has been established that maintenance of long-term memory and synaptic plasticity requires *de novo* protein synthesis, and recent studies indicate AD-associated impairments in protein synthesis. Here we sought to explore AD-associated brain pathology and molecular signaling in aged (14-29-year-old), naturally occurring T2DM cynomolgus monkeys. We examined the prefrontal cortex, hippocampus, and cerebellum using western blot, ELISA, and immunohistochemistry. Our preliminary findings indicate that diabetic monkeys exhibited an increase in phosphorylated tau, compared to age-matched controls. Additionally, we observed in diabetic monkeys decreased phosphorylation of AMP-activated protein kinase (AMPK), a central molecular sensor to regulate energy metabolism. In agreement with recent studies in AD, T2DM monkeys also exhibited elevated phosphorylation of eukaryotic elongation factor 2 (eEF2), indicating repression of general protein synthesis. Taken together, our data provide further evidence to support a relationship between T2DM and AD-associated dementia syndromes.

Title: Full length APP regulates the size and cellular location of the axon initial segment with implications for Alzheimer's disease

Authors: *F. MA, K. HERRUP;
Hong Kong Univ. of Sci. and Technol., Hong Kong, Hong Kong

Abstract: The axon initial segment (AIS) is a specialized neuronal structure that is strategically located between the somatodendritic and axonal domains of a neuron where it serves as a barrier to membrane and protein trafficking. The AIS also serves as the initiation site for an action potential with its size and distance from the soma serving to dramatically alter action potential firing. These essential functions make the AIS a vulnerable feature of any neural network. Indeed, disruption of AIS structural integrity is closely connected to cognitive dysfunction in many neurodegenerative diseases. In the current study we probe the response of the AIS to the progression of Alzheimer's disease (AD). We examined the R1.40 transgenic mouse model of AD in which the entire human APP gene, with the Swedish mutation (APP_{Swe}), is inserted into the mouse genome. We found that in R1.40 neocortex and hippocampus the density AIS profiles (seen by immunostaining with ankyrin G or β4-spectrin) was reduced as was AIS length. Similarly, in primary cultures, R1.40 neurons had axons with shorter AIS located at an increased distance from the cell body. This is in part a developmental problem as the appearance of the AIS of R1.40 neurons in culture is delayed. To confirm that this was a direct effect of APP itself, we showed that overexpression of APP or APP_{Swe} in wild type neurons also reduced AIS length; the reduction was greater with APP_{Swe} than with wild type. By contrast, treatment with fibrillar Aβ had no effect on AIS properties. These effects appear to be partly calcium mediated. Blocking the calcium-dependent protease, calpain, improved but did not fully rescue the AIS phenotype following APP overexpression. To further explore the mechanistic basis of the APP/AIS interaction we showed with immunocytochemistry that APP localizes to the proximal end of the AIS. We also found that APP and Ankyrin G can be co-immunoprecipitated with each other from mouse brain (gray or white matter). Taken together our findings suggest that rather than merely being a source of Aβ, the APP holoprotein potentially fine tunes neuronal activity by dynamically regulating the length and position of the AIS. The implication is that in AD APP increases as neuronal damage increases dampening neuronal responsiveness. Finally, the AIS changes become irreversible and the resulting neuronal malfunctions contribute to the neurological symptoms of Alzheimer's.

Title: Neuronal DNA double strand breaks in the CK-p25 mouse model of severe neurodegeneration

Authors: *G. M. WELCH[1], J. D. CHENG[1], Q. SU[2], M. KELLIS[1], A. PFENNING[2], L.-H. TSAI[1];
[1]The Picower Inst. for Learning and Memory, MIT, Cambridge, MA; [2]Carnegie Mellon Univ., Pittsburgh, PA

Abstract: Failure to repair lesions in DNA is associated with neurodegenerative phenotypes. A particularly hazardous form of DNA damage is the DNA double strand break (DSB), which at pathological levels can induce cytotoxicity. The transcriptomic and epigenetic effects of DSBs in mature post-mitotic neurons in the context of neurodegenerative disease is currently undefined. We have previously shown increased levels of DSBs in neurons of the CK-p25 mouse model of severe neurodegeneration (Kim et al., Neuron, 2008). Presence of DSBs is concomitant with onset of an inflammatory response in microglia and precedes neuron cell death and cognitive decline in these mice (Fischer et al., Neuron, 2005; Cruz et al., Mathys et al., Cell Reports, 2017). In the present study, we hypothesized neuronal DSBs contribute to CK-p25 neurodegeneration. To address this hypothesis, we proposed this contribution could be traced through transcriptomic and epigenomic changes in neurons bearing the largest amount of DSBs. We used fluorescence-activated nuclei sorting (FANS) to isolate populations of neurons with high levels of γH2AX, a robust marker for DSBs, from the adult CK-p25 cortex. RNA sequencing of these nuclei revealed "γH2AX-positive" neurons show differential expression of a number of genes related the DNA damage response compared to "γH2AX-negative" neurons. To assess changes in chromatin associated with DSBs, we performed H3K27ac chromatin immunoprecipitation (ChIP) followed by next-generation sequencing. Differential analysis of these H3K27ac peaks revealed enrichment of peaks associated with p53 activity, a critical mediator of the DNA damage response, in γH2AX-positive neurons. Fluorescent in-situ hybridization and western blot analysis were used to confirm differential expression of genes of interest at the mRNA and protein level. We propose increased DNA damage response and p53 activity precede the onset of apoptotic activity in these cells. Indeed, γH2AX signal in the CK-

p25 cortex co-localizes with pyknotic nuclei by the time neuronal death and cognitive decline are observed (Kim et al., 2008). Combined, these data characterize a specific population of neurons with high levels of DSBs, and demonstrate a role for DSBs in the initiation of a neurodegenerative phenotype.

Title: HCN channelopathy in the ventral hippocampus of Alzheimer's disease mouse models

Authors: ***A. ROGALSKY**[1], T. F. MUSIAL[1], E. MOLINA-CAMPOS[1], N. YBARRA[1], L. A. BEAN[1], Y. VOSKOBIYNYK[1], M. L. RUSSO[1], M. M. OH[2], R. J. VASSAR[2], J. F. DISTERHOFT[2], D. A. NICHOLSON[1];
[1]Rush Univ. Med. Ctr., Chicago, IL; [2]Northwestern Univ. Feinberg Sch. of Med., Chicago, IL

Abstract: Background
Alzheimer’s disease (AD) is marked by the accumulation of Amyloid beta peptides, neuronal cell death, and synapse loss. However, dysregulation of voltage gated ion channels may also contribute to AD progression. Our lab has shown that in the dorsal hippocampus of transgenic mouse models of AD, CA1 pyramidal neurons exhibit a channelopathy in which hyperpolarization-activated cyclic-nucleotide gated (HCN) channels are mislocalized. However, magnetic resonance imaging (MRI) studies have shown that the anterior hippocampus, corresponding to the ventral hippocampus of rodents, atrophies at a faster rate than the posterior. Additionally, the ventral hippocampus in AD mouse models appears to have more aggressive plaque pathology than the dorsal portion. Therefore, it is important to investigate the possibility that the HCN channelopathy observed in the dorsal hippocampus is also present in the ventral hippocampus.
Methods
Both 3xTg and 5xFAD mouse models were used. Immunogold electron microscopy was used to assess the relative quantity and location of HCN channels within neurons. And whole cell patch clamp was used to measure accommodation, sag, and rebound slope.
Results

Similar to the dorsal hippocampus, the ventral hippocampus exhibits altered physiology that suggests mixed HCN channelopathy. There was little to no evidence of exacerbated accommodation in the ventral hippocampus. However the transgenic mouse neurons showed both gain and loss of function indicated by altered sags and rebound slopes.
Preliminary experiments indicate that ventral HCN channels are mislocalized similarly to dorsal channels in transgenic mouse models of AD.
Conclusion
Besides the lack of exacerbated accommodation, the ventral and dorsal hippocampi exhibit similar patterns of channelopathy. Additionally, it appears likely that the measurably altered physiology from the wild type mice is due to mislocalization of HCN channel proteins.

Title: Single particle tracking of functional mutants of PERK to understand cell specific activation mechanism under stress

Authors: *H. GUDLAVALLETI, R. VISWANATHAN, B. STOVEKEN, D. HOLSTEIN, P. MOZOLEWSKI, R. DOBROWOLSKI, J. LECHLEITER;
Cell Systems and Anat., Univ. of Texas Hlth. Sci. Ctr. At San Antonio, San Antonio, TX

Abstract: PKR like endoplasmic reticulum kinase (PERK) is a transmembrane protein in the ER that phosphorylates elf2α under cellular stress and inhibits protein translation. Neurodegenerative diseases that have been associated with the accumulation of unfolded proteins in brain cells have been shown to activate PERK mediated translational control. It has been proposed that the PERK luminal domain senses the misfolded proteins and it undergoes dimerization and oligomerization to activate PERK via autophosphorylation on its cytosolic domain. However, a detailed molecular understanding of PERK activation is unknown. By tagging PERK with a photoconvertible fluorescent protein (FC-FP) like mEos3.2, we can measure the diffusion rates and trajectories of PERK in a cell under normal physiological conditions and under stressed conditions using single particle super resolution microscopy. Our working hypothesis is that the diffusion rates decrease as PERK molecules form multimeric complexes with each other or with

other proteins under ER stress.
Our strategy to test this hypothesis is to introduce mutations in luminal domain of PERK to prevent oligomerization or in the cytosolic domain to inhibit kinase activity. All PERK variants will be fused with the FC-FP mEos3.2 for sptPALM and expressed at near endogenous levels in PERK knock out mouse embryonic fibroblasts (MEFs). In preliminary experiments, single particle tracking of PERK in MEFs revealed an average diffusion constant of 8.68 +/- 3.95 um/sec. After thapsigargin treatment (1 uM for 10 minutes), the diffusion rate of PERK was reduced to 6.83 +/- 2.76 um/sec, consistent with our hypothesis. Data were obtained from 2223 counts in 3 cells. Our plan is to use a similar strategy in human pluripotent stem cells (iPSCs) to test whether PERK activation differs in iPSC derived neurons and astrocytes.

Abstract: Misfolded proteins are a common phenotype of many neurodegenerative diseases like Alzheimer’s, Frontotemporal dementia, and Progressive supranuclear palsy. When misfolded proteins accumulate in the endoplasmic reticulum (ER), cells respond to this stress through activation of the unfolded protein response (UPR). The UPR stress-sensor, PERK, is activated in the brains of patients with neurodegenerative tauopathies, and evidence indicates that both positive and negative modulation of its activity may be therapeutic. However, the exact mechanism of PERK activation and how it contributes to neurodegenerative diseases is poorly understood. It has been proposed that PERK activation requires assembly into homo-oligomeric complexes, but evidence of these structures *in situ* is scarce. Super-resolution optical techniques like photoactivated localization microscopy (PALM) and Stochastic optical reconstruction

microscopy (STORM) enable us to visualize and track PERK with nanometer resolution inside the cell and to better understand its basic biology and role in disease. However, the accuracy of PALM is limited by the detection efficiency of fluorescent proteins (e.g. the fraction of fluorescently-tagged PERK molecules detected in an experiment). We hypothesized that detection efficiency may be reduced by chemical fixatives such as formaldehyde and glutaraldehyde, which are commonly employed in PALM experiments. The goal of our study is to measure PERK at near-endogenous expression levels and to map its location throughout the ER with combined PALM/STORM.
Our first goal was to optimize fixative conditions required for STORM as this impacts the photo-convertible fluorescent protein (PC-FPs) efficiency and counting accuracy with PALM. Through fluorescence activated cell sorting (FACS), we have obtained data on the impact of fixation on the fluorescence of various PC-FPs. This information should enable us to optimized conditions to do concurrent PALM/STORM microscopy, which in turn, will permit us to measure and track the movement and diffusion rates of wild-type PERK in the ER in different cell systems, including undifferentiated IPSCs, differentiated neurons and astrocytes. Ultimately, this information on PERK dynamics will help us understand its mechanism of activation in both neurons and astrocytes as well as its dysregulation in neurodegenerative disorders.

Title: Role of parkin-mitofilin interaction in Parkinson’s disease stressor-induced neuron death

Authors: *A. IMAM ALIAGAN, M. DARAEI AHWAZI, N. MADUNGWE, L. LIU, N. TOMBO, Y. FENG, J. C. BOPASSA;
Univ. of Texas Hlth., San Antonio, TX

Abstract: Parkinson’s disease (PD) is a neurodegenerative disease characterized by a gradual and preferential loss of dopaminergic neurons in the brain (substantia nigra). Genetic mutations or environmental toxins and drugs (PD) stressors have been found to cause mitochondrial dysfunction and parkin has been identified as a protein playing a critical role in this mechanism. However, the exact mitochondrial-dependent mechanisms resulting in PD stressor-induced

dopaminergic neuron death observed in PD remains elusive. Recently, we have shown that knockdown of the inner mitochondrial membrane (IMM) protein; mitofilin, which controls mitochondrial cristae morphology results in increased cell death in H9c2 myoblasts. In this work, we hypothesize that preferential dopaminergic neuron death induced by PD stressors might be initiated by the reduction in mitofilin protein level through parkin-mediated ubiquitination. Using N27-A+ dopaminergic neurons, we found that treatment with PD stressors (rotenone, oxidized dopamine (DA) and MPP+) led to: i) increased translocation of parkin into mitochondria where it ubiquitinates mitofilin and causes its degradation, ii) reduced mitochondrial membrane potential, increased oxidative stress (ROS), which is associated with abnormal mitochondrial structure and dysfunction as well as increased ER stress, iii) increased neuron apoptosis via AIF-PARP cleavage pathway. We identified the lysine residue of mitofilin that is ubiquitinated by parkin in response to PD stressors activation, and found that this ubiquitination is prevented when K◊R mutated mitofilin was expressed. Conversely, overexpressing the mitochondrial deubiquitinase, USP30, attenuated mitofilin loss induced by PD stressors leading to an increased survival of N27-A+ cells. In male wild type mice eliciting PD phenotype in response to rotenone, MPTP, or 6-OHDA unilateral administration, we found a remarkable loss of mitofilin, effect that was not present in male parkin knockout mice. Together, these results indicate that parkin translocates into mitochondria in response to PD stressors to promote the ubiquitination of mitofilin and its loss in the IMM resulting in mitochondrial structural damage and dysfunction that causes cell death via AIF-PARP pathway. Our results provide a better understanding of mitochondrial-dependent mechanism of neuronal death observed in PD and a novel potential therapeutic target in cases where mitochondrial dysfunction is implicated.

Title: The adaptive defense mechanism associated with HFE genotype and its association with the vulnerability to paraquat-induced toxicity

Authors: *I. SONG, E. NEELY, A. SNYDER, S. LEE, J. CONNOR;
Penn State Col. of Med., Hershey, PA

Abstract: Parkinson’s disease, which over 10 million people suffer from worldwide, is characterized by motor impairment including bradykinesia. Past studies have identified the link between environmental toxins and mitochondrial dysfunction in Parkinson’s disease. Recently,

our laboratory reported protection from paraquat-induced motor impairment and cellular changes in HFE (H67D) mutant mice. The HFE protein regulates iron uptake by interacting with the transferrin receptor. Based on our previous study, we hypothesize that an antioxidant defense system, such as the Nrf2 pathway, is elevated in association with the HFE mutation. Because the Nrf2 pathway is preferably activated in astrocytes, we hypothesize that the HFE mutant astrocytes are responsible for the proposed neuroprotection. We performed immunostaining and immunoblotting on primary astrocytes in cell culture that revealed a visible increase in both Nrf2 and L-ferritin staining in the HFE mutant astrocytes prior to paraquat treatment. Moreover, we have found that the expression of Keap1, which is a negative regulator of Nrf2, was reduced in the HFE mutant astrocytes. Based on this data, we examined the difference in vulnerability to paraquat toxicity in association with HFE genotype. As we hypothesized, paraquat treatment induced a mitochondrial damage in the WT astrocytes only as shown by the changes in mitochondrial mass and loss of mitochondrial membrane potential. Furthermore, there was a significant increase in the astrocytic senescence marker ß-galactosidase in the WT after paraquat treatment, compared to that of H67D astrocytes. To further elucidate the role of HFE mutant astrocytes in neuroprotection against paraquat-induced toxicity, we have developed a SH-SY5Y neuroblastoma model that is stably transfected with WT or H63D HFE. With this model, we conducted a conditioned media experiment, in which the astrocytes were treated with a sublethal dose of paraquat and then the conditioned media from the paraquat treated astrocytes was added to the WT SH-SY5Y cells. A significant decrease in the viability of the WT SH-SY5Y cells was observed after treatment with WT astrocyte conditioned media in a dose-dependent manner but not with the H67D astrocyte conditioned media. By performing cytokine array, we have found that there was a significantly larger increase in IL-6 secretion in the WT astrocyte conditioned media compared to the H67D astrocyte conditioned media. The results of our study suggest that there is a difference in vulnerability to paraquat toxicity associated with HFE genotype, possibly due to a higher baseline activation of the antioxidant defense system in the HFE mutant astrocytes.

Title: Striatal alterations in mitochondrial function and α-synuclein in a rat model of methamphetamine-induced risk for Parkinson's disease

Authors: *I. CALMA, A. L. PERSONS, T. NAPIER;
Rush Univ., Chicago, IL

Abstract: Methamphetamine (meth) abusers have a greater risk to develop Parkinson's disease (PD) later in life than non-abusers. PD is characterized by motor disturbances, degeneration of nigrostriatal dopaminergic neurons, and emergence of α-synuclein rich protein aggregates. In meth self-administering (SA) male Sprague Dawley rats, we revealed an abstinence time-dependent bradykinesia that co-varied with reduced striatal tyrosine hydroxylase (TH) and mitochondrial electron transport proteins (ETP), increased mitochondrial membrane permeability, and decreased number of nigral TH+ neurons. These findings indicated that mitochondrial dysfunction is involved in protracted PD-like pathology initiated by meth abuse. To study this concept, we used osmotic minipumps to administer after meth SA a mitochondrial complex I inhibitor that can produce PD, rotenone. We determined that a mild treatment (1mg/kg/day X 6 days), which had no behavioral effects on its own, was able to exacerbate meth SA-induced bradykinesia, striatal TH loss and mitochondrial dysfunction. Here we extend these findings by evaluating the ETP, complex I, and α-synuclein, which normally binds to, and promotes complex I function. We tested four treatment groups: meth+rotenone (MR), meth+vehicle (MV), saline-yoked+rotenone (YR) and saline-yoked+vehicle (YV). Striatal tissues were collected 60 days after the SA task (40 days after rotenone). Complex I activity, measured with a colorimetric assay of the conversion of NADH to NAD, was significantly decreased in MR rats ($p<0.01$); activity in YV and MV rats was unchanged and YR was slightly (non-significantly) reduced. The ability of meth to potentiate the effects of rotenone on complex I activity implicates this enzyme in the persistent, pathogenic effects of meth. Optical density of immunohistochemical staining for striatal endogenous α-synuclein revealed a main ANOVA effect for rotenone ($p<0.05$), but this largely reflected a significant reduction in α-synuclein in MV rats. Thus, the proclivity of meth SA to promote PD-like pathology may involve striatal complex I processes that compensate for a meth-induced decrease α-synuclein, but succumb to the stress imposed by a subsequent exposure to even subthreshold doses of rotenone.

Title: Estradiol lowers axonal mitochondrial oxidant stress in dopaminergic neurons

Authors: *K. STOUT[1], S. M. GRAVES[2], J. KONDAPALLI[1], D. SURMEIER[3];
[1]Northwestern Univ., Chicago, IL; [2]Pharmacol., Univ. of Minnesota Twin Cities, Minneapolis, MN; [3]Prof. Dept. Physiology/ NUIN, Northwestern Univ. Dept. of Physiol., Chicago, IL

Abstract: Parkinson's disease (PD) is the most common neurodegenerative movement disorder, with cardinal motor symptoms arising from the progressive degeneration of dopaminergic (DA) neurons in the substantia nigra pars compacta (SNc). PD risk is strongly affected by sex, as men have increased risk compared to women. How sex alters dopaminergic vulnerability is not currently known, but evidence suggests that the phenomenon is estradiol-dependent.
Previous work has shown that in dopaminergic neurons mitochondrial oxidative phosphorylation (OXPHOS) is coupled to activity in two ways. First, spiking increases the entry of Ca^{2+} into the mitochondrial matrix, accelerating OXPHOS. Second, activity-dependent elevation in cytosolic dopamine stimulates OXPHOS through mitochondrially anchored monoamine oxidase (MAO). While these measures ensure sustained activity and dopamine release in the short-term, both mechanisms increase mitochondrial oxidant stress, resulting in mitochondrial damage and increased vulnerability to other risk factors associated with PD, like age.
We hypothesized that estradiol diminishes mitochondrial oxidant stress, resulting in neuronal resilience. Indeed, axonal mitochondria in SNc DA neurons from intact female mice had lower oxidant stress than those from male or ovariectomized (OVX) female mice. Further, acute application of 17β-estradiol lowered axonal mitochondrial oxidant stress; this effect was eliminated by the estrogen receptor inhibitor, 4-hydroxytamoxifen. While 17β-estradiol did not affect cytosolic Ca^{2+} concentration in axons, it reduced mitochondrial Ca^{2+} entry in OVX female mice. We tested the functional consequences of these changes by measuring dopamine release. 17β-estradiol increased dopamine release by 50% in both male and female mice. To tax energy reserves, we used a 0.1 Hz stimulation train; this frequency causes a progressive drop in dopamine release, due in part to depletion of ATP. 17β-estradiol exaggerated this drop dopamine release with repetitive stimulation. Thus, our working hypothesis is that 17β-estradiol lowers axonal mitochondrial oxidant stress (and increases resilience) in SNc DA neurons by diminishing mitochondrial Ca^{2+} entry. Currently, we are exploring the possibility that 17β-estradiol also controls MAO activity.

Title: Spiking drives mitochondrial respiration through a calcium-dependent, anticipatory control system in substantia nigra dopaminergic neurons

Authors: *E. ZAMPESE[1], J. KONDAPALLI[1], D. L. WOKOSIN[1], D. SURMEIER[2];
[1]Physiol., Northwestern Univ., Chicago, IL; [2]Prof. Dept. Physiology/ NUIN, Northwestern Univ. Dept. of Physiol., Chicago, IL

Abstract: Mitochondrial dysfunction is widely thought to be a primary factor underlying the selective vulnerability of substantia nigra (SN) dopaminergic neurons in Parkinson's disease (PD). This dysfunction has been linked to sustained mitochondrial oxidant stress in SN dopaminergic neurons. Although the opening of plasma membrane Cav1 (L-type) Ca^{2+} channels is known to be necessary for mitochondrial to manifest oxidant stress, precisely how they are coupled to mitochondria is unclear.
To answer this question, electrophysiological and optical approaches were used to interrogate SN dopaminergic neurons in ex vivo brain slices from mice expressing genetically encoded sensors targeted to specific sub-cellular locations. These studies revealed that opening of plasma membrane Cav1 Ca^{2+} channels triggers a cascade of intracellular events leading to entry of Ca^{2+} into the mitochondrial matrix. A key step in this cascade is Ca^{2+}-induced Ca^{2+} release (CICR) from the endoplasmic reticulum that is mediated by ryanodine receptors (RYRs). CICR results in flux of Ca^{2+} through the mitochondrial Ca^{2+} uniporter (MCU) into the matrix, where it stimulates oxidative phosphorylation (OXPHOS). Stimulation of OXPHOS results in elevated production of reactive oxygen species and engagement of oxidant defenses in SN dopaminergic neurons.
A fundamental question is why this mitochondrial control mechanism is in place. Our working hypothesis is that the proteostatic burden created by their enormous axonal arbor and their sustained regenerative (spiking) activity poses a substantial bioenergetic challenge to SN dopaminergic neurons. To meet this challenge without compromising cellular function, SN dopaminergic neurons must anticipate bioenergetic demand, rather than rely upon feedback mechanisms that would allow cytosolic adenosine triphosphate (ATP) levels to drop. One anticipatory signal that would predict bioenergetic demand associated with transmitter release

and maintenance of ionic gradients is the spike. Indeed, spike rate was linearly related to mitochondrial matrix Ca^{2+} levels. Moreover, the slope of this relationship was dependent upon sub-cellular region, suggesting it was tuned to local bioenergetic demand.
Taken together, our results suggest that mitochondrial oxidant stress in SN dopaminergic neurons is a deleterious by-product of an adaptive, anticipatory bioenergetic control mechanism designed to meet the needs posed by their extraordinary design and role in basal ganglia function.

Title: Analysis of mitochondria and endoplasmic reticulum contacts by genetically encoded tag and volume electron microscopy in neuron cell

Authors: *M. JUNG, J. MUN;
Korea Brain Res. Inst., Daegu, Korea, Republic of

Abstract: Cellular organelles, such as mitochondria and endoplasmic reticulum (ER), create a network to perform a variety of functions. Mitochondria and ER contact sites are very dynamic and specialized protein enriched region that determines their structure and functions. The contact sites play important roles in essential biological regulation of exchange of calcium (Ca^{2+}), lipids transfer between both organelles, autophagosome formation, and mitochondrial fission. Recently, many research has shown that disturbances to mitochondria and ER contacts occur in neurodegenerative diseases like as Alzheimer's disease, Parkinson's disease and Amyotrophic Lateral Sclerosis. Visualization of this network between mitochondria and ER has been attempted using super-resolution fluorescence imaging and light microscopy; however, the limited resolution is insufficient to observe the membranes between the mitochondria and ER in detail. Transmission electron microscopy provides good membrane contrast and nanometer-scale resolution for the observation of cellular organelles. However, it is very difficult to distinguish between fragmented ER and other membrane structures (e.g. Golgi structure or vesicles) in electron micrographs. In addition, these highly curved cellular organelles are not easy to analyze because they exist in a three-dimensional structure throughout the cell. Therefore, we observed the morphology of mitochondria and ER via correlative light-electron microscopy (CLEM) and

volume electron microscopy techniques using enhanced ascorbate peroxidase 2 (APEX2) and horseradish peroxidase (HRP) staining. An en bloc staining method, ultrathin serial sectioning (array tomography), and volume electron microscopy were applied to observe the 3D structure. In this study, we suggest a combination of CLEM and 3D electron microscopy to perform detailed structural studies of mitochondria and ER in a whole neuronal cell.

Title: Parkinson's disease protein DJ-1 interacts with f1fo ATP synthase to regulate protein synthesis

Authors: *R. CHEN[1], P. LICZNERSKI[1], M. GRAHAM[1], G. COSSU[2], W. MANDEMAKERS[3], V. BONIFATI[3], E. A. JONAS[1];

Abstract: Parkinson's disease (PD) is a progressive neurodegenerative disorder characterized by loss of dopaminergic (DA) neurons in the substantia nigra pars compacta (SNpc). DJ-1 is a peptidase C56 family protein with known and uncharacterized cellular functions, mutations of which are linked to early onset familial PD. Skin fibroblasts are a good *in vitro* model to study the early pathological alterations present in the neurodegenerative patients' brains. Mitochondrial dysfunction is a hallmark of the development of PD. In this context, we studied mitochondrial functional properties (morphology and bioenergetics) in fibroblasts obtained from two different DJ1 PD patients and one aged-match healthy individual. We observed that the average mitochondrial electron density in the PD fibroblast cells that lack DJ-1 (Pt 1) is greater (or darker) than that in the normal mitochondria or in cells containing mutant DJ-1 (Pt 2). Both sets of PD patient fibroblast mitochondria carry dramatically low number of cristae, and most of these cristae are in an abnormal shape. Pt1 fibroblasts presented a significant reduction in mitochondrial length and an increased number of total mitochondria per measured area. Pt2 PD fibroblasts showed decreased proliferation, and the mitochondrial ATP synthase beta-subunit protein level was dramatically decreased in these cells, consistent with our previous studies showing a large inner mitochondrial membrane leak in DJ-1 KO neuronal mitochondria. In addition, we also noticed that Pt2 fibroblasts have much lower overall protein synthesis rates,

which were improved by overexpression of the ATP synthase β subunit, presumably because this enhanced mitochondrial inner membrane coupling. Attempting to close the leak with pharmacological reagents CsA, or Dex, however, was unsuccessful at rescuing the level of β subunit protein level itself in mitochondria, although the effect on overall rates of protein synthesis of these reagents has not yet been ascertained. Complementary to these changes, both PD fibroblasts showed dysfunctional mitochondrial bioenergetic profiles. This also differentiated these cells from aged-matched healthy control fibroblasts. These observations suggest a connection between ATP synthase complex stoichiometry, protein synthesis rate and PD. These findings comprise a promising new strategy to develop therapies for PD patients.

Title: Abnormal mitochondria in a non-human primate model of MPTP-induced Parkinson’s disease: Drp1 and CDK5/p25 signaling

Authors: *J. PARK;
Natl. Primate Res. Ctr., Korea Res. Inst. of Biosci. & Biotechno, Cheongju, Korea, Republic of

Abstract: Mitochondria continuously fuse and divide to maintain homeostasis. An impairment in the balance between the fusion and fission processes can trigger mitochondrial dysfunction. Accumulating evidence suggests that mitochondrial dysfunction is related to neurodegenerative diseases such as Parkinson’s disease (PD), with excessive mitochondrial fission in dopaminergic neurons being one of the pathological mechanisms of PD. Here, we investigated the balance between mitochondrial fusion and fission in the substantia nigra of a non-human primate model of 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP)-induced PD. We found that MPTP induced shorter and abnormally distributed mitochondria. This phenomenon was accompanied by the activation of dynamin-related protein 1 (Drp1), a mitochondrial fission protein, through increased phosphorylation at S616. Thereafter, we assessed for activation of the components of the cyclin-dependent kinase 5 (CDK5) and extracellular signal-regulated kinase (ERK) signaling

cascades, which are known regulators of Drp1(S616) phosphorylation. MPTP induced an increase in p25 and p35, which are required for CDK5 activation. Together, these findings suggest that the phosphorylation of Drp1(S616) by CDK5 is involved in mitochondrial fission in the substantia nigra of a non-human primate model of MPTP-induced PD.

Title: Characterization of the *in vivo* effects of alpha-synuclein preformed fibrils on mouse brain mitochondria

Authors: R. B. CREED[1], A. A. MEMON[2], S. P. KOMARAGIRI[2], ***M. S. GOLDBERG**[3]; [1]Ctr. for Neurodegeneration and Exptl. Therapeutics, Dept. of Neurol, Univ. of Alabama At Birmingham, Birmingham, AL; [2]Neurol., Univ. of Alabama at Birmingham, Birmingham, AL; [3]Univ. Alabama At Birmingham, Birmingham, AL

Abstract: Alpha-synuclein pathology is one of the main pathological hallmarks of Parkinson's disease (PD). Mutations in the alpha-synuclein gene are causally linked to dominantly inherited forms of PD. Although the cause of PD remains uncertain, mitochondrial dysfunction is implicated in both familial and idiopathic PD. Some of the most widely used animal models of PD are based on toxins that inhibit mitochondrial complex I, such as MPTP and rotenone. There is substantial evidence that abnormal forms of alpha-synuclein cause mitochondrial dysfunction and this could be a common pathogenic mechanism for idiopathic and familial forms of PD. Recently, promising PD animal models have been generated by injection of pre-formed fibrils (PFF) of purified recombinant alpha-synuclein into the striatum or the substantia nigra of rats or mice. The effects of intracranial injection of alpha-synuclein PFFs on mouse brain mitochondria remains to be determined. To help fill this knowledge gap, we performed unilateral striatal injections of C57/BL6 mice with alpha-synuclein monomer or PFFs and euthanized the mice at 3 months and 6 months post injection to harvest brain tissue for analysis of mitochondrial function and abundance. In PFF but not monomer-injected mice, we observed prominent immunoreactivity using antibodies specific for alpha-synuclein phosphorylated at serine 129, which is a relatively selective marker of synuclein pathology in human postmortem brains and animal models. Functional analysis of striatal mitochondria revealed significantly altered

complex I activity in the PFF-injected mice at 6 months post-injection, but not at 3 months post-injection. These results indicate that the alpha-synuclein preformed fibril intracranial injection animal model of PD may be useful for mechanistic and therapeutic studies involving mitochondrial dysfunction caused by aggregated forms of alpha-synuclein.

Title: Using mouse cell-type-specific expression patterns of GWAS-implicated genes to identify vulnerable cell types and circuits in Parkinson disease

Authors: *R. M. COWELL[1,2], S. BOAS[1,2], L. J. MCMEEKIN[1,2], S. N. FOX[1,2], K. JOYCE[1,2], M. SIMMONS[1], K. L. GAMBLE[2];

Abstract: To accurately predict how genetic variation and/or cellular dysfunction influences disease etiology, one must consider the neuroanatomical location of the gene in a normal state. Until recently, this has been challenging to do in an unbiased way due to the magnitude of cellular heterogeneity in the brain, as well as the lack of cell-type-specific resolution in GTEx datasets. Recently, large efforts have been made to generate single-cell mRNA sequencing data to characterize transcriptional identity of brain cells in mice and humans. Here, we leverage publicly available mouse single-cell sequencing datasets to investigate the neuroanatomical distribution of GWAS-implicated genes for the purpose of exploring gene-gene interactions and convergent functional consequences of genetic variation. Principal component analyses of PD GWAS-implicated gene expression across nine regions of mouse brain revealed seven clusters of genes based on cell type and one set of genes with low to no brain expression. The largest set of genes showed enrichment of expression in neurons, with few genes being selectively enriched in dopaminergic neurons of the substantia nigra. Other neuroanatomical categories included polydendrocytes and oligodendrocytes, endothelial cells, astrocytes, and microglia. Interestingly, a cluster of genes was characterized by its enrichment in both prefrontal cortical and striatal neurons and relatively lower expression in dopaminergic neurons. Subsequent analyses of these seven gene clusters revealed unique information about functional categories, putative upstream

regulators of gene expression, and potential consequences of loss of function, with substantially greater statistical power than when all GWAS-associated genes were considered collectively. Additionally, analyses of the neuroanatomical location of genes associated with familial PD revealed previously unknown distributions of these genes in mouse brain, with differential association with the seven neuroanatomical clusters. Evaluation of cell-type-specific distribution of these genes in human midbrain revealed striking similarities between mouse and human cell-type-specific enrichment, suggesting that the seven neuroanatomical categories in mouse could represent distinct circuits and cell types relevant for understanding disease etiology. Altogether, these data suggest that PD etiologies may be defined by cellular identity and serve as a guide for choosing the appropriate cell types for investigating functional consequences of genetic variation.

Abstract: DJ-1 knockout (KO) rats are one of several recently developed transgenic rat lines whose development was funded by the Michael J. Fox Foundation to improve the tools available to Parkinson’s disease (PD) researchers. DJ-1 KO rats have been shown to exhibit a motor phenotype, with deficits in some gross motor behaviors (e.g., rearing frequency, grip strength) appearing by ~6 months of age. In the current studies, we tested whether DJ-1 KO rats also exhibit deficits in motor skill learning or long-term performance, using a behavioral task previously demonstrated to be a sensitive assay of forelimb motor coordination and strength. Male DJ-1 KO rats (n = 8) and wild-type Long Evans controls (WT, n = 8) were trained on an isometric pull task that required subjects to reach for and pull a lever placed 1.5 cm outside the training box. Rats began training on the pull-bar task at 2 months of age, and received two 30-minute training sessions daily, 5 days per week. Rats also underwent weekly assessments of

general locomotor activity in an open field. Behavioral experiments were performed by personnel blinded to genotype. Preliminary results after 5 weeks of training indicate that DJ-1 animals do not exhibit deficits in acquisition or stable performance on the pull task prior to 3 months of age. Nor were differences between DJ-1 and WT groups observed in the open field in total distance traveled or in rearing frequency prior to 3 months of age. Behavioral assessments will continue in these animals up to at least 8 months of age, and further analysis of longitudinal motor performance will be presented. The results of these experiments will provide detailed longitudinal characterization of the skilled motor abilities of the DJ-1 KO rat model of PD.

Abstract: Gastrointestinal (GI) disturbances are some of the earliest non-motor symptoms affecting most patients with Parkinson’s disease (PD). In many cases, these symptoms occur years before motor deficits become apparent, yet the molecular and cellular mechanisms that contribute to this early GI dysfunction remain poorly understood. The MitoPark model is a chronic, progressive mouse model that recapitulates several key pathophysiological aspects of PD. However, GI dysfunction has not been characterized in this model. Here, in comparison to age-matched littermate controls, we show that GI motility was one of the first non-motor symptoms to develop in MitoPark mice, and was detected as early as 8 weeks with significantly different transit times from 12 weeks onward. GI symptoms were observed well before motor symptoms develop, paralleling PD progression in humans. At age 24 weeks, we observed increased colon transit time and reduced fecal water content, indicating constipation. Intestinal

inflammation was also observed with increased expression of iNOS and TNFα in the small and large intestine. Specifically, iNOS was observed mainly in the enteric plexi of the MitoPark model. Also at 24 weeks, a pronounced loss of tyrosine hydroxylase-positive neurons was observed in enteric neurons, leading to a corresponding decrease in dopamine production in the intestinal tissue. We also observed decreased DARPP-32 expression in the colon, validating the loss of dopaminergic neurons in the gut. MitoPark mice also develop misfolded proteins as evidenced by positive oligomeric protein expression. Our 16s genomic analysis revealed changes in the fecal bacterial population, while fecal metabolites, including fatty acid glycerol and deoxycholic acid, showed significant changes among other metabolites. Together, our data shed more light on the GI pathology of the MitoPark mouse model of PD. Importantly, this model recapitulates the chronology and development of GI dysfunction, along with other non-motor symptoms, and offers an attractive model for pre-clinical assessment of the efficacy of new anti-Parkinsonian drugs for treating gut dysfunction in PD. Title: Parkin misregulation of clathrin-mediated synaptic vesicle recycling drives dopamine oxidation in Parkinson's disease patient neurons

Authors: *P. SONG[1], S. JEON[2], T. KRAINC[3], Y. C. WONG[1], D. KRAINC[4];
[1]Northwestern Univ., Chicago, IL; [2]Univ. of Illinois at Chicago, Chicago, IL; [3]Princeton Univ., Princeton, NJ; [4]Northwestern Univ. Feinberg Sch. of Med., Chicago, IL

Abstract: Loss of function mutations in both the E3 ubiquitin ligase *Parkin* and the synaptic protein *Synaptojanin-1* lead to early-onset PD. However, whether they functionally act in the same cellular pathway to drive neurodegeneration of human dopaminergic neurons in PD remains unclear. Here, we identified a novel role for parkin in modulating the synaptic complex Synaptojanin-1/Dynamin-1/Endophilin A1 to regulate dopamine oxidation and downstream associated pathogenic phenotypes, using PD patient dopaminergic neurons with Parkin

mutations. We found that loss of parkin ubiquitination in patient neurons inhibited the synaptic membrane recruitment of Synaptojanin-1 and Dynamin-1 by Endophilin A1 during clathrin-mediated synaptic vesicle recycling. Moreover, parkin mutant neurons demonstrated defective clathrin uncoating and recycling of synaptic vesicles, leading to the subsequent accumulation of cytosolic oxidized dopamine and downstream pathogenic defects. Importantly, expression of Endophilin A1 in parkin mutant neurons was sufficient to rescue both DA oxidation and downstream dysfunction including defective glucocerebrosidase activity. This study thus highlights a role for synaptic vesicle recycling defects in driving oxidized dopamine accumulation and PD pathophysiology, and further suggests converging mechanisms for two PD genes Parkin and Synaptojanin-1 in the synaptic function of human dopaminergic neurons.

Abstract: The balance between fission via dynamin-related protein (DRP1) and fusion via mitofusin (MFN) is critical for mitochondrial health in axons. Defects in fission-fusion and disruption of mitochondrial movement within axons have been linked to mitochondrial dysfunction and neurodegeneration. While α-synuclein (α-syn) has been proposed to influence mitochondrial dynamics within axons the mechanistic details of how α-syn effects mitochondrial homeostasis remains unknown. We found that excess α-syn causes mitochondrial fragmentation, similar to what is observed with excess DRP1, but in contrast to excess MFN2, which causes elongated mitochondria. Intriguingly, co-expression of DRP1 rescues α-syn-mediated mitochondrial fragmentation, indicating that α-syn and DRP1 likely have synergistic functions. Deletion of the acidic C-terminal domain of α-syn (α-syn1-120) which is thought to prevent membrane binding, or the NAC domain (α-synΔNAC) which is thought to promote self-aggregation did not affect α-syn-mediated mitochondrial fragmentation. Further, α-syn-mediated mitochondrial fragments were oxidized, while α-syn 1-120-mediated fragmented mitochondria

were healthier. Together our *in vivo* observations suggest that mitochondrial size is independent of mitochondrial health, and proposes domain specific roles for α-syn during mitochondrial homeostasis. These findings uncover a novel role for α-syn during mitochondrial homeostasis and highlight a common pathological mechanism for targeted therapeutics early before neuronal loss or clinical manifestation of Parkinson's disease.

Title: Parkin loss-of-function *Drosophila* dopaminergic neurons show signs of mitochondrial dysfunction during pupal development

Authors: *L. M. BUHLMAN[1], G. BERTOLIN[3], G. B. CALL[2];
[1]Biomed. Sci., [2]Pharmacol., Midwestern Univ., Glendale, AZ; [3]Inst. of Genet. and Develop., Univ. of Rennes 1, Rennes, France

Abstract: The search for the mechanism by which parkin loss of function causes neurodegeneration has led to discoveries that parkin-mediated maintenance of mitochondrial function and turnover may be critical for neuronal survival. Parkinson's disease clinical trials in which mitochondrial function is targeted have been unsuccessful, possibly because intervention occurs after substantial degeneration has taken place. Most cells are not susceptible to degeneration in the absence of parkin; however, parkin-null *Drosophila* have selective degeneration in protocerebral posterior lateral 1 (PPL1) dopaminergic neurons, which are functionally homologous to those of the mammalian substantia nigra. In order to identify unique properties of vulnerable dopaminergic neurons, we express fluorescent protein markers and use confocal microscopy to measure mitochondrial size, morphology, turnover, motility and network volume in PPL1 in *park*$^{25/25}$ (parkin-null) flies. We have previously reported that adult *park*$^{25/25}$ PPL1 mitochondrial networks have increased protein oxidation, fragmentation and transiently decreased mitophagy initiation - all of which are undetectable in non-degenerating dopaminergic neurons. In order to determine whether onset of mitochondrial pathology can be detected during development, we used super resolution confocal microscopy and 3D digital image processing to measure mitochondrial morphology, fusion/fission events and motility in PPL1 of living *park*$^{25/25}$ pupa. While fusion/fission events and mitochondrion size are unaffected, mitochondria have

decreased motility and network volume. Future studies will address whether changes in mitophagy initiation can be detected in living pupa PPL1. Our results demonstrate that vulnerable dopaminergic neuron pathology can be detected during *park*$^{25/25}$ development, and support earlier administration of potential therapeutic interventions with the goal of preventing neurodegeneration.

Abstract: Homozygous mutations of the lysosomal enzyme glucocerebrosidase (GBA1) cause Gaucher disease (GD), a lysosomal storage disorder which includes a severe neuronopathic form. Heterozygous mutations of GBA1 are the major genetic risk factor for Parkinson's disease (PD). GBA1 depletion and defects were associated with impaired autophagy and mitochondrial dysfunction by us and others.
We have now explored the impact of mitochondrial dysfunction on cell physiology in primary neurons from a *gba1*$^{-/-}$ mouse model of neuronopathic GD. Our data reveal dysregulated calcium handling and decreased bioenergetic reserve, which increased vulnerability to otherwise innocuous glutamate concentrations. Strikingly, *gba1*$^{+/-}$ neurons showed a behaviour that was

more similar to *gba1*$^{-/-}$ than to *gba1*$^{+/+}$, consistent with a role of these mechanisms in the pathogenesis of PD. *Gba1*$^{-/-}$ neurons also showed increased reactive oxygen species production that may explain the difference between *gba1*$^{+/-}$ and *gba1*$^{-/-}$ mice in the disease phenotype. These data reveal the fundamental role of bioenergetic capacity in protecting cells from dysregulation of calcium homeostasis.
We are now investigating the role of GBA1 trafficking and stability in PD models, also in relationship to the other PD-related protein Leucine-Rich Repeat Kinase 2 (LRRK2), which may affect the proper functioning or localization of GBA1. The idea of stabilizing GBA1 to improve its delivery to the lysosomes and/or its activity may be crucial in the development of new therapeutic strategies.

Abstract: Cessation of dopamine (DA) transmission largely depends on reuptake by the DA transporter (DAT) encoded by the Slc6a3 gene. DAT expression/activity is reduced in several neurological disorders and after exposure to drugs of abuse (e.g. cocaine, methylphenidate, amphetamine). Our aim was to characterize behavioral, neurochemical and electrophysiological effects of eliminating DAT activity in a novel DAT knockout rat generated using CRISPR/Cas9. As expected, DAT-KO rats displayed no DAT immunoreactivity in the striatum, increased basal locomotor activity, and paradoxical calming by amphetamine. Fast-scan cyclic voltammetry (FSCV) in brain slices demonstrated a large decrease in the clearance of electrically stimulated DA release in the dorsal striatum and to a lesser extent in the Substantia Nigra *pars compacta*

(SNc). Cocaine increased the amplitude of DA release and slowed its clearance in slices from wild-type (WT), but not DAT-KO rats. Basal extracellular DA concentration ($[DA]_{out}$), measured with fast-scan controlled-adsorption voltammetry (FSCAV; Burrell et al., ACS Chem. Neurosci. 2015, 6:1802), was higher in DAT-KO rats compared to WT littermates, and was enhanced by L-DOPA, showing that DA release after L-DOPA is not due to DAT reversal. Baseline firing frequency of SNc neurons and $GABA_B$-mediated inhibition were similar in DAT-KO and WT rats. However, D_2-mediated inhibition (by quinpirole, amphetamine and L-DOPA) was blunted in DAT-KOs, likely due to downregulation of D_2 receptors previously reported in DAT-KO mice. Amphetamine increased $[DA]_{out}$ in the dorsal striatum of WT rats, and this effect was strongly attenuated in DAT-KOs. Surprisingly, amphetamine increased $[DA]_{out}$ in the SNc of DAT-KOs, which did not differ to the response seen in WTs. The mechanism of this release is likely through reversal of low-affinity, high capacity uptake-2 transporters. These results not only validate our DAT-KO model, but also provide novel insights into the mechanism of DA releasing agents and form the basis for our future *in vivo* studies.

Title: Forced, but not spontaneous behaviors are initially upheld as dopamine transmission declines in Parkinson model

Authors: *Y.-H. CHEN[1], B. J. HOFFER[2], L. OLSON[3];
[1]Dept. of Neurolog. Surgery, Natl. Def. Med. Center/Tri-Service Gen. Hosp., Taipei City, Taiwan; [2]Scientist Emeritus, NIDA/NIH, Lyndhurst, OH; [3]Dept. of Neurosci., Karolinska Inst., Solna, Sweden

Abstract: To determine the role of reduced dopaminergic transmission for declines of forced versus spontaneous behavior, we used a model of Parkinson’s disease with progressive degeneration of dopamine (DA) neurons, the MitoPark mouse. Mice were subjected to rotarod tests of motor coordination, and open field and cylinder tests for spontaneous locomotor activity and postural axial support. To measure DA release in dorsal striatum and the shell of Nucleus Accumbens (NAc) we used ex vivo fast-scan cyclic voltammetry (FSCV) in 6 to 24 week old mice. To determine decline of DA transporter function we used 18FE-PE2I PET. We show here

that FSCV is a sensitive tool to detect evoked DA release dysfunction in MitoPark mice and that electrically evoked DA release is affected earlier in nigrostriatal than mesolimbic DA systems. DA reuptake was also affected more slowly in NAc shell. PET data showed DA uptake to be barely above detection level in 16 and 20 weeks old MitoPark mice. Rotarod performance was not impaired until mice were 16 weeks old, when evoked DA release in striatum had decreased to ≈ 40% of wild type levels. In contrast, impairment of open field locomotion and rearing began at 10 weeks, in parallel with the initial modest decline of evoked DA release. We conclude that forced behaviors, such as motivation not to fall, can be partially maintained even when DA release is severely compromised, whereas spontaneous behaviors are much more sensitive to impaired DA release, and that presumed secondary non-dopaminergic system alterations do not markedly counteract or aggravate effects of severe impairment of DA release.

Title: Determining the role of the dorsal striatum in D1R-D3R cooperativity in dyskinesia: Implications for L-DOPA-induced dyskinesia

Authors: *K. E. LANZA[1], K. CHEMAKIN[1], N. E. CHAMBERS[1], J. SERGIO[1], C. BISHOP[2]; [2]Psychology, [1]Binghamton Univ., Binghamton, NY

Abstract: Although L-DOPA remains the gold standard pharmacotherapy to treat most motor symptoms of Parkinson’s Disease (PD), the majority of patients will develop L-DOPA-Induced dyskinesia (LID) characterized by Abnormal Involuntary Movements (AIMs). There are many pre and postsynaptic factors that contribute to LID. Among these, postsynaptic sensitization of the dopamine D1 receptor (D1R) and upregulation of the dopamine D3 receptor (D3R) have been identified as key mechanisms in LID manifestation. D3R upregulation occurs primarily on striatal D1R-bearing cells where D1R-D3R physically and functionally interact. This interaction facilitates D1R-D3R cooperativity to augment LID severity. We previously demonstrated that systemic pharmacological co-stimulation of D1R and D3R results in synergistic dyskinesia that is correlated with enhanced downstream phosphorylation of striatal ERK1/2 (pERK1/2), a known substrate of LID. Although the striatum is a potential site of action of D1R-D3R synergy, D1R-D3R may interact extrastriatally to modulate circuit-level effects. Therefore, the present study sought to localize the striatal contributions of D1R-D3R cooperativity on the expression of

dyskinesia. To this end, Sprague Dawley rats were rendered hemi-parkinsonian with 6-hydroxydopamine into the medial forebrain bundle. Three weeks later, rats underwent chronic L-DOPA administration (6 mg/kg; s.c.) for 14 days. LID was quantified on days 1,7, and 14 using the AIMs scale. Dyskinetic animals entered into microinjection experiments. In two separate cohorts, intrastriatal doses were established for both the D1R agonist SKF38393 (0, 1.0, or 5.0 μg/μl) and the D3R agonist PD128907 (0, 0.5, or 5.0 μg/μl). Agonists were microinjected in a within-subject counterbalanced design. After threshold doses were established, a third cohort was tested for the presence of striatal D1R-D3R synergy. After each microinjection, AIMs were monitored for a period of 3 hours. Dose response data revealed dose-dependent effects of D1R and D3R agonists on dyskinesia. Preliminary data of D1R-D3R co-administration point to striatal specific contribution to D1R-D3R synergy and by extension, implicate aberrant D1R-D3R interactions as treatment targets for LID management.

Abstract: Dopaminergic medication to treat motor signs in Parkinson´s disease (PD) may come at a cost inducing non-motor complications such as impulse control disorders (ICD). ICD is a side-effect of anti-parkinsonian medication whereby patients experience enhanced desire towards natural rewards resulting in uncontrolled actions. Yet, the precise neural and behavioural mechanisms associated to ICD and of each specific subdomain are unclear. The objective was to decipher the network and neural connectivity change in one specific ICD (i.e. hypersexuality). Eighteen PD-ICD and 16 PD+ICD patients were scanned while on and off medicated for 10-minute resting period. Behavioural assessments done on medication included a stop signal task

(with erotic images), the Frontal Assessment Battery (FAB), Stroop test and the Questionnaire for Impulsive-Compulsive Disorders in Parkinson's Disease (QUIP). A dual-regression analysis was performed to extract four independent components representing the salience, sensoriomotor, default-mode and central executive networks per subject. Also a seed-based connectivity analysis was performed using as subcortical seeds. Two-way ANOVA comparison was performed to identify drug (on vs. off) or disease (PD-ICD vs. PD+ICD) main effects (uncorrected *P*-value of 0.001 using $P_{FWE}<0.05$ at the cluster level). Finally, correlations between networks and neuropsychological variables were performed.
The right inferior frontal gyrus (IFG) had a significant disease-effect within the salience network, being higher the connectivity for the PD+ICD group. Seed-based connectivity analyses showed main effects from motor striatum (drug-effect) to the temporal pole that correlated with the $QUIP_{sex}$ ($p<0.01$) for the PD+ICD group (while medicated). The connectivity with the executive striatum showed a significant disease-effect in the precuneus and superior parietal cortex, both correlating in the PD+ICD group with $QUIP_{total}$ ($p<0.02$) and $QUIP_{sex}$ ($p<0.03$), respectively. Finally, the limbic striatum showed a significant drug-effect in the parahipocampal gyrus which correlated with stop signal RT in ICD+PD ($p<0.01$) and controls ($p<0.01$).
The deficit in activating the salience network (including the right IFG) in PD+ICD is indicative of a probable dysfunction in stimulus detection, necessary for adaptive and controlled behaviour. Striatal seed-based connectivity indicates significant changes in frontal, parietal and temporal changes associated to hypersexual PD+ICD.

Title: Noradrenaline axons and alpha adrenoceptors in human and macaque thalamic nuclei involved in basal ganglia circuits

Authors: *I. PÉREZ-SANTOS[1], N. PALOMERO-GALLAGHER[2,3], K. ZILLES[2,3], C. CAVADA[1];

[1]Anatomía, Histología y Neurociencia, Facultad De Medicina, Univ. Autonoma De Madrid, Madrid, Spain; [2]Inst. of Neurosci. and Med. (INM-1), Res. Ctr. Jülich, Jülich, Germany; [3]Med. Faculty, RWTH Aachen, and JARA - Translational Brain Med., Aachen, Germany

Abstract: There is a significant loss of noradrenaline (NA) in the thalamus of Parkinson's disease patients and MPTP parkinsonian monkeys. NA depletion mainly affects the ventral motor nuclei, both in humans and monkeys; in humans, there is also significant NA reduction in other thalamic nuclei, including the intralaminar nuclei. In this work, we studied the normal distribution of NA axons and two types of Alpha-adrenoceptors in thalamic regions of humans and macaques which are connected directly or indirectly with the striatum, i.e. the ventral anterior (VA), ventral lateral (VL), intralaminar, and midline nuclei. We used immunohistochemistry against dopamine beta-hydroxylase and the noradrenaline transporter to reveal NA axons; and quantitative autoradiography to detect Alpha-1 and Alpha-2 adrenoceptors, using tritiated Prazosin and UK-14,304, respectively, as ligands. NA axonal maps were created using Neurolucida software, and Alpha receptor maps using a Matlab-based in-house developed software. The patterns of axonal distribution were comparable in the human and macaque thalamus. VA and VL exhibited a moderate NA innervation. The intralaminar nuclei exhibited higher NA axonal densities. Within the posterior intralaminar centromedian-parafascicular complex, NA axons were more abundant in parafascicular than in the centromedian nucleus. Humans appear to have a denser NA innervation than macaques in the centromedian nucleus. The midline nuclei were the most densely innervated. Alpha-1 receptor densities were higher than Alpha-2 densities, with the exception of the centromedian nucleus in the macaque thalamus. This particularity was not present in the human thalamus. The parafascicular nucleus exhibited high Alpha-1 and Alpha-2 receptor densities. Anterior intralaminar nuclei held low Alpha receptor concentrations, despite the dense NA innervation present in the axonal maps. This could be due to the presence of other receptors not analyzed (e.g. Beta family). VA and VL held a moderate density of Alpha-1 and a low density of Alpha-2 receptors, with higher densities in some regions, such as the ventromedial subdivision of VA (VAvm) and area X in macaques, and the magnocellular subdivision of VA (VAmc) in humans. The midline nuclei held the highest receptor densities. The thalamic regions with the most outstanding NA system are mainly connected to the caudate nucleus and ventral striatum. We conclude that the complex distributions of axons and receptors in thalamic nuclei involved in basal ganglia circuits suggest an important role for NA signaling, particularly in associative and limbic thalamo-striatal circuits.

Title: Chemogenetic and pharmacological interrogation of pedunculopontine nucleus cholinergic neuron involvement in L-DOPA-induced dyskinesia and gait deficits in hemi-parkinsonian rats

Authors: *N. E. CHAMBERS[1], J. SERGIO[1], A. MCLUNE[1], K. E. LANZA[2], C. R. BISHOP[2]; [2]Psychology, [1]Binghamton Univ., Binghamton, NY

Abstract: Parkinson's disease (PD) is a movement disorder characterized by loss of nigrostriatal dopamine neurons and brainstem acetylcholine (ACh) neurons in the pedunculopontine nucleus (PPN). Recent evidence suggests that PPN ACh neurons contribute to PD gait deficits and L-DOPA-induced dyskinesia (LID), a debilitating side effect of chronic L-DOPA-administration. To date, bimodal effects of PPN ACh neurons on LID and gait are unknown. Furthermore, although M4R positive allosteric modulators (PAM) show efficacy as an anti-LID therapeutic, the role of the PPN in M4R effects is not established. Rats in the current study were rendered hemiparkinsonian through unilateral infusion of 6-OHDA. In experiment 1, ChAT-cre+ Long-Evans rats received PPN infusions of excitatory (hM3dq), inhibitory (hM4di), or control (mCherry) designer receptors exclusively activated by designer drugs (DREADDs) viral vectors for selective modulation of PPN ACh neurons. Thereafter, rats received the DREADD ligand Compound 21 to determine chemogenetic effects on motor behaviors. L-DOPA was then administered for 2 weeks to elicit stable LID. Next, rats received C21 30 min before L-DOPA to examine the effects of chemogenetic modulation on LID and L-DOPA's motor efficacy. In experiment 2, wild-type Long-Evans rats received unilateral PPN-targeted cannulae. Following establishment of baseline motor deficits and stable LID, rats received a PPN microinfusion of M4R PAM VU0467154, followed 5 min later by L-DOPA. In both experiments, after L-DOPA administration LID was tested for 3h and gait and motor efficacy were assayed at the 30- and 60 min time points, respectively. At study end, lesion efficacy (TH-ir), successful transfection (PPN ChAT and mCherry co-expression), cellular activation (PPN ChAT + c-fos co-expression) and cannula placement were verified. Overall, chemogenetic stimulation of PPN cholinergic neurons appeared to improve movement, increase LID severity, and elevate ChAT and c-fos co-expression. Conversely, inhibition appeared to worsen motor performance, reduce LID severity, and decrease ChAT and c-fos co-expression. Finally, VU0467154 dose-dependently reduced

LID and c-fos-ChAT co-expression without affecting L-DOPA's motor efficacy, suggesting PPN cholinergic neurons as potential targets to reduce LID and PD motor deficits.

Title: Thalamic dopamine changes in Parkinsonism: Insight into novel pathogenic mechanisms

Authors: *M. H. G. MONJE[1,2], J. BLESA[3], M. GARCIA-CABEZAS[4], J. A. OBESO[3], C. CAVADA[5];
[1]Anatomy, Histology and Neurosci. Dept., Univ. Autónoma De Madrid, Madrid, Spain; [2]Hm-cinac, [3]HM-CINAC, Hosp. HM Puerta del Sur, Mostoles, Spain; [4]Hlth. Sci. (Neural Systems Lab), Sargent College, Boston Univ., Boston, MA; [5]Anatomy, Histology and Neurosci. Dept., Univ. Autónoma Madrid, Madrid, Spain

Abstract: Dopamine loss in Parkinson's disease (PD) affects most intensely the mesostriatal system. In order to understand a series of ill-defined pathogenic mechanisms and clinical manifestations, it is relevant to understand how dopamine changes affects brain structures beyond the striatum. The primate thalamus is densely innervated with dopaminergic axons that express the dopamine transporter (DAT); they have a diverse and complex origin and distribution. We hypothesized that dopamine changes may be present in the thalamus of the parkinsonian brain. Also, given the heterogeneity of the thalamus, differences might be present among the different nuclei. The toxin 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) was administered to adult macaque monkeys using a slow intoxication protocol. The intoxicated monkeys were classified into two groups by motor tests: non-symptomatic and parkinsonian. Dopaminergic innervation was studied by immunohistochemistry against DAT. The total length and length density of DAT-ir axons were estimated with stereology using a 3D fractionator. We also generated maps of the distribution of the DAT-ir axons. Compared to control animals, parkinsonian monkeys exhibited less DAT-ir axonal length density in the mediodorsal (MD) and centromedian-parafascicular (CnMd-Pf) nuclei. In MD, the dopamine denervation was present early, that is, in monkeys non-symptomatic at the time of sacrifice and with moderate substantia nigra cell loss (40-60%); MD dopamine denervation was greatest in the most severe parkinsonian animals. In the reticular (R) nucleus, DAT-ir axonal length density exhibited an

inverse pattern, with a progressive increase up to a maximum density in parkinsonian animals. DAT-ir axonal length density in the ventral thalamic nuclei did not show differences between groups. DAT-ir axons maps supported the quantitative findings. These results show that the dopaminergic axons innervating the thalamus show a heterogeneous reaction to MPTP, present even in the presymptomatic stages of the parkinsonism. Changes in the dopaminergic thalamic system may result in dysfunction of thalamocortical, thalamostriatal and intrathalamic transmission, and may contribute to motor and non-motor manifestations of PD, in particular attention and sleep disturbances.

Title: Compartments of dopaminergic neurons within the macaque monkey ventral substantia nigra have differential vulnerability to MPTP degeneration

Authors: J. BLESA[1], C. GIMÉNEZ-RODRÍGUEZ[2], P. ANDRÉS-CAMAZÓN[2], M. H. G. MONJE[2], N. LÓPEZ-GONZÁLEZ DEL REY[1], L. JIMÉNEZ-SÁNCHEZ[2], J. A. OBESO[1], ***C. CAVADA**[2];
[1]HM CINAC, Hosp. HM Puerta del Sur, Móstoles, Spain; [2]Univ. Autonoma Madrid, Fac Medicina, Madrid, Spain

Abstract: Human dopaminergic neurons within the calbindin-poor nigrosomal compartment of the substantia nigra (*SN*) are distinctly prone to degeneration in Parkinson’s disease (PD). One study (n= 5) indicated that those neurons die earlier and in larger numbers than the neurons within the calbindin-rich matrix. No longitudinal study, particularly in the early period of neurodegeneration (pre-symptomatic), is available. We have re-examined the macaque monkey *SN* using immunohistochemistry for calbindin-D28k. We confirmed that dorsal tier neurons express calbindin while ventral tier neurons do not. We also observed two compartments within the ventral tier of the *SN pars compact*a: calbindin-poor neuropil surrounded by a calbindin-rich zone. We propose to name these compartments nigrosomes and matrix, respectively, by analogy with the compartments of the human *SN*. We then verified that the nigrosomes and the matrix are present in the *SN* of monkeys rendered parkinsonian with the neurotoxin MPTP. We additionally

tested if the macaque monkey nigrosomes and matrix hold dopaminergic neurons with differential vulnerability to neurodegeneration. We used sixteen brains of diversely affected MPTP-treated monkeys (pre-symptomatic and symptomatic) and four control brains from non-MPTP-treated monkeys. We estimated the numbers and densities of tyrosine-hydroxylase-immunoreactive neurons (TH-ir) using stereology. In control monkeys, the densities of TH-ir neurons are 2.5 times higher in the nigrosomes than in the matrix. In MPTP-treated monkeys, TH-ir cell loss is higher in the nigrosomes than in the matrix. When parkinsonian symptoms are present, the numbers and densities of TH-ir neurons are similar or lower in the nigrosomes than in the matrix. These results indicate that the dopaminergic neurons within the monkey nigrosomes, known to project to the sensory-motor striatum, are the most vulnerable in the MPTP model of parkinsonism. The present observations confirm and expand earlier findings in humans and strengthen the value of the MPTP monkey model of PD to explore novel paths of research into this condition.

Title: Inhibition of striatal dopamine D5 receptor-mediated pathway attenuates levodopa-induced dyskinesia in a rat model of Parkinson’s disease

Authors: G. ZHANG, ***Y. WANG**, L. YAO, J. FENG, Y. SUN;
Dept. of Physiol. and Pathophysiology, Sch. of Basic Med. Sciences, Xi'an Jiaotong Univ., Xi'an, China

Abstract: Levodopa-induced dyskinesia (LID) is experienced by most patients of Parkinson’s disease (PD) upon the long-term use of the dopamine precursor levodopa. Dopaminergic signaling plays a critical role in the pathogenesis of LID through its interactions with dopamine receptors in striatum. The specific roles of striatal D5 receptor in the pathophysiological process of LID is still poorly established. In the study, we used PD rats with or without dyskinetic symptoms after chronic levodopa administration. The results showed that the expression level of D5 receptors in the sensorimotor striatum of dyskinetic rats are significantly higher than that of

the non-dyskinetic controls. The administration of levodopa increased c-Fos expression in a subpopulation of sensorimotor striatum neurons of dyskinetic rats, but not in non-dyskinetic rats. The majority of the c-Fos+ neurons activated by levodopa in striatum are positive for D5 receptor staining. Intrastriatal injection of D1-like (D1 and D5) dopamine receptor antagonist, R(+)-SCH-23390, significantly inhibited dyskinetic behavior and c-Fos expression in striatal D5 receptor positive neurons in dyskinetic rats after the injection of levodopa. Intrastriatal perfusion of small interfering RNA directed against DRD5 downregulated D5 receptors expression and moderately inhibited dyskinetic behavior of dyskinetic animals. The results suggested that striatal dopamine D5 receptor might play a novel role in the pathophysiology of LID.

Title: Perturbations of the dopaminergic pathway in the olfactory bulb may contribute to prodromal Parkinson's disease-related hyposmia

Authors: *L. C. BEAUCHAMP[1], L. J. VELLA[2], A. I. BUSH[2], K. J. BARNHAM[2];
[1]The Dept. of Pharmacol. and Therapeut., The Univ. of Melbourne, Parkville, Australia; [2]The Florey Inst. of Neurosci. and Mental Hlth., Parkville, Australia

Abstract: Parkinson's disease (PD) is a neurodegenerative disorder that is aligned with an extensive prodromal phase defined by the presence of an array of non-motor symptoms, including hyposmia. Disruptions in hyposmia are a well characterised feature of PD. Understanding the biological basis for this symptom should assist in the creation of early diagnostic criteria and potentially inform future therapeutic trials.
The protein tau has been identified as a genetic risk factor in the development of sporadic PD. The tau knockout (KO) mouse has been reported as an age-dependent model of PD and we have shown previously that these animals display *pre-motor* hyposmia, making them a model of interest for investigations of prodromal disease. We examined the tissue of these animals, including the olfactory bulb, to elucidate hyposmia-related changes and compare these to post-mortem tissue from PD patients.
One of the major findings from this study was a significant increase in the level of tyrosine hydroxylase (TH) in the olfactory bulb of 7-month-old tau KO mice (n=6) compared to wildtype (WT) littermate controls (n=6). TH is the rate limiting enzyme in dopamine synthesis and this increase was recapitulated in the human PD olfactory bulb tissue, suggesting that modulation of the dopamine pathway may related to PD hyposmia. Initially we examined if modulating

dopamine levels had a functional effect on olfaction in healthy animals by dosing 7-month-old WT mice with either vehicle (n=10), 20 mg/kg cocaine (dopamine agonist) (n=9), or 0.33 mg/kg haloperidol (dopamine receptor antagonist) (n=10) and measured olfaction using the odour detection test (ODT). WT mice treated with either cocaine or haloperidol demonstrated significant hyposmia on the ODT, whereas vehicle treated animals had preserved olfaction. Given the increase of TH in both the tau KO mice and human tissue, it was hypothesised that an increase in the level of TH was reflective of dopaminergic changes that are underlying PD-related hyposmia. As such, 7-month-old tau KO animals underwent the same drug trial. Tau KO mice dosed with vehicle (n=10) or 20 mg/kg cocaine (n=10) had no change in the presentation of their hyposmia. Tau KO animals treated with 0.33 mg/kg haloperidol (n=11) had significantly restored olfaction.
These data suggest that the olfactory system is sensitive to perturbations of dopamine metabolism and antagonism of dopaminergic receptors in tau KO mice rescues the pre-motor hyposmic phenotype. The refelective increase of TH in human PD post-mortem olfactory bulb suggests that hyposmia in PD may be a dopamine-mediated phenomenon.

Abstract: Parkinson’s disease (PD) is a neurodegenerative movement disorder characterized primarily by motor impairment that results from nigrostriatal dopamine cell loss. However, several non-motor symptoms associated with PD severely impact patients’ and caregivers’ quality of life yet remain understudied and/or poorly treated. Prominent among these symptoms is psychosis, which affects the majority of patients within 20 years of diagnosis. Unfortunately, clinical evidence suggests that L-DOPA, the gold standard for treatment of PD may increase risk of psychosis, particularly hallucinations. Thus, this study investigated the effects of L-DOPA in rat PD model on prepulse inhibition (PPI), a measure of sensorimotor gating often disrupted in neuropsychiatric disorders and preclinical models of psychosis. To test this, we rendered rats

hemi-parkinsonian with a 6-OHDA lesion to the left medial forebrain bundle. These rats were split into two groups: half received a single injection of either L-DOPA (6 mg/kg) or vehicle 20 minutes prior to PPI testing, and half underwent a 14 day regimen of daily L-DOPA injections and received either L-DOPA or vehicle 20 minutes prior to PPI testing. The results revealed that although DA lesion alone was not sufficient to alter PPI, chronic administration of L-DOPA and on treatment day significantly decreased PPI. Interestingly, this same group of rats also developed moderate to severe L-DOPA-induced dyskinesia during repeated L-DOPA treatment. This suggests that the DA loss and chronic L-DOPA treatment together exacerbate dysfunction in sensorimotor gating neurocircuitry that elevates risk for psychosis and also implicate treatment strategies for complications.

Title: Pharmacological blockade of monoacylglycerol lipase reduces L-DOPA-induced dyskinesia in MPTP-lesioned macaques

Authors: *J. R. CLAPPER[1], T. H. JOHNSTON[2], J. M. BROTCHIE[2], S. H. FOX[3], J. L. BLANKMAN[1], A. VIADER[1], A. B. EZEKOWITZ[1], G. P. O'NEILL[1], C. R. BEALS[1]; [1]Abide Therapeut., San Diego, CA; [2]Atuka Inc., Toronto, ON, Canada; [3]Univ. of Toronto, Toronto, ON, Canada

Abstract: In patients with Parkinson’s disease, long-term dopamine-replacement therapy with L-DOPA invariably leads to the development of disabling involuntary movements, L-DOPA-induced dyskinesia (LID). LID can be as troublesome as the underlying disease itself and can take the form of dance-like movements, chorea, or sustained, abnormal postures, dystonia. Although, the precise mechanisms that contribute to the expression of LID are not fully understood, dysregulation of dopaminergic and nondopaminergic neurotransmitter systems in the basal ganglia have been implicated. The endocannabinoid system (ECS) mediates multiple forms of synaptic plasticity in the basal ganglia. In LID, disruption of endocannabinoid plasticity in the striatum leads to overactive cortico-striatal glutamate signaling and may contribute to the motor fluctuations associated with this disease. We propose that enhancing levels of the principal endocannabinoid, 2-arachidonoylglycerol (2-AG), in the brain through inhibition of its enzymatic hydrolysis by monoacylglycerol lipase (MGLL) would normalize dysregulated cortico-striatal neurotransmission and improve symptoms of LID. To test our hypothesis, we

evaluated the potential of the selective MGLL inhibitor, ABD-1970, to reduce established LID in MPTP-lesioned macaques. Following oral administration, ABD-1970 produced a significant reduction in peak LID (including both dystonia and chorea) with LID typically being reduced from disabling to absent or non-disabling levels. The reduction of LID by ABD-1970 (up to 45%), was greater than the clinically used reference treatment, amantadine (29%). Importantly, ABD-1970 was not associated with a decrease in the anti-parkinsonian benefit of L-DOPA or the total duration or quality of associated on-time. The study demonstrates, in a well-validated non-human primate model, the potential of MGLL as a therapeutic target for LID.

Title: Impulse control disorder and sub-second dopamine fluctuations during risky decision-making in Parkinson’s disease

Authors: *B. LIEBENOW[1], E. ALADNANI[4], R. MORAN[5], J. WHITE[4], T. LOHRENZ[4], A. W. LAXTON[2], S. B. TATTER[2], P. MONTAGUE[4], K. T. KISHIDA[3];

Abstract: Impulse Control Disorder (ICD) secondary to Parkinson's disease (PD) treatment is a devastating non-motor morbidity and possible side-effect of effective motor symptom treatment. Dopamine agonist therapy is the most common culprit for medication-induced ICD. Understanding ICD propensity and development represents an unmet need in the increasingly recognized demand for greater treatment of non-motor morbidity in PD. PD patients with (n = 3) and without (n = 3) ICD secondary to dopamine agonist therapy performed a gambling task incentivized by monetary rewards while we monitored dopamine release using human voltammetry (i.e., elastic net electrochemistry). We assess the hypothesis that ICD positive individuals have a higher propensity to gamble corresponding to differences in sub-second dopamine fluctuations during risky decision-making. Both groups used a video game interface to manage their investments and receive feedback on their results real-time. Data analyses comprised of a fixed effect analysis to measure the differences in investment behavior between patients with and without ICD. First, we show that the distribution of all investment levels in ICD positive participants shows a rightward skew towards investments of greater monetary value versus a more uniform distribution across all bet sizes in the ICD negative participants. Indeed, on average ICD positive participants invested at a significantly higher level (risked more) than ICD negative participants (p-value = 3.8133e-11). ICD positive participants also expressed a lower magnitude change in bet when increasing (p = 6.4979e-05) or decreasing (p-value = 4.5731e-06) investment levels compared to ICD negative participants. This suggests that ICD positive individuals enter the market with bets of high monetary value and maintain these high bets in the face of losses, a characteristic pattern that contrasts ICD negative individuals who may consider investment gains and losses when selecting their bet sizes. Future directions include analyzing human voltammetry data collected during the task to assess the role of dopamine in these decisions, and to increase sample size to make results more widely applicable to the PD population.

Title: The endocannabinoid system in Parkinson's disease

Authors: *G. FLIK[1], M. HEINS[1], P. VOEHRINGER[2], B. FERGER[3];
[1]Charles River Labs., Groningen, Netherlands; [3]CardioMetabolic Dis. Res., [2]Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, Germany

Abstract: The endocannabinoid system is an important modulator of a number of physiological processes. Endocannabinoids and cannabinoid receptor signaling have been linked to inhibition of excitatory transmission via cannabinoid receptor 1 (CB1) and modulation of immune responses via cannabinoid receptor 2 (CB2) and might therefore be promising targets in neurodegeneration and neuroinflammation. Changes in this system have been seen in several disease states including Parkinson's disease. The endocannabinoid (eCB) system and the monoaminergic system interact specifically within the basal ganglia. Here, CB1 receptors co-localize with dopamine D1/D2 receptors in dopamine projecting areas. Acute blockade of CB1 receptor potentiates the activating role of dopamine D2 receptor agonists on locomotor activity. While CB1 stimulation results in sensitization of the motor effects of indirect dopaminergic agonists. Moreover, pre-clinical research suggests that modulation of eCB signaling could improve motor symptoms. The CB2 receptor has been reported to be upregulated in neurodegenerative and neuroinflammatory diseases. An upregulation of CB2 receptors implicates activation of microglia, which can produce a variety of cytokines. Using microdialysis, it is possible to determine the effect of different modulators of the eCB system on the monoaminergic system, the immune system and also on the eCB system itself. Levels of the eCB's: anandamide (AEA), 2-arachidonoylglycerol (2-AG) are difficult to determine due to the lipophilic properties of these fatty acids. We have optimized both the eCB sampling technique to allow for microdialysis and the analytical method. Optimization of the analytical method allows us to combine high sensitivity and low LLOQ with good specificity (separation of 2-AG and its isomer 1-AG). Using a dual probe approach it is even possible to simultaneously evaluate neuroinflammation by analysing these microdialysate samples for a variety of cytokines. We use the above described method to demonstrate effects of a highly selective FAAH and a MAGL inhibitor on levels of AEA, 2-AG and 1-AG in microdialysate from the nucleus accumbens of freely moving rats. These data show that our optimized experimental design and sensitive bio-analytical methods allows better examination of the effects of potential new medication on the interaction between different neurotransmitter systems, the immune system and the endocannabinoid system.

Title: Effects of 6-hydroxydopamine lesions of the substantia nigra, the dorsal striatum, the medial accumbens and the lateral accumbens on free-choice high-fat high-sugar diet component preference

Authors: *A. JOSHI[1,2,3], F. FAIVRE[1], T. KOOL[2,3], L. L. KOEKKOEK[2,3], C. DIEPENBROEK[2], J. D. MUL[2], I. YALCIN[1], S. E. LA FLEUR[2,3], M. BARROT[1];

Amsterdam, Univ. of Amsterdam, Amsterdam, Netherlands; [3]Metabolism and Reward, Netherlands Inst. of Neuroscience, Royal Netherlands Acad. of Sci. (KNAW), Amsterdam, Netherlands

Abstract: Dopamine (DA) signaling regulates feeding-related behavior. Conversely, caloric intake, especially of palatable dietary items, can modulate DA-related brain circuitries. For example, it has been observed that increased intake of dietary fat results in blunted DA signaling, and, to compensate for this lowered DA function, caloric intake may subsequently increase. To determine how DA signaling regulates food preference, we utilized 6-hydroxydopamine (6-OHDA)-mediated lesioning to deplete DA-related signaling in specific brain regions of male Sprague Dawley rats. Food preference was assessed by providing the rats with free-choice access to control diet (CD), fat, tap water, and 30% sucrose solution. Rats with lesions of the substantia nigra pars compacta (SNc; which also offers a model of Parkinson's disease) consumed less calories ($P< 0.05$), as reflected by a decrease in CD intake ($P< 0.05$), but displayed an increase in fat intake ($P< 0.05$), without change in sucrose solution intake compared to non-lesioned controls. To determine which of the SN projection areas contributed to these effects, we next compared 6-OHDA lesions targeted to DA neuron terminals in the dorsal striatum, the medial nucleus accumbens (NAc) or the lateral NAc. We observed that 6-OHDA lesioning of the lateral NAc, but not the dorsal striatum or medial NAc, led to increased fat intake ($P< 0.05$). These

findings indicate a role for DA signaling in the lateral NAc in regulating food preference, in particularly the intake of fat. Title: PET imaging studies of PDE10A in a nonhuman primate model of Parkinson disease

Authors: H. LIU[1], Z. LUO[1], J. GU[1], Y. YU[1], H. WHITE[1], H. FLORES[1], Y. ZHOU[1], V. CARROLL[2], G. D. TAMAGNAN[3], J. S. PERLMUTTER[1], ***Z. TU**[1];

Abstract: Objectives Phosphodiesterase 10A (PDE10A) is located almost exclusively in striatal medium spiny neurons and hydrolyzes cAMP and cGMP. PDE10A levels reflect post-synaptic activity of the nigrostriatal dopaminergic (DA) pathway. Thus, PET radioligands for PDE10A have potential to investigate pathophysiology, disease progression or drug effects for diseases with striatal pathologies such as Parkinson disease (PD). Since the change of pre-synaptic biomarkers of DA pathway do not fully reflect the severity of motor parkinsonism and the loss of nigral DA cell bodies, PDE10A could potentially serve as a key biomarker to assess PD severity. Herein we reported our initial evaluation of two PDE10A PET radioligands (^{11}C-TZ1964B and ^{18}F-MNI659), along with dopaminergic D1 and D2 receptor radioligands (^{11}C-NNC and ^{11}C-NMB), in an MPTP-induced PD model in nonhuman primates (NHPs). **Methods** Six male adult

macaques underwent a series of 2-hour dynamic PET scans (59 scans in total) before and after unilateral internal carotid MPTP (0.25 mg/kg). Post-MPTP scans were done at week 14-16 to detect nigrostriatal injury and changes in DA pathway including PDE10A. A simplified reference tissue model was used to analyze PET data and generate binding potential (BP) values, with cerebellum as the reference. **Results** Test-retest variability analysis of baseline scans of ^{11}C-TZ1964B, ^{18}F-MNI659, ^{11}C-NNC and ^{11}C-NMB revealed good reproducibility. Right-to-left ratio of striatum BP values for each tracer is approximately 1. The tracer uptake is 7-15 % higher in caudate than putamen for these 4 tracers. Ipsilateral nigrostriatal injury was confirmed by a 77% reduction in ipsilateral striatal ^{11}C-DTBZ PET at week 14 post-MPTP. The tracer uptake of PDE10A radioligands in right striatum (ipsilateral side) was 96% (^{11}C-TZ1964B) and 82% (^{18}F-MNI659) of baseline levels, while the uptake of ^{11}C-NNC and ^{11}C-NMB dropped more dramatically to 61% and 59% of baseline levels. The contralateral side (left striatum) showed no change of PDE10A level, but modest decline of D1 and D2 tracer uptake (72% and 70% relative to baseline, respectively). **Conclusion** The four radioligands, targeting PDE10A, D1 and D2 receptors respectively, showed small test-retest variability and responded differently to MPTP treatment. The change of PDE10A PET measures is more modest than that of D1 and D2 PET, demonstrating indirect regulation of PDE10A levels via DA pathway. Larger sample size and statistical analysis are warranted to explore the relationship between striatal tracer uptake of each tracer with motor behavior and *in vitro* measure of nigrostriatal and striatal neurons.

Title: L-tryptophan is a biomarker for Parkinson's disease

Authors: *P. A. BRODERICK, J. R. HORDOF, M. CABRERA;
Mol. Cell. and Biomed. Sci., The City Univ. of New York Sch. of Med., New York, NY

Abstract: Globally, the catecholamine neurotransmitter dopamine is well known as a biomarker for Parkinson's (PD) disease. But, we have found that the indoleamine, serotonin (5-HT) may well be a more sensitive biomarker for Parkinson's than dopamine. Here, we show that L-Tryptophan (L-TP) is indeed a unique biomarker for PD as well! Thus, we set about to study the effects of L-3,4-dihydroxyphenylalanine (L-DOPA), the main stay treatment for PD, with Neuromolecular Imaging, (NMI) and BRODERICK PROBE® nanobiosensors. This nanobiotechnology for the first time demonstrates the ability to observe in real-time the release and quantification of neurochemicals in pursuit of unknown biomarkers in neurodegenerative disease to find a more suitable treatment with less adverse effects. Moreover, these nanobiosensors live streams directly online and originates from precise neuroanatomic brain sites such as, in this case, the dorsal striatum in basal ganglia. Thus, the nanobiotechnology herein imaged neuromolecules with and wihout (L-DOPA) in dorsal striatal basal ganglia neurons. PD and non-PD animals were videotracked, and images were readily seen on a laptop via a potentiostat using a semiderivative electrical circuit. Administered L-DOPA doses were 50 and 100 mg/kg intraperitoneally (ip); the same experimental paradigm was used to image and then contrast data. Results show that the baseline release of biogenic amine molecules was significantly above detection limits in non-PD animals and after administration of L-DOPA, biogenic amines increased significantly in these same animals. Nevertheless, it is intriguing to see that L-DOPA could not enable synaptic DA release in PD animals, thus confirming biogenic amines as biomarkers for PD. Importantly, there were other significant biomarkers present in PD animals and absent in non-PD animals in the brain; peptide neurotransmitters including dynorphin and somatostatin, which also increased following L-DOPA. However, to treat the PD brain, it is the L-TP biomarker that must first be metabolized by Indoleamine 2,3-dioxygenase I,II (IDO) in the Kynurenine pathway (KP). It has been shown that through KP in the brain, 5% of L-TP remains with potential for synthesis of 5-HT. This is a good starting point for novel drug administration to increase 5-HT release without hindrance of the blood-brain barrier. Alternatively, medications that increase5-HT release *a priori*, gives us an effective way to treat PD (Piercey, MF, Svensson, KA, Lin, CH, Haadsman-Svensson, SR, McCall, RB, Smith, MW, Broderick, PA & Carlsson, A, SFN,1993).(Tribute to Arvid, in memoriam).

Title: Extra-striatal dopamine in Parkinson's disease with rapid eye movement sleep behaviour disorder

Authors: *M. VALLI, S. CHO, J. KIM, M. DIEZ-CIRARDA, A. MIHAESCU, A. STRAFELLA;
Res. Imaging Ctr., Ctr. for Addiction and Mental Hlth., Toronto, ON, Canada

Abstract: Rapid eye movement sleep behaviour disorder (RBD) is a common condition found in 50% of Parkinson's disease (PD) patients. Molecular imaging evidence shows that PD with RBD (PD-RBD+) has a distinct striatal dopamine phenotype compared to PD without RBD (PD-RBD-) where PD-RBD+ show lower dopamine transporter activity within the caudate and putamen. However, the characterization of the extra-striatal dopamine within the mesocortical and mesolimbic pathways remains unknown. Therefore, we aim to elucidate this with PET imaging in PD patients with and without RBD, while having healthy older adults as controls (HC). A total of 45 participants were enrolled in the imaging study: 15 were PD-RBD+ (mean age = 68.1 ± 6.48 years), 15 were PD-RBD- (70.7 ± 5.67 years) and 15 were HC (67.1 ± 5.14 years). Each participant underwent a single PET scan with [^{11}C]FLB 457 to detect the D2 receptors within the extra-striatal regions of interest (ROI), including the prefrontal and temporal areas. They also underwent a single MRI scan to rule out structural lesions and to provide anatomical reference for the parametric PET image analysis. [^{11}C]FLB 457 retention was expressed as the non-displaceable binding potential (BP_{ND}) using the simplified reference tissue model 2 with the cerebellum as a reference region. Analysis of variance was used to compare the BP_{ND} between the three groups for each ROI. Post hoc independent sample *t* tests were used to test for differences between conditions and were corrected for multiple comparisons using false discovery rate. The main effect of group condition on [^{11}C]FLB 457 binding was tested and revealed significant effect within the superior temporal region on the right [$F(2, 42)=3.98$, $p=0.026$] and left [$F(2, 42)=4.29$, $p=0.02$] hemisphere; and left uncus para-hippocampus [$F(2, 42)=4.43$, $p=0.018$]. Specifically, we found that PD-RBD- binding was lower than HC in the superior temporal region in both right ($p=0.039$) and left ($p=0.021$) hemispheres. However, the PD-RBD+ binding was found to be lower relative to HC ($p=0.045$) on the right side only, and slightly higher than PD-RBD-, but this did not reach significance. For the left uncus para-hippocampus, both PD-RBD+ ($p=0.027$) and PD-RBD- ($p=0.027$) binding was lower than HC, but PD-RBD+ was slightly higher than PD-RBD-, which did not reach significance. Our results implicate that relative to HC, PD-RBD+ has lower levels of D2 receptor availability within the left uncus para-hippocampus, a region involved in the limbic system, which influences sleep; and the right superior temporal region. Results imply that extra-striatal dopaminergic system may play a role in contributing to the RBD in PD patients.

Title: CRISPR Cas9 mouse model to study glutamate co-transmission by sertonin neurons of the dorsal raphe nucleus

Authors: *L. SAIDI, M. PARENT, C. PROULX;
CERVO, Québec, QC, Canada

Abstract: Ascending serotonin (5-hydroxytryptamine, 5-HT) projections arise mainly from the dorsal raphe nucleus (DRN). The vast majority of 5-HT DRN neurons express the atypical type III vesicular glutamate transporter (VGluT3), allowing co-release of glutamate and 5-HT by their axons terminals. The aim of this study is to generate and characterize a new mouse model to determine the role of glutamate co-transmission by 5-HT neurons of the DRN. To do so, we used CRISPR/Cas9 technology, allowing region and neuron-specific conditional knock-out, in adult mice. To knock-out the expression of VGluT3 specifically in 5-HT neurons of the DRN, an AAV encoding a guide RNA for the *vglut3* gene was injected in the DRN of transgenic ePet-cre+/Cas9flox+ mice. RT-qPCR assay, RNAscope and immunohistochemistry confirm the depletion of VGluT3 in AAV-infected 5-HT neurons. Moreover, high-resolution confocal analysis reveals a decrease in the number of axon varicosities in VGluT3-depleted 5-HT neurons. In open-field behavioral test, VGlut3-depleted mice tend to show an increase in spontaneous motor activity as well as to remain at the periphery rather than the center of the arena. The shredding nestlet test also supports a high level of anxiety in our model. Moreover, VGluT3-depleted mice have a lack of interest for sweetened liquid reward. Using this model, we were able to highlight the involvement of VGluT3 in the regulation of anxious and spontaneous motor behaviors as well as in behaviors involving the reward system. In addition, our preliminary results suggest the involvement of VGluT3 in the maintenance of 5-HT axon morphology.

Abstract: Introduction: Deep brain stimulation (DBS) is a standard of care for patients with advanced Parkinson's disease. More than 30 years since its introduction in its current form, the mechanism of action of DBS remains elusive. It is well known that patients who respond favorably to levodopa also respond favorably to DBS. Also, it has been observed that the therapeutic benefits of DBS are maximal in the off phase of medication when the drug concentration falls below a therapeutic level. Therefore, we hypothesize that DBS in Parkinson's disease may act via modulation of striatal tonic dopamine concentration. Recently, we developed multiple cyclic square wave voltammetry (MCSWV) technique for measuring tonic levels of dopamine. In this study, we investigated how the tonic dopamine levels were modulated during subthalamic nucleus electrical stimulation using MCSWV for elucidating our hypothesis. **Method:** Normal male, Sprague Dawley rats weighing between 250-315 grams were anesthetized with urethane (1.5 g/kg i.p.) and administered buprenorphine (0.1 mg/kg s.c.) for pain control. Concentric bipolar stimulation electrodes were placed in the subthalamic nucleus (STN; ML:+2.5, AP:-3.8, DV:-7.6 in mm), a common DBS target for Parkinson's disease. Carbon fiber microelectrodes were placed in the dorsal striatum (ML:+2, AP:+1.2, DV:-3.5 to -4.5 in mm) for recording dopamine concentration. MCSWV was used to measure stimulation-evoked tonic level changes in dopamine. Fast-scan cyclic voltammetry was used to measure stimulation-evoked phasic changes in dopamine concentrations. Pharmacological confirmation of the dopamine responses was performed with nomifensine (20 mg/kg i.p.), a dopamine reuptake inhibitor. **Results:** STN electrical stimulation (0.4 mA, 90 Hz, 2 ms biphasic pulse width) for 2 sec resulted in stimulation time-locked phasic increase in oxidation current at 0.6 V. Tonic dopamine levels, recorded over a period of 3-4 hours, increased in response to 5 min of

STN stimulation with therapeutic DBS parameters. Increase in the tonic dopamine signal post nomifensine injection confirmed that the electroactive species being measured was dopamine. **Discussion:** These results demonstrate that modulation of tonic dopamine levels could be a possible mechanism of therapeutic effect of STN DBS in Parkinson's disease. Tonic dopamine levels measured using MCSWV may be used for a feedback biomarker in development of closed-loop DBS system. This would be anticipated to optimize symptom control in Parkinson's disease subjects, and prolong battery life. Also, MCSWV could potentially be used for elucidation of mechanism of action of DBS in other diseases.

Title: Electrophysiological and neurochemical considerations of distinct neuronal populationsin the rat pedunculopontine nucleus and their responsiveness following 6-hydroxydopamine lesions

Authors: *X. WANG, M. LI, D. CHEN, M. WANG;
Shandong Normal Univ., Jinan, China

Abstract: Pedunculopontine nucleus (PPN) is composed of a morphologically and neurochemically heterogeneous population of neurons, which is severely affected by Parkinson's disease (PD). However, the role of each subtype neuron within the PPN in the pathophysiology of PD has not been fully elucidated. In this paper, we present the discharge profiles of three classified subtypes of PPN neurons and their alterations treated by 6-hydroxydopamine (6-OHDA) lesion. Following 6-OHDA lesion, spike timing of Type III neuron (glutamatergic) had a tight coordination with the oscillations in the 12-30 Hz frequency range in PPN. We also provide a morphological evidence showing either loss of neurons or altered somatic cell size occurred on the glutamatergic neurons in PD cases. These findings showed electrophysiological detection methods combined with immunohistochemistry have revealed that Parkinsonian variation in distinct firing characteristics has a close relationship with the neuronal morphology, which would make contributions to the divergence dysfunctions in Parkinsonism.

Title: Glutamatergic neurons in the subthalamic nucleus regulate mechanical and thermal pain thresholds in Parkinsonian mice

Authors: *C. ZHOU, Y. LUAN, D. TANG, H. WU, W. GU, C. XIAO;
Xuzhou Med. Univ., Xuzhou City, China

Abstract: In PD patients, pain is a prevalent non-motor symptom. Poor understanding of its underlying mechanisms posits difficulty in optimizing its therapy. Deep brain stimulation (DBS) in the subthalamic nucleus (STN) of PD patients has been reported to relieve motor deficits, and pain symptoms, as well, suggesting that the STN could be a promising therapeutic target for PD pain. Parkinsonian mouse models were established with unilateral injection of 6-OHDA in the medial forebrain bundle to lesion DA neurons (by 60% in two weeks) in the substantia nigra pars compacta (SNc), and exhibited hypoactivity in the open field arena and apomorphine-induced contralateral rotations. From 7 days after 6-OHDA lesion, the mouse models displayed reduced mechanical and thermal pain thresholds in both hind paws. Meanwhile, the STN neurons on the lesion side fired twice as fast as those on the non-lesion side, and optogenetic inhibition of hyperactive STN glutamatergic neurons on the lesion side significantly elevated pain threshold. Direct stimulation of both STN glutamatergic neurons and their axonal projections to the substantia nigra pars reticulata (SNr) and internal segment of the globus pallidus (GPi) / ventral pallidum (VP) sufficiently reduced thermal and mechanical pain thresholds in healthy mice. Furthermore, selective inhibition of STN projections to the SNr and GPi/VP with optogenetics differentially increased mechanical and thermal pain thresholds in PD. Our c-fos staining data show that in control mice, optogenetic stimulation of STN glutamatergic neurons caused

hyperactivity in multiple nuclei implicated in pain perception and modulation, while in PD mice, optogenetic inhibition of the STN neurons reversed hyperactivity in ascending pain pathway, in contrast, enhanced neuronal activity in descending pain pathway. Our results support that STN glutamatergic neurons are projection-specifically implicated in pain hypersensitivity in PD models via regulating ascending and descending pain pathways, and can be a therapeutic target for pain symptoms in PD.

Title: Changes in beta oscillatory activity within and across the basal ganglia-thalamocortical network in a progressive MPTP non-human primate model of Parkinson's disease

Authors: *Z. T. BUSBY[1], Y. YU[1], J. ZHANG[1], W. C. FRYLING[2], D. ESCOBAR SANABRIA[1], M. D. JOHNSON[3], L. A. JOHNSON[1], J. L. VITEK[1];

Abstract: Alterations in beta band oscillatory activity and synchronization in the basal ganglia-thalamocortical (BGTC) network have been linked to the development motor signs in Parkinson's disease (PD). Although these changes are thought to occur throughout the BGTC network, most previous studies have only examined individual nodes in the circuit. Our understanding of how the progression of PD motor signs is associated with changes in oscillatory activity across multiple nodes in the BGTC network simultaneously is limited. We addressed these issues in this study by examining low and high beta band activity in local field potentials (LFP) recorded simultaneously across cortical and subcortical areas in a progressive non-human primate (NHP) model of PD.LFP activity was recorded with a 96 channel Utah array in primary motor cortex (M1) and two DBS leads targeting the subthalamic nucleus (STN) and globus pallidus internus (GPi). After normal state recordings, the animal was given intramuscular injections of MPTP weekly or biweekly. Following each injection, the severity of parkinsonism was evaluated using a modified clinical rating scale (mUPDRS) and spontaneous resting state LFPs were obtained. Beta band power within each site and coherence across sites were

calculated in the low (10-20 Hz) and high beta band (21-35Hz). Within several days after the second injection and the emergence of parkinsonian motor signs we observed an increase in low beta band activity in the STN and GPi but a decrease in M1. In the STN and GPi low beta power continued to increase coincident with increasing severity of PD. High beta band activity also changed in the parkinsonian condition, increasing early in M1 but only in more severe stages in STN and GPi. We observed an increase in coherence across M1-GP and STN-GP, but not in M1-STN. These changes occurred early in the low beta band although less consistently in the the high beta band.These results suggest that alterations in beta band activity occur early in the parkinsonian condition across both subcortical and cortical structures, and include both low and high beta bands. The differences between changes in low and high beta band as motor signs progressed suggests the possibility of distinct roles for low and high beta power changes in the development of parkinsonism. The significant correlation of low but not high beta band activity to the severity of parkinsonism, and the stronger and more consistent relationship between changes in the STN and GPi and motor signs would suggest that low beta band activity in these sites might be a better signal for biomarker-based stimulation strategies (e.g. closed-loop DBS).

Title: Oscillatory activity in the pallidum is subject and location specific in Parkinson’s disease

Authors: *L. A. JOHNSON[1], J. E. AMAN[1], D. ESCOBAR SANABRIA[1], J. WANG[1], R. PATRIAT[2], M. E. HILL[1], S. E. COOPER[1], L. E. SCHROCK[1], N. HAREL[2], M. C. PARK[3], J. L. VITEK[1];

Abstract: Background: Local field potential (LFP) recordings from recently introduced directional deep brain stimulation (dDBS) leads may provide insights into the pathophysiology of Parkinson’s disease (PD) and be a useful tool to inform programming strategies that optimize

clinical benefit. There is little data, however, regarding LFP activity in the globus pallidus internus (GPi), a target increasingly used for DBS in PD. The goal of this study was to utilize dDBS leads to characterize the spectral characteristics and spatial topography of LFP activity in the GPi in patients with PD.

Methods: Data were collected from externalized dDBS leads of three patients with idiopathic PD after overnight withdrawal of parkinsonian medication. Bipolar LFPs were created by subtracting recordings from vertically adjacent contacts, and spectral analysis was performed using customized scripts in MATLAB. Oscillatory activity across lead segments was examined in the context of lead locations and segment orientations determined using co-registered preoperative 7-T MRI and postoperative CT scans, as well as clinical DBS settings chosen in subsequent patient programming visits.

Results: We found that each of the three patients had a unique topography of oscillatory activity in the pallidum, with prominent peaks in the 5-35Hz range occurring at different frequencies and spatial locations. Despite subject-specific spectral profiles, a consistent finding across patients was that oscillatory power was strongest in LFPs recorded from segments facing the posterior-lateral "sensorimotor" region of GPi, whereas medial segmented contacts facing the internal capsule had the weakest LFP activity. Interestingly, the clinically chosen contact configurations for optimizing benefits in the three subjects aligned with the contact pairs showing the largest amplitude of LFP oscillations relative to the other contacts within the same lead.

Conclusions: These data support the hypothesis that optimal improvement in motor signs is location specific and localized to the sensorimotor territory of the GPi and corresponds to the site of maximal power in LFP activity within frequency spectrums that is patient specific. These data also provide compelling evidence for the use LFP activity obtained perioperatively for the development of local predictive stimulation models that may optimize patient benefits while reducing clinic time needed for programming.

Title: Intermittent delivery of coordinated reset deep brain stimulation is more effective than continuous delivery

Authors: *S. P. FERGUS[1], K. M. SWITALLA[1], J. ZHANG[1], L. A. JOHNSON[1], M. D. JOHNSON[2], J. WANG[1], J. L. VITEK[1];

Abstract: Parkinson's disease (PD) has been closely linked to abnormal neuronal synchrony in the basal ganglia-thalamocortical network. A novel deep brain stimulation (DBS) technique, termed coordinated reset (CR), was developed to disrupt this pathological synchrony. CR DBS randomly delivers low intensity bursts across multiple contacts of the DBS lead. Modeling studies have shown that intermittent CR might be more effective at inducing carryover benefits than continuous delivery of CR DBS. In this study, we tested this hypothesis by comparing the effect of CR DBS delivered continuously and intermittently. A within-subject experiment design in a nonhuman primate (NHP) model of PD was used to evaluate the relative effect of CR DBS delivered continuously versus intermittently. The NHP was made parkinsonian using the neurotoxin MPTP (1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine) and implanted with an 8-contact DBS lead in the subthalamic nucleus. With the same total amount, i.e. 48 hours, of stimulation, continuous CR was delivered for two days while intermittent CR was delivered over four days with a 2-hour ON: 2-hour OFF cycle. Motor assessments including a clinical rating scale modified for NHPs (mUPDRS) and a reach task were performed daily on treatment days and for six days after treatment. We observed that intermittent CR produced greater acute and carryover motor benefit than continuous CR. The percent improvement in mUPDRS scores during intermittent CR (23.5%) was significantly higher than during continuous CR (14.1%). Therapeutic effects of intermittent CR persisted after stimulation cessation, with up to 20.7% mUPDRS improvement through the fourth day after treatment, while continuous CR did not induce any carryover improvement. Intermittent CR also produced greater acute and subacute improvement in movement velocity. These findings support our hypothesis that CR DBS

delivered intermittently will be more effective in alleviating PD motor signs with a longer carryover effect. Although additional studies in more subjects will be needed for further validation of this finding, these data provide the rationale for further innovation in how we can modify DBS approaches to optimize its benefit for patients with PD.

Title: Task-related modulations of beta oscillatory activity in the basal ganglia and motor cortex are altered in Parkinsonism

Authors: *Y. YU[1], D. H. ROSS[1], S. NEBECK[1], J. ZHANG[1], M. D. JOHNSON[2], L. A. JOHNSON[1], J. L. VITEK[1];
[1]Dept. of Neurol., Univ. of Minnesota Dept. of Neurol., Minneapolis, MN; [2]Biomed. Engin., Univ. of Minnesota, Minneapolis, MN

Abstract: Beta band oscillatory activity in the basal ganglia-thalamocortical (BGTC) network is known to play an important role in motor control, and excessive beta activity has been suggested to be associated with the development of motor signs in Parkinson's disease (PD). The nature of how parkinsonism might disrupt the temporal dynamics of beta band oscillatory activity across the BGTC network during motor tasks, however, is not well understood. Using a within subject design, in this study we recorded local field potentials (LFPs) from basal ganglia and cortical sites simultaneously during a reaching task to investigate how the induction of parkinsonism alters movement-related modulations of beta oscillatory activity in the BGTC.One non-human primate (rhesus macaque) was trained to perform a food reach and retrieval task while LFP data was simultaneously collected from a microelectrode array in the primary motor cortex (M1) and macroelectrodes in the subthalamic nucleus (STN) and internal globus pallidus (GPi) in the normal, mild and moderate parkinsonian state. Parkinsonism was induced by sequential injections of MPTP. Perievent spectrograms were calculated to investigate the changes in low (10-20 Hz) and high (21-30 Hz) beta band LFP activity that occurred during the reaction and reaching time periods on a trial by trial basis relative to the pre-movement baseline period.

Increasing parkinsonian severity was associated with higher pre-movement baseline levels of low beta activity in the STN, GPi and M1, which was significantly reduced during movement. Similar changes were observed for high beta activity in the STN and M1 but not GPi. In the parkinsonian condition during the reaction time period (following cue presentation prior to movement) low beta was reduced across all three sites while high beta was increased in the STN and M1.These data support the hypothesis that the coordination of oscillatory activity across multiple power spectrums are required for normal movement and that the abnormal movement observed in parkinsonism likely results from a disruption in the temporal dynamics of this activity across nodal points in the BGTC circuit.

Title: Longitudinal analysis of local field potentials recorded from deep brain stimulation leads in the subthalamic nucleus

Authors: *A. BRINDA[1], A. M. DOYLE[2], J. D. KRIEG[1], J. ALISCH[1], L. K. WILMERDING[3], M. BLUMENFELD[1], J. DAO[1], M. D. JOHNSON[1];

Abstract: The electrode-tissue interface around a deep brain stimulation (DBS) lead is known to be highly dynamic and spatially heterogeneous following implantation, which may have implications on interpretation of recorded local field potentials (LFPs) and use of these signals in the context of closed-loop DBS therapies. Electrochemical impedance spectroscopy (EIS) is a useful tool for characterizing the formation of a fibrous tissue encapsulation layer around a DBS lead during the post-implant immune reaction. In this study, we longitudinally tracked the resting-state LFP spectral power beginning right after lead implant and ending two weeks post-implant. This time period captures the acute microvasculature disruption and immune reaction, consisting of vasogenic and cellular edema, leading to a chronic tissue response in which fibrous tissue encapsulation layers begin to stabilize. Two drug-naive, non-human primates (*macaca*-

mulatta, female) were each implanted with a directional DBS lead in the subthalamic nucleus. In parallel to LFP recordings, EIS was collected each day and analyzed using an equivalent circuit model to aid in characterizing the electrode-tissue interface dynamics. Significant increases in both electrode site impedances (1kHz and 20Hz) and LFP spectral power were observed for both animals in the period between putative vasogenic edema (low tissue impedances, days 1-2) and cellular edema (high tissue impedances, days 7-9) (paired, two-sided Wilcoxon signed-rank test, p=0.03, n=6 and n=12). In subject A, these changes in average impedance and spectral power are both confirmed to have occurred after days 2 and 8 by a change-point analysis (CPA). For subject B, the average impedances directly correlated with the average LFP spectral power over the 15 days after surgery (Pearson Correlation, p=1.1e-5 and p=3.7e-4, n=15). Interestingly, CPA reveals a major time point in equivalent circuit model parameters, but not in LFP spectral power, after day 2 in subject B. Both impedance and LFP data show a significant change after day 5, suggesting the cellular edema phase progressed at a faster rate than in subject A. These results suggest that LFP spectral power is relatively weak in the peri-implant stage as compared with the chronic, post-implant stage in which electrode site impedance has significantly increased. Not only do these results show dramatic changes in LFPs recorded post-implant, they additionally suggest that electrochemical impedance spectroscopy can be helpful in relating electrode-tissue interface dynamics to interpretation of LFPs.

Title: Dynamic changes in oscillatory activity in the pallidum during motor tasks in Parkinson's disease

Authors: *J. WANG[1], J. E. AMAN[1], D. ESCOBAR SANABRIA[1], L. A. JOHNSON[1], M. HILL[1], S. E. COOPER[1], L. E. SCHROCK[1], R. PATRIAT[2], N. HAREL[3], M. C. PARK[4], J. L. VITEK[1];
[1]Neurol., Univ. of Minnesota, Minneapolis, MN; [2]Radiology, Univ. of Minnesota, Woodbury, MN; [3]Radiology, [4]Neurosurg., Univ. of Minnesota, Minneapolis, MN

Abstract: Background: Parkinson's disease (PD) has been associated with exaggerated low frequency (~5-35 Hz) oscillatory activity in the subthalamic nucleus (STN). Relatively few studies, however, have examined local field potential (LFP) activity in the internal segment of the globus pallidus (GPi) in PD patients, particularly its relationship to movement and severity of PD motor signs. The goal of this study was to characterize the dynamic changes in LFP activity in the GPi during motor tasks in PD patients with externalized directional DBS leads. **Methods**: Three PD patients were implanted with DBS leads in the GPi. LFPs were recorded from the externalized DBS leads in the patients' off medication and off DBS state at rest, during a cued reach-to-target task, and during a passive movement task designed to measure rigidity of the forearm. Lead location and orientation were determined using pre-operative high resolution 7T MR images registered to post-operative CT scans. **Results**: During the active reaching task subject-specific modulations of both high (>20Hz) and low (<20Hz) beta band oscillatory activity were observed. High and low beta oscillatory activity desynchronized coherently during movement in one subject, while in a second low beta desynchronized during movement while high beta power was reduced between each reach and return movement. A third subject showed only low beta modulation. The passive motor task revealed modulation of beta oscillatory activity in specific frequency bands that was also subject specific. **Conclusions**: Our results show that GPi oscillatory activity in the 5-35 Hz range is modulated during movement, and is both patient, location and task specific. Optimization of closed loop DBS algorithms will likely need to address these variables in order to develop customized algorithms based on each patient's unique physiological profile.

Abstract: Deep brain stimulation (DBS) targeting the subthalamic nucleus (STN) can be an effective neurosurgical treatment for the motor signs of Parkinson's disease (PD). While parkinsonian tremor, rigidity, and bradykinesia are often readily straightforward to treat, STN-DBS typically has more mixed effects on parkinsonian gait. Given that levodopa therapy exhibits similar mixed effects, parkinsonian gait is thought to involve network dysfunction beyond the nigrostriatal dopaminergic pathway. The pedunculopontine nucleus (PPN) within the brainstem is known to be involved in gait, has connections to and from the basal ganglia, and has axons that course through and/or adjacent to the STN. In this study, we developed subject-specific computational models built from a combination of segmented 7T patient imaging data, patient lead localization, finite element models predicting DBS-induced extracellular tissue voltages and multi-compartment biophysical neuron models predicting the degree to which neuronal pathways are modulated by a given STN-DBS set of stimulation settings. The models consisted of nine pathways in and around the STN, including (1) a pallidofugal pathway that projected along the lenticular fasciculus and to motor thalamus and pedunculopontine nucleus, and (2) pedunculopontine efferents that coursed through the STN en route to the globus pallidus via the ansa lenticularis. The models showed activation (~40-80%) of the pedunculopontine pathway for most clinically-optimized STN-DBS settings across subjects (n=5 hemispheres). The activation of the pallidofugal pathway at these settings was robust for only 1/3 subjects, in which ~70% activation of the pallidofugal pathway was observed. The models also suggest that it is possible to design stimulation settings that can more selectively activate pathways in and around the STN. These results have important implications for better treatment of individual motor signs of Parkinson's disease.

Title: Investigating the role of the centromedian nucleus in gait

Authors: *A. M. DOYLE[1], J. D. KRIEG[2], L. K. WILMERDING[2], K. BRACKMAN[1], A. R. RUPPERT[1], A. JACOBSON[1], A. GRAY[1], D. BOUDANI[1], J. L. VITEK[3], M. D. JOHNSON[2]; [1]Neurosci., [2]Biomed. Engin., Univ. of Minnesota, Minneapolis, MN; [3]Dept. of Neurol., Univ. of Minnesota Dept. of Neurol., Minneapolis, MN

Abstract: Parkinson's disease has been characterized by degeneration in the centromedian-parafascicular nucleus (CM-PF) of the thalamus. Changes in CM-PF activity are known to reflect arousal and abrupt changes in behavior, and may have relevance to several parkinsonian motor signs including challenges with selecting new motor actions in changing environments and potential contribution to freezing-of-gait. In this study, we investigated how firing rate, firing patterns, and oscillations changed with the onset of parkinsonism and how these changes relate to gait behaviors including gait initiation and reaction to new obstacles or environmental stimuli. A non-human primate was implanted with a 96-channel microdrive that targeted the CM-PF amongst other brain regions. Wide-band wireless recordings were collected from the microdrive channels while the subject ambulated through a custom-designed habitrail enclosure. The habitrail included two boxes, in which food rewards were administered, that were connected through an 9'-long walkway with a pressure mat to rapidly quantify the spatial and temporal dynamics of gait. Obstacles were introduced into the habitrail walkway periodically during the course of the subject navigating the habitrail. Drug-naive spike recordings from CM-PF cells showed no clear modulation to individual limb movements; however, cells were robustly modulated in response to gait cessation, gait initiation, and the presentation of novel stimuli in the habitrail environment. These results suggest that the degeneration within the CM-PF in Parkinson's disease may be responsible in part to motor signs that are triggered by environmental cues including freezing of gait. Title: Thalamic white matter investigated with serial PS-OCT imaging

Authors: ***M. YEATTS**[1], C. LIU[1], S. R. HEILBRONNER[2], M. D. JOHNSON[3], T. AKKIN[1]; [1]Univ. of Minnesota, Minneapolis, MN; [2]Neurosci., Univ. of Minnesota, New Brighton, MN; [3]Biomed. Engin., Univ. of Minnesota, Minneapolis, MN

Abstract: Introduction: Deep brain stimulation (DBS) targeting neural pathways within the thalamus has been used to treat individuals with essential tremor, epilepsy, and schizophrenia, among others. The precise neural pathways underlying the therapy are often difficult to disentangle since the thalamus has heterogeneous axonal tractographies that are not readily visible with traditional imaging techniques such as diffusion tensor imaging (DTI). In this study, we developed a polarization-sensitive optical coherence tomography (PS-OCT) approach to visualize axonal pathways within and adjacent to non-human primate (NHP) thalamus with 10-micron lateral resolution.
Methods: Two perfused and paraformaldehyde-fixed rhesus macaque brains were blocked about the right thalamus. The initial exposed face was scanned in a tiled array using PS-OCT before removing a 100-micron thick slice to access the deeper regions. One thalamus was imaged in the sagittal plane, and the other was imaged in the coronal plane using repeated imaging and slicing procedures. For each exposed face, the reflectance, retardance, and cross polarization images were collected. The images were stitched, aligned, and stacked into a three-dimensional block to render thalamic axonal tracts.
Results: PS-OCT enabled visualization of both afferent and efferent pathways that across multiple thalamic nuclei relevant to DBS therapy. For example, distinct tracts of differing orientations in the region of the anteriomedial and centromedian thalamic nuclei, the mamillothalamic tract, the habenulopeduncular tract, and separable bundles of the internal capsule. The stria medularis and fornix were also visualized with highly aligned and dense white matter tracts.
Conclusions: Improved understanding of axonal tractography within thalamus will be important to optimize DBS therapy for a range of existing and emerging clinical indications. This imaging

approach is poised to enable rendering of axonal tracts in three dimensions and help guide future DBS lead designs and programming algorithms.

Title: Comparison of therapeutic efficacy between multiple current sources and multiple stimulation sets

Authors: *J. D. S. KRIEG[1], A. M. DOYLE[2], J. SLOPSEMA[1], F. AGNESI[3], M. D. JOHNSON[1];
[1]Biomed. Engin., Univ. of Minnesota, Minneapolis, MN; [2]Neurosci., Univ. of Minnesota, Twin Cities, Minneapolis, MN; [3]Abbott, Dallas/Fort Worth, TX

Abstract: Deep brain stimulation (DBS) is a well-established surgical therapy for a growing list of neurological and neuropsychiatric disorders. With this fully implantable therapy, electrical pulse trains are delivered to key nodal points within the brain, and aim to disrupt the propagation of pathological information throughout the larger brain network. Successful therapy relies heavily on the precision by which stimulation through one or more electrodes along the DBS lead can disrupt this pathological information. One approach to improve targeting precision has been leveraging technology from the cochlear implant field that integrates multiple independent current sources (MICS) into the neurostimulator hardware. However, the utility of such technology comes at the cost of hardware design complexity. In this study, we investigated a novel sequential, multiple stimulation set (MSS) approach using a single current source that rapidly switches between electrodes along a DBS lead. We specifically compared these MICS and MSS approaches in computational models and *in vivo* in two non-human primates, who were implanted with a 6-channel directional DBS lead in the subthalamic nucleus. The models suggest that while stimulation thresholds between MICS and MSS (evaluated at 0.5, 1.0, 1.5, 2.5, and

3.75 ms switching delays) were not significantly different overall, there are likely to be subtle differences in axonal orientation selectivity as the delay between pairs of MSS pulses increases. In the *in vivo* study, as proof of principle, there were no significant differences in stimulation thresholds for inducing motor contraction side effects during STN-DBS. The results suggest that MSS at short switching delays has promise to augment single current source stimulation paradigms and refine targeting of DBS therapy in cases when neurostimulator hardware is limited to a single current source.

Title: Limited trunk motion and variability during gait contribute to FOG and improve during STN DBS

Authors: *J. O'DAY[1], C. ANIDI[2], R. W. ANDERSON[3], J. PARKER[1], M. N. PETRUCCI[4], R. NEUVILLE[1], H. BRONTE-STEWART[5];
[2]Neurol. and Neurolog. Sci., [1]Stanford Univ., Stanford, CA; [3]Neurol., Stanford Univ., San Francisco, CA; [4]Neurol., [5]Dept. of Neurol., Stanford Univ., Stanford, CA

Abstract: Objective: Limited truncal motion during forward walking may contribute to freezing of gait (FOG) in PD but has not been extensively investigated. Lower (60Hz) and high (140Hz) subthalamic deep brain stimulation (STN DBS) may improve FOG (Xie 2015, Anidi 2018) but whether this is associated with changes in lumbar motion during gait is not known. We hypothesized that PD freezers would exhibit restricted lumbar motion and variability during a turning and barrier course (TBC) known to elicit FOG (Syrkin-Nikolau 2017) and that these would improve during STN DBS.
Methods: Twelve PD subjects (7 male), off medication, received randomized presentations of no, 60 Hz, and 140 Hz STN DBS, while walking in the ellipses and figures of eight through narrow openings of the TBC. Nine age-matched healthy controls completed the TBC. A validated logistic regression model identified periods of FOG based on shank inertial measurement unit (IMU) data. The root mean square angular velocity (Vrms) of trunk motion and the standard deviation of the trunk’s linear acceleration (SD_{LA}) was calculated from a lumbar IMU, in the anterior-posterior (AP) and medio-lateral (ML) directions during the TBC.

Results: Freezers (N = 7) had reduced trunk Vrms (AP and ML) and SD_{LA} (AP) while OFF therapy during the TBC compared to controls ($p < 0.02$). Both 60Hz and 140Hz DBS improved freezers' percent time freezing ($p < 0.05$) to that of non-freezers. Freezers' lumbar AP Vrms increased on 140 Hz DBS compared to OFF ($p < 0.05$), and to a value similar to that of controls and non-freezers. Freezers' lumbar ML Vrms also increased during both 60 Hz and 140 Hz DBS ($p < 0.05$). Freezers' AP SD_{LA} increased during 60 Hz and 140 Hz DBS, ($p < 0.03$). Freezers' normal ML SD_{LA} showed no change during DBS. Non-freezers' AP and ML SD_{LA} increased during 140 Hz DBS ($p < 0.05$) toward control levels, though non-freezers' lumbar AP and ML Vrms did not change during DBS.
Conclusions: During the TBC, freezers demonstrated FOG and reduced truncal motion and variability compared to that of non-freezers and controls. STN DBS at 60Hz and 140Hz resolved FOG and improved truncal motion and variability in freezers. These results support our hypotheses that freezers exhibit reduced truncal motion and variability during gait, which improve during STN DBS, in association with resolution of FOG. This suggests that reduced truncal motion and variability contribute to FOG and that lumbar kinematics may be useful control variables for closed loop DBS systems aimed at improving FOG. To our knowledge this is the first study to investigate truncal kinematics during a gait task that mimics real life situations that elicit FOG and during lower and high frequency STN DBS.

Title: Alternations in M1 LFP oscillations of Parkinsonian mice during different movement states

Authors: *J. WEI, K. WANG, Y. CUI, Y. LIANG, J. JIA;
Capital Med. Univ., Beijing City, China

Abstract: Neural oscillation impairment is thought to be a candidate pathophysiological mechanism underlying movement disorders such as Parkinson's disease. There remains, however, a pressing need to carefully characterize neural oscillations in PD during different movement states. At present, the research in humans and rats has become increasingly rich, but

the research in mice is poor. To address this, we simultaneously recorded local field potentials (LFPs) from M1 of mice (control and 6-OHDA group) when they performed an open field test, to investigate the properties of neural oscillatory activity. The behavioral results showed that the 6-OHDA mice spent significantly less amount of time moving, but more time freezing compared with the control group. And we detected that in 6-OHDA, the power of M1 LFP oscillations at the beta (11-30Hz) and gamma (30-55Hz) range frequencies were stronger than those of control mice during resting state. The opposite was observed for moving state. Furthermore, we investigated whether the two oscillations would change between the different behavioral states. In the control mice, the oscillations at beta frequencies diminished considerably in moving states compared to resting. And the opposite was found for the gamma oscillations. It is worth noting that the 6-OHDA mice didn't display the similar trends when a change in behavioral state occurred. The results show that the oscillatory activity across the M1 in the normal and 6-OHDA states reveals two characteristic frequency bands which may be associated with movement. Thus, our findings suggest that pathological beta and gamma oscillations might be the much more sensitive neurophysiological markers for Parkinson' mice.

Title: A comparison of methods for quantifying subthalamic beta burst dynamics in people with Parkinson's disease

Authors: *R. W. ANDERSON, R. S. NEUVILLE, C. M. ANIDI, M. N. PETRUCCI, J. E. PARKER, A. VELISAR, H. M. BRONTE-STEWART;

Abstract: Parkinson's disease (PD) is a progressive neurological disorder, the neural signature of which includes an increase in synchronization of neuronal activity in the beta frequency range (13-30 Hz) in the basal ganglia and motor cortex. Increases in neural synchrony have been measured by averaging local field potential (LFP) power in overlapping bins and representing this in power spectral density (PSD) analysis and time frequency spectrograms. These techniques are well suited to examine the average power in the signal but are less sensitive to the temporal fluctuations in neural (or beta) synchrony ('beta burst' dynamics) that may be more relevant to distinguish pathological from physiological neural activity. Recently, four methods (termed Anderson1, Anderson2, Feingold, and Tinkhauser) have been proposed to quantify beta burst dynamics, all of which use bandpass filtering and rectification but which differ in the calculations of the threshold, critical in determining the duration of elevated LFP power. In addition it is not known whether the width of the frequency band chosen for analysis affects burst dynamics.
In this study we compared the four methods of beta burst analysis using chronic LFP recordings in the resting state from PD subjects implanted with an investigative sensing neurostimulator (Activa PC+S, Medtronic Inc.). Each method was sensitive to different aspects of the LFP and the choice of method affected the range of beta burst durations captured and mean beta power. Using 1000 trials of 1/f pink noise, it was evident that the choice of filter bandwidth affected burst duration. We also compare the four methods in the analysis of beta burst dynamics in the akinetic rigid and tremor dominant phenotype of PD. The choice of burst analysis method will be important for different objectives, such as when focusing on pathological (longer) burst dynamics or when examining both physiological and pathological burst dynamics, and when designing closed loop neurostimulation algorithms.

Title: The relationship between beta burst durations and the conversion to freezing of gait in Parkinson's disease

Authors: *M. N. PETRUCCI[1], R. S. NEUVILLE[1], R. W. ANDERSON[1], J. E. PARKER[1], C. M. ANIDI[1], J. J. O'DAY[2], A. VELISAR[1], H. M. BRONTE-STEWART[1];
[1]Neurol. and Neurolog. Sci., [2]Bioengineering, Stanford Univ., Stanford, CA

Abstract: Freezing of gait (FOG) is a debilitating symptom of Parkinson's disease (PD) that worsens with disease progression and impacts quality of life. Increased burst durations in the beta band of local field potentials (LFPs) in the subthalamic nucleus (STN) have been observed in people with PD and FOG compared to those without FOG, and burst durations are longer during a FOG episode (Anidi et al., 2018). The purpose of this study was to investigate if burst durations in the beta band are associated with the development of FOG symptoms in people with PD. Participants that had FOG, did not have or develop FOG, or developed FOG, performed a stepping in place (SIP) and a rapid alternative finger tapping task (RAFT) with simultaneous bilateral recording of STN LFPs using a fully implanted neurostimulator (Medtronic Activa® PC+S system). Burst durations within the high and low beta bands during the SIP task were compared between two time points 35 ± 3 months apart. Burst durations in the same bands during the RAFT task performed within 1-3 months of the first time point were compared to the SIP task at the second time point. Kolomogrov-Smirnov tests were used for all comparisons between tasks within each band. Preliminary results suggest that FOG may be associated with a significantly broader distribution of bursts (towards longer durations) in the low and high beta bands in participants that had or developed FOG. This increase in beta bursts was associated with an increase in arrhythmicity and percent time freezing within the SIP task. Furthermore, the distribution of burst durations within the RAFT task was not different than the SIP task performed at the second time point for these participants, suggesting that beta burst associated with freezing behavior in the RAFT task may precede the development of FOG. No difference in burst durations or movement kinematics in the SIP task was observed in the participant without FOG between time points. Overall, an increase in the amount of longer burst durations in the beta band and worsening movement was found in participants with FOG or who developed FOG in the SIP and RAFT tasks, potentially providing an additional biomarker for predicting the conversion to FOG.

Title: Neuromodulatory effects of electroacupuncture on corticostriatal beta synchronization and motor dysfunction in Parkinsonian rats

Authors: *J. JIA, X. JIANG, Y. YAN, K. WANG, J. WEI;
Dept. of Physiol. and Pathophysiology, Capital Med. Univ., Beijing city, China

Abstract: Exaggerated beta synchronized oscillation in the cortico-basal ganglia circuit is a hallmark of disease-specific motor symptoms in Parkinson's disease (PD). Series of studies have shown that Electro-acupuncture (EA) could improve the motor symptoms of PD, yet the potential mechanism remains unclear. In the present study, injection of 6-hydroxydopamine (6-OHDA) into the right medial forebrain were used as parkinsonian model. And the electrical stimulation at 100 Hz was administrated on the specific acupoints "Baihui" and "Dazhui" (GV20 and GV14, respectively). So the effects of EA on the motor symptoms, the striatal glutamate levels and corticostriatl beta synchronized oscillations were investigated. Four weeks EA treatment significantly alleviated the motor signs of 6-OHDA lesioned rats including the decreased latency of fall in the rotarod and the reduced movement distance in the open-field test. Notably, EA exhibited a time-dependent effect on the improvement of motor symptoms. However, neither the dopaminergic neurons in the substantia nigra nor the dopamine levels in the striatum were restored by the EA stimulations. Conversely, the increased release of glutamate in the striatum of 6-OHDA rats was inhibited by the EA stimulation in a time-dependent manner. Enhanced high beta (25–40 Hz) oscillations and coherence between the motor cortex and dorsolateral striatum were found in 6-OHDA lesioned rats. EA treatment obviously reduced the beta oscillations and desynchronization of corticostriatal circuit in a time-dependent manner. In additional, selectively inactivation of glutamatergic projection with the chemogenetical strategy reduced the beta oscillatory synchronization in the corticostrital circuit and alleviated motor symptoms in 6-OHDA lesioned rats. Thus, these data suggested that chronic EA treatment produced the dynamic modulatory effects on the striatal glutamate release, the synchronized beta oscillations of coritcostriatal circuit and the motor behaviors in 6-OHDA-lesioned rats.

Glutamate transmission probably mediated the alternation of the corticostriatal coordination in the pathophysiology of parkinsonism.

Title: Freezing of gait and subthalamic neural dynamics during stepping are modulated when altering optic flow in a virtual environment in Parkinson's disease

Authors: ***J. E. PARKER**[1], J. O'DAY[2], R. S. NEUVILLE[1], M. N. PETRUCCI[1], R. W. ANDERSON[1], A. VELISAR[1], H. M. BRONTE-STEWART[1];
[1]Neurol. and Neurolog. Sci., [2]Bioengineering, Stanford Univ., Stanford, CA

Abstract: Freezing of Gait (FOG) in Parkinson's disease (PD) is exacerbated when optic flow during forward motion is limited. Congruent optic flow in normal or virtual environments may improve/minimize FOG. We recently reported that subthalamic (STN) beta (movement) band burst dynamics differentiated PD freezers from non-freezers during non-freezing gait (Anidi 2018). In this study we investigated whether altered optic flow in a virtual environment during a stepping in place (SIP) task changed gait/FOG and/or STN neural dynamics.
Seven PD subjects (14 STNs), off therapy, performed 100s of SIP on dual forceplates with a visual surround (Bertec Corp., OH, USA) with no optic flow (nOF), and with a virtual optic flow environment not linked to their cadence (altered optic flow, aOF). STN local field potentials (LFPs) were recorded from an implanted, sensing neurostimulator (Activa® PC+S, Medtronic, Inc.) and synchronized with kinetics. Band burst dynamics (mean duration, normalized burst power) were analyzed from the alpha (8-12 Hz) and the beta movement band (4Hz band around the peak frequency during SIP) and compared between SIP/nOF and SIP/aOF. Comparisons with a forward walking task with optimized congruent optic flow will be investigated.
Gait impairment and FOG were worse during SIP/aOF: frequency of stepping decreased in 100%

of subjects and arrhythmicity increased in 86% of subjects; the percent time freezing increased in 4 subjects, who already exhibited FOG in the SIP/nOF condition, and FOG appeared during SIP/aOF when not apparent during SIP/nOF in one subject. Neural dynamics of the movement band (MB) became more pathological: during SIP/aOF, MB normalized mean burst power increased in 69% of STNs, and MB mean burst durations increased in 54% of STNs. Alpha band mean burst power increased in 71% of STNs and alpha mean burst durations decreased in 57% of STNs during SIP/aOF.
Gait/FOG and STN MB neural dynamics (mean burst duration and power) became worse during stepping with altered optic flow in the majority of PD subjects. Alpha band burst power increased in the majority of subjects and burst durations decreased in 57% of subjects; whether this was related to cognitive impairment will be investigated. While some studies have shown the positive impact of virtual reality on FOG, this virtual environment was not linked to the subject-specific cadence and acted as incongruent optic flow, disrupting FOG and STN neural dynamics. These results demonstrate that STN neural signatures of FOG are sensitive to altering the congruency of optic flow during motion, substantiating their role in the pathogenesis of FOG in PD.

Title: Beta peak frequency and burst dynamics are conserved across different movements in Parkinson’s disease

Authors: R. S. NEUVILLE, R. W. ANDERSON, M. N. PETRUCCI, J. E. PARKER, A. VELISAR, ***H. BRONTE-STEWART**;
Neurol. and Neurolog. Sci., Stanford Univ., Stanford, CA

Abstract: Adaptive or closed-loop deep brain stimulation (aDBS) driven by STN beta band power when PD subjects are seated works; it is unknown if the same neural control variable(s) will be relevant when subjects are performing different movements, such as typing, eating, or walking. To investigate whether an aDBS system would have to continually update its classifier algorithms when subjects performed different movements, we compared the beta movement band peak frequency and burst metrics during fine, limb, and axial movement tasks in freely moving PD subjects. STN local field potentials (LFPs) were recorded from a sensing neurostimulator (Activa® PC+S, Medtronic, Inc.) in 11 PD subjects (22 STNs), during thirty seconds of repetitive alternating finger tapping, wrist-flexion extension, stepping in place, and free walking; subjects were off medication/off DBS, 1-2 months after DBS implantation. A peak detection algorithm determined and compared the peak frequency in the beta band during each movement. Subject-specific, movement bands were ± 3 Hz around the averaged peak frequency of the four movement tasks. Movement band burst dynamics were calculated and compared among tasks and to a gamma band in which there was no peak detected above the 1/f curve. The peak frequency was similar among the four movement tasks ($p=0.588$). There was no difference between mean movement band burst duration, burst peak power, and burst average power among tasks ($p=0.192$, 0.464, 0.433 respectively). There was no difference within these burst metrics between tremor dominant and akinetic rigid subjects, regardless of task ($p=0.286$, 0.205, and 0.196 respectively). Mean burst duration, peak power, and burst average power were longer/greater in the movement band than in the gamma band, regardless of the task ($p=0.003$,<0.001,<0.001 respectively). The peak frequency of exaggerated beta synchrony (beta peak) was conserved among fine, limb, and axial movements. The movement band mean burst duration, peak and average power were also conserved among tasks. The conservation of a PD subject's neural profile during different movements supports the feasibility of aDBS using the same beta band power or burst metrics during different activities of daily living. Burst durations and power were longer/greater in a band with elevated power over the 1/f curve compared to one without, supporting the premise that prolonged LFP burst durations are a feature of a pathological rather than physiological neural network.

Title: Reinforcement learning requires balanced activation of dopamine and sonic hedgehog pathways in striatal cholinergic interneurons

Authors: *S. URIBE-CANO[1], D. R. ZUELKE[3], L. B. MALAVE[4], A. H. KOTTMANN[2];

Abstract: Cholinergic interneurons (CIN) in the striatum act as critical circuit integrators of the model free- and procedural- learning machine housed in the basal ganglia. CIN activity is modulated by mesencephalic-dopamine (DA) neuron (DAN) projections which, according to reinforcement learning theories, provide a "teaching signal" that can modulate the strength of glutamatergic synapses in the striatum. The mechanisms of DAN action on CINs and how CIN activity mediates reinforcement learning are not completely understood. In particular, the finding that DANs communicate with their targets not only via DA but through multiple factors suggests that the "teaching signal" they produce may be a composite of several signaling molecules. We previously found that in the adult brain all DANs selectively signal to striatal CINs and fast spiking interneurons via the secreted cell signaling molecule Sonic hedgehog (Shh). Conditional ablation of Shh from DANs results in decreased cholinergic tone, a selective loss of cortical glutamatergic inputs onto CINs, progressive CIN degeneration in aged mice, and slowed reinforcement learning with precocious motor habit formation in young adult mice in a conditional T-Maze paradigm (Gonzalez Reyes et al., 2012). As proof of principle, we found that the pharmacological activation of Smoothened (Smo) on CINs, a GPCR required for Shh signal transduction, in parkinsonian rodent models can ameliorate L-Dopa induced dyskinesia, a form of aberrant motor learning (Malave et al., 2019, preprint at BioRX). Based on this data we hypothesize that successful reinforcement learning requires balanced Smo and DA receptor activation on CINs. To test this hypothesis, we produced an allelic series of recombinant mice with ablated, partially reduced, and constitutively activated Smo activity in CINs. These mouse lines are currently being tested in motor habit learning paradigms using a conditional T-maze. Further, we have produced a series of chimeric Melanopsin-Smo GPCRs hoping to gain optical control over Smo signaling selectively in CINs. These recombinant receptors are being tested *in vitro* with assays for Smo specific G protein recruitment and phospholipase A2 activation. Lastly, we have begun identifying protein targets of Smo signaling in the intact striatum through metabolic labeling of the CIN specific proteome. Analysis of protein abundance and modifications among enriched samples of striatal CIN synaptosomes will be carried out via mass spectrometry.

Laboratory, Toronto Western Hospital, Univ. of Toronto, Toronto, ON, Canada; [4]Dept. of Med. Imaging, Univ. of Toronto, Toronto, ON, Canada; [5]Dept. of Kinesiology and Hlth. Science, California State Univ., Sacramento, CA

Abstract: *Introduction*: Parkinson's disease (PD) is associated with excessive beta-gamma phase amplitude coupling (PAC) within thalamocortical motor loops. Recent research suggests that this coupling is linked to sharper beta band waveforms, and is normalised by DBS. Here we employed magnetoencephalography (MEG) and beamforming to non-invasively measure thalamocortical PAC, waveform sharpness and their relationship in individuals with predominantly akinetic rigid PD (on and off medications) compared the results to healthy controls (HC). *Methods*: Individuals with PD (n = 16, 10 men, mean age 63.4 years) and age matched HC (n = 17, 8 men, mean age 63.3 years) were recruited. PD individuals attended two sessions(ON and OFF dopaminergic medications); HC attended a single session. MEG comprised a 4.5 minute scan (eyes closed) with head tracking sensors. MEG was registered to individual anatomical MRIs. Clinical severity was assessed using the Unified Parkinson's disease Rating Scale (UPDRS). PAC across beta (13-30 Hz) and gamma (50-150 Hz) bands and beta band waveform sharpness were measured. PAC was calculated in motor cortex, thalamus and occipital cortex (control region), and between thalamus and motor cortex or occipital cortex. *Results*: PAC was significantly elevated in both the more and less affected motor cortices and between thalamus (beta) and motor cortex (gamma band) in the PD OFF compared to PD ON condition and to HC. Beta band waveform sharpness was modestly higher in PD OFF compared to PD ON ($p = 0.027$) and HC ($p = 0.029$) in the motor cortex but not in thalamus in the more affected hemisphere only. There was a non-significant ($p=0.086$), positive, association between PAC and waveform sharpness in PD OFF in the more affected motor cortex. Control analyses in the occipital cortex indicated that neither PAC nor waveform sharpness were elevated in PD ON or OFF medication conditions relative to HC. *Discussion*: Our data provide the first noninvasive demonstration of elevated thalamocortical PAC in motor regions but not in control regions in

PD. Our findings of elevated cortical PAC in PD OFF and its normalization by dopaminergic medication are consistent with previous reports. In addition, our findings suggest that increased PAC in PD cannot be explained by high waveform sharpness, but PAC and sharpness may be related biological phenomena.

Title: Transcriptional profiling of striatal cholinergic interneurons with and without dopamine neuron provided sonic hedgehog

Authors: *D. R. ZUELKE[1,2], L. B. MALAVE[1,3], P. BARKAUS[1], S. MAHARJ[1], K. KENNEDY[1], A. H. KOTTMANN[1,4];
[1]CUNY Sch. of Med., New York, NY; [2]Biol., [3]Neurosci., [4]CUNY Grad. Ctr., New York, NY

Abstract: Sonic hedgehog (Shh) competent cholinergic interneurons (CINs) in the striatum are key members of the striatal microcircuits involved in movement and procedural learning. Aberrant CIN activity is implicated in progressive neurodegenerative diseases involving the basal ganglia like Parkinson disease (PD). Previously we showed that conditional ablation of Shh from DAN (Shh_{DAN}) results in decreased cholinergic tone, a selective loss of cortical glutamatergic inputs onto CINs, and progressive CIN degeneration in aged mice (Gonzalez-Reyes et al., 2012). Recently, we implicated activation of the Shh pathway in the attenuation of L-Dopa induced dyskinesia in parkinsonian rodent and macaque models (Malave et al., 2019, BioRX). The Shh pathway is well known to regulate gene expression in target cells. The transcriptional changes in CINs with and without Shh_{DAN} has not been explored. As CINs comprise only 1-2% of striatal neurons, we utilized translating ribosome affinity purification to isolate mRNA for RNAseq. Analysis revealed differentially expressed genes involved in G-protein signaling, glutamate signaling, transcriptional control, and neurodegeneration. Among these targets of Shh, hedgehog interacting protein (Hhip), a factor modulating Shh signaling strength, was significantly downregulated in CINs lacking Shh_{DAN}. Here we validate the differential expression of Shh regulated candidate genes using a combination of qRT-PCR, *in situ* hybridization, and immunohistochemistry. Our work will contribute to defining the Shh/Smo

based connectome within the basal ganglia and the functional consequences of disturbed Shh/Smo signaling in basal ganglia diseases.

Title: Distinct subpopulations of parvalbumin-expressing neurons in the external globus pallidus (GPe) mediate different behavioral functions

Authors: *V. LILASCHAROEN, E. H. WANG, N. DO, A. N. TRAN, X. WANG, B. LIM; UCSD, La Jolla, CA

Abstract: The external segment of the globus pallidus (GPe), a subcortical nucleus centrally located in the indirect pathway of the basal ganglia, plays a pivotal role in processing and broadcasting information received from the striatum and the subthalamic nucleus through its widespread projections across major basal ganglia nuclei. One of the largest neuronal populations of the GPe expresses the Ca^{2+}-binding protein parvalbumin (PV) and projects to multiple nuclei of the basal ganglia and the thalamus and has been shown to be involved in movement disability in Parkinson's disease (PD). However, most studies to date considered GPe PV neurons as a homogeneous population. We found that the GPe PV neurons can be further subdivided into two non-overlapping populations based on their projections to either the substantia nigra pars reticulata (SNr) or the parafascicular thalamus (PF) and their intrinsic electrophysiological properties. We further investigated the circuit-specific roles of these subpopulations in locomotion and reversal learning as well as their contributions to the impairments of motor and cognitive flexibility in a PD mouse model. Our findings establish the behavioral significance of two distinct GPe PV neuronal populations embedded in discrete neural pathways and their differential contributions to specific subdomains of Parkinsonian-like behaviors.

Title: Sonic Hedgehog signaling from mesencephalic and cortical projections stimulate striatal cholinergic and fast spiking interneurons altering L-Dopa induced dyskinesia formation and expression

Authors: *L. B. MALAVE[1], D. R. ZUELKE[2], S. URIBE-CANO[3], A. H. KOTTMANN[4]; [1]CUNY Sch. of Medicine, CCNY, New York, NY; [2]CUNY Sch. of Med., New York, NY; [3]CUNY City Col. of New York, New York, NY; [4]Physiology, Pharmacol. and Neurosci., City Univ. of New York, New York, NY

Abstract: Cholinergic (CIN) and fast spiking (FSI) interneurons of the striatum are critical components of the striatal microcircuit that integrate cortical and thalamic information streams onto medium spiny output neurons. Both populations of neurons have become implicated in L-Dopa induced dyskinesia (LID), a severe complication of DA substitution therapy in Parkinson's disease (PD), which is caused by the degeneration of dopamine neurons (DAN). While all neurons of the striatum express various receptors for the neurotransmitters dopamine (DA), acetylcholine (ACh), GABA, and Glutamate, CIN and FSI are the only neuronal subtypes that express the signal transduction components of the secreted cell signaling protein Sonic Hedgehog (Shh). All mesencephalic DAN and pyramidal tract (PT) neurons, which project collateral axons into the striatum express Shh throughout life. We previously showed that conditional ablation of Shh from DAN (Shh_{DAN}) results in decreased cholinergic tone, a selective loss of cortical glutamatergic inputs onto CINs, progressive CIN degeneration in aged mice, and slowed reinforcement learning with precocious motor habit formation in young adult mice in a conditional T-Maze paradigm. Further, the pharmacological activation of Smoothened (Smo) on CINs, a GPCR required for Shh signal transduction, in parkinsonian rodent and macaque models can ameliorate LID. We find that Smo agonist treatment blunts the DA mediated inhibition of CIN. Interestingly, D2R as well as Smo couple to Gα/i pointing to the possibility that these pathways share downstream effectors. Conditional ablation of Smo from CINs results in progressive CIN degeneration, and reduced p-rpS6 levels, a neuronal activity marker, which cannot be rescued by Smo agonist treatment. Interestingly, the conditional ablation of Shh from PT neurons, in contrast to the ablation of Shh from DAN, increases neuronal activity of CIN as

measured by p-rsP6 levels. This observation suggests that Shh_{PT} might signal selectively to FSI, which provide negative control over CIN. To further investigate this phenomenon we produced allelic series of recombinant mice with ablated, partially reduced, and constitutively activated Smo (SmoM2) activity in CIN and FSI to test whether graded Smo activity will correlate with p-rpS6 levels, degree of neuroprotection and reduction in the formation and display of LID. Our results reveal that Shh_{DAN} is an important regulator of neuroplasticity of CIN, further suggests that Shh_{PT} signals selectively on FSI, and demonstrate, that dysregulation of Shh signaling in the striatum is a significant contributor to primary and therapy induced pathology in PD.

Title: Neural selectivity, efficiency, and dose equivalence in deep brain stimulation through pulse width tuning and segmented electrodes

Authors: *C. J. ANDERSON[1], D. N. ANDERSON[2], S. M. PULST[5], C. R. BUTSON[3], A. D. DORVAL[4];
[1]Neurol., [3]Scientific Computing & Imaging Inst., [4]Dept. of Bioengineering, [2]Univ. of Utah, Salt Lake City, UT; [5]Univ. of Utah Clin. Neurosciences Ctr., Salt Lake City, UT

Abstract: Background: Achieving deep brain stimulation (DBS) dose equivalence is challenging, especially with pulse width tuning and directional contacts. Further, the precise effects of pulse width tuning are unknown, and recent reports of the effects of pulse width tuning on neural selectivity and side effects seemingly contradict classic biophysical studies.
Methods: We created multicompartment neuron models for two axon diameters and used finite element modeling to determine extracellular influence from standard and segmented electrodes. We analyzed axon activation profiles and calculated volumes of tissue activated.

Results: We find that long pulse widths focus the stimulation effect on small, nearby fibers, suppressing distant white matter tract activation (responsible for some DBS side effects) and improving battery utilization. Directional leads enable similar benefits to a greater degree. We derive equations for equivalent activation with pulse width tuning and segmented contacts. Reexamining previous reports of short pulse stimulation reducing side effects, we find that short pulse stimulation was not dose equivalent and consistently featured substantially less spread of neural activation.
Interpretations: We find agreement with classic studies and reinterpret recent articles concluding that short pulse widths focus the stimulation effect on small, nearby fibers, decrease side effects, and improve power consumption. The DBS field may need to reconsider the use of shortened pulse widths. Future work examining pulse width tuning must ensure dose equivalence rather than stimulating with energy- or charge-equivalent settings.

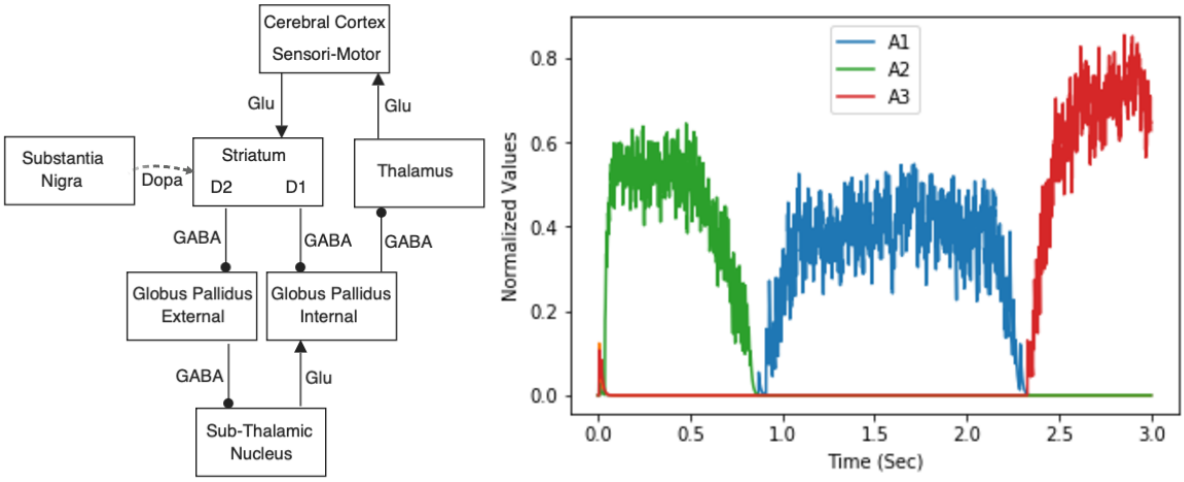
Title: Dynamic spiking network model of basal ganglia for movement disorders

Authors: *A. DUTTA;
Electrical and Computer Engineering, Biomed. Engin., Univ. of Connecticut, Storrs, CT

Abstract: Basal ganglia dysfunction is a problem with the deep brain structures that help start and control movements, most likely caused by a degeneration of neurons in the BG and is responsible for a variety of neurological disorders. This necessitates the development of a spiking network model of BG-Thalamus-Cortex loop based on the interplay of excitatory, inhibitory and modulatory dynamics leading to decision making and execution, hopefully leading to new therapies.
The Cortex makes/receives excitatory/glutamatergic connections to/from Striatum (D1, D2) and Thalamus respectively. The Striatum projects inhibitory/GABAergic connections to Globus Pallidus (GP) extending to Sub-Thalamic Nucleus (STN) which makes a reciprocal inhibition to GP in turn exciting Thalamus. The Substantia Nigra (SN) projects neuro-modulatory/Dopaminergic connection to Striatum.
A representative population of spiking neurons are used to model each region of BG as show in

the figure. Rate coding is used to interconnect with appropriate excitatory/inhibitory synaptic weights. The SN though is used for neuromodulation of Striatum's synaptic strength. The Cortical neurons encode states and the BG does sequential decision-making based on rewards modulated by Dopamine and communicate back the decoded actions through Thalamus.



A degeneration of neural cells in Striatum, SN is known to cause Huntington's and Parkinson's disease respectively. A sequence of actions with maximum rewards in the order of 2, 1, 3 during 1, 2, 3 secs is fed into BG modeled with lower neuro-modulatory Dopamine levels and the results from the Thalamus are plotted. It is evident that actions are triggered with hesitation. This can cause trouble in sequential decision making of cognitive actions possibly explaining Parkinson's and its mechanics.This spiking neural network model based on population rate coding and interconnected by excitatory, inhibitory and modulatory synapses is shown to be a valuable aid in analyzing and treating neurological disorders.

Title: Differential ultrastructural alterations in the Vglut2 (STN) glutamatergic input to the substantia nigra pars compacta/pars reticulata following nigrostriatal dopamine loss in a progressive mouse model of Parkinson's disease

Authors: *C. K. MESHUL[1,2], C. MOORE[3], M. XU[4], J. K. BOHLEN[5];
[1]Res. Services/VA Med. Ctr., VA Med. Ctr., Portland, OR; [2]Behavioral Neurosci., Oregon Hlth. & Sci. Univ., Portland, OR; [3]Res. Services/VA Med. Ctr., Cindy Moore, Portland, OR; [4]Res. Services/VA Med. Ctr., Mo Xu, Portland, OR; [5]Res. Services/VA Med. Ctr., Jerry Bohlen, Portland, OR

Abstract: Parkinson's disease (**PD**) is the second most common neurodegenerative disease. Loss of nigrostriatal dopamine (**DA**) results in the over-activation of the subthalamic nucleus (**STN**). The STN sends axonal projections to both the substantia nigra pars compacta (**SNpc**) and pars reticulata (**SNpr**). The vesicular glutamate transporter 2 (**Vglut2**) is localized within STN terminals synapsing within the SN. A lesion of the nigrostriatal pathway results in a decrease in the extracellular striatal glutamate, which is inversely associated with an increase in the density of nerve terminal glutamate immuno-gold labeling. We have developed a chronic/progressive mouse model of PD where MPTP, or vehicle (**VEH**), is administered weekly at increasingly higher doses for 4 weeks. The aim of the current study was to determine if there were differential changes in either the density of Vglut2+ nerve terminal glutamate immuno-gold labeling within the SNpc/SNpr and/or in the proportion of Vglut2+ terminals synapsing on tyrosine hydroxylase (**TH**) positively or negatively labeled dendrites. Within the SNpc, there was no change in the density of nerve terminal glutamate immuno-gold labeling within Vglut2+ terminals. There was a significant shift in the percentage of Vglut2+ terminals contacting TH+ vs TH- labeled dendrites (GABA?) in the VEH vs MPTP treated group, possibly due to DA cell loss: TH+ dendrites: VEH: 81.6% vs MPTP: 50.2%; $p = 0.01$; TH- dendrites: VEH: 21.7% vs MPTP: 51.8%, $p = 0.005$. Within the SNpr, there was a significant decrease in the density of glutamate immuno-gold labeling (#/um^2) in Vglut2+ terminals contacting TH+ and TH- labeled dendrites: TH+ dendrites: VEH vs MPTP: 74.9 vs 47.6, $p = 0.03$; TH- dendrites: VEH vs MPTP: 87.4 vs 53.7, $p = 0.02$. Within the SNpc, there was no change in the density of glutamate immuno-gold labeling within Vglut2+ terminals following MPTP treatment, suggesting no change in glutamate release. Within the SNpr, the decrease in the density of glutamate immunogold within Vglut2+ terminals suggests an increase in glutamate release, a finding consistent with the model of basal ganglia function in PD. We conclude that there is a differential effect of nigrostriatal DA loss on the glutamate input from the STN synapsing either within the SNpr and SNpc.

Title: Unravelling the neural circuits related to movement disorders: Pedunculopontine nucleus

Authors: *M. RIDDER[1], H. INAGAKI[2], L. XU[1], K. SVOBODA[2], P. SAH[1];
[1]The Queensland Brain Inst., Univ. of Queensland, St Lucia, Australia; [2]HHMI / Janelia Farm Res. Campus, Ashburn, VA

Abstract: Parkinson's disease (PD) is a progressive neurological disorder that results from loss of dopaminergic neurons in the midbrain. Freezing of gait (FOG) and postural instability are often seen in patients with advanced PD. FOG is defined as a brief, episodic absence or marked reduction of forward progression of the feet despite the intention to walk. It is one of the most debilitating motor symptoms in patients with PD as it may lead to falls and a loss of independence. Deep brain stimulation of the pedunclopontine nucleus (PPN) offers relief of FOG for some patients, yet its mechanism is unknown.
Persistent activity in a thalamocortical loop involving anterior lateral motor cortex (ALM) and parts of VM, VAL, MD) underlies motor planning. To initiate movements, the brain converts motor plans into movement commands, which is associated with large and rapid changes in activity in the thalamocortical loop. Ascending projections from PPN to thalamus could play a key role in terminating motor planning and movement initiation. Indeed, optogenetic stimulation of PPN ascending pathway triggers movement initiation in mice trained on a delayed-response task. Here we mapped the connectivity of PPN projection neurons to the thalamus. We expressed channelrhodopsin 2 (ChR2) in PPN neurons using viral transduction. Whole-cell recording were made from VM and MD neurons in brain slices while PPN axons were stimulated in the vicinity of the recording. In some cases neurons projecting to ALM were identified by retrograde labeling. Stimulation of PPN axons produced robust glutamatergic responses in a majority of thalamic neurons, including those that project to ALM. The responses were mediated by AMPA and NMDA-receptors. We found little evidence for cholinergic or GABAergic input from PPN to VM and MD. A better understanding of PPN neural circuits in relationship to motor thalamocortical loop may explain pathophysiology of FOG and the mechanism of DBS treatment.

Title: Multimodal PET and fcMRI reveals regional modulation by STN DBS correlating to motor outcomes

Authors: *J. R. YOUNCE[1], A. TANENBAUM[2], M. C. CAMPBELL[3], J. S. PERLMUTTER[5], S. A. NORRIS[4];
[1]Neurol., Washington Univ. In St Louis, Saint Louis, MO; [2]Neurol., Washington Univ. in St Louis, Saint Louis, MO; [3]Neurol., [4]Neurology, Radiology, Washington Univ. Sch. of Med., Saint Louis, MO; [5]Neurology, Radiology, Neuroscience, Physical Therapy, Occup. Therapy, Washington Univ. Sch. Med., Saint Louis, MO

Abstract: STN DBS is an effective treatment for Parkinson disease (PD), but predictors of clinical response are limited. ^{15}O PET reveals changes in brain activity in DBS without many of the methodological difficulties found in fMRI related to device safety and unpredictable MRI artifact. Regional blood flow responses to STN DBS have been observed with ^{15}O PET and in some cases correlate with clinical outcomes. A multimodal approach associating blood flow responses during STN DBS and motor outcomes with preoperative functional connectivity (BOLD fMRI) may permit improved prediction of clinical response to DBS. Forty-one participants with STN DBS had ^{15}O PET in OFF, unilateral dorsal STN stimulation ON, and unilateral ventral STN stimulation ON conditions, and we compared rCBF using paired T-tests. We used a whole-brain approach in addition to an *a priori* set of regions to identify responses to STN DBS. We then used the sites of regional responses for seed-based correlation in 80 participants with STN DBS and preoperative resting state fcMRI, as well as 300 seeds divided into 17 canonical networks. Connectivity of each PET-defined region to STN and intra-network seeds were correlated to change in UPDRS after DBS. DBS produced significant changes in 13 regions in the PET analysis. Connectivity of each region to canonical networks using fcMRI revealed that these activations related to basal ganglia, thalamic, dorsal sensorimotor, salience, parietal memory, and frontoparietal networks. Connectivity of left STN to ipsilateral internal globus pallidus strongly correlated with motor outcomes ($R = -0.41$, $p < 0.001$), with higher connectivity being associated with greater improvement in motor outcomes. Primary motor cortex connectivity to sensorimotor network was the network-level connectivity most correlated with change in motor scores after DBS. We conclude that DBS modulates a diverse set of brain regions. These regions not only pertain to networks typically associated with motor activity, e.g. basal ganglia, thalamic, and sensorimotor networks, but also memory, executive and associative functions. Motor outcomes are highly associated with STN connectivity to particular regions modulated by DBS.

Title: Inhibitory and excitatory DREADD-induced modulation of parafascicular thalamic nucleus projections to the basal ganglia alters motor function in hemiparkinsonian rats

Authors: N. NOVIKOV, E. BRAZHNIK, A. J. MCCOY, M. W. PRESTON, ***J. R. WALTERS**;
Neurophysiological Pharmacol. Section, NIH NINDS, Bethesda, MD

Abstract: The parafascicular thalamic nucleus (Pf) receives inputs from the basal ganglia (BG), cortex, and cerebellum and provides segregated projections to the striatum (STR) and subthalamic nucleus (STN). However, the Pf's impact on the pathophysiology of Parkinson's disease (PD) is unclear. Data from PD patients and animal models suggest that emergence of excessive beta oscillations in BG circuit activity contributes to PD motor dysfunction. Our previous studies in hemiparkinsonian rats support the view that synchronized activity in the substantia nigra pars reticulata (SNr) promotes the transmission of 25-35 Hz high beta oscillations throughout BG-thalamocortical circuits. Yet, these excessive oscillations are not evident in recordings from the Pf in PD rats. The current study uses the hemiparkinsonian rat to gain insight into the potential role of the Pf in modulating motor circuit activity and motor function after loss of dopamine, and explores the hypothesis that reduction in Pf activity has a therapeutic effect on motor deficits in PD. Three groups of rats received infusion of the inhibitory Cre-dependent DREADD viral vector AAV2/8-hSyn-HA-KORD-IRES-mCitrine (KORD) into the Pf. Cre-recombinase was delivered to Pf projecting cells via infusion of AAV pmSyn1-EBFP-Cre directly to the Pf (group 1), or retrogradely from STR (group 2) and STN (group 3) to selectively inactivate Pf projections to these nuclei. Also, the effect of activation of Pf neurons with the excitatory viral vector AAV2/5-hSyn-hM3-DIO-mCherry (hM3-DIO) was examined. Electrodes were implanted in the motor cortex (MCx), dorso-lateral STR and SNr. Histology revealed modest DREADD expression in Pf. High beta power in the MCx, STR and SNr local field potential (LFP) activity and coherence between the regions were observed during walking in a circular treadmill. At 4-6 weeks post-surgery, stimulation of the novel inhibitory receptors expressed in KORD-transfected Pf neurons with salvinorin B (SalB, 1 mg/kg) substantially improved clockwise walking in all three groups. Notably, high beta LFP

power/coherence in motor circuits was not altered. In contrast, stimulation of novel excitatory receptors expressed in hM3-DIO-transfected Pf neurons with clozapine-N-oxide (CNO, 5 mg/kg) increased bradykinesia. Results support the view that SalB-mediated reduction of activity in Pf projections to the BG modulates activity in BG output in a manner which reduces motor deficits, while CNO-mediated activation enhances deficits. Ongoing DREADD experiments explore how changes in Pf activity may affect the pattern of high beta bursts as well as spiking activity in the STR, SNr, and MCx during bradykinesia.

Title: Right arm flexion during magnetoencephalography demonstrates more focal and robust sensorimotor beta attenuation in Parkinson's patients versus healthy controls

Authors: ***I. E. HARMSEN**[1], N. C. ROWLAND[3], L. G. DOMINGUEZ[2], A. M. LOZANO[1]; [1]Neurosurg., [2]Neurol., Univ. of Toronto, Toronto, ON, Canada; [3]Neurosurg., Med. Univ. of South Carolina, Charleston, SC

Abstract: *Background:*
Parkinson's disease is a neurodegenerative movement disorder that is characterized by abnormal local field potential beta (13-30 Hz) activity in the basal ganglia that correlates with reduced voluntary movement. In contrast, our prior study using electrocorticography (ECoG) suggests the sensorimotor cortex of patients with Parkinson's has an oscillatory profile that may act to promote movement.
Objective:
To more clearly define the role of oscillatory activity in Parkinson's, we conducted whole-head magnetoencephalography (MEG) recordings to measure oscillatory changes in brain regions beyond the reach of ECoG.
Methods:
MEG recordings were performed in 5 Parkinson's patients (1 female, ages 52-71) with deep brain stimulation (DBS) in the off state. We analyzed MEG signals during a right arm flexion (RAF) motor task and compared findings to similar recordings in 9 healthy controls (4 females,

ages 17-79). MEG signals were analyzed in sensor- and source-space to assess whole-brain as well as motor-specific oscillatory changes.
Results:
We show that (1) the sensorimotor cortical region involved in beta desynchronization is more focal and robust in Parkinson's patients during RAF compared to controls (p=0.039) and (2) within the Parkinson's cohort, disease severity as measured by tremor score is inversely correlated with the ability to attenuate sensorimotor beta power (Pearson's correlation coefficient = 0.952, p=0.048).
Conclusions:
Our findings suggest that voluntary movement modulates beta activity within a more restricted cortical region in Parkinson's patients than in healthy controls, and within that more focal region the beta attenuation during movement is more robust. This supports the conclusion from our prior study that the Parkinsonian cortex instantiates compensatory changes in order to preserve voluntary movement. Characterizing these neurophysiological differences improves our understanding of Parkinson's pathophysiology and lays the foundation for understanding the modulatory effects of DBS.

Title: Pathological response of striatal projection neurons to dopamine is associated with abnormal involuntary movements in Parkinsonian rats

Authors: *X. CAO[1], **C. ZHENG**[1], G. CHEN[2], W. ZENG[1], Y. XU[1];

Abstract: L-DOPA-induced dyskinesia (LID) is a major complication of long-term dopamine replacement therapy in Parkinson's disease. Dysregulation of striatal projection neurons (SPNs) is thought to play a role in the mechanisms underlying LID development. However, functional changes in the SPN response to dopamine have not been fully profiled in rodent models of LID.

This study was aimed at examining the SPN activity changes in response to dopamine during the development of abnormal involuntary movements (AIMs, the equivalent of the primate LID) in hemi-parkinsonism rats. Fifteen rats with unilateral 6-OHDA-lesion were injected with L-DOPA (12 mg/kg plus benserazide 6 mg/kg, i.p.) for 7 days to induce stable AIMs. On L-DOPA treatment days 1 and 7, motor behavior (AIMs scores) was correlated with in vivo electrophysiology analyzing LFP and single cell activity in both primary motor cortex and dorsolateral striatum. The pharmacological response to the classic antidyskinetic agent amantadine (60 mg/kg, i.p.) or a metabotropic glutamate group II receptors 2/3 (mGluR2/3) agonist LY354740 (12 mg/kg, i.p.) was used to assess the specificity of physiological changes. As AIMs established during L-DOPA treatment for one week, high γ (hγ) oscillation predominated during the motor response in cortex and striatum, the number of unstable SPN responses to dopamine increased, and the coherence between these patterns of oscillation and spiking activity also increased. Amantadine significantly reduced AIMs scores, in parallel to reduction of hγ oscillation, and more markedly to a decrease in unstable SPN responses to dopamine. In contrast, LY354740 significantly shortened LID duration, but was weaker in diminishing the strength of LID or decreasing the proportion of unstable SPN responses. In conclusion, the development of AIMs in the rat model of PD is associated with the typical changes in corticostriatal network and SPN activity that characterize altered dopamine responses. The physiological correlation of amantadine or LY354740's antidyskinetic effect supports a key role of unstable SPN responses in the generation of the rodent LID.

Title: Modulation of D3 receptor expression by D3nf isoform in striato-nigral projections of the 6-OHDA denervated rat

Authors: *B. CAMPOS[1], J. AVALOS-FUENTES[2], C. PIÑA LEYVA[2], H. CORTÉS[3], F. PAZ-BERMUDEZ[2], B. FLORÁN GARDUÑO[2];
[1]Pharmacol., [2]Physiology, Biophysics and Neurosciences, CINVESTAV, Mexico City, Mexico; [3]CENIAQ, Inst. Nacional de Rehabilitacion, Mexico City, Mexico

Abstract: The functional response to dopamine D3 receptors (D3R) activation in striato-nigral projections can be mediated by two different signaling pathways, one designated as "typical" in which D3R are coupled to Gi proteins inhibiting adenylyl cyclase activity and in consequence cAMP formation. A second called "atypical" in which D3R stimulates Gs proteins when D1R

are co-activated, increasing adenylyl cyclase activity. It has been suggested that the abundance of the non-functional isoform of the D3R called D3nf determines the density of D3R at the plasma membrane level. In striato-nigral projections, signaling of D3R normally “atypical” becomes “typical” during experimental Parkinson. In the present study we determined whether the two modalities of signaling are correlated with the relative expression of D3R and its isoform during experimental Parkinson. We induced hemiparkinsonism in adult male Wistar rats by the unilateral administration of 6-OHDA in the middle forebrain bundle. Using RTq-PCR we found a decrease in D3nf’s mRNA expression in the lesioned striatum. Western Blot determinations showed a decreased in protein expression levels of D3nf isoform in striatum and substantia nigra reticulata (SNr) of the lesioned hemisphere. This decrease in the relative expression of D3nf isoform was accompanied by an increased in the Bmax of D3R in the striatum of the lesioned hemisphere as indicated by binding with [^{3}H] 7-OH-DPAT. Further, there was a change in the functional response to D3R activation; in the control hemisphere, D3R activation potentiated cAMP formation and [^{3}H]-GABA release induced by high K^+ with D1R co-activation, i.e. an “atypical” response in striatum as well as SNr. In contrast, in the lesioned hemisphere, D3R activation inhibited cAMP formation and [^{3}H]-GABA release induced by D1R activation, i.e. a “typical” response was observed. Furthermore, *in vivo* intranigral co-activation of D3R in the lesioned hemisphere has opposing effects over D1R activation, evaluated by contralateral rotational behavior, this “typical” response was changed to “atypical” once we pharmacologically eliminated the D3R signaling pathway with N-Ethylmaleimide (alkylating agent of Gi proteins). These data indicate that the relative expression of D3Rs and D3nf isoform correlates with the functional response produced by D3R activation and this response is probably mediated by changes in the number of D3R located at the plasma membrane level.

Abstract: Whereas the nature of the etiology of the process underlying clinical deterioration remains unknown, PD is characterized by the progressive loss of Substantia Nigra neurons with two main phases: a prodromal and a symptomatic phase. Despite years of research, we still lack surrogate biomarkers of disease progression. Accumulative evidences have demonstrated the presence of aberrant oscillatory synchronization of neuronal activity across the cortico-basal ganglia-thalamo-cortical circuit in both PD patients and experimental animal models in the symptomatic phase. Using state-of-the-art EEG methodologies, we here investigated the development of beta-band (~30Hz) in two rat models of PD as well as their response to the reference dopamine replacement therapy, L-DOPA, once degeneration is established. We used the unilateral 6-OHDA rat model that mimics PD late stage and the bilateral AAV-alpha-synuclein (alpha-Syn) rat model that allows investigating the progression of the degeneration over several weeks. In the late stages of the two models, a prominent beta-band (~30Hz) was observed in the motor cortex (inexistent in control rats) that was reduced after L-DOPA challenge. This treatment also induced a prominent increase in the gamma (γ)-band (80-100Hz). In the AAV-alpha-Syn rat model, we observed the progressive rise in beta-band power from the prodromal phase onwards. Since the late stage data fit with the clinical literature, we propose that the beta-band rise may represent a predictive, reliable, objective and clinically-relevant biomarker for the validation of disease modifying experimental therapeutics. In addition, our data call for a clinical validation of this biomarker.

Title: Freezing of gait in Parkinson's disease leads to lateralized alterations of resting state functional connectivity

Authors: *O. MIRANDA-DOMINGUEZ[1], A. RAGOTHAMAN[2], M. MANCINI[3], R. J. HERMOSILLO[1], E. J. FECZKO[4], J. G. NUTT[3], D. A. FAIR[1], F. B. HORAK[3];

Abstract: Freezing of gait (FoG) is a brief, episodic absence or marked reduction of forward progression of the feet, despite the intention to walk. Most people with Parkinson's disease (PD) will develop this condition as the disease progresses. FoG might be triggered by different stressors, such as turning or dual-tasking, suggesting that not only motor, but higher order attention systems may be impaired in this condition. In this study, we used resting state functional MRI data to characterize differences in functional connectivity (FC) that might be specific to FoG.
We used well characterized imaging, gait, and balance data from 43 individuals, specifically: 13 participants with PD and FoG, 14 participants with PD and without FoG and 16 healthy controls. Groups were matched on age, disease severity, cognitive status, and levodopa medication. MRI data was processed using surface-based registration plus in-house denoising methods (https://github.com/DCAN-Labs). Time courses were strictly scrutinized for head movement. Surviving frames (5 minutes of data, frame displacement <= 0.3 mm) were used to characterize FC using a pre-defined set of Regions of Interest (ROIs) that also groups ROIs based on functional networks, including motor and attention systems. Differences in FC secondary to diagnosis (healthy controls, people with PD with and without FoG), ROIs, functional networks, and their interaction were identified using repeated a measures ANOVA test.
We found significant differences in FC between groups. Post hoc analysis revealed alterations at different spatial resolutions: Functional systems and ROIs. Control and PD participants exhibited significant differences in sensorimotor, subcortical, visual and higher order heteromodal systems (Dorsal Attention, Cingular-Opucular, Default). FC between the dorsal attention and visual systems indicated a trend in discriminating participants with and without FoG. Seed-based post hoc analysis revealed significant differences in FC between participants with and without FoG for several ROI pairs in the left hemisphere: the globus pallidus and two regions in the somatosensory cortex and between two ROIs belonging, one to the default mode network, and the other ROI to the insular/vestibular system. We also found significant associations between FC and objective measures of FoG for the areas identified as relevant for FOG.
These observations suggest that the interplay between motor, dorsal attention and visual systems are critical in the pathology of FOG.

Abstract: The dopaminergic (DA) neurons of the Substantia nigra *pars* compacta (SNc) are of great interest as their degeneration underpins the debilitating motor symptoms of Parkinson's disease (PD). DA neurons of the ventral SNc (vSNc) are more vulnerable than those of the dorsal SNc (dSNc) and of the Ventral Tegmental area (VTA). Recent single cell studies have furthered our understanding of DA heterogeneity and have identified multiple molecularly distinct subtypes, at least one of which is particularly vulnerable in a toxin model of PD. How these subtypes develop remains unclear. Here, using intersectional and subtractive lineage tracing techniques, we aim to determine a developmental basis for DA neuron diversity. We also use these genetic methods to unambiguously target subtypes and study their axonal projections and functions.

For Parkinson's Dis. and Dept. of Neurol., Atlanta, GA

Abstract: Despite extensive research, our understanding of the pathophysiology of the basal ganglia-thalamocortical functional circuitry in Parkinson's Disease (PD) remains incomplete. One key feature of parkinsonism is an increased GABAergic inhibition of the ventral motor thalamic nuclei, namely the ventral anterior and ventral lateral (VA/VL) nuclear group. According to current models of the basal ganglia circuitry, this increased thalamic inhibition originates from an abnormally overactive GABAergic tone from the basal ganglia output nuclei. A less studied source of GABA in the VA/VL are the inhibitory GABAergic interneurons. Because these interneurons are absent from the rodent motor thalamus, little is known about their anatomy, function, or role in this thalamic region, and in the centromedian/parafascicular (CM/Pf) nuclear group, another main target of basal ganglia outflow in primates. Therefore, the present project aims to generate a detailed characterization of the abundance and synaptic integration of interneurons into the functional basal ganglia-thalamocortical circuitry in normal and parkinsonian states. We utilized 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) to induce parkinsonism in adult rhesus monkeys. We performed an unbiased stereological count of interneurons and thalamocortical cells in VA/VL and CM/Pf by immunostaining with anti-GABA and anti-NeuN, respectively. Data obtained so far from 3 control and 2 parkinsonian monkeys indicate that GABAergic interneurons account for ~17% and ~8% of the total neuronal population in VA/VL and CM/Pf, respectively, without any significant difference between control and parkinsonian monkeys. Three-dimensional electron microscopic reconstruction of VA/VL and CM/Pf interneurons is in progress to determine potential changes in the synaptic microcircuitry of these interneurons in parkinsonian monkeys. Results of this study will set the stage for a deeper understanding of the functional integration of GABAergic interneurons in the physiology and pathophysiology of the basal ganglia-thalamocortical circuitry in normal and parkinsonian state.

Title: Using diffuse optical tomography to understand deep brain stimulation's impact on cortical networks

Authors: *A. SHERAFATI[1], A. T. EGGEBRECHT[1], T. M. BURNS-YOCUM[2], H. M. LUGAR[1], A. NARAYANAN[1], T. DOTY[1], S. EISENSTEIN[1], A. M. SVOBODA[1], M. L. SCHROEDER[1], A. Z. SNYDER[1], M. USHE[1], J. P. CULVER[1], T. HERSHEY[1]; [1]Washington Univ. In St. Louis, St. Louis, MO; [2]Indiana Univ., Bloomington, IN

Abstract: Deep brain stimulation of the subthalamic nucleus (STN DBS) in Parkinson disease (PD) can provide substantial motor benefit yet can also produce unwanted cognitive side effects. Current neuroimaging tools lack either necessary temporal resolution (PET), or optimal safety due to contraindications (fMRI) for measuring the neural mechanisms underlying the effects of STN DBS. In this study, we asked 2 questions related to this observation. First, is High-Density Diffuse Optical Tomography (HD-DOT) a feasible tool with sufficient resolution for studying PD patients and understanding the neural activity underlying benefits and side effects of the STN DBS? Second, can we measure the impact of STN DBS on functional connectivity (FC)? To answer these questions, 11 PD patients (2f; ages 55-66) with STN DBS and 11 controls (8f; ages 52-71) were scanned with a previously described HD-DOT device [1] during auditory and visual tasks, and resting state, while controls also underwent an fMRI scan with the same protocol. We validated the feasibility of HD-DOT for scanning controls and PD patients with their STN DBS ON and OFF, recapitulating fMRI results, using a previously described data analysis pipeline [2]. Auditory and visual tasks evoked anatomically appropriate patterns in both controls and PD patients. In addition, PD subjects with DBS OFF had reduced within network FC in somatomotor, visual, and auditory resting state networks and between network FC with

somatomotor and auditory, replicating findings by Gratton et al using fMRI [3]. We also found that FC between somatomotor and frontoparietal networks was greater in PD than controls. Finally, turning DBS ON appears to alter within and between network connectivity for somatomotor, auditory, and DMN (Fig 1). These preliminary results validate that HD-DOT has sufficient feasibility and resolution to accurately map task responses and FC within and between cortical networks in PD patients with STN DBS.

Title: Parkinsonian affected basal ganglia output shows condition specific attenuation

Authors: *A. TEKRIWAL[1], M. LINTZ[2], J. A. THOMPSON[3], G. FELSEN[4];
[1]Physiol. and Biophysics, Neurosurg., Univ. of Colorado Sch. of Med., Denver, CO; [2]Psychiatry, [3]Neurosurg., [4]Physiol. and Biophysics, Univ. of Colorado Sch. of Med., Aurora, CO

Abstract: Parkinson's disease (PD) is a progressive neurodegenerative disorder caused by loss of dopaminergic neurons (DANs) in the basal ganglia (BG). Motor impairment in PD is highly heterogenous and the severity and expression of impairment may depend on the context of the movement. Although the context-dependent variability of motor impairment is well documented in the clinical literature, the underlying neural mechanisms are not well understood. To investigate, we recorded neural activity from BG output nuclei of hemi-PD and control mice trained on a two-alternative forced choice task. We elicited unilateral DAN loss via 6-hydroxydopamine infusion into the left substantia nigra pars compacta and recorded from a principal output nucleus of the BG, the substantia nigra pars reticulata (SNr), ipsilateral to DAN loss. We compared behavior and neural activity between hemi-PD and control mice, and between two conditions requiring otherwise-identical orienting movements. Under the "stimulus-guided" condition, the direction of movement (left vs. right) was selected based on the identity of the stimulus. Under the "internally-specified" condition, the direction of movement was selected based on recent history of rewarded movements. Blocks of stimulus-guided and internally-specified trials were interleaved within each behavioral session. We found that DAN loss led to an ipsilateral bias on both stimulus-guided and internally-specified trials. Consistent with this bias, we found that a larger proportion of SNr neurons in hemi-PD than control mice exhibit movement-related activity promoting ipsilateral movement. In addition, in control mice, we found that SNr activity depended more strongly on movement direction (i.e., activity was more direction selective) in internally-specified than stimulus-guided trials. In hemi-PD mice, the distribution of direction preferences closely resembled that of control mice on internally-specified trials, but differed on stimulus-guided trials: specifically, SNr activity in hemi-PD mice was less direction-selective than in control mice on stimulus-guided trials. These results suggest a neural substrate for how PD may alter movements performed under some conditions more than others.

Neuropharm. Unit, Oxford, United Kingdom

Abstract: Parkinsonism and its associated motor impairments have been attributed to an aberrant rhythmicity of large-scale neural dynamics in the basal ganglia. The biophysical mechanisms concerning the origins and control of this rhythm, occurring at beta frequencies (14-30 Hz), are currently unknown. Multiple hypotheses exist to explain the emergence of pathological oscillations as arising from alterations in the strength of connections in the cortico-basal-ganglia network. In this work we employ an inverse modelling framework in which we fit parameters to simulate data close in form to that observed empirically. Specifically, we optimize model parameters to match the spectral power and directed functional connectivity of a set of experimental recordings: local field potentials from striatum, external globus pallidus, and subthalamic nucleus; and electrocorticography from primary motor cortex in Parkinsonian rats with 6-OHDA induced dopamine depletion. After model parameters are fit to time averaged statistics of the data, we move beyond the steady state to investigate the time evolving processes that act to shape the intermittencies in rhythms- so called beta bursts -which have become of recent interest to the field.
Using a formal model comparison approach, we identify the optimal network architecture to explain the empirical data. Having established the best fitting model we then conduct a systematic *in-silico* lesion and stimulation study in order to a) determine the origin and evolution of beta rhythms in the network; b) analyse the roles of particular pathways in shaping the properties of intermittent beta activity such as burst length, duration, and phase synchronization; and c) investigate novel stimulation strategies to suppress pathological network dynamics. We find evidence for the role of the so called cortico-subthalamic "hyperdirect" pathway in modulating subcortical beta activity by supplementing antecedent bursts arising in the striatum. Overall this work provides testable predictions for experimental manipulations of pathological dynamics in the basal ganglia.

Title: Dissociable locations of beta frequency power and coherence in patients with Parkinson's disease

Authors: ***P. M. LAURO**[1], M. PINTO[1], E. SCHAEFFER[1], S. LEE[1], W. F. ASAAD[2]; [1]Neurosci., [2]Neurosurg., Brown Univ., Providence, RI

Abstract: Exaggerated beta frequency (13 − 30 Hz) oscillations in basal ganglia nuclei such as the subthalamic nucleus (STN) are associated with Parkinson's disease (PD). Symptoms of PD are currently measured by the Unified Parkinson Disease Rating Scale (UPDRS). To understand the relationship between beta frequency oscillations, UPDRS scores, and basal ganglia anatomy, we examined microelectrode recordings (MER) from 18 patients with PD receiving deep brain stimulation (DBS) surgery. We then calculated beta frequency power at intraoperative recording sites with at least 20 seconds of data (N = 2310). As patients typically had 3 microelectrodes along the same trajectory, beta coherence was calculated between adjacent electrodes (N = 1540). Beta power and coherence from each hemisphere were then regressed with each patient's lateralized UPDRS III scores. Beta coherence was found to significantly positively correlate (r^2 = 0.15, p = 0.02) with UPDRS scores, whereas beta power showed no such relationship (r^2 = 0.04, p = 0.21). Using intraoperative CT and preoperative MR images, all MER sites were then reconstructed to patient imaging, and combined across patients to the MNI PD25 atlas. Beta power and coherence were then plotted separately. To determine where beta power or coherence were observed above chance, each voxel's average metric value was compared to a bootstrapped (10000 iterations) distribution of all metric values across voxels. Each voxel's empirical p-value was determined to be significant based on the Benjamini-Hochberg correction at a FDR of 10%. For beta power, a significant cluster of 27 $1mm^3$ voxels was found in the dorsolateral STN (MNI coordinates: x = +15.8, y = +12.0, z = -3.5). For beta coherence, four significant 7 $1mm^3$ voxel clusters were found throughout several structures superior to the STN, including the thalamus and globus pallidus pars interna (GPi). Together, these results suggest that different spectral properties of beta frequency oscillations exhibit dissociable spatial locations throughout the basal ganglia, and relate differently to PD symptoms. Future work will examine the relationship of specific PD symptoms and subtypes to spectral features and spatial locations.

Abstract: Background: Body weight gain is observed in the majority of patients with Parkinson's disease (PD) who undergo deep brain stimulation (DBS) of the subthalamic nucleus (STN). Aside from changes in energy expenditure, an abnormal modulation of the mesolimbic system is accounted for changes in motivated behavior, food intake, and body weight. **Objectives:** To investigate the modulatory impact of STN DBS on the neural responses to food stimuli in PD patients.**Methods:** Fifteen medicated PD patients (mean age 63.7 years (SD 8.89)), mean disease duration 13 yrs (SD 3.49) were investigated using functional MRI (1.5T) during (i) active and (ii) switched off DBS. Food and neutral images (kitchen equipment) were presented in a slow event related design. A whole brain and a ROI-based analysis were performed. **Results:** Whole brain GLM revealed a main effect of DBS in the left lingual gyrus, right cuneus, right middle cingulate gyrus and the central operculum bilaterally (cluster level, uncorrected, $p \leq 0.001$). An interaction was found for food images during active DBS in the left lingual gyrus and the superior parietal lobe bilaterally (FWE, $p \leq 0.001$). During inactive DBS, food images were associated with an increased BOLD response in the left lingual gyrus (FWE, $p \leq 0.001$). In contrast, processing of non-food images showed an increased BOLD response in the left superior parietal lobe (FWE, $p \leq 0.001$) and during inactivated DBS in the left superior occipital gyrus (FWE, $p \leq 0.001$). ROI-based analysis revealed a decreased activation of the left amygdala (%signal change; $p=0.037$, uncorrected) and an increased activation of the right insula ($p=0.044$) during food image processing. **Discussion:** DBS may exert complementary actions on neural networks that could collectively give rise to an increased vulnerability to food cues. Firstly, DBS

globally increased attentional control and may thus bias the brain to an increased awareness of external stimuli. Secondly, reward-related circuits were activated as a function of STN DBS arguing that a co-activation of the limbic portion of the STN may influence hedonic control of food intake.

Abstract: Objective: Deep brain stimulation (DBS) has become a widely adopted treatment for Parkinson's disease (PD) and is thought to modulate the balance of activity between the direct and indirect pathways of the basal ganglia. Typically, high-frequency stimulation (~130 Hz) is delivered to a target such as the subthalamic nucleus (STN), a node in the indirect pathway of the basal ganglia. Lower frequency stimulation at the STN is generally less effective and may in fact exacerbate patient symptoms. We hypothesized that stimulating a node in the direct pathway (the Substantia Nigra pars reticulata, SNr) rather than the indirect pathway may elicit a different response to high vs. low frequency stimulation.
Methods: We recruited 6 PD patients with implanted STN DBS systems. Patients engaged in a continuous motor performance task while stimulation location and frequency were varied on different trials. Specifically, we compared stimulation at the therapeutic contact vs. the deepest implanted contact, closest to the SNr.
Results: High frequency (130 Hz) stimulation at the therapeutic contact (more dorsal) typically improved motor performance by 15% compared to lower frequency (20 Hz) stimulation at the same contact ($p<0.001$). In contrast, at the deepest contact, lower frequency stimulation often improved motor performance by 28% compared to high frequency stimulation ($p=0.066$).
Conclusions: These results suggest that lower frequency stimulation at the deepest contact (closest to the SNr) may in fact be more beneficial than high frequency stimulation at that location, consistent with the notion that driving the SNr may provide some therapeutic benefit.

Title: Phase-related high-beta oscillations in Parkinson's disease during stepping in a virtual environment

Authors: J. K. BAARBÉ, ***S. TRAN**, K. J. LIZARRAGA, J. SARAVANAMUTTU, P. SAHA, R. CHEN;
Toronto Western Hosp., Toronto, ON, Canada

Abstract: Background: Patients with Parkinson's disease (PwPD) have increased high-beta oscillations (21-35 Hz) in the sensorimotor cortex, which may be anti-kinetic and disrupt motor preparation. It is unknown how high-beta oscillations in the sensorimotor cortex change during progressive stepping in PwPD and how it is modulated by dopaminergic medications.
Hypothesis: We believe that high-beta oscillations will synchronize during progressive phases of visually-guided steps during OFF medication states in PwPD, while dopaminergic medications will desynchronize these oscillations.
Methods: We recorded whole-head EEG in 10 PwPD [2 women, median age = 65 years, median PD duration = 8 years]. PwPD were assessed on two separate days, ON-medication and OFF-medication after a 12-hour withdrawal period. PwPD were required to step on foot pedals to progress down a virtual hallway while seated. Practice trials were conducted using a metronome set at 2 Hz and subjects were asked to maintain the same pace during testing. Time-frequency data was time-warped to individual rates. High-beta power was averaged over right toe and right heel phases. The difference in high-beta power between the phases was assessed (heel-down versus toe-down) at three EEG regions: premotor/frontal (F1, Fz, F2, FC1, FCz, FC2), motor (C1, Cz, C2), and parietal (CP1, CPz, CP2, P1, Pz, P2).
Results: No difference in high-beta power was observed between toe- and heel-down phases. Stepping amplitudes remained the same between phases in both medication states. However, high-beta power between ON- and OFF-medication states was significantly different in both motor ($p = 0.04$) and parietal ($p = 0.02$) regions. As such, OFF-medications increased high-beta power compared to ON-medication states, which decreased high-beta power, during the transition from toe-to-heel phases.
Conclusion: This study demonstrates that dopaminergic medications reduce high-beta power in the motor and parietal regions during progressive phases of stepping in a virtual environment.

Title: Frequency specific neural circuit modulation during optogenetic deep brain stimulation in subthalamic nucleus

Authors: *C. YU[1], I. R. CASSAR[2], J. SAMBANGI[3], W. M. GRILL[3];
[1]Michigan Tech. Univ., Houghton, MI; [2]Biomed. Engin., [3]Duke Univ., Durham, NC

Abstract: Deep brain stimulation (DBS) is an effective therapy for the motor symptoms of Parkinson's disease (PD). The therapeutic effects of DBS are highly dependent on stimulation frequency. High frequency DBS alleviates PD motor symptoms, while low frequency stimulation is ineffective. The subthalamic nucleus (STN) is a well-documented DBS target and has been proven clinically effective. However, the neural mechanisms underlying the therapeutic effects of STN-DBS for PD are still less understood. Here we used the unilateral 6-OHDA-lesioned rat model of PD and applied optogenetic stimulation in the STN using an ultrafast opsin (Chronos) that is able to follow high-frequency DBS. The Chronos construct was packaged into an adeno-associated virus serotype 5 (AAV5) under the control of calcium/calmodulin-dependent protein kinase II (CaMKII) promoter. We quantified the behavioral effects of different frequencies of optogenetic STN DBS on motor symptoms using pathological circling behavior and the adjusting steps test. We performed single unit recordings to quantify changes of neural circuit activity during different frequencies of optical stimulation in the STN of urethane-anesthetized rats (1.2g/kg, subcutaneous). We found that cell-specific optogenetic stimulation of STN local neurons exhibited a strong dependence on stimulation frequencies; high frequency DBS (75, 100, 130Hz) alleviated ipsilateral turning and corrected forelimb stepping bias while low frequency (5Hz and 20Hz) DBS was not effective. Different frequencies of optogenetic stimulation differentially increased or decreased the neural activity in the STN, globus pallidus externa (GPe) and substantia nigra pars reticulata (SNr). High frequency optical stimulation produced larger increases or decreases in neuronal firing rates in comparison to low frequency stimulation. As well, high frequency optogenetic DBS reduced pathological beta band oscillations in the STN and SNr, while low frequency optogenetic DBS had no effect on beta band oscillations. Our results suggest that optical stimulation at high frequencies resulted in stronger reduction of abnormal oscillatory activity in the STN-associated neural circuit and thereby was more effective

than low frequency stimulation at ameliorating pathological circling behavior and improving forelimb stepping. **Funding**: This work was partially supported by the National Institute of Neurological Disorders and Stroke under Award Numbers NIH R01 NS091236, R37 NS040894 and R03 NS108097

Abstract: Parkinson disease (PD) is characterized by the early loss of dopaminergic neurons in the Substantia nigra *pars compacta* (SNpc) ventral tier, which leads to PD cardinal symptoms: postural instability, bradykinesia, rigidity and tremor. Currently, levodopa (L-DOPA) is the most effective therapy used, but long-term treatment is associated with the development of L-DOPA-induced dyskinesias (LIDs). We have previously reported in a rat model that simultaneous optogenetic activation of the direct and indirect striatal pathways elicited abnormal movements (optodyskinesias) that resemble those evoked by levodopa (Hernandez et al, *Mov. Dis*., 2017). Here, we present the data obtained from transgenic mice that allowed us to dissect the striatal circuitry by optically activating each pathway separately. We have found that simultaneous activation of both pathways induces abnormal movements in both control (sham) and dopamine depleted animals (different from what was obtained in rats). Moreover, when we stimulated each pathway separately, optical activation of direct pathway (D1R-expressing) neurons evoked light-induced dyskinesias, while optical activation of indirect pathway (D2R-expressing neurons) promoted freezing behavior and/or ipsilateral rotations. These experiments show that co-activation of both pathways can elicit abnormal movements, but the stimulation of direct

pathway neurons is sufficient and necessary to elicit dyskinetic movements. Finally, we show that while the inhibition of direct pathway is insufficient to block LIDs, activating the indirect pathway shows a striking blockage of this behavior, which may offer a novel way of suppressing these distressing side effects of L-DOPA therapy in PD.

Title: The relationship between temporal sensory discrimination and locomotor ability in Parkinson's disease

Authors: *C.-W. HUANG[1], C.-H. LIN[2], M.-T. TSENG[3];
[1]Grad. Inst. Of Clin. Medicine, NTUCM, Taipei, Taiwan; [2]Dept. of Neurology, Natl. Taiwan Univ. Hosp., Taipei, Taiwan; [3]Grad. Inst. of Brain and Mind Sciences, NTUCM, Taipei, Taiwan

Abstract: Parkinson’s disease (PD) is one of the most widespread neurodegenerative diseases in the world. Patients usually experience motor difficulty such as gait freezing which limits their daily life apparently. Compelling evidence suggests early sensory declination predates motor symptoms of the disease. Since sensorimotor integration plays a key role on locomotor fluency and stability, investigation of sensory abnormality in early stage of PD provides an opportunity to elucidate deterioration of gait dysfunction. The objective of the present research is to examine the interactions of sensory and locomotor aberrance in PD. We has recruited twenty patients with PD (8 men) aged between 54 and 76 years (mean: 63.9) and twenty age- and sex-matched healthy controls (HC). Sensory and gait performances were measured in all participants. Vibrotactile stimuli were delivered from two stimulators to medial dorsum of left calf of subjects for sensory function testing. Somatosensory detection threshold (DT), temporal discrimination threshold (TDT), and spatial discrimination threshold (SDT) were evaluated. Seven-meter walking test was applied for obtaining gait velocity (GV), stride length (SL), and gait cadence (GC) which are central parameters in gait function. Our results showed that both sensory and gait performances in PD patients were impaired compared with HC. Furthermore, there was a significant task-by-group interaction, suggesting that abnormality of temporal discrimination was more severe than that of spatial discrimination in patients. Most importantly, prolonged TDT but not SDT correlated with shortened SL in patients with PD. In conclusion, these results indicate a

unique role of high-level sensory function in gait ability and suggest that impairment in the temporal processing of somatosensory stimuli might contribute to motor dysfunctions in PD.

Title: Parkinsonian slow oscillations in the indirect pathway precede M1 oscillations and predict motor dysfunction

Authors: *T. C. WHALEN[1], A. M. WILLARD[3], J. E. RUBIN[4], A. H. GITTIS[2];
[2]Biol. Sci., [1]Carnegie Mellon Univ., Pittsburgh, PA; [3]Clarion, Clarion University, PA;
[4]Mathematics, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Oscillations in a wide range of frequency bands have been implicated in Parkinson's disease (PD), but due to low frequency noise in awake subjects, slow (0.5-3 Hz) oscillations have been understudied. We developed a novel phase metric to reliably detect single unit spike oscillations embedded in pink noise to dissect the oscillatory content of neurons in the basal ganglia of healthy and Parkinsonian (6OHDA dopamine depleted) mice. In dopamine depleted animals, a large number of neurons exhibit a 0.5-3 Hz oscillation not seen in healthy animals, but we find no oscillations in any other frequency bands Using nonparametric regression, we demonstrate that these slow oscillations are a good predictor of dopamine loss and motor dysfunction, strongly outperforming other physiological measures such as changes in firing rate, irregularity, bursting and synchrony. These slow oscillations arise immediately after loss of D2, but not D1, receptor activation, and are present throughout the indirect pathway - the substantia nigra pars reticulata (SNr), globus pallidus externa, and subthalamic nucleus. A regression analysis shows that small variations in the shape and timing of spike oscillations in the SNr predict similar changes in the motor cortex (M1) approximately 150 msec later. This suggests that slow oscillations are a major contributor to Parkinsonian dysfunction, arise in the basal

ganglia and entrain M1. Similar slow oscillations which have been observed but sparsely studied in human PD patients could be an important target for PD treatment.

Abstract: Neuropsychiatric complications, such as anxiety and depression, are common in patients with Parkinson's disease (PD). Previous studies using the amplitude of low-frequency fluctuations (ALFF) method on resting-state functional magnetic resonance imaging (fMRI) have reported abnormal spontaneous brain activity associated with these mood disturbances in Parkinson's disease (Skidmore et al., 2013; Wang et al., 2018; Wen et al., 2013). Here, we utilized a dynamic ALFF (dALFF) method to examine the temporal variability of local brain activity in PD patients. Thirty-nine PD patients ON medication and twenty-six healthy controls (HCs) underwent 8 min 4-sec resting-state fMRI scans on a GE 3-T scanner (TR = 2s; eyes closed). Pre- and post-processing of resting-state fMRI data were performed using the CONN toolbox (motion correction, spatial normalization to MNI template, spatial smoothing with a 6 mm FWHM Gaussian kernel, nuisance signal regression via a CompCor, and band-pass filtering of 0.0227-0.1 Hz). We captured the dynamic patterns of the ALFF using a sliding windows approach implemented in the DynamicBC toolbox (Liao et al., 2014). Resting state data were segmented into a series of overlapping windows (length = 44s, overlap =90%). For each window, a whole-brain ALFF map, defined as the intensity of low-frequency oscillations, is calculated using a Fourier transformation, resulting in 72 time-varying ALFF maps. These maps were standardized by dividing the mean ALFF values. The temporal variability of the dALFF was quantified as the variance of time-varying ALFF maps. Here, we examined the group differences

between the PD and HC groups on the temporal variability map of the dALFF as well as its relationship with the degree of depression and anxiety symptoms, as measured by the Beck Depression Inventory-II and State-Trait Anxiety Inventory respectively, in the PD group (cluster-level FWE corrected $p < 0.05$). We found that PD patients compared to HC showed decreased temporal variability of the dALFF in the bilateral ventrolateral prefrontal cortex and brain stem. In addition, the depression severity in the PD group was positively correlated with the degree of the dALFF temporal variability in the right thalamus, indicating PD patients with more severe depressive symptoms exhibited more variant intrinsic brain activity in the thalamus. We also found a significant positive correlation between the degree of the anxiety symptoms and the dALFF temporal variability in the cerebellum. Our findings support the involvement of subcortical regions in mood disturbances in PD, providing further insight into behavioral complications of the disease.

Dept Neurol., New York Univ. Langone Hlth., New York, NY

Abstract: Levodopa therapy is the most effective treatment for PD, but long-term use is often complicated by abnormal involuntary movements termed levodopa-induced dyskinesia (LID). PD and LID arise from complex compensatory changes throughout the basal ganglia, including the internal segment of the globus pallidus (GPi) and substantia nigra pars reticulata (SNr). GABAergic neurons are the main neurons in the SNr and these project to the mesencephalic locomotor region (MLR), parafascicular nucleus (PF), ventrolateral nucleus (VL), ventromedial nucleus (VM), and reticular nucleus (RT). Here, we explored the role of SNr in PD and LID by selectively regulating SNr GABAergic neurons activity in VGAT-Cre mice using chemogenetic and optogenetic techniques. Using activating (hM3d-Gq) and inhibitory (hM4d-Gi) DREADDs + clozapine-N-oxide, we bidirectionally modulated SNr GABAergic neuron activity in non-lesioned mice, dopamine-depleted mice, and mice with LID while measuring forepaw stepping,

openfield activity, and abnormal involuntary movements (AIM). In non-lesioned mice we found that increasing SNr GABAergic neuron activity with hM3d-Gq caused akinesia similar to dopamine-depleted mice (unilateral MFB 6-OHDA lesion), while the inhibition of SNr GABAergic neurons with hM4d-Gq had the opposite effect. However, in 6-OHDA-lesioned mice, both activation and inhibition of SNr GABAergic neuron activity improved PD symptoms. In mice with LID we found that increasing SNr GABAergic neuron activity significantly attenuates LID, and inhibiting SNr GABAergic neuron activity increased LID expression. To address whether specific SNr targets mediated these changes, we expressed ChR2 in SNr GABAergic neurons and stimulated their cell bodies or axonal projections to the PF, VM/VL, RT, and MLR with blue light. Optogenetic activation of SNr cell bodies improved both PD and LID symptoms. Interestingly, stimulating SNr axon terminals in PF improved PD symptoms, but did not affect LID, while stimulation SNr axon terminals in MLR significantly decreased LID without affecting PD symptoms. Because the PF is expected to be inhibited in the PD state, it was surprising to find that further inhibition could improve PD symptoms. To further address this, we expressed the activating hM3d-Gq construct in PF glutamatergic neurons in VGLUT2-CRE mice and found that increasing PF activity significantly improved LID. Our study suggests that direct modulation of basal ganglia output of the SNr GABAergic neurons improve PD symptoms and LID expression through SNr targets.

Title: Layer-specific cortical changes in response to deep brain stimulation of the subthalamic nucleus

Authors: *D. M. TAYLOR[1,2,3], T. JOHNSON[1,2,3], S. MORALLE[1,2], S. MEADE[1,2], B. CAMPBELL[1], K. BAKER[1];
[1]Neurosciences, Cleveland Clin., Cleveland, OH; [2]Functional Electrical Stimulation Ctr. of Excellence, Louis Stokes Cleveland VA Med. Ctr., Cleveland, OH; [3]Biomed. Engin., Case Western Reserve Univ., Cleveland, OH

Abstract: Deep brain stimulation (DBS) of the subthalamic nucleus is often used clinically to treat symptoms of advanced Parkinson's disease. However, the mechanism of action of DBS is still uncertain as DBS likely alters firing behavior in multiple parts of the motor control network. DBS was traditionally thought to improve Parkinson's symptoms by orthodromic modulation of the basal ganglia-thalamo-cortical pathway. However, in recent years, antidromic activation of the cortex via 'hyperdirect pathway' neurons has been posited as a potential therapeutic mechanism of DBS. The hyperdirect pathway consists of cortical projection neurons that send axonal branches to the subthalamic nucleus. Modeling work suggests antidromic activation of these axons from the subthalamic nucleus to the cortex has the potential to have a widespread modulatory impact on the cortical network. This is because the DBS-induced action potentials not only travel antidromically to the somas in the cortex, they can also propagate throughout the extensive cortical axonal branching structure to engage synapses across a range of cortical layers and neuronal targets. In this study, we used intracortical microelectrodes to simultaneously record from different layers in the motor cortex while applying DBS to the subthalamic nucleus in animal models of Parkinson's disease. Our initial results showed slow layer-specific shifts in the baseline recorded voltages when continuous DBS is turned on/off. In addition, we also saw rapid layer-specific pulse-synced evoked response patterns reflecting the direct and synaptic effects of each individual stimulation pulse. To further tease out the therapeutic relevance of these two cortical responses occurring at different time scales, we are systematically varying DBS patterns across a range of therapeutic and non-therapeutic settings to identify response features that consistently appear across a wide range of therapeutic settings. Results from this analysis could suggest refinements in how DBS is delivered in order to maximize the therapeutic benefit while reducing side effects and power consumption.

Title: Potentials evoked by directional deep brain stimulation of the subthalamic nucleus region recorded using electrocorticography in the non human primate

Authors: *B. A. CAMPBELL[1], H. CHO[1], C. E. WYANT[1], A. G. MACHADO[2], K. B. BAKER[1];

Abstract: Electrical stimulation in the region of the subthalamic nucleus (STN) is known to induce widespread changes in neural activity across the basal ganglia thalamocortical network. A better understanding of how deep brain stimulation (DBS) modulates cortical activity holds potential to inform its mechanistic underpinnings and help efforts to identify control signals for next-generation, adaptive DBS paradigms. In the current study, the effects of STN DBS on cortical LFP activity was examined in two, naïve non-human primates instrumented with scaled, six contact directional DBS lead (Abbott Medical) in the area of the STN combined with bilateral, twelve-channel subdural, ECoG paddle electrodes spanning anterior parietal to prefrontal cortical regions. The relative effect of annular versus directional and biphasic versus monophasic (anodal versus cathodal) stimulation paradigms as well as changes in pulse width (20 - 200 usec) and frequency (3.1 - 185.1 Hz) on evoked cortical LFPs was evaluated in the awake animal. Annular stimulation below the threshold for motor activation (~ lateral capsule spread) was associated with multi-phasic cortical potentials marked by early, high-frequency components that included peaks as early as 0.5 ms post-stimulation, maximal across motor and premotor cortices, followed by sequentially broader peaks that persisted for as long as 100 ms post-stimulation. Marked differences in the cortical potentials were observed based upon stimulus polarity, with pseudo-monopolar cathodal stimulation yielding larger evoked responses than anodal stimulation conditions. During biphasic, symmetric stimulation, the order of the anode/cathode pulses failed to have a significant impact on component latencies or amplitudes. Responses were further sensitive to directionality, with differences in response morphology observed across the three, 120-degree directions afforded by the lead. Finally, the short-latency (<10 ms) components did not appear to be significantly influenced by pulse frequency up to 185.1 Hz. These data begin to characterize the effects of STN DBS stimulation parameters on LFP activity across cortical motor and premotor regions and provide the foundation for further comparisons to be made across the parkinsonian state, including untreated and treated conditions.

Abstract: Parkinson's Disease (PD) leads primarily to motor impairments such as tremor, rigidity, bradykinesia and postural instability. The pathogenesis of these impairments is related to dopaminergic neurotransmission in the basal ganglia. Despite having shown an enormous potential to help maintain motor function in PD, little is known about how cardiovascular exercise interacts with dopamine (DOPA). Understanding this interaction is crucial because the rapid loss of dopaminergic neurons is the pathophysiological signature of PD and impairs their capacity to acquire and retain motor skills. We investigated the interactive effects of cardiovascular exercise and DOPA on motor learning in people with PD. Twenty-five individuals (52-75 years old) diagnosed with moderate PD reported to the laboratory at 8 a.m. in a fasting state after an overnight withdrawal of levodopa (L-DOPA) and were randomly divided into four groups: DOPA+EXE, DOPA+CON, NDOPA+EXE, NDOPA+CON. Before practicing a visuomotor task the DOPA groups received their normal dose of L-DOPA while the NDOPA groups received a placebo administered in a double-blinded fashion. Twenty minutes after practicing 5 blocks of a visuomotor task, the EXE groups performed 15 mins of high-intensity interval training cycling while the participants of the CON groups underwent 15 mins of rest. Participants performed one block of the motor task 48 hours after motor practice to assess skill retention. A linear mixed model with group and block of motor practice as fixed interaction terms and subject as random intercepts was used to assess differences among groups in motor skill acquisition and retention. The linear mixed model revealed a significant group x block interaction ($F = 3.36$; $p < 0.001$). Planned comparisons revealed no differences among groups at baseline (p-value range: 0.46-0.92) or when comparing the changes from baseline to the last block of motor practice (i.e. skill acquisition) (p-value range: 0.19-0.88). In contrast, motor skill retention (estimate ± standard error) was significantly greater in DOPA+EXE than NDOPA+CON (5.51 ±1.67, z=3.92, p = 0.001) and in DOPA+EXE compared to DOPA+CON (3.45 ± 1.74, z=1.99, p = 0.05). These preliminary findings indicate that a single bout of intense cardiovascular exercise can improve skill retention in PD but only when dopamine precursors are co-administered. Conclusively, exercise appears to have a synergistic relationship with DOPA to optimize motor learning. Timely combining the effects of L-DOPA medication with sessions of exercise and motor learning could maximize the effects of cardiovascular exercise on motor function in people with PD.

Title: Optimizing dance interventions to improve motor function in people with Parkinson's disease and older adult

Authors: *P. GATES[1], J. H. KIM[1], R. MELCZAK[1], J. MEGGITT[1], F. DISCENZO[2], A. L. RIDGEL[1];
[1]Kent State Univ., Kent, OH; [2]Rockwell Automation (retired), Cleveland, OH

Abstract: Dance comprises a broad range of techniques and styles which have been utilized in classes specifically designed for individuals with Parkinson's disease (PD) and healthy older adults. Previous studies have shown that a series of dance sessions can improve balance, posture and mobility for people diagnosed with PD and healthy older adults. However, these studies have not analyzed the linkage between repetitive movement types and persistent changes in motor skills. In order to begin understanding the causative factors of repetitive movement types that result in improved motor skill performance, the functional relationship between movement features and observed performance improvements needs to be examined. PURPOSE: To identify dance movement patterns resulting in the greatest improvement in tests of gait, balance and upper extremity function using partnered and non-partnered dance to music in PD and healthy older adults. We hypothesize that scripted variation in movement will promote improvements in motor performance. METHODS: Participants with and without PD in structured group dance classes were recruited for this study. Performance measures of upper and lower extremity were collected before and after each dance class. Motion capture, video and live observations were used to examine movement patterns. RESULTS: Individuals with PD had slower baseline performance in the 9 hole peg test (9HPT) than healthy older adults in both left ($p=0.026$, 33.5s vs 24.9s) and right hand ($p=0.008$, 31.2s vs 26.5s). There was also a significant improvement in the 9HPT for the left hand after the dance classes in the individuals with PD ($p=0.035$, 3.44s). Participants with PD saw no differences in hip range of motion or maximum movement angles between the different dance types, however those without PD did see such differences ($p< 0.01$ for left and right hip flexion, and left and right hip rotation). Factors that led to observed improvements in mobility and movement execution included: repetition of foundational weight shifts in a separate exercise, engagement of the spine and arms in counterbalancing movement in the legs, incorporating flexion at the knee into the dance stride, and partnering with a moderately-skilled dancer. Increased amplitude and ease of stride and greater lift in the feet in

locomotion were also documented. CONCLUSION: These preliminary results suggest that repetitive shifts in balance and movement during dance with music can lead to upper extremity motor performance and increased amplitude of movement in the lower extremity in individuals with PD. The differences in ROM and maximum angles of motion suggest possible future directions for dance instruction.

Title: Deep brain stimulation of the subthalamic nucleus may not modulate beta burst activity in persons with Parkinson's disease

Authors: *S. L. SCHMIDT, J. J. PETERS, D. A. TURNER, W. M. GRILL;
Duke Univ., Durham, NC

Abstract: Oscillations in the local field potential (LFP) represent synchronous neural activity and have traditionally been viewed as relatively stable over the time scale of seconds. However, recent focus has shifted to short, high-amplitude LFP events known as bursts. The presence of bursts was correlated to increased performance on working memory tasks and decreased performance on motor and sensory perception tasks. Further, bursts of beta frequency oscillations within the motor circuit appear to be highly correlated with the motor symptoms of PD. Effective treatment of motor symptoms of PD by DBS or administration of levodopa appears to decrease the duration of beta bursts, and adaptive DBS controllers based on the amplitude of the beta signal have shown promising results. However, it remains unclear what the appropriate timescale is for burst analysis. We examined the effect of traditional signal processing methods including filtering, thresholding and minimum burst duration on burst analysis. We used methods drawn from publications on burst dynamics and compared the results to ground truth using an on/off burst oscillator. The number and duration of bursts were highly dependent on the amplitude threshold and smoothing applied by the filter. Specifically, the selection of the threshold determined the amount of time spent in bursts, and the mean burst duration was highly constrained by the smoothing caused by the filter. We then quantified

subthalamic LFPs collected from 18 participants (15 male) with PD during lead placement or battery replacement surgery. All clinical studies were approved by the IRB of Duke University Health System and participants provided written informed consent. We found that using thresholds determined by matching raw amplitudes greatly changed the fraction of time spent in bursts and therefore constrained burst amplitude, duration and rate, thereby leading to biased results. We then analyzed the performance of burst classification with two support vector machines (SVM) using continuous and cycle-by-cycle amplitude data. The resulting burst dynamics were not constrained by a predefined fraction of time spent in bursts. When applied to the participant data, the SVMs produced a range of time spent in bursts (0.5- 47%) across participants. However, there was no significant effect of DBS on time in bursts, burst rate, or duration. Unbiased identification of burst features may lead to identification of biomarkers generally and, in the case of PD, inform adaptive DBS strategies to improve symptom control and reduce side-effects.

Title: Comparative analysis of structural deficit between olfaction and gustation in terms of diagnostic accuracy and consistency in Parkinson’s disease

Authors: *N. S. OSAKWE, H. CHATTERJEE, G. ELUMALAI, N. SEWRAM;
Texila American Univ., East Bank Demerara, Guyana

Abstract: Smell and taste deficit can be diagnostically challenging to the otolaryngologist as patients with Parkinson’s disease are usually unable to differentiate between deficits of smell and taste. Standardized questionnaire and procedures, good medical history taking and some diagnostic tools like CT scans, MRI etc. have been employed to differentiate and diagnose smell from taste disorder in previous research but no structural analysis have been used for this purpose. Hence, this study demonstrates a structural analysis between the deficit of olfaction and gustation in patients with Parkinson’s disease. With the Institutional Review Board approval, we used 80 Magnetic resonance imaging (sMRI) scans obtained from Parkinson’s Progression Markers Imitative. The total of 40 subjects (20 male and 20 female) with Parkinson’s disease and 40 subjects (20 male and 20 female) as the control group; with the age range from 30- 80 years were used. The main eligibility criteria for diagnostic accuracy and consistency from scans

obtained includes a diagnosis of Parkinson disease within 2 years at Screening with confirmation from imaging core that screening dopamine transporter SPECT scan is consistent with dopamine transporter deficit (or for sites where DaTSCAN^{TM} is not available, that VMAT-2 PET scan is consistent with VMAT deficit) and patients not on PD medication within at least 6 months. Exclusion: Received any drugs that might interfere with dopamine transporter SPECT imaging within 6 months of Screening. The Inclusive criteria for the control group of both sex is same age range with the subjects with PD at Screening. Exclusion includes: Current or active clinically significant neurological disorder, first degree relative with idiopathic PD, received any drugs that might interfere with dopamine transporter SPECT imaging within 6 months of Screening. The datasets from the subjects with PD and the control group are processed and fiber analysis are performed with Diffusion Imaging fiber tractography tracing fiber tracts extending from the VPM nucleus and the gustation system and from the primary cortex to the temporoparietal junction for the olfaction system. Data was statistically analyzed using structural equation modeling (SEM), mean and standard deviation (SD) .There is a significant p-value of .0008 between the both groups of Gustation system and shows a significant p-value of .00001 between both groups of olfaction system. These findings serve as a source for therapeutic intervention for Diagnostic Accuracy and Consistency of Patients with PD; Future research could focus on the functional implications of degeneration in PD, using techniques such as fMRI.

Title: Long-term post-mortem studies following neurturin gene therapy in advanced Parkinson’s disease

Authors: *Y. CHU[1], B. T. RAYMOND[3], W. C. OLANOW[4], J. H. KORDOWER[2];
[2]Dept Neurol Sci., [1]Rush Univ. Med. Ctr., Chicago, IL; [3]RTBioconsultants Inc, San Diego, CA; [4]Mount Sinai Sch. of Med., New York, NY

Abstract: We performed postmortem studies on 2 patients with advanced Parkinson’s disease 8 and 10 years following AAV2-neurturin (CERE120) gene therapy. CERE120 was delivered to

the putamen bilaterally in one case (10 years), and to the putamen plus the substantia nigra pars compacta (SNc) bilaterally in the second (8 years). In both patients there was persistent, albeit limited, neurturin expression in the putamen covering approximately 3 & 12% of the dorsal putamen. In the putamen dense staining of tyrosine hydroxylase (TH)-positive fibers were observed in areas that contained detectable neurturin expression. In the SNc, neurturin expression was detected in 9.8% & 18.95% and 22.02% & 39% of remaining melanin-containing neurons in the patient with putamenal and combined putamenal and SNc gene delivery, respectively. Melanized neurons displayed intense TH and RET proto-oncogene expression in SNc neurons in the patient where CERE120 was directly delivered to the nigra. There was no evidence of increased inflammation or activated microglia in areas of CERE120 delivery. There was also no difference in the degree of Lewy pathology in comparison to control PD patients. Our observations demonstrate long-term transgene expression with limited axonal sprouting and TH upregulation, though the TH upregulations was greater following CERE120 gene delivery to the putamen plus nigra, compared to putamen alone. However, neither dosing approach showed clinical benefit. Therefore, if these cases are representative of other patients their respective cohorts, the dopaminergic changes observed were not likely sufficient to provide significant anti-parkinsonian benefits. This study provides the longest term evidence of persistent transgene expression following gene delivery to the CNS and the first human results when targeting the terminal fields in the putamen as well as in the cells of origin.

Title: Do spatiotemporal measures of functional gait predict straight-line gait in individuals with Parkinson's disease?

Authors: *K. L. DOYLE, M. TOEPFER, K. A. PICKETT;
Kinesiology, Univ. of Wisconsin -- Madison, Madison, WI

Abstract: Introduction. As Parkinson disease (PD) progresses, postural instability leads to loss of independent function and inability to perform gait-dependent activities of daily living (ADLs)

and instrumental activities of daily living (IADLs). Spatiotemporal measures of straight-line gait, collected on an instrumented walkway are commonly used to measure gait function in both clinical and research settings. We examined standardized spatiotemporal measures of straight-line gait compared to functional gait performed during an instrumented kitchen task in individuals with PD. **Methods.** Individuals who met the inclusion and exclusion criteria for a larger randomized control intervention study and completed the baseline assessment were included in this cross-sectional analysis. All individuals were previously diagnosed with "definite PD". Each participant performed straight-line normal forward and dual task walking on a Protokinetics Zeno® walkway, followed by non-linear walking on a similar Zeno© walkway designed for placement in a research kitchen (Fig1, A & B). The non-linear task involved performance of an IADL task (cooking) as outlined in a standardized assessment battery (Performance Assessment of Self-Care Skills). Means were compared between gait tasks and a linear regression model was used to analyze correlations between spatiotemporal parameters (cadence, velocity, stride length, base of support, and percent of cycle in double support). **Results.** Preliminary findings for this exploratory study are presented here. Overall, stride width and length were smaller during the functional task while time spent in double support was longer and mean velocity was slower. **Discussion.** To better understand disease progression and treatment efficacy on community-dwelling individuals with PD, it is important to implement the use of ecologically valid and novel measures that capture performance of "real world" functional tasks. Moreover, portable gait mats may enable researchers and clinicians to assess patients in-home and identify individualized treatment options.

Title: Enhancement of hand functions in individuals with Parkinson’s disease: Impact of virtual reality training

Authors: *Z. ELIAS[1], B. BALAKRISHNAN[1], M. GANESAN[2];
[1]Univ. of Dubuque, Dubuque, IA; [2]Clarke Univ., Dubuque, IA

Abstract: Background: Individuals with Parkinson's disease (PD) have impaired hand function due to tremors, rigidity, and bradykinesia. Purpose: The purpose of this project is to test the feasibility, and efficacy of virtual reality training of hand functions in PD. Design: A pre-post quasi-experimental study design. Methods: In this pilot study, 3 individuals with idiopathic PD diagnosed by a neurologist were recruited from the community. Hand functions were assessed using the hand components of the motor score section of the Unified Parkinson's Disease rating scale (UPDRS) at baseline and after the 4 weeks of training. Intervention: The intervention includes virtual hand exercise using a RAPAEL Smart Glove™ with a visual display that focuses on hand functions including pronation, supination, radial deviation, ulnar deviation, flexion and extension of the wrist. In addition, the training also focuses on timing and coordination of movement. Both training and assessment were carried out during the "ON" period of medication. Results: All the three patients showed improvement of the hand functions reflected through a decrease in the UPDRS motor score hand components. The improvement obtained in each patient was more than the minimal clinical important difference (MCID) score of 4.63 in UPDRS motor score. The decrease in score was found in both the more affected side and the less affected side. Conclusion: The training result favors safety, feasibility and improvement of hand functions in individuals with PD.

Title: Plasticity of frequency dependent tremor control in Parkinson disease (PD) subthalamic nucleus (STN) deep brain stimulation (DBS) implanted individuals

Authors: *E. L. HARGREAVES[1], D. P. SCHNEIDER[2], R. DIPAOLA[2], J. CHEN[2], S. F. DANISH[1], D. L. CAPUTO[2];
[1]Neurosurg., [2]Neurol., Robert Wood Johnson Med. Sch. – Rutgers Univ., New Brunswick, NJ

Abstract: Plasticity of tremor control in DBS implanted individuals targeting the STN for PD is demonstrated. Specifically, over time the necessary frequency lessens. The DBS records of 85 sequential cases implanted at our institution from January 2013 to August 2016 were examined. From these records we drew 20 tremor dominant PD STN cases, 8 nontremor dominant PD STN cases, and 9 Essential Tremor (ET) VIM DBS cases. The value of the DBS frequency parameter

at the end of the initial contact screen was contrasted to the same parameter immediately following an initial device exchange. Frequency is minimized throughout programming to assist gait and reduce battery depletion, while maintaining adequate symptom control. Tremor dominant PD individuals had a mean UPDRS III “Off” tremor subscore at the contact screen of 5.61 (sem=1.05) and a total UPDRS III “Off” score of 33.58 (sem=2.11). The final frequency parameter value for the Tremor group at the end of the contact screen was an average of 182.22Hz (sem=5.56 range 150Hz-200Hz). By the programming session following battery exchanges, an average of 3.64 years later, the frequency had been reduced to an average of 131.39Hz (sem=7.59 range 75Hz-170Hz). At this time the Tremor group had a mean UPDRS III “On” tremor subscore of 0.39 (sem=0.153) and a total UPDRS III “On” score of 11.61 (sem=1.84). The NoTremor group exhibited a similar reduction in frequency from the contact screen to the device exchange some 4.35 years later (119.37Hz sem=4.99 - 76.25Hz sem=4.92). The accompanying UPDRS III “Off” tremor subscore was 0.50 (sem=0.40) and total score was 27.6 (sem=6.29), at the device exchange the “On” tremor subscore was 0.37 (sem=0.28) and the total “On” score was 17.64 (sem=7.33). In contrast the ET group exhibited no difference in frequency from the contact screen to the device exchange across some 4.16 years (177.27Hz sem=2.04 - 185.91Hz sem=7.96).As such, both the Tremor and NoTremor PD groups exhibited similarly significant reductions in the necessary frequency value over time, which did not hold true for the ET group. However, both initial and endpoint frequencies were different in the PD subgroups. The higher frequency necessary to maintain tremor may also have contributed to a shorter device duration. Similar comparison cannot be made to the ET group as different individuals deactivated the device diurnally. Identifying the necessary frequency for the Tremor and ET groups is straight forward, whereas it is not so straight forward for the NoTremor group. Thus, it is definitive to say that the frequency parameter and its control over tremor in the Tremor group exhibits plasticity, which cannot be said for the NoTremor PD and ET groups.

Dept. of Physiol., Chicago, IL; [5]Eli Lilly Pharmaceuticals, Indianapolis, IN; [6]Dept. of Neurol., Univ. of South Florida, Tampa, FL; [7]Parkinson Fndn. Patient Advocate, Rochester, NY; [8]Movement Disorders Ctr., Toronto Western Hosp., Toronto, ON, Canada; [9]NINDS, Natl. Inst. of Hlth., Rockville, MD; [10]Neurol., Northwestern Univ., Chicago, IL

Abstract: Background: Isradipine is a dihydropyridine calcium channel inhibitor that has demonstrated concentration-dependent protective effects in animal models of Parkinson's disease (PD). Moreover, systemically administered isradipine engages calcium channels in brain dopaminergic neurons in mouse models, lowering mitochondrial oxidant stress and mitophagy. In addition, epidemiological studies showed association of dihydropyridine use with reduced risk of PD. Hence, a phase 3, randomized, double-blinded, placebo-controlled trial tested whether 10 mg of isradipine administered twice daily - the highest dose tolerated by PD patients in a phase 2 study - slowed the progression of PD. The study collected plasma pharmacokinetic samples to conduct posthoc analysis of correlation of PK with the clinical outcomes and as indirect proxy of subject compliance. **Methods:** Sparse samples for quantification of plasma isradipine concentrations were collected 3 and 6 months post-baseline visit. The samples were collected during the following time windows relative to last dose: ~2 - 3 hours (i.e., maximum concentration [C_{max}]), ~4 - 8 hours, and ~12 hours (i.e., trough [C_{min}]) post-dose. Quantitation of isradipine was performed using a validated liquid chromatography with tandem mass spectrometry assay. The assay measurement range for isradipine was from 0.100 to 100 ng/mL. **Results:** The study recruited 336 participants of whom 170 received isradipine. Of these participants, 166 had PK samples for analysis. Six samples from four different participants were below the assay limit of quantitation suggesting adherence issues, rapid metabolism of isradipine, or other pharmacokinetic factors. In the remaining participants, the median (minimum, maximum) C_{max} and C_{min} isradipine concentrations were 3.1 (0.4, 17.4) ng/mL and 0.6 (0.1, 4.1) ng/mL, respectively. **Conclusions:** There was substantial variability in the plasma concentrations of isradipine in our clinical trial participants. Additionally, the observed C_{max} value was lower than expected compared to previously reported values for isradipine in non-PD populations. Population pharmacokinetic modeling of these data is underway to identify individual characteristics associated with the inter-individual pharmacokinetic variability of isradipine. Correlations between isradipine exposure, PD sub-type, age and PD progression also will be determined.

Title: Intravenous administration of nicotinamide adenine dinucleotide alleviates tremors associated with Parkinson's disease: A case report

Authors: *L. E. RUTHERFORD, II[1], *S. L. BROOM[2,3], T. OLDS[1], R. F. MESTAYER[1,3], P. N. MESTAYER[1];
[1]Springfield Wellness Ctr., Springfield, LA; [2]Dept Psychol, William Carey Univ., Hattiesburg, MS; [3]NAD Research, Inc., Springfield, LA

Abstract: Introduction: A number of pharmacological agents currently exist for treating symptoms associated with Parkinson's disease (PD), however these drugs are not optimal because they typically target dopamine reuptake in depleted dopaminergic systems. Nicotinamide Adenine Dinucleotide (NAD+) is present in all cells and serves a vital role in cell function; in fact, disruption or depletion of NAD+ is associated with a number of disease states, including PD. Clinicians in Springfield, LA developed an intravenous administration protocol of NAD+ for a patient experiencing symptoms associated with PD. Subsequent observation of a rapid and sustained treatment effect on alleviation of PD symptoms ***provide rationale for further describing and quantifying the positive effects of IV NAD+ on tremors associated with PD.*** **Method:** Client, male age 59 was diagnosed with PD four years prior and reported taking traditional PD medications with no alleviation of symptoms. Client received IV NAD+ (two days of 1,500mg) followed by (four days of 750mg) for a total of six days. Tremors were recorded in the client's dominant right hand using an accelerometer and gyroscope built into the client's smart phone. Researchers recorded measurements (Hz) for baseline (day 0; 44.5Hz average at 34hr), day 4 and day 6 (13 measurements total) on three axes; vertical, lateral and anterior-posterior. Following day 6, client received sublingual NAD+ tablets (300mg 2Xday) and recorded mean tremors for 14 days. **Findings:** 1) Overall, the vertical axis tremors decreased by 75.9%, the lateral axis by 83.0% and the anterior-posterior axis by 9.1%. 2) Mean tremor on day six was 20.6Hz, resulting in a decline from baseline by 54.7%. 3) Client self-report of tremors continued to decline two weeks post IV NAD+ (average 12Hz) by using maintenance supplements and application of a relaxation technique. **Conclusion:** These data show the longevity and endurance of the initial IV NAD+ followed by sublingual tablets (300mg 2x/day)

in maintaining decline and alleviation of PD symptoms. Additionally, these results replicate previous findings and establish a protocol for empirically measuring the effects of IV NAD+ on PD symptoms (specifically tremors), and longevity of treatment results as compared to traditional pharmacotherapies.

Title: Analyzing the differences in neural activation between conventional and interleaving deep brain stimulation of the subthalamic nucleus for dyskinesia suppression

Authors: *G. DUFFLEY[1], C. AQUINO[2], C. R. BUTSON[3];
[1]Biomed. Engin., [2]Neurol., [3]Biomed. Engineering, Neurology, Neurosurg. & Psychiatry, Univ. of Utah, Salt Lake City, UT

Abstract: Introduction: Dyskinesias are a common side effect of dopaminergic therapy, a common treatment for the symptoms of Parkinson’s disease (PD). Deep brain stimulation (DBS) of the subthalamic nucleus (STN) has been shown to reduce PD symptoms and thereby reduce the need for dopaminergic medications, but it is not thought to have a direct effect on dyskinesias. Interleaving stimulation (ILS), which is a stimulation modality where two distinct stimulation waveforms are delivered to the patient out of phase with each other, has shown potential to improve dyskinesias. The objective of this study was to evaluate how neural activation differs between conventional and ILS in order to improve dyskinesias following STN DBS.
Methods: We identified 23 PD patients who had received ILS of the STN. Of those patients, 11 received bilateral ILS and 12 received unilateral ILS, for a total of 34 DBS leads to analyze. We computed the volume of tissue activated (VTA) for each patient’s best conventional setting and

ILS setting. For each ILS setting, we computed two separate volumes one, where activation occurred at the frequency of the either of the independent waveforms and one where activation occurred at the total frequency of the waveforms combined. We generated heatmaps of activation resulting from each type of VTA across patients.
Results: The heatmaps revealed that both ILS and conventional DBS most commonly activated the lateral portion of STN, but ILS additionally activated the region of zona incerta (ZI), located dorsal-lateral to the STN. Out of the 34 DBS leads, 28 interleaving stimulation settings generated a volume of high frequency activation. The most common location of the high frequency activation was on the border of dorsal STN and ventral ZI.
Conclusions: ILS causes two primary changes as compared to conventional DBS; there is a small region of high frequency activation on the border of STN and ZI, and the center of ZI is activated. Future work will analyze if stimulation of ZI activates pallidothalamic fibers in H field of Forel, which is a hypothesized mechanism of ILS dyskinesia suppression.

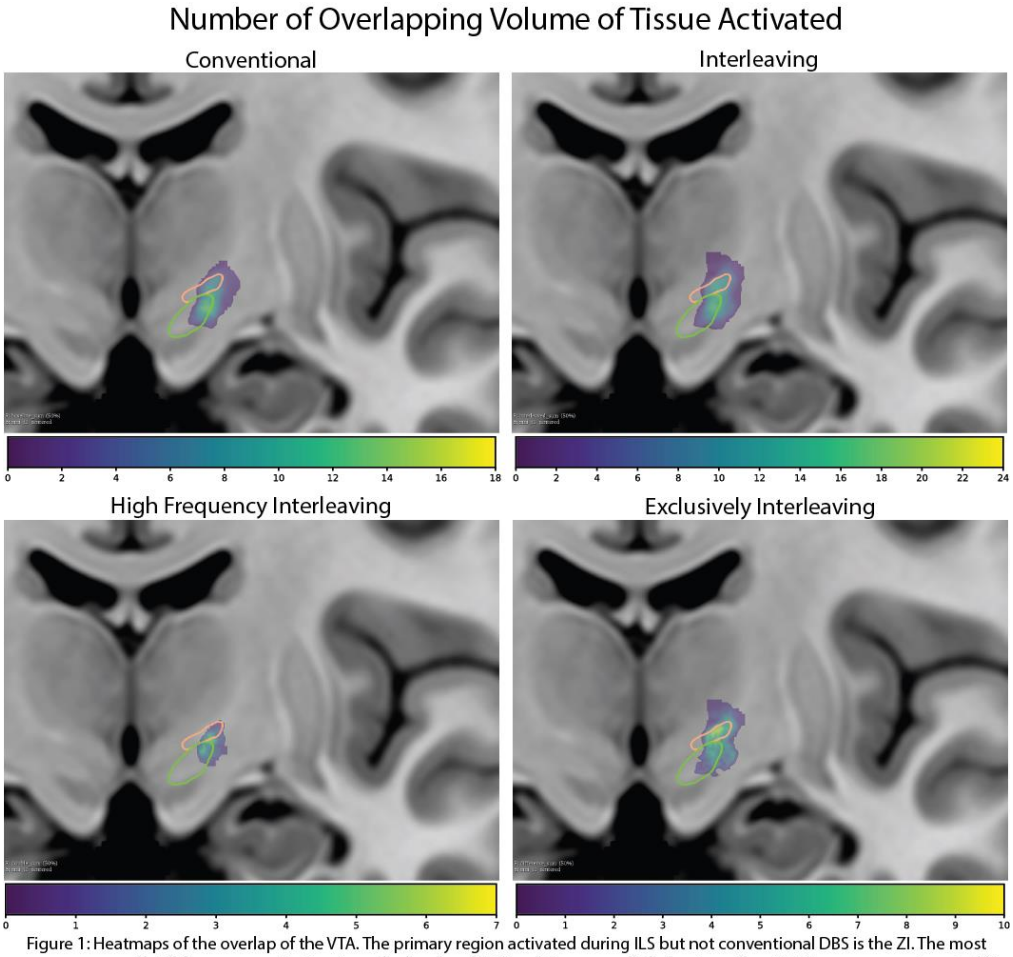

Figure 1: Heatmaps of the overlap of the VTA. The primary region activated during ILS but not conventional DBS is the ZI. The most commona area of high frequency activation is on the border of STN and ZI. green: subthalamic nucleus (STN), orange: zona incerta (ZI).

Title: Biomarkers to guide directional DBS for Parkinson's disease: 2 year interim analyses from a randomized, double-blind crossover trial

Authors: *H. C. WALKER[1], C. GONZALEZ[1], Z. IRWIN[1], C. HURT[2], D. KUHMAN[2], A. NAKHMANI[3], R. MARTIN[4], S. BLACK[5], M. WADE[1], M. AWAD[3], R. VADEN[1], N. BENTLEY[5], B. GUTHRIE[5];
[1]Neurol., [2]Physical Therapy, [3]Electrical Engin., [4]Neuropsychology, [5]Neurosurg., UAB, Birmingham, AL

Abstract: Introduction
Deep brain stimulation (DBS) is effective for motor symptoms of Parkinson's disease (PD), but improvement varies significantly across trials, within individuals, and over time. Directional DBS electrodes allow greater precision and flexibility, but at the cost of markedly increased complexity during postoperative programming. Our overall goals are to contrast the clinical effects of directional and circular DBS and to identify electrophysiology biomarkers that rapidly and objectively identify effective, well-tolerated stimulation contacts.
Methods
We are conducting a randomized, double-blind crossover study of directional versus circular unilateral subthalamic DBS for PD. Our primary clinical outcomes include within-participant contrasts in the UPDRS part 3 motor score "off" meds and novel patient preference measures incorporating the NIH PROMIS battery at 2 and 4 months post-op versus pre-op baseline. During surgery, we record stimulus-evoked potentials with scalp EEG and an ECOG strip over ipsilateral primary sensorimotor cortex as well as subcortical local field potentials from the directional DBS lead both at rest and during simple arm, mouth, and leg movements. We are building predictive models to examine whether stimulus evoked activity or subcortical local field potentials (LFPs) better guide rapid, effective activation of directional DBS leads. We have implanted 12 of 30 participants (10 male, 2 female) as of year 2 of 5. Primary clinical outcomes are blinded until study conclusion.
Results
Both directional and circular DBS significantly improved motor outcomes at 2 and 4 months versus baseline (54.0±16.9 to 30.4±12.6 and 33.1±14.3, 43.7% and 38.6% improvement,

respectively, p<0.001, n=7, linear mixed effects model). Within individuals, directional DBS technology differentially modulates motor improvement, side effect thresholds, stimulus-evoked activity, and subcortical LFPs. One patient experienced an isolated seizure the day after surgery without neuroimaging abnormalities, and there have been no other SAEs.

Discussion

Directional DBS therapy is safe and effective for motor symptoms. Our interim analyses show significant within-participant contrasts in motor outcomes and both stimulus evoked activity and LFPs, in the context of directional DBS therapy. These contrasts show considerable promise as potential biomarkers to guide new approaches to DBS therapy with next-generation directional and closed-loop DBS systems.

Abstract: Nilotinib is a drug approved for treatment of chronic myeloid leukemia, but not for PD. Several studies in cells and animal models show that nilotinib can reduce alpha-synuclein pathology and thereby has the potential to slow PD progression; this hypothesis gained supported from a preliminary, open-label study in moderate to advanced PD patients (Pagan et al., 2016) raised the additional possibility of a symptomatic effect. A recent study conducted by Pagan et al. (2019) showed that cerebrospinal fluid (CSF) concentrations of nilotinib are approximately 0.5 to 1% of those in the plasma and are associated with alterations in dopamine metabolite levels. However, the pharmacokinetic (PK) profile CSF exposures and biomarker changes after a steady-state level of nilotinib, have not been systematically studied. We initiated a Phase 2a randomized, double-blind, placebo-controlled, parallel group study termed NILO-PD. The primary outcome of NILO-PD is safety and tolerability. Secondary/exploratory outcomes include nilotinib serum PK, CSF exposures together with a battery of serum and CSF biomarkers, whichs include levels of CSF dopamine and its metabolites in CSF. The study has enrolled 76 participants with moderate to advanced PD randomized 1:1:1 to a once daily dose of placebo:nilotinib (150 mg):nilotinib (300 mg) for 6 months. Recruitment started in November 2017 and was completed in December 2018. Baseline characteristics of study participants are summarized in the table below.

Characteristics	**Mean (SD)**
Age (years)	64.6 (7.5)
Sex (% female)	31.6
Age at diagnosis (years)	54.7 (8.0)
Disease duration (years)	9.9 (4.7)
MDS-UPDRS Off score	66.4 (19.5)
MDS-UPDRS On score	48.3 (16.1)
MoCA score	27.1 (2.2)

The study is scheduled to complete data collection in September 2019. Here we report the protocol-specified interim analyses at baseline and 3 months for serum PK, CSF exposures and CSF dopamine metabolite levels as well as correlations between exposures and dopamine metabolite changes. The primary outcome results are expected by December 2019.

Title: Anti-Parkinsonian medication improves impaired eye-hand coordination in participants with Parkinson's disease

Authors: *M. J. MUNOZ[1], R. ARORA[2], E. GEORGE[1], G. PAL[3], L. A. VERHAGEN METMAN[3], L. C. GOELZ[1,4], D. M. CORCOS[1], F. J. DAVID[1];
[1]Physical Therapy and Human Movement Sci., Northwestern Univ., Chicago, IL; [2]Biol. Sci.,

Northwestern Univ., Evanston, IL; [3]Rush Univ. Med. Ctr., Chicago, IL; [4]Kinesiology and Nutr., Univ. of Illinois at Chicago, Chicago, IL

Abstract: Eye-hand coordination has been infrequently studied in Parkinson's disease (PD) despite being an important skill of everyday life. In addition, the effect of medication on eye-hand coordination remains unclear. Studying the effect of medication on eye-hand coordination can provide insight into the role of the basal ganglia in the control of eye-hand coordination. Thus, we addressed the following two questions: 1) what is the effect of anti-Parkinsonian medication on eye-hand coordination while performing a visually guided reaching task, and 2) does anti-Parkinsonian medication improve performance to the levels of age and sex matched healthy control participants? Twenty-one participants with PD (19 male) and 8 healthy controls (7 male) completed a visually guided reaching task. Participants were asked to look and reach as accurately as possible to a target LED that appeared in their periphery immediately after fixating on a central fixation LED. Visual stimuli were presented in total darkness. The PD participants performed this task over two days; one day was on medication while the other day was off medication. The order of on and off medication was randomized. Eye-hand coordination was operationally defined as the latency between the onset of eye movement and the onset of hand movement, i.e., eye-hand latency. The outcome measures were eye-hand latency, pointing latency (the time taken to begin movement), pointing peak velocity normalized to amplitude, and pointing error magnitude normalized to peak velocity. All statistical analyses were performed using SAS Proc Mixed. The fixed effect was medication status (on vs off). Subjects were considered random effects. Covariates were off medication Movement Disorders Society-Unified Parkinson's disease Rating Scale Part III score, Montreal Cognitive Assessment total score, age, and sex. In addition, independent t-tests were performed to compare outcomes between PD on medication and healthy control participants. Relative to off medication, anti-Parkinsonian medication 1) reduced eye-hand latency, 2) had no effect on pointing latency, 3) increased pointing velocity, and 4) reduced pointing error. Medication improved eye-hand latency to healthy control participant levels, but deficits in pointing latency, peak velocity, and error magnitude remained. Our findings showed that medication improved eye-hand coordination and suggest a basal ganglia role in the circuitry controlling visually guided limb movements.

Title: Effects of cycling cadence variability on motor function and cortical inhibition in Parkinson's disease

Authors: *A. L. RIDGEL[1,2], A. J. GARBIN[3], Y.-C. CHUNG[3], J. AXELROD[3], S. YASSA[3], B. E. FISHER[3];
[1]Exercise Physiol., Kent State Univ., Kent, OH; [2]KSU Brain Hlth. Res. Inst., Kent, OH; [3]USC, Los Angeles, CA

Abstract: Prior research has demonstrated that forced cycling improves motor symptoms commonly experienced by individuals with PD. Further, the degree of improvement is predicted by the variability in one's cadence. However, the mechanisms behind these changes are poorly understood. The purpose of this study was to assess the effect of cadence variability (degree of complexity) on motor function and cortical inhibitory mechanisms during forced and voluntary cycling in adults with Parkinson's disease (PD).We hypothesized that an increase in cortical inhibition, a cortical mechanism that is reduced in individuals with PD, may be responsible for the motor improvements secondary to forced cycling. Individuals with mild to moderate PD completed three 30-minute cycling sessions consisting of high cadence variability forced cycling (HCV), low cadence variability forced cycling (LCV), and voluntary cycling (VC) while off medication. During the two forced cycling conditions, cadence was set to 80 rpm, while participants were encouraged to maintain this same cadence during voluntary cycling. Motor function was assessed using the Unified Parkinson's Disease Rating Scale III and cortical inhibitory mechanisms were assessed using a transcranial magnetic stimulation paradigm of short interval cortical inhibition (SICI) before and after each cycling session. Variability in cadence and power during each session was calculated using entropy analysis. Mean cadence was greater during HCV and LCV relative to VC (80.3 & 81.4 vs. 75.5 rpm). Cadence variability was higher during HCV (1.4) compared to LCV (1.1), while power and power variability were higher during LCV (4.6 & 0.32) compared to HCV (2.9 & 0.14). We observed the greatest increase in cortical inhibition as indicated by reduced SICI following HCV (Pre 0.724, Post 0.527) while the greatest improvement in UPDRS was seen following LCV (5.5). While our inhibitory and behavioral changes following high and low cadence variability forced cycling at first seem counter-intuitive, we postulate they may be secondary to different mechanisms. Specifically, increased modulation in kinematic output and somatosensory input during the high cadence variability condition may be responsible for increased inhibition. The increased power and power variability in the low cadence variability condition is indicative of greater kinetic variability and motor output, potentially resulting in the observed greater impact on motor behavior. Further, these effects are less apparent in the voluntary cycling condition due to their significantly lower cadence.

Title: A smartphone-based motor function battery to assess Parkinson's disease patients in the community setting

Authors: E. E. ECK, ***B. L. TRACY**;
Hlth. and Exercise Sci., Colorado State Univ., Fort Collins, CO

Abstract: Parkinson's disease produces slow movement, motor variability, postural instability, and impaired gait. It is often difficult for patients in studies to access laboratories with sophisticated measurement tools. It can be of interest to capture symptom severity and the extent of functional disability in remote clinical settings or in studies at exercise facilities. Smartphones contain quality movement sensors, are portable, user friendly, lightweight, and feasible when remote community-based testing is desired. Here we describe a smartphone-based motor function battery to measure PD symptoms before and after a rehabilitative exercise training session (boxing). Eight smartphone-instrumented (iPod Touch) functional tasks were devised to assess key features of PD-related function. Raw movement data was acquired on the device in the boxing gym and transferred wirelessly to the lab for subsequent analysis. Postural Stability: device attached to the lateral hip, the SD of acceleration for the X and Z axes (A/P and M/L) was measured with eyes closed and open. Walking (10m gait test): Devices strapped above the ankle. Heel strike timestamps were detected from acceleration spikes from both feet separately; gait speed, step/stride length, and variability of step/stride times were calculated. 5x Sit-To-Stand: Device attached to thigh. The speed of the rising phase of each repetition, body mass, and rise distance was be used to calculate chair rise power. Upper and lower body movement speed: Device attached to the distal forearm or distal shank. The peak acceleration of the initial phase of an abbreviated horizontal arm punch (jab) or isolated knee extension kick was measured. Functional Reach: Device attached to lateral trunk. Flexing at the hip, the standing subject reached out as far as possible with horizontal arms and without losing balance. The greatest trunk tilt value and the stability at the maximum position indicates the ability to maintain balance under challenge. Rapid tapping (20s): Seated at a table, the subject tapped the device as rapidly as possible for 20s. The mean rate and variability of tapping rate was calculated using the timestamps of acceleration spikes. Tremor: Devices attached to the distal forearm of both arms separately. Arms were held steady for 30s. The SD of acceleration in three axes was taken as a measure of tremor amplitude. Smart devices may allow efficient, low cost field assessment and increase access to testing for community-based intervention studies when lab visits are not possible.

Title: Niacin supplement for Parkinson's disease

Authors: *B. GIRI[1], M. SEAMON[2], B. BABAN[2], R. CHONG[2], J. C. MORGAN[3], S. PUROHIT[2], C. WAKADE[4];

Abstract: We propose over-the-counter niacin supplementation to improve inflammation in Parkinson's disease (PD). α-synuclein is known to form aggregates in brains of PD patients, contributing to neuroinflammation. We have reported up-regulation of niacin receptor (GPR109A) in PD patients and niacin intervention has been beneficial in reducing inflammation. In this exploratory study, we examined GPR109A expression, cytokine (pro and anti-inflammatory) profile, and α-synuclein load in the plasma samples of early- and late-stage patients (based on H & Y) at baseline and after 6 months of niacin supplementation. In this double-blind within-subjects study, informed consent was obtained on PD subjects under protocols approved by the Institutional Review Board. Behavioral, cognitive assessments, and blood biochemistry testing were carried out at baseline and after 6 months of niacin supplement. Exosomes were separated through size exclusion chromatography from plasma samples. Exosomes were identified by electron microscopy as well as by exosome markers. Western blot densitometry analyses were performed on high exosome fractions to determine α-synuclein oligomers to exosome marker ratio. Levels of niacin metabolites, GPR109A, and cytokines were determined in the blood. Our study showed that α-synuclein oligomers to exosome marker ratio in PD patients was higher at baseline compared to that after 6 months of niacin supplement. Baseline GPR109A expressions were significantly lower in late stage patients compared to early stage at baseline and after niacin treatment. Niacin supplements reduced GPR109A, increased niacin metabolite levels and decreased α-synuclein oligomers level in exosomes. Niacin may be beneficial in PD by its anti-inflammatory effects through GPR109A mechanisms, as well as modulating α-synuclein load.

Title: Electrophysiological responses to deep brain stimulation in Parkinson's disease

Authors: A. C. GUEST[1], D. GRAHAM[2], K. J. O'NEILL, III[2], Z. MIRZADEH[3], F. PONCE[3], *B. GREGER[2];

Abstract: Deep brain stimulation (DBS) is a technique used to alleviate motor symptoms of advanced Parkinson's disease (PD). DBS electrodes are surgically placed into deep brain structures, e.g. subthalamic nucleus (STN), and when current is passed to the electrodes, the motor symptoms of PD are relieved. Although DBS is a well-established treatment for PD, its mechanism is poorly understood. In this study, patients with PD underwent neurosurgery for DBS electrode placement. Intraoperatively, we recorded action potentials (APs) from isolated neurons and local field potentials (LFPs) from a microelectrode placed in STN. We simultaneously recorded LFPs from an epicortical micro-electrocorticography (micro-ECoG) grid placed over premotor cortex. The micro-ECoG grid consisted of 16 microelectrodes with an inter-electrode spacing of 1 mm. DBS was performed while recording from these two devices. The microelectrodes were placed either ipsilateral or contralateral to the DBS electrodes. LFPs recorded on the micro-ECoG grid placed over premotor cortex that were aligned on APs from neurons in the STN and averaged showed increased amplitude. This increase in LFP amplitude was only present on a subset of micro-ECoG electrodes that varied for each STN neuron. These results demonstrate functional connectivity between single neurons in the STN and patterns of small regions of premotor cortex. We also examined the electrophysiological responses to DBS on the microelectrode placed in STN using subtherapeutic, therapeutic, and supratherapeutic stimulation frequencies (30, 70, 140, and 250 Hz). AP aligned and averaged LFPs in the ipsilateral STN showed an increase in amplitude in the theta band during 140 Hz DBS, a therapeutic frequency. There was a moderate increase in amplitude in the theta band with 250 Hz DBS, but there were little or no changes in LFP amplitude at frequencies of 30 Hz, 70 Hz, or for recordings on the contralateral side. Our results provide insight into the effects of DBS on neural tissue and the functional connectivity between the STN and premotor cortex. Future studies will be performed with patients undergoing awake neurosurgical procedures allowing us to simultaneously record the electrophysiology measures described above and the parameters of the patient's tremor during DBS. By linking the dynamics in electrophysiological recordings from micro- and meso-scale neural circuits with the reduction of tremor during DBS we aim to

advance the understanding of the mechanism of DBS, and provide insight into the pathophysiology of PD.

Ctr., Phoenix, AZ; [6]Neurol., Univ. of Arizona, Tucson, AZ

Abstract: Common motor impairments in Parkinson's disease (PD) include reduced step length, shuffling gait, and postural instability; these can be aggravated by the presence of stooped posture. The severity of these impairments worsen over time and affect quality of life. Neurorehabilitation therapies may help to sustain, or possibly improve, motor function and the ability to perform daily activities. The application of visual and auditory cues is one such neurorehabilitative therapy which has been shown to provide some benefits in gait in PD. However, due to impaired proprioception, people with PD are not aware if they are following the cues successfully. This limitation may be overcome by providing real-time feedback of performance, which can encourage modulation of movement patterns to improve gait and posture. In earlier work, we demonstrated that, in a single session, people with PD could successfully follow treadmill-based real-time feedback (RTF) of step length and back angle to improve gait and posture during and immediately after walking with feedback. To investigate whether the observed immediate benefits can be sustained and transferred to overground walking without feedback, we are conducting a long-term (3 sessions/week for 6 consecutive weeks) real-time feedback training (RTFT). Thus far, five participants (age 69 +/- 5 years) with mild to moderate PD (Hoehn and Yahr stage III or below) received RTFT that involves providing real-time feedback of step length or back angle by displaying it (pictorially) on a monitor placed in

front of the participant, at eye-level. The target step length was set between 110-120% of the step length obtained during a baseline non-feedback walking trial, and the target back angle was set at the maximum upright posture exhibited during a quiet standing task. Evaluation sessions conducted post-training (after 6-week training) and at follow-up (after 12 weeks) indicate increases in step length, gait speed, and cadence, and decreases in step time and double support in four of five participants, and these benefits are sustained at follow-up. These results provide preliminary evidence that RTFT can be an effective rehabilitative modality in improving gait and posture in people with PD.

Title: Gait and balance monitoring using wearable technology for real-time feedback in Parkinson’s disease

Authors: ***N. MUTHUKRISHNAN**[1], J. ABBAS[1], P. TURAGA[2], T. INGALLS[2], N. KRISHNAMURTHI[3];
[1]Sch. of Biol. and Hlth. Systems Engin., [2]Sch. of Arts Media and Engin., [3]The Edson Col. of Nursing and Hlth. Innovation, Arizona State Univ., Tempe, AZ

Abstract: Several recent studies have employed real-time feedback (RTF) of gait parameters to improve walking patterns in Parkinson’s disease (PD). In earlier work, we investigated the effects of RTF of step length and back angle during treadmill walking and observed that people with PD could follow the feedback and utilize it to modulate movements favorably in a manner that transferred, at least acutely, to overground walking. Our study, and most others with RTF in the literature, utilized training while walking on a treadmill. However, people in the moderate to advanced stages of PD experience balance impairments and therefore may find it difficult to train on a treadmill and may not be willing to go through a specialized program involving RTF. Recent advances in wearable sensors can be leveraged to develop a wearable real-time feedback (WRTF) system that can evaluate movements and provide feedback during daily activities that involve overground walking. The work presented here addresses the challenge of obtaining

accurate gait and balance measures from wearable sensors in real-time. We have developed algorithms to detect gait events and calculate parameters such as step-length and trunk uprightness using data from wearable sensors (inertial measurement units) that were placed on the feet, sternum and lumbar region of the back. The algorithms perform quaternion-based correction of the sensor‘s orientation using a computationally simple complementary filter for position and posture calculations. Data collected during 30-meter walking trials from healthy individuals and people with PD were used to calculate gait and posture measures. Preliminary results demonstrate accurate and reliable gait detection and subsequent calculation of step/stride length, swing time, and back angle. The algorithms do not incur substantial computational demands and therefore are suitable for real-time applications. In an ongoing study, we are testing the validity of the measures from the wearable system against gold-standard measurements. In subsequent work, the WRTF system will be evaluated as a potential rehabilitation tool for use in a home/community setting by investigating the impacts of using the system on walking patterns and posture in people with PD.

Abstract: Introduction: Reduced production of dopamine in Parkinson’s Disease (PD) substantially affects motor skills and other primary body functions, including mood and cognition. At the same time, losses occur in the autonomic nervous system, which can be estimated by heart rate variability (HRV). **Objectives:** To assess HRV and its relationship with symptoms of anxiety, depression, cognition and severity of the disease. **Methods**: Twenty-six patients were evaluated according to scales of anxiety and depression (HADS-A and HADS-D), Mini-Mental Parkinson (MMP) cognition scale, and disease severity scales (UPDRS - motor examination and Hoehn & Yahr scale). HRV was measured with the patients standing and sitting. **Results**: We observed high levels of anxiety (30.7%), depression (34.6%) and impaired

cognition (64%). Parasympathetic activity, inferred by the RMSSD values, was associated with the intensity of depressive symptoms ($r = -0.382$; $p \leq 0.05$), while the LF/TP values, which reflect both sympathetic and parasympathetic activity, were associated with the score obtained in the MMP ($r = 0.503$; $p \leq 0.05$). Severity and overall time of the disease were also associated with autonomic function. **Conclusions**: It is suggested that HRV works as an integrative measure and peripheral marker of the body's adaptability and self-regulatory capability, as well as a practical and sensible resource regarding the disease's progression.

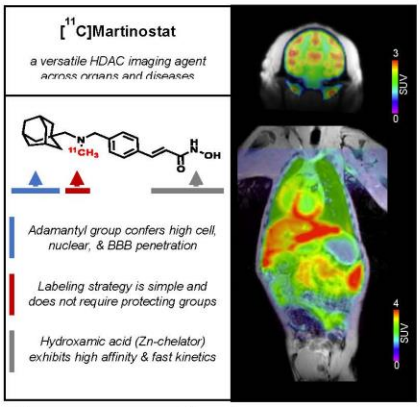
Title: The investigation of epigenetic mechanisms *in vivo* in Parkinson's disease patient brains quantified by non-invasive PET imaging using a PET/MR

Authors: *S. FIEDLER[1], L. WERNECK[1], B. NTAGANDA[1], S. N. GOMPERTS[2], C. WANG[1]; [1]Massachusetts Gen. Hosp., Boston, MA; [2]Massachusetts Gen. Hosp., Charlestown, MA

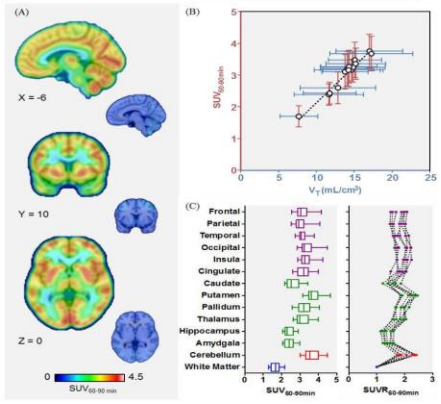
Abstract: The purpose of this study is to evaluate altered regional histone deacetylase (HDAC) expression in Parkinson's Disease (PD) brains using [^{11}C]Martinostat as a positron emission tomography (PET) radiotracer. The hypothesis tested is that HDAC enzyme expression is altered in PD brains. A combined PET/magnetic resonance imaging (MRI) system will be taken advantage of to collect simultaneous images. Research from diverse disciplines supports the hypothesis that HDAC dysfunction can lead or contribute to brain diseases, including PD, but limited investigation of the underlying processes and mechanisms relevant to PD. To overcome this limitation, the first HDAC radiotracer was developed (Figure 1). Our laboratory has now successfully imaged a growing cohort of healthy adults (18-65 years; >50) (Figure 2), and PD patients. In our first publication, we performed PET imaging on eight healthy volunteers. Standard uptake value-Revised (SUVR)$_{60\text{-}90min}$ showed that the regional distribution patterns test-retest reliability of [^{11}C]Martinostat binding are remarkably consistent in all subjects and volume of distribution (V_T) is well correlated with SUVR. These results support the use of SUVR$_{60\text{-}90min}$ as an appropriate surrogate outcome measurement for V_T (Figure 3). Our PET HDAC imaging in PD is the first time ever to visualize epigenetic expression in the brain of these patient

populations. In our preliminary study, HDAC binding in PD subjects (a 74-year-old cognitively normal and a 71-year-old man with left-predominant PD-Mild cognitive impairment (MCI)) differed from that of a 65-year-old normal control in two respects. First, binding in the putamen was markedly asymmetric in PD, with elevated binding greatest in the hemi-putamen underlying the greater motor impairment. Second, occipital cortical binding was increased markedly and selectively in the PD-MCI patient with visual hallucinations. These early imaging data represent a major step forward in understanding epigenetic mechanisms in vivo and are already providing insights into regional HDAC expression.



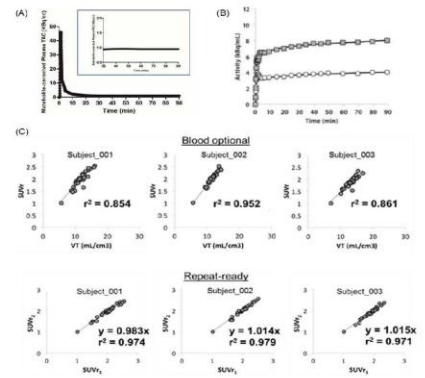
The Design of [^{11}C]Martinostat

Figure 1. [^{11}C]Martinostat: a translational PET imaging probe. We have developed a potent HDAC imaging agent, termed [^{11}C]Martinostat, incorporating three key structural features to create a versatile and translational probe for visualizing HDAC expression in vivo. Intravenous injection of trace amounts of [^{11}C]Martinostat (nanogram scale) in baboon and imaging by PET/MR demonstrates quantifiable uptake in the brain and in diverse peripheral organs. This illustrates the potential for [^{11}C]Martinostat as a broadly-applicable tool in evaluating HDAC density in humans.



Human Brain PET/MR Imaging with [^{11}C]Martinostat

Figure 2. Group [^{11}C]Martinostat $SUV_{60\text{-}90min}$ images show small intersubject variation of localized, regional [^{11}C]Martinostat binding. (A) Mean images (upper left) and standard deviation images (inset on the lower right) of $SUV_{60\text{-}90min}$ from healthy volunteers (n=8; 4 males, 4 females, mean age ± standard deviation: 28.6 ± 7.6 years). (B) Correlation of regional distribution volume (V_T) values, derived from a two-tissue compartmental model using metabolite-corrected arterial plasma as input function, and $SUV_{60\text{-}90min}$ values (n=6). The V_T values and $SUV_{60\text{-}90min}$ were significantly correlated (r^2=0.96; correlation analysis, p<0.0001). (C) *(Left)* Regional $SUV_{60\text{-}90min}$ of cortical (purple), subcortical (green), cerebellar (red), and white matter (blue) volumes of interest. *(Right)* Regional $SUV_{60\text{-}90min}$ values were normalized to the subject's white matter $SUV_{60\text{-}90min}$ value ($SUVR_{60\text{-}90min}$). Each dashed line represents $SUVR_{60\text{-}90min}$ values from a single subject (n=8).



Test-Retest and Blood Analysis for Human Imaging

Figure 3. Human data: (A) Metabolite-corrected time activity curves (TAC) from human plasma (inset: 30-90 min TAC); (B) TACs and compartmental model fitting (two-tissue compartmental model) results for superior frontal cortex and white matter. TACs of the superior frontal cortex (square) and white matter (circle) regions from all subjects are shown for the 90-minute scan duration. (C) (Top) Quantitation of [^{11}C]Martinostat distribution in human brain PET scans. SUVr, standardized uptake with normalization to white matter, is purely image-based however aligns incredibly well with distribution volumes (VT) obtained using plasma-input function from sampled arterial blood. (Bottom) High reliability in PET test-retest with [^{11}C]Martinostat. Excellent correlations of HDAC density measures in whole brain from same day test-retest demonstrate stability of repeated HDAC measures.

Title: Cognitive outcomes of STN-DBS in GBA-PD

Authors: *G. PAL[1], E. HILL[1], T. FOLTYNIE[2], V. LYTHE[2], R. ALCALAY[3], P. GARCIA[3], K. MARDER[3], R. SAUNDERS-PULLMAN[4], S. BRESSMAN[4], J. AASLY[5], B. OUYANG[1], Y. LIU[1], S. ANDERSON[1], B. BERNARD[1], L. VERHAGEN[1];
[1]Rush Univ. Med. Ctr., Chicago, IL; [2]Univ. Col. London, London, United Kingdom; [3]Columbia Univ., New York, NY; [4]Mount Sinai, New York, NY; [5]Norwegian Univ. of Sci. and Technol., Trondheim, Norway

Abstract: Objective: To determine the rate of cognitive decline in glucocerebrosidase (GBA) mutation carriers with subthalamic nucleus deep brain stimulation (STN-DBS).
Background: About 12-17% of Parkinson's disease (PD) subjects undergoing DBS carry mutations in the GBA gene. The rate of cognitive decline in GBA mutation carriers after DBS has never been examined in a large cohort.
Methods: PD subjects with bilateral STN-DBS and GBA genotyping were identified from Rush University Medical Center, University College London Institute of Neurology, Norwegian University of Science and Technology, Icahn School of Medicine at Mount Sinai, Columbia University, and Parkinson's Progression Markers Initiative (PPMI). Data collected included age, age of onset, sex, years before DBS, years since DBS, family history, UPDRS, MMSE, MoCA, and Mattis Dementia Rating Scale (MDRS). MMSE and MoCA scores were converted to MDRS scores(1). Subjects were required to have a baseline MDRS score >=130 to be included in the analysis. Subjects were fully sequenced for GBA mutations and categorized into 4 groups: risk variants, mild, severe, or non-mutation carriers. Linear mixed modeling was used to compare rate of change in MDRS scores over time comparing the four groups, adjusting for age, sex, years before DBS, and years since DBS.
Results: Data were available for 30 GBA mutation carriers and 44 non-mutation carriers. GBA mutation carriers included 11 subjects with risk variants, 15 subjects with mild mutations, and 4 subjects with severe mutations. There was no significant difference in age, sex, age of onset, years before DBS, years since DBS, baseline MDRS scores, family history, or baseline UDPRS-III (OFF/ON) scores between GBA mutation carriers and non-mutation carriers. MDRS scores worsened over time in all 4 groups (-0.84 points per year, p = 0.0007). MDRS scores decreased faster in mild GBA mutation carriers (-1.68 points per year p = 0.0004) and severe GBA

mutation carriers (-1.8 points per year, p = 0.01) compared with non-mutation carriers. Median follow-up time was 5.5 years and was not significantly different between the groups (p = 0.68). By the time of meeting, additional subject data will be available and the analyses will be updated accordingly.
Conclusions: PD subjects with mild or severe GBA mutations with STN-DBS have faster cognitive decline compared with non-mutation carriers. This is the largest cohort to date to examine cognitive decline in GBA mutation carriers after STN-DBS. Additional studies are needed to compare cognitive decline in GBA mutation carriers with and without STN-DBS.

Feinberg Sch. of Med., Chicago, IL; [8]Dept. of Neurolog. Sci., Rush Univ. Med. Ctr., Chicago, IL; [9]Dept. of Neurol., Univ. of Chicago Med., Chicago, IL; [10]Dept. of Publ. Hlth. Sci., Med. Col. of South Carolina, Charleston, SC

Abstract: Neurite orientation dispersion and density imaging (NODDI) uses a three-compartment model to probe brain tissue microstructure, whereas free-water (FW) imaging models two-compartments. It is unknown if NODDI detects more disease-specific effects related to neurodegeneration in Parkinson's disease (PD) and atypical Parkinsonism. We acquired multi- and single-shell diffusion imaging at 3 Tesla across two sites. NODDI (using multi-shell; isotropic volume [Viso]; intracellular volume [Vic]; orientation dispersion [ODI]) and FW imaging (using single-shell; FW; free-water corrected fractional anisotropy [FAt]) were compared in 44 PD, 21 multiple system atrophy Parkinsonian variant (MSAp), 26 progressive supranuclear palsy (PSP), and 24 healthy control subjects in the basal ganglia, midbrain/thalamus, cerebellum, and corpus callosum. There was elevated Viso in posterior substantia nigra across Parkinsonisms, and Viso, Vic, and ODI were altered in MSAp and PSP in the striatum, globus pallidus, midbrain, thalamus, cerebellum, and corpus callosum relative to controls. The mean effect size across regions for Viso was 0.163, ODI 0.131, Vic 0.122, FW 0.359, and FAt 0.125, with extracellular compartments having the greatest effect size. A key question addressed was if these techniques discriminate PD and atypical Parkinsonism, using regions previously identified in a different cohort (putamen, superior cerebellar peduncle, vermis). Both NODDI (AUC: 0.946) and FW imaging (AUC: 0.932) had high accuracy, with no significant difference between models. This study provides new evidence that NODDI and FW imaging offer similar discriminability between PD and atypical Parkinsonism, and FW had higher effect sizes for detecting Parkinsonism within key regions across the basal ganglia and cerebellum.

Title: Associations between cortical thickness and white matter connectivity

Authors: *L. LUO[1], N. VANEGAS[2], D. TOMISHON[2], Y. GAZES[2];
[1]Dept. of Neurol., [2]Columbia Univ. Med. Ctr., New York, NY

Abstract: The regionally-specific relationship between longitudinal changes in white matter (WM) microstructure and cortical thinning across adult lifespan was studied in a few previous studies to evaluate the causal relationship between changes in white matter integrity and cortical degeneration. In the current cross-sectional study, we further investigated the white-to-grey matter relationship in a group of Parkinson's patients and healthy controls in order to explore the associations in the context of pathological degeneration. Instead of the often-used fractional anisotropy to characterize white matter integrity, we examined white matter connectivity between cortical region pairs in order to understand how variability in cortical thickness relates to the variability in the connectivity between the region pairs. Nine Parkinson's patients (3F/6M; age:58±9.4 years) and 13 healthy controls (10F/3M; age: 65±6.6 years) received both T1-weighted structural imaging and multi-shell diffusion weighted imaging (DWI) using a 3T GE scanner. T1 images were parcellated with the DKT atlas using FreeSurfer v6.0 and the DWI data were pre-processed with the MRtrix3 software. After pre-processing, the multi-shell multi-tissue constrained spherical deconvolution model was estimated for the DWI data, then ten million streamlines were estimated by a probabilistic fiber tracking algorithm among all pairings of the parcellated regions. Connectivity between region pairs was quantified with the intensity of structural connectivity. To relate cortical thickness with the connectivity between region pairs, linear regression model was tested with age, gender and mean cortical thickness of each region pair as the explanatory variables, while connectivity was the outcome variable. Using the False Discovery Rate to correct for multiple comparisons, we found that the mean cortical thickness of (1) the left lateral occipital and the middle temporal area significantly predicted the WM connectivity at $P < 0.0001$, and (2) the right posterior cingulate and the precuneus predicted the associated WM connectivity with $P < 0.0001$. The findings demonstrate the interconnectedness between grey and white matter health and warrants further exploration in longitudinal data.

Title: Cytoskeletal alterations contributing to synapto-axonal dysfunction in Parkinson's disease

Authors: *C. C. WARTH PEREZ ARIAS[1], L. CALDI GOMES[1], C. LENZ[2], H. URLAUB[2], H. WARTMANN[3], S. BONN[3], S. RIZZOLI[1], P. LINGOR[4];

Chem., Goettingen, Germany; [3]ZMNH Inst. für Medizinische Systembiologie, Hamburg, Germany; [4]Tech. Univ. of Munich, Munich, Germany

Abstract: Parkinson´s disease (PD) is a movement disorder with a strong degeneration of dopaminergic neurons. Motor symptoms arise once ~30% of these neurons are lost. However, more than 50% of tyrosine hydroxylase positive striatal dopaminergic terminals have degenerated by this point. Synapto-axonal degeneration preceding the loss of the somata in a dying back manner is hence an early pathological step in PD. The aim of this project is to establish the alterations of the synapto-axonal proteins levels in PD as a quantitative description of pathological changes in the synapse, and to identify novel potentially therapeutically relevant molecular targets.

To this end, we analysed the proteome of human post mortem hippocampal tissue of 16 PD patients and 14 age-matched controls (AMC). Via Selected Window Acquisition of All Theoretical Precursors (SWATH) mass spectrometry, 2089 proteins were quantified across all samples. A linear model was fitted to the data with moderated t-statistics via empirical Bayes, followed by Benjamini-Hochberg correction for multiple-testing. 55 proteins were found to be differentially expressed. Amongst these we identified proteins involved in the synapse organization: synapsin 1, a neural phosphoprotein coating synaptic vesicles that regulates neurotransmitter release; neuromodulin, a major component of growth cones and involved in axonal and dendritic filopodia induction; and myristoylated alanine-rich C-kinase substrate, the most prominent cellular substrate for protein kinase C, which binds to proteins like calmodulin, actin and synapsin.

To correlate human post-mortem data with longitudinal disease development, we analysed three time points in the hippocampus of male prnp.aSyn.A53T mice. Animals were analysed at 100, 250, and 400 days of age and compared to age-matched wild-type litter mates (n=5, each). 1734 unique proteins were identified, from which 2, 14, and 12 differentially expressed proteins were identified in 100, 250, and 400 days old mice, respectively. Amongst these, synapsin 1 was identified in both mouse (at all 3 time points) and human samples.

Our results demonstrate the feasibility of comparative proteomics from human post-mortem tissue and mouse animal models. Furthermore, they support the idea of synapto-axonal alterations contributing to PD pathogenesis and identify molecular correlates that could represent therapeutic targets.

Title: Fostering inclusivity in research engagement for underrepresented populations in Parkinson's disease: The FIRE-UP PD study

Authors: *A. V. SANCHEZ[1,2], H. HEMLEY[1], J. D. JACKSON[1,2];
[1]Massachusetts Gen. Hosp., Boston, MA; [2]Harvard Med. Sch., Boston, MA

Abstract: Greater diversity in clinical trial enrollment improves study generalizability and therapy efficacy. However, underrepresented groups (URGs) in Parkinson's disease (PD) research remains rare, even in online PD research platforms such as Fox Insight (FI). We define URGs as women, racial and ethnic minorities, individuals of low socioeconomic status (SES; below the US median household income of $57,000), or rural residents. This study addresses barriers to research for URGs in PD research as well as the awareness of PD clinical research opportunities for underrepresented participants. This pilot study focuses on enrollment to FI via a small exploratory intervention. We hypothesized that interventions at sites focused on engaging URGs would enroll a greater proportion of URGs than at passive control sites serving similar populations. We implemented a stratified randomization design for eight sites within the Parkinson Study Group (PSG) network, in which pairs of sites were assigned to either intervention or control conditions. Sites were paired based on ability to address specific recruitment barriers outlined by Picillo and colleagues (2015). Each intervention site additionally identified a URG population and a 6-month intervention to address the URG barrier. Sites in Chicagoland, Boston, Denver, and Miami were randomly assigned to the intervention condition. Sites targeted low SES, racial and ethnic minorities; Black/African Americans; and two sites targeted Hispanic/Latino URG populations, respectively. Sites in Chicago; the rural Midwest; King County, WA; and San Francisco served as controls. Control sites maintained current recruitment infrastructure and workflow modified through the display of FI materials and a dedicated tablet device for surveys and FI registration. All sites report the Trust in Medical Researchers Scale (TIMRS), attitudes towards genetic testing, surveys regarding awareness, engagement, and interest in PD research, as well as URG accrual to FI, prior to and following the intervention period. Intervention and follow-up continue through December 2019. We report change in site-level TIMRS and accrual to PD research studies, as well as digital media metrics to determine engagement with PD research.

Title: Application of tract-based spatial statistic analysis of Parkinson's disease

Authors: *Z.-L. DI[1,2], T. WANG[1], J. YANG[3], Q. ZHANG[4], X. WU[4], Z. LIU[4], X. WANG[4]; [2]Neurol. Dept., [1]Xi’An Central Hosp., Xi’An, China; [3]Xi'An Central Hosp., Xi’An, China; [4]Xi'An Central Hosp., Xi'An, China

Abstract: Parkinson's disease (PD) is a common nervous system degenerative disease in the aged, which mainly manifested as resting tremor, bradykinesia, rigidity and postural balance disorder. we used tract-based spatial statistics (TBSS) to analyze the microstructure of white matter in PD patients with different courses and explore whether TBSS method may be used as an imaging biomarker of PD diagnosis and monitoring.30 Parkinson's disease (PD patients in our hospital were collected. The whole brain T1 structure image and diffusion tensor imaging (DTI) function image were obtained . A data processing software PANDA is used to preprocess DTI data. We compared brain white matter by TBSS. The fractional anisotropy(FA) value of the brain region was obtained by PANDA software. The fiber bundle of FA decreased in early PD group,including the body of corpus callosum, splenium of corpus callosum, middle cerebellar peduncle,left posterior thalamic radiation, genu of corpus callosum, right posterior thalamic radiation,right posterior corona radiata, left anterior corona radiata, right superior corona radiata, right external capsule, right anterior limb of internal capsule, left anterior limb of internal capsule,and right superior longitudinal fasciculus as well($P<0.05$, FWE correction, voxel>500).The fiber bundle of FA decreased in advanced PD group, including genu of corpu callosum, body of corpus callosum, right anterior coron radiata, left anterior coron .radiata,right posterior thalamic radiation, right superior coron radiata, right posterior corona radiata, right anterior limb of internal capsule,right external capsule, left superior corona radiata,left anterior limb of internal capsule, and left posterior thalamic radiation as well($P<0.05$, FWE correction, voxel>500). Extensive white matter fiber bundles were damaged in PD patients,and the damage of the white matter fiber bundles was more severe in advanced PD patients. The FA value of the damaged white matter fiber bundle in PD patients was negatively correlated with the H-Y classification. The FA value of impaired white matter fiber bundle in PD patients was not correlated with the score of UPDRS- I and UPDRS- III scale.

Title: Atlas-independent, individualized tissue activation modeling to map the optimal location of subthalamic deep brain stimulation for Parkinson's disease

Authors: *K. A. MALAGA[1], J. T. COSTELLO[2], K. L. CHOU[3,4], P. G. PATIL[1,3,4];
[1]Biomed. Engin., [2]Electrical Engin., [3]Neurosurg., [4]Neurol., Univ. of Michigan, Ann Arbor, MI

Abstract: Deep brain stimulation of the subthalamic nucleus (STN DBS) is an established treatment for the motor symptoms of Parkinson disease (PD). Motor outcomes after STN DBS can vary considerably across patients and depend strongly on the location of stimulation relative to the surgical target. The objective of this retrospective study was to map the optimal location of STN DBS for PD using an atlas-independent, individualized tissue activation modeling approach and to assess the relationship between the therapeutic volume of tissue activated (VTA) and motor improvement. The stimulation-induced electric field in the brains of 40 PD patients treated with STN DBS was modeled using finite element analysis. Neurostimulation models were tailored to each patient, incorporating individual STN anatomy, anisotropic brain conductivity, electrode position and orientation, and stimulation settings. A voxel-based analysis of the VTAs was used to map the optimal location of stimulation. The amount of stimulation in specific regions relative to the STN was measured and compared between patients with optimal and sub-optimal stimulation, as determined by their motor outcomes (MDS-Unified Parkinson's disease Rating Scale III) and VTA. The relationship between VTA location and motor improvement was assessed using linear regression. Variability across patients in terms of STN anatomy, active contact position, and VTA location was also evaluated. Individualized VTA modeling mapped the optimal location of stimulation to a region medial, posterior, and dorsal to the STN centroid. This region was external to the STN and corresponds to the zona incerta (ZI). VTA location and active contact position differed significantly between patients with optimal and sub-optimal stimulation in the dorsal-ventral and anterior-posterior directions. There were significant linear relationships between the amount of dorsal and posterior stimulation, as measured by the VTA, and motor improvement. These relationships were more robust than those between active contact position and motor improvement. There was high variability in STN anatomy, active contact position, and VTA location across patients. Accurate predictions of the spread of stimulation in the brain are important for optimizing STN DBS for PD. High variability across patients in terms of neuroanatomy and stimulation location highlights the need for individualized modeling approaches. This study mapped the optimal location of stimulation to a region external to the STN, which provides further evidence for ZI as an optimal stimulation target for PD.

Title: Polygenic risk for Parkinson's disease in unaffected individuals associates with microstructure of disease-related white matter regions

Authors: *J. BRIGHT[1], L. DING[1], M. BORNSTEIN[1], M. LAANSMA[2], Y. VAN DER WERF[2], P. M. THOMPSON[1], N. JAHANSHAD[1];

Abstract: Parkinson's disease (PD) affects up to 10 million people worldwide; still, little is known about its cause or progression. Early structural brain changes in PD may occur in the white matter (WM; Worker et al., 2014), which can be studied using diffusion tensor imaging (DTI) derived fractional anisotropy (FA). Identifying genetic risk factors underlying WM abnormalities may help in the detection of PD in presymptomatic stages, and allow for targeted treatments, yet the effect of the genetic risk for PD on WM is unknown. Here we calculated a PD polygenic risk score (PRS) for 8,632 subjects from the UK Biobank (4,518F/4,114M; mean age: 62.5 yrs, range 45-79 yrs) by summing risk variants, weighted by association statistics from Nalls et al. (2014), using a $p<10\text{-}5$ threshold. FA estimates were extracted and averaged bilaterally for 27 regions of interest (ROIs) per subject. For each ROI, we used a linear regression to test the association between PRS and FA, covarying for age, sex, and ancestry using the first four components from multi-dimensional scaling analysis. The anterior limb of the internal capsule (ALIC) showed a significant positive association after multiple comparisons correction using the false discovery rate method; higher genetic risk was associated with higher FA ($p=0.002$). A follow-up study of separate left and right ALIC showed significant positive associations ($p=0.001$ and $p=0.006$, respectively). To assess disease relevance of the ALIC, we then compared ALIC FA of 142 PD patients to 63 healthy controls (HC) from the Parkinson's Progression Markers Initiative. PD patients showed significantly higher FA in the bilateral ALIC compared to HC ($p=0.015$). Higher FA in PD compared to HC was also seen in left and right ALIC separately ($p=0.017$, and $p=0.025$ respectively). The association of higher genetic risk for PD with higher FA in the ALIC follows the pattern of effects seen in patients vs HC suggesting the disease-related microstructure differences may be partially driven by genetic risk. We note that the ALIC contributes to thalamic connections; larger thalamic volumes observed in PD patients vs HC (Van der Werf, 2019) may be partially driven by genetic risk and WM

differences. Our study suggests genetics as a promising target for future research on PD-related brain changes.

Title: Distribution of tremorogenic activity and tremor in the upper limbs of persons with essential tremor

Authors: *S. K. CHARLES[1], D. STANDRING[2], A. PIGG[2], J. THOMPSON-WESTRA[3], K. MENTE[4], C. MAURER[4], D. HAUBENBERGER[3], M. HALLETT[4];

Abstract: Although Essential Tremor is one of the most common movement disorders, we do not currently know where to intervene (which muscles or joints) to suppress tremor in an optimal manner. To start addressing this challenge, we characterized the distribution of tremorogenic muscle activity and tremor throughout the upper limb. We recorded surface electromyography (sEMG) in the 15 major superficial muscles of the upper limb and motion capture data from the torso to the hand in 25 subjects with ET while they performed both postural and kinetic tasks. The amount of tremorogenic activity in each muscle was computed as the power in the normalized, high-pass filtered, and rectified sEMG, integrated over the tremor band (4-12 Hz). To compute the amount of tremor in each of the 7 main degrees of freedom (DOF) comprising the shoulder, elbow, forearm, and wrist, we used inverse kinematics algorithms to transform motion capture data into angular displacement in each DOF, differentiated to obtain angular displacement in each DOF, and calculated the tremor-band power in the angular acceleration.

Averaged across all subjects, we found that the anterior deltoid had the most tremorogenic activity overall and much more tremorogenic activity than neighboring proximal muscles. Wrist extensors also had high amounts of tremorogenic activity compared to other distal muscles. The triceps longus had the least amount of tremorogenic activity. Tremor was found to be most pronounced in wrist flexion-extension, then forearm pronation-supination, and then shoulder internal-external rotation. Shoulder abduction-adduction exhibited the least amount of tremor. Importantly, the distribution of both tremorogenic activity and tremor were quite stereotyped, being similar across repetitions, postures, tasks, and subjects. For example, the mean correlation coefficients characterizing the distribution of kinetic tremor across repetitions, postures, tasks, and subjects were 0.94, 0.86, 0.52, and 0.72, respectively. We are currently working on elucidating the relationship between tremorogenic muscle activity and tremor to determine which muscles have the largest effect on tremor and should therefore be targeted to suppress tremor in an optimal manner.

Title: Exploring phosphorous metabolites in Parkinson's disease at 7Tesla

Authors: *K. THOMAS[1], P. BEDARD[1], D. EHRLICH[2], M. HALLETT[1], S. G. HOROVITZ[1]; [1]Med. Neurol. Branch, Human Motor Control Section, [2]Med. Neurol. Branch, Parkinson's Dis. Clin., NIH - NINDS, Bethesda, MD

Abstract: Parkinson's disease (PD) is a neurodegenerative disorder in which neurons in the substantia nigra (SN) of the basal ganglia die, leading to its hallmark motor symptoms. Because impaired mitochondrial function may contribute to cell death in PD, we are motivated to investigate signs of mitochondrial dysfunction in the SN. To do so we explored phosphorous metabolites in PD patients and healthy volunteers (HV) using magnetic resonance spectroscopy imaging (MRSI).

28 datasets (14 PD, 14 HV) collected in a 7T siemens scanner using a $^{31}P/^{1}H$ birdcage coil are included in this study. Data consisted of an MPRAGE and a whole brain 3D ^{31}P-MRSI with voxel size of 17.28 cc (FOV=200 x 180 x 180 mm^3, matrix=12 x 12 x 12). MPRAGE data were segmented in Freesurfer. Spectroscopy data were processed in JMRUI to fit eight phosphorous metabolites indicative of energy and phospholipid metabolism. This data was registered to the MPRAGE with in-house programs.

Four regions of interest (ROIs) were selected bilaterally: left SN, right SN, left putamen (PUT) and right PUT. Two metabolites of interest were selected for this analysis: glycerophosphoethanolamine (GPE) to assess membrane integrity and phosphocreatine (PCr) to assess cell energy. We compare groups with t-tests assuming unequal variance between the HV and PD patients for each ROI separately.

Our results showed that PD patients have significantly ($p = .0419$) larger GPE/PCR in the right SN compared to HV. To determine whether an increase in GPE or decrease in PCr the reason for this difference, we also did t-tests of the ratios GPE over total (sum of all eight metabolites we calculated), as well as PCr over total. We found in the right SN that there was a trend towards significance between the groups in the ratio GPE/total ($p = .081$) compared to the ratio PCr/total ($p = .3479$). None of the ratios assessed were found to be associated with the subjects' age or intracranial volume, and the tissue composition of the voxel selected that encompassed the SN was similar for both groups. These ratios in the left and right PUT showed no significant difference between groups.

We were able to detect changes in the area where the disorder is believed to start, the SN. Our results would be compatible with an increase in membrane breakdown in PD patients when compared to HV. Our results suggest that the increased degradation seen in the SN of PD patients is not detectable in the PUT. Further exploration of other metabolites and brain areas will provide a better understanding of the energetics and membrane integrity in PD.

Abstract: Transcriptomic analysis of whole blood samples has the potential to uncover biological pathways disrupted by disease processes. Detectable changes in the transcriptome of a readily accessible biofluid, such as blood, have the potential to be valuable biomarkers. The goal of this project was to develop and share a comprehensive RNA resource from whole blood samples taken from normal healthy control subjects, patients diagnosed with Parkinson's disease (PD), and subjects at-risk for PD, for the purposes of biomarker discovery and to provide a broader understanding of RNA changes associated with PD. Approximately 4700 whole blood samples from 1610 subjects were obtained from the Michael J. Fox Foundation's Parkinson's Progression Markers Initiative cohort, including longitudinal samples at baseline, 6 months, 1 year, 2 year, and 3 years. High quality RNA samples were globin and ribodepleted, and strand-specific libraries were created for sequencing. Targeted sequencing depth was 100 million read pairs per sample, yielding a highly diverse transcriptome for downstream analyses. We identified a large number of coding and non-coding RNA transcripts. We will present data comparing the transcriptomic landscape of PD and normal controls, as well as transcriptomic changes associated with disease progression. These data include not only protein-coding RNA, but several RNA biotypes, including lncRNA and circRNA, and their potential deregulation in association with PD. We will also provide details on how to access the data and how to access a web portal built specifically to visualize and query the RNASeq data.

Title: H3K27 acetylation landscape dysregulation in patients with Parkinson's disease

Authors: *J. SUNDARESAN, G. T. TRAN, L. TOKER, G. S. NIDO, C. DÖLLE, C. TZOULIS;
Univ. of Bergen, Bergen, Norway

Abstract: Parkinson's disease (PD), is the most common movement disorder and second most common neurodegenerative disease. It has a lifetime risk of 1-2% with a steady increase of prevalence with age, affecting 1-2 per 1000 of the population at a given time. Risk factors for the disease range from lifestyle and environment to genetics with no particular factor taking precedence over others. Our previous work suggested alteration in some of the histone acetylation profile, in particular H3K27, between PD and age matched control brains. Here, we compare genome-wide enrichment of H3K27ac in the pre-frontal cortex (BA9) of PD individuals against age matched cognitively normal controls. The dataset includes 17 PD and 11 control brains for whom H3K27ac profile was determined by CHIP sequencing. We find a distinct difference in H3K27ac binding pattern between the two groups. Furthermore, we elucidate the genomic locations of significant H3K27ac changes with expression quantitative trait loci. Our results establish the basis for an epigenetic link to PD pathology.

Title: Cortical and subcortical microstructural alterations detected by diffusion tensor imaging in early-stage Parkinson's disease

Authors: *M. AMANDOLA[1], H.-C. LEUNG[2];
[1]Stony Brook Univ., Stony Brook, NY; [2]SUNY Stony Brook, Stony Brook, NY

Abstract: Previous diffusion tensor imaging (DTI) studies of Parkinson's disease (PD) have shown alterations in microstructure integrity, particularly in frontal white matter and subcortical grey matter. The progression of these microstructure degradations in PD is not fully understood. Our objective is to examine changes in microstructure integrity in early-stage PD in relation to cognitive and motor decline using a prospective approach.
Using data from the Parkinson's Progression Markers Initiative (PPMI), we examined individuals in early-stage PD who had diffusion images at both 12-month (N = 60, aged 39-76, 20 F) and 24-month (N = 44, aged 39-77, 12 F) timepoints. We conducted a paired t-test across the two timepoints, and multiple regression analyses at each timepoint to test for alterations in whole brain voxel-wise fractional anisotropy (FA) and mean diffusivity (MD) in associations with cognitive and motor symptoms.
In accordance with previous findings, advanced age was associated with higher MD and lower FA in widespread brain regions at both timepoints. This age-related pattern of microstructural degradation seemed to relate to cognitive impairment across subjects in the 12-mo timepoint, but less so in the 24-mo timepoint. Significantly higher MD in the right medial frontal white matter was observed in the 24-mo relative to 12-mo timepoint. At both timepoints, cognitive and motor impairment across subjects were associated with higher MD and lower FA in frontal white matter and various cortical and subcortical regions. Intriguingly, severity of rigid and akinetic symptoms was associated with higher FA and lower MD in the pons, thalamus, and cerebellum in the 12-month timepoint. A similar pattern of FA and MD effects was found with rigid/akinetic symptoms across subjects at 24 months. These findings suggest that impairment in cognitive and motor abilities in early-stage PD may relate to degradation in frontal white matter, and that alterations of microstructure integrity in subcortical regions may uniquely relate to more severe rigid and akinetic symptoms in early-stage PD. Tracking such microstructural changes may have implications in treatment management.

Title: Subcortical brain volumes as potential markers of Parkinson's disease progression

Authors: *R. M. WALES, M. WONG, M. KARIBIAN, H.-C. LEUNG;
SUNY Stony Brook, Stony Brook, NY

Abstract: Several recent volumetric longitudinal studies have proposed the volumes of subcortical structures as potential biomarkers of early Parkinson's disease (PD), but the relationship between these brain volumes and cognitive and/or motor outcomes remains unclear. In this study, we examined hippocampus, caudate, and putamen volumes in relation to cognitive functions (executive function, memory, and visuospatial domains) and motor symptom severity (UPDRS III total, akinetic/rigidity, and tremor scores). Imaging (T1 MRI), clinical, and behavioral data from early stage PD patients and healthy controls were obtained from the Parkinson's Progression Markers Initiative database. FreeSurfer was used to extract subcortical volumes from each individual at each time point (baseline, 12-, 24-, and 48-mo follow-ups). Changes in cognitive and motor assessments were measured by calculating the slope between time points. Multiple regressions, accounting for age, gender, years of education, and study site, were used to examine the relationships between volumetric, cognitive, and motor measures.Comparing subcortical volumetric rates of change between PD and healthy controls revealed significantly more hippocampal atrophy in PD patients over a one year period than healthy controls. This effect remained even after controlling for intracranial volume. A multiple regression analysis of the relationship between volumetric, cognitive, and motor measures revealed that, at baseline, smaller putamen volumes were associated with more severe rigid/akinetic symptoms across subjects. Intriguingly, more severe rigid/akinetic symptoms at baseline seemed to predict putamen atrophy over four years. Some of these associations may also be driven by a combination of age, gender, and cognitive dysfunctions. These data suggest that hippocampal atrophy is evident in early PD, and that the baseline motor symptom profile (e.g., rigid/akinetic) may predict subcortical atrophy during early stage of the disease

Title: Sensory weighting for postural control and fall-risk changes with progression of Huntington's disease

Authors: *M. B. MAY[1], J. COREY-BLOOM[5], P. E. GILBERT[2], D. J. GOBLE[3], H. S. BAWEJA[4];
[2]Dept Psychol, [3]Exercise and Nutritional Sci., [4]Doctor of Physical Therapy Program, [1]San Diego State Univ., San Diego, CA; [5]Dept. of Neurol., Univ. of California San Diego, San Diego, CA

Abstract: Huntington's disease (HD) is a genetic neurodegenerative movement disorder caused by more than 36 repetitions of the CAG nucleotide sequence. HD is typically diagnosed between the ages of 30-50 years. Prior to diagnosis the gene carriers are considered *pre-manifest*. Chorea, characterized by involuntary hyperkinetic motor movements, is a hallmark symptom of manifest HD. Dynamic posturography is an effective test to distinguish the movement dysfunction between pre-manifest and manifest HD. Furthermore, postural sway measurements during sensory information manipulations are of great value in understanding disease progression. However, the role of sensory information in postural control with disease manifestation remains unclear. Therefore, the purpose of this study was to understand the effect of sensory information processing on postural control in Huntington's disease. 82 subjects participated in the study: 26 gene-negative (ARN), 20 gene-positive (ARP), 26 HD, and 10 healthy controls (HC). All subjects performed a static balance assessment using a portable force plate (Balance Tracking Systems, San Diego, CA). Testing consisted of 1 familiarization and 3 experimental trials of quiet standing with feet shoulder width apart and hands on the hips. This was performed twice to examine sensory weighting: once with eyes open (EO) and once with eyes closed (EC). Each trial lasted 10 seconds during which the total center of pressure (COP) sway, COP antero-posterior sway, COP medio-lateral sway excursions, velocities and 95% CIs of the COP area were quantified. All subjects' exhibited greater postural sway with eyes closed versus open in all directions. However, HD patients demonstrated the most significant decline in balance with their eyes closed when compared with pre-manifest (HD>ARP>ARN) and healthy control subjects. Previous studies from our group suggest that this decline in postural control with the absence of vision is
indicative of a higher risk for falls. Our findings also indicate that manifest HD patients are at a higher risk for falls and are highly dependent on vision for postural control when compared with pre-manifest and healthy older adults.

Title: Wearable-sensor driven responsive deep brain stimulation for the improved treatment of essential tremor

Authors: *S. CERNERA[1], J. ALCANTARA[1], E. OPRI[2], J. CAGLE[1], M. S. OKUN[1], A. GUNDUZ[2];
[2]Biomed. Engin., [1]Univ. of Florida, Gainesville, FL

Abstract: **Introduction:** Essential tremor (ET) is one of the most common adult onset tremor disorders that is clinically associated with chronic, disabling action tremors within the 4-12 Hz range. For patients unresponsive to medication, deep brain stimulation (DBS) is an effective therapeutic option. Despite significant improvements with DBS, its paradigm is continuous. Additionally, the current methodology is an inefficient solution for patients with tremor, which can dynamically change throughout the day. Since ET symptoms are paroxysmal, DBS does not have to be continuously delivered. We hypothesize that wearable sensors, specifically those that measure the electromyogram (EMG), are capable of detecting correlates of tremor or movement that will provide the control signal for responsive DBS (R-DBS) in a targeted and personalized manner. **Rationale:** R-DBS could reduce adverse effects of continuous DBS, deliver personalized stimulation, and decelerate battery depletion of the implantable neurostimulator (INS), while delivering an equally effective treatment. **Methods:** EMG data were recorded using Trigno Acquisition Unit (Delsys, Inc, Natick, MA) sensors from three ET subjects. Sensors were bilaterally placed on seven upper limb muscles. Data were recorded while the subject was performing several tasks in both DBS-on and -off states. From EMG signals, we extracted correlates that accurately delineated both tremor from voluntary movement and movement from rest conditions through power analysis. Correlates that separated movement from rest conditions were used in the R-DBS algorithm. Feasibility of R-DBS using wearable sensors was evaluated using Nexus-D, which is a Medtronic investigational system able to titrate stimulation parameters by communicating with the subject's INS. For R-DBS, two separate paradigms were tested. The first focused on a linear detector using a calibrated threshold, while the second was a multi-sensor paradigm using a support vector machine. The feature used in both paradigms was

the power within the subject's tremor frequency band (±2 Hz). **Results:** Across subjects, DBS decreased tremor power by -66.44±-28.10% within the EMG. Additionally, R-DBS decreased the average voltage by 1.51±0.63V across trials. The average sensitivity of movement detection during R-DBS was 78.7±7.85%; however, DBS was always active during movement since stimulation amplitude was continuously titrated. **Conclusions:** From these results, we have proven the feasibility of an R-DBS paradigm based solely on external wearable sensors. Furthermore, R-DBS was more efficient than and just as efficacious as continuous DBS.

Title: Reduction of tremor in essential tremor patients using electrical stimulation of afferent pathways

Authors: A. PASCUAL VALDUNCIEL[1], *F. O. BARROSO[1], M. GONZALEZ SÁNCHEZ[2], J. PEREZ SÁNCHEZ[2], S. MUCELI[3], M. K. JUNG[3], F. GRANDAS[2], D. FARINA[3], J. L. PONS[1];

Abstract: Essential Tremor (ET) is one of main disorders leading to pathological tremor, which is the most prevalent movement disorder in the world and may hamper the execution of activities of daily living. Tremor management approaches such as Deep brain stimulation or medication are not effective in about 25% of the patients. Thus, other solutions should be considered, especially those that present less risks and are less invasive. Functional electrical stimulation has been tested as an alternative to suppress tremor. However, the development of fatigue, the discomfort and interference with voluntary movements are drawbacks that may impede the adaptation of similar solutions in long-term rehabilitation of tremor patients.
Recently, stimulation of muscle afferents has been proposed as a novel approach to reduce pathological tremor: the stimulation of Ia afferents may inhibit antagonist α-motoneurons (a mechanism known as reciprocal inhibition). Specifically, for the case of pathological tremor, the

reciprocal inhibition may be modulated via stimulation of Ia afferents of the muscle without tremor in order to suppress tremor in the antagonist muscle. To evaluate this application, we used surface stimulation of wrist flexors and extensors of ET patients using low-level intensity of stimulation and tested two different strategies: 1) out-of-phase stimulation of the antagonist of the muscle presenting the tremorogenic burst of activity (based on EMG activity); and 2) simultaneous stimulation of the two muscles. Periods of stimulation and without stimulation were alternated every 30s. IMUS were placed over the hand and forearm to quantify the tremor reduction. Preliminary results indicated that the out-of-phase strategy achieved better tremor suppression results than continuous stimulation. This reduction of tremor was even higher when stimulation was applied over the nerves innervating each muscle and not over the muscle belly directly.
Electrical stimulation of afferent pathways poses as a promising approach for reducing tremor in ET patients. We are currently evaluating if intramuscular stimulation can improve tremor reduction when compared to superficial stimulation of the nerves. Our long-term goal is to use fully deployable technologies to maximize tremor suppression.

Title: Efficacy of long term intrathecal 2-hydroxypropyl-ß-cyclodextrin treatment on balance and gait deficits in Niemann-Pick type C1

Authors: *J. A. O'KEEFE[1], J. M. JOYCE[2], K. E. WROBEL[3], N. PURCELL[2], B. OUYANG[4], Y. LIU[5], E. BERRY-KRAVIS[6];
[1]Cell & Mol. Med., Rush Univ. Med. Ctr., Chicago, IL; [2]Cell & Mol. Med., [3]Rush Med. Col., [4]Neurolog. Sci., [6]Pediatrics and Neurolog. Sci., [5]Rush Univ., Chicago, IL

Abstract: Niemann-Pick Type C (NP-C) is an autosomal recessive neurodegenerative disorder characterized by lysosomal accumulation of cholesterol in brain and peripheral tissues. NPC is caused by mutations in NPC1 or NPC2, proteins that normally transport cholesterol. There is great phenotypic variability but cerebellar ataxia, apraxia, dystonia and cognitive decline are seen in many patients. 2-Hydroxypropyl-ß-cyclodextrin (HP-ß-CD) extends life and slows disease in NPC animal models. We examined the efficacy of HP-ß-CD in slowing neurological deterioration in patients with NPC via balance and gait testing. Six patients were treated with HP-ß-CD intrathecally in an Expanded Access Protocol (IND119856) at Rush University Medical Center (RUMC) for 15-60 months. Six additional patients were enrolled in a RCT (Vtesse, VTS301) at the RUMC site. Balance and gait outcome measures were tracked longitudinally with computerized dynamic posturography (CDP) and an inertial sensor system, to determine potential modification of disease course and longitudinal change over time. The primary balance outcome measure was the composite postural sway score on CDP. Gait variables were secondary outcome measures. Longitudinal change of each measure was analyzed using linear mixed models. Global function was assessed by the NPC-Neurological Severity Scale (NPC-NSS). CDP composite scores improved significantly over time ($p=0.0006$). Double support and swing times and cadence were stable ($p=0.24$-0.45). Stride length and velocity and gait variability worsened significantly ($p<0.0001$) and turn duration significantly increased ($p=0.002$). These findings of improved balance support the concurrent lack of worsening or mild improvement on the NPC-NSS, which deviates from the expected disease trajectory based on the natural history of NPC. Cadence, time in double support and swing phase showed overall stabilization likely due to stabilization of ataxia, while stride length and velocity, gait variability and turns worsened, likely due to worsening dystonia in 5/12 patients. Future studies are needed to explore the effect of dystonia on worsening gait measures in NPC. CDP balance measures and inertial sensor based gait and turn outcomes are feasible to determine efficacy of pharmaceutical interventions in neurological populations. Ongoing tracking with these sensitive measures will quantify the chronic impact of HP-ß-CD on balance and gait function in NPC, help differentiate good responders from poor responders and may distinguish improvements in balance/ataxia from worsening dystonia, a symptom which might be based on differences in regional brain penetration of the drug.

Title: Neuroprotective effects of melatonin pretreatment on a Parkinson's disease experimental model induced by manganese mixture inhalation

Authors: M. RODRÍGUEZ-ALCÁNTARA, O. MEJÍA-GARCÍA, A. GUTIÉRREZ-VALDEZ, E. MONTIEL-FLORES, J. ESPINOSA-VILLANUEVA, J. ORDOÑEZ-LIBRADO, P. ALEY-MEDINA, *M. AVILA-COSTA;
Neurosci., UNAM, Neuromorphology Lab., Mexico, Mexico

Abstract: Parkinson disease (PD) is a neurodegenerative process characterized for the depletion of substantia nigra compacta dopaminergic cells and striatal dopamine innervation, an as a consequence the patients show motor coordination and cognitive impairments. We developed a useful PD experimental model, where the animals inhale the mixture of MnCl2and Mn(OAc)3. This model promote the auto-oxidation of the dopamine, inducing bilateral and progressive degeneration of the SNc dopaminergic neurons in mice, bilateral tremor and rigidity. On the other hand, Melatonin (Mel) has antioxidant properties, increasing the mitochondrial complexes I and IV activity, furthermore it has been suggested that this action contribute to the protective effect in neurodegenerative diseases. Therefore in this study we aim to determine if Mel pre-treatment has a neuroprotective effect against the alterations produced by the inhalation of the mixture of MnCl2and Mn(OAc)3 one hour two times a week for five months. Before Mn exposure, animals were trained to perform motor tests and were evaluated each week after the exposure. The experimental groups were: control group, Mn mixture without Mel pretreatment exposed mice and Mel pretreated/Mn exposed group, the treatment was given orally for a month (10mg/kg). After five months of Mn inhalation we found that Mel-pretreatment, partially reduced the motor and cytological alterations observed in the exposed group. Therefore, Mel pretreatment is a promising procedure to delay the disease progression.

Title: Postural control deficits with progressive supranuclear palsy differ from idiopathic Parkinson's disease

Authors: *K. E. DILLON[1], C. J. MCELROY[2], I. LITVAN[2], J. FILOTEO[2], D. J. GLOBE[3], H. S. BAWEJA[1];
[1]San Diego State Univ., San Diego, CA; [2]Univ. of California at San Diego, La Jolla, CA; [3]Oakland Univ., Rochester, MI

Abstract: Progressive Supranuclear Palsy (PSP) is an atypical degenerative Parkinsonian disorder affecting the basal ganglia and brainstem. Cardinal signs include muscle weakness, oculomotor impairments, difficulty speaking, trouble swallowing, imbalance and lack of coordination. Postural control assessments using force platforms can provide an objective window into a disease mostly studied subjectively. These measurements can also be used to distinguish postural sway signatures unique to PSP from other Parkinsonian disorders. Therefore, the purpose of this study was to determine postural control deficits accompanying PSP and idiopathic Parkinson's disease (PD). 6 PSP (61-80 years), 12 PD (66-84 years) and 12 older adults (OA; 60-85 years) volunteered to participate in the study. All subjects performed a static balance assessment using a portable force plate. All testing consisted of 3 trials each of quiet unperturbed standing with eyes closed and eyes open; feet shoulder width apart and hands on the hips. Each trial lasted 20 seconds during which the total center of pressure (COP), COP antero-posterior (AP), and COP medio-lateral (ML) sway displacements were calculated. A principle component analysis was used to calculate the 95 and 99% confidence intervals (CI) of the area within which the COP would lie. Furthermore, changes in low-frequency postural oscillations were quantified by examining the absolute wavelet power in 3 frequency bins from 0-4 Hz. We found that low frequency oscillation in postural sway varied differentially with removal of vision (eyes closed v. eyes opened) and disease (PSP vs. PD). Furthermore, these postural oscillations increase with increasing fall risk. This effect is most pronounced in the PSP>PD>OA. Furthermore, PSP and PD patients at high fall risk are highly dependent on vision for postural control when compared to healthy controls and patients at low risk for falls. Most importantly, our findings suggest that non-linear measures of postural sway are more sensitive to changes in sensory weighting and neuropathologies than standard linear measures of postural sway assessment.

Title: Adaptive cortico-thalamic closed-loop deep brain stimulation for an enhanced treatment of essential tremor

Authors: *E. OPRI[1], S. CERNERA[1], R. MOLINA[2], M. S. OKUN[3], K. D. FOOTE[4], A. GUNDUZ[1];
[1]Biomed. Engin., [2]Electrical Engin., [3]Neurol., [4]Neurosurg., Univ. of Florida, Gainesville, FL

Abstract: Essential tremor (ET) is defined as a rhythmical, involuntary oscillatory movement of the limbs and is one of the most common movement disorders. Intention tremor occurs mostly in the upper limbs (with slow oscillations between ~4-12 Hz) during the initiation and execution of goal-directed reaching motions, while it is absent at rest. It has currently been suggested that a synchronous pathological oscillation in a network that includes the premotor (PM) and primary motor (M1) cortices, the ventral intermediate nucleus (Vim), and the cerebellum is suppressed through deep brain stimulation (DBS) by jamming the “tremor cells” in the thalamus. Three patients affected by ET were chronically implanted with both cortical (M1) and thalamic (VIM) leads, connected to a Medtronic Activa PC+S neurostimulator. Together with inertial and EMG collected data, it was possible to explore biomarkers related to movement intention/execution, and to tremor. The Activa PC+S neurostimulator allows us to use thalamocortical neuromarkers to modulate the stimulation parameters in real time, enabling a truly responsively delivered DBS. This closed-loop system was tested in real-case scenarios, such as reaching for a cup to drink from it. Hence, we show the feasibility and implementation of a closed-loop system using cortical neuromarkers evoked during different behavioral tasks, such as moving a hand or reaching a cup, to enable the control of stimulation activation and deactivation. We show that responsive DBS efficiently suppresses tremor modulating the amplitude of the stimulation based on the patient state (i.e., rest: no stimulation, movement: stimulation). Our results suggest that a reliable control of responsive DBS is possible with the use of a single or a combination of targeted brain areas. In addition, standard DBS and closed-loop DBS was shown to have similar performances in tremor suppression. Hence, this enhanced DBS therapy solution has the potential to decrease the possible patient’s side effects, such as balance and speech impairment,

and slow down battery depletion, by being inactive during non-tremor statuses, while delivering an equally effective but more efficient treatment.

Title: Stimulation rebound in deep brain stimulation for essential tremor

Authors: *B. I. FERLEGER[1], S. S. COOPER[2], A. B. BROWN[2], A. L. KO[3], H. J. CHIZECK[1], J. A. HERRON[3];
[1]Electrical and Computer Engin., [2]Neurosci., [3]Dept. of Neurolog. Surgery, Univ. of Washington, Seattle, WA

Abstract: Deep brain stimulation (DBS) is an established treatment for Parkinson's disease (PD), essential tremor (ET), dystonia, and several other movement and behavioral disorders [Baizabal-Carvallo 2014, Rodriguez-Oroz 2005, Krauss 2004]. Adaptive DBS (aDBS) seeks to mitigate battery drain and side effects of DBS by using feedback from biomarkers to modulate stimulation parameters, generally with a binary, all-or-nothing stimulation control system [Herron 2016, Opri 2016, Houston 2019]. A recent study identified and quantified a "rebound effect" in patients receiving DBS treatment for ET [Paschen 2019]. This effect manifests when sudden DBS deactivation results in a temporary increase in the severity of motor symptoms before settling to a steady state. In three trials across two patients receiving DBS for ET, videos of patients completing the drawing task of the Fahn-Tolosa-Marin (FTM) tremor rating scale were taken at 8-10 minute intervals. Inertial measurement unit (IMU) gyroscope data and recordings from one electrode implanted over the hand portion of the motor cortex were logged in one of these trials. One to four ratings were taken before DBS deactivation to account for motor task learning, with four after to evaluate rebound. Videos were blinded and shuffled for review by two neurologists. Rebound effect was present in all trials by clinical ratings and IMU data from the applicable trial. Mean clinical time-to-peak was T_p=10 min (SD=5.7), far longer than the near instantaneous peak reported previously [Paschen 2019]. Mean time-to-settle, defined as rating r_i for which $|r_{i-1}-r_i|$<0.5 points, was T_s=34 min (SD=1.7). Mean difference between peak (r_p) and steady-state (r_s) rating was r_p-r_s=0.83 (SD=0.24). IMU data yielded T_{gp1}=4 min, with 41% difference between peak and steady state 4-8 Hz band-power [Neumann 2017]. This diverges from the clinical assessment of T_{p1}=13 min. Cortical recordings show 12-30 Hz band power 27% lower at T_{gp1} than at T_{s1} during identical motor tasks. This additional beta

desynchronization may result from the increased effort required to complete tasks in the presence of tremor or correlate with tremor severity itself [Kondylis 2016, Weiss 2015]. Rebound effect has potential implications for the mechanism of DBS treatment in ET, indicative of an acute accommodation in response to DBS and a period of post-DBS washout comparable to the ramp-up washout seen in PD [Cooper 2013]. These findings imply inadvertent complications may stem from binary aDBS, supporting the case for nuanced, non-binary aDBS control systems [Little 2013, Priori 2013]. Rebound effect itself may serve as a testbed for future work in tremor estimation from cortical data.

Abstract: Multiple sclerosis (MS) and neuromyelitis optica spectrum disorder (NMOSD) are autoimmune demyelinating diseases of the CNS, having distinct immunologic features. The target antigen of autoimmunity in NMOSD is the water channel aquaporin-4 on astrocytes. Meanwhile, primary targets of MS are myelin and oligodendrocytes. As demyelinating diseases progress, emotional symptoms can develop. Here we compared the prevalence and clinical features of anxiety and depressive symptoms between MS and NMOSD. A total of 98 patients (72 with relapsing remitting MS, 26 with NMOSD) were evaluated for emotional symptoms with Hospital anxiety and depression scale (HADS). The HADS consists of two divisions, HADS-anxiety and HADS-depression; each score ranges from 0 to 21 (≥10 suggests significant anxiety or depression). As for baseline characteristics, female proportion was higher in NMOSD patients, while age was comparable. Clinically. although annualized relapse rates were

significantly higher in the NMOSD group (MS vs. NMOSD: 0.3 [0.1−0.5] vs. 0.6 [0.3−1.0], p=0.005), current functional status was similar (Expanded Disability Status Scale [EDSS], 2.5 [1.0−4.0] vs. 3.5 [1.0−3.5], p=0.550). As for emotional symptoms, both HADS-anxiety (6 [3−9] vs. 7.5 [5−9], p=0.403) and HADS-depression (6 [3−8] vs. 7 [5−8], p=0.600) were comparable between the disease groups; the proportion of patients with significant anxiety (38.9% vs. 50.0%, p=0.325) and depression (34.7% vs. 42.3%, p=0.492) were also comparable. As for disease phenotypes in the MS group, the most common first-attack phenotype in patients with significant anxiety was brain lesion (32.1%), while the phenotype in those with significant depression was myelitis (40.0%). In contrast, in NMOSD patients with significant emotional symptoms, the most common first-attack phenotype was optic neuritis (46.2% for anxiety, 45.5% for depression). In both disease groups, a low EDSS level was the only factor significantly associated with anxiety and depression. These findings suggest that anxiety and depression are fairly common in both MS and NMOSD patients, and their presence are associated with poor functional status. In addition, disease phenotypes related with emotional symptoms might be distinct between MS and NMOSD.

Title: A novel non-human primate model of essential tremor

Authors: *M. APANAVICIUTE[1], L. SAIEVA[1], M. BAKER[1], S. BAKER[2];
[1]Inst. of Neurosci., Newcastle Univ., Newcastle upon Tyne, United Kingdom; [2]Inst. of Neurosci., Inst. of Neurosci., Newcastle upon Tyne, United Kingdom

Abstract: Essential tremor (ET) is the most common movement disorder, affecting ~1% of people and characterized by a 4-12Hz postural/kinetic tremor affecting the hands, which progresses over years to involve head, arms, face and voice. Histological examination of autopsy tissue from some ET patients has demonstrated pathological changes in locus coeruleus (LC) and cerebellar cortex (Louis et al., 2007), suggesting a role for noradrenergic LC projections to cerebellum (LC-NA) in the pathogenesis of ET.
Two female rhesus macaques were trained to hold the right hand outstretched and maintain this posture for 3.5 seconds for food reward. The animals were then implanted surgically

(subcutaneous EMG electrodes in shoulder, arm and hand muscles; head piece with EMG output connectors; chamber with microelectrode access to cerebellum/brainstem). LC neurons were first stimulated using an excitatory DREADD (for technical details see Vazey & Aston-Jones, 2014) to increase LC firing rate (confirmed by single unit recordings from LC) and thus increase NA activity in cerebellar cortex. LC-NA terminals in the hand/arm area of cerebellar cortex were then lesioned by injecting 6-hydroxydpamine (6OHDA). The effects on kinetic/postural upper limb tremor were quantified by spectral analysis of EMG.
Upper limb tremor was not observed following LC overactivation. However, 1 day after 6OHDA injections a postural 4Hz tremor indistinguishable from ET emerged in both distal and proximal muscles. Tremor was attenuated significantly ($p<0.05$) by the following medications commonly used to alleviate ET (% reduction): propranolol (~40%); primidone (~40%); and carbamazepine (~30%).
Loss of LC-NA terminals in cerebellar cortex is thus sufficient to produce upper limb tremor resembling ET in non-human primates.

Title: The efficacy of phase-specific stimulation essential tremor during daily activities

Authors: *C. REIS[1], N. HALIASOS[3], P. BROWN[2], M. WOOLRICH[4], H. CAGNAN[2]; [1]Nuffield Dept. of Clin. Neurosci., [2]Nuffield Dept. of Clin. Neurosciences, Brain Network Dynamics Unit, Oxford, United Kingdom; [3]Barking, Havering and Redbridge Univ. Hosp. NHS

Trust, Romford, United Kingdom; [4]Oxford Ctr. for Human Brain Activity, Oxford, United Kingdom

Abstract: Essential tremor is one of the most common movement disorders. Although its cause remains unknown, several lines of evidence have shown that specific neurons in the ventral thalamus fire synchronously with peripheral tremor. Such synchrony is effectively disrupted with Deep Brain Stimulation (DBS), which delivers a continuous high frequency (130-180Hz) electric current to the target nucleus – e.g. ventral intermediate thalamus (ViM), posterior subthalamic area or zona incerta, achieving symptom suppression of up to 80%. Yet, around 50% of DBS implanted patients report side-effects, suggesting that stimulation may also disrupt physiological neural activity. A novel stimulation strategy is currently being developed with the aim of targeting only the tremor related neural activity termed phase-specific DBS. Hitherto, Phase-specific DBS has been delivered to the ViM, phase locked to patient's tremor as the patient was holding a static posture. This achieved tremor reduction by 85% whilst using less than half of the energy of conventional DBS. However, as tremor severity is variable across daily activities, i.e. during different movement states, it becomes crucial to investigate whether this strategy can provide sustained tremor suppression while the patient is moving. Here we aim to evaluate the feasibility of phasic DBS during movement by testing alternating stimulation strategies (sham, continuous and phasic-specific) and alternating movement states (rest, holding a posture and moving freely). Moreover, using Hidden Markov Modelling, which allows for a thorough description of the evolution of observed states dependent on hidden factors, we will model the variability of tremor amplitude during different stimulation and movement states. From such, we expect to provide a patient-specific description of the internally (movement) and externally (stimulation) generated perturbations that lead to the transition between different tremor severities.
Overall, the importance of this work is twofold: 1) to determine the applicability of phase-specific DBS as a novel clinical approach and 2) to better understand the dynamic relationship between central and peripheral tremor activity.

Abstract: Deep brain stimulation (DBS) can be an effective therapy for select cases of Tourette syndrome (TS), but clinical outcomes remain variable across patients. Our recent study showed that the anatomical location of stimulation does not predict outcomes, but it is unknown if there are specific pathways that are associated with improvement in TS symptoms. Our objective was to identify the pathways that predict clinical outcomes of DBS for TS in a large multisite cohort. Retrospective imaging and Yale Global Tic Severity Scale (YGTSS) scores of 34 TS patients receiving bilateral globus pallidus internus (GPi) DBS were collected in a collaboration with the International TS DBS Database and Registry and the International Neuromodulation Registry. Volumes of tissue activated (VTA) were generated using stimulation parameters for each patient. The VTA were used to generate probabilistic tractography in diffusion-weighted imaging of 40 Human Connectome Project subjects. A map of average connectivity weighted by percent improvement in YGTSS scores was computed across patients to identify the pathways associated with the highest improvement in TS symptoms. The pathways were used to perform a leave-one-out regression analysis of connectivity versus percent improvement in YGTSS scores. The

pathway associated with the greatest improvement in TS symptoms projected through thalamus, anterior cingulate cortex (ACC), and regions in prefrontal cortex (PFC). Average connectivity along this pathway was significantly correlated with percent improvement in YGTSS scores ($R = 0.46$, $p = 0.007$), and the correlation remained significant across leave-one-out iterations ($p < 0.01$). Average connectivity along the thalamus-ACC-PFC pathway reliably predicted response across TS patients receiving GPi DBS. Interestingly, regions within thalamus have been targeted with DBS for TS, and there may be a common pathway that should be modulated to improve TS symptoms. Future work will compare connectivity maps across GPi and CM thalamus to converge on networks to target with DBS to improve outcomes of DBS for TS.

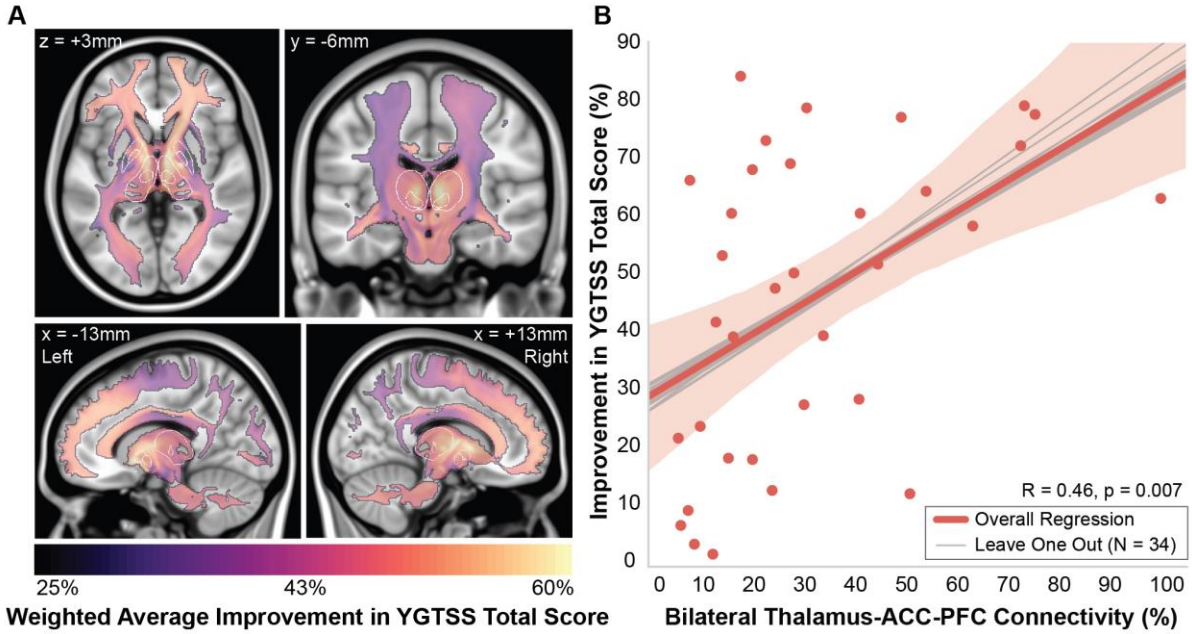

Figure 1. (A) The pathway associated with the the highest percent improvement (≥ 53%) included thalamus, anterior cingulate cortex (ACC), and regions in prefrontal cortex (PFC). **(B)** Average connectivity along the thalamus-ACC-PFC pathway was correlated with percent improvement in YGTSS total score. The correlation remained significant in a leave-one-out analysis, and the regression lines were relatively stable (as shown with the gray lines).

Title: Regulation of orchestrated glial cell activation and neurodegeneration by anti-semaphorin 4D antibody pepinemab (VX15/2503) as a potential therapeutic strategy for Huntington’s and Alzheimer’s disease

Authors: *E. EVANS[1], T. FISHER[1], J. LEONARD[1], A. READER[1], V. MISHRA[1], C. MALLOW[1], A. HOWELL[1], E. SMITH[1], A. FEIGIN[2], M. ZAUDERER[1];
[1]Vaccinex, Rochester, NY; [2]NYU Langone Hlth., New York, NY

Abstract: SEMA4D signaling through its receptors (PLXNB1, PLXNB2) triggers activation of inflammatory glial cells, inhibits migration and differentiation of glial progenitor cells, and disrupts endothelial tight junctions that are required for the integrity of the BBB. Blockade of SEMA4D in neurogenerative and neuroinflammatory disease is investigated in preclinical mechanistic studies and the first clinical trial of anti-SEMA4D antibody, pepinemab

(VX15/2503), to evaluate therapeutic potential in a randomized, double-blind, placebo-controlled phase 2 study of patients with late prodromal and early manifest Huntington's disease (HD). Mechanistic studies include histopathological observations of marked differences in expression, distribution, and colocalization of SEMA4D with neuronal and glial markers in transgenic Q175 HD mice compared to wild type controls. Preclinical studies suggest that SEMA4D plays an important role in inflammatory activation of astrocytes, in which state they downregulate glucose transporter, reducing their normal function in brain energy metabolism. Several clinical studies have demonstrated that loss of FDG-PET signal, a measure of glucose uptake, correlates with cognitive decline in Alzheimer's disease (AD) patients. Antibody neutralization of SEMA4D ameliorates neurodegenerative processes in preclinical transgenic YAC128 HD and CVN AD mouse models. SIGNAL is the first trial of anti-SEMA4D antibody pepinemab administered to HD subjects evaluating safety, tolerability and efficacy. Study endpoints include clinical features of HD and FDG-PET and volumetric MRI imaging in prospectively defined brain regions of interest (ROI), along with cognitive, motor, and patient-reported outcomes. In SIGNAL Cohort A (n=36), no concerning safety signals were identified following up to 12 monthly IV administrations; blinded safety data from cohort B suggest a similar safety profile. Pepinemab treatment trended toward stabilization of disease-related reduction in MRI volume and was favored over placebo in 24/31 ROI. FDG-PET also favored pepinemab in all ROI, with median increase in FDG uptake from baseline of 8.6% (range: 0.5-20.4%) compared to placebo achieving significance ($p<0.05$) in a majority of frontal and parietal brain ROI (11/14). Analysis of cohort A guided the design of Cohort B, enrolling 265 HD subjects for 17 to 35 months of treatment. Enrollment in cohort B was completed Dec 31, 2018 and clinical evaluation will continue through June 2020. These findings have shown pepinemab to be well tolerated in subjects with HD and warrants further investigation in neurodegenerative diseases including HD and AD.

Title: Abnormal electrocortical responses during vocalization as a neural correlate of the dystonic voice symptoms in spasmodic dysphonia

Authors: *J. KONCZAK[1], S. KHOSRAVANI[1], A. MAHNAN[1], Y. ZHANG[2], P. J. WATSON[2];
[1]Sch. of Kinesiology, [2]Speech, Language & Hearing Sci., Univ. of Minnesota, Minneapolis, MN

Abstract: Spasmodic dysphonia (SD) is a voice disorder that results in choked or strained speech. It is considered to be a form of focal dystonia. Onset occurs spontaneously during mid life and becomes chronic thereafter. There is no effective cure for SD. The neural features of abnormal cortical processing associated with SD are largely unknown. To obtain a better understanding of the underlying cortical neural mechanism of the disease, we analyzed electroencephalographic (EEG) signals of 10 SD individuals and 10 healthy age and gender matched volunteers. The participants produced 50 vowel /a/ vocalization epochs for duration of 2500ms. During early vocalization (500-1000ms) the SD group showed significantly larger alpha band spectral power over the left motor cortex. During late vocalization (1000-2500ms) SD patients showed a significantly larger gamma band coherence between left somatosensory and premotor cortical areas (see Fig. 1). The results indicate two atypical patterns of cortical activity in people with spasmodic dysphonia during voice production: 1) a reduced movement-related desynchronization of motor cortical networks, 2) an excessively large synchronization between left somatosensory and premotor cortical areas. These findings document that the pathophysiology of SD is characterized by an abnormally high synchronous activity within and across cortical neural networks involved in voice production that is mainly lateralized in the left hemisphere. Fig. 1 Spectrograms of somatosensory (CP5) and premotor (FC5) cortical electrodes in one healthy and one SD participant during vocalization. Green indicates no significant change in relation to rest. Blue color depicts the suppression of oscillatory activities in relation to the baseline, and the red color shows the excitation of oscillations in relation to the baseline level. Vocalization in the healthy participant is associated with the suppression of lower frequency

oscillations and gamma band excitation. The SD patient shows a smaller degree of suppression in the majority of frequency bands.

Title: Effects of long term laryngeal vibrotactile stimulation in people with spasmodic dysphonia

Authors: ***N. ELANGOVAN**[1], A. MAHNAN[2], G. S. GODING, Jr[1], Y. ZHANG[4], P. WATSON[1], J. KONCZAK[3];
[1]Univ. of Minnesota, Minneapolis, MN; [2]Univ. of Minnesota, Saint Paul, MN; [3]Human Sensorimotor Control Lab., Univ. of Minnesota, Minneapolis, MN; [4]Speech, Language, Hearing Sci., Univ. Minnesota, Minneapolis, MN

Abstract: Spasmodic dysphonia (SD) is a primary focal dystonia characterized by involuntary laryngeal muscle spasms that cause disfluent speech with a strained-strangled voice quality. Lack of a permanent cure, unresponsiveness to traditional speech therapies, and only temporary relief through botulinum toxin injections have led researchers to evaluate alternate approaches to symptom relief. Specifically the finding of proprioceptive dysfunction in SD has allowed researchers to exploit the somatosensory afferent signals by manipulating mechanoreceptor responses in the laryngeal muscles and the skin above the thyroid cartilage. Recent work from our group applied a single session laryngeal vibro-tactile stimulation (VTS) to people with SD. Results showed both empirical and self-reported improvements in speech quality as well as changes in somatosensory-motor cortical activity. However, the optimal dosage and the long-term effects of laryngeal VTS in SD are unclear. In this study, we evaluate the effects of laryngeal VTS over a period of 3 months. People with SD were randomly assigned in 2 groups (high vs low frequency) x 2 dosage (high vs low dosage). Participants in the high frequency group received a 100 Hz VTS whereas people in the low frequency group received a 40 Hz VTS. Participants in the two groups were divided in two sub-groups: high dosage group received 3 sessions x 20 minutes VTS/week and the low dosage group received 1 session x 20 minutes VTS/week. Participants' voice quality and the cortical activity during vocalization of vowels were tested at baseline, at 6 weeks and at 12 weeks. We provide preliminary results on the long term effects of VTS on people with SD. These results provide first insights on the long-term efficacy of VTS as a non-invasive form of neuromodulation, determining effective VTS frequencies and the optimal treatment dosage to enhance the voice quality in people with SD.

Title: First evidence that laryngeal vibration can improve voice symptoms in the voice disorder spasmodic dysphonia

Authors: *A. MAHNAN[1], S. KHOSRAVANI[3], P. WATSON[2], Y. ZHANG[2], J. KONCZAK[1]; [1]Human Sensorimotor Control Lab., [2]Speech, Language, Hearing Sci., Univ. of Minnesota, Minneapolis, MN; [3]Harvard Univ., Boston, MA

Abstract: Spasmodic dysphonia (SD) is a focal dystonia affecting the larynx. It leads to a chocked or strained speech. SD is not responsive to traditional speech therapies. There is no cure for SD. Injection of Botulinum toxin to laryngeal muscles brings temporary voice symptom relief to some patients, but is not well tolerated by all. Proprioceptive deficits are an underlying feature of SD - a finding that opens an avenue for a missing behavioral treatment for the disease. Specifically, vibro-tactile stimulation (VTS) as non-invasive form of neuromodulation could be the suitable tool, given that it alters afferent signals from the mechanoreceptors in the vibrated muscles and skin. METHOD: Here, we examined the effect of laryngeal VTS on speech quality and cortical activity in 13 SD participants. The task involved the repeated vocalization of the vowel /a/ while receiving VTS for a total duration of 34 minutes. Cortical activity was monitored concurrently using EEG. RESULTS: In response to VTS, 8 participants (62%) exhibited a reduction of voice breaks and/or a meaningful increase in *smoothed cepstral peak prominence*, an acoustic measure of voice/speech quality. Symptom improvements persisted for 20 minutes past VTS. The application of VTS induced a significant suppression of theta band power over the left somatosensory-motor cortex and a significant rise of gamma rhythm over right somatosensory-motor cortex indicating that VTS reduces. CONCLUSION: Our results document that a one-time application of laryngeal VTS can effectively reduce the voice symptoms of SD. The suppression of theta band oscillations has been observed in patients with cervical dystonia who apply effective sensory tricks, suggesting that VTS in SD may activate a similar neurophysiological mechanism. Our results promote the development of wearable, non-invasive, voice-activated, user-programmable medical devices that could apply VTS on laryngeal muscles while monitoring its effect on speech production in real-time.

Abstract: Dystonia is a movement disorder in which sustained or repetitive muscle contractions cause abnormal postures and/or movements. There are a variety of forms of dystonia that can differ by the region of the body affected, provoking triggers, and additional features such as tremor. In this study, we recorded 128 channel high-density electroencephalography (HD-EEG) and kinematic data during the performance of visually-guided motor control tasks. Normal control subjects and two separate groups of patients with cervical dystonia (-/+ dystonic head tremor) were studied to determine how task-related cortical oscillatory activity might differ between patients and controls. We also investigated whether any differences in cortical oscillations were 1) specific to motor tasks involving muscles that were clinically affected by dystonia or 2) influenced by associated features such as dystonic head tremor. In the first cohort we studied the cortical dynamics of horizontal head turning movements and in the second cohort we studied grip force production. We found that patients with cervical dystonia had increased beta-band power over the motor cortices in event-related spectral perturbations (ERSP) compared to controls during both head turning tasks and grip force tasks, and that this increase was consistent across both dystonia groups. These results suggest that motor control in patients with cervical dystonia is fundamentally abnormal, regardless of whether the muscles involved in the task are clinically affected by dystonia or whether dystonic tremor is present as an associated phenomenological feature.

Title: Neurofibrillary tangles accelerate the degradation of fractal motor regulation

Authors: P. LI[1,2], L. YU[3], A. S. P. LIM[4], A. S. BUCHMAN[3], J. A. SCHNEIDER[3], D. A. BENNETT[3], ***K. HU**[1,2];

Abstract: Motor activity in health young humans possesses fractal temporal structures as characterized by similar fluctuation patterns across multiple time scales from seconds to hours. Advanced age and Alzheimer's disease (AD) perturb such fractal regulation (FR) and lead to increased randomness in the fluctuations especially at larger time scales (i.e., >2h), which is believed to reflect circadian disruptions according to animal studies. Here, we examined how AD pathology affects longitudinal FR changes. We studied 515 older adults (age: 85.0±5.9[SD]) in the Rush Memory and Aging Project who already came to autopsy and had post-mortem examinations of brain pathologies. All subjects had at least two antemortem motor activity assessments that were administered on a yearly basis. The average follow-up duration since the first motor activity assessment (baseline) was 4.8±2.8[SD] years. The temporal correlations in activity fluctuations at time scales from 2 up to 10h were examined to assess FR. Post mortem β-amyloid and phosphorylated tau were considered as pathological AD biomarkers. In a linear mixed effect model adjusted for age, sex, and education, increased burden of phosphorylated tau tangles was associated with accelerated FR degradation. Specifically, for each 1-unit increase in the burden of tangles, the annual rate of FR degradation (i.e., increased randomness in motor activity fluctuations at >2h) was increased by 4% (p=0.015). Interestingly, burden of tangles was associated with the degree of randomness in the activity fluctuations proximate to death in females (p=0.01) but not in males. In contrast, β-amyloid was not associated with either longitudinal FR changes or the FR proximate to death. These results indicate a link between tau pathology and fractal degradation.

Title: Loss of iron metabolism regulation causes motor and behavioral defects

Authors: *C. A. M. PORRAS[1,2], M. C. GHOSH[1], H. WILSON-OLLIVIERRE[1], T. A. ROUAULT[1];
[1]Eunice Kennedy Shriver NICHD, Bethesda, MD; [2]Brown Univ. Neuroscience-NIH Grad. Partnership Program, Providence, RI

Abstract: Iron is an important cofactor for many proteins. It is used to create Fe-S clusters and heme prosthetic groups that enzymes use to catalyze redox reactions. This redox ability however can also result in the production of harmful radicals by Fenton chemistry causing oxidative stress during iron overload conditions. Therefore, iron homeostasis is critical for a cell to maintain. Proteins involved in the import, export, and sequestering/storage of iron are regulated by Iron Regulatory Proteins (IRP1/2). These two proteins become activated when the iron concentration in a cell falls too low. They bind to Iron Response Elements (IRE) present on mRNA transcripts of iron regulatory proteins. If the IRE is on the 5' end of the transcript, IRP1/2 prevent translation. Conversely if the IRE is on the 3' end, the transcript is stabilized by IRP1/2 and translation is promoted. This allows IRP1/2 to upregulate iron import proteins while simultaneously downregulating iron export and sequestering proteins during iron depletion. IRP1 and IRP2 are very similar proteins that are equally able to bind to IREs, but their expression profiles and regulation differ. IRP2 is the dominant IRP in neurons. Because of the high ATP demand necessary to maintain polarized membranes, neurons are particularly sensitive to changes in iron concentration which is used to create Fe-S clusters in the mitochondrial respiratory chain. We predict that loss of IRP2 causes a functional iron deficiency due to a decrease in iron import and an increase in iron sequestering. This results in mitochondrial dysfunction and eventually neurodegeneration. Recently, a patient with bi-allelic loss of function mutations in IREB2 leading to an absence of IRP2 protein has been identified. This patient has been diagnosed with dystonic cerebral palsy, epilepsy, and microcytic hypochromic anemia. The patient is also non-verbal and failed to achieve developmental milestones which could indicate a cognitive impairment. To investigate this further an $Irp2^{-/-}$ mouse model on a backcrossed C57Bl/6J background was created. The Irp2-null mice have a significant motor defect demonstrated by reduced performance on rotarod and hanging wire tests (approximately 45%

and 22% of wildtype respectively). Counterintuitively Irp2-null mice have more ambulatory movement in an open field test of spontaneous movement. The difference is greatest during the first 10 minutes of a 60-minute trial suggesting that the mice have delayed habituation to a novel environment. These results suggest that loss of Irp2 in mice causes motor and behavioral defects matching the IRP2 patient's neurodegenerative disorder.

Title: Loss of D2R-expressing torsinA impairs sensory-evoked brain activation and connectivity in a mouse model of dystonia

Authors: J. C. DESIMONE[1], ***H. LIU**[2], Y. LIU[3], Y. LI[3], D. E. VAILLANCOURT[4]; [1]Dept. of Applied Physiol. and Kinesiology, [2]Dept. of Biomed. Engin., [3]Dept. of Neurol., [4]Applied Physiol. and Kinesiology; Dept. of Neurology; Dept. of Biomed. Engin., Univ. of Florida, Gainesville, FL

Abstract: Early-onset generalized dystonia (DYT1 dystonia) is caused by a loss-of-function mutation in torsinA, leading to involuntary muscle co-contractions, and abnormal movements and postures. Dopamine type-2 receptor (D2R)-expressing medium spiny neurons and cholinergic interneurons of the striatum are centrally involved in the convergence of sensory input and mediation of motor output. Dysfunction of these neurons has been extensively implicated in dystonia pathogenesis. Providing *in vivo* markers of network-level brain function related to loss of D2R-expressing torsinA is fundamental to our understanding of dystonia pathophysiology and developing new therapies. The current study used *in vivo* functional and diffusion magnetic resonance imaging to examine brain function and microstructure in a mouse model of dystonia characterized by conditional knock-out of torsinA from striatum-specific D2R-expressing cells (Dyt1 d2KO mice). Until now, neuroimaging studies in dystonia mouse models have used resting-state paradigms to understand network-level brain dysfunction that may characterize the expression of dystonia. Sensorimotor deficits in dystonia highlight a critical need for brain imaging that can gain insight into the dysfunction of task-related sensorimotor pathways. To this end, a novel aspect of the current study is the use of sensory-evoked fMRI to understand how loss of D2R-expressing torsinA in striatal neurons influences blood-oxygen-

level dependent (BOLD) activation and functional connectivity within sensorimotor brain regions. Here, d2KO mice revealed widespread reductions in brain activation of the cortex, striatum, globus pallidus, and thalamus compared to controls, and BOLD signal in d2KO mice correlated with motor deficits. D2KO mice also revealed anti-correlated striatal activation during the sensory task. Resting-state fMRI in combination with striatal seed-based correlation revealed abnormalities in cortical and brainstem connectivity. Neurite orientation dispersion and density imaging (NODDI), a technique sensitive to microstructural properties of tissue and free-water compartments in the brain, revealed no volumetric or diffusivity differences between d2KO mice and controls. This study provides fresh evidence that loss of torsinA in striatal D2R-expressing neurons impairs the integration of exogenous sensory information, which may contribute to motor deficits in dystonia. Furthermore, this study establishes the utility of sensory-evoked fMRI to explore substrates of sensorimotor adaptations underlying dystonia pathophysiology in human and animal studies.

Title: Assessment of the effects of Kinesiotaping on musical motor performance in musicians suffering from focal hand dystonia. A pilot study

Authors: R. BRAVI[1], C. I. IOANNOU[2], S. CAPPELLI[1], A. ANDORLINI[1], E. J. COHEN[1], E. O. ALTENMULLER[2], ***D. MINCIACCHI**[1];
[1]Univ. of Florence, Florence, Italy; [2]Hanover Univ. of Music, Drama and Media, Hanover, Germany

Abstract: Purpose: Intensive training regimes can lead musicians to the manifestation of focal dystonia, a highly disabling movement disorder that often terminates their careers. In most cases, musician’s dystonia, only appears focally in the context of instrument playing as a painless muscular incoordination of refined movements. To date, this condition is not easily treated and the most effective therapies often fail to restore fine motor control in musicians. Given the limitations of the available treatment methods, alternative strategies are continuously explored. This pilot study explores the immediate and short-term effects of a Correction Kinesiotaping intervention (CKT) on fine motor control in musicians with focal hand dystonia (FHD). Kinesiotaping (KT) is a kinesthetic method, consisting of a tape having elastic properties and stretching capabilities, that recently has emerged in clinical practice as an interesting tool for

managing neurological disorders.
Methods: Seven male musicians with FHD performed musical exercises under the following conditions: without KT (baseline); during a CKT intervention and immediately after tape removal (block 1); during a Sham KT (SKT) intervention and immediately after tape removal (block 2). Blocks were randomly presented across participants. A tailored CKT intervention on affected fingers was provided based on the dystonic pattern that each patient manifested while playing. Motor performance was video-documented and four independent experts assessed blindly the general performance and fingers' posture on visual analogue scales. Also, musicians' self-reports of the musical abilities were evaluated. Finally, electromyographic activity and co-activation index of wrist antagonist muscles were analyzed.
Results: No significant differences of effects between CKT and SKT were reported by the experts, either for general performance or for fingers' posture; any subtle benefits observed during CKT were lost after the tape was removed. Musicians estimated that CKT was ineffective in improving their musical abilities. Also, no significant changes with respect to the co-activation index were found among the conditions.
Conclusions: CKT may not be useful to reduce dystonic patterns, nor to improve playing ability, in musicians with FHD.

Title: Overexpression of a torsina paralog rescues motor symptoms and neuropathology in a mouse model of DYT1 dystonia

Authors: *J. LI, S. PAPPAS, W. DAUER;
Univ. of Michigan, Ann Arbor, MI

Abstract: DYT1 dystonia is a dominantly inherited movement disorder caused by a loss-of-function mutation in the *TOR1A* gene that encodes the torsinA protein. ~30% of mutation carriers develop disease, and those who do exhibit mild to severely debilitating symptoms. A barrier to genetic therapy in DYT1 dystonia is that treatments based on increasing torsinA expression will simultaneously increase expression of the mutant protein, which may have

deleterious effects. TorsinB is a paralog of torsinA that that modulates the time course and tissue specificity of abnormal nuclear envelope budding, a pathologic hallmark of torsinA loss-of-function (Kim et al., 2010, Tanabe et al., 2016). Consequently, we hypothesized that torsinB overexpression would suppress torsinA loss-of-function-related motor and neuropathological phenotypes. We tested this hypothesis by generating a mouse line that expresses torsinB from the ROSA26 locus in a Cre-dependent manner. We then ingressed this allele into the Dlx-CKO model (Pappas et al., 2015) that exhibits developmental onset of abnormal twisting movements responsive to clinically used antimuscarinic drugs. These mice also exhibit selective degeneration of striatal cholinergic interneurons (ChIs). We find that torsinB overexpression essentially eliminates the abnormal twisting movements and ChI degeneration that are characteristic of the Dlx-CKO model. Critically, control mice that overexpress torsinB have no discernable behavioral or neuropathological phenotype, suggesting that overexpression of torsinB in the Dlx5/6-Cre field is not overtly deleterious. These findings indicate that torsinB is a potent modifier of torsinA loss-of-function-related behavioral and neuropathological phenotypes, identifying it as a potentially promising therapeutic target in DYT1 dystonia.

Title: Increased randomness in motor activity predicts cognitive impairment in older adults

Authors: *P. LI[1,2], L. YU[3], A. S. P. LIM[4], A. S. BUCHMAN[3], J. A. SCHNEIDER[3], D. A. BENNETT[3], K. HU[1,2];

Abstract: Human motor activity fluctuations are not random but possess strong temporal correlations across multiple time scales from seconds to hours. Such correlations are reduced with aging, and the reduction predicts faster cognitive decline and higher risk of Alzheimer’s

dementia independent of age. Here we examined the link between the reduction in motor activity correlations and brain pathologies, and their contributions to cognitive impairment/decline. We studied 580 older adults (age at death: 90.4±6.2 [SD]) who had post-mortem examinations of brain pathologies (including β-amyloid, tangles, Lewy body, gross chronic infarcts, chronic microinfarcts, cerebral atherosclerosis, cerebral amyloid angiopathy, arteriolosclerosis, hippocampal sclerosis, and TAR DNA-binding protein 43). For all subjects, antemortem motor activity recordings of up to 10 days and global cognition score based on 21 neuropsychological test batteries were collected annually for 4.8±2.8 [SD] years. The temporal correlations in activity fluctuations at time scales ~0.1-1.5h were examined and were quantified by an exponent α (i.e., α=0.5 indicates total randomness, and large values indicate stronger correlations). For the last assessed motor activity (2.2 years before death on average), α was closer to 0.5 in subjects with higher burden of arteriolosclerosis (p=0.0004), and female subjects with gross chronic infarcts had smaller α as compared to those females without infarcts (p=0.002). No significant associations were observed for the other 8 pathological measures. Total 37% variations in global cognition proximate to death were explained by the 10 measures of brain pathologies, age, sex, and education. The α close to death accounted for an extra 10% of the variations (p<0.0001). In addition, α at baseline (averagely 5.2 years before death) predicted faster cognitive decline (p=0.037) independent of the 10 measures of brain pathologies, age, sex, and education. These results indicate that increased randomness in motor activity fluctuations at <1.5h reflects/predicts cognitive impairment, and the effects cannot be fully explained by the known biomarkers of brain pathologies. Reduction in motor activity correlations may contribute to the etiology of dementia.

Title: The mechanism of motor dysfunction in Prrt2-deficient mouse

Authors: *S. LOU, Z. XIONG;
Inst. of Neuroscience, Chinese Acad. of Scie, Shanghai, China

Abstract: Paroxysmal kinesigenic dyskinesia (PKD), a brain disorder characterized by sudden attacks of involuntary movements, was caused by loss-of-function mutations in *PRRT2* gene. In

our previous study, genetically engineered animal models of PKD has been generated and they exhibited stimulus-triggered dystonia. However, how does the lost of PRRT2 contribute to motor dysfunction is still not fully understood. In this study, we found dystonia was closely accompanied with hyperexcitability in cerebellum of *Prrt2*-mutant mice. We found that optical stimulation induced more extended excitability in cerebellum of *Prrt2*-mutant mice compared to which in wild type mice. The carbamazepine, an effective medicine for preventing PKD attack in clinical, reduced cerebellar excitability and alleviated dystonia attack in animal model of PKD. Together, our findings provided persuasive evidence for the hypothesis that cerebellar hyperexcitability might be an underlying neuropathological mechanism in *Prrt2*-associated Paroxysmal kinesigenic dyskinesia.
Key words: Paroxysmal kinesigenic dyskinesia; *Prrt2*; cerebellum

Title: UCHL1 is necessary and sufficient for maintaining cytoarchitectural integrity of upper motor neurons

Authors: *B. GENC[1], J. H. JARA[1], S. S. SANCHEZ[1], A. K. B. LAGRIMAS[1], C. G. BROOKS[1], N. KOCAK[1], Y. ZHU[2], P. OZDINLER[1];
[1]Davee Dept. of Neurol. and Clin. Neurolog. Sci., [2]Departments of Ophthalmology and Physiol., Northwestern Univ. Feinberg Sch. of Med., Chicago, IL

Abstract: UCHL1 (ubiquitin C-terminal hydrolase-L1) is crucial for the maintenance of free ubiquitin in cells, especially in neurons. In the absence of UCHL1 function, corticospinal motor neurons (CSMN) show selective, progressive and most profound degeneration. Their cellular defects become evident very early in the *Uchl1*^{nm3419} (UCHL1$^{-/-}$) mice, which lack all UCHL1 function, as assessed by shrinkage of soma size, apical dendrite disintegration and massive spine loss. CSMN are the upper motor neurons in mice and this neuron population is central for numerous motor neuron disorders and neurodegenerative diseases, such as amyotrophic lateral

sclerosis (ALS), primary lateral sclerosis (PLS), and hereditary spastic paraplegia (HSP) in patients. Thus, it is important to determine whether UCHL1 function would be sufficient to improve upper motor neuron health and integrity, and whether upper motor neurons would be appropriate cellular targets for gene therapy approaches. We generated two lines of UCHL1 conditional knockout mice: one lacked UCHL1 only in layer 5 subcerebral projection neurons (SCPN) and the other lacked UCHL1 in spinal motor neurons (SMN). Knocking out UCHL1 only from layer 5 SCPN was sufficient to generate neuronal defects similar to that observed in the $UCHL1^{-/-}$ mice, and when UCHL1 activity was ablated from SMN, the CSMN remained intact. In addition, using AAV mediated gene delivery, we demonstrated that restoring UCHL1 activity specifically in CSMN of $UCHL1^{-/-}$ mice, successfully improved the soma size and integrity of apical dendrites of CSMN. Our results bring a novel mechanistic insight on the role of UCHL1 function for CSMN and establish upper motor neurons as proper cellular targets for gene delivery approaches.

Title: Transforming growth factor beta signaling in motor neurons in the $SOD1^{G93A}$ mouse model

Authors: *C. BRAINE[1], D. CASTRO[2], I. HUBBARD[3], M. CUEVAS[1], S. MANIATIS[3], R. BONNEAU[2], T. MANIATIS[1], H. PHATNANI[3];
[1]Columbia Univ., New York, NY; [2]New York Univ., New York, NY; [3]New York Genome Ctr., New York, NY

Abstract: Amyotrophic Lateral Sclerosis (ALS), also known as Lou Gherig's Disease, is a fatal neurodegenerative disease caused by the death of motor neurons in the spinal cord and brain. ALS is a genetically complex disease; diverse mutations cause motor neuron death by disrupting various interrelated pathways. To date no therapy targeting a single factor can rescue motor neuron loss. Transforming Growth Factor Beta (TGF-β) is upstream of many of the pathways changed in disease and has been shown to be dysregulated in ALS. Upregulation of TGF-β signaling has been identified as neuroprotective in many neurodegenerative disease models; however, there is conflicting evidence about the role of TGF-β signaling in ALS.

In the first part of this study we use *in vitro* pharmacological approaches to manipulate different pathways within the TGF-β superfamily in co-cultured ES-derived motor neurons and astrocytes. Inhibition of the Classical arm of the pathway improved $SOD1^{G93A}$ motor neuron survival *in vitro*. Through RNAseq we identified drug induced changes in in MTOR, PI3k-AKT signaling, and P53 signaling in motor neurons.
We also seek to understand how disease related changes in TGF-β signaling in the spinal cord directly affect motor neuron survival and gene expression in the $SOD1^{G93A}$ model of ALS. We have preliminary data to suggest that disruption of Smad7, a key mediator of TGF-β signaling, in motor neurons contributes to their death. We will continue to explore how ablation of two different TGF-β receptors in motor neurons or glia in the $SOD1^{G93A}$ ALS animal model affects motor neuron survival. We will follow up these studies with spatially resolved gene expression profiling to understand how these manipulations affect expression in different cell types in the spinal cord.

Title: MCP1-CCR2 and neuroinflammation in the ALS motor cortex with TDP-43 pathology

Authors: *N. KOCAK[1,2], J. JARA[1,2], M. GAUTAM[1,2], E. F. XIE[1,2], Q. MAO[3], E. H. BIGIO[3], P. OZDINLER[1,2];
[1]Neurol., Northwestern Univ. Feinberg Sch. of Med., CHICAGO, IL; [2]Les Turner ALS Ctr., Chicago, IL; [3]Pathology, Northwestern Univ., Chicago, IL

Abstract: The involvement of non-neuronal cells and the cells of innate immunity has been attributed to the initiation and progression of ALS. TDP-43 pathology is observed in a broad spectrum of ALS cases and is one of the most commonly shared pathologies. The potential involvement of the neuroimmune axis in the motor cortex of ALS patients with TDP-43 pathology needs to be revealed. This information is vital for building effective treatment strategies. We investigated the presence of astrogliosis and microgliosis in the motor cortex of ALS patients with TDP-43 pathology. prpTDP-43^{A315T}-UeGFP mice, corticospinal motor neuron

(CSMN) reporter line with TDP-43 pathology, are utilized to reveal the timing and extent of neuroimmune interactions and the involvement of non-neuronal cells to neurodegeneration. Electron microscopy and immunolabeling techniques are used to mark and monitor cells of interest. We detected both activated astrocytes and microglia, especially rod-like microglia, in the motor cortex of patients and TDP-43 mouse model. Besides, CCR2+ infiltrating monocytes were detected as they penetrate the brain parenchyma. Interestingly, Betz cells, which normally do not express MCP1, were marked with high levels of MCP1 expression when diseased. There is an early contribution of a neuroinflammatory response for upper motor neuron (UMN) degeneration with respect to TDP-43 pathology, and MCP1-CCR2 signaling is important for the recognition of diseased upper motor neurons by infiltrating monocytes. The findings are conserved among species and are observed in both ALS and ALS-FTLD patients.

Title: P2X4 ATP-gated receptor channels play key role in amyotrophic lateral sclerosis pathogenesis

Authors: ***E. BERTIN**[1], A. MARTINEZ[1], A. FAYOUX[2], P.-O. FERNAGUT[1], S. S. BERTRAND[2], E. BOUÉ-GRABOT[1];
[1]IMN, CNRS UMR 5293, Univ. Of Bordeaux, Bordeaux, France; [2]INCIA, CNRS UMR 5287, Univ. of Bordeaux, Bordeaux, France

Abstract: Amyotrophic lateral sclerosis (ALS) is a fatal motoneuron (MN) disease characterized by protein misfolding and aggregation leading to cellular degeneration. To date neither biomarker, nor effective treatment have been found. ATP and upregulated P2X4 receptor (P2X4) expression, a non-selective cationic ATP-gated channel, are involved in various diseases such as ischemia, chronic pain, and several neurodegenerative diseases including ALS. In this context, ATP and P2X4 appeared as attractive novel targets for understanding and fighting the ALS disease. To unravel the implication of P2X4 in ALS pathogenesis, we generated innovating double transgenic mice carrying the human SOD1-G93A mutation and either lacking the P2X4

gene (SOD1/P2X4KO) or knocking for the AP2 binding site responsible for the constitutive internalization of P2X4 (SOD1/P2X4KI). In P2X4KI mice, the substitution of the endocytosis motif by the fluorescent protein mCherry prevents clathrin-dependent endocytosis of P2X4 specifically thus mimicking the pathological upregulation of surface P2X4 receptors. Analysis of the onset, progression and duration of the ALS-like disease in SOD1/P2X4KO and SOD1/P2X4KI compared to SOD1 mice shows that the ablation of the P2X4 gene as well as the expression of non-internalized P2X4 have a significant and positive impact on motor performances and animal survival. These results reveal that P2X4 are active and complex players in ALS progression in SOD1 mice. Immunostaining using nanobodies against P2X4 or antibodies against the mCherry protein in the mouse spinal cord confirmed the increased of P2X4 expression in SOD1 mice over the progression of the disease. This expression, initially restricted to MN, increased in microglia and peripheral macrophages during the symptomatic phase of ALS. In addition, heterologous expression of wild type mP2X4 and several mutants of the hSOD1 protein in *Xenopus* oocytes showed that both ATP-evoked current amplitude and surface P2X4 number are higher in cells expressing mutant hSOD1 indicating that misfolded mutant hSOD1 alters P2X4 surface trafficking. Co-immunoprecipitation and pull-down experiments from WT and SOD1 mice spinal cord demonstrated that misfolded SOD1-G93A protein interacts with AP2 and alters the interaction between AP2 and P2X4 as the disease progress. This result explains the increase in surface P2X4 in SOD1-G93A models over the time.

Title: Role of arginine methylation in the intercellular transmission of FUS

Authors: *N. WATANABE[1], K. MATSUKAWA[1], M. SUAREZ-CALVET[2], D. DORMANN[3], T. HASHIMOTO[1], T. IWATSUBO[1];
[1]Dept. of Neuropathology, The Univ. of Tokyo, Bunkyo-Ku, Tokyo, Japan; [2]Dept. of Neurology, Hosp. del Mar, Barcelona βeta Brain Res. Center, Pasqual Maragall Fndn., Barcelona, Spain; [3]Munich Cluster for Systems Neurol. (SyNergy), BioMedical Ctr. (BMC), Ludwig-Maximilians-University Munich, Planegg, Germany

Abstract: Intercellular transmission of disease-related proteins is emerging as a key process in the spreading of neurodegeneration, although the underlying mechanisms still remain unclear. Cytoplasmic accumulation of fused in sarcoma (FUS) is a pathological signature of a subset of

patients with amyotrophic lateral sclerosis (ALS) or frontotemporal lobar degeneration (FTLD); however, the intercellular spreading of FUS has not been documented yet. To examine whether FUS can be transmitted interneuronally in brains, we generated an adeno-associated virus-based expression vector encoding dTomato-P2A-FUS (AAV-FUS), which expresses both dTomato and FUS in neurons. AAV-FUS-infected “donor” neurons express dTomato and FUS as individual proteins; this may result in the positivity of “recipient” neurons exclusively for FUS but not dTomato, if the intercellular protein transmission takes place. Four weeks after infection in newborn mice, nuclei and cytoplasm of a subset of neurons in the cerebral neocortex were positive for FUS and dTomato; notably, cytoplasm of neurons closely apposed to the FUS/dTomato-positive neurons were positive for FUS but not for dTomato, supporting the interneuronal transmission of FUS. Arginine residues in the carboxy-terminal region of FUS are highly methylated, whereas the cytoplasmic inclusions in FTLD brains were reported to be positive for unmethylated (UMA) FUS. We found that the cytoplasm of the “donor” and “recipient” neurons in the AAV-FUS-infected mice were UMA FUS-positive, which prompted us to speculate that FUS hypomethylation is causative to its interneuronal transmission.
To test this idea, we developed a cell-based transmission assay using NanoBiT split-luciferase complementation. We co-cultured the stably transfected HEK293 cell lines expressing LgBiT-(Lg-FUS) or SmBiT-tagged FUS (Sm-FUS), to detect the luminescence elicited by the reconstitution of luciferase through an interaction of Lg-FUS and Sm-FUS. Co-culture of the Lg-FUS and Sm-FUS stable cells caused an increase in the luminescence, suggesting the intercellular transmission of FUS. Treatment of the co-culture with a methyltransferase inhibitor, adenosine-2’,3’-dialdehyde, caused a significant increase in the luminescence compared with the control, suggesting that hypomethylation enhanced FUS transmission.
The parallel between the hypomethylated form of FUS and the possible interneuronal transmission of FUS *in vivo*, together with the increase in intercellular transmission and polymerization of FUS in cultured cells upon demethylation treatment, raise the possibility that hypomethylation is causative to the transmission of FUS.

Title: Characterization of SOD1G93A crossed with CDNF KO mouse line

Authors: *F. DE LORENZO, A.-S. E. KORPELAINEN, M. LINDAHL, M. SAARMA, M. H. VOUTILAINEN;
Inst. of Biotech., Univ. of Helsinki, Helsinki, Finland

Abstract: Amyotrophic Lateral Sclerosis (ALS)´s etiology remains, to date, largely unknown: only about 5-10% of the cases are familial, while for the remaining 90-95% the disease occurs in a sporadic form, indicating the influence of multiple factors in ALS pathogenesis. Excess of free radicals or intracellular calcium, excitoxicity, loss of neurotrophic factors, oxidative stress and endoplasmic reticulum (ER) stress are few of the proposed causes that may lead to the degeneration, although the reason of the selective vulnerability of motor neurons (MNs) is still unclear. No effective therapy is currently available. We previously showed that a single intracerebroventricular injection of cerebral dopamine neurotrophic factor (CDNF) is able to halt the progression of the disease, increase survival and improve motor behavior in SOD1-G93A mice. Furthermore, CDNF rescues MNs by regulating the ER stress response. CDNF is normally expressed at high level in mouse skeletal muscles. CDNF KO mice are viable mice that lack CDNF ubiquitously.
The aim of this study was to evaluate whether SOD1-G93A mice lacking CDNF would develop symptoms and die earlier than classical SOD1-G93A.
The motor coordination and strength of the new line and controls were evaluated through an extensive battery of tests, including rotarod, grip strength, hanger test and locomotor activity, while gait impairment was analysed since pre-symptomatic stage utilizing a Digigait device. The animals were monitored for weight changes and development of symptoms until total hind-limbs paralyses. Post-mortem samples of gastrocnemius muscle, lumbar spinal cord and motor cortex were analysed for changes in the ER stress and autophagy markers.
Here we show that mice totally lacking CDNF indeed showed the first symptoms significantly earlier than the classical SOD1-G93A mice and SOD1-G93A mice expressing only partially CDNF (CDNF heterozygous crossed with SOD1-G93A). The CDNF KO – SOD1-G93A mice showed also more motor deficit. These mice, however, did not die earlier than their littermates. In the skeletal muscle, we found a higher upregulation of ER stress markers in the CDNF KO – SOD1G93A compared to transgenic and WT littermates. No significant difference in ER stress or autophagy markers was observed in spinal cord and motor cortex
Therefore our results suggest that lack of CDNF, especially in the muscle where CDNF is normally highly expressed, can exacerbate the symptoms in the SOD1-G93A mice.

Title: Preclinical evaluation of phytocannabinoid-based neuroprotective therapies for the treatment of amyotrophic lateral sclerosis using TDP43 transgenic mice

Authors: *L. GARCÍA TOSCANO[1,2,3], C. RODRIGUEZ-CUETO[1,2,3], W. HIND[4], R. GRAY[4], J. FERNÁNDEZ-RUIZ[1,2,3], E. DE LAGO[1,2,3];

Ltd, Cambridge, United Kingdom

Abstract: Amyotrophic lateral sclerosis (ALS) is a progressive and disabling disease characterized by muscle denervation, weakness and atrophy. It is caused by the progressive loss of upper and lower motor neurons triggered by different factors. The disease has no cure and only a few treatments (e.g. riluzole, edavarone, masitinib) are currently available for patients, but their efficacy is limited. Due to a currently unmet need, efforts are being done to find new neuroprotective agents which also includes cannabinoids. In this study, we have investigated classic phytocannabinoids, such as Δ^9-tetrahydrocannabinoid (Δ^9-THC) and cannabidiol (CBD), as well as other minor phytocannabinoids, such as Δ^9-tetrahydrocannabivarin (Δ^9-THCV), cannabidivarin (CBDV) and cannabidiolic acid (CBDA) in experimental ALS.
We first compared the neuroprotective potential of these five phytocannabinoids (all at 10 mg/kg, i.p., and provided by GW Research Ltd, Cambridge, UK) in Prp-hTDP-43(A315T) transgenic mice. Next, we conducted a dose-dependent study with CBDA (0.1, 1 and 10 mg/kg, i.p.). Lastly, we compared the efficacy of CBDA with riluzole (both at 10 mg/kg, i.p), the most common drug for ALS patients. In all studies, male mice were daily treated from early to symptomatic stage (65th to 90th days of age) before being euthanized. Their neurological status was evaluated weekly using the rotarod test and analysis of limb clasping. Their spinal cords were collected for the histopathological evaluation, which included Nissl-staining for motor neurons and immunostaining for GFAP (astrocytes) and Iba-1 (microglia).
The neuroprotective efficacy of the five phytocannabinoids was in the following order: CBDA >

CBDV > Δ^9-THCV > CBD = Δ^9-THC. CBDA was the only one able to improve the neurological decline, to completely restore the loss of Nissl-stained motor neurons, and to attenuate the astroglial and microglial reactivity. Such activity was not dependent on its decarboxylation to CBD, as this phytocannabinoid was not particularly active by itself. The dose-response study of CBDA confirmed this robust neuroprotective activity at 10 mg/kg, being also more effective than riluzole, which only partially improved the neurological status and attenuated microglial reactivity, but with no effects on astroglial reactivity and the recovery of motor neurons. These results provide robust evidence towards the development of a CBDA-based neuroprotective therapy in ALS, either alone or in combination with other agents. However, additional research is still necessary to promote the translation of these results to patients.

Title: C9orf72 promotes autophagy-lysosomal functionsand has dose-dependent roles against motor deficits in a mouse model of C9ALS/FTD

Authors: *C. LIANG[1], Q. SHAO[2], Q. CHANG[2], W. ZHANG[2], M. YANG[2], J.-F. CHEN[2]; [1]Univ. of Georgia, Athens, GA; [2]USC, Los Angeles, CA

Abstract: Hexanucleotide repeat expansions in C9orf72 intron are the most common cause of familial amyotrophic lateral sclerosis and frontotemporal dementia (collectively, C9ALS/FTD). C9orf72 homozygous knockout mice surprisingly exhibit no phenotype in motor neurons (MNs). In vivo significance of C9orf72 haploinsufficiency and downstream disease mechanisms remain to be established. We reported that C9orf72 null and haploinsufficiency in a mouse model of C9ALS/FTD exacerbate motor behavior deficits in a dose-dependent manner, and this occurs early in the course of pathogenesis (Acta Neuropathol Commun., 2019). Previously we identified a C9orf72/Smcr8-containing protein complex (Science Advances, 2016). Here we found that Smcr8 knockout (KO) mice exhibited motor behavior deficits. Mechanistic studies reveal that deficiency of Smcr8 disrupts axonal transport in MNs, impairs autophagy-lysosomal degradation, and leads to abnormal axonal swellings in spinal cords and neuromuscular junctions (NMJs) in mice. Furthermore, abnormal axonal swellings are also found in MNs derived from

C9ALS/FTD patient's induced pluripotent stem cells (iPSCs). Using a new mouse model with combined loss- and gain-of-function, we found that C9orf72 has critical and dose-dependent roles against motor deficits, and identified novel disease mechanisms based on C9orf72/Smcr8-mediated regulation of axonal transport and autophagy-lysosome functions.

Title: Comparative analysis of resistant and vulnerable neuromuscular junction in a mouse ALS model

Authors: *F. PROVOST[1,2], R. NADEAU[3], D. ARBOUR[1,2], M.-S. GAUTHIER[4], M. LAVALLÉE-ADAM[3], B. COULOMBE[4], R. ROBITAILLE[1,2];

Abstract: Introduction: Amyotrophic lateral sclerosis (ALS) is a motor neuron (MNs) disease characterized by the precocious loss of neuromuscular junctions (NMJs) and muscular paralysis. The denervation of NMJs at striated muscles is an early event that occurs before the loss of spinal cord MNs. Recent data revealed an alteration of synaptic transmission, morphological instability and inappropriate repair in NMJ of SOD1 mice model prior to motor symptoms. Interestingly, these mechanisms are known to be regulated by the Perisynaptic Schwann cells (PSCs), glial cells at NMJ, suggesting that the alteration of PSC functions may contribute to NMJ vulnerability. While numerous studies demonstrated a motor unit type-dependent susceptibility to denervation, the extraocular muscles (EOM) innervation show a prominent resistance to disease progression. We hypothesized that PSCs functions and properties at extraocular NMJs contribute to the resistance of disease progression. Methods: NMJ morphological analysis by immunostaining and confocal imaging, functional properties of PSCs by calcium imaging and a differential proteome analysis using Tandem Mass Tags coupled to

quantitative mass spectrometry was performed between the resistant muscle EOM and the vulnerable muscle, *soleus* (SOL) or *Extensor digitorum longus* (EDL), in $SOD1^{G37R}$ mouse model. Results: Although fewer denervated NMJs were observed in the EOM in comparison to the EDL, we also observed more abundant signs of glial repairs in the EOM in comparison to WT at symptomatic stage. Ca^{2+} responses elicited by ATP and muscarine in PSCs of EOM's were smaller than in the SOL. However, EOM PSC Ca^{2+} responses were larger in $SOD1^{G37R}$ in comparison to WT. Proteomic analysis between EOM and EDL at presymptomatic (P380) and symptomatic stages (P480) in $SOD1^{G37R}$ and WT is underway. Perspectives: Understanding the functional and molecular differences between vulnerable and resistant NMJs will help to provide insights into the denervation mechanisms involved and identify potential therapeutic targets.

Title: Aberrant cap-dependent translation in TDP-43 model of ALS

Authors: *N. PENA, R. BEAR, D. ZARNESCU, B. ZAEPFEL, S. YAMADA;
Univ. of Arizona, Tucson, AZ

Abstract: Amyotrophic lateral sclerosis (ALS) is a progressive and fatal neurodegenerative disorder which targets motor neurons. An overwhelming majority of brain and spinal tissue samples from ALS patients contain TAR DNA-binding protein-43 (TDP-43) aggregates. A wide range of cellular processes have been studied in the context of TDP-43 pathology, including RNA metabolism. In particular, dysregulation of mRNA translation has been reported in several models of ALS. Little is known about how TDP-43 could exert toxic effects on protein synthesis. We investigated genetic interactions of TDP-43 with eukaryotic initiation factors (eIFs) in *Drosophila melanogaster*. TDP-43-positive RNA granules have previously been shown to contain eIFs. Our experiments provide evidence of TDP-43 disrupting the initiation step of translation, possibly through interactions with eIFs. In-vivo locomotor assays highlight the relationship between translation initiation and TDP-43 toxicity. Substantiating a role for TDP-43 in translation are findings that enhanced activity of eukaryotic initiation factor 4E binding protein (4EBP) worsened locomotor phenotypes in larvae expressing TDP-43. Furthermore, we directly tested translational activity via puromycin incorporation into nascent peptide chains.

Preliminary data from *Drosophila* ventral nerve cord (VNC) and neuromuscular junction (NMJ) samples, as well as human lymphoblastoid cells, suggest reduced translation in our ALS models of TDP-43 proteinopathy. Finally, we are using non-canonical amino acid tagging (BONCAT/FUNCAT) to measure translation in-vivo. This will allow for identification of newly synthesized proteins with tandem MS, or in situ visualization of global translation levels.

Title: C-bouton activity is detrimental to muscle innervation in a mouse model of amyotrophic lateral sclerosis

Authors: T. L. WELLS, J. R. MYLES, *T. AKAY;
Med. Neurosci., Dalhousie University, Brain Repair Ctr., Halifax, NS, Canada

Abstract: Amyotrophic lateral sclerosis (ALS) is a disease characterized by the withdrawal of motor neuron axons from muscles followed by the death of motor neurons. Over time, patients with the disease lose their ability to move, talk, eat, and breathe. There is currently no cure for ALS, and patients usually die within five years of being diagnosed. C-boutons are cholinergic synapses on motor neurons that modulate motor neuron excitability in a task-dependent manner. Recently, we showed that the C-boutons are important for maintaining near-normal mobility despite muscle denervation and motor neuron loss during ALS disease progression (Landoni et al, 2019; Behav. Brain. Res.). Here, we aim to understand the relationship between C-bouton activity, muscle denervation, motor neuron survival, and physical capability in ALS. We show that, in ALS model mice ($SOD1^{G93A}$) in which C-boutons are silenced ($SOD1^{G93A}$*;Dbx1::cre;*$ChAT^{flox/flox}$) (SDC; n = 7), innervation in the gastrocnemius muscle after an age of P100 is higher when compared to $SOD1^{G93A}$ ALS mice with C-boutons (SOD1; n=7) (SDC = 81.18% ± 9.31, SOD = 57.18% ± 13.08; two-tailed student's t-test: $p \leq 0.01$). This suggests that the C-bouton modulation of motor neurons is detrimental to motor neuron health during ALS. We also show that, despite this effect, SDC (n = 6) and SOD1 (n = 11) mice reach the humane end-point of the disease at similar ages (SDC = P149 ± 10; SOD1 = P155 ± 10; two-

tailed student's t-test: p = 0.31). This suggests that C-boutons do not affect the overall health of ALS mice. By using an exercise regime to induce different levels of C-bouton activity, we are investigating how different levels of C-bouton activity influence the disease. These experiments will provide insight into how C-bouton activation affects ALS disease progression.

Title: Knockdown of GADD34 ameliorates ALS in mutant SOD1 mice

Authors: *A. CAMARENA[1], G. D. GHADGE[2], Y. SONOBE[2], C. R. DRIGOTAS[2], R. P. ROOS[2];
[1]Univ. of Chicago Pritzker Sch. of Med., Chicago, IL; [2]Dept. of Neurology, Univ. of Chicago Med. Ctr., Chicago, IL

Abstract: Mutant (mt) Cu/Zn superoxide dismutase (SOD1) is thought to cause familial amyotrophic lateral sclerosis (FALS) because of misfolding and aggregation of the mutant protein. Here, we investigated whether GADD34 shRNA delivered by AAV9 can ameliorate disease in mtSOD1 transgenic mice through an enhancement of the unfolded protein response/integrated stress response (UPR/ISR), which is a normal cellular response to misfolded proteins. Initial studies showed that compared to control shRNA, GADD34 shRNA decreased GADD34 mRNA and protein expression and increased phosphorylated eIF2α in cultured NSC-34 cells with thapsigargin-induced ER stress. Additional experiments involved intravenous injections of neonatal C57BL/6J mice with AAV:control-shRNA or AAV:GADD34-shRNA followed 81 days later with tunicamycin intracerebroventricular injection to induce ER stress. Three days later, AAV:GADD34-shRNA-injected mice showed significantly less GADD34 mRNA in the spinal cord compared to AAV:control-shRNA-injected mice. Subsequent investigations showed that neonatal G93A and G85R mtSOD1 mice injected intravenously with AAV:GADD34-shRNA had a significantly increased lifespan compared to AAV:control-shRNA, along with reduced disease pathology, SOD1 load and aggregates, astrocytosis, and microgliosis. The results show that GADD34 shRNA is effective in ameliorating disease in mtSOD1 mice, and the feasibility of targeting the UPR/ISR as a therapy in mtSOD1-induced

FALS. The results also suggest that the UPR/ISR can be targeted in ALS in general and other neurodegenerative diseases in which misfolded proteins and ER stress have been implicated.

Title: Loss of function of astroglial exosomes in the SOD1G93A mouse model of ALS

Authors: *S. JIN[1], T. YANG[1], Y. MEN[1], J. M. YELICK[2], R. JARVIS[1], Y. YANG[3];
[1]Neurosci., [2]Tufts Univ., Boston, MA; [3]Neurosci., Tufts Univ. Sch. of Med., Boston, MA

Abstract: Exosomes are generated from endosomal compartment and known to be released by most cell types including neurons and glia cells in the CNS. These vesicles are proposed to be involved with the clearance and cell-to-cell spreading of toxic molecules. Recent research suggested that the majority of pathogenic proteins of neurodegenerative diseases such as amyloid beta, mutant SOD1, TDP43, phosphor-Tau are detected in exosomes fraction of patients CSF or in vitro cell model of disease. However, the role of cell type-specific exosomes in the spreading of pathogenic protein in neurodegenerative disease is still unclear. In the current study, we developed a cell-type specific exosome reporter mouse line (hCD63-GFP conditional knock-in, CD63-CKI) in which a GFP-fused CD63, can be induced in a particular cell type when bred with the cell-type specific Cre-driver mice or stereotaxic injection of Cre expressing AAV. By employing this mouse tool, we found that both neuronal and astrocyte-derived exosomes are widely present in the CNS. We performed stereotaxic injection AAV-CamkII-Cre and AAV-GFAP-Cre virus to ventral horn of lumber spinal cord in CD63f/+ or CD63f/+G93A SOD1 transgenic mice in disease on set (day90~100). We observed spread of astrocyte derived exosomes is significantly decreased in the direction of thoracic and sacral spinal cord in SOD1 transgenic (Tg) mice compare to non-Tg mice. The spreading of neuronal exosomes is not changed in SOD1 Tg mice compare to non-Tg mice. Moreover, we found a surprising loss-of-function effect of SOD1 Tg astrocyte's exosomes to cortical neurons. Non-Tg astrocyte's exosomes are able to significantly stimulate neuron dendrite morphological complexity, synapse number, and synapse activity (miniEPSC). In contrast, SOD1 Tg astrocyte's exosomes are

unable to stimulate neuron as non-Tg astrocyte's exosomes. On the another hand, both non-Tg and SOD1 Tg astrocyte's exosomes treated neurons are healthier and more active than non-treated control neurons. In summary, we investigated in vivo dynamics of astrocyte and neuron's exosomes in SOD1 Tg and non-Tg mice. Our preliminary data also suggests a potential loss-of-function of astroglial exosomes in the SOD1G93A mouse model of ALS.

Title: Mitochondrial dysfunction in the gastrocnemius-associated motorneurons of muscle-synthesized BDNF- deficient mice

Authors: M. L. CAWLEY, R. L. MUELLER, C. M. KIMBER, *E. N. OTTEM;
Northern Michigan Univ., Marquette, MI

Abstract: Mitochondria are essential for the high energy demands of the neuromuscular junction and leave motorneurons highly susceptible to potential dysfunction. Neuromuscular diseases (NMDs) are characterized by a loss of function between motorneurons and the muscles they innervate, and mitochondrial dysfunction is a common hallmark. A potential origin of progressive pathology associated with NMDs may be a reduction in brain-derived neurotrophic-factor (BDNF). We have shown that mice deficient in skeletal muscle-synthesized BDNF(msBDNF) demonstrate progressive motorneuron and muscle pathology at 120 days. Our recent studies have demonstrated a significant decrease in MitoTracker labeling at the pre-synapse of msBDNF homozygous knockout animals and no significant difference at the post-synapse (ANOVA; n=5, $P<0.001$). However, MitoTracker dyes are only sequestered by actively respiring mitochondria, and may limit estimates as dysfunctional mitochondria are unable to sequester the probe. We now aim to assess mitochondrial density and functionality in the gastroc-associated motorneurons of msBDNF deficient-mice. At 117 d, msBDNF deficient-mice received intramuscular injections of MitoTracker dye targeting the right gastrocnemius muscle. At 120 d experimental groups underwent a gastrocnemius harvest (n=8 per group) or a sciatic nerve ligation protocol (n=8 per group) prior to sacrifice. In combination with MitoTracker injections, we used immunohistochemical labeling to target the outer mitochondrial membrane protein TOM20. We used immunolabeling to further delineate potential pathology within

gastroc-associated motorneurons. We targeted the pre-synaptic vesicular protein synaptophysin, post-synaptic acetylcholine receptors, and retrograde transport-associated protein dynactin. To determine if experimental groups exhibit mitochondrial dysfunction, we used confocal microscopy and IMARIS 3D rendering software. Immunolocalization was measured throughout the axon and axon terminals of motorneurons. Preliminary results suggest mitochondria co-labeled with an activity-dependent dye and immunoassayed protein show a significant difference in colocalization. Results indicate that co-labeling mitochondria in a sciatic nerve ligation model illustrate mitochondrial density, as well as utility during transport. Ongoing studies suggest that mitochondrial mobility may be as dynamic as mitochondrial function and assisted by the coexistence of several signaling mechanisms. Co-labeling mitochondria in msBDNF deficient-mice further elucidates the role of growth factor signaling in the maintenance of motorneurons.

Title: Cortical interneuron-mediated inhibition delays the onset of amyotrophic lateral sclerosis in the SOD1 mouse model

Authors: C. S. KHADEMULLAH[1], A. J. AQRABAWI[2], K. M. PLACE[1], Z. DARGAEI[1], X. LIANG[1], ***J. C. PRESSEY**[1], S. BEDARD[1], J. YANG[1], D. GARAND[1], A. GASECKA[3], D. CÔTÉ[3], Y. DE KONINCK[3], J. KEITH[4], L. ZINMAN[4], J. ROBERTSON[5], J. KIM[2], M. A. WOODIN[1];

Abstract: A balance between synaptic excitation and inhibition is essential for normal brain function. When this delicate balance is disrupted, it can lead to neuronal hyperexcitability, resulting in alterations in neuronal network activity and the onset of various neurological disorders. Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disease that affects both lower and upper motor neurons. While hyperexcitability is a hallmark feature during the pre-symptomatic stages of ALS, there has yet to be a systematic analysis of inhibitory synaptic function during the progression of this disorder. Using electrophysiological patch-clamp recordings, we revealed parvalbumin (PV^+) interneurons to be hypoactive in the pre-symptomatic SOD1*G93A mouse model of ALS. We discovered that using AAV-mediated

delivery of chemogenetic technology targeted to increase the activity of the interneurons within layer 5 of the primary motor cortex (L5-M1), we were able to rescue intracortical inhibition and reduce pyramidal neuron hyperexcitability. Increasing the activity of interneurons in the L5-M1 was effective in delaying the onset of ALS-associated motor deficits, slowing symptom progression, preserving neuronal populations, and increasing the lifespan of SOD1*G93A mice. Taken together, this study provides novel insights into the pathogenesis and treatment of ALS.

Abstract: Amyotrophic lateral sclerosis (ALS) is an adult-onset neurological disease characterized by the selective degeneration of motor neurons leading to paralysis and immobility. Missense mutations in the gene coding for the Cu2+/Zn2+ superoxide dismutase 1 (SOD1) accounts for 15-20% of familial ALS, and mice overexpressing ALS-linked SOD1 mutants have been frequently used as an animal model for ALS. Degeneration of motor neurons in ALS progresses in a manner called "dying back", in which the degeneration of synapses and axons precedes the loss of cell bodies. Phosphorylation of collapsin response mediator protein 2

(CRMP2) is implicated in the progression of neuronal/axonal degeneration of different etiologies. To evaluate the role of CRMP2 phosphorylation in ALS pathogenesis, we utilized CRMP2 S522A knock-in (CRMP2ki/ki) mice, in which the serine residue 522 was homozygously replaced with alanine and thereby making CRMP2 no longer phosphorylatable by CDK5 or GSK3B. We found that the CRMP2ki/ki/SOD1G93A mice showed delay in the progression of the motor phenotype compared to their SOD1G93ATg littermates. Histological analysis revealed that the CRMP2ki/ki/SOD1G93A mice retained more intact axons and NMJs than their SOD1G93A-Tg littermates. These results suggest that the phosphorylation of CRMP2 may contribute to the axonal degeneration of motor neurons in ALS.

Title: Characterization of metabolic defects across multiple models of ALS

Authors: *H. BALL[1], E. MANZO[1], D. C. ZARNESCU[2];
[1]MCB, [2]Univ. of Arizona, Tucson, AZ

Abstract: Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disease that disrupts muscle function and has no cure. TAR DNA Binding Protein (TDP-43) is an RNA binding protein that has been found in cytoplasmic aggregates in 97% of ALS cases regardless of etiology. *Drosophila* is a well established genetic model for human disease that we used to develop a model for ALS based on TDP-43. Flies expressing either wild-type or mutant human TDP-43 (wild-type and mutant) recapitulate several symptoms of ALS, including motor dysfunction and a reduced survival. Recently, we found that glycolysis is upregulated in this model as a compensatory mechanism that improves locomotor function and increases lifespan. To determine whether glycolysis is similarly altered in other types of ALS we are using different fly models based on C9, SOD1 and a recently generated CRISPR model of TDP-43 proteinopathy. Preliminary results suggest that similar to the TDP-43 proteinopathy model based

on overexpression, the CRISPR model as well as SOD1 and C9 models can also benefit from increased glucose availability. We will report on the neuroprotective potential of increased glycolysis on key ALS phenotypes including locomotor function, neuromuscular junction morphology and lifespan across several *Drosophila* models of ALS.

Title: Knocking down the metabotropic glutamate receptor 5 in the $SOD1^{G93A}$ mouse model of amyotrophic lateral sclerosis ameliorates the reactive phenotype of spinal cord astrocytes

Authors: *C. USAI[1], C. TORAZZA[2], F. PROVENZANO[2], S. RAVERA[3], T. BONIFACINO[2], G. BONANNO[2,4,5], M. MILANESE[2,4];

Research, Univ. of Genova, Italy, Genova, Italy; [5]IRCCS - San Martino Polyclinic Hospital, Genova, Italy, Genova, Italy

Abstract: The ultimate cause of disease progression in amyotrophic lateral sclerosis (ALS) is motor neuron (MN) death. However, there is a large consensus that MN damage is supported by degeneration of non-neuronal cells, such as microglia and astrocytes. Therefore, to unveil the precise role of each cell population will be crucial to design targeted therapies. Group I metabotropic glutamate (Glu) receptors (mGluR1, mGluR5) play a role in ALS, since their expression and function are altered in the disease. We demonstrated that mGluR1 and mGluR5 activation sustains abnormal Glu release in the spinal cord of the $SOD1^{G93A}$ mouse model of ALS (Neuropharmacol 66: 253-63. 2013) and that knocking-down mGluR1 or mGluR5 in $SOD1^{G93A}$ mice significantly prolongs survival and ameliorates the clinical progression of the disease (Neurobiol Dis. 64: 48-59. 2014; Neuropharmacol. 123: 433-445, 2017). We investigated here the effects of halving mGluR5 in $SOD1^{G93A}$ mice, on the reactive phenotype of spinal cord astrocytes cultured from 120 day-old symptomatic $SOD1^{G93A}$ mice, age-matched $SOD1^{G93A}Grm5^{+/-}$ (heterozygous for mgluR5) or WT mice. The basal and the mixed mGluR1 and mGluR5 agonist 3,5-DHPG-stimulated intracellular Ca^{2+} concentration was increased in astrocytes from $SOD1^{G93A}$ vs. WT mice and it was significantly reduced in astrocytes from

$SOD1^{G93A}Grm5^{+/-}$ mice. The expression of the astrocyte activation markers GFAP, vimentin, and S100β was increased in $SOD1^{G93A}$ and significantly reduced in $SOD1^{G93A}Grm5^{+/-}$ astrocytes. The same was true for accumulation of cytosolic misfolded-SOD1. $SOD1^{G93A}$ astrocytes showed increased oxygen consumption and reduced ATP synthesis, which were normalized in $SOD1^{G93A}Grm5^{+/-}$ astrocytes. $SOD1^{G93A}$ astrocytes were characterized by a significant increase of IL1β, TNFα e IL6 expression and release respect to WT astrocytes. The abnormal expression and release of the cytokines was strongly reduced in $SOD1^{G93A}Grm5^{+/-}$ astrocytes. Finally, to verify the impact of the mGluR5 down-regulation in astrocytes on MN viability, spinal MNs from $SOD1^{G93A}$ embryos were co-cultured with astrocytes from $SOD1^{G93A}$ or $SOD1^{G93A}Grm5^{+/-}$ adult mice. MN cell death was strongly reduced when they were seeded on $SOD1^{G93A}Grm5^{+/-}$ compared to $SOD1^{G93A}$ astrocytes. Thus, a low constitutive level of mGluR5 in $SOD1^{G93A}$ mice has a positive impact on the spinal cord astrocyte phenotype, supporting the idea that the *in-vivo* disease amelioration, observed after mGluR5 ablation, may rely on a shift toward less noxious reactive astrocytes.

Title: Behavioral characterization of low copy SOD1 G93A transgenic mice

Authors: S. FLUNKERT, *R. RABL, A. KASZA, V. NIEDERKOFLER, E. AUER, B. HUTTER-PAIER;
QPS Austria GmbH, Grambach, Austria

Abstract: Introduction: Amyotrophic lateral sclerosis (ALS) is a progressive neurodegenerative disorder that results in the death of motor neurons in the brain and spinal cord. So far no effective treatments are available. Several causative genes are known and, of these, mutant superoxide dismutase 1 (SOD1) is by far the most frequent, accounting for up to 20% of familial ALS cases. A range of human mutant SOD1 transgenic mouse models has been developed that model the human disease. Of these, the most widely used is the SOD1(*G93A)1Gur mouse, which expresses a human SOD1 transgene with G93A mutation (Gurney et al., 1995). Mice become paralyzed in one or more limbs beginning around 12 weeks of age. Life expectancy is only four to six weeks beyond onset of symptoms. Although the SOD1G93A mouse has been a bedrock for ALS research and a well-used model for over a decade, there are some concerns about its use caused by its very strong and early phenotype. The low copy number SOD1 mouse

model might thus be a suitable alternative since it presents with a delayed onset of the ALS phenotype compared to the original high copy number strain because of a reduction in transgene copy number.
The aim of this study was to evaluate the behavioral phenotype onset and survival of low copy number SOD1G93A mice.
Method: SOD1G93A mice with a low copy number (JAX mouse #002300) of mixed sex were longitudinally analyzed from week 24 to 30 for motor deficits using the wire suspension test and grip strength test. Additionally, animals were analyzed in the Beam walk test, RotaRod and Pasta Gnawing test at the age of 24, 27 and 30 weeks.
Results: Behavioral tests are almost completed and will afterwards be statistically analyzed. So far, animals seem to develop a progressive motor phenotype that starts at 24 to 28 weeks of age and thus much later compared to the widely used SOD1G93A high copy number mouse model.
Conclusion/ Summary: The slow progressive pathology observed in SOD1G93A low copy number mice could provide a more appropriate model for studying early-stage pathological processes in ALS by having a longer treatment window for the development of new therapies.

Title: Delayed disease onset and progression in SOD1^{G37R}/Thy1-YFP16 ALS mouse model

Authors: É. MARTINEAU[1,2], ***F. FIORE**[1,2], S. MARCHAND[1,2], R. ROBITAILLE[1,2]; [1]Neurosciences, Univ. De Montréal, Montréal, QC, Canada; [2]Groupe de Recherche sur le Système Nerveux Central (GRSNC), Montréal, QC, Canada

Abstract: In amyotrophic lateral sclerosis (ALS), neuromuscular junctions (NMJ) undergo denervation and re-innervation as part of a global degeneration process occurring early in the disease. In an effort to investigate this mechanism, we crossed SOD1^{G37R} transgenic mice to

thy1-YFP mice (line 16). To our surprise, SOD1-YFP16 mice showed a delayed disease onset and slower disease progression. To better understand this partial rescue of the ALS phenotype, we monitored the ALS progression and motor phenotype of SOD1-YFP16 mice, quantified the differences in NMJ denervation and motor neuron survival and performed electrophysiological recordings at the NMJ to compare synaptic activity. We observed that disease onset in SOD1-YFP16 mice was delayed by ± 49 days. Progression of the disease was slowed, resulting in an increase in SOD1-YFP16 mice survival of ± 133 days. In addition, these mice preserved their motor function for a longer period of time. Morphologically, they displayed reduced NMJ damage in both fast-twitch (EDL) and slow-twitch (SOL) muscles in comparison to their age-matched SOD1 littermate, as assessed by immunohistochemical staining. Spinal alpha-motoneuron survival was also increased in these mice. No differences in spontaneous or evoked synaptic transmission was detected at the NMJ between SOD1-YFP16 and SOD1 mice, suggesting that rescuing synaptic activity may not be necessary for restoring motor function and NMJ phenotype in this ALS mouse model. Importantly, this delay was not associated with a reduction in human SOD1 copy number. Finally, we identified the YFP16 transgene insertion site, on chromosome 5 at position 5qC2 (5' of the 4933402J10Rik gene). Altogether, we report a significant delay in ALS progression in this SOD1-YFP16 mouse model, possibly linked to the YFP transgene insertion in a novel disease-modifying locus. Further investigation into the molecular mechanism underlying this delay could be of significance for our understanding of ALS pathogenesis.

Title: Altered expression of circadian clock genes in mice expressing amyotrophic lateral sclerosis-linked mutant superoxide dismutase 1

Authors: *K. M. KILLOY, B. A. HARLAN, M. PEHAR, M. R. VARGAS;
Cell and Mol. Pharmacol., Med. Univ. of South Carolina, Charleston, SC

Abstract: Amyotrophic lateral sclerosis (ALS) is an adult-onset disease characterized by specific degeneration of motor neurons. Beyond progressive motor impairment, patients with ALS suffer from yet incompletely characterized defects in energy metabolism. Several endocrine factors that display circadian rhythmicity and participate in metabolic synchronization of

peripheral tissues are altered in ALS patients and animal models. In addition, circadian control of NAD^+ availability directly modulates mitochondrial oxidative metabolism and antioxidant defenses. In mammals, most physiological processes are subject to daily oscillations that are governed by a circadian rhythm. Circadian timekeeping is orchestrated at a molecular level by cell-autonomous molecular clocks found on almost every cell. A group of neurons located in the suprachiasmatic nucleus (SCN) synchronizes this multitude of oscillators across brain regions and the entire body. The SCN clock is itself synchronized to local time by phase-setting signals, the most salient of which is the daily light/dark cycle, and sustains rhythmicity in complete absence of external synchronization cues. In turn, the SCN synchronizes the oscillators in peripheral tissues through secreted factors, feeding-fasting rhythms and body temperature. Loss of circadian timekeeping has been associated with cellular and system-wide alterations in metabolism, redox homeostasis and inflammation. Here we examined the expression of circadian clock and clock-controlled genes in the central nervous system and peripheral tissues of mice expressing ALS-linked mutant human superoxide dismutase 1 ($hSOD1^{G93A}$). We found that over a 24-hour period, early symptomatic $hSOD1^{G93A}$ mice exhibit aberrant oscillation in the expression of circadian clock and clock-controlled genes in several tissues when compared to age-matched non-transgenic mice. This work identifies the molecular clock as a potential target for the development of future ALS therapies.

Title: Elevated expression of the ALS-linked DNA/RNA-binding protein FUS in astrocytes induces reactivity and spinal motor neuron death *in vivo*

Authors: K. MCAVOY, ***B. K. JENSEN**, N. M. HEINSINGER, K. MAYER, T. WESTERGARD, A. C. LEPORE, A. R. HAEUSLER, D. TROTTI, P. PASINELLI; Thomas Jefferson Univ., Philadelphia, PA

Abstract: Mutations in the DNA/RNA binding protein Fused in Sarcoma (FUS) cause Amyotrophic Lateral Sclerosis. Ubiquitously expressed in all cells, FUS regulates gene expression at multiple stages of DNA/RNA processing, from transcription to translation. While

ALS ultimately targets the motor neurons, non-neuronal cells, like astrocytes, are also important drivers of disease. We hypothesized that in addition to causing motor neuron dysfunction, mutations in FUS may also invoke cellular alterations in astrocytes. Here, we explore the contribution of astrocytes to neurodegeneration in models of FUS-ALS *in vivo.* Previously, we found that astrocytes expressing mutant FUS (mFUS) are toxic to wildtype (WT) motor neurons *in vitro*. We identified that the mechanism of toxicity is via activation of the astrocytic NF-κB pathway and release of pro-inflammatory cytokine TNFα. In motor neurons, TNFα signaling alters AMPA receptors, sensitizing them to excitotoxic cell death. Now, we developed an *in vivo* model expressing WT and mFUS specifically in astrocytes by direct cervical intraspinal delivery of AAV9 vectors encoding GFP-tagged FUS variants under control of the gfa_{104} promoter in adult mice. GFP-alone and sham surgeries were controls. Immunocytochemistry and qPCR revealed that expression of FUS (WT or mFUS) caused astrocytic reactivity, upregulation of TNFα, and alteration of AMPA receptor subunits. We observed reduced grip strength and wire-hang endurance in FUS-expressing animals. This was correlated to significant loss of MMP9/ChAT+ motor neurons in the spinal cord. No differences were detectable between males and females, 8 animals per group were used to ensure reproducibility and appropriate power for statistical analysis. Finally, we tested whether FUS-mediated effects could be attenuated through prevention of TNFα signaling. mFUS intraspinal injections (5 animals/group) were performed with or without TNFα-neutralizing antibody (anti-TNFα). In animals receiving anti-TNFα, we observed significant rescue of grip strength performance, as well as reduction in astrocyte reactivity and downstream NF-κB targets. Loss of motor neurons was significantly prevented. Controls included IGG-antibody injections or sham surgeries. These studies further substantiate that astrocytes contribute to disease in genetic models of ALS. We provide novel findings that astrocytic expression of FUS is sufficient to induce pathogenic changes *in vivo* through activation of the NF-κB and TNFα pathway. We also provide evidence that therapeutics designed to diminish activation of this pathway may be effective in reducing motor neuron degeneration in FUS-ALS.

Title: A human induced pluripotent stem cell-derived neuronal model to assess developmental neurotoxicity upon exposure to chemical mixtures

Authors: *F. PISTOLLATO[1], E. MENDOZA[1], S. BOPP[1], C. NUNES[2], A. WORTH[1], A. BAL-PRICE[1];
[1]European Commission, Joint Res. Ctr., Ispra, Italy; [2]Univ. of Lausanne, Lausanne, Switzerland

Abstract: Human induced pluripotent stem cell (hiPSC)-derived neurons and astrocytes represent unique cellular models to study in vitro brain developmental processes, such as synaptogenesis, neurite outgrowth and neuronal network formation. These models are nowadays considered for the assessment of developmental neurotoxicity (DNT) in vitro, enabling mechanistic understanding of chemically-induced adverse effects. Moreover, since infants and children are co-exposed to more than one chemical at a time, novel mixture risk assessment strategies for the evaluation of DNT should be implemented. Here we used hiPSC-derived neural progenitors differentiated into mixed cultures of neurons and astrocytes to assess the acute and repeated dose effects of chemicals belonging to different classes (e.g., pesticides, industrial chemicals, heavy metals, polychlorinated biphenyls, endocrine disruptors, etc.) and that have all been associated with learning and memory deficits in children. Selected chemicals were grouped based on their mode of action (MoA) into 'similar' and 'dissimilar' MoA compounds and cells have been treated with both single compounds and different chemical mixtures to assess cumulative effects on DNT specific endpoints (i.e., synaptogenesis, neurite outgrowth, and brain derived neurotrophic factor (BDNF) protein levels), described as common key events in different DNT-related adverse outcome pathways. Data suggest that chemicals (in particular those working through similar MoA), individually present at non-toxic concentrations, can have neurotoxic effects in mixtures. This methodological approach represents a valuable conceptual framework to evaluate chemical mixtures with potential to cause learning and memory impairment in children, which nowadays represents an ever increasing public health concern.

Title: NADPH oxidase and endoplasmic reticulum stress contribute to neuroinflammation and neurodegeneration in postmortem human alcoholic brain

Authors: *L. QIN, R. P. VETRENO, F. T. CREWS;
Bowles Ctr. for Alcohol Studies, Univ. North Carolina, Sch. Med., Chapel Hill, NC

Abstract: The endoplasmic reticulum (ER) is susceptible to oxidative stress that can activate cell death mechanisms like apoptosis. In the current study, real-time PCR and immunohistochemistry were used to study expression of NADPH oxidase (NOX) and ER stress markers. NOX and ER stress markers in post-mortem human orbital frontal cortex (OFC) were compared to markers of neurodegeneration in moderate drinking controls and alcoholics. In the alcoholic OFC, we found significant increases in NOX mRNA levels, specifically alcoholics compared to moderate drinking control subjects had increases in NOX2 subunit gp91^{phox} (272%), NOX3 (206%), and NOX4 (215%). Our previous studies have shown significant increases in the number of NOX2 gp91^{phox}+immunoreactive (IR) cells in the alcoholic OFC. We also observed significant increases in mRNA levels of ER stress markers: caspase-12 (181%), glucose-regulated protein 78 (GRP78 [150%]), activating transcription factor 6 (ATF6 [208%]), C/EBP-homologous protein (CHOP [204%]), and protein kinase R-like endoplasmic reticulum kinase (PERK TV1 [195%], PERK TV2 [168%]) in the alcoholic OFC, relative to moderate drinking controls. Immunohistochemistry (IHC) to assess protein expression of ER stress markers showed increases in the number of caspase-12, GRP78, ATF6 and CHOP+IR cells in the alcoholic OFC. To evaluate the association of increased NOX and ER stress with neurodegeneration in the post-mortem alcoholic OFC, we investigated caspase cell death cascade proteins; i.e. caspase-3, -7, -8, -9 mRNA, and activated caspase-3 IHC protein expression. We found significant increases in mRNA levels of caspase-3 (158%), -7 (193%), -8 (166%), and -9 (181%) as well as increased activated caspase-3+IR (155%) in the alcoholic OFC, compared to moderate drinking controls. Double fluorescent IHC showed that ER stress markers: caspase-12, GRP78, ATF6 and CHOP were colocalized with NOX gp91^{phox}+IR which was colocalized with activated caspase-3 and Neu-N+IR cells in the human alcoholic OFC, suggesting that the enhanced expression of NOX and ER stress in human alcoholic brain neurons could contribute to chronic ethanol-induced neuroinflammation and neurodegeneration.

Abstract: The anesthetic ketamine is a non-competitive antagonist of the calcium-permeable N-methyl-d-aspartate (NMDA) receptor. High doses have been implicated in cardiotoxicity and neurotoxicity. These toxicities are often thought to be mediated by reactive oxygen species (ROS). However, findings to the contrary showing ketamine reduces ROS in mammalian cells and neurons *in vitro* are emerging. Here, we determined the effects of ketamine on ROS levels in zebrafish larvae *in vivo*. Based on our earlier studies demonstrating a reduction in ATP levels by ketamine, we hypothesized that as a calcium antagonist, ketamine would also prevent ROS generation which is a by-product of ATP synthesis. To confirm that the detected ROS in a whole organism, such as the zebrafish larva, is specific, we used diphenyleneiodonium (DPI) which blocks ROS production by inhibiting the NADPH oxidases (NOX). After 20 h exposure, DPI (5 and 10 μM) and ketamine (1 and 2 mM) reduced ROS in the 72 hours post-fertilization zebrafish larvae *in vivo*. Exposure to the dietary supplement acetyl l-carnitine (ALCAR) that induces mitochondrial ATP synthesis, caused elevated ROS generation with increasing doses. Combined, ketamine and ALCAR counter-balanced ROS generation in the larvae suggesting that ketamine and ALCAR have opposing effects on mitochondrial metabolism. This may be key to maintaining ROS homeostasis in the larvae and affords ALCAR the ability to prevent ketamine toxicity. These results show, for the first time, ketamine's antioxidative and ALCAR's prooxidative effects in a live vertebrate.

Title: Micrornas expressed differentially in the hippocampus of female and male rodents after chronic alcohol treatment

Authors: *M. CHOI, J. HAN, D.-J. KIM;
Addiction Inst., Seoul, Korea, Republic of

Abstract: Alcohol abuse causes various health problems including liver disease, stroke, and cognitive impairments. Drinking the same amount of alcohol causes more severe brain damage in women compared to men. Therefore, it is necessary to investigate whether alcohol-induced epigenetic modification influences differentially gene expression related to brain damage depending on sex differences. This study aimed to identify microRNAs (miRNAs) expressed differentially in the hippocampus of female and male rodents in response to alcohol. After chronic administration of ethanol (3-3.5 g/kg/day) in the female (control, n=10; alcohol, n=12) and male (control, n=10; alcohol, n=12) Sprague-Dawley rats for 6 weeks, we measured body weights during the experiment and analyzed up- or down-regulated miRNAs using miRNA arrays. We found that increase of body weights between ethanol-treated male and control male groups during ethanol administration was significantly different, while there was little difference in the increase of body weights between ethanol-treated female and control female groups during ethanol administration. When comparing ethanol-treated male group with control male group, 118 miRNAs were more than 1.5-fold up- or down-regulated in ethanol-treated male group than control male group. Among them, 6 miRNAs were significantly up-regulated, while 3 miRNAs were significantly down-regulated in ethanol-treated group compared to the male control group. And 477 target genes of up- and down-regulated 9 miRNAs were identified. On the other hand, 64 miRNAs were more than 1.5-fold up- or down-regulated in ethanol-treated female group than female control group. Among them, 3 miRNAs were significantly up-regulated, while 4 miRNAs were significantly down-regulated. And 327 target genes of up- and down-regulated 7 miRNAs were identified. Therefore, our results suggest that exposure to chronic alcohol differentially affects weight gain and miRNA expression depending on sex differences.

Title: Early synaptopathology in organophosphate-exposed hippocampal explants is governed by neuron-specific β_1 integrin responses

Authors: M. ALMEIDA[1], B. A. BAHR[2], *K. G. FARIZATTO[1];
[1]Biol., [2]Biotech Ctr. / William C. Friday Lab., Univ. of North Carolina at Pembroke, Pembroke, NC

Abstract: Organophosphates account for the world's deadliest poisons, causing severe symptoms and death in exposed individuals and first responders to nerve agent attacks. These toxins inhibit acetylcholinesterase which leads to cholinergic crises, seizures, and long-term neurological problems. Besides being used in warfare atrocities, organophosphates are still widely used as agricultural pesticides, thus a public health concern. We previously found that the organophosphate paraoxon produces oxidative and synaptic toxicity, leading to behavioral deficits (Farizatto et al. 2017, *J. Mol. Neurosci*. 63:115). Hippocampal explants exposed to paraoxon were also found to exhibit unique synaptotoxicity associated with selective integrin dynamics, implicating a compensatory response through the β1 integrin-cofilin pathway (Farizatto et al. 2019, *Scientific Reports*: **9**:6532 nature.com/articles/s41598-019-42934-z). In this follow-up study, paraoxon-exposed hippocampal cultures exhibited declines in synaptic proteins, independent of overt cellular, neuronal, or dendritic pathology. Synaptotoxic profiles were evident in the dendritic zones of the CA1, CA3, and dentate subfields, and they corresponded with β1 integrin responses. Noting that integrins form a bridge in many types of cell-cell interactions, it is of interest the enhanced β1 integrin staining was only evident in the neuropil, with no induction of such staining found in the astrocyte-rich area extending from the paraoxon-treated tissue. The active conformation of β1 integrin was targeted to synapses in response to the exposure, co-localizing with prominently-stained, synapsin II-positive puncta, even though this synaptic labeling had an overall reduction across the full dendritic area examined. As previously suggested, the stochastic events of β1 integrin signaling may signify a compensatory pathway to explain the apparent protection of select synapses. When the β1 integrin was blocked in hippocampal slices with the highly potent $\alpha_4\beta_1$ inhibitor BIO 5192, the tissue exhibited enhanced vulnerability to paraoxon. Disrupting the specific integrin potentiated the observed declines in synaptophysin and GluR1 levels 24 h after exposure. These findings suggest that anticholinesterase toxins mediate distinct synaptic damage, and the integrin signaling pathway plays an important compensatory role. Synaptic compromise in the hippocampus can be detrimental to many brain functions and integrin-linked responses activated by toxic insults appear to govern the extent of the synaptotoxicity.

Title: Transient receptor potential channel 1 involved in blood brain barrier disruption in mice treated with chlorpyrifos

Authors: *W. LI, M. EHRICH;
Virginia Tech., Blacksburg, VA

Abstract: We previously demonstrated that chlorpyrifos (CPF), a cholinesterase inhibitor, compromised the integrity of the blood-brain barrier (BBB) when used at low concentrations *in vitro*. To further explore the underlying molecular mechanism of the transient and reversible BBB disruption induced by CPF, we analyzed the expression levels of genes and proteins associated with transient receptor potential canonical (TRPC) channels in mouse brains at different time points after CPF treatment. The BBB integrity and function after CPF treatment were also evaluated by measuring the brain water content and molecule leakage into brain tissues. The results demonstrated that TRPC1 mRNA expression was significantly decreased in mouse brain 2-8 hours after CPF treatment. The TRPC1 protein levels in mouse brain were significantly increased at 1 hour post-CPF treatment. Corresponding to these TRPC1 gene and protein alterations, mild BBB leakage was observed in mice treated with CPF as measured by FITC-dextran extravasation. Results suggest that CPF treatment temporarily increased BBB permeability by transiently affecting TRPC1 protein expressions. Such a transient and reversible disruption of BBB has potential implications for CNS drug delivery.

Title: Accumulation of cytoplasmic DNA in ATM deficiency activates the microglial viral response system with neurotoxic consequences

Authors: *F. X. SONG[1,2], F. MA[1], K. HERRUP[2];
[1]Hong Kong Univ. of Sci. and Technol., Hong Kong, Hong Kong; [2]Dept. of Neurobio., Univ. of Pittsburgh Sch. of Med., Pittsburgh, PA

Abstract: ATM (ataxia-telangiectasia mutated) is prominently involved in DNA damage repair, especially in DNA double-strand breaks in the double helix. Mutations in ATM cause a rare progressive multi-systemic disease known as ataxia telangiectasia (A-T). The neurological

symptoms of ataxia are profound Purkinje cell degeneration in the cerebellum. In addition to the neurological symptoms, however, patients with A-T suffer from a wide variety of symptoms such as telangiectasia, cancer and dysfunction of the immune system. The latter is characterized by low levels of antibodies and other immunoglobulins. The immunodeficiency in A-T is a logical consequence of the inefficient repair of DNA breaks during the process of V(D)J recombination which is crucial for T-cells and B-cells maturation. Given these problems in serum lymphocytes, most immunobiological studies focus on the role of ATM in V(D)J recombination. This downplays the potential impact of ATM deficiency on the brain. Yet anti-inflammatory strategies targeting the innate immune system have proven effective in A-T. So we have begun to examine the effects of ATM deficiency on the cells of innate immune system - microglia in the brain. We show that ATM dysfunction causes an accumulation of cytosolic DNA to trigger the anti-viral immune response of brain microglia via DNA sensor, STING, and active inflammatory pathway. Meanwhile, cytosolic DNA promotes signaling through the AIM2-containing inflammasome, resulting in the enhanced processing of inactive precursors into their fully active forms. Interestingly, DNA-seq revealed a unique distribution pattern of the cytosolic DNA among the genome. The small fragments within the cytoplasm belong to the intergenic regions which are far from the genes. More importantly, they match with the features of retroelements within the genome which can be used to precisely modify gene expression. We propose that, the cytosolic DNA fragments are signals for the communication between the nucleus and cytoplasm rather than random cut of the genome. Together, these processes create an inflammatory environment with strong neurotoxicity. The present findings highlight the significance of microglia-neuron interactions in the progression of the neurodegenerative symptoms of A-T and show how defective DNA damage repair can lead to an inflammatory response that has lethal consequences for neurons. We propose that, beyond their clear implications for the neurological symptoms in A-T, the present findings suggest the involvement of microglial DNA damage as a trigger for neuroinflammation during the etiology of other neurodegenerative conditions.

Title: Sevoflurane and propofol have different potency to provide dual effects of neuroprotection and neurotoxicity in Alzheimer's disease cells

Authors: X. GAO[1], X. WANG[2], L. ZHANG[1], **G. LIANG**[1], R. MUND[2], H. WEI[1];
[1]Dept Anesthesiol. & Critical Care, [2]Univ. of Pennsylvania, Philadelphia, PA

Abstract: General anesthetics have different potencies in causing neurotoxicity. We have compared the potency of propofol vs. sevoflurane on cell survival and its mechanisms via the effects on cytosol ([Ca2+]c) or on mitochondria ([Ca2+]m) concentrations, in SH-SY5Y human neuroblastoma cells overexpressing wild type PS1 or mutated PS1 M146V. The cells were cultured and exposed to propofol or sevoflurane at various concentrations and durations. Cell viability was measured by the 3-(4,5-dimethylthiazol-2yl)-2,5-diphenyltetrazolium bromide (MTT) reduction assay. We treated the cells to equivalent propofol or sevoflurane (1 MAC or 0.455 mM vs. 2 μM) then measured both [Ca2+]c and [Ca2+]m using jellyfish photoprotein aequorin-based probes. Only 200 μM Propofol caused cell damage with equal potency in two types of cells, (clinically relevant concentrations: 1-20 μM). Sevoflurane at 4% for 3 hrs or 2% for 12 hrs promoted cell survival, but at 1% for prolonged exposure (24 hrs) resulted in significantly and equally increased cell damage in both types of cells. Only sevoflurane at 1 MAC but not equipotent propofol at 2 μM for 6 hrs was able to cause significantly and equally increased cell survival in both types of cell. Both sevoflurane and propofol had significantly higher cell response rate to the elevation of [Ca2+]c or [Ca2+]m in the presence of extracellular Ca2+ influx than in its absence. Propofol at 2 μM only slightly increased [Ca2+]c but not [Ca2+]m, which was more obvious in the presence of extracellular Ca2+ influx. Sevoflurane at 0.455 mM (equipotent to 1 MAC) caused significantly greater increase of peak and overall [Ca2+]c in AD than in control cells. This was ameliorated by the absence of extracellular Ca2+ influx. Sevofluane, but not propofol, caused a more significant increase in overall [Ca2+]m in WT than AD cells, in the presence of extracellular Ca2+ influx. In the absence of extracellular Ca2+ influx, sevoflurane, but not propofol, caused more significant elevations of overall [Ca2+]m in AD than control cells. Both Ca2+ influx from extracellular space and Ca2+ release coming from the endoplasmic reticulum contributed to the sevoflurane mediated elevation of [Ca2+]c or [Ca2+]m. However, propofol at clinically relevant concentrations affected intracellular Ca2+ homeostasis primarily through Ca2+ influx alone. Sevoflurane has a greater potency to affect cell survival than propofol, which is likely associated its effects on the elevation of [Ca2+]c or [Ca2+]m. Sevoflurane, but not propofol, at clinically relevant concentrations and durations provide dual effects of both neuroprotection and neurotoxicity at in both normal and AD cells.

Title: The impact of early developmental arsenic exposure on hippocampal synaptic plasticity

Authors: *K. F. W. FOLEY[1], D. A. CORY-SLECHTA[2], H. XIA[3];
[1]Neurosci., [2]Dept. of Envrn. Med., [3]Pharmacol. & Physiol., Univ. of Rochester Med. Ctr., Rochester, NY

Abstract: Early life exposure to toxic chemicals and environmental pollutants is associated with learning deficits and behavioral changes. An estimated 200 million people worldwide are exposed to arsenic concentrations in drinking water that exceed the World Health Organization's recommended limit (10ppb). Increased arsenic exposure is associated with increased all-cause mortality and deficits in children's cognitive and motor functions. While arsenic levels are kept below 10ppb in municipal water supplies, private wells are unregulated and ground water commonly exceeds 10ppb, including 20 out of 37 principal aquifers in the United States. Previous studies on arsenic exposure and synaptic function have demonstrated a decrease in synaptic transmission and long-term potentiation (LTP) in adult rodents, but have relied either on *in vitro* exposure or extended, adulthood exposure. Here, we study the effects of gestational and early developmental arsenic exposure in juvenile mice. C57BL/6 females were exposed to arsenic (0, 50ppb, 36ppm) in their drinking water starting at two weeks of age. These mice began breeding at ~1 month of age and continued to be exposed to arsenic after parturition. We then performed field recordings in acute hippocampal slices from the pre-weaning, juvenile offspring (P17-P23). In this paradigm, the juvenile mice are only exposed to arsenic *in utero* and via the mother's milk. Surprisingly, even with relatively low arsenic exposure (50ppb), we observed changes in basal synaptic transmission and plasticity in the offspring. These results suggest that indirect, ecologically-relevant arsenic exposure in early development impacts hippocampal synaptic transmission and plasticity.

Title: Neurogenesis in the adult hippocampus is affected via glial cells in the rat model of delayed carbon monoxide encephalopathy

Authors: *S. OCHI[1], K. SEKIYA[2], N. ABE[2], T. NISHIHARA[2], Y. YOSHINO[1], J. IGA[1], S.-I. UENO[1];
[1]Neuropsychiatry, [2]Dept. of Anesthesia and Perioperative Med., Ehime Univ. Grad. Sch. of Med., Toon, Japan

Abstract: Delayed carbon monoxide (CO) encephalopathy occurs following recovery after several weeks from acute CO poisoning. However, the mechanism of delayed neuronal injury remains unknown. Previously, we reported that the rat model of delayed CO encephalopathy showed cognitive impairment and hippocampal cell death, especially in the lesions of dentate gyrus (DG) and also the number of microglial cells and the mRNA expressions of several neurotrophic factors in the hippocampus at 7 days after CO exposure were decreased. Neurogenesis in the adult hippocampus plays important roles in a developmental process of cognitive function. Glial cells, especially astrocytes, are known to play a key role in promoting adult neurogenesis. Therefore, in the current study, we hypothesized that neurogenesis in the hippocampus may be affected in delayed CO encephalopathy and investigated the effects of delayed neuronal CO poisoning on neural precursor cells and glial cells. Wistar male rats (6 weeks old) were exposed to 1000 ppm CO for 40 min and then 3000 ppm for 20 min until they lost consciousness. If they did not lose consciousness in this 60 min, rats were exposed to 10000 ppm until they lost consciousness. Behavioral effects on learning and memory function were measured by the passive-avoidance test in controls and CO treated rats until 3 weeks. The latencies were significantly shorter in the CO models. Immunohistochemical analyses revealed that cell numbers in Sex determining region Y-box 2 (SOX2) and glial fibrillary acidic protein (GFAP) positive cells and microglia in the lesions of DG were significantly decreased in the CO rats compared with those in controls. Flow cytometry analyses also revealed that the number of microglia in the hippocampus were significantly reduced in CO rats. Realtime-PCR revealed that the mRNA expressions of Sox2, Gfap, CD11b, Fgf2 and Gdnf were significantly lower in CO rats (n=8) than those in the controls. However, there were no significant differences in the expression of Slc1a2, Slc1a3 and Bdnf between CO rats and controls. These results suggested that delayed CO injury might damage especially microglia, immature astrocytes and neural precursor cells and impede the restoration of them for several weeks. Thus, the impairment of neural precursor cells via abnormalities of glial cells may have important role in the pathogenesis of delayed CO encephalopathy.

Title: Ketamine-induced adverse effects on the dopaminergic and serotonergic neuronal development is prevented by N-acetylcysteine in zebrafish

Authors: *Q. GU, B. ROBINSON, J. KANUNGO;
FDA Natl. Ctr. for Toxicological Res., Jefferson, AR

Abstract: The pediatric anesthetic ketamine is a non-competitive antagonist of the calcium-permeable N-methyl-D-aspartate (NMDA) receptor. In laboratory models, prolonged exposure to ketamine can induce cardiotoxicity and neurotoxicity in mammals and zebrafish. Here, we evaluated ketamine's effects on the development of dopaminergic (DA) and serotonergic (5-HT) neurons in zebrafish embryos. We also examined whether the antioxidant, N-acetylcysteine (NAC), could prevent ketamine's effects on those monoaminergic neurons. Using whole mount immunohistochemistry, the effects of ketamine were monitored on the brain 5-HT and tyrosine hydroxylase-immunoreactive (TH-IR) DA neurons. Ketamine exposure began at 28 hours post-fertilization (hpf) embryos and static exposure continued for 20 h. We used a ketamine concentration (2 mM) that produces an internal embryo exposure level comparable to human anesthetic plasma concentrations. At this concentration, ketamine exposure significantly reduced the areas occupied by 5-HT neurons in the brains of 48 hpf embryos. Additionally, TH-IR neurons in the brain and TH-IR cells in the trunk were significantly reduced. Previously, we described that acetyl-l-carnitine (ALCAR) prevented ketamine-induced neurotoxicity. Our current data show that co-treatment with NAC (1 mM) prevented ketamine's adverse effects on development of DA and 5-HT neurons in zebrafish embryos.

Title: Primary cilia related genes and neonatal anesthesia neurotoxicity in congenital heart disease

Authors: F. SOMAA, ***N. SARIC**, L. WANG, R. JONAS, K. HASHIMOTO-TORII, N. ISHIBASHI;
Children's Natl. Med. Ctr., Washington, DC

Abstract: Protein-damaging de novo gene mutations have been demonstrated to be strong predictors of neurodevelopmental anomalies in congenital heart disease (CHD). At least 15% of these genes have been found to be associated with primary cilia structure and/or function. Recent clinical studies have demonstrated a strong link between anesthetic exposure and neurodevelopmental outcomes in children with CHD. Studying the combined effect of anesthesia and primary cilia gene mutations will determine whether genetic alterations identified in CHD patients with neurodevelopmental abnormalities affect the molecular/cellular programs underlying brain development. Using Emx1cre; Ift88 f/f, in which primary cilia are lost specifically in cortical excitatory neurons we administered either PBS or Ketamine (20mg/kg) at postnatal day 7 (P7). We examined caspase-3, fractin and cleaved tubulin at P8 in the medial prefrontal cortex (mPFC). At P30, mice were behaviorally tested using water T-maze to assess their spatial memory performance and cognitive flexibility. To assess pyramidal neuron dendritic morphology, we used two other inducible Cre/lox mice to specifically label layer II (Nes-Cre/ERT2) and layer V (ER81-Cre/ERT2) neurons. We found significant enhancement of caspase-3, fractin and cleaved-tubulin immunoreactivity in the Ift88 knockout mice that were exposed to ketamine (cKO+Ket) compared to the other three groups (HT+PBS, HT+Ket, and cKO+PBS). During the reversal learning paradigm, cKO+Ket mice showed a strongly reduced ability to learn the task compared to other groups, indicating a cognitive flexibility deficit in this treatment group. We found that ketamine injection only had an effect on dendritic morphology in the Ift88 cKO mouse. Primary cilia play a key role in protecting cortical neurons from anesthesia-induced neurodegeneration. Our current results suggest that primary cilia deficiency, due to a common genetic predisposition with CHD, exacerbates the toxicity of neonatal anesthesia, thereby exaggerating neurobehavioral deficits in children with CHD.

Title: Long-lasting behavioral effects of embryonic exposure of zebrafish to retinoic acid receptor acting environmental pesticides

Authors: *Z. R. HOLLOWAY[1], A. B. HAWKEY[1], D. UNAL[2], C. L. DEAN[2], A. AKHIESH[2], S. W. KULLMAN[3], E. D. LEVIN[1];
[1]Duke Univ. Med. Ctr., Durham, NC; [2]Duke Univ., Durham, NC; [3]North Carolina State, Durham, NC

Abstract: Retinoic acid receptor (RAR) signaling is known to play key roles in neurodevelopment. Disruption of RAR signaling in early neurodevelopment has been shown to be a key factor for increasing the risk of autism. Our previous work with the zebrafish model showed that embryonic disruption of RAR signaling with excess vitamin A (retinol) or exposure to valproic acid (VPA) causes behavioral dysfunction in larval zebrafish and also causes lasting behavioral disruption into adulthood. Recent high throughput screening of environmental contaminants has revealed a variety of chemicals which act on the retinoic acid receptor, including select several pesticides (see below). Further work is needed to link their putative retinoid activity to adverse behavioral outcomes. The present study measured the behavioral effects of embryonic exposure to these compounds in larval zebrafish, and these fish were assessed again in adulthood to determine if the effects persisted. Zebrafish embryos were exposed to vehicle (DMSO), chlorothalonil (CTL, 10- 100nM), imazalil (IML, 0.1-1μM), endosulfan-I (ESF, 0.1-1nM) or buprofezin (BPF, 0.3-3μM) from 5-120 hours post-fertilization (hpf). Doses fell below the threshold for overt toxicity as measured by increased lethality and dysmorphogenesis. Larval motility was assessed at 144hpf. Adult testing took place at 5-7 months of age. Each of the selected compounds significantly altered larval motility. The high doses of BPF and IML reduced motility under both light and dark conditions, while the lowest dose of IML increased motility regardless of lighting condition. The highest dose of CTL reduced motility in the dark, as did the lowest dose. The highest dose of ESF enhanced motility in the dark. For select compounds, behavioral effects were also found to persist into adulthood. In a novel tank dive test the highest dose of CTL reduced total motility and fish exposed to the moderate dose spent more time near the top of the tank, suggesting altered anxiety processes or increased risk-taking. For IML, both low and moderate doses reduced overall motility, while all three doses led to an increase in the time spent near the bottom of the tank, implying an increase

in anxiety. Further research is underway to complement behavioral functions tested in zebrafish developmentally exposed to these compounds. Zebrafish can provide an economic model to screen compounds for neurobehavioral toxicity to help prioritize further testing with rodent models.

Abstract: Cadmium (Cd) is a heavy metal, classified as a carcinogen whose exposure could affect the function of the Central Nervous System. Studies suggest that Cd modifies neuronal morphology in the hippocampus, consequently affecting cognitive tasks. The oxidative stress pathway is proposed as the mechanism of toxicity. However, this mechanism is not clear yet. The aim of the present work was to study the effect of Cd administration on oxidative stress markers in rat hippocampus for 2, 3 and 4 months. For this, one-month old male Wistar rats weighing between 80 to 100 g were used. Animals were randomly divided into two groups (n=30/ group): 1) control (drinking water) and 2) treatment with Cd. 32.5 ppm of Cd was added to the water in the form of cadmium chloride ($CdCl_2$) for the treatment group, while the control group received only purified water, provided daily *ad libitum*. Each group was subdivided into three groups (n = 10), with the purpose of evaluating the effect of Cd-exposure over two, three and four-month periods. The data were reported as the mean ± standard error (SE). A Student's t-Test where $p < 0.05$ was considered significant was used to analyze the results of Cd, ROS, MDA and glutathione (reduced and oxidized) concentration, and the activity of antioxidative

enzymes (superoxide dismutase, catalase, glutathione reductase, peroxidase and transferase). The results show that the oral administration of Cd increased the Cd concentration in hippocampus after 3 y 4 months. Likewise, it caused an increase in MDA (a marker of lipoperoxidation) and in the activity of glutathione enzymes. While the levels of ROS, the activity of catalase and superoxide dismutase and glutathione content didn't change through the study. These results suggest that oral administration of Cd promotes its accumulation in hippocampus. Accordingly, oxidative response events exacerbate, which in long term contribute to the hippocampal neurodegeneration and to deterioration of memory. Our results suggest that the exposure to Cd represents a critical health problem, which if not addressed quickly, could cause much more serious problems in the quality of life of the human population, as well as in the environment in which they develop.

Title: Protein PICALM has an important role in neuronal health and brain homeostasis

Authors: *D. LAZIC[1], A. MONTAGNE[1], Z. DAI[1], Z. ZHAO[1], K. KISLER[1], A. SAGARE[1], T. MAEDA[2], B. ZLOKOVIC[1];
[1]Physiol. and Neurosci., USC, Los Angeles, CA; [2]Brigham and Women's Hospital, Harvard Med. Sch., Boston, MA

Abstract: *PICALM*, a gene encoding phosphatidylinositol-binding clathrin assembly protein is associated with Alzheimer's disease (AD). Besides its well-known role in regulating intracellular trafficking of endocytic vesicles, studies in $APP^{Sw+/0}$; $Picalm^{+/-}$ mice revealed that PICALM is involved in the clearance of amyloid-β across the blood-brain barrier. Additionally, genetic analyses and magnetic resonance imaging (MRI) in humans suggested the positive correlation of protective *PICALM*-associated single-nucleotide polymorphism (SNP) $rs3851179^{A}$ with higher hippocampal volume and increased entorhinal cortical thickness, when compared to SNP $rs3851179^{G}$. Because PICALM is crucial for embryonal development and it plays essential roles

in regulating axonal growth and turnover of synaptic vesicles and receptors, a complete deletion of PICALM from neurons *in vivo* can be detrimental to neuronal homeostasis. In order to examine the role of neuronal PICALM *in vivo*, we generated tamoxifen-inducible neuron-specific PICALM knockout mouse line, *Picalm$^{lox/lox}$; Camk2a-CreER*. Four weeks after 4-hydroxy tamoxifen administration, *Picalm$^{lox/lox}$; Camk2a-CreER* mice showed impaired performances in hippocampal-dependent behavioral tests. Volumetric MRI studies and immunohistochemistry showed that *Camk2a-CreER* mice exhibit brain atrophy, most prominent in hippocampus, and enlargement of lateral and third ventricles. Studies in primary neuronal culture using *Picalm$^{-/-}$* embryos showed increased baseline activity, increased cell surface expression of glutamate receptors and higher susceptibility to glutamate toxicity. Altogether, our data suggest that PICALM plays an important role in cognition and neuronal health, and that the mechanism of neurotoxicity in PICALM-deficient neurons may involve altered localization of glutamate receptors.

Title: Abnormal activation of NMDA receptors by glufosinate ammonium

Authors: *D. WOO, Y. KIM, D. KANG;
Res. Ctr. of Convergence Toxicology, Korea Inst. of Toxicology, DaeJeon, Korea, Republic of

Abstract: (GLA) (Glufosinate-ammonium) is widely known as an herbicide and is known to cause neurotoxicity and thereby affect neural development. However, much of the mechanism of GLA has not been studied. Because the structure of GLA is similar to that of Glutamate, the effect of GLA on N-Methyl-D-aspartic acid (NMDA) receptors was evaluated by monitoring Fura-2 binding intracellular Ca2+. 100 μM Glutamate / 50 μM Glycine activated NMDA receptors of the primary cortical neurons of postnatal rat day 2. The cells treated with 1 mM GLA / 50 μM Glycine showed 44.5 ± 6.34 % of NMDA receptor-activated Ca2+ transient responsive cells and 0.055 ± 0.007 peak ratio compared to 0.38 ± 0.31 mediated by the activation of NMDA receptor. On the other hands, we did not have Ca2+ transients of primary cortical astrocytes. These results suggest that GLA targets NMDA receptors of neuronal cells. We also tasted that D-2-amino-5-phosphonopentanoate (DAP5), competitive NMDA receptor antagonist

inhibited GLA/Glycine-induced Ca2+ transient by decrease of 20.5 ± 18.3 % peak ratio. In addition, free Mg2 + of external solution increased GLA/Glycine responsiveness by 41.8% in number and 37.4% in peak ratio compared to those of 2mM external Mg2+. The evidences suggest that GLA activates NMDA receptors therefore and affect critical time in brain development stage.

Title: Beta-methylamino-L-alanine induces neuronal injury via kinase dependant mechanisms in rat primary neuronal cultures

Authors: C. DUCHEMIN-NEVEU, ***E. ANDRIAMBELOSON**, S. WAGNER;
Neurofit SAS, Illkirch, France

Abstract: Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disease that leads to the death of patients within 3-5 years after diagnosis. The only drug (riluzole) that exists prolongs the lifespan of patients by a few months. Although the pathophysiology of ALS is not completely understood, it shows close similarities with other neurodegenerative disease like AL-SPDC (Amyotrophic lateral sclerosis/parkinsonism-dementia complex) characterized by clusters of dysfunctional proteins within neurons. Indeed, several studies have pointed to the potential role of dietary exposure to the cyanobacteria-derived non-amino acid, β-Methylamino-L-alanine (L-BMAA) as a possible risk factor for ALS or ALS/PDC. Furthermore, post-mortem analyses indicate the presence of L-BMAA in the brains of patients that suffered from non-genetic progressive neurodegenerative disease, including ALS. The present study was undertaken to evaluate the neurotoxicity of L-BMAA in primary neuronal cultures prepared from the brain and spinal cord of rat embryos. In order to assess the putative role of protein phosphorylation in the neurotoxicity of L-BMAA, the potential neuroprotective effect of two candidate protein kinases (casein kinase 1-δ and Glycogen synthase kinase-3) inhibitors were investigated. The results showed that L-BMAA induces the death of different population of rat neurons in a dose-dependent manner. Neuronal damage was detected as early as 24h after exposure to L-BMAA but became substantial when the exposure was extended up to 7 days. Whilst the L-BMAA neurotoxicity was detected under the different cultures of neurons, those from the spinal cord appeared to be the most sensitive when compared to those from the brain. Furthermore, in the presence of a casein kinase 1 inhibitor (LH-846 or PF670462) and of GSK3 inhibitor (A1070722 or TCS-2002), the neurotoxicity of L-BMAA was suppressed. Thus, the above results suggest an

enhanced neurotoxicity of L-BMAA towards spinal motor neurons. It appears that L-BMAA neurotoxicity is mediated by protein phosphorylation mechanisms involving protein kinases such as casein kinase 1-δ or Glycogen synthase kinase-3.

Title: Investigating interactions between microglia and astrocytes as models of hand

Authors: *D. A. ODHIAMBO;
Drug Discoveryand Biol. Sci., Univ. of South Carolina, Columbia, SC

Abstract: While the deployment of combination antiretroviral therapy [CART] has seen to the decline in AIDS-associated deaths, HIV-associated neurocognitive disorders [HAND] remain increasingly high. The production of HIV-proteins mainly Tat and gp120 in the central nervous system is characterized by direct or indirect neuronal toxicity. Studies have reported heightened severity in HAND in combination with the abuse of drugs such as cocaine. In elucidating mediators of immune activation in the brain, studies have suggested a role for microglia and astrocytes in the production of toxic factors that promote neuronal damage and subsequent inflammation in the brain.
In this regard, we are investigating the role of HIV-1 regulatory protein, Tat in combination with cocaine, in microglia and astrocyte activation. We compared the direct effects of the HIV-Tat and cocaine, on cortical mixed neuronal and glial cultures, as well as the effects of conditioned medium produced by treated glial cultures on mixed neuronal cultures. Neurotoxicity of Tat and cocaine; and conditioned medium; and their effects on microglia and astrocytes activation were analyzed.
Astrocytes-microglial cells were isolated from adult rat, cultured and treated with Tat, cocaine and a combination thereof. Conditioned medium was collected from the treated astrocyte-microglial cultures and applied on mixed neuronal cultures. These astrocytes-microglial cultures were then immunostained for microglia and astrocyte specific markers. Primary cortical cultures were also analyzed for apoptosis/cell death. Effects of conditioned medium were compared with

the effects of direct Tat and cocaine treatment on mixed neuronal cultures.
Contrary to effects of HIV-Tat and cocaine on mixed neuronal cultures, there was no evident microglial activation; microglia activation is characterized by an increase in size and number of microglia. There was, however, a change in the standard astrocyte phenotype to the activated neurotoxic A1 phenotype. Neurons exposed to treated astrocyte-microglia conditioned medium showed an increase in cleaved Caspase3/7 and ethidium bromide positive cells, suggesting cell death.
Our lab has recently shown that Tat and cocaine dependent astroglia activation is inhibited by RK-33, a selective inhibitor of Dead Box RNA helicase 3 [DDX3]. We demonstrated that DDX3 inhibition protects neurons from combined toxicity of HIV proteins and cocaine. Combined, these results suggest a role for both astrocytes and microglia in the production of neurotoxins that cause neuronal damage with indication that astrocytes are possibly the primary target of HIV regulatory protein Tat.

Title: Resveratrol prevents the ethanol-induced oxidative stress on hippocampus of Wistar rats

Authors: *D. JUÁREZ SERRANO[1], I. CESAR-ARTEAGA[1], F. RAMOS-COLLAZO[2], J. C. MORALES-MEDINA[4], A. D. DIAZ-FONSECA[3], P. AGUILAR-ALONSO[1];
[1]Bioquimica-Alimentos, [2]Bioterio Claude Bernard, BUAP, [3]Farmacia, Benemerita Univ. Autonoma De Puebla, Puebla, Mexico; [4]CINVESTAV, Ctr. De Investigacion En Reproduccion Animal, Tlaxcala, Mexico

Abstract: Ethanol is a psychoactive substance with dependency-causing properties, a high intake is associated with memory loss and neuronal disturbance associates to oxidative stress. Oxidative stress is an imbalance between oxidants and antioxidants leaning towards an oxidative environment, which potentially leading to cell and molecular damage. Free radicals are eliminated by antioxidant endogenous, if these is not enough to counteract oxidative damage there are used antioxidant exogenous. It has been found that chronic ethanol intake favors deterioration of the hippocampus, inhibiting cell survival and altering neuronal morphological maturation. To counteract these effects, various antioxidant both natural and synthetic, have been described, one of which is Resveratrol, a polyphenol with antioxidant, anti-aging, anticancer and neuroprotective properties. The aim of this work is to analyze if resveratrol is able to prevents the ethanol-induced oxidative stress hippocampus Wistar rats. Male Wistar rats, 3 months old,

were divided into the following categories: Control (without treatment), 4 groups administered with high doses of ethanol (20, 30, 40 and 50% ethanol), respectively and other 4 groups administered with resveratrol 10 mg / kg / day. All groups were daily administered orally for 2 months and all groups have n=3 animals. Posteriorly, the hippocampus was obtained for quantification of nitrite production, malondialdehyde (MDA), MDA + 4-hydroxinonenal (4-HDA) and enzymatic activity of Catalase and Superoxide Dismutase. The levels of nitric oxide and lipoperoxidation products rise significantly when the concentration of ethanol increases compared to the control group, however, the treatment with Resveratrol significantly reduces the oxidative stress caused by a high consumption of Ethanol. The enzymatic activity studied (catalase and superoxide dismutase) did not present significant changes with respect to the controls. Results show that resveratrol prevents damage by acting as an independent scavenger to the endogenous system. In addition, there is a decrease in markers of oxidative stress when resveratrol is administered in high alcohol consumption. In conclusion, resveratrol prevents the ethanol-induced oxidative stress on hippocampus of Wistar rats decreasing cellular lipoperoxidation but not to the activation of the enzymes catalase and superoxide dismutase.

Title: Resveratrol protects from oxidative stress produced by chronic administration of ethanol in rat cerebellum

Authors: *C. GARCÍA-OLVERA[1], D. JUÁREZ SERRANO[2], I. CESAR ARTEAGA[3], G. PULIDO-FERNANDEZ[4], A. R. NAVARRO-CRUZ[2], L. G. GARCÍA-ALBARRÁN[2], P. AGUILAR-ALONSO[5];

Autonoma De Puebla, Puebla, Mexico; [4]Posgrado en Ciencias Químicas, [5]Bioquímica-Alimentos, BUAP, Puebla, Mexico

Abstract: The abuse of alcohol consumption is a public health problem. Chronic consumption of ethanol has been associated with permanent impact on the morphology, structural function and membrane lipid organization of brain. An important region affected is cerebellum, which is

responsible for regulating vascular tone, posture, spinal movements, balance and the execution of fine movements. During a chronic consumption of ethanol, both the execution of movements and the balance are affected. A mechanism to explain cerebellar degeneration is oxidative stress, where Reactive Oxygen Species (ROS) and Reactive Nitrogen Species (RNS) are involved. It is mediated by the endogenous antioxidant system. The use of natural antioxidants as Resveratrol have a neuroprotector activity. The aim of this work is evaluate oxidative stress induced by chronic consumption of ethanol in rat cerebellum. Male Wistar rats of 3 months of age divided into the following groups were used: control (without treatment), 8 groups treated with ethanol (2.5, 5, 7.5, 10, 20, 30, 40 and 50 %) and other 8 groups treated with 10 mg/ kg/day of resveratrol + ethanol concentrations mentioned above. All groups were daily administered oral via for 2 months (n=3). Cerebellums were obtain for quantification of nitrites and hydroperoxydes production. Results show a significant decrease in levels of nitric oxide in groups administered with ethanol compared with the control group, although this levels rise when ethanol increases, also it is observed that the combined administration of ethanol + resveratrol in high doses prevents the elevation of these levels. When lipoperoxidation intermediates was analyzed, hydroperoxide levels are increased from the 10% ethanol group and progressively maintained until 50%. In the resveratrol groups, the protective effect is observed that inhibits the formation of hydroperoxides when it is exceeded at 50% ethanol. The large amount of polyunsaturated fatty acids in cerebellums makes it susceptible to lipoperoxidation reactions. The reduction and degradation of hydroperoxides is carried out by the glutathione system coupled to other enzymes of the endogenous antioxidant system, such as catalase and superoxide dismutase. The daily intake of resveratrol favors the reduction of these lipoperoxidation intermediates generated during chronic consumption of ethanol. It also acts as a regulator of the production of nitrites, and could prevent the formation of RNS such as peroxynitrites, associated with various neurodegenerative diseases.

Title: Vanadium pentoxide inhalation effects on motor performance and motor cortex cytology

Authors: O. MEJÍA-GARCÍA[1], M. RODRÍGUEZ-ALCÁNTARA[1], E. MONTIEL-FLORES[1], A. GUTIÉRREZ-VALDEZ[1], *L. REYNOSO-ERAZO[2], J. ESPINOSA-VILLANUEVA[1], J.

ORDOÑEZ-LIBRADO[1], M. AVILA-COSTA[1];
[1]Neurosci., [2]Hlth. Educ., Univ. of Mexico, Mexico, Mexico

Abstract: Vanadium (V) is a transition metal that which has three oxidations states in the environment. The population is daily exposed to low levels of V on food and water, however, the inhaled way is the most important route since this metal is emitted into the atmosphere after the burning of fossil fuels. For these reasons there have been studied different experimental models with inhaled exposition to Vanadium pentoxide (V_2O_5)in mice, which have showed that this metal causes CNS alterations, including dendritic spines alterations and neuronal necrotic-like cell death in hippocampus, as well as decrease in TH^+neurons in the Substantia nigra compacta (SNc). The neuronal alterations are related to the capacity of V to enter into the cells to cause oxidative stress, lipoperoxidation, besides the alterations in the intracellular pathways and cytoskeleton. Furthermore, it has been reported that V oral exposition produces motor and memory alterations in rats. Therefore we aim to assess if V_2O_5inhalation in rats induces motor alterations and morphological changes in motor cortex pyramidal neurons. 10 Wistar rats inhaled V_2O_5 [0.02 M] 1 h twice a week for 6 months and motor activity was evaluated in the beam-walking task once a month. All rats was sacrificed and perfused after the last inhalation and processed for Golgi stain to determine the dendritic spines number in pyramidal neurons of the primary motor cortex. Our findings show that after 6 months of V inhalation there were not significative differences in the motor activity compared to the control group. However, V causes significant cytological damage in the number of dendritic spines in experimental group (mean= 5) compared to the control group (mean= 9.1). We concluded that after 6 months, V_2O_5inhalation induces motor cortex pyramidal neurons alterations. Nevertheless, is not enough to cause motor activity impairments.

Title: The effects of different combinations of plant extracts and traditional chinese medicine on hydrogen peroxide- and thapsigargin-induced neurotoxicity

Authors: *K. SUEN[1], Y. CHEUNG[1], T. HSU[1], S. WONG[1], S. CHAN[1], H. CHENG[1], S. LAW[1], Y. CHONG[1], K. HUNG[1], H. WONG[1], K. WAN[1], H. LEUNG[1], K. LIU[1], T. LI[1], W. TANG[1], M. LIN[1], H. CHEUNG[1], R. C. CHANG[2];

[1]Biol. and Biotech., Po Leung Kuk Laws Fndn. Col., Hong Kong, China; [2]Lab. of Neurodegenerative Diseases, LKS Fac. of Medicine, Univ. of Hong Kong, Hong Kong, China

Abstract: Oxidative stress and endoplasmic reticulum (ER) stress have been known as some of the significant causes of neuronal cell death in many neurodegenerative diseases. Agents that can attenuate these stresses are believed to have neuroprotective effects. *Allium fistulosum* has been shown to have antioxidant and antimicrobial activities (Chang et al., 2016). The root extract of *Clitoria ternatea* has been found to improve memory in the chronic cerebral hypoperfusion rat model (Damodaran et al., 2018). *Hibiscus sabdariffa* aqueous extract has been shown to have protective effects against acute cerebral ischaemia (Owoeye and Gabriel 2017). *Sterculia lychnophora* has been reported to have neuroprotective effects against hydrogen peroxide-induced toxicity (Wang et al., 2013) while its activity against ER stress has not yet been studied. Traditional Chinese medicine is usually formulated as a complex of herbs which may have synergistic effects for a disease (Zhou et al., 2016). In the present study, the effects of different combinations of extracts of *Allium fistulosum*, *Clitoria ternatea*, *Hibiscus sabdariffa* and *Sterculia lychnophora* against hydrogen peroxide- and thapsigargin-induced neuronal cell death were studied. The extracts were prepared by dissolving the powder of ground dried *Allium fistulosum*, *Clitoria ternatea*, *Hibiscus sabdariffa* and *Sterculia lychnophora* in absolute ethanol and insolubles were filtered out by 0.22 micro-meter membrane filter. Undifferentiated SH-SY5Y cells were pre-treated with a single or multiple plant extracts for 24 hours in DMEM supplemented with 2% fetal bovine serum. Following the removal of the extracts, SH-SY5Y cells were treated with 400 micro-molar of hydrogen peroxide or 0.5 micro-molar of thapsigargin for 24 hours in DMEM supplemented with 2% fetal bovine serum. Results indicated that there were differential effects of the extracts against hydrogen peroxide- and thapsigargin-induced cytotoxicity, implying that the combined applications of these herbal extracts may have different effects on neuronal cell death induced by oxidative stress and ER stress.

Title: Double-hit of inflammation and general anesthesia causes persistent impairment in executive function

Authors: *S. KHODAEI[1], D. WANG[1], B. A. ORSER[2];
[1]Physiol., Univ. of Toronto, Toronto, ON, Canada; [2]Depts. Physiol & Anest, Univ. Toronto, Toronto, ON, Canada

Abstract: Cognitive impairment in patients during the postoperative period is common and associated with poor long-term outcomes, prolonged length of hospital stay, and increased mortality. The mechanisms underlying such cognitive impairments are likely multifactorial but poorly understood. Preclinical findings suggest that general anesthetic drugs and preoperative inflammation contribute to postoperative cognitive deficits; however, to date, the two factors have been studied in isolation. The consequences of a "double-hit" of inflammation and anesthesia on cognition are unknown. Here, we tested the hypothesis that a double-hit of inflammation and anesthesia causes greater impairment in cognitive performance than each factor alone. To induce inflammation, adult male C57BL/6 mice were injected with lipopolysaccharide (LPS; 1.0 mg/kg, i.p.) or vehicle. The mice were next treated with the general anesthetic drug etomidate (20 mg/kg, i.p.) or vehicle 24 hours later. Over the next 4 days, memory and executive function were studied using the novel object recognition (NOR) assay and the 3-day puzzle box assay, respectively. The results showed that in the NOR task, LPS but not etomidate alone impaired recognition memory. The combination of LPS and etomidate caused memory deficits that were no different than LPS alone. In contrast, in the puzzle box assay, mice treated with either LPS or etomidate alone showed no impairment in executive function, whereas the double-hit caused impairment. These results suggest that different cognitive domains are differentially affected by the combination of anesthesia and inflammation. Ongoing studies will examine other cognitive domains such as spatial memory, the effects of more commonly used anesthetic drugs such as sevoflurane and propofol, and the molecular mechanisms underlying the performance deficits.

Title: Protective effects of astrocyte-specific deletion of yin yang 1 in the substantia nigra on manganese-induced dopaminergic neuronal injury in mice

Authors: *J. A. JOHNSON, Jr[1], E. PAJARILLO[1], A. RIZOR[1], M. ASCHNER[2], E. LEE[1]; [1]Col. of Pharm. and Pharmaceut. Sci., Florida A&M Univ., Tallahassee, FL; [2]Dept. of Mol. Pharmacol., Albert Einstein Sch. of Med., New York, NY

Abstract: Chronic manganese (Mn) exposure causes a Parkinson's disease (PD)-like neurological disorder referred to as manganism. Our previous studies have shown that Mn increased expression of transcription factor yin yang 1 (YY1) which repressed astrocytic glutamate transporters, glutamate transporter 1 (GLT-1) and glutamate aspartate transporter 1 (GLAST) in astrocytes. Since the reduced astrocytic glutamate transporter expression could result in Mn-induced excitotoxicity in vivo, in this study, we have tested if astrocytic YY1 mediates Mn-induced dopaminergic neurotoxicity via reduction of astrocytic GLT-1 and GLAST in the substantia nigra pars compacta (SNpc) of mouse brain. To test the hypothesis, we injected AAV viral vectors expressing Cre recombinase and green fluorescent protein under the control of glial fibrillary acidic protein (GFAP) promoter (AAV5-GFAP-Cre-eGFP) into the SNpc of YY1-loxP mice bilaterally to delete YY1 only in astrocytes of the SNpc region of YY1 loxP mice. AAV5-GFAP-eGFP vectors were used as controls. Three weeks after the injection, mice were exposed to Mn (or H_2O as a vehicle, intranasal instillation, 30 mg/kg, daily) for 21 days prior to behavioral tests such as open field and rotarod assessment, followed by immunohistochemistry (IHC) and protein/mRNA expression levels of tyrosine hydroxylase (TH), YY1, GLT-1 and GLAST in the midbrain of mice. Results showed that Cre recombinase was expressed and it deleted YY1 efficiently in astrocytes. The behavioral studies revealed that deletion of astrocytic YY1 in SNpc attenuated Mn-induced reduction of locomotor activity and motor coordination compared with control. Astrocytic YY1 deletion in SNpc also reversed the Mn-induced reduction of TH mRNA/protein levels. Moreover, astrocytic YY1 deletion in SNpc also attenuated Mn-induced repression of GLT-1 and GLAST in midbrain, suggesting that astrocytic YY1 is involved in Mn-induced dopaminergic neurotoxicity potentially via reduction of astrocytic glutamate transporters GLT-1 and GLAST. These findings suggest that astrocytic YY1 could serve as a potential target for the development of therapeutics to restore astrocytic glutamate transporter function and prevent excitotoxic neuronal injury.

Title: General anesthesia causes a persistent decrease in brain-derived neurotrophic factor in the hippocampus

Authors: *A. ALAVIAN-GHAVANINI[1], M. A. MANZO[1], D.-S. WANG[1], L. KAUSTOV[3], B. A. ORSER[1,3,2];

Abstract: Postoperative neurocognitive disorder occurs in some patients and general anesthetic drugs may be a contributing factor. Our previous preclinical studies have shown that many commonly used anesthetic drugs trigger a sustained increase in cell-surface expression of extrasynaptic $GABA_A$ receptors in neurons and cause cognitive deficits. Co-treatment with the α2 adrenergic receptor agonist dexmedetomidine, prevents overexpression of extrasynaptic $GABA_A$ receptors and attenuates cognitive impairment. Dexmedetomidine is neuroprotective likely because it increases the levels of Brain-Derived Neurotrophic Factor (BDNF) in the brain. Based on these results, we hypothesize that general anesthetic drugs reduce BDNF, leading to overexpression of $GABA_A$ receptors and cognitive deficits. The goal is to determine whether a clinically relevant dose of a general anesthetic drug causes a persistent decrease of BDNF in the brains of adult mice. Male C57BL/6J mice (2-3 months old) were treated with isoflurane (1.3% for 1 hr) or air. One or 7 days later, BDNF mRNA and protein levels were measured in ex vivo hippocampi with qPCR and Western blotting, respectively. The results showed that BDNF mRNA levels were slightly reduced at Day 1 (74.2 ± 29.0% of control; mean ± SD, $n = 3$, $p = 0.34$ compared with control) and significantly reduced at Day 7 (22.3 ± 10.3% of control; $n = 3$, $p < 0.05$ compared with control). BDNF protein was 112.5 ± 16.2% of control at Day 1 ($n = 3$, $p = 0.39$ compared with control) and 65.6 ± 9.6% of control at Day 7 ($n = 3$, $p < 0.05$ compared with control). Thus, a clinically relevant dose of isoflurane downregulates BDNF gene expression and protein levels for at least 7 days. Interestingly, our previous results have shown that overexpression of $GABA_A$ receptors persists for one week after isoflurane, so the two mechanisms correlate in time. Ongoing studies will determine whether other anesthetic drugs alter the BDNF levels and the time course of BDNF recovery.

Title: Chlorpyrifos (CPF)-induced neurobehavioral deficits and neuropathology in adult male rat

Authors: *Y.-H. TSAI, N. LEVOE, J. VU, D. A. BRUUN, P. J. LEIN;
VM: Mol. Biosci., Univ. of California, Davis, Davis, CA

Abstract: Organophosphate (OP) cholinesterase inhibitors are a family of potent neurotoxic chemicals that includes nerve agents and pesticides. Chronic low-level exposures to OPs are associated with cognitive deficits in humans but the mechanism(s) underlying chronic OP neurotoxicity remain speculative, although mechanism(s) other than acetylcholinesterase inhibition are widely postulated to be important. Here, we investigated the hypothesis that subchronic exposure to the OP chlorpyrifos (CPF) causes neurobehavioral deficits via oxidative stress and/or neuroinflammation. Using a rat model based on documented human occupational exposures to CPF, adult male Long Evans rats were exposed to 10 mg/kg/d CPF (s.c.) or vehicle (10% Ethanol+90% Neobee M-5) for up to 21 d. A subset of animals were pretreated with the antioxidant Trolox (1 mg/kg/d i.p.) beginning 5 d prior to and continuing throughout CPF exposure. Brains collected after 3, 10, 15, or 21 d of CPF exposure were evaluated for: (1) neurodegeneration as assessed using FluoroJade C staining; (2) microglial activation and astrogliosis, as assessed by IBA-1 and GFAP immunoreactivity, respectively; and (3) neuronal oxidative stress as determined by co-immunoreactivity for 3-nitrotyrosine (3-NT), a marker of protein nitration, and NeuN label neurons. Animals treated with CPF for 21 d exhibited deficits in cued fear conditioning test compared to vehicle controls. In contrast, performance in cued fear conditioning was not significantly different between CPF-exposed animals treated with Trolox and vehicle controls. Chronic CPF exposure did not increase FJC staining in multiple brain regions (such as hippocampus, thalamus, piriform cortex, and amygdala) at the time points examined, and levels of neurodegeneration were not altered by Trolox treatment. CPF exposure increased GFAP immunoreactivity in a brain- and exposure length-dependent manner, and these effects were attenuated in CPF-exposed animals pretreated with Trolox. Trolox treatment also altered CPF effect on 3-NT immunoreactivity. Collectively, these results identify neuroinflammation, and potentially oxidative stress, as novel mechanism(s) of chronic CPF-induced neurotoxicity, and suggest that antioxidants may be useful in protecting against the neurotoxic effects of OPs.

Title: Evaluation of glutamate homeostasis, ATPases and depressive status in rats subjected to mild hyperhomocysteinemia

Authors: *T. M. DOS SANTOS, C. SIEBERT, L. D. BOBERMIN, A. Q. DOS SANTOS, C. A. NETTO, A. T. S. WYSE;
Biochem. Dept., Univ. Federal Do Rio Grande Do Sul, Porto Alegre, Brazil

Abstract: Increased levels of homocysteine (HCY) can be associated with several disorders, including psychiatric diseases. However, the mechanisms related to these changes are not well-known. In the present study, we evaluate depressive-like parameters such as body weight gain, adrenal/body weight ratio, sucrose preference and forced swimming tests, as well as activity and protein abundance of catalytic (α1 and α3) and regulatory (β1) subunits of Na^+, K^+-ATPase in the amygdala and prefrontal cortex of male rats submitted to chronic mild hyperhomocysteinemia (HHCY) chemically-induced. Mg^{2+}-ATPase, glutamate uptake, and cell viability were also evaluated. Wistar male rats received a subcutaneous injection of HCY (0.03µmol/g of body weight) or saline (0.9% 0.5mL/g of body weight) twice a day for 30^{th} to 60^{th} days of life. From 61 days of life, rats were submitted to behavior analyzes (n=13 animals/group) and euthanatized for brain and adrenal dissection (n=7-8 animals/group). Statistical analyzes were performed by Student's t-test. Mild HHCY did not impair body weight gain, adrenal/body weight ratio, 1% sucrose preference and swimming tests (both $p>.05$). Chronic mild HHCY increased total ATPases activities (Na^+, K^+-ATPase + Mg^{2+}-ATPase) in amygdala ($t=2.155$, $p>.05$) and prefrontal cortex ($t=3.642$, $p>.01$). In the amygdala, Na^+, K^+-ATPase was increased ($t=3.84$, $p<.01$) without alterations on Mg^{2+}-ATPase ($p>.05$). In the prefrontal cortex, Mg^{2+}-ATPase was increased ($t=5.029$, $p<.001$) without alterations on Na^+, K^+-ATPase ($p>.05$). Na^+, K^+-ATPase subunits protein abundance (α1, α3 and β1), glutamate uptake, and cell viability were not altered by HHCY-induced model (both $p>.05$). The amygdala and prefrontal cortex presented HHCY-specific responses. Our findings suggest that although chronic mild HHCY may have promoted an adaptation, leading to ATPases increase (Na^+, K^+-ATPase and Mg^{2+}-ATPase) in the amygdala and prefrontal cortex, such modifications did not

cause depressive-like behavior, and not compromised glutamate uptake and cell survival. These alterations may be related to the risk for several disorders that leads to an increase in Na^+, K^+-ATPase activity in the amygdala. These finds help to better understand the involvement of brain structures in chronic mild HHCY. Supported by CNPq and INCT EN/CNPq.

Title: Alcohol drinking decreases the glutamate aspartate transporter to enhance methamphetamine excitotoxicity

Authors: *A. L. BLAKER[1,2], E. R. MOORE[2], B. K. YAMAMOTO[2];
[1]Neurosciences, Univ. of Toledo, Toledo, OH; [2]Pharmacol. and Toxicology, Indiana Univ. Sch. of Med., Indianapolis, IN

Abstract: A high comorbidity exists between alcohol and methamphetamine (Meth) but the neurochemical consequences of their co-abuse are poorly understood. Alcohol and Meth individually increase glutamatergic transmission in the brain but the effects of their co-exposure on excitotoxicity and its possible role in mediating damage to dopamine is unknown. Male Sprague Dawley rats were allowed intermittent access to 10% ethanol (EtOH) every other day over 28 days. Rats underwent a binge Meth or saline regimen the following day. Rats that drank EtOH displayed decreases in the glutamate aspartate transporter (GLAST) and increases in basal glutamate collected by microdialysis in the striatum 24 hrs after the last day of drinking. Consistent with the known effects of ceftriaxone to increase the expression of glutamate transporter, ceftriaxone treatment during EtOH drinking attenuated the decreases in GLAST and increases in basal glutamate concentrations. EtOH drinking also enhanced the increases in extracellular glutamate, cleaved caspase-3 mediated spectrin proteolysis, and dopamine depletions 7 days later. Ceftriaxone attenuated these enhanced responses to the serial exposure to EtOH and Meth. These data indicate the EtOH-induced decreases in GLAST and the associated increases in extracellular glutamate converge with Meth-induced glutamate efflux in the striatum to enhance spectrin proteolysis through cleaved caspase-3. Furthermore, this vulnerability to Meth-induced excitotoxicity produced by EtOH drinking synergistically contributes to long-

lasting dopamine depletions produced by Meth. These results elucidate a novel mechanism of neurotoxicity after the serial exposure to EtOH and Meth that is different than either drug alone.

Title: Nasal administration of mesenchymal stem cells reverses chemotherapy-induced peripheral neuropathy

Authors: *N. BOUKELMOUNE, J. MA, G. O. LAUMET, A. KAVELAARS, C. J. HEIJNEN; Symptom Res., Univ. of Texas MD Anderson Cancer Ctr., Houston, TX

Abstract: Background: Chemotherapy-induced peripheral neuropathy (CIPN) is one of the most commonly reported adverse side effects of cancer treatment. CIPN affects 30 to 80% of cancer patients and often persists after treatment completion, having detrimental effects on patient's quality of life. Currently, there are no effective FDA-approved drugs to prevent or reverse CIPN and the mechanisms associated with the pathogenesis of CIPN are not completely understood. However, growing evidence identifies mitochondrial dysfunction in the etiology of this condition. Mesenchymal stem cells (MSC) have been shown to stimulate tissue repair and ameliorate the outcome of various neurodegenerative diseases. We have shown previously that nasal administration of MSC resolves cisplatin-induced cognitive impairment (Chiu et al., Oncotarget, 9:35581, 2018).
Hypothesis/Goals: In this study we tested the hypothesis that nasal MSC treatment reverses central and peripheral neuropathy and restores mitochondrial bioenergetics in cisplatin-treated mice.
Methods: Male and female mice were treated with two cycles of cisplatin (2.3 mg/kg for 5 days), followed by nasal administration of MSC at 48 and 96 h after the last dose of cisplatin. Behavioral testing was performed prior to cisplatin and MSC treatment as well as 5-21 days after the last MSC dose. Mechanical allodynia was measured using von Frey hairs and spontaneous pain was tested using a conditioned place preference test. Mitochondrial function in the dorsal root ganglia (DRG) as well as peripheral nerve was determined by Seahorse Flux analysis.
Results: Nasal MSC administration resolved cisplatin-induced mechanical allodynia in both male and female mice, while mechanical allodynia persisted in mice treated with cisplatin only. MSC treatment also alleviated spontaneous pain. Furthermore, MSC administration normalized the

cisplatin-induced decrease in mitochondrial dysfunction in DRG neurons as well as in tibial nerve as compared to mice who received cisplatin alone.
Conclusions: Our results show that administration of two doses of nasal MSC is sufficient to reverse symptoms of cisplatin-induced peripheral neuropathy, including mechanical allodynia and spontaneous pain by restoring mitochondrial function in dorsal root ganglia and peripheral nerve.

Title: Alzheimer's and Parkinson's disease modeling using iPSC derived neurons, astrocytes and microglia for screening of neurotoxic and/or neuroprotective compounds

Authors: *S. ANKAM[1], K. GORDON[1], R. BASA[1], C. T. MARTIN, III[1], C. HANDLEY[1], S. L. FENG[1], J. V. KARPIAK[1], T. ROHN[2], J. PRICE[1,3], P. MCDONOUGH[1];

Abstract: The role of inflammation in neurodegenerative diseases is an emerging area of study. Microglia, the neuroimmune cell, can play a neuroprotective or a neurotoxic role depending on the specific disease circumstance. Recent advances have led to the development of various protocols for differentiating microglia, neurons, and astrocytes from human iPSCs. By using cells derived from either healthy or genetically susceptible patients, we can develop co-culture systems to study neuroinflammation and neurotoxicity in various disease conditions. Here we describe the use of Vala Sciences' imaging platform, the IC200 Kinetic Image Cytometer™ (KIC), to characterize and develop screening assays in co-cultures with microglia and neurons, as well as astrocytes. We developed advanced, custom algorithms for our CyteSeer image analysis software, and it is now possible for us to automate neurite tracing, nucleus mapping, and analysis of calcium activity for single cells in a co-culture system. In this study, microglia were derived from human iPSCs and were characterized using the biomarkers CX3CR1, TREM2, IBA1, P2RY12, and TMEM119 by immunofluorescence. We then assessed microglial functionality by performing an engulfment assay using pHrodoRed Zymosan beads. Increased

engulfment after stimulation with IL-4, but not after stimulation with lipopolysaccharide (LPS), demonstrated polarizability to different microglial activation states (M2 vs. M1, respectively). Next, we developed co-culture systems with microglia, dopaminergic neurons or glutamatergic neurons, and astrocytes to further examine the role of microglia in co-culture models of Parkinson's Disease (PD) and Alzheimer's Disease (AD). Addition of microglia to a glutamatergic neuron culture increased neurite outgrowth by 50%, suggesting a neuroprotective role for microglia in this co-culture system. Additionally, we have demonstrated differential engulfment of β-amyloid 1-40 and β-amyloid 1-42 (the AD-relevant β-amyloid fragment) by microglia in co-culture. Neurite outgrowth and calcium imaging assays are being performed on the co-culture systems with stressors for AD (ApoE and β-amyloid) or PD (paraquat) to determine if microglia protect neurons from or sensitize neurons to these specific disease-relevant insults.

Abstract: Although the underlying causes of neurodegeneration are still under investigation, the immune system likely plays a key role in disease onset and pathogenesis. However, the specific function of cytokines and other immune signalling pathways in disease pathogenesis is unclear. The nuclear receptor coactivator 7 (NCOA7) is a poorly characterized gene containing the Tre2/Bub2/Cdc16 (TBC), lysin motif (LysM), domain catalytic (TLDc) domain. This motif is present in a family of proteins known to protect against oxidative stress-related insults, including TBC1 domain family member 24 (TBC1D24), a protein mutated in a range of disorders characterized by epilepsy, hearing loss and neurodegeneration. The TLDc domain is highly conserved across species, although the structure-function relationship is unknown. Interestingly, a short isoform of NCOA7 (NCOA7B) - containing just the TLDc domain - has been shown to

be significantly induced by bacterial lipopolysaccharides (LPS) and interferons, as well as being able to modulate endosome-mediated viral entry. Here, using unique mouse models, we report for the first time that NCOA7 and NCOA7B act in different cell types in the brain, attenuating an exaggerated immune response and promoting proper neuronal connectivity in vivo.

Abstract: Interactions between the nervous system and the immune system protect neurons from pathogens. Since dysfunctions of the neuroimmune system underlie many neurodegenerative and neurological diseases, methods of manipulating neural immunity have strong therapeutic potential. The neuroimmune system includes neurons and microglia as well as cytokines, signaling proteins which allow communication between cells. Prior work has shown that exposing mice to lights flickering at 40Hz induces neural spiking activity at 40 Hz (within the gamma frequency) and recruits microglia in primary visual cortex. By recruiting both neuronal activity and immune cells, this paradigm has potential clinical applications, but the effect of 40Hz flicker on neuroimmune biochemical signaling remains unknown because the fields of neural oscillations and neuro-immunology are rarely examined together. We exposed mice to 40Hz flicker, and using a Luminex multiplex assay, we assessed differences in networks of cytokines and phosphoproteins known to play a role in immune function. We found that 40Hz flicker leads to significant increases in cytokine expression, such as IL-6 and IL-4, which promote microglial engulfing states, as well as microglial chemokines, such as M-CSF and MIG. To identify possible mechanisms underlying cytokine expression, we then quantified the effects of 40Hz flicker on internal signaling pathways known to control cytokine expression. We found that 40Hz flicker up-regulates phospho-signaling within the MAPK and NF-kB pathways, both

of which regulate cytokine expression. We found that while changes in cytokine levels occur after 1 hour of 40Hz flicker stimulation, changes in protein phosphorylation occur more rapidly, within a few minutes. These results are the first to show how gamma frequency neural spiking activity affects neuroimmune signaling. Identifying the effects of 40Hz frequency neural stimulation on immune signaling in the brain will enable new strategies to promote and interrogate healthy brain immune function.

Title: Modelling the *Toxoplasma gondii* infection in human neural cells: Role of metalloproteinases and neuroinflammation

Authors: *E. C. LOIOLA[1], R. M. MARIANTE[2], P. TRINDADE[1,3], L. O. PORCIUNCULA[4], S. K. REHEN[5,1];
[1]IDOR, Rio de Janeiro, RJ, Brazil; [2]Oswaldo Cruz Inst., Rio de Janeiro, RJ, Brazil; [3]UNIRIO, Rio de Janeiro, RJ, Brazil; [4]UFRGS, Porto Alegre, RS, Brazil; [5]UFRJ, Rio de Janeiro, RJ, Brazil

Abstract: The intracellular parasite *Toxoplasma gondii* is a common pathogen within worldwide population and latent toxoplasmosis is usually considered asymptomatic. However, there are evidences that toxoplasmosis could cause behavioral changes in humans and many studies highlight the link between *T. gondii* infection and increased incidence of psychiatric disorders. Neuroinflammation itself also plays a major role in several mental illness and high levels of pro-inflammatory substances as cytokines and metalloproteinases (MMPs) have been described in the blood and cerebrospinal fluid of schizophrenic and bipolar disorder patients. Activated glial cells are an important source of MMPs in CNS and toxoplasma infection could induce the production of these enzymes. Here, we used human induced pluripotent stem cells (hIPSC)

differentiated into neural stem cells, neurospheres and astrocytes. Individual predisposition to parasite infection could be accessed by *T. gondii* immunolabeling in infected cultures. This approach permits the study of molecular mechanisms involved in parasite infection and the outcome on human neural cells. The effect of MMP9 activity in the parasite infection were estimated after treatment with apigenin (a flavonoid that inhibits MMPs expression) and 1-10-phenathroline (a MMP inhibitor). Both treatments abrogate *T. gondii* infection in neurospheres. To evaluate the role of infection inhibitors drugs on MMP9 production, hIPSC derived astrocytes were treated with apigenin or 1-10-phenantroline. The treatment induced a decrease in MMPs activity evaluated by gel zymography. Taken together these results offer new methodologies to study parasite interactions and its effects in human neural cells and suggest mechanistic links between neuroinflammation and *T. gondii* infection.

Title: What happened to the *in vitro* blood-brain barrier (BBB) model with activated microglia in the brain side-activated microglia can trigger the BBB disruption and modulate the related chemokines and cytokines via the interactions with astrocytes and blood vessels

Authors: *K. SATO[1], K. HOSHIKAWA[2], Y. SHIGEMOTO-MOGAMI[1];
[1]Lab. Neuropharmacol, Div. Pharmacol, [2]Lab. Neuropharmacol, Div. Pharmacol, Natl. Inst. Hlth. Sci., Kanagawa, Japan

Abstract: BBB disruption is associated with the various brain disorders with neuroinflammation. Although microglial activation and the subsequent changes in cytokines/chemokines (C/Cs) have already been reported to be important for the development of neuroinflammation, little data are available concerning whether it is cause or consequence. In this study, we investigated the interaction of activated microglia (LPS-MG) with BBB using in vitro BBB model composed of endothelial cells (EC), pericytes (Peri), and astrocytes (Ast). When we added LPS-MG to the abluminal side of the model, BBB functions were severely lowered as revealed by decreases in the trans-endothelial electrical resistance (TEER) and in the expression levels of tight junction (TJ) proteins. We also confirmed that the cell surface localizations of TJ proteins were

disappeared immunocytochemically. Furthermore, 19 C/Cs were markedly increased in the abluminal side. Unexpectedly, although LPS-MG alone released 10 of the 19 C/Cs, their real concentrations were rather lower compared with the C/C changes in the abluminal side of with LPS-MG. Co-culture of LPS-MG with Ast caused remarkable increases in 12 of the 19 C/Cs, while co-culture of LPS-MG with EC and Peri also resulted in a significant increase in fractalkine. These results suggest that activated microglia can trigger BBB disruption and also modulate the related C/Cs via the interactions with astrocytes and blood vessels.

Title: Apabetalone epigenetically inhibits monocyte adhesion to brain endothelial cells by downregulating key neuroinflammation markers *in vitro* and *in vivo*

Authors: *S. WASIAK[1], E. DAZE[1], L. M. TSUJIKAWA[1], S. DAS[1], L. FU[1], D. GILHAM[1], B. D. RAKAI[1], S. C. STOTZ[1], C. D. SARSONS[1], D. STUDER[2], K. D. RINKER[2], R. JAHAGIRDAR[1], N. C. W. WONG[1], M. SWEENEY[3], J. O. JOHANSSON[3], E. KULIKOWSKI[1]; [1]Resverlogix Corp., Calgary, AB, Canada; [2]Univ. of Calgary, Calgary, AB, Canada; [3]Resverlogix Inc., Calgary, AB, Canada

Abstract: Objectives and Rationale: Leukocyte infiltration across the blood brain barrier (BBB) contributes to the initiation and exacerbation of neuroinflammation, leading to neuronal injury. Cytokine-driven activation of endothelial cells enables monocyte binding to BBB. Thus, inhibiting this process is an attractive therapeutic approach. Epigenetic modulation of gene expression contributes to vascular inflammation. Here we evaluate anti-inflammatory properties of the clinical stage small molecule apabetalone that inhibits bromodomain and extraterminal domain (BET) proteins on models of brain inflammation. Methods: THP-1 monocyte transcriptional responses to TNF alpha with or without apabetalone were examined. Human brain microvascular endothelial cells (HBMVECs) stimulated with TNF alpha and IFN gamma with or without apabetalone were assayed for gene expression, cytokine secretion, surface adhesion protein level, and THP-1 adhesion under flow conditions. *In vivo* neuroinflammation was assessed in C57BL/6 male mice pretreated with 150 mg/kg apabetalone for 7 days and then injected with 10 mg lipopolysaccharide (LPS) intraperitoneally. Brain mRNA was analyzed 24h post LPS injection. Results: Apabetalone suppressed the expression of THP-1 genes induced by

TNF alpha, including IL-1 beta, chemokine MCP-1, chemokine receptors CCR1 and CCR2 and adhesion molecule VLA-4 (ranging from 40% to 90% reduction). In cytokine stimulated HBMVECs, apabetalone reduced the mRNA induction of vascular activation markers IL-6, MCP-1, VCAM-1, and E-selectin (55% to 97% reduction). Surface expression of adhesion proteins VCAM-1 and E-selectin as well as secretion of IL-6 and MCP-1 were also reduced. Consequently, apabetalone countered THP-1 adhesion to HBMVECs in laminar flow assays. In mice, apabetalone attenuated the LPS-induced brain mRNA expression of inflammation markers including E-selectin, ICAM, CCR2, and CD68. Conclusions: Apabetalone decreased neuroendothelium's activation and interactions with monocytes, potentially reducing immune cell transmigration in neuroinflammatory conditions. Apabetalone's effect on cognition in in diabetes patients following acute coronary syndrome older than 70 years is being evaluated by repeat MoCAs in the phase 3 BETonMACE trial (Q2 2019).

Abstract: Inflammation is a hallmark of neurodegenerative disease and a significant component of the pathology of Alzheimer’s disease (AD). Patients present with extensive microgliosis along with elevated pro-inflammatory signaling in the central nervous system. Animal models of AD recapitulate these findings and neuroinflammation is now a potentially important target for therapeutic intervention. Peripheral immune cell entry into the CNS and the extensive neuro-immune talk between the periphery and the CNS are increasingly recognized as important modulators of neurodegeneration. However, the specific role of peripheral myeloid cells in mediating and influencing AD pathogenesis remains unresolved. Our study describes specific peripheral immune cell alterations during disease progression including immune cell populations, phenotypes, and gene expression profiles. Patients were evaluated for disease severity using Clinical Dementia Rating (CDR) and peripheral myeloid cells were isolated from peripheral blood of patients with prodromal AD (CDR0.5, n = 44), mild AD dementia (CDR1, n = 25), moderate/severe AD dementia (CDR2/3, n = 28), and age-matched controls (n = 54). During stages of AD dementia (CDR1 and 2/3) peripheral myeloid cells increase their pro-inflammatory gene expression while at early stages of disease (prodromal AD—CDR0.5) pro-inflammatory gene expression is decreased. Suppressive myeloid-derived suppressor cells

(MDSCs) are increased in number and function in prodromal AD compared to controls but lose their numbers and suppressive function as patients progress to AD dementia. This loss of suppression in late stages of AD provides a therapeutic opportunity whereby immunomodulation via anti-inflammatory cell-based therapies could ameliorate the pro-inflammatory phenotype of immune cells. We have initiated studies to determine whether macrophages differentiated to an anti-inflammatory (M2) phenotype could restore the impaired suppressive function. Prolonging the early protective suppression while also reversing the later loss of suppressive activity may offer a beneficial therapeutic strategy for halting the progression of disease.

Title: Remyelination of regenerating CNS axons: The optic nerve model

Authors: *S. DE LIMA[1], N. M. S. PORTS[2], N. P. BISCOLA[3], N. ZHANG[3], L. A. HAVTON[4], P. A. ROSENBERG[5], L. BENOWITZ[1];
[1]Neurosurg. and Neurobilology, Boston Childrens Hosp. - Harvard Med. Sch., Boston, MA; [2]Inst. of Biomed. Sci., USP, Sao Paulo, Brazil; [3]Neurol., [4]Dept. of Neurol., UCLA, Los Angeles, CA; [5]Neurol., Boston Children's Hosp., Boston, MA

Abstract: Several recent studies have achieved appreciable optic nerve regeneration by activating the growth potential of mature retinal ganglion cells (RGCs). Our lab reported that, with appropriate stimulation, some RGCs can extend axons from the eye to appropriate central target areas (de Lima et al., PNAS, 2012), and that some regenerating axons become myelinated and re-establish the electrically excitable domains that are important for action potential generation and propagation (Marin, de Lima et al., J. Neurosci, 2016). However, the re-formation of electrically excitable domains accompanying myelination progresses much more slowly than axon regeneration. Relatively few studies have addressed the problem of myelination of regenerating axons, which is critical for functional recovery. To gain insight into the possible

causes of its impairment, we have addressed the following questions: (1) how early does myelination begin after the onset of regeneration?; (2) Is myelination related to the size of regenerating axons?; and (3) is there a change in oligodendrocyte population dynamics after nerve injury and during regeneration? We induced regeneration in these studies by combining *pten* deletion in RGCs with the growth factor oncomodulin + cAMP elevation. Using pre-embedding immunogold labeling, we detected myelin wrapping regenerating axons (GAP-43+; CTB+) close to the injury site 2 - 4 weeks post-injury. However, whereas myelination starts when axons reach a diameter ≥ 300 nm during development, there was no clear relationship between axon diameter and myelination during regeneration. Surprisingly, we found a substantial increase in the number of oligodendroglia (olig2+ cells) along the regenerating optic nerve 3 weeks after injury and the onset of regeneration. For example, at 2.5 mm distal to the injury site, whereas in normal optic nerves we found 1927 +/- 131 olig2+ cells/mm2, in cases with optic nerve injury only we found 10% more cells 3 weeks after nerve injury (n.s; n = 4), while in cases with the pro-regenerative treatment we found an increase of 37% (p = 0.001; n = 9). Only 5-10% of these cells were preoligodendrocytes (PDGFRα+), whereas the vast majority were mature oligodendrocytes (CC1+). Thus, myelin wrapping starts shortly after the onset of axon regeneration close to the site of injury and oligodendrocyte population dynamics does not seem to be limiting in this region. However, myelination in regenerating axons does not seem to have the same dependence on axon diameter as during development, and nodal formation is delayed. These results suggest the possibility of a deficit in signaling between regenerating axons and axons in the setting of regeneration.

Title: Cerebrospinal fluid neopterin as a marker for central nervous system inflammation in sudden infant death syndrome (SIDS)

Authors: *M. RIEHS[1], H. HARB[2], B. W. OKATY[4], E. HAAS[5], B. PAUNOVIC[6], K. HYLAND[7], M. GORMAN[3], G. T. BERRY[8], R. D. GOLDSTEIN[9], R. L. [8]Div. of Genet. and Genomics, [9]Dept. of Pediatrics, Boston Children's Hospital, Harvard Med. Sch., Boston, MA

Abstract: The sudden infant death syndrome (SIDS) is the sudden death of an infant under 12 months of age that remains unexplained after a complete autopsy and death scene investigation. SIDS is likely multifactorial with the pathogenesis related to varying biological vulnerabilities, risk factors, and stressors or triggers of sudden death. Risk associations in SIDS have been linked to infection, with a subpopulation of SIDS infants having a history of acute illness preceding death. To test the hypothesis that SIDS involves central nervous system inflammation, we analyzed the levels of neopterin and the cytokine interferon-gamma (INF-γ) in the cerebrospinal fluid (CSF) of 66 SIDS infants and 15 non-SIDS controls dying of acute causes. Neopterin is produced by monocytes and macrophages upon stimulation with INF-γ and is considered a specific marker for central nervous system inflammation. There was no overall statistical difference in SIDS and controls in neopterin [SIDS, 55.9 +/- 67 nmol/L; controls, 45.0 +/- 31.4 nmol/L] or INF-γ [SIDS, 13.8 +/- 25 pg/mL; controls, 10.6 +/- 9.4 pg/mL]. There were, however, 7 SIDS cases with neopterin levels greater than 2 standard deviations above the mean of the controls (>107 nmol/L), levels considered as clinically significant for CNS inflammation. In controls cases, neopterin and INF-γ levels correlated suggesting an appropriate immune response to INF-γ. However, SIDS cases with high levels of neopterin generally had INF-γ levels within the control range, a finding that suggests an inappropriate or heightened immune response of these SIDS cases to an immunological trigger. Given the role of microglial response in immune activation within the brain, we are beginning to examine microglial phenotypes in SIDS using droplet-based single nuclei RNA sequencing. Preliminary data show differing expression patterns of microglial genes, including genes related to microglial activation and function. The CSF data support the hypothesis that a subpopulation of SIDS cases have a significant immune system response. Preliminary sequencing data support the potential role of microglia in this response.

Title: IL-2 enhances IFNγ signals in subpopulations of T lymphocytes from treatment naïve relapsing remitting multiple sclerosis (RRMS) patients

Authors: *B. J. POPE[1], V. SHARMA[2], C. RAMAN[3], S. BRIDGES[4], W. MEADOR[5];
[1]Med. Scientist Training Program, Univ. of Alabama At Birmingham, Birmingham, AL; [2]Grad. Biomed. Sci., Univ. of Alabama at Birmingham, Birmingham, AL; [3]Div. of Clin. Immunol. and Rheumatology, Univ. of Alabama at Birmingham Sch. of Med., Birmingham, AL; [4]Dept. of Clin. Immunol. and Rheumatology, Univ. of Alabama Sch. of Med., Birmingham, AL; [5]Dept. of Neurol., Univ. of Alabama Sch. of Med., Birmingham, AL

Abstract: BACKGROUND: Multiple sclerosis (MS) is a common, CNS demyelinating disorder and more than 85% of patients have a relapsing form of MS (RMS). Dysregulated lymphocytes within the adaptive immune system contribute to disease progression and severity in MS. IFNγ producing myelin-specific T lymphocytes correlate with functional impairment in MS (J. Neuroimmunol.141(1-2):132-140) and IFNγ administered to patients with RRMS worsens the disease. Regulatory T cells require interleukin-2 for lineage function and maintenance but this role in RMS has been underexplored.
OBJECTIVES: We tested the possibility that IL-2 would dampen IFNγ induced STAT activation in subpopulations of effector and regulatory T cells in a disease specific context. We sought to elucidate how IL-2 can alter IFNγ signaling in RMS to broaden our understanding of how these soluble mediators of disease resolution and inflammation act synergistically in the context of autoimmunity.
METHODS: We stimulated PBMC from treatment naïve RMS patients with IFNγ and/or IL-2. Using a multi-dimensional phospho-flow approach we evaluated the activation of STAT1, STAT3, and STAT5 in each subpopulation of T cells. PBMC from patients with rheumatoid arthritis (RA) was used as disease control. The data was analyzed using t-SNE and SPADE visualization tools to interrogate changes in the activation and proportion of these cell populations.
RESULTS: We found IFNγ stimulation broadly induced greater activation of STAT1 in MS than in RA within multiple lymphocyte populations. IL-2 co-stimulation in a subset of RMS patients further increased IFN-γ induced activation of STAT1 in multiple T cell populations and Treg cells. IL-2 induced activation of STAT5 was not altered by IFN-γ co-stimulation.
CONCLUSIONS: Our results suggest that in some MS patients, IL-2 will promote autoimmune neuroinflammation through activation of the IFNγ-STAT1 signaling axis in CD4 and CD8 T cell populations. This is in contrast to the role of IL-2 as a regulatory cytokine in inflammation/autoimmunity through attenuation of effector Th1 and Th17 cells and promotion of Treg cell activity. Low dose IL-2 is being explored as a therapy for autoimmune diseases, and our results indicate that in some MS patients, such treatment may exacerbate disease.

Title: EP2 antagonism blocks monocyte brain recruitment after status epilepticus

Authors: *N. H. VARVEL[1], A. HSIEH[1], T. GANESH[2], R. J. DINGLEDINE[3];
[2]Pharmacol., [1]Emory Univ., Atlanta, GA; [3]Dept Pharmacol, Emory Univ. Sch. Med., Atlanta, GA

Abstract: Status epilepticus (SE) is a life-threatening medical emergency that triggers a succession of molecular and cellular events involving selective neuronal cell loss, blood brain barrier (BBB) leakage, activation of brain-resident microglia, recruitment of inflammatory blood-borne monocytes, and engagement of neuroinflammatory prostanoid signaling. Our group has identified brain-invading blood-borne monocytes and, independently, activation of prostaglandin receptor EP2 as a driver of SE-induced neuroinflammation and neuronal damage, contributing to mortality and neurobehavioral deficits. Blocking monocyte brain recruitment, via *Ccr2* knockout, or systemic EP2 antagonism, via a small-molecule, enhances weight regain and relieves multiple consequences of SE including erosion of the BBB, neuronal damage, andneuroinflammation, confirming that inflammatory pathways drive some of the deleterious consequences of pilocarpine-induced SE. Notably, EP2 antagonism after kainate-induced SE also enhances weight regain, quenches hippocampal inflammation, prevents deterioration of the BBB, provides neuroprotection, and, interestingly, nearly abolishes monocyte brain recruitment into the brain. Taken together these findings suggest that the beneficial consequences of EP2 antagonism are model-independent and might be attributed, in part, to inhibiting brain monocyte infiltration after SE.

Title: The role of mitochondria associate er membranes in the specific subcellular localization of inflammatory responsive microRNAs in the mammalian brain

Authors: *W.-X. WANG[1], P. PRAJAPATI[2], P. T. NELSON[3], J. E. SPRINGER[4];
[1]Univ. Kentucky, Lexington, KY; [3]Sanders-Brown Ctr. on Aging, [2]Univ. of Kentucky, Lexington, KY; [4]Spinal Cord and Brain Injury Res. Ctr., Univ. Kentucky Sch. Med., Lexington, KY

Abstract: Mitochondria associated ER membranes (MAMs) are specific ER domains that are attached to mitochondria. MAMs play a critical role in the communication between ER and mitochondria, facilitating processes such as lipid synthesis and exchange, calcium transport and homeostasis, and mitochondria dynamics. MAMs also play an important role in the formation of the autophagosome and inflammasome. Disruption of mitochondria and ER contact is associated with a variety of pathophysiological conditions and human diseases including inflammation, metabolic diseases, cancers, traumatic brain injury (TBI), and neurodegenerative diseases, such as Alzheimer's disease and Parkinson's disease. Our new findings from human and rat brains indicate that the MAM is a subcellular site enriched for specific microRNAs (miRNAs). MiRNAs are an important class of regulators that mediate gene expression post-transcriptionally. We performed subcellular fractionation from human and rodent cerebral cortex and analyzed miRNA expression in purified MAM, mitochondria, ER, and cytosol fractions. The human brains were short-postmortem samples collected from research subjects of the University of Kentucky Alzheimer's Disease Center autopsy cohort. RT-qPCR analysis revealed that MAM contains a substantial number of miRNAs and enriched for several inflammatory miRNAs including miR-146a, miR-142-3p, and miR-142-5p; enrichment of miR-223 was only observed in human brains. Previously, we showed that these same inflammatory responsive miRNAs are highly associated with mitochondria fractions isolated from rat hippocampus and translocate to cytoplasm following TBI. Here we report that, events that compromise mitochondrial function, such as mitochondria uncoupling and TBI, result in MAM to ER translocation of these inflammatory miRNAs and down-regulation of miRNA-targeted genes involved in inflammatory signaling. These findings shed new light on the role of MAMs and suggest the shuttling of

cellular miRNAs as a potentially novel gene expression regulatory paradigm relevant to neuroinflammation in TBI and neurodegenerative diseases.

Title: L-DOPA-induced dyskinesia in mice leads to the production of astrocyte-derived TNF-alpha through a glutamate-dependent mechanism

Authors: *M. DOS SANTOS PEREIRA[1], G. DIAS DE ABREU[1], J. ROCCA[2], S. HAMADAT[3], R. RAISMAN-VOZARI[3], P. MICHEL[3], E. DEL BEL[1];
[1]Univ. De São Paulo, Ribeirão Preto, Brazil; [2]Inst. du Cerveau et de la Moelle Épinière, Paris, French Guiana; [3]Inst. du Cerveau et de la Moelle Épinière, Paris, France

Abstract: Here we addressed the hypothesis that L-DOPA-induced dyskinesia (LID) could be favored by the striatal pro-inflammatory environment resulting from abnormal glutamate (GLU) release from the motor cortex induced by L-DOPA dyskinesiogenic treatment. To this aim, we used 6-OHDA-lesioned C57BL/6 dyskinetic mice (L-DOPA 25 mg/kg + benserazide 10 mg/kg i.p. for 21 days) to quantify striatal inflammatory markers. LID development was accompanied by GFAP (astrocyte) and IBA-1 (microglia) activation and by an elevation of TNF-α, IL-1β and IL-6 in in the denervated dorsal striatum. Interestingly, the anti-dyskinetic treatment with cannabidiol (CBD) and capsazepine (CPZ) (30 mg/kg, 5 mg/kg, i.p.) partially reduced TNF-α production in L-DOPA-treated mice while having no effect on IL-1β and IL-6 levels. Using purified microglial cells and astrocytes in culture, we tested the possible role of L-DOPA/DA and GLU in the induction of neuroinflammatory events in LID. While L-DOPA or DA failed to induce a pro-inflammatory response in both types of glial cells, GLU increased the expression of the astrocytic marker GFAP and the production of TNF-α by astrocytes. GLU failed, however, to stimulate cytokine production in pure microglial cell cultures. A treatment combining cannabidiol (CBD) and TRPV1 antagonist capsazepine (CPZ; dos Santos Pereira et al., 2016) abolished the increase of GFAP expression and TNF-α production triggered by GLU in astrocyte cultures. By using purified cortical neurons in culture, we also demonstrated that a chronic treatment with TNF-α (50 ng/ml) was able to stimulate GLU release. Interestingly, this effect

was blocked by a pretreatment with CPZ+CBD (0.1 µM). Overall, we conclude that TNF-α produced by GLU-activated astrocytes might have a crucial role in promoting inflammatory-type reactions in the dyskinetic striatum and this event may occur through a vicious circle mechanism.

Title: The involvement of NG2 expressing cells in methamphetamine induced neurotoxicity and neuroprotective role of melatonin in rat brain

Authors: *Z. M. HEIN, N. KRAIWATTANAPIROM, B. CHETSAWANG;
Res. Ctr. for Neurosci., Inst. of Mol. Biosciences, Mahidol Univ., Nakhon Pathom, Thailand

Abstract: Among the residential cells in the brain, Neuron-Glial2 (NG2) expressing cells are described as the new member of the glial cells and are evenly distributed in both white and grey matter of the brain. Previously they had been assumed as oligodendrocyte precursor cells (OPCs) and they can present into oligodendrocytes and promote myelination of axons in demyelination diseases. Moreover, NG2 cells become activated in pathological conditions and they may have other functions than OPCs which have not been elucidated yet. Therefore, the aims of this study are to investigate the possible involvement of NG2 cells under methamphetamine (METH)-induced neurotoxicity in rat. In addition, the neuroprotective capacity of melatonin against this neurotoxicity was also investigated. The results showed that the levels of NG2 expression in rat brain gradually increase from postnatal day 0 to postnatal day 8 and then the lower levels of NG2 expression is shown in adults when compared with postnatal period. However, in adult rats, the levels of NG2 and COX-2 expression in brain was significantly increased in lipopolysaccharide-treated when compared to control-untreated rats. Taken together, intra-peritoneal injection of 5 mg/kg METH for 7 days significantly increased the levels of NG2 expression in brain when compared to control-untreated rats. Pretreatment of 10 mg/kg melatonin prior to treat with METH was able to reduce an increase in the levels of NG2 expression. Thus, these findings would extend the current knowledge of NG2 expressing cells in adult brain during pathological condition such as neuroinflammation.

Title: The effects of nadph oxidase inhibitor, diapocynin, treatment in diisopropylfluorophosphate (DFP)- induced long-term neurotoxicity

Authors: *M. PUTRA[1], M. GAGE[1], G. GASSER[2], S. SHARMA[1], V. ANANTHARAM[2], T. THIPPESWAMY[1];
[1]Biomed. Sci., Iowa State Univ., Ames, IA; [2]PK Biosci., Ames, IA

Abstract: Organophosphate (OP) compounds are among the most catastrophic threats to the military and civilian population. Upon exposure of OP, cholinergic crisis and *status epilepticus* arise as a result of irreversible inhibition of acetylcholinesterase that can be life-threatening if left untreated. As for OP survivors, long-term morbidity develops over time which includes progressive neurodegeneration and neuroinflammation and delayed cognitive impairment. Currently available medical countermeasures (atropine, oxime, and diazepam) fail to rescue these pathologies. Therefore, many efforts are directed to target neuroinflammation and oxidative stressors. This study examined the antioxidant properties of diapocynin (DPO), an oxidative metabolite of apocynin, in the rat diisopropylfluorophosphate (DFP) model. Adult Sprague-Dawley rats were intoxicated with DFP (4mg/kg, sc), treated with atropine sulfate and pralidoxime, and two hours later SE was terminated with diazepam. Further two hours later, DPO (300mg/kg) or 10% ethanol was administered orally, twice daily for the first three days. Neurobehavioral tests, electroencephalographic profile, immunohistochemistry, Western blots, multiplex assays were performed to evaluate the effects of DPO. DPO significantly improved DFP-induced motor impairment. Electrographically, there was no difference in epileptiform spike rate between the vehicle and DPO groups. Although DFP-induced reactive microgliosis was not significantly suppressed by DPO, several pro-inflammatory cytokines and chemokines such as IL-1α, IL-2, IL-17A, Leptin, IP-10 were significantly reduced in the hippocampus. Importantly, DPO significantly attenuated the DFP-induced neurodegeneration in the hippocampus and piriform cortex. However, DPO did not reduce DFP-induced nitro-oxidative stress markers such as iNOS, 3-NT, and 4HNE. Collectively, these data support the neuroprotective effects of DPO, possibly by dampening the upregulation of proinflammatory cytokines, in the rat model of DFP-induced neurotoxicity.

Title: Enriched environment housing protects the visual pathway alterations against experimental glaucoma in adult rats

Authors: ***M. GONZÁLEZ FLEITAS**, J. DEVOUASSOUX, M. L. ARANDA, H. DIEGUEZ, D. DORFMAN, S. CALANNI, M. CHIANELLI, R. E. ROSENSTEIN;
Sch. of Medicine, Univ. of Buenos Aires, Buenos Aires, Argentina

Abstract: Glaucoma is a leading cause of blindness, characterized by retinal ganglion cell (RGC) loss and optic nerve (ON) damage. Increased intraocular pressure (IOP) is the most accepted risk factor for glaucomatous neuropathy, however many patients with successful IOP control continue to lose vision. Enriched environment (EE) consists of a manipulation in which animals are exposed to complex conditions through adaptations in the physical and social environment. Since it has been shown that EE provides a better recovery from different neuropathologies, the aim of this work was to analyze whether the exposure to EE is able to prevent glaucomatous damage. Adult male Wistar rats received 30% of chondroitin sulfate in the anterior chamber of one eye and vehicle in the contralateral eye, once a week, and were housed in standard environment (SE) or EE for 10 weeks. Animals were subjected to functional (electroretinogram and flash visual evoked potentials (VEPs)), and histological analysis. EE housing which did not affect IOP, prevented the decrease in VEPs and oscillatory potential amplitude, as well as the RGC loss (assessed by Brn3a-immunoreactivity). The axon number (assessed by toluidine blue staining) was also preserved by the exposure to EE. Moreover, EE housing prevented the decrease in the immunoreactivity for myelin basic protein (MBP) and luxol fast blue staining in the ON, as well as the increase in Iba1 (a microglia/macrophage marker) positive area in the retina and ON. These results suggest that the EE housing, a non-invasive strategy, protects the visual pathway against retina and optic nerve damage induced by experimental glaucoma. Although care must be taken when extrapolating data obtained in experimental models to humans, the protective effect of EE could reflect a scenario in which a physically and mentally active lifestyle promotes the visual pathway resiliency to damage induced by glaucoma.

Title: Transcriptomic changes associated with neuroinflammation in a mouse model for cLINCL: Role of microglia

Authors: ***M. S. DOMOWICZ**[1], W.-C. CHAN[2], C. B. WARE[1], J. ANDRADE[2], N. B. SCHWARTZ[1];
[1]Pediatrics, [2]Ctr. for Res. Informatics, The Univ. of Chicago, Chicago, IL

Abstract: Neuronal Ceroid Lipofuscinoses (NCLs), are a group of inherited, early onset, fatal neurodegenerative diseases associated with mutations in 13 genes and characterized by lysosomal accumulation of fluorescent storage material. Using a well characterized mouse model of classical late infantile NCL (cLINCL), in which the tripeptidyl peptidase 1 (*Tpp1*) gene is disrupted by gene targeting resulting in loss of detectable TPP1 activity, we have analyzed the progression of the neurodegenerative process by global RNA-sequencing at different ages (2, 3 and 4 months) in forebrain/midbrain and cerebellum (n=3). Our data indicate that a progressive neurodegenerative-inflammatory response involving microglia, astrocytes and endothelial cell are taking place, accompanied by activation of leukocyte extravasation signals and upregulation of NO and ROS production. Several astrocytic (i.e., *Gfap, C4b, Osmr, Serpina3n*) and microglial (i.e., *Ctss, Itgb2, Itgax, Lyz2*) genes were identified as good markers for assessing disease progression as they showed increased expression levels *in vivo* over time. Based on these gene expression changes we concluded that neuroinflammation starts, for the most part, after 2 months in the *Tpp1*$^{-/-}$ brain and that activation of microglia and astrocytes occur more rapidly in cerebellum than in the rest of the brain; confirming increased severity in this region. As in other neurodegenerative diseases, upregulation of *Csf1* and Csf1 receptor, possibly associated with astrocytic and microglial sources, respectively, were observed in *Tpp1*$^{-/-}$ cerebellum. Thus, we analyzed how the treatment with an inhibitor of Csf1 receptor, PLX5622, which have been reported to eliminate microglia *in vivo*, affected disease progression. Two-week treatment of 3-month old *Tpp1*$^{-/-}$ animals with PLX5622 in their diet, downregulated expression of microglial genes, but markedly upregulated expression of astrogliosis markers like Aquaporin 4 and *Gfap*. Furthermore, long term exposure to PLX5622 accelerated lethality in *Tpp1*$^{-/-}$ mice. This increase

in astrogliosis indicates that microglia play a protective role during the neuroinflammation process in *Tpp1*$^{-/-}$ mice and that microglia-astrocyte communication is essential in controlling the progression of the neurodegenerative process.

Title: Bacterial pneumonia elicits structural damage to neurons

Authors: *M. T. LIN[1], A. C. JAGER[1], M. GREENE[1], A. ANDREW-FORTUNE[2], A. M. SCOTT[1];
[1]Univ. of South Alabama, Mobile, AL; [2]Dillard Univ., New Orleans, LA

Abstract: Patients who develop pneumonia are at increased risk of cognitive decline. The risk may linger for more than a year even after the patients have fully recovered from pneumonia. While the mechanisms underlying bacterial pneumonia initiated cognitive dysfunction remain elusive, our recent studies show that *Pseudomonas aeruginosa,* an opportunistic bacterium that causes nosocomial pneumonia, induces cytotoxic amyloid production and release from pulmonary endothelial cells. Lung infection with this bacterium results in detectable amyloids in the blood, even in the absence of bacteremia. When injected into the cerebral ventricle, the endothelial derived amyloids impair mouse performance in hippocampal-dependent tasks. In this study, we determined the neurotoxic effects of endothelial derived amyloids on hippocampal CA1 pyramidal neurons. We performed stereotaxic intracerebral ventricular, intratracheal, and intraperitoneal injections of endothelial amyloids and quantified dendritic spine morphologies using Golgi staining. Our results showed that endothelial derived amyloid neurotoxicity is dependent upon the *P. aeruginosa's* virulence factor PcrV. Intracerebral ventricular injection and intratracheal instillation reduced spine density, and spine density reduction was greater in apical dendrites, compared to basal dendrites, in a time-dependent manner. Thus, in patients who contract bacterial pneumonia, lung infection may elicit endothelial amyloids that are capable of neurocognitive impairment.

Title: Expression profiles of noncoding RNAs in the CSF of PPMS and RRMS patients

Authors: *A. IACOANGELI, N. FAVRET, C. ARNDTSEN, S. A. SADIQ;
Tisch MS Res. Ctr. of New York, New York, NY

Abstract: Studies of the expression profiles of noncoding RNAs (ncRNAs) have been of diagnostic and prognostic value in several diseases. Multiple sclerosis (MS) is an inflammatory neurodegenerative disease and the two main clinical manifestations are primary progressive MS (PPMS) and relapsing remitting MS (RRMS). Interestingly, there is no single molecular test for the diagnosis of PPMS and RRMS. Our aim was to identify molecular markers for PPMS and RRMS patients by analyzing the expression of ncRNAs in cerebrospinal fluid (CSF) samples of these patients. We performed an exploratory differential strand-specific RNA sequencing analysis of small and long ncRNA. Total RNA was isolated from CSF samples of (n=4) PPMS patients, (n=4) RRMS patients, and (n=4) healthy donors. Using the DEseq2 package, statistically significant expression levels were determined as ncRNAs with an adjusted p-value of less than 0.1 and a log2fold change greater than 1. Gene ontology and splice variant expression analyses were performed on the statistically significant ncRNAs. The RNA sequencing analysis of CSF samples identified 78 ncRNAs that were differentially expressed in PPMS patients in comparison to RRMS patients. A bioinformatic analysis reported that the expression levels of 7 ncRNAs were significantly different. Notably, noncoding vault RNAs — vtRNA 1-1 and vtRNA 3-1P — were upregulated in CSF samples of PPMS patients. The vtRNAs are an integral part of the vault complex, a large ribonucleoprotein complex. Although their functions are still obscure, recent studies have shown their involvement with multidrug resistances and autophagy modulation. In conclusion, these results highlight the expression profiles of 7 newly identified ncRNAs as potential molecular markers for the diagnosis of PPMS and RRMS. Further investigations will also elucidate the functional meaning of the unique expression levels of vtRNA 1-1 and vtRNA 3-1P in PPMS and RRMS, two very diverse clinical manifestations of multiple sclerosis.

Title: Obesity impairs cognition and leads to morphological and neurogenic alterations

Authors: C. FERNANDES[1], L. FORNY-GERMANO[1], S. FERREIRA[1], J. JÚNIOR[2], F. DE FELICE[1];
[1]Federal Univ. of Rio de Janeiro, Rio de Janeiro, Brazil; [2]São Paulo Univ., São Paulo, Brazil

Abstract: Overweight and obesity are public health problems that affect 30% of the world's population. It is known that this accumulation of body mass causes increased blood pressure, insulin resistance, diabetes, among other comorbidities. But overweight also affects the nervous system which increases the propensity to develop neurodegenerative diseases. However, it is not clear yet how and when such changes occur. We used, as an obesity model C57/Bl6 transgenic ob/ob mice, and C57/Bl6 wild type as a control. Magnetic resonance imaging (MRI) was initially performed for in vivo brain volume analysis, from which was possible to measure a 10% decrease in the total brain volume of the obese when compared to controls. To investigate if mass loss impairs cognition, we performed an object recognition test. Ob/ob mice exhibit low learning performance and locomotion. Therefore, we evaluate markers of neurogenesis and cell proliferation. A 50% decrease in neuroblast-labeled cells (doublecortin), as well as cell cycle markers (ki-67 and BrdU), were seen in the hippocampus and lateral ventricle regions of ob/ob. Then, we check microglia and astrocytes in the hippocampus region. The ob/ob animals showed not only an increase in the number of microglial cells but a severe modification in their structure. Increased microglial activation and a greater number of amoeboid cells were observed. Astrocytic cells also presented increased numbers in obese. Our data suggest that obesity may impair cognitive function and bring early neurodegeneration in mice.

Title: Serine racemase expression in hippocampal neurons and astrocytes is modified in aging and by inflammation

Authors: *S. BELTRAN-CASTILLO, M. TRIOLO, R. VON BERNHARDI;
Neurol., Pontificia Univ. Católica de Chile, Santiago, Chile

Abstract: Neuroinflammation is frequently observed during aging and in neurodegenerative diseases. Our "glia-dysregulation" hypothesis proposes that aging results in the impairment of glial cell regulation leading to neuroinflammation and a neurotoxic environment, which in turn could result in neurodegenerative diseases as the late-onset Alzheimer disease (LOAD). D-serine is a dextro amino acid synthesized in mammals' brain by serine racemase (SR). It acts as a co-agonist of the glutamate N-methyl-D-aspartate receptor (NMDAR). Whereas D-serine can facilitate memory formation through NMDA-mediate long-term potentiation (LTP), it can also facilitate glutamate-induced excitotoxicity, leading to synaptic impairment and neurodegeneration. Here, we assessed the expression and distribution of SR in the hippocampus in aging and during systemic inflammation. We induced systemic inflammation administering a single i.p. injection of LPS (0.5 mg kg-1), or vehicle (PBS) in juvenile, adult and old mice (3-, 12- or 20-month old C57/BL6/j mice, respectively). After 24 h, mice were perfused with Hank's buffer for obtaining brain lysates, or with PBS and fixative (4% PAF) for obtaining 20 µm brain cryosections. SR content in the brain lysates was measured by western blot, and its expression in the hippocampus was evaluated by immunofluorescence, together with NeuN and GFAP immunolabeling for neurons and astrocytes identification, respectively. We observed an increased expression of SR in brain lysates in aging, reaching a 1.5- to 2.0-fold the level observed in juvenile mice at 12- and 20-month-old mice, respectively. SR expression increase was conspicuously associated with NeuN labeling in the stratum pyramidale of CA3 in 12- and 20-month old mice. Systemic inflammation induced a substantial increase in SR content in brain lysates from juvenile and adults' mice, although the already high content of SR in old mice was not further increased. Increased SR content after LPS was mainly associate to GFAP positive astrocytes at all ages. Our data reveal an aging- and neuroinflammation-associated increase of SR in the brain, which could facilitate D-serine- and glutamate-induced excitotoxicity, impairment of synaptic plasticity, neurodegeneration, and thus, be part of LOAD pathogenesis.

Title: The effect of chronic neuroinflammation on the kinetics of Dextran clearance from the brain parenchyma

Authors: *S. SURESH, J. LARSON, K. JENROW;
Central Michigan Univ., Mount Pleasant, MI

Abstract: Clearance of macromolecular waste from the brain parenchyma is achieved by a complex circulation of cerebral spinal fluid (CSF) within perivascular spaces, facilitating the diffusion of these ‘waste’ products through interstitial space and their transit to the cervical lymphatics where they are ultimately deposited into the serum.To investigate the influence of chronic neuroinflammation in this context, we induced a persistent inflammatory condition in the rat brain using a single high-dose administration of lipopolysaccharide (LPS, 5 mg/kg, i.p.). At eight weeks post-induction we measured the distribution kinetics of macromolecular florescent tracers following their injection into the subarachnoid CSF in healthy and chronically-inflamed rat brains. Two fluorescently-labeled dextran tracers, (3 and 10 kilodaltons, respectively), dissolved in a single 10 µl volume of artificial CSF, were infused directly into subarachnoid space via the cisterna magna and subsequently assayed in both parenchyma and serum at 15-, 30-, and 45-minutess post-infusion. From the subarachnoid space (Compartment 1), these dextran can be taken up directly into the dural/cervical lymphatics and deposited in the serum (Compartment 5). Alternatively, they can penetrate the brain by convection within perivascular space (Compartment 2) and diffuse within the parenchyma (Compartment 3). Clearance of these tracers from the parenchyma involves diffusion back into perivascular space (Compartment 4) and convective transport to the cervical lymphatics and removal to the serum. Our data show that the distribution kinetics of these dextran tracers is significantly impacted by neuroinflammation, and also by the size of the dextran. Here we have modeled these distribution kinetics using compartmental analysis. Our results reveal that the critical rate constant impacted by neuroinflammation involves the convective transport of tracer out of the parenchyma.

Title: Using patient iPSC derived motor neurons as a model for leukoencephalopathy with brainstem and spinal Ccord Involvment and lactate elevation

Authors: *B. O'BRIEN[1], C. L. NEMETH[2], P. HUBO[1], S. N. TOMLINSON[1], A. SMITH[3], A. FATEMI[4];
[2]Neurosci., [1]Kennedy Krieger Inst., Baltimore, MD; [3]Kennedy Krieger Inst. / Johns Hopkins, Baltimore, MD; [4]Neurol., Johns Hopkins Univ., Baltimore, MD

Abstract: Leukoencephalopathy with Brainstem and Spinal Cord Involvement and Lactate Elevation (LBSL) is a rare autosomal recessive disease most commonly affecting white matter regions of the brain, pyramidal tract, and dorsal column. Disease onset typically occurs during childhood or adolescence, but has also been reported during infancy and adulthood with phenotypes more severe and mild, respectively. Symptoms include slowly progressive ataxia, dysarthria and spasticity. Individuals with LBSL are compound heterozygotes for mutations in the gene *DARS2*, which encodes for the Class II Mitochondrial Aspartyl-tRNA Synthetase and plays an essential role during the translation of proteins in the mitochondria by charging aspartic acid to its cognate tRNA. Due to the large number of pathogenic variants found in LBSL patients, establishing a genotype/phenotype correlation has shown to be difficult. The most frequently observed pathogenic variant presents at the end of intron 2 on one allele, affecting the splicing efficiency of exon 3 resulting in nonsense mediated decay of the mature mRNA transcript. This splice site mutation pairs with a more variable missense mutation on the second allele. Despite the ubiquitous expression of *DARS2* throughout the body, mutations in this gene appear to only affect cell types found in the central nervous system (CNS), likely due to the extreme energy demands of the brain. To date, conditional knockout mouse models for *DARS2* have been established; however, these models fail to illustrate the true nature of the mutations found in LBSL due to the differences in murine splicing mechanisms and failed attempts to induce missense mutations. Patient derived induced Pluripotent Stem Cells (iPSCs) provide an excellent model for any disease, as they harbor the potential to rapidly differentiate into cell types of all three germ layers and exhibit the true pathology caused by disease triggering mutations. Using motor neurons rapidly derived from patient iPSCs, we show cell-type specific differences in the efficiency of splicing of *DARS2* in motor neurons compared to undifferentiated iPSCs. RT-qPCR and Western Blot analysis show an increase in abnormally spliced mRNA transcripts and a severe decrease in *DARS2* protein expression in motor neurons. In addition, live cell monitoring and electrophysiology analysis of motor neurons help to elucidate both

functional and developmental differences between LBSL and control cells. Establishing a patient derived neuronal cell model for LBSL allows for the opportunity to understand cell-type specific mechanisms for this disease, and serves as a test bed for potential therapeutics.

Title: tcMEP and tcSEP in myelin oligodendrocyte glycoprotein (MOG) induced experimental autoimmune encephalomyelitis (EAE) in mice

Authors: Y. SHULMAN[1], Y. LEVI[1], L. FINKELSTEIN[1], I. LEVI[1], A. SCHAUDER[1], D. CASTEL[2], ***S. B. MEILIN**[1];
[1]MD Biosci., Nes Ziona, Israel; [2]Tel Avivi Univ., Tel Aviv, Israel

Abstract: Myelin Oligodendrocyte Glycoprotein (MOG) induced EAE is one of the most common murine models for multiple sclerosis. Yet, very little is known about the electrophysiology of the motor system and even less is known about the electrophysiology of the sensory system. EAE was induced by a single inoculum injection on study commencement. The inoculum injection consists of a homogenate emulsion mixture of MOG and CFA (200 μg MOG / 300 μg CFA). This was followed by pertussis toxin (PT) intraperitoneal injections (300 ng/mouse) on two occasions: once at the time of EAE induction and again 48 hours later on study day 2. In this study we assessed trance cranial motor evoked potential (tcMEP) and trance cranial sensory evoked potential (tcSEP) as a quantitative marker for *in vivo* monitoring of corticospinal tract damage. This study shows, for the first time, unique electrophysiology sensory (SEP) and motor (MEP) phenomena in early stages of EAE. The results show that in animals with mild EAE symptoms, the duration of MEP and connotative potentials increased without any change in the amplitude. However, the SEP amplitude increased significantly. As the disease progressed, a decrease in MEP and SEP amplitude was recorded. These results demonstrate a-synchronized neural motor activity at early stages followed by complete loss of signal in sever EAE disease. Additionally, the data show that early stage of the disease is also characterize by hyper-sensitivity of the sensory system. These significant findings can serve as a basis for a new drug screening model for treating early Multiple Sclerosis symptoms.

Title: Characterization of relevant mouse models for new biomarker

Authors: V. NIEDERKOFLER, T. LOEFFLER, E. AUER, S. FLUNKERT, *J. NEDDENS, B. HUTTER-PAIER;
QPS Austria GmbH, Grambach, Austria

Abstract: Introduction: For pre-clinical and clinical assessment of neurodegenerative diseases peripheral biomarker are needed to determine disease state and progression in a minimally invasive way. Recently established biomarkers like Neurofilament-light chain (NF-L) or sTREM2, are of importance to ensure early diagnosis and monitor disease progression in humans. Use of the same biomarkers in preclinical and clinical studies may thus be an option to overcome translational issues.
The aim of this study was to evaluate NF-L and sTREM2 levels in plasma and CSF of well-described mouse lines used for neuropharmacological studies in different indications.
Method: 5xFAD, Line61, NPC-/- and TDP43 mice as models of Alzheimer's, Parkinson's, Niemann-Pick Disease and Amyotrophic lateral sclerosis, respectively, were used at different ages. To explore Neurofilament light chain levels in CSF and plasma, the NF-Light® ELISA by UmanDiagnostics was used. For the detection of sTREM2 an immunosorbent assay specific for mouse TREM2, developed on the MSD (Mesoscale Discovery) platform was used. Immunohistochemical evaluation of neuronal loss and neuroinflammation was additionally performed.
Results: Besides other markers for neuroinflammation, also an increase in TREM2 levels was observed in 5xFAD mice. NF-L, a marker for neurodegeneration was found to be significantly increased in plasma already at an age of 6 months, before neuronal loss can be determined in the Alzheimer's disease 5xFAD mouse model. In contrast, in the alpha-synuclein overexpressing Line61, NF-L levels started to rise very late, reflecting data obtained from PD patients. Evaluations of additional mouse models are ongoing.
Conclusion/ Summary: Recently developed peripheral biomarkers for neurodegeneration, like NF-L, are also a valuable tool in preclinical mouse models. Additionally to their potential translational value, these models may also be a tool to longitudinally monitor neurodegeneration and neuroinflammation in the same animals by analyzing samples obtained from *in vivo* bleedings.

Title: Effect of Myrtillocactus geometrizans (garambullo) concentrations on the memory and the glucose, lipid peroxidation and neurotransmitter levels in the frontal cortex of rats high sugar diet fed

Authors: *C. SANDOVAL SALAZAR[1], A. ALAMO LEON[2], S. N. JIMENEZ GARCIA[2], X. S. RAMIREZ GOMEZ[2], V. BELTRAN CAMPOS[2];
[1]Salud e Ingenierías, Univ. De Guanajuato, Celaya, Mexico; [2]Salud e Ingenierías, Univ. de Guanajuato, Celaya, Mexico

Abstract: Obesity reduces life expectancy due to the factors like food habits. The consumption of high sugar diets promote weight gain, oxidative stress, increased glucose levels and affects learning and memory processes. Given this, it is necessary to explore prevention strategies through fruits such as *Myrtillocactus geometrizans*(garambullo); that contain antioxidant properties, which could decrease the oxidative.The aim of this study was to explore the antioxidant effect of three different garambullo concentrations on the memory, glucose, lipid peroxidation, neurotransmitter levels (glutamine, glutamate and GABA) in the frontal cortex of rats high sugar diet fed. A total of 50 healthy male rats were divided equally into five groups: 1)Standard diet+water; 2)High sugar diet+water; 3)High sugar diet+garambullo 150mg; 4)High sugar diet+garambullo 300mg 5)High sugar diet+garambullo 450mg. All the groups were fed over a six month period, but in the fifth month the third, fourth and fifth group received garambullo starting at four weeks. Subsequently, the water Morris maze test was performed. Tissues were obtained and the plasma glucose levels were measured using a spectrophotometric method. Lipid peroxidation levels were analyzed by measuring thiobarbituric acid reactive substances. The neurotransmitters concentration were quantified using HPLC electrochemical detection.The rats fed with a standard diet consumed approximately 50% more higher than the

rats who consumed a high sugar diet and the garambullo have no effect. Glucose and lipid peroxidation levels were high in the groups who consumed sugar compared to the standard diet and garambullo did not decrease the concentrations. With respect to the neurotransmitters, GABA levels decreased in the high sugar diet rats, however the glutamine and glutamate levels increased and the garambullo's only effect showed to decrease glutamate levels in the 450mg concentration. Likewise, the sugar diet impairs spatial memory. Accordingly, it is necessary to probe more doses of garambullo, as well as, subchronic or chronic administration to determine the optimal dose and time to understand how the treatment with fruits like garambullo may have effects on the brain and improve the negative effects of high sugar diets intake.

Title: Rab10 mediated regulation of endocytic vesicle trafficking

Authors: *Z. LIU[1], A. B. WEST[2];
[1]Dept. of Pharmacol. and Cancer Biol., Duke Univ., Durham, NC; [2]Dept. of Pharmacol. and Cancer Biol., UAB, Durham, NC

Abstract: Common genetic variants in the *Rab10* gene have been identified as protective in genome-wide association studies in Alzheimer's disease (AD), and Rab10 expression is elevated in AD compared to controls. Recently, Rab10 has been discovered as a substrate for phosphorylation by the Parkinson's disease-associated protein leucine-rich repeat kinase 2 (LRRK2), further implicating the Ras-family Rab10 in neurodegeneration. Proteomic studies reveal that professional phagocytic cells in the innate immune system have some of the highest LRRK2 expression in humans, although the function of Rab10 in vesicle trafficking is not clear. Here we find that Rab10 regulates clathrin independent endocytosis in macrophages and microglia. Knock down of Rab10 reduces the uptake and clearance of a variety of soluble proteins and polysaccharides. We are further characterizing the role of Rab10 positive endosomes in macrophage activation and polarization, and how phosphorylation of Rab10 via the LRRK2 protein kinase affects Rab10 function. Overall we hypothesize that Rab10 mediates important aspects of upregulation of endolysosomal maturation in macrophage pro-inflammatory polarization.

Abstract: Overproduced reactive oxygen species (ROS) are closely related to various neuroinflammation and neurodegeneration. Abnormally high ROS levels can cause serious oxidative damage to biomolecules, cells, and, tissues. A series of nano- or micro-sized particles has been developed to reduce the oxidative stress level by delivering antioxidant drugs. However, most systems are often plagued by slow molecular discharge which reduces therapeutic efficacy or uncontrollably fast release which abolishes crucial physiological roles of ROS entirely. Herein, this study demonstrates the polymeric particles whose internal pressure can increase upon exposure to H_2O_2, one of the ROS, and, in turn, discharge antioxidants when needed. The on-demand pressurized particles are assembled by simultaneously encapsulating water-dispersible manganese oxide (MnO_2) nanosheets and green tea-derived epigallocatechin gallate (EGCG) molecules into a poly(lactic-co-glycolic acid) (PLGA) spherical shell. In the presence of H_2O_2, the MnO_2 nanosheets in the PLGA particle generate oxygen gas by decomposing H_2O_2 and increase in the internal pressure. The pressurized PLGA particles release antioxidative EGCG actively and, in turn, protect vascular and brain tissues from oxidative damage more effectively than the particles without MnO_2 nanosheets. This H_2O_2 responsive, self-pressurizing particle system would be useful to improving therapeutic efficacy of a broad array of neuromedicine.

Title: Effect of metabolic syndrome on the clearence of amyloid beta peptide through the blood brain barrier and neuroinflammation in rat hippocampus

Authors: *C. F. AGUILAR-GAMAS, Sr, E. MARTINEZ-ABUNDIS, E. DE LA CRUZ-HERNANDEZ, N. GOMEZ-CRISOSTOMO;
Univ. Juarez Autonoma de Tabasco, Comalcalco, Mexico

Abstract: Obesity and the metabolic syndrome (MS) are a growing health problem worldwide due to the consumption of high-calorie diets (high sugar and high fat content diets) in combination with a sedentary lifestyle. Several studies shown that obesity and the metabolic syndrome are accompanied by the state of systemic inflammation, the nervous system is not exempt, where the activation of the vascular endothelium, microglia and astrocytes predominates, promoting the production of β-amyloid peptide (AB), as well as a dysfunction in the blood-brain barrier (BBB) -involved in the clearance of this protein-, which could lead to cognitive impaired and increased risk of developing Alzheimer's disease. The objective of this study is to evaluate the effect of MS on the function of the BBB through the evaluation of the clearance of AB such as the neuroinflammation process and its participation in cognitive impairment. Newly weaned male Wistar rats were fed chow with high sugar or high fat diets during 8, 10 and 12 months. Blood pressure, glucose, cholesterol, triglyceride levels and the percentage of retroperitoneal fat were determined to confirm the presence of MS. The memory was evaluated with Morris water maze. The hippocampus was dissected and the expression of amyloid beta, glial fibrillary acidic protein (GFAP) and Ionized calcium binding adaptor molecule 1 (IBA1) protein were determined to evaluate neuroinflammation and the elimination of AB through BBB. The results shown that the animals present the alterations of the metabolic syndrome at 10 and 12 months with both diets and an increased level of GFAP observed in both hypercaloric diets and is more significantly after 12 months consumption of the high-fat diet. The expression of IBA1 also was increase at 10 and 12 months of consumption of both diets, correlating with an increase in the expression of AB levels observed in all treatment times, being more remarkable at 12 months. These results indicate astrocytic and glial activation and therefore neuroinflammation in addition to the increase in AB hippocampal levels suggest an alteration in

the clearance process through the BBB. It is observed that at 8, 10 and 12 months with both diets there is a significant increase in the amount BA this is more marked in the diet high in fat, in the amount of IBA-1 the increase at 10 and 12 months is more notorious at 12 months, in both diets. These events could explain, at least in part, the association between MS and the neurodegenerative process that characterizes AD.

Title: Anti-inflammatory effects of SM07883, a novel, potent, and selective oral DYRK1A inhibitor in mouse models of neuroinflammation

Authors: *S. ANDERSON, M. W. AKHTAR, K. DUONG-POLK, C. LAI, B. GUNER, S. HABROUN, B. MELCHIOR;
Samumed, LLC, San Diego, CA

Abstract: Neuroinflammation contributes to many neurodegenerative disorders, including Alzheimer's disease and Multiple Sclerosis. Inhibition of dual-specificity tyrosine phosphorylation-regulated kinase 1A (DYRK1A) activity reduced tau and amyloid pathology as well as associated gliosis in AD transgenic mice. This study dissected the mechanisms by which SM07883, an oral DYRK1A inhibitor, inhibited neuroinflammation *in vitro* and in mouse models innate and adaptive CNS immune responses. To measure inflammation *in vitro*, cytokine concentrations were measured with MSD platform in supernatants from BV2 microglial cells and primary mouse astrocytes challenged by lipopolysaccharide (LPS). STAT3 and NFATc1 phosphorylation and nuclear translocation were measured by Western blot, ELISA, and imaging. In 3 experiments, sorted BALB/C mouse splenocytes were stained with CFSE and stimulated for 5 days with anti-CD3/CD28 antibodies. Cell division was analyzed by flow cytometry. Brains from BALB/c mice challenged with intracerebral or intraperitoneal LPS were analyzed after SM07883 (10mg/kg, QD, 5 days, n =5) or vehicle administration. C57BL/6 wild type mice with induced experimental autoimmune encephalomyelitis (EAE) after MOG_{35-55} immunization were treated with SM07883 (5-10mg/kg, QD and 5mg/kg, BID, 35 days) or vehicle (n =15 for each group). Clinical scores were measured daily and cytokines in spinal cord tissue were analyzed by Milliplex assays. *In vitro*, SM07883 inhibited LPS-induced cytokine secretion compared to DMSO control in microglial cells (e.g., TNFα EC_{50} =71nM) and in primary astrocytes (EC_{50}: TNFα =932nM; IL-6 =698nM; KC/GRO =2.1uM). These effects were associated with dose-

dependent reductions in phosphorylation and nuclear translocation of NFATc1 and STAT3 ($p<0.05$). Potent reduction in T cell proliferation was associated with decrease in proinflammatory cytokines (EC_{50} =15nM, IFNγ =41nM, TNFα =46nM) with SM07883 compared to DMSO. Innate responses, measured by proinflammatory cytokines TNFα, IFNγ, IL-1β, and IL-6 as well as the chemokine KC/GRO, were increased in brains from LPS-challenged mice and significantly reduced with SM07883 treatment compared to vehicle. EAE mice treated with SM07883 improved clinical scores with reduced adaptive immune responses measured by decreased cytokines ($p<0.05$) and lymphocyte count in spinal cord compared to vehicle. SM07883, an oral DYRK1A inhibitor, significantly reduced proinflammatory mediators and associated inflammation in both innate and adaptive inflammatory mouse models compared to vehicle. SM07883 may potentially modulate neuroinflammation in neurodegenerative diseases.

Title: Aberrant miRNA expression in multiple system atrophy contributes to neuroinflammation and may affect oligodendrocyte maturation

Authors: T. KIM[1], **L. AKHMETOVA**[1], L. E. CROMBERG[1], *P. A. DESPLATS[2]; [1]Neurosciences, [2]Neurosciences and Pathology, UCSD, La Jolla, CA

Abstract: Multiple System Atrophy (MSA) is a neurodegenerative disease characterized by the accumulation of α-synuclein (α-syn) in oligodendrocytes; resulting in demyelination, neuronal damage and inflammation. Micro-RNAs (miRNA) regulate gene expression by triggering the degradation of their target mRNA molecules. There is ample evidence for the involvement of miRNA deregulation in neurodegeneration. The purpose of this study was to perform a comprehensive appraisal of miRNA alterations in *post mortem* striatum samples from MSA cases and a parallel transcriptome analysis of genes associated with neurodegeneration. In addition, since immature oligodendrocytes are increased in MSA brains, we evaluated whether

miRNA alterations mediate the effects of α-syn on oligodendrocyte maturation using an *in vitro* model.
We profiled 800 miRNAs using the nCounter® Human v3 miRNA panel and 770 genes related to neuropathology using the nCounter® Human Neuropathology panel in 18 brain samples. For the *in vivo* model, we differentiated neuronal progenitor cells from adult rat hippocampus (ARHNPC) into oligodendrocytes and used lentiviral constructs to overexpress α-syn. We applied the nCounter® Rat v1.5 miRNA panel to profile the expression of 420 miRNAs at different time points of the maturation protocol. Data was analyzed using nSolver® software v4.0, Ingenuity Pathway Analysis and Diana mirPath v3.
We identified 60 miRNAs with abnormal levels in MSA brains that are involved in extracellular matrix receptor interactions, prion disease, inflammation, ubiquitin-mediated proteolysis and addiction pathways. We also identified 96 differentially expressed genes, related to inflammation, myelination, autophagy and vesicle transport pathways. Importantly, based on the correlation between miRNA expression and the abundance of their known targets, miR-124-3p, miR-19a-3p, miR-27b-3p, and miR-29c-3p were identified as key regulators altered in MSA, mainly contributing to neuroinflammation.
Analysis of the *in vitro* model uncovered distinct miRNA profiles associated with oligodendrocyte maturation that were altered by α-syn overexpression.
We provide evidence for the role of miRNA deregulation in MSA pathology, increasing inflammation and altering oligodendrocyte maturation.

Inst., UCL, London, United Kingdom; [12]Univ. of Wisconsin, Madison, Madison, WI

Abstract: While delirium is associated with cognitive decline and dementia, there is limited evidence to support causality for this relationship. Clarification of the mechanism through which delirium could cause cognitive decline would enhance plausibility for a causal relationship. We tested whether delirium is associated with neuronal injury in 114 surgical patients recruited to a prospective biomarker cohort study. Patients underwent perioperative testing for changes in neurofilament light (NfL), a neuronal injury biomarker, as well as a panel of 10 cytokines, with contemporaneous assessment of delirium severity and incidence as well as sampling for inflammatory. A subset of patients underwent preoperative magnetic resonance imaging. Initially we confirmed prior reports that NfL levels correlated with markers of neurodegeneration (hippocampal volume [$\Delta R^2 = 0.129$, $p = 0.015$] and Fractional anisotropy of white matter [$\Delta R^2 = 0.417$, $p<0.001$]) in our cohort and that surgery was associated with increasing NfL from preoperative levels ([mean difference = 0.240 [0.178, 0.301] $\log_{10}$(pg/mL), $p < 0.001$]), suggesting putative neuronal injury. Next, we tested the relationship with delirium. NfL rose more sharply in participants with delirium compared to non-sufferers ([mean difference = 0.251 [0.136, 0.367] $\log_{10}$(pg/mL), $p < 0.001$]). This relationship showed dose-dependence, such that NfL rose proportionately to delirium severity [$\Delta R^2 = 0.199$, $p < 0.001$]. Given that inflammation is considered an important driver of postoperative delirium, next we tested whether NfL, as a potential marker of neurotoxicity, may contribute to the pathogenesis of delirium independent of inflammation. From a panel of 10 cytokines, the pro-inflammatory cytokine IL-8 exhibited a strong correlation with delirium severity ($\Delta R^2 = 0.208$, $p < 0.001$). Therefore, we tested whether the change in NfL contributed to delirium severity independent of IL-8. NfL was independently associated with delirium severity after adjusting for the change in inflammation ($\Delta R^2 = 0.040$, $p = 0.038$). These data suggest delirium is associated with exaggerated increases in NfL and that this putative neurotoxicity may contribute to the pathogenesis of delirium itself, independent for changes in inflammation. Dose-dependence with delirium severity enhances the biological plausibility for this relationship.

Title: Neuroprotective effects of a novel carnosine-hydrazide derivative on hippocampal CA1 damage after cerebral ischemia

Authors: *M. MORIOKA[1], K. NOGUCHI[2], T. F. ALI[3], M. OHTSUKA[4];
[1]Neurosurg., Kurume Med. Sch., Kurume, Japan; [2]Kurume UNiv.Sch Med., Kurume, Japan; [3]Fac. of Pharm., Minia Univ., Minia, Egypt; [4]Dept. of Bioorganic and Medicinal Chem., Kumamoto Univ., Kumamoto, Japan

Abstract: Ischemia-reperfusion injuries produce reactive oxygen species that promote the peroxide lipid oxidation process resulting in the production of an endogenic lipid peroxide, 4-hydroxy-trans-2-nonenal (4-HNE), a highly cytotoxic aldehyde that induces cell death. We synthesized a novel 4-HNE scavenger - a carnosine-hydrazide derivative, L-carnosine hydrazide (CNN) - and examined its neuroprotective effect in a model of transient ischemia. PC-12 cells were pre-incubated with various doses (0-50 mmol/L) of CNN for 30 min, followed by incubation with 4-HNE (250 μM). An MTT assay was performed 24 h later to examine cell survival. Transient ischemia was induced by bilateral common carotid artery occlusion (BCCO) in the Mongolian gerbil. Animals were assigned to sham-operated (n = 6), placebo-treated (n = 12), CNN pre-treated (20 mg/kg; n = 12), CNN post-treated (100 mg/kg; n = 11), and histidyl hydrazide (a previously known 4-HNE scavenger) post-treated (100 mg/kg; n = 7) groups. Heat shock protein 70 immunoreactivity in the hippocampal CA1 region was evaluated 24 h later, while delayed neuronal death using 4-HNE staining was evaluated 7 days later. Pre-incubation with 30 mmol/L CNN completely inhibited 4-HNE-induced cell toxicity. CNN prevented delayed neuronal death by >60% in the pre-treated group ($p < 0.001$) and by >40% in the post-treated group ($p < 0.01$). Histidyl hydrazide post-treatment elicited no protective effect. CNN pre-treatment resulted in high heat shock protein 70 and low 4-HNE immunoreactivity in CA1 pyramidal neurons. Higher 4-HNE immunoreactivity was also found in the placebo-treated animals than in the CNN pre-treated animals. Our novel compound, CNN, elicited highly effective 4-HNE scavenging activity *in vitro*. Furthermore, CNN administration both pre- and post-BCCO remarkably reduced delayed neuronal death in the hippocampal CA1 region via its induction of heat shock protein 70 and scavenging of 4-HNE.

Title: Hyperoxic resuscitation following canine cardiac arrest increases cerebellar Purkinje neuronal death

Authors: *G. FISKUM[1], D. LEE[2], T. PEARSON[2], J. PROCTOR[2], R. E. ROSENTHAL[2]; [1]Anesthesiol., [2]Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract: Maintaining physiologic O_2 levels (normoxia) immediately after restoration of spontaneous circulation (ROSC) from cardiac arrest (CA) results in less hippocampal neuronal death compared to animals ventilated during the first hr of ROSC. However, other brain regions, e.g., those that undergo post-ischemic hypoperfusion, might actually benefit from hyperoxic reperfusion. This study tested the hypothesis that when compared to hyperoxic reperfusion, pulse-oximetry guided normoxic resuscitation following ventricular fibrillation (VFib) CA reduces short-term cerebellar neuronal death and inflammatory microglial activation. Female beagles were anesthetized and ventilated. CA was induced by electrical myocardial stimulation and cessation of ventilation. Ten min later, dogs were ventilated with 100% O_2 and resuscitated using 3 min of open chest CPR followed by electrical defibrillation. Dogs were then ventilated for one hr with 100% O_2 (hyperoxia) or with O_2 titrated rapidly to maintain hemoglobin saturation at 94 to 96% (normoxia). Following 24 hr critical care, dogs were euthanized and the cerebellum analyzed for neuronal death (Calbindin D) and microglial activation (Iba1). StereoInvestigator and GraphPad software were used for stereologic quantification of neuronal death and microglial activation. Calbindin-stained Purkinje cells were classified morphologically into "healthy" and "damaged" neurons. Healthy neurons displayed an intact morphology, with darkly stained nuclei and more lightly stained axons and dendrites. Dying neurons were characterized by the lack of nuclear staining and loss of intact morphology. Hyperoxic resuscitation significantly increased the number of dying Purkinje cells by 278%. The morphology of Iba-1 immunopositive microglia was classified as either "resting", with small cell bodies and extensive dendritic processes, or "activated", with large cell bodies and retraction of cell processes. Hyperoxic resuscitation increased the number of activated microglial/macrophages by 18% in comparison to values obtained after normoxic resuscitation. Hyperoxic resuscitation increased the number of dying Purkinje cells by almost 300% and the number of activated microglial by 20%. These results indicate that the favorable histopathologic outcomes following CA and normoxic compared to hyperoxic resuscitation are observed in the

cerebellum and therefore not limited to the hippocampus. These findings emphasize the importance of avoiding unnecessary hyperoxia during at least the first hr following CA and ROSC. Supported by NIH 1 R01 NS091099

Title: Search of novel purinergic P2x4 receptor antagonists for the treatment of ischemic stroke

Authors: *P. SRIVASTAVA[1], V. K. RAO[1], B. T. LIANG[1], T. O'BRIEN[2], R. VERMA[1]; [1]Neurosci., Uconn Hlth., Farmington, CT; [2]Atomwise, San Francisco, CA

Abstract: Stroke remains a leading cause of disability in the United States. Despite recent advances, interventions to reduce damage and enhance recovery after stroke are lacking. As the both resident and peripheral immune response (specifically myeloid origin cells) contributes to secondary tissue damage and poor recovery even after several hours of stroke onset, targeted inhibition of myeloid cell response has become an area of major therapeutic interest. We have recently shown that P2X4R, a purinergic receptor for adenosine triphosphate (ATP), regulates activation of myeloid immune cells (infiltrating monocytes/macrophages and brain-resident microglia) after stroke injury (Verma et al., 2017). Over activation of P2X4Rs, due to ATP released from dying or damaged neuronal cells, contributes to ischemic injury. Motivated by this work, we hypothesize that acute inhibition of P2X4R is beneficial after stroke. As commercially available P2X4R inhibitor has several limitations in their in vivo use e.g. insoluble in biological vehicle and limited blood brain barrier (BBB) permeability. Using cutting edge artificial intelligence technique available through the AIMS program at Atomwise, a high throughput virtual screen was used to identify novel small molecular inhibitors of P2X4R. The best scoring compounds from the screen were then clustered for scaffold diversity and then filtered for drug-like properties to arrive at a final subset of 72 potential P2X4R inhibitors. These 72 compounds and the standard P2X4R inhibitor
5-BDBD were tested using Ca++ influx assay in Human P2X4R expressing cell line (HEK293). We found 6 active compounds with inhibitory activity in μM concentration. Out of these six one

compound was comparable with 5-BDBD in its P2X4R inhibitory activity. In summary, we identify a total of six potential small molecule inhibitors of P2X4R, which are presumably soluble in biological solvent and are BBB permeable. In next series of experiments, we will confirm their P2X4R inhibitory activity in primary microglial culture as well as in *in-vivo* model of ischemic stroke in rodents.

Abstract: Neurodevelopmental impairment is an important challenge for survivors after pediatric cardiac surgery. Cardiopulmonary bypass (CPB) can cause substantial systemic inflammation and trigger prolonged microglial activation in the brain. Mesenchymal stromal cells (MSCs) have significant immunomodulatory properties. We hypothesize that MSC delivery through CPB is neuroprotective by modulating systemic and neuro-inflammatory responses. Two-week old piglets (n=16 total) were randomly assigned to one of 3 groups: (1) Control, (2) Deep hypothermic circulatory arrest (DHCA), (3) DHCA followed by MSC administration. In group 3, ^{18}F-FDG or superparamagnetic iron oxide (SPIO)-labeled MSCs ($10x10^6$ per kg) were

delivered through CPB. Positron emission tomography (PET) was performed 1hr after MSC delivery to determine the whole body distribution of cells. Animals were sacrificed 3hrs after CPB for analysis with magnetic resonance imaging (MRI) and immunohistochemistry. Total cortical RNA was extracted and sequenced, followed by differential expression analysis. Gene ontology (GO) was assessed using Enrichr on differentially expressed genes (DEGs) whose normalized read count displayed a rescue profile upon MSC delivery. Plasma cytokine/chemokine levels were determined by multiplex immunoassay. Clinically-relevant physiological biomarkers determined the effect of MSC delivery on multi-organ function. PET study showed that intra-arterial delivery through CPB uniformly distributed MSCs to all organs analyzed such as the brain, heart, and kidney except that lungs and intestine showed lower uptake. T2* weighted brain MRI showed diffuse distribution of SPIO particles throughout the entire brain. Immunohistochemistry revealed an even distribution of delivered MSCs within the cortex and white matter. MSCs were noted to have migrated into the extra-vascular space. Analysis of the RNA sequencing data identified 262 DEGs between the DHCA and DHCA/MSC groups. Of these, 53 upregulated genes were significantly enriched for WNT signaling in the GO analysis, indicating a potential mechanism for MSC-mediated neuroprotection. MSC delivery through CPB also modulated plasma cytokine/chemokine expression following surgery. In the brain MSC treatment reduced microglia expansion and caspase activation resulting from CPB. Various biomarkers after MSC delivery did not differ compared with CPB group. No evidence of either embolic events or microstrokes was observed by MRI and histology. MSC delivery during CPB has the translational potential to minimize systemic inflammation and reduce microglial expansion and caspase activation in children undergoing CPB.

Title: 4R, a cembranoid compound, improves sensorimotor and cognitive functions after ischemic stroke

Authors: *J. WANG, J. WANG, J. HAO;
Dept. of Pharmaceut. Science, Col. of Pharm., Univ. of Cincinnati, Cincinnati, OH

Abstract: *Objective:* Our previous reports revealed 4R neuroprotective effects on rodents' cerebral ischemic disease model or 6-hydroxydopamine-induced Parkinson's disease model. Present studies focused on determine the effects of 4R on cognitive functions after ischemic stroke in mice, and elucidating relative mechanisms.
Methods: In vivo study: 4R (5 mg/kg/day) or same volume of DMSO or PBS was Intraperitoneally injected as early as 1 h after 60 min transient Middle Cerebral Artery Occlusion and up to 4 days. The sensorimotor functions (corner test) and cognitive functions (Y-maze test) were evaluated following the treatment. In vitro study: To determine the regulating mechanism of 4R on N9 cells (murine-derived microglia cell line) polarization under lipopolysaccharide (LPS)-induced inflammatory or oxygen glucose deprivation (OGD) conditions. And to evaluate the effects of conditioned medium derived from 4R-treated post-OGD N9 cells on viability of neuro2a cells (a murine neuroblastoma cell line).
Results: Corner test results indicated that 4R treatment improved corner test score to 0.41 compared to 0.86 of DMSO group at 24 h post ischemic stroke. Y-maze test results illustrated that 4R treatment group presented better memory retrieval ability than vehicle control group. In vitro results revealed the expression of N9 cell inducible nitric oxide synthase (iNOS), a Microglial M1 phase marker, was attenuated by 1uM 4R treatment to 69.4% and 56.4% of vehicle control under LPS or OGD conditions, respectively. The expression of N9 cell Argnase-1, a M2 phase marker, was increased by 1uM 4R treatment to 192.7% and 188.0% of vehicle control under LPS or OGD conditions, respectively. Furthermore, the viability of Neuro2a cells increased by 54.5% after treatment with the conditioned medium of 4R-treated post-OGD N9 cells, which associated with inhibiting pro-inflammatory cytokine TNF-α release and promoting anti-inflammatory cytokine IL-10 segregation.
Conclusions: 4R improves sensorimotor and cognitive functions after ischemic stroke in mice, which may due to the anti-inflammatory mechanism of 4R regulated microglia polarization.

Title: Neuroprotective effects of palmitic acid methyl ester on neuroinflammation and mitochondrial function in cerebral ischemia

Authors: *C. Y.-C. WU[1], A. COUTO E SILVA[2], G. A. CLEMONS[2], R. H.-C. LEE[1], H. LIN[1];
[1]Neurol., [2]Cell. Biol. and Anat., LSU Hlth. Sci. Ctr. Shreveport, Shreveport, LA

Abstract: We previously discovered that palmitic acid methyl ester (PAME) is a potent vasodilator released from the superior cervical ganglion. Post-treatment with PAME can enhance cortical cerebral blood flow and functional learning and memory, while it inhibited neuronal cell death in the CA1 region of the hippocampus under pathological conditions (i.e. cerebral ischemia). Since mechanisms underlying PAME-mediated neuroprotection remain unclear, we investigated the possible neuroprotective mechanisms of PAME after 6 min of asphyxia cardiac arrest (ACA, an animal model of global cerebral ischemia). Our results from capillary-based immunoassay suggest that PAME (0.02 mg/kg) can decrease neuroinflammatory markers, such as ionized calcium binding adaptor molecule 1 (IBa1, a specific marker for microglia/macrophage activation), interleukin-2 (IL-2), and monocyte chemoattractant protein-1 (MCP-1/CCL2) after cardiopulmonary resuscitation. Additionally, the oxygen consumption rate (OCR) and mitochondrial respiratory function in the hippocampal slices were restored following ACA (via Seahorse XF24 Extracellular Flux Analyzer) suggesting that PAME can ameliorate mitochondrial dysfunction. Finally, PAME improved memory-related long-tern potentiation (LTP) in the hippocampus reducing neurological deficits after ACA. Altogether, our findings suggest that PAME can provide neuroprotection in the presence of ACA to alleviate neuroinflammation and ameliorate mitochondrial dysfunction.

Title: Effects of deletion of peroxiredoxins II on bilateral common carotid artery occlusion-induced impairments of hippocampal function

Authors: *Y.-S. JANG, J.-S. HAN;
Konkuk Univ., Seoul, Korea, Republic of

Abstract: Peroxiredoxins II (Prx II) act as an antioxidant enzyme that reduce peroxide levels. Evident immunoreactivity of Prx II is observed in hippocampal neurons. Prx II is expected to inhibit ROS accumulation in the hippocampus. Previous studies demonstrated that aged Prx II knock-out mice showed spatial memory impairments and altered levels of the proteins associated with learning and memory in the hippocampus. Therefore, it is suggested that Prx II play a neuroprotective role against brain injury through scavenging intracellular ROS. The present experiment was conducted to examine whether Prx II knock-out make more vulnerable to a sudden injury. Transient bilateral common carotid artery occlusion (BCCAo), one of the experimental animal models for transient global ischemia, was conducted. Mice were divided into 4 groups: sham-operated wild type (WT), WT with 20 min BCCAo, sham-operated Prx II KO, and Prx II KO with 20 min BCCAo. Cognitive status and neuronal death of these mice was evaluated using the hippocampus dependent tasks including Morris water maze task and novel object recognition test, and Fluoro-jade C. Severe significant memory impairments were found in the Prx II KO mice with BCCAo, compared with the other groups. But, no difference between WT with BCCAo and Prx II KO with BCCAo was observed in the Fluoro-jade C intensities of the hippocampus CA1. These results indicate that the Prx II play a protective role against brain injury, though its neurobiological mechanism is needed to be revealed. Title: LFP based analysis of brain injured anesthetized animals undergoing closed-loop intracortical stimulation

Authors: A. AVERNA[1], ***F. BARBAN**[1,2], D. J. GUGGENMOS[3], R. J. NUDO[4], M. CHIAPPALONE[1];
[1]Inst. Italiano Di Tecnologia, Genoa, Italy; [2]Dept. of Informatics, Bioengineering, Robotics and Systems Engin., Univ. of Genoa, Genoa, Italy; [3]Dept. of Physical Med. and Rehabil., [4]Univ. of Kansas Med. Ctr., Kansas City, KS

Abstract: Acquired brain injuries, such as stroke, are a major cause of long-term disability worldwide. When an injury occurs within primary motor cortex (M1), as is common in stroke,

there is an initial loss of descending information to the spinal cord, which leads to hemiparesis and other motor dysfunctions. In addition, it results in global changes in functional connectivity between spared, interconnected regions throughout the brain. Recently, activity-dependent stimulation (ADS), a closed loop intracortical neurostimulation technique, was shown to significantly improve behavioral recovery in rodent models that suffered a traumatic brain injury in the primary motor cortex. While the behavioral benefits are established, the neurophysiological changes underlying this effect remain unclear. In this study we attempt to understand how local field potential signal are modified in response to the ADS treatment following an injury to primary motor cortex. We used a rodent (Long Evans) model of induced ischemic injury in which endothelin-1, a potent vasoconstrictor, was injected unilaterally through the extent of the forelimb area of primary motor cortex. A total of two 4-shank, 16-site intracortical microelectrode array (MEA) were inserted in the ipsilesional rostral forelimb area (RFA) and forelimb-responsive somatosensory cortex. Rats were randomly assigned to either a non-stimulation control group (N=5) or ADS treatment group (N=7). Neural activity was recorded from all electrode sites in both groups. In the ADS group, therapeutic stimulation was initiated one hour after the lesion, with a user-identified single unit in RFA set to trigger the center channel in the S1 array. Stimulation was turned off after one hour, with recording continuing an additional 30 minutes. We performed analyses addressing power and connectivity changes in the LFP domain. Functional connectivity was measured using a power envelope correlations method developed by Hipp et al. (2012). Ischemic injury to M1 led to an overall decrease in LFP power within RFA. The number of functional connections between RFA and S1 increased after the stroke. Treatment with ADS induced a broadband increase in LFP power in both RFA and S1, while functional connections between the two areas decreased, which may be the one mechanism in which ADS operates.

Title: Neuropeptide Y modulation via protein arginine methyltransferase in cerebral ischemia

Authors: *H. POSSOIT[1], A. COUTO E SILVA[2], C. Y.-C. WU[3], C. T. CITADIN[2], R. H.-C. LEE[3], H. LIN[3];
[2]Cell. Biol. and Anat., [3]Neurol., [1]LSU Hlth. Sci. Ctr. Shreveport, Shreveport, LA

Abstract: According to the American Heart Association, there are more than 350,000 Americans affected by cardiopulmonary arrest (CA) each year. CA is one of the leading causes of morbidity and mortality for those affected. No neuroprotective therapies are currently available to decrease neuronal cell damage and improve the cognitive outcomes of those affected; therefore, our goal is to identify novel targets that provide potential neuroprotective therapies.
The consequences of CA triggers the enhancement of the sympathetic nervous system (SNS) due to current resuscitation protocols (i.e. epinephrine) and the body's general autoregulation to raise blood perfusion back to nominal levels. This phenomenon is characterized by hypoperfusion (low blood perfusion). The onset of hypoperfusion can be from hours to days, which is the thought to be the primary cause of neuronal cell death and learning/memory deficits after ischemia. Additionally, the release of neuropeptide Y (NPY) during hypoperfusion induces potent vasoconstriction that is 100-fold more potent than neuronal-derived vasoactive substances to further incur more ischemic damage. We have discovered that the number of normal neurons was decreased in the CA1 region of the hippocampus 7 days after asphyxial cardiac arrest (ACA)(global cerebral ischemia) (527±19) (via H&E and fluoro-jade C staining), while inhibition of NPY release from pre-synaptic sympathetic nerves via peptide YY (PYY)3-36 (NPY2R agonist) inhibited neuronal degeneration (881.5±21.6) of normal neurons. Additionally, post-treatment with PYY3-36 enhanced cortical CBF (56.90±4.48%) (detected via two-photon) 24hrs after ACA as compared to ACA-treated rats (-33.20±2.65%). However, the regulation of NPY is multi-faceted and currently unknown. We propose that protein arginine methyltransferases (PRMTs, known methylators of molecular targets) can be possible modulators of NPY. Both NPY and PRMT 8 (specific PRMT in the brain) mRNA expression was decreased at days 3 and 7 after ACA as compared to control. These results suggest that NPY may be a modulator of PRMT8 activity, in turn, have cellular and/or physiological consequences during ischemia.

Title: Phytoestrogen isoflavone increases brain aspartate levels and protects against ischemic stroke injury

Authors: S. KHANNA[1], S. C. GNYAWALI[2], H. HARRIS[2], M. BALCH[2], S. NIMJEE[2], ***C. L. RINK**[2];
[1]Indiana Ctr. for Regenerative Med. and Engineerings and Dept. of Sur, Indiana Universty, Indianapolis, IN; [2]Neurolog. Surgery, The Ohio State Univ. Wexner Med. Ctr., Columbus, OH

Abstract: Glutamate Oxaloacetate Transaminase (GOT) metabolizes glutamate by transferring the amino group from glutamate (Glu) to oxaloacetate, forming aspartate (Asp) and the 5-carbon TCA cycle intermediate alpha-ketoglutarate in the process. We previously reported that transamination of Glu by GOT protects against ischemic stroke-induced injury by (1) clearing neurotoxic extracellular Glu from the ischemic site and (2) generating TCA cycle intermediates that sustain cellular respiration for neural cells in the absence of glucose. Therapeutic strategies that up-regulate GOT expression for protection against ischemic stroke are therefore of interest. We recently identified that phytoestrogen isoflavone Biochanin A (BCA) induces expression of glutamate metabolizing GOT in stroke-affected brain. Against that background, here we sought to determine the effect of BCA treatment on brain metabolites during cerebral ischemia *in vivo* using ^{1}H magnetic resonance spectroscopy. C57BL/6 mice received daily intraperitoneal injections of placebo vehicle or BCA (5 and 10 mg/kg) for five weeks prior to experimental stroke. After 30 min stroke onset, and while ischemia persisted, brain metabolites in the stroke-affected hemisphere were measured *in vivo* by ^{1}H magnetic resonance spectroscopy using a high-field strength (9.4T) magnet. Compared to placebo controls, BCA treated mice had strikingly higher levels of aspartate, the product of GOT transamination in stroke-affected brain. The ratio of aspartate to glutamate was also significantly higher in BCA treated mice as compared to placebo controls. Furthermore, BCA treatment significantly improved post-stroke sensorimotor function and attenuated stroke-induced lesion volume as measured by MRI. Taken together, outcomes support evidence that BCA induces expression and activity of GOT in brain and protects against ischemic stroke-induced injury.

Title: Dendrimer-based n-acetyl-l-cysteine therapy improves long term outcome after cardiac arrest in rat model

Authors: *H. R. MODI[1], Q. WANG[1], E. S. SMITH[3], S. J. BERTRAND[4], S. KANNAN[2], R. KANNAN[1], N. V. THAKOR[5];

Abstract: Cardiac arrest (CA) entails significant risks of coma resulting in poor neurological and behavioral outcomes after resuscitation. Significant subsequent morbidity and mortality in post-CA patients are due largely to the cerebral dysfunction that accompanies prolonged whole-body ischemia called as Post-CA syndrome (PCAS). PCAS involves strong inflammatory responses including neuroinflammation. Currently, there are no proven neuroprotective therapies to improve post-CA outcomes apart from therapeutic hypothermia. Furthermore, there are no acceptable approaches which can target neuroinflammation and lead to good neurological outcome post-CA. Moreover, delivering drugs across the blood-brain barrier to the target injured cells for treating diffuse brain injury is a major challenge. We hypothesize that dendrimer-based N-acetyl-L-cysteine (D-NAC) therapy ameliorates neuroinflammation and leads to a marked improvement in post-CA neurological outcome. We used an asphyxic CA rat model to determine the effects of D-NAC treatment. D-NAC was administer 30-minute post return of spontaneous circulation after cardiopulmonary resuscitation (ROSC). The behavioral neurologic deficit score (NDS score) was evaluated at 4, 24 and 48 hrs post-CA. Overall there was a dramatic decrease in NDS score following CA. D-NAC treatment increased NDS scores compared to the saline group. We also tested long term (7 days) behavior outcome (novel object and fear conditioning) post-CA. Seven days post-CA performance on novel object and fear conditioning tasks was evaluated. Administration of D-NAC decreases freezing behavior in a novel context suggesting a long-term cognitive effect of D-NAC.D-NAC also improve long term survival rate. In sum, acute administration of D-NAC following CA results in physiological and behavioral improvements.

Title: Effect of endogenous estrogen fluctuations on the post-ischemic innate inflammation in the brain of female rats

Authors: *V. G. REDDY[1], C. FURONES[1], J. DE RIVERO VACCARI[2], A. P. RAVAL[1]; [1]Peritz Scheinberg Cerebral Vascular Dis. Res. Laboratory, Dept. of Neurol., Univ. of Miami, Miami, FL; [2]Dept. of Neurolog. Surgery, The Miami Project to Cure Paralysis, Miami, FL

Abstract: One out of five women suffer stroke after menopause in the United States. Menopause is characterized by decline in endogenous estradiol-17 beta (E2). Estrogen is neuroprotective against ischemia; however, concern regarding the safety of E2 therapy in menopausal women has prohibited translation of this phenomenon to the clinic. In spite of these findings, women appear to be naturally protected against ischemic neuronal damage during pre-menopausal life, suggesting some estrogen-influenced neuroprotective mechanism. Thus, a better understanding of the cellular and molecular mechanisms by which endogenous estrogen fluctuations govern the female brain is required. In a recent study, we presented data suggesting a key role of estrogen in regulation of inflammasome activation in the female rat brain. Inflammasome is a multiple protein complex and is the main component of innate immune response. The aim of current study is to test effects of higher and lower levels of endogenous E2 on post-stroke inflammasome proteins. We hypothesized that prevailing higher levels of endogenous E2 during estrus would protect the brain from ischemic injury by reducing inflammasome activation. The proposed hypothesis was tested using young female (4-6 months), retired breeder (9-13 months), and age-matched male Sprague-Dawley rats. Rats were randomly exposed to transient middle cerebral artery occlusion (tMCAO; 90 min) or sham surgery. Twenty-four hours after tMCAO, brains were removed rapidly and sectioned into 1 mm slices beginning from the rostral end, and the area of infarction was visualized by incubating the sections in 1.5% TTC (2,3,5-triphenyltetrazolium chloride; Sigma Aldrich) in PBS for 15mins at 37°C. The infarct volume was measured using ImageJ software. In a separated cohort of rats, brain tissue was collected for western blot analysis 24h after tMCAO/sham surgeries. We observed significantly ($p<0.05$) reduced infarct volume in young female rats, which underwent tMCAO during estrus stage (higher levels endogenous E2) as compared to diestrus (lower levels of circulating E2). Results also showed that the brain of young rats had significantly lower infarct volume and reduced inflammasome activation in the brain as compared to reproductively senescent female rats. Our study demonstrated that endogenous E2 regulates innate immune response in the brain of female rats.

Title: Microbiota immune cell interaction: The critical role of gut metabolites in stroke

Authors: *C. BENAKIS[1], R. SADLER[2], D. FINK[3], A. LIESZ[4];
[1]Inst. For Stroke and Dementia Res., Munich, Germany; [2]Inst. for Stroke and Dementia Res., Ludwig-maximilians-Universität München, Muenchen, Germany; [3]Inst. for Stroke and Dementia Res., Munich, Germany; [4]Inst. for Stroke and Dementia Res., Univ. Med. Ctr. Munich, Munich, Germany

Abstract: Stroke is characterized by the recruitment of circulating immune cells to the injured brain. We have shown that immune cell function is modulated by the gut microbiota and migrate from the gut to the brain where they contribute to neuroinflammation and secondary brain injury [Benakis et al. *Nat. Med.* 2016, Singh et al. *J. Neurosci.* 2016]. There is accumulating evidence showing that metabolites derived from the gut microbiota influence brain diseases via the regulation of intestinal immune cell function. In particular, indole metabolites derived from the amino acid tryptophan play a crucial role in immune tolerance. Importantly, indoles are ligands of the transcription factor aryl hydrocarbon receptor (AhR), which is highly expressed in immune cells. Upon binding, AhR ligands induces T cell polarization directly or via dendritic cells (DCs).
Here, we seek to determine how the AhR pathway regulates peripheral immune homeostasis after stroke. Understanding how immune cells are modulated by gut metabolites may have strong therapeutic implications in stroke.
Cerebral ischemia was induced by the transient occlusion of the middle cerebral artery in wild-type C57Bl6 male mice leading to intestinal dysbiosis (Singh et al. *J. Neurosci.* 2016). Using 16S sequencing of the feces, we found that bacteria from the genus *Lactobacillus*—known to produce indoles—were significantly reduced in mice subjected to stroke in comparison to sham surgery. Immune cells were isolated from the intestine and analyzed by flow cytometry and by qPCR for AhR-related gene expression. We demonstrated that the AhR pathway is down-regulated after stroke in comparison to sham surgery, shown by a decreased expression of AhR-related genes (*Cyp1a1, Cyp1b1*) in DCs and T cells isolated from the gut. We tested the tolerogenic function of DCs in mice with AhR-deficient DCs ($CD11c^{cre}xAhr^{f/f}$). We identified that the intestinal frequency of the DC1 subpopulation of DCs was AhR-dependently upregulated after stroke, and correlated with an increased expression of regulatory (Foxp3+) T cells and a

concomitant decrease of Th17 cells in the mesenteric lymph nodes.
These results are the first to link stroke-induced dysbiosis and the AhR pathway as immunomodulators of DCs and T cells. Findings derived from this study may allow for the identification of microbial metabolites-based therapies to alleviate the neuroinflammatory response to stroke.

Title: Altered sensorimotor pathways post unilateral subcortical stroke

Authors: *H. KARBASFOROUSHAN[1], J. P. DEWALD[2];
[2]Physical Therapy and Human Movement Sci., [1]Northwestern Univ., Chicago, IL

Abstract: Previous stroke brain imaging studies have frequently reported the damage to the corticospinal tract in individuals with subcortical stroke. However, less is known about other altered sensorimotor pathways. One reason for this lack of knowledge is that the previous studies have only investigated the morphological changes in the brain, where majority of descending and ascending brain pathways mostly overlap, while these pathways only delineate from each other in the brainstem. The goal of this study was therefore to use high resolution anatomical MRI and DTI of brainstem to identify the altered sensorimotor pathways post chronic unilateral stroke. Twenty individuals with chronic (>1yr) unilateral subcortical stroke and 20 age-matched controls were recruited to this study. The MRI scans were collected on a 3T Siemens Prisma magnetic resonance scanner. High resolution T1-weighted anatomical and diffusion weighed images were obtained from whole brain and brainstem. T1 weighted anatomical images were acquired with 0.8 x 0.8 x 0.8 isotropic resolution, TR = 2.3s, TE 1 = 1.86 ms, TE 2 = 3.78 ms, field of view (FOV) = 256 x 256 mm. Diffusion weighted images were acquired using spin-echo echo-planer imaging with the following parameters: TR = 3620 ms; TE = 68.40 ms; FOV = 222 x 222 mm^2; 8 B0 images and 68 diffusion directions at B = 1000 s/mm; flip angle = 90°; matrix size = 150 x 150; voxel size = 1.5 mm isotropic; number of slices = 108. Voxel-wise statistical analysis of the DTI data was carried out using Tract-Based Spatial Statistics (TBSS) in FSL. All subjects' FA images were aligned to the standard MNI template and the mean FA image was created and

thinned to create a mean FA skeleton representing the centers of all tracts. Each subject's aligned FA map was then projected onto this skeleton, resulting in each subject's brainstem skeletonised FA image. Randomise analysis with 50,000 permutations was then run on brainstem skeletonized FA between individuals with stroke compared to controls to identify the tracts with significant change in white matter integrity. The stroke patients compared to controls showed significant decrease in white matter integrity (FA) of lateral corticospinal tract, lateral reticulospinal tract and medial longitudinal fasciculus of lesioned hemisphere. Furthermore, our results indicated a significant increase in the white matter integrity of medial reticulospinal tract of non-lesioned hemisphere which projects ipsilaterally to the paretic side of body.

Title: A pilot study to understand the differences in the cortical activation between healthy controls and individuals with brain injury

Authors: *K. K. KARUNAKARAN[1,2,3], N. EHRENBERG[1,3], K. J. NOLAN[1,3];
[1]Kessler Fndn., West Orange, NJ; [2]Biomed. Engin., New Jersey Inst. Of Technol., Newark, NJ; [3]Children's Specialized Hosp., New Brunswick, NJ

Abstract: Brain injury is one of the leading causes of motor deficits in children and adults. It often results in lower extremity motor control and balance impairments due to cortical changes induced by injury. The objective of this study is to understand the differences in cortical activation in the cortical motor control network (bilateral supplementary motor area, secondary somatosensory cortex, premotor areas, and primary motor cortex) using Functional Near Infrared Spectroscopy (fNIRS) while performing lower extremity dynamic tasks (ex: ankle dorsiflexion and plantarflexion) in healthy controls (HC) and individuals with Brain Injury (BI). The outcome measures will include block averaged hemodynamic response (HDR) due to changes in oxygenated hemoglobin (O-Hb) and deoxygenated hemoglobin (DO-Hb) levels, and laterality index differences between the hemispheres' activation during the task in HC and BI. The results showed asymmetric activation of the cortical motor control network between the lesioned and non-lesioned hemispheres in BI compared to HC. Furthermore, increased neural activity was observed in the contralesional hemisphere in BI during the task compared to HC.

Title: Biomechanical and electrophysiological assessment of the effect of botulinum neurotoxin injection in stroke survivors with spastic hypertonia

Authors: Y.-T. CHEN[1], C. ZHANG[2], E. MAGAT[3], M. VERDUZCO-GUTIERREZ[3], G. E. FRANCISCO[3], P. ZHOU[3], Y. ZHANG[2], ***S. LI**[3];
[1]Physical Med. and Rehabil., UTHealth, Houston, TX; [2]Univ. of Houston, Houston, TX; [3]Univ. of Texas Hlth. Sci. Ctr. - Houston, Houston, TX

Abstract: Spasticity is a common and disabling motor consequence after stroke. Botulinum toxin (BoNT), which acts on the neuromuscular junction, is considered as the first-line treatment for focal spasticity management. The study aimed to quantitatively assess biomechanical and electrophysiological effects of BoNT injection. 9 stroke subjects (Age: 52.4 ± 10.3 yrs; 3 women) received 100 units of ona- or inco-BoNTA to the biceps muscle. Elbow flexor spasticity was 1^+ ~ 2 on the Modified Ashworth Scale (MAS). Clinical and biomechanical assessment and electrophysiological assessment with maximum evoked action potential (M-wave) were measured before (Pre-injection), three weeks (3-wk) and three months (3-mon) after the injection. A computerized passive stretching was applied to the elbow flexors. Reflex torque (neural component of spasticity) of the elbow flexors was quantified as the difference between the baseline torque at 5°/second of stretching (indicative of passive muscle stiffness) and the peak torque at 100°/second of stretching. MAS decreased to 1~1^+ at the 3-wk visit and then returned to the pre-injection level at the 3-mon visit. The peak torque reduced at 3-wk (6.5 ± 1.0 Nm) from the pre-injection value (8.1 ± 1.1 Nm) and then returned at 3-mon (8.0 ± 1.3 N-m) after injection, ($p<0.05$). A similar pattern of reduction in the reflex torque was observed (pre-injection: 3.8 ± 0.7 Nm; 3-wk: 2.6 ± 0.5 Nm; 3-mon: 3.5 ± 0.7 Nm; $p = 0.052$). Similarly, the M-wave value reduced at 3-wk (6.3 ± 0.5 mV) and returned at 3-mon after injection (9.1 ± 1.1 mV) as compared to the pre-injection value (9.1 ± 0.8 mV) ($p<0.05$). Notably, both the M-wave and reflex torque reduced about 30% at the 3-wk visit. Nonetheless, the baseline torque (Pre-injection: 4.3 ± 0.6 Nm; 3-wk: 4.0 ± 0.5 Nm; 3-mon: 4.5 ± 0.9 Nm; $p = 0.4$) was not affect by BoNT injection. Interestingly, the baseline torque, as percent of total peak torque, inversely correlated with the reflex torque reduction at the 3-wk visit ($r = - 0.78$, $p = 0.01$), i.e., the higher the percent of passive muscle stiffness, the less the effect of BoNT. Our results provide

electrophysiological evidence of BoNT effects and its relation to the baseline passive muscle stiffness.

Title: Determine the usage of indirect motor pathways following a hemiparetic stroke: A pilot study

Authors: *Y. YANG[1], R. TIAN[1], M. CUMMINGS[1], C. H. E. Y. HOGENHUIS[1,2], J. DEOL[1], J. DROGOS[1], J. P. A. DEWALD[1];
[1]Physical Therapy and Human Movement Sci., Northwestern University, Feinberg Sch. of Med., Chicago, IL; [2]Delft Univ., Chicago, IL

Abstract: A hallmark impairment after hemiparetic stroke is a loss of independent joint control resulting in abnormal co-activation of shoulder abductor and elbow/wrist/finger flexor muscles in the paretic arm, known as the flexion synergy. The flexion synergy appears while generating shoulder abduction (SABD) torques such as when lifting the paretic arm. This is thought to be caused by an increased reliance on contralesional indirect motor pathways following damage to direct corticospinal projections. The assessment of functional connectivity between brain and muscle signals, i.e., cortico-muscular connectivity (CMC), may provide insight into such changes regarding the usage of motor pathways.
However, previous studies of CMC focused on its linear portion, i.e., EEG-EMG coherence, which mainly reflects motor command transmission via the direct corticospinal tract. In contrast to that direct pathway, indirect motor pathways involve multiple intermediate synaptic connections. Our recent neural model simulation suggested that multi-synaptic interactions of indirect motor pathways can lead to the nonlinear distortion of motor command transmission, showing nonlinear CMC.
We hypothesize that increased usage of contralesional indirect motor pathways (as when increasing shoulder abduction load) will lead to an increase of nonlinear CMC from the contralesional hemisphere. To test this hypothesis, we measured scalp EEG, EMG from the

Intermediate Deltoid (IDL) and Bicep Branchii (BIC) muscles as well as flexion synergy-induced elbow torques when eight stroke participants generated 20% and 40% of the maximum SABD torque with their paretic arm.
We computed both linear and nonlinear CMC between EEG and IDL EMG. Additionally, EMG-EMG coherence was also computed between IDL and BIC muscles. We found the greatest nonlinear CMC over the contralesional/ipsilateral hemisphere for stroke, its magnitude at the peak channel increased with SABD load. The increased IDL-BIC coherence was also shown with the higher (40%) SABD load and is associated with flexion synergy elbow torques.
These results support our hypothesis, and indicate that nonlinear CMC does provide a novel quantitative indicator for determining the usage of indirect motor pathways following a hemiparetic stroke. As such, this study may permit a precision diagnostic tool for evaluation of motor recovery after a hemiparetic stroke.

Title: Are resting state EEG measures longitudinally associated with spontaneous neurological recovery early post-stroke? A prospective cohort study

Authors: M. SAES[1], S. B. ZANDVLIET[1], A. S. ANDRINGA[1], *C. G. M. MESKERS[1,2], A. DAFFERTSHOFER[3], F. C. T. VAN DER HELM[4,2], E. E. H. VAN WEGEN[1], G. KWAKKEL[1,2]; [1]Dept. of Rehabil. Med., Amsterdam Univ. Med. Ctr., Amsterdam, Netherlands; [2]Dept. of Physical Therapy and Human Movement Sci., Feinberg Sch. of Medicine, Northwestern Univ., Chicago, IL; [3]Dept. of Human Movement Sciences, Fac. of Behavioural and Movement Sci., Vrije Univ. Amsterdam, Amsterdam, Netherlands; [4]BioMechanical Engin. Department, Fac. of Mechanical, Maritime and Materials Engin., Delft Univ. of Technol., Delft, Netherlands

Abstract: Stroke has been shown to result in increased low frequency oscillations, depending on stroke severity. The time course of cortical activation expressed by EEG-based power spectral density (PSD) measures and its relation with clinical measures during recovery after a first ever ischemic stroke is unclear and may reveal underlying mechanisms of spontaneous neurological recovery (SNR). First, we aimed to investigate the time course of cortical reorganization as revealed with PSD measures during awake rest in the first six months post stroke. Second, we

aimed to investigate development of PSD in relation to global neurological and motor recovery. Resting state 62-channel EEG was measured serially in 41 patients after a first-ever ischemic stroke within 3 and at 5, 12 and 26 weeks post-stroke. PSD measures Delta-Alpha Ratio (DAR), Brain Symmetry Index (BSI) and directional BSI (BSIdir) were derived. Additionally, DAR was calculated per hemisphere, and BSI was calculated per frequency band. At the same measurement moments the National Institutes of Health Stroke Scale (NIHSS) and Fugl-Meyer motor assessment of the upper extremity (FM-UE) were measured as reflection of SNR. The time course of PSD measures, as well as their longitudinal association with NIHSS and FM-UE within- and between-subjects were analysed using linear mixed models. All investigated PSD measures showed a gradual decrease over time post-stroke. They changed within and beyond the time window of SNR. A within- and between-subject association with NIHSS was found for DAR_{AH} (ß:0.16, p<0.01; ß:0.36, p<0.01) and $BSIdir_{Delta}$ (ß:0.67E-2, p<0.01; ß:0.02, p<0.01). This means that a decreasing DAR_{AH} or $BSIdir_{Delta}$ over time within a patient or a lower value compared to other patients is congruent with reduced neurological deficits. $BSIdir_{Delta}$ also demonstrated within- and between-subject associations with FM-UE (ß:-0.12E-2, p=0.01; ß:-0.18E-2, p=0.01). DAR_{AH} showed to be increased in patients who did not show recovery, compared to patients who did show recovery. DAR_{AH} and $BSIdir_{Delta}$ are suggested to reflect global severity of neurological deficits in the brain. Only $BSIdir_{Delta}$ probably reflects motor impairments. It was concluded that DAR_{AH} and $BSIdir_{Delta}$ potentially have added value in individual prediction of recovery, reflecting SNR over time within a subject and might have added value in distinguishing between patients with different recovery patterns.

Title: Brain wide circuit dynamics of post-stroke recovery induced by optogenetic stimulation

Authors: *S. VAHDAT[1], A. V. PENDHARDAR[2], S. HARVEY[2], T. CHIANG[2], H. LEE[3], M. Y. CHENG[2], J. LEE[4], G. K. STEINBERG[2];
[1]Dept. of Neurol. and Neurolog. Sciences, and Neurosurg., [2]Dept. of Neurosurg., [3]Dept. of Neurol. and Neurolog. Sci., [4]Dept. of Neurol. and Neurolog. Sciences, and Neurosurgery, and Bioengineering, Stanford Univ., Stanford, CA

Abstract: Background: Post-stroke optogenetic pan-neural stimulation has been shown to promote functional recovery. However, the cellular and circuit mechanisms underlying such recovery remain unclear. Elucidating critical neural circuits involved in post-stroke recovery will be important for optimal translation of neuromodulation for stroke therapy. Here we used a technique called optogenetic functional magnetic response imaging (ofMRI) to examine brain-wide circuit reorganization induced by optogenetic stimulation treatment (OST) following ischemic stroke in mice.
Method: We performed ofMRI experiments targeting ipsilesional M1 (iM1) layer V excitatory neurons in mice by injecting AAV1-CamKIIa-ChR2-eYFP viral vector. Global brain circuit activation using ofMRI were performed on pre-stroke and post-stroke days (PD) 3 (prior to OST), 15 and 29. Sensorimotor rotating beam tests were conducted one day prior to ofMRI. Mice underwent transient middle cerebral artery occlusion (intraluminal suture model, 30 minutes). Mice were balanced into two groups based on their infarct: stim group (stroke mice received 10 consecutive days of 10Hz iM1 OST), and no stim group (stroke mice without OST). By comparing the areas of brain activation between the stim and no stim groups at different time points, we identified key brain circuits that recovered by the effect of OST. We also performed western blot to examine the expression of plasticity marker GAP43.
Result: Our results show that 1) Optogenetic excitatory neuronal stimulation in iM1 promotes motor performance after stroke (n=9 per group). 2) At pre-stroke, iM1 stimulation activates expected network including the ipsilateral M1, M2, S1, striatum, and thalamus, and the contralateral M1 and cerebellum. 3) On PD3, all mice exhibit a depressed response throughout the brain after iM1 stimulation. 4) On PD15, ipsilesional thalamus and S1 circuits are significantly recovered and strengthened by OST. Moreover, restoration of thalamic activation is correlated with behavioral recovery in the stim group. 5) On PD15, iM1 stimulated mice exhibited higher level of plasticity marker (GAP43) in the ipsilesional thalamus (n=5 per group). 6) On PD29, iS1 activation remains significantly higher in the stim compared to the no stim group.
Conclusion: Overall, our findings indicate that restoration of cortico-thalamic projections play an important role in stimulation-induced recovery at early phase post-stroke, while sustained strengthening of ipsilesional cortico-cortical connections may be critical in the later phase of recovery. Thus our findings revealed key circuits underlying stimulation-induced post-stroke recovery.

Title: Effects of acetyl l-carnitine on the dendritic morphology of hippocampal pyramidal neurons of the CA1 and CA3 region of female pubic rats denervated sensorially at birth

Authors: *E. D. CASTILLO LÓPEZ[1,2], A. RODRÍGUEZ-RUBÍ[3], D. LÓPEZ-GUADALUPE[3], D. LÓPEZ-MORALES[3], R. A. VAZQUEZ-ROQUE, SR[4], G. FLORES[5], U. QUIRÓZ-LÓPEZ[2];

Autonoma de Puebla / Inst. de Fisiologia, Puebla, Mexico

Abstract: The onset of puberty and reproduction are processes that are regulated by the neuroendocrine axis hypothalamus-pituitary-gonads. In addition to this axis, there is a neural pathway between various structures of the CNS and the gonads, which contributes to fine regulation to these processes. Sensory innervation is one of the components of the neural pathway. We previously reported that in the newly born female rat sensory denervation induced by the administration of capsaicin (CAPS) causes a delay in the onset of puberty and decreased fertility. We have also shown that in the adult female rat in the estrus phase an increase of dendritic spines in pyramidal CA3 neurons of the left side of the hippocampus is observed. On the other hand, there are substances that can stimulate mechanisms that lead to neuroprotection, reinnervation and neuronal plasticity, such as acetyl l-carnitine (ALCAR) which has aroused great interest as an alternative in neurodegenerative diseases. The objective of this work is to analyze the effects of the administration of ALCAR on the dendritic morphology of pyramidal neurons of the CA1 and CA3 regions of the hippocampus of rats denervated at birth with capsaicin. Eighteen female rats newly born from strain CII-ZV were used, which were equally divided into three groups: one group received a dose of 50 mg / kg of capsaicin and from day 21 was administered saline solution i.p. (Group: CAPS + VH), another group was also administered the same dose of capsaicin and from day 21 of age and until their sacrifice they received a daily dose of 50 mg / kg of ALCAR i.p. (Group: CAPS + ALCAR). A third group received only ALCAR (Group: ALCAR). When the animals presented the first vaginal estrus, perfusion was performed and the brains were dissected for the Golgi Cox staining technique and the morphological analysis of CA1 and CA3 neurons of the hippocampus under the Sholl technique. The analysis of the dendritic morphology of the CA1 region of the hippocampus of the CAPS + ALCAR rats showed a significant increase in dendritic length and arborization and the number of order in comparison to the VH + ALCAR and CAPS + VH groups. On the other hand, in the CA3 region, there was only a significant increase in dendritic arborization in the CAPS + ALCAR group in contrast to the other two groups. Our results allow us to suggest that in the sensed denervated rat at birth, the systemic administration of acetyl L-carnitine induces changes in the dendritic morphology in pyramidal neurons of CA1 and CA3 of the hippocampus that probably regulates neuroendocrine and / or neural mechanisms that participate in the regulation of reproduction.

Title: Persistent hydrocephalus and activated microglia drive the spatial memory decline after intraventricular hemorrhage in rodents

Authors: *K. KAMAL[1], T. BINYAMIN[1], J. '. KEITER[1], A. R. VERGARA[1], A. IZADI[1], K. ONDEK[1], R. F. BERMAN[1], F. R. SHARP[2], G. G. GURKOFF[1], B. WALDAU[1];
[1]Neurolog. Surgery, Univ. of California, Davis, Davis, CA; [2]Departments of Neurol., Univ. of California, Davis, Sacramento, CA

Abstract: Intraventricular hemorrhage (IVH) can result in significant cognitive deficits and spatial memory impairments that can prevent over half of IVH patients from returning to work after recovery. The mechanism of this memory decline, however, is incompletely understood. To understand the role of mechanical trauma caused by rapid ventricular expansion versus the presence of blood components, such as thrombin, in IVH deficits, we developed a rodent model of IVH along with controls using 40 male Sprague-Dawley rats. IVH was induced by injecting 200 μL of autologous arterial blood into the animals' ventricles. The IVH animals' spatial memories were then assessed along with sham (no injection), vehicle control (200 μL aCSF), and intraventricular thrombin (IVT) (20 U thrombin in 5 μL aCSF) animals using Morris water maze. The IVH group performed worse on this spatial memory task compared to all other groups, and significantly worse than the sham group ($p=0.04$), indicating that ventricular expansion and presence of blood components both contribute to memory deficits. Based on MRI results, the IVH group was also the only group that developed persistent hydrocephalus. Contrary to our hypothesis that the cognitive deficits of IVH are due to decreased hippocampal neurogenesis, we did not find any statistical difference in the numbers of dentate gyrus progenitor cells (labeled with BrdU and DCX) nor neurons (labeled with NeuN) between the different groups. The number of microglia (labeled with Iba1) was also compared among the groups using stereology and found to be not statistically different. The microglia in IVH and vehicle control animals, however, were found to have significantly lower fractal dimension ($p<0.01$) and higher lacunarity ($p<0.01$) numbers compared to those of sham animals, indicating a more activated

state, likely caused by the mechanical trauma. Based on our results, microglial activation and hydrocephalus seem to be the drivers of spatial memory deficit after intraventricular hemorrhage.

Title: Stepwise regression modeling of impairments contributing to reaching function in chronic stroke

Authors: *G. C. BELLINGER[1], M. D. ELLIS[2];
[1]Interdepartmental Neurosci. (NUIN), [2]Dept. of Physical Therapy and Human Movement Sci., Northwestern Univ., Chicago, IL

Abstract: Chronic stroke survivors demonstrate a myriad of impairments impacting reaching function including flexion synergy, passive range of motion limitations, spasticity (i.e., hyperactive stretch reflexes), and weakness. Flexion synergy results in loss of independent joint control due to the abnormal coupling of shoulder abductors with elbow, wrist, and finger flexors. The relative and concurrent contributions of each of these underlying factors has not yet been quantitatively explored in depth. 34 individuals (23 males, 58.3 ± 10.8 years old) with chronic stroke (11.8 ± 8.3 years post-stroke) participated in the study. The upper extremity Fugl-Meyer Motor Assessment scores (26 ± 7) ranged from 15 to 49 indicating moderate to severe generalized levels of impairment. Reaching function was measured with a robotic device and defined as maximum reaching distance against gravity. The regressors were quantified using kinematics and electromyography (EMG). A stepwise regression analysis was implemented to investigate the constitutive elements of reaching function. The regressors included: 1) maximal shoulder abduction and elbow extension strength normalized to the unaffected side, 2) spasticity-related biceps activation measured as the increase in EMG occurring after elbow extension onset during reaching at a standardized load, 3) flexion synergy that was measured as the highest abduction load at which the participant could successfully lift the arm and reach two standardized targets, and 4) passive range of motion at the elbow. All regressors were z-scored and MATLAB was used to find an optimized regression model with an R-squared of 0.390 ($p < 0.001$). Interestingly, the model only included the flexion synergy emergence threshold with a regression coefficient of 0.217 and standard error of 0.057 ($p < 0.001$). Reaching function (mean ± SD; 0.608 ± 0.358) was significantly correlated with flexion synergy emergence threshold

(0.310 ± 0.244, r = 0.634, p = 0.001), shoulder abduction strength (0.557 ± 0.193, r = 0.390, p = 0.023), and elbow extension strength (0.437 ± 0.186, r = 0.407, p = 0.017). Passive range of motion, active flexor spasticity, and flexion synergy takeover threshold did not significantly correlate with reaching function. The results of the stepwise regression analysis indicate that impairments such as weakness, flexor spasticity, and passive range of motion limitations may not contribute to reaching dysfunction to the same extent as flexion synergy. The findings of this study suggest flexion synergy impairment may be the primary therapeutic target when attempting to restore reaching function in chronic moderate to severe stroke.

Ctr., Temple Sch. of Med., Philadelphia, PA

Abstract: Bidirectional protein trafficking is essential for neurons to exchange information regarding the health of their cell soma and distal axons and thus coordinate survival versus degeneration decisions for these two subcellular locations. Healthy neurons transport the survival factor NMNAT2 anterogradely to maintain distal axon integrity, but simultaneously supply DLK, a kinase that is critical for sensing distal axonal damage and subsequent retrograde axon-to-soma signaling. Here, we report that this ‘trust but verify’ system is controlled by a single palmitoyl acyltransferase, ZDHHC17, which directly binds and palmitoylates both DLK and NMNAT2. In the healthy optic nerve *in vivo*, ZDHHC17-dependent palmitoylation is essential for NMNAT-dependent distal axon integrity, while following optic nerve injury, ZDHHC17-

dependent palmitoylation of DLK is critical for retrograde injury signaling and subsequent somal degeneration. Similar ZDHHC17-dependent palmitoylation controls somal and axon integrity in cultured sensory neurons, and at the molecular level we identify specific motifs in DLK, NMNAT2 and ZDHHC17 that are essential for this mutual, coordinated regulation. This previously unappreciated mechanism enables neurons to monitor and respond to changes in axonal health and coordinate responses in both distal axons and neuronal cell bodies.

Title: Genetic deletion of fractalkine receptor promotes hematoma resolution in the acute-phase of intracerebral hemorrhage via Nrf2/HO1 signaling pathway

Authors: *X. LAN[1], X. HAN[2], A. QIAN[2], J. WANG[3];
[1]Johns Hopkins Med., Baltimore, MD; [2]Johns Hopkins Sch. of Med., Baltimore, MD;
[3]Anesthesiology/Critical Care Med., Johns Hopkins Univ., Baltimore, MD

Abstract: Intracerebral hemorrhage (ICH) remains the most lethal type of all strokes. Exploring the endogenous mechanism of hematoma removal is critical in ICH study. Fractalkine receptor (Cx3cr1), expressed in microglia, participates in microglia migration and recruiting. Nuclear factor erythroid 2-related factor 2 (Nrf2)/ heme oxygenase-1 (HO-1) is an important pathway to protect against acute brain injuries by exerting antioxidant and regulating microglia phagocytosis. Our study is to investigate the role of Cx3cr1 after ICH and explore the mechanisms of Cx3cr1 in hematoma absorption. We subjected wild-type (WT), $Cx3cr1^{gfp/+}$ and $Cx3cr1^{gfp/gfp}$ [knockout (KO)] mice to ICH and assessed the short-term outcomes. To study the role of Cx3cr1 in microglia function, we labeled PKH26 dye to red blood cells (RBCs) from WT mice and then injected them into striatum. Microglia engulfing RBCs was observed under fluorescence microscope. We then studied the microglia activation and neuroinflammation after ICH. To further measure the relationship between Cx3cr1 and Nrf2/HO-1 signaling pathway, we examined the HO-1 level by immunostaining and western blotting. We then evaluated Nrf2 activation and nuclear translocation *in vivo* and in primary microglia. Lastly, we used a

phagocytosis PCR array to determine the key factor that regulates microglia phagocytosis after ICH. Our results showed that: **1)** Cx3cr1 deletion reduced injury volume and brain edema on day 3 post-ICH. It also decreased neurologic deficit score in 24-point evaluation test and increased the time mice were able to remain on a suspended wire. **2)** Cx3cr1 deletion suppressed the hemoglobin content after ICH and Cx3cr1-depleted microglia exhibited stronger phagocytosis ability in RBC-injection mouse model. **3)** Microglia were more activated in KO mice on day 3 post-ICH with a reduction of proinflammatory cytokines and upregulation of antiinflammatory markers. **4)** Cx3cr1 deletion increased nuclear Nrf2 expression both *in vivo* and *in vitro*. Moreover, Cx3cr1 deletion promoted more HO-1 to express in microglia than in astrocytes, indicating that Cx3cr1-mediated inhibition of the microglial HO-1 might be important in hematoma resolution. **5)** PCR array showed that the gene for the receptor for advanced glycation end products (RAGE) was suppressed in KO mice after ICH. In conclusion, we found that Cx3cr1 deletion contributes to accelerating hematoma clearance by enhancing microglial phagocytosis ability and promoting polarization of microglia antiinflammatory phenotype via Nrf2/HO-1 signaling pathway. The results suggest that targeting on Cx3cr1 might represent a new direction for developing methods of ICH treatment.

Title: Characterizing smoldering inflammation in progressive MS by a multimodal approach combining CSF proteomics and quantification of slowly expanding/ evolving lesions

Authors: *I. LEAF, K. FERBER, D. P. BRADLEY, S. BELACHEW, E. CAHIR-MCFARLAND;
Biogen, Cambridge, MA

Abstract: Development of successful treatments for progressive multiple sclerosis (MS) is extremely challenging, as molecular mechanisms driving pathophysiology at this stage are poorly understood partially due to the failure of current animal models to recapitulate relevant biology. Therefore, it is important to focus on **human biology** in understanding disease-associated mechanisms in progressive MS.
Here we apply a multimodal approach to investigate molecular mechanisms contributing to disease progression in MS by integrating CSF proteomics with radiological measurements of chronic active white matter lesions.
In MS patients, smoldering inflammation driving chronic white matter lesion activity in the

absence of ongoing active inflammation has been demonstrated to represent a pathological hallmark of progressive forms of MS and can be measured by conventional Magnetic Resonance Imaging (MRI) as slowly expanding/evolving lesions (SELs). The number and volume of SELs in progressive MS patients were shown to be significantly higher than in relapsing form of MS but biological mechanisms driving these processes are unclear. To elucidate the underlying biology, we applied an unbiased mass-spectrometry profiling approach and quantified 1,500 proteins in the Cerebrospinal Fluid (CSF) in SPMS patients (n = 34) with MRI measurements and SEL detection. To identify protein signatures and pathways associated with increased SEL burden and associated tissue loss, we performed a multi-variate analysis with disease progression and disability measurements (clinical: EDSS, 9PHT, T25FW) and SEL measurements (SEL number/volume and change in T1 signal intensity in SELs).
This work will help define protein signatures and pathways contributing to disease progression and allow selection of relevant *in vitro* and *in vivo* translational models that in turn will provide support for drug and biomarker discovery and development in progressive MS.

Title: Increased motoneuron excitability in a rabbit hypoxia ischemia model of cerebral palsy

Authors: P. STEELE[1], C. F. CAVARSAN[2], *K. A. Q. QUINLAN[2];
[1]George and Anne Ryan Inst. for Neurosci., UNIVERSITY OF RHODE ISLAND, KINGSTON, RI; [2]George and Anne Ryan Inst. for Neurosci., Univ. of Rhode Island, KINGSTON, RI

Abstract: Cerebral palsy (CP) is caused by a variety of factors related to early brain damage, resulting in permanently impaired motor control, marked by muscle stiffness and spasticity. To study mechanisms of motor dysfunction, we use the rabbit hypoxia-ischemia (HI) model of developmental injury at 79% pregnancy (E25). After HI, kits are born with deficits including muscle stiffness and motor deficits, though there is a range in severity. At birth kits were classified as severely affected, mildly affected, or unaffected based on modified Ashworth scores. Whole cell patch clamp of motoneurons was performed on lumbar and cervical spinal cord slices. Properties of the motoneurons from kits severely affected by HI were significantly different from control and mildly affected kits. Specifically, using a multivariate analysis we

found severely affected motoneurons had depolarized resting membrane potential (-52.8 +/- 5.6mV vs -60.3 +/-6.6mV in control), higher frequencies of firing (129Hz +/- 23Hz instantaneous maximum firing rate in severe vs 98Hz +/-29Hz in control), more sustained firing on the downslope of current ramps (control motoneurons fire less on downslope: the difference in current between onset and offset of firing is 191pA +/- 160pA vs 84pA +/- 63pA in severe). While the most dramatic differences were observed in motoneurons from severely affected kits, mildly affected and unaffected motoneurons also showed some variation from the motoneurons from sham control kits (n=8 severe, n= 10 mild, n= 11 unaffected, n = 8 sham).

Title: Longitudinal multimodal mapping of neural activity and blood flow reveals neurovascular dissociations in an awake mouse model of microinfarcts

Authors: *F. HE[1], C. SULLENDER[1], H. ZHU[1], T. A. JONES[2], C. XIE[1], A. DUNN[1], L. LUAN[1];
[1]Biomed. Engin., The Univ. of Texas at Austin, Austin, TX; [2]Psychology, Univ. Texas Austin, Austin, TX

Abstract: Brain functions and dysfunctions involve complex interactions between neuronal and other cellular and vascular activities at diverse spatiotemporal scales. This vast complexity demands novel technologies that are able to simultaneously resolve multifaceted brain activities at sufficient spatiotemporal resolutions and to longitudinally track their evolution over a long span of time. Here we demonstrate the development of a longitudinal multimodal neural platform that enables simultaneous mapping of neural activity and cerebral blood flow (CBF) in the same behaving brain. This multimodal neural platform combines intracortical neural recording using the ultra-flexible nanoelectronic threads (NETs) that permit exceptional tissue-compatibility, and a wide-field imaging system capable to quantifying both CBF and inducing targeted photothrombosis at controlled locations, size and onset time. We demonstrate the application of this multimodal neural interface in a mouse model of microinfarcts, for which the microscopic ischemic injuries are often associated with vascular dementia but are too small in size to be

detected using conventional techniques. Through the ability to simultaneously track the underlying neuronal and hemodynamic changes from the acute to the chronic phase, we are able to reveal their distant pathological evolutions. In the acute sections following the awake induction of microinfarcts, we observe that neurovascular coupling weakens with the level of ischemia and that short-lasting neuronal bursting precedes peri-infarct depolarizations. The neurovascular dissociation becomes the most severe at the sub-acute phases, during which reperfusion and hyperperfusion in the occluded arterioles and nearby tissue occur, but neural activity remains significantly suppressed. Furthermore, while restoration of CBF occurs promptly at a similar time, the deficits in neural activity are long-lasting, the magnitude and duration of which are injury dependent. These observed discrepancies in neural and hemodynamic responses alert the interpretation of neuroimaging that infer neural activity from hemodynamic responses and demonstrates the need for direct neurological measurements to evaluate brain impairment and recovery.

Children's hospital, Hanoi, Viet Nam; [5]Dept. of Womens and Children's Hlth., Uppsala Univ., Uppsala, Sweden

Abstract: Aim: To evaluate if a matress made of phase changing material (PCM) can be used for transportation and during regular therapeutic hypothermia of asphyxiated newborns in need of cooling. And to evaluate if the cooling have neuro impact on child. Methods: A study to evaluate using rectal temperature (Tr) and measuring deviations from normal temperature range, by using the phase changing material mattress (PCM-melting point 32ºC). Hypothermia was induced with in the first 6h after birth and maintained for 72hrs by the PCM mattress then reheating according to international hypothermia guidelines. (target Tr:33-35 ºC). Results: A total of 52 babies were cooled using PCM between September 2014 and May 2016. The mean gestational age 39.25 ±

1.09 weeks. The mean temperature at initiation of cooling was 35.54 ± 1.14°C. The median time to reach the target temperature was 2±1.63 hours. The mean ± SD temperature during the cooling phase was 33.95 ± 0.2°C. Throughout the cooling phase, the target temperature range (33.5-34.5°C) was maintained in 80% of the time. Rate of rewarming is 0.5±0.14°C/hour. Conclusion: Phase changing maternial can be used as an effective cooling method. Though not a servo-controlled system, it is easy to induce hypothermia, maintain target temperature and rewarm babies in a slow and controlled manner using PCM without need for frequent changes, and minimum risk of skin injury. There is also a potential for PCM to be used for transport.

Title: Exploring the effects of oxygen-glucose deprivation in a 3D cortical microtissue model

Authors: *R. M. MCLAUGHLIN[1,2], J. SEVETSON[1,2,3], L. L. LIVI[4], D. HOFFMAN-KIM[2,3,4,5];
[1]Dept. of Neurosci., [2]Carney Inst. for Brain Sci., [3]Ctr. for the Advancement of Predictive Biol., [4]Dept. of Mol. Pharmacology, Physiology, and Biotech., [5]Ctr. for Biomed. Engin., Brown Univ., Providence, RI

Abstract: Stroke is a leading cause of death and disability worldwide. The most common form of stroke is ischemic stroke, caused by a blockage of blood flow to a specific part of the brain. Treatments for ischemic stroke include clot removal and prevention of clot reformation, but there is a lack of pharmaceuticals to prevent secondary injury during reperfusion and/or promote regeneration. Here our goal was to develop an *in vitro* model of ischemic stroke. We explored the effects of oxygen-glucose deprivation (OGD) on morphology and function in our previously established, high-throughput compatible, 3D, *in vitro* cortical microtissue model (Dingle 2015). Additionally, we looked at oxygen (OD) and glucose (GD) deprivation separately to investigate

how these components contribute to ischemic injury. We used self-assembled, scaffold-free cellular spheroidal microtissues of 4000-8000 cells/microtissue, derived from postnatal (P0-P3) female rat primary cortical tissue and evaluated at culture day 10-14. These microtissues have cellular composition, tissue stiffness, and cell density similar to those found *in vivo*. Neurons in these microtissues are electrically active and form networks. For 24h deprivation assays (n = 6-10 microtissues), we replaced cortical media with glucose-free media and/or placed the microtissues in a chamber containing a BD GasPak EZ sachet which sequesters oxygen. Blinded analysis of immunohistochemistry showed that after OGD, OD, or GD, microtissues had increased reactive astrocytes and increased disruption of neurites. Microtissues exposed to OGD were also evaluated for neural activity using calcium imaging; they showed fewer active cells and no synchrony, as compared to controls. The deprivation assays we performed on our 3D cortical microtissue model have helped us characterize an *in vitro* model of ischemic stroke and start to parse out the separate effects oxygen and glucose deprivation have on our model. Future work will focus on characterizing this model quantitatively and using it to screen potential therapies to minimize the damage cause by ischemic injury.

Abstract: United States military Veterans from recent conflicts are coping with symptoms related to mild traumatic brain injury (mTBI), persistent post concussive (PPC) symptoms, and posttraumatic stress disorder (PTSD). One potential common underlying feature of both mTBI and PTSD is exaggerated inflammation, both peripherally and in the central nervous system, which is thought to play an important role in the vulnerability to, aggravation of, and perpetuation of adverse consequences of these co-occurring conditions. Therefore, a novel intervention strategy would be the use of immunoregulatory/anti-inflammatory probiotics to reduce inflammation. In this study, we investigated the effects of an immunoregulatory probiotic on both biological signatures of systemic inflammatory processes and proximal signatures of probiotic administration. Up to 40 Veterans ages 18 to 50 with a history of mTBI, PPC symptoms, and PTSD were enrolled in this feasibility and acceptability trial. Feasibility and safety were measured by the Adult AIDS Clinical Trials Group, Modified Morisky Medication-Taking Adherence Scale, and Probiotics Usage Log. Acceptability was measures using the Credibility and Expectancy Scales and Modified Treatment Satisfaction Questionnaire. Tolerability and safety were measured by the Generic Assessment of Side Effects, and Irritable Bowel Severity Scoring System. Final analyses are underway. Data regarding acceptability and feasibility will be presented along with results associated with inflammatory markers among those with TBI and PTSD. Results from this study are expected to provide key information

necessary to develop interventions aimed at reducing inflammation among those with co-occurring symptoms.

Title: Persistent astroglial pathology in repetitive head impacts blast injury and CTE

Authors: *B. R. HUBER[1], K. BABCOCK[2], J. D. CHERRY[2], V. ALVAREZ[2], T. D. STEIN[3], A. C. MCKEE[2];

Abstract: Neurotrauma is associated with reactive astroglial changes and alterations in the expression of Aquaporin-4 (AQP4). Reactive astrocytosis is identified by increased expression of Glial Fibrillary Acidic Protein (GFAP) and is observed in many neuroinflammatory processes. In animal models of mild traumatic brain injury (mTBI) reactive astrocytosis appears soon after the initial injury, peaks after a few days, and then slowly resolves after weeks to months. The expression of the water channel AQP4 is also increased following neurotrauma and redistributed from the astroglial endfeet to the cell body (depolarization). Less is known about this process in humans. In our preliminary results using human brain tissue, with cumulative exposure to mTBI we have found that reactive astroglial changes persist long after the exposure stops and that the pattern of reactive glial changes shares features with Alzheimers Disease (AD) and aging. Recently, blast neurotrauma was shown to generate a distinct astroglial response referred to as interface astrocytosis. This pattern consists of astrocytosis at the glial externa (surface of the brain) and the gray-white matter junction. Using the Veterans Administration Brain Bank Biorepository (VABBB) and the Chronic Traumatic Encephalopathy (CTE) Brain Bank we have assembled cohorts of brains with different types of neurotrauma exposure. We examined the premise that interface astrogliosis was specific to blast neurotrauma. In our comparison, we examined four groups including: blast TBI with CTE, athlete TBI with CTE, repetitive head impacts (RHI) without CTE, and controls without a history of neurotrauma. Our results indicate

that blast neurotrauma is associated with a significant increase in gray/white matter interface astrocytosis compared with other forms of mTBI and with controls. Blast neurotrauma was also associated with a significant increase in glial limitans interface astrocytosis when compared with controls. The difference between blast neurotrauma and other forms of neurotrauma was not significant at the glial limitans externa, but had a similar trend to the gray-white matter interface. These findings indicate that blast neurotrauma results in more interface astrocytosis than other forms of neurotrauma, but that all forms of neurotrauma cause interface astrocytosis.

Title: Mechanisms of secondary injury and auditory deficits following mild blast induced trauma

Authors: *J. FERNANDEZ[1], E. HAN[1], E. L. BARTLETT[1], R. SHI[2];
[1]Weldon Sch. of Biomed. Engin., [2]Depat. Basic Med. Sci., Purdue Univ., West Lafayette, IN

Abstract: Blast-induced hearing difficulties affect thousands of veterans and civilians each year. The long-term impact of blast exposure on the central auditory system (CAS) can last months, even years, without major external injury, and is hypothesized to contribute to many behavioral complaints associated with mild blast traumatic brain injury (bTBI). Our group has previously documented the short-term (two-weeks) and long-term (2-months) effects of acute blast and non-blast acoustic impulse trauma on click/tone pip and sinusoidally amplitude modulated (AM) carriers in adult rats. However, the mechanisms that underlie these long-term impairments are still poorly understood. Examining the acute time course and pattern of neurophysiological impairment (within the first two weeks), as well as the underlying molecular and anatomical post injury environment is therefore critical to understanding the mechanisms that lead to long-term CAS impairments. Ultimately this research can inform improved diagnostic and therapeutic strategies for bTBI related deficits. Although initial mechanical injury likely plays a role in central auditory damage, a secondary molecular mechanism of damage likely results in the chronic auditory deficits following mild bTBI. Oxidative stress, along with inflammation, have been suggested as key players in secondary molecular damage in other models of CNS injury, including other TBIs, and may underlie functional auditory deficits in mild bTBI as well. Here, we recorded the changes in auditory brainstem response (ABR) and auditory evoked potential

(AEP) response to amplitude modulation (AM) and speech-like stimuli in blast-exposed and control rats over the course of two months. We compared these results to molecular and anatomical changes observed in immunohistochemistry staining. Taken together, our results suggest that a cascade of (axonal) membrane damage, oxidative stress, and excitatory/inhibitory imbalance contributes to blast-induced subcortical CAS impairments.

Title: Alterations in CNS 5-HT_{2A} signaling and the generation of aberrant social behavior following blast-induced traumatic brain injury

Authors: *S. M. COLLINS[1], E. L. REEDER[1], K. LUNGANI[1], A. HUSSAIN[2], C. J. O'CONNELL[1], G. A. GUDELSKY[1], M. J. ROBSON[1];
[1]Pharmaceut. Sci., [2]Pharmacol. and Systems Physiol., Univ. of Cincinnati, Cincinnati, OH

Abstract: Traumatic brain injury (TBI) is a leading cause of death and disability in the United States, accounting for approximately 2.8 million emergency room visits and an economic burden of nearly $75 billion annually. The lack of any FDA approved medications to treat the acute or chronic effects of TBI contributes greatly to the societal and economic costs. Among the enduring comorbidities of mild to moderate TBI is the generation of neuropsychiatric disorders including altered social function and depression, which are strongly linked to altered serotonin (5-HT) signaling. The effects of neurotrauma on the normal, physiologic function of the 5-HT system are currently not well understood. We hypothesize that TBI alters 5-HT signaling networks, effects that impact mood and behavior states. To test this hypothesis, adult, wild type C57Bl/6J mice were subjected to either a single, moderate blast-induced TBI or sham treatment. Molecular and behavioral assays were performed 0-10 days post injury (dpi). High performance liquid chromatography (HPLC) revealed a significant increase (10 dpi) in total 5-HT and 5-HIAA levels within the raphe nucleus of TBI subjects compared to their sham counterparts, an effect not found in the prefrontal cortex (PFC) or somatosensory cortex (SSC). Administration of the 5-HT_{2A} agonist DOI (3 and 10 dpi) resulted in a significant potentiation of head twitch response (HTR) in TBI subjects as compared to their sham counterparts. This potentiation of DOI-induced HTR by TBI is dependent upon 5-HT_{2A} receptor activity, as HTR is attenuated by

pretreatment with the 5-HT_{2A} antagonist M100907. Western blot analysis of serotonin transporter (SERT) expression revealed a significant decrease within the dorsal raphe (3 dpi) in TBI subjects. As 5-HT signaling is a determinant of social behavior, we hypothesized that TBI-induced changes in homeostatic 5-HT signaling would impact social behavior. Using the Crawley Three Chamber Sociability Assay, significant social deficits were found in TBI subjects (10 dpi) as compared to their sham counterparts. Further corroborating these data, social deficits were observed (10 dpi) using the Tube Test Social Dominance Assay. Collectively, our studies suggest TBI alters 5-HT signaling within the CNS that drive TBI-induced changes in behavior. An understanding of how various forms of neurotrauma alter 5-HT signaling may lead to the discovery of pharmacotherapies aimed at ameliorating the neuropsychiatric complications of TBI.

Title: Blast waves delivered into the ear canal induced traumatic brain injury (TBI) in rats

Authors: Y. OU[1], Y. PANG[2], T. CHEN[1], J. HUANG[1], J. ALLISON[1], D. SANDLIN[3], F. FAN[4], R. ROMAN[4], W. ZHOU[1], ***H. ZHU**[1];
[1]Otolaryngology, [2]Pediatric, [3]MD/PhD Program, [4]Pharmacol., Univ. MS Med. Ctr., Jackson, MS

Abstract: Exposures to blast shockwaves generated by explosions often cause traumatic brain injury (TBI) in military and civilian populations. How the primary blast waves affects the brain is not well understood. As air-filled structures and directly exposed to the surrounding air, the unprotected ears are among the most frequently damaged sites during blast exposure. Studies of blast victims reveal that there is a significant association between tympanic membrane perforation and loss of consciousness in blast exposure. In a previous study (Sandlin et al., 2018, ARO abstract), we showed that blast-exposure via the ear canal induced damage in the vestibular end organs and vestibulo-ocular reflexes (VOR) deficits. However, it is not known whether blast

exposure via the ear canal also causes damage to the brain. To address this issue, we developed a novel model that delivers precise blast overpressure waves solely into the ear canal. Adult female Long-Evans rats were anesthetized and exposed to a single blast of 0-40PSI to the left ear. Brain tissues were harvested for histology at 6 hours, 1, 3, 7, 14, 30, 60 and 500 days after blast exposure. A single blast through the ear caused substantial neuropathological changes in the brain, including increased expression of c-fos, chronic activation of microglia, macrophage infiltration, neuronal apoptosis and increased expression of beta amyloid precursor protein (APP). These changes occurred not only in the brain regions close to the internal auditory meatus, but also in distant areas of the brain related to cognitive functions (e.g. cortex and hippocampus). We further showed that the animals exposed to the blast exhibited signs of anxiety in an open-field test 2 months and 4 months after exposure and impairments of learning and memory in an 8-arm water maze test 13 months after the blast. These results provided evidence that the unprotected ear provides a vulnerable locus for blast waves to impact the brain and cause TBI. This study not only establishes a novel model of blast-induced TBI, but also highlights the necessity for wearing ear protection in blast-prone locations, such as battlefield, training or industrial environments, not only to protect hearing, but also to protect from blast-induced neurotrauma.

Title: High-rate overpressure influences on pro-oxidative potential in primary astrocytes

Authors: *F. GUILHAUME CORREA[1], N. HLAVAC[2], P. J. VANDEVORD[2,3];
[1]Translational Biology, Medicine, and Hlth., [2]Biomed. Engin. and Mechanics, Virginia Tech., Blacksburg, VA; [3]Salem Veterans Affairs Med. Ctr., Salem, VA

Abstract: Blast traumatic brain injury (bTBI) is a frequent injury within military personnel and Veterans due to their exposure to explosives with 80% of mild head injuries attributed to the blast exposure. Treatments for bTBI remain elusive and are limited to symptom management. bTBI can trigger secondary cellular responses, which include neuroinflammation, excitotoxicity and oxidative stress. There is a critical knowledge gap in understanding the cellular and molecular responses after blast. Astrocytes are central for homeostatic, repair, and signaling process mechanisms, critical for maintaining neural circuit post trauma and are important as therapeutically targeted cell for brain diseases and injury. In this study, we aimed to identify

unique injury mechanisms in astrocytes after exposure to blast. Oxidative stress occurs when there is an imbalance between the production of reactive oxygen species (ROS) and their elimination mechanisms. These pro-oxidative conditions caused by ROS are considered to play a role in neuronal toxicity and subsequent neurodegeneration. Cells respond to oxidative stress through different mechanisms such as epigenetic alterations. We hypothesize that astrocytes undergo oxidative stress related to cellular and epigenetic changes as a result of blast exposure. Using a 2D *in vitro* model of bTBI, primary rat astrocytes were exposed to an overpressure wave by using a high-rate fluid-filled device, which mimics transmission of a shock-like wave intracranial profile. The peak overpressure was 17psi to correlate with mild injury outcomes observed in animal models. Following insult, samples were collected for analyses at 4 or 24 hours. We measured protein levels of two oxidative stress markers, NOX4 and SOD2. The membrane-permeant JC-1 dye was used to estimate mitochondrial health and DHF-DA for intracellular ROS detection. Examination of gene expression for oxidative stress, as well as, epigenetic-related genes, thymine DNA glycosylase (TDG) and DNA methyltransferase enzymes (DNMT1 and DNMT3) was analyzed for an epigenetic link with oxidative stress. The results indicated a significant increase (p-value= 0.0079) in the expression of NOX4 between sham and blast at 24 hours. Changes of mitochondrial membrane potential was observed post exposure. Further, an oxidative stress gene array indicated multiple targets suggesting that astrocytes are reactive to oxidative stress mechanisms at 24 hours. Collectively, the results demonstrate that oxidative stress contributes to the astrocytes' reactivity post blast. We expect to identify potential pathways for intervention whereby a healthy astrocyte environment could be restored.

Abstract: The combination of post-traumatic stress disorder (PTSD) with traumatic brain injury (TBI) is known to produce a syndrome more severe than PTSD or TBI alone. Neuroinflammation produced by PTSD and TBI likely contribute to their chronic affective and

cognitive sequelae. We examined behavioral deficits and neuroinflammation in C57BL/6 mice that received; sham, closed head injury (CHI), a model for TBI 3) chronic variable stress (CVS), a model for PTSD; or combined CHI and CVS , CHI → CVS, or CVS → CHI. The CVS → CHI group had the largest cognitive deficits on a spatial task, Barnes Maze, and an Active Place Avoidance (APA) task (Barnes Maze, latency to target latency, $p<0.001$ & APA, $p<0.005$). The CVS→CHI group also had increased Iba-1 and Arginase-1 expression suggesting greater hippocampal inflammation (Iba1: Dentate; $p < 0.005$; CA1; $p < 0.01$; CA3, $p < 0.05$) Arginase 1: $p < 0.005$ in DG, CA1 and CA3 regions). Neuroinflammation in Dentate Gyrus (DG), and CA1 hippocampal area significantly correlated with the extent of behavioral deficits on Barnes Maze and Active Place Avoidance. (Barnes Maze: DG: $r =0.84$, $p<0.005$ APA: DG, $r =0.80$, $p<0.005$). These results suggest an importance of the insult order since the CVS→CHI group had larger deficits and greater inflammation than the CHI → CVS group and that neuroinflammation contributes to neurobehavioral deficits in co-morbid TBI and PTSD. Based on these results, a second model of co-morbid CHI and CVS was devised, consisting of 14 days of combined CVS and CHI (CVS/CHI). The mice underwent a modified CVS protocol in the morning session, followed by CHI injury in the afternoon session. The mice showed significant spatial memory deficits on Morris Water Maze (MWM) on Post Injury Day (PID) 30 and 90 (ANOVA, $p<0.0001$), as well as Novel Object Recognition Test (NORT) on PID 90 (ANOVA, $p< 0.0001$). They had increased entries to open arms in the elevated plus maze on PID 30 and PID 90 (t-test, $p<0.0001$) suggesting greater anxious behavior. Mice were sacrificed for further immunohistological analysis following behavioral testing. Levels of total Tau level and PHF-1 Tau significantly differed between the CVS/CHI group and sham group in total levels ($p=0.0079$). TDP-43 levels also differed significant between CVS/CHI group and sham group. These results suggest that the CVS/CHI model produces a persistent neurocognitive deficits accompanied by tauopathy, and alterations in TDP-43.

Abstract: Introduction: The advancement from traditional voxel-based- to graph theory analyses provides a novel means to study complex brain networks in post-traumatic stress disorder (PTSD). Initial investigations demonstrate altered small-worldness neural networks in PTSD with functional data, but little is known about the structural network topology, or the common comorbidity of PTSD and mild traumatic brain injury (mTBI). **Purpose:** Compare structural brain network characteristics of active duty Service members (SMs) with PTSD, co-morbid PTSD and mTBI, compared to controls (CON). **Methods:**Sixty male SMs (mean age: 33.0±6.4 years) were split into three groups based on diagnosis: 28 CON, 18 PTSD+mTBI and 14 PTSD. All participants completed T1-weighted structural magnetic resonance (MRI) scans to determine cortical thickness on a voxel-basis and in 56 individual regions of interest (ROI). Further, cortical thickness values were used to compute a ROI×ROI adjacency matrix using Pearson correlations and setting negative correlations to zero. A weighted and binary undirected graph was created with each ROI representing a node and the connectivity between ROIs presenting the edges. Graph measures including average degree, characteristic path length, clustering, global efficiency and small-worldness were compared using nonparametric permutation tests repeated 1000 times. Two-tailed t-tests and ANCOVAs (covariate = age; α=.05) were used to test for between-group differences. **Results:** CON demonstrated significantly greater cortical thickness than PTSD in smaller temporal and parahippocampal voxels, while thinner cortex in the right temporal pole compared to PTSD+mTBI. No significant differences were observed for any of the global graph measures in neither the weighted, nor binary undirected graph. However, small-worldness trended towards a significant reduction in PTSD+mTBI relative to CON (0.93 vs. 0.88 respectively, p=.06, 95%CI [-0.05, 0.05]). **Discussion:** SMs with PTSD and PTSD+mTBI only demonstrated subtle cortical thickness, but no small-world topography differences, at least globally. Ongoing subnetwork and nodal analyses investigate whether structural network topology may change network- or node-specifically and if graph theory measures can be linked to behavioral outcomes.

Title: Neural correlates of severe cognitive impairment and posttraumatic stress disorder: Preliminary analysis of World Trade Center responders

Authors: E. RECHTMAN[1], E. DE WATER[1], D. B. HAZELTINE[1], L. ONYEBEKE[1], E. WONG[1], S. GANDY[2], M. SANO[3], S. CLOUSTON[5], E. BROMETT[5], J. NG[4], Y. DERI[5], C. TANG[4], R. LUCCHINI[1], B. J. LUFT[5], ***M. K. H. HORTON**[1];
[1]Envrn. Med. and Publ. Hlth., [2]Neurol., [3]Psychiatry, [4]Radiology, Icahn Sch. of Med. At Mount Sinai, New York, NY; [5]Publ. Hlth., Stony Brook, Long Island, NY

Abstract: World Trade Center (WTC) responders experienced multiple toxic and traumatic exposures during search, rescue, and clean-up efforts. A recent study of responders found that nearly 20% of them developed posttraumatic stress disorder (PTSD) and 13% had mild-severe cognitive impairment (CI). PTSD is increasingly recognized as a risk factor for CI and Alzheimer's disease and related dementias (ADRD). Little is known about mechanisms underlying this relationship between PTSD, CI and ADRD. The objective of this study was to analyze neural correlates of PTSD and CI in WTC responders. This report provides preliminary results comparing anatomical connectivity between CI cases, PTSD cases, CI and PTSD cases, and controls. The parent sample included 3,022 SBU WTC responders. A subset of 57 responders (13 with CI only, 18 with PTSD only, 9 with both CI and PTSD, and 17 with neither CI or PTSD) underwent a diffusion-weighted imaging (DWI) MRI scan acquired on a Siemens 3T PET/MRI scanner. Preprocessing was performed using FSL and whole brain voxel-wise group comparisons of fractional anisotropy (FA) were carried out in each clinical group vs the control group. All analyses were adjusted for age and sex, and are corrected for multiples comparisons. Preliminary results showed reduced FA in 3 clusters in CI compared to controls: the genu of the corpus callosum, posterior corona radiata and the superior longitudinal fasciculus ($p < 0.05$). When compared to control, PTSD cases presented reduced FA in the right genu of the corpus callosum ($p < 0.05$). PTSD+CI group showed reduced FA in the right superior longitudinal fasciculus and the right splenium of the corpus callosum compared to controls ($p < 0.05$). These preliminary results support anticipated trends observed in the literature suggesting that CI may be associated with decreased FA in the corpus callosum and the left superior longitudinal fasciculus. Corpus callosum white matter abnormalities have also been previously reported in PTSD. Results in the PTSD+CI group show some overlaps with the ones seen in the PTSD only and CI only groups. These results are important for completing the long-term clinical picture of WTC exposure effects and have implications for brain aging.

Abstract: Service members during military actions or combat training are exposed to primary blast generated by explosive weaponry. The majority of military-related neurotraumas are mild TBI, often characterized as "*invisible*" and "*signature*" injuries of current military conflicts due to their prevalence. While prior studies have mostly focused on moderate to severe brain injuries, the mechanisms of low-intensity blast (LIB)-mediated pathobiology and subsequent neurological deficits require further definition. We have developed a militarily relevant, open-field LIB injury in mice, the "*Missouri Blast*" model, by detonating 350 grams of high-energy explosive C4. The open-field LIB formed incident and ground reflected shock waves generating a static peak overpressure of 46.7 kPa, where a primary shockwave velocity was 409 m/s and a secondary ground reflection 388 m/s, and the maximal impulse 60 kPa x ms measured at 3-m distance away 1-m above ground detonation. Using high-speed videography, we confirm the absence of visible impact / acceleration on the blast-exposed mice in prone position. Our previous studies have shown that LIB exposures resulted in nanoscale subcellular myelin and mitochondrial damages and subsequent behavioral disorders in the absence of gross or detectable cellular damage. In this study, we used transmission electron microscopy to delineate the LIB effects at the

ultrastructural level specifically focusing on the neuron perikaryon, axons, and synapses in the cortex and hippocampus of mice at 7- and 30-days post-injury (DPI). We found dysmorphic dark neuronal perikaryon and ‘‘cytoplasmic aeration’’ of dendritic processes, as well as increased microtubular fragmentation of the myelinated axons, along with biochemically measured elevated tau / phosphorylated tau / Aβ levels. The number of cortical excitatory synapses decreased along with a compensatory increase of the post-synaptic density (PSD) thickness both at seven and 30 DPI, while the amount of hippocampal CA1 synapses increased with the reduced PSD thickness. In addition, we observed a significant increase in protein levels of PSD95 and synaptophysin mainly at seven DPI indicating potential synaptic reorganization. These results demonstrated that a single LIB exposure can lead to ultrastructural brain injury with accompanying multi-focal neuronal organelle alterations. The *Missouri Blast* model provides an understanding of open field energy impacts including energy from shockwave velocity. This pre-clinical study provides key insights into disease pathogenesis related to primary blast exposure, and may link to dementia.

Title: Impact of mild traumatic brain injury and fear conditioning on dendritic plasticity in the basolateral amygdala and prefrontal cortex of mice

Authors: L. K. ALFILER[1], J. K. BABB[2], K. A. LEITE-MORRIS[3], S. C. HEINRICHS[1], ***G. B. KAPLAN**[3];

Abstract: Mild traumatic brain injury (mTBI) and post-traumatic stress disorder (PTSD) have emerged as the signature injuries suffered by US military personnel due to an increased probability of developing PTSD symptoms following a deployment-related mTBI. In an effort to

examine the behavioral and neurobiological consequences of these two conditions at a subacute phase of injury (3 weeks post-TBI), our project aims to develop a comprehensive model of comorbid mTBI and PTSD and examine impacts on structural plasticity in key brain regions. In order to explore whether mTBI alters fear learning in this study mTBI was administered by lateral fluid percussion at 1.7 atm force (LFP 1.7) after which fear conditioning (FC) and fear extinction (FE) was measured. Fear acquisition training generated significantly increased conditioned freezing responses over time in fear conditioned groups compared to naïve controls. Following fear extinction training in experimental groups, conditioned freezing decreased significantly over time. In addition, these results revealed significantly enhanced FE in groups previously exposed to fear and mTBI (fear/LFP 1.7) compared to the craniectomy control (fear/ LFP 0.0 atm) and surgically naïve controls that were fear conditioned. Consequently, our focus became to examine dendritic plasticity in the prelimbic (PL) and infralimbic (IL) regions of the prefrontal cortex, and the basolateral nucleus of the amygdala (BLA), which are critical nodes involved in FE learning. After the last day of testing, all mice were perfused and brains were sectioned and prepared for Golgi staining. Images of full neurons from the PL, IL, and BLA were analyzed using a microscope-based image analysis program. Fear conditioned mice that underwent extinction had significantly increased spine density in the IL compared to the non-fear conditioned group. Mice in the Fear/LFP 1.7 group had increased spine density in the BLA compared to fear-conditioned craniectomy controls (Fear/LFP 0.0) and unoperated controls. In summary, during subacute phase of injury, our model of coinciding TBI and fear interventions shows increases in FE learning that are accompanied by co-occurring increases in dendritic spines in the BLA in the fear/LFP 1.7 group. These findings suggest a potential treatment window post-injury in which FE processes are more robust after mTBI. Further research is critically needed to examine the converging neurobiological and pathophysiological mechanisms underlying the comorbid condition leading to more effective diagnostic and treatment approaches.

Title: Early life stress alters the threshold for cognitive impairments in mild traumatic brain injury

Authors: *C. M. ATKINS, F. PLACERES-URAY, N. M. WILSON, J. E. FREUND, D. J. TITUS;
Univ. of Miami Miller Sch. of Med., Miami, FL

Abstract: Mild traumatic brain injury (mTBI) accounts for more than 70% of all TBIs. Although the majority of these patients fully recover within two weeks, a subset of people suffer long-term neurocognitive dysfunction. Pre-injury comorbidities that contribute to long-term neurocognitive dysfunction after mTBI are poorly understood. One potential risk factor is early life stress. Early life stress includes child maltreatment such as neglect or abuse, and hampers the normal construction of cortical and hippocampal circuits. In the present study, we tested whether early life stress prior to mTBI in adulthood exacerbates neuroinflammatory sequelae and impairs hippocampal synaptic plasticity. Sprague Dawley pups were separated from their nursing mothers for 3 hours daily from postnatal days 2 to 14. At 2 months of age, the male rats received sham surgery or mild parasagittal fluid-percussion brain injury. At 24 hours after injury, inflammatory gene expression was measured in the hippocampus. PCR gene array analysis revealed that early life stress exposure upregulated the inflammatory genes toll-like receptor 4 (*Tlr4),* NOD-like receptor family, pyrin domain containing 3 (*Nlrp3),* caspase 1 *(Cas1)* and interleukin-1β (*Il-1β)* in mTBI animals. Further, we assessed whether this upregulation in neuroinflammation was associated with changes in synaptic dysfunction by evaluating long-term potentiation (LTP) in area CA1 of the hippocampus. At 2 weeks post-surgery, LTP was significantly impaired in mTBI animals exposed to early life stress as compared to non-stressed mTBI animals. These results indicate that pre-injury exposure such as early life stress may be a potential factor that worsens outcome after mTBI by exacerbating neuroinflammation and impairing hippocampal synaptic plasticity.

Title: Detrimental effects of mild blast traumatic brain injury are augmented by chronic stress

Authors: *M. G. OYOLA[1], A. L. RUSSELL[2], S. E. SAPERSTEIN[1], T.-Y. J. WU[1];
[2]Program in Neurosci., [1]Uniformed Services Univ., Bethesda, MD

Abstract: Traumatic brain injury (TBI) affects 1.7 million people in the United States every year, resulting in increased morbidity and mortality. A significant portion of TBIs experienced by military personnel is induced by explosive blast devices. Active duty military personnel are especially vulnerable to mild blast-induced (mb)TBIs and their associated long-term effects, such as anxiety disorders, memory impairment, and mood disorders. Moreover, virtually every mbTBI on the battlefield is preceded and followed by a constant period of stress. However, how stress affects the brain to deal with an insult, like mbTBI, remains unknown. This work aims to identify the brain targets affected by mbTBI and to elucidate how chronic stress could prime the brain for worse outcomes after mbTBI. First, we examined the effect of mbTBI on restraint-induced limbic-HPA axis reactivity in mice 7-10 days post-injury. The study showed increased anxiety-like behaviors, marked by decreased entries into and time spent in open arms of the Elevated Zero Maze ($p<0.05$). We then extended our studies to interrogate the potential effects of mbTBI on the prefrontal cortex (PFC) and found that mbTBI blunted the restraint-induced neuronal activation of c-Fos immunoreactivity ($p<0.05$) in male and female infralimbic and prelimbic regions of the PFC. These data suggest that the PFC is a potential target of mbTBI in both sexes. In a second experiment, we used the Thy1-eGFP transgenic mouse model to elucidate the effects of mbTBI during a chronic variable stress (CVS) paradigm. Comprising this paradigm were two weeks of CVS prior to our single mbTBI model, followed by another week of CVS after the single blast. Animals exposed to mbTBI+CVS showed higher anxiety-like behaviors ($p<0.05$) and heavier adrenals compared to the Sham+CVS animals ($p<0.05$). These data suggest that CVS makes the system more vulnerable to the effects of mbTBI. Our preliminary data studying the effects of CVS and mbTBI on the dendritic spine architecture of the PFC indicates that the spine length in the prelimbic PFC is decreased. We detected significant gliosis (astroglia and microglia) in the corpus callosum region adjacent to the prelimbic PFC in the CVS treated mice. Interestingly, this response was dampened in the animals treated with mbTBI+CVS ($p<0.05$), suggesting that CVS compromises the brain's response to an insult. These data will help us understand the mbTBI effects observed in the PFC and whether the psychiatric disorders seen following mbTBI result from changes in the dendritic connectivity and architecture on the PFC.

Title: Social stress potentiates negative outcomes for male prairie voles (Microtus ochrogaster) in polytraumatic injury

Authors: G. A. PRATT, III[1], V. D. CHAPLIN[1], M. C. NORMANN[2], M. MCWATERS[2], O. I. AKINBO[2], W. WATANASRIYAKUL[2], A. J. GRIPPO[2], *N. MCNEAL[1];
[1]Naval Med. Res. Unit - San Antonio, San Antonio, TX; [2]Dept. of Psychology, Northern Illinois Univ., DeKalb, IL

Abstract: Background: Psychological factors are known to influence long-term health; however, there is a dearth of evidence evaluating its impact upon biological and behavioral outcomes following injury. This experiment utilized prairie voles because they regulate cardiac function similar to humans and have been successfully used to model autonomic and cardiac dysfunction, compromised complement and innate immunity, and endothelial dysfunction. **Methods:** All subjects (N=36) were housed in male/female pairs for 5 days, then half of the pairs were isolated (for 7 days) resulting in 4 injury study groups: (1) Paired-Female; (2) Paired-Male; (3) Isolated-Female; (4) Isolated-Male and (5) Anesthesia-Shams. On injury day, electrocardiogram was monitored and all animals received a traumatic brain injury (TBI) impact then ~30% hemorrhage. Animals were held for 1 hour, then resuscitated with 2x Lactated Ringers bolus (with 1 hour wait), allowed to regain consciousness (20 minute stabilization period); procedure ended with an open field behavior test and tissue collection. **Results:** All isolated subjects displayed significantly higher mortality (p=0.050); Isolated-Males were more likely to die than Paired-Males (p=0.080). Electrocardiogram data indicates significantly elevated heart rate for injury animals over Anesthesia-Shams and impaired cardiac regulation (i.e. decreased heart rate) during resuscitation for Isolated-Males (p=0.003). Isolated-Males were unable to complete the open field, but Isolated-Females tended to display elevated anxiety-like behavior (p=0.129). Isolated-Males displayed significantly higher glucose (p=0.015), lower anion gap (p=0.011), and tended to have a higher iCa (p=0.125). Size issues limited other group blood comparisons. **Conclusions:** Results imply the polytrauma prairie vole injury model can be used to further investigate the psychological factors that impact traumatic injury recovery. This model provides insight into the protective influence of social bonds on recovery from a physical injury, potentially informing future interventions and treatment strategies.

Title: Diet factors and psychological insults (TBI vs. psychological stress) co-perturb gut-brain axis

Authors: N. CHAKRABORTY[1], J. C. DEMAR, JR[3], A. GAUTAM[2], *J. L. MEYERHOFF[1], R. HAMMAMIEH[2], M. JETT[1], J. LONG[4];
[1]USACEHR, Fort Detrick, MD; [2]USACEHR, Frederick, MD; [3]Blast-Induced Neurotrauma Br., Walter Reed Army Inst. of Res., Silver Spring, MD; [4]WRAIR, Silver Spring, MD

Abstract: Recent data suggest a significant role of alterations in the microbiome and gut microflora architecture in association with traumatic brain injury (TBI) and psychological comorbidities, such as anxiety. To determine how a shift in the microbiome population is coordinated with physical injury and stress responses, two animal models were examined. Rats were fed either a standard house chow diet (w-3:w-6 fatty acids (FA)=1:6, where w-3FA supplied by DHA, EPA, aLNA and w-6 FA supplied by ARA, LA) or a special diet simulating common US consumption (w-3:w-6FA=1:1, where w-3 FA supplied by aLNA, but no EPA, DHA, and w-6FA supplied by ARA, LA). At 6 w of age, a closed-head TBI model consisting of a blast overpressure wave exposure coupled with a weight drop concussion (named Blast) was used on a group of adult male rats. In parallel, an independent group of rats were subjected to an underwater trauma (UWT) psychological stressor, known to elicit “anxiety”. Rats were euthanized 14d post-stress. Dual-dye microarray analysis was performed using hemi-brain and blood samples, and the fecal bacterial populations were characterized by 16s ribosomal RNA. The special diet on its own activated neuroinflammation networks in the brain. Subsequent stress effects showed divergent trends in apoptotic pathways in brains. Notably, the PTEN-PPAR network was activated, but the P38-MAPK/ERK-MAPK/NFkb network was inhibited in the UWT cohort fed the special diet. Alternatively, the PTEN-PPAR network was inhibited, but the P38-MAPK/ERK-MAPK/NFkb network activated, in the Blast cohort provided the special diet. Principal coordinate analysis revealed the special diet as the dominant factor in separating the taxonomic phylogenetic profiles. Two-way ANOVA determined the specific phyla that could be the markers of neurological stress types influenced by the special diet. Predictive network analysis associated the gut microbial shift with bioenergetics perturbations. The special diet exclusively influenced host bioenergetics networks including the glycolysis, gluconeogenesis, and pentose phosphate pathways. In conclusion, the simulated US diet caused considerable disruption of the gut-brain axis; and additional neurological stress aggravated the condition.

Title: Traumatic brain injury in the neonate rat impairs adaptation to stress in adolescence: Role of hippocampal glucocorticoid receptors

Authors: *D. LENGEL[1], J. W. HUH[2], R. RAGHUPATHI[3];
[1]Neurobio. & Anat., Drexel Univ., Philadelphia, PA; [2]Children's Hosp. of Philadelphia, Philadelphia, PA; [3]Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: Each year, an estimated 250,000 children under the age of 4 sustain a traumatic brain injury (TBI). Children are at high risk for developing dysfunction of stress response systems following TBI, leading to abnormal stress reactivity later in life. Clinical studies have reported a stress-associated increase in new onset psychological disorders following childhood TBI, which may be indicative of increased vulnerability to stress. However, little is known about the relationship between neurological changes following TBI during childhood and long-term stress-related functional outcomes. Therefore, we subjected 11-day-old male and female Sprague-Dawley rats to closed-head injury or sham-injury and assessed changes in affective behavior at adolescence (postnatal day 35-45). In the Forced Swim Test (FST), there were no behavioral differences between sham an injured groups during the pretest. However, during the test phase when animals were re-exposed to the swim chamber 24 hours later, both male and female brain-injured rats showed a significant *decrease* in time spent immobile. This suggests that TBI may impair the ability of rats to adapt or habituate to stressful stimuli, leading to maladaptive responses to stress. Therefore, we hypothesized that brain-injured animals may exhibit greater stress coping deficits following exposure to repeated stress. In order to assess coping deficits, rats were exposed to three consecutive days of restraint stress and were subsequently tested in a shuttle box avoidance test. Brain-injured rats showed an increase in both escape latency and the number of escape failures relative to sham-injured rats exposed to the same stress paradigm, indicating a “learned helplessness” phenotype. Previous studies have demonstrated that downregulation or suppression of the glucocorticoid receptor (GR) within the hippocampus decreases both the retention of the immobility response in the FST and resilience to stress. Thus, in order to investigate the molecular mechanisms underlying our behavioral findings, we determined whether TBI affects the expression of hippocampal GRs using real-time quantitative

PCR (rt-qPCR). Our findings revealed that GR mRNA expression was significantly decreased within the hippocampus at 3 days after injury. Further experiments are needed to determine the role of the glucocorticoid system in these behavioral deficits, and whether transfection of GRs within the hippocampus following TBI can reverse stress coping deficits. These findings could provide support for targeting the glucocorticoid system to treat stress-related symptoms in children with TBI.

Abstract: Abuse is one of the leading causes of traumatic brain injury (TBI) in children. Animal models have shown that TBI affects cognitive performance, hippocampal neurogenesis, and increases inflammation. Although stress can occur early in life in cases of child abuse, studies on non-accidental TBI in pediatric populations do not consider the possible increase in vulnerability caused by stress. Hence, we sought to determine whether stress exposure during early life increases the effects of TBI on hippocampal neurogenesis and neuroinflammation. Male Sprague-Dawley rats were subjected to maternal separation (MS) or used as controls (CONT) during the first 21 postnatal days (PND). At PND 21 a controlled cortical impact (CCI) or sham injury was produced. At PND 32 they were injected with the cell proliferation marker

Bromodeoxyuridine (BrdU, 50mg/kg), evaluated for cognitive performance in a water maze, and sacrificed ten days after injection. BrdU, Ki67 and Iba1, immunostaining was performed as was immunofluorescent staining for GFAP, DCX, and NeuN to determine the cellular phenotype of the BrdU+ nuclei. CCI reduced the volume of the granular and subgranular layer of the dentate gyrus, as well as the number and density of BrdU+ cells. MS partially reversed the CCI-induced reduction on BrdU+ cell density. Stress increased the percentage of active microglia in the CA1 region of both hemispheres, as well as the density of Iba1+ cells in the ipsilateral hemisphere. Approximately 60% of the BrdU+ cells differentiated into neurons. The findings suggest that MS partially reverses the effects of TBI on hippocampal neurogenesis but increases hippocampal neuroinflammation.

Title: Early life stress increases cytokine expression in the hippocampus after TBI in juvenile rats

Authors: *M. A. ROQUE[1,2], L. KUTASH[3], A. IOUCHMANOV[2], I. H. BLEIMEISTER[4], J. CHENG[2], C. O. BONDI[2], N. LAJUD[6,7], A. E. KLINE[5];

Abstract: Early life stress (ELS) increases vulnerability for anxiety, depression, and impaired cognition in adulthood. Traumatic brain injury (TBI) is also associated with the development of psychiatric disorders and cognitive dysfunction. Moreover, repeated stress and TBI induce

molecular and cellular abnormalities in the hippocampus and prefrontal cortex, which correlate with memory disturbances. Hence, the aim of this study was to analyze the impact of ELS and TBI in juvenile rats on executive function, as well as hippocampal and prefrontal cortex cytokine expression. Male Sprague-Dawley pups were removed from the mother's nest once daily for 3 hr (i.e., 180 minutes) from postnatal day (PND) 1 to PND21 (maternal separation, MS180), while control rats were left undisturbed. At PND21, all litters were weaned and the rats were randomly assigned to four groups: Control + Sham, Control + TBI, MS180 + Sham, and MS180 + TBI. Rats received a controlled cortical impact (2.2 mm cortical deformation depth at 4 m/sec) or Sham injury and were allowed to recover for two weeks. From PND35 to PND40, all groups were evaluated for executive function using the well-established attentional set shifting task (AST). All groups were sacrificed at PND42 and the brains were dissected to analyze cytokine expression (IL-1b, IL-6, and TNF-a) by real time polymerase chain reaction (PCR). Trunk blood was collected to analyze corticosterone levels. The data showed that TBI, but not MS180, affected AST in the first reversal stage. The combination of MS180 and TBI increased IL-1b expression in the ipsilateral hippocampus, but not in the prefrontal cortex. Moreover, MS180 + TBI increased plasma corticosterone levels at sacrifice. In conclusion, early life stress and TBI affect cytokine expression in the hippocampus, but not prefrontal cortex, in juvenile rats sustaining a TBI of moderate severity.

Title: Effects of concussive-like head injury on fear-related behaviors in rats

Authors: *M. RIVERA LOPEZ[1], M. CÁCERES-CHACÓN[1], O. MARTÍNEZ-GUZMÁN[1], R. Y. RAMOS-SÁNCHEZ[2], D. M. OJEDA-MARTÍNEZ[2], P. ALVELO-FERNÁNDEZ[3], C. J. REYES-SEPÚLVEDA[3], D. SIERRA-MERCADO[1];

Abstract: Each year 40 million people worldwide suffer from brain injury, and the most common type is concussion. Sustaining a concussion often leads to emotional deficits including fear-related disorders. Although human studies show a correlation between acquiring a concussion and enhanced fear, animal studies show conflicting results. Testing the effects of the injury too soon (one to two weeks post-injury) may be contributing to this conflict given that concussion-induced deficits worsen over time. We hypothesize that concussive-like injury will increase fear behaviors in rats 1 month post-injury. To test this hypothesis, we mimicked concussion in rodents using closed head injury (CHI) and sham injury. After 1 month, we examined fear behaviors using the elevated plus maze (EPM) and Pavlovian fear conditioning. In the EPM, time spent in the open arms was measured as an index of innate fear. In fear conditioning a tone was paired with a foot shock, followed by subsequent tests for memory. Here, freezing behavior was measured as an index of learned fear. Results showed no significant difference in time spent in open arms (Sham: 59s, n=8; CHI: 38s, n=8) or in percent freezing during conditioning (Sham: 76%, n=7; CHI: 53%, n=8). This suggest that emotional deficits induced by CHI may be detected at later time points where neurodegeneration takes place and behavioral deficits become more evident. Future studies will focus on examining longer time points and injury severity in the hopes of establishing how these contribute to anxiety behaviors following a concussion.

Title: Methylphenidate differentially alters risk-based decision-making in rats after TBI

Authors: *T. K. SHAVER, C. T. LAFFERTY, M. A. FRANKOT, J. E. OZGA-HESS, K. M. MARTENS, C. VONDER HAAR;
West Virginia Univ., Morgantown, WV

Abstract: 2.8 million people in the United States suffer from traumatic brain injuries each year (Taylor, Bell, Breiding, & Xu, 2017). Brain injury often results in chronic, functional deficits that affect cognitive processes such as decision making and impulse control. Altered dopamine

signaling has been proposed to be a large driver of these cognitive deficits, however one of our previous studies found that a dopaminergic drug (methylphenidate) actually decreased optimal decision-making on the Rodent Gambling Task in both TBI and Sham groups. To better understand why this shift occurred, we continued investigating the effects of methylphenidate by assessing rats (N = 39) on the Risk Preference Task (RPT), a variation of the Rodent Gambling Task where rats chose among reinforcer-rate-matched options with varied probabilities of receiving reinforcement. The three options were 1 pellet (90% probability), 2 pellets (45% probability), or 3 pellets (30% probability). Motor impulsivity, or the inability to inhibit responses before trials was also concurrently assessed. Rats were given either a bilateral, frontal controlled cortical impact injury (AP/ML/DV: +3.0/0.0/-2.5 @ 3 m/s; n = 20) or sham procedures (n = 19) before training on the RPT. Half of rats were then treated daily with oral methylphenidate (5.0 mg/kg; n = 19) or saline (n = 20) fifteen minutes prior to behavioral assessment. TBI caused a significant increase in choice of the safest option. Methylphenidate caused differential effects on the medium and high risk options, with TBI-methylphenidate animals increasing choice of the medium-risk and sham-methylphenidate animals increasing choice of the high-risk choice. There was no significant difference in motor impulsivity between the various groups. These findings suggest that MPH may affect choice behavior through differential mechanisms in TBI versus intact animals. Further research will be needed to understand the mechanism by which these differences occur.

Title: Repeat closed-head injury selectively impairs attention in rats

Authors: *V. J. MILLESON[1], J. S. ADKINS[2], K. M. MARTENS[2], C. VONDER HAAR[2]; [2]Psychology, [1]West Virginia Univ., Morgantown, WV

Abstract: Traumatic brain injury (TBI) can result in significant cognitive and motor impairments, specifically deficits in attention and impulsivity. Notably, even mild TBIs can impair function, a problem that is compounded by multiple injuries. The current study investigated the effects of five closed-head injuries on impulsivity and attention in rats. Twenty-three Long-Evans rats were concurrently trained on two tasks, the five-choice serial reaction time task (5CSRT) and the delay discounting task (DDT). The 5CSRT measures motor impulsivity and attention, while the DDT measures choice impulsivity. Rats completed two

sessions daily, 5CSRT in the morning and DDT in the afternoon. Once trained to a stable baseline, injuries were delivered using the Closed Head Impact Model of Engineered Rotational Acceleration (CHIMERA) system, with a 100 g, 5-mm impact tip centered just in front of bregma, delivered at 8 m/s. Rats received TBI weekly (n = 14) for five weeks or sham procedures (n = 9). Testing continued for four weeks after the last injury was administered. Three deaths occurred as a result of the injuries. Attention was significantly impaired as a result of repeated injury, while choice and motor impulsivity were not affected by TBI. TBI rats also omitted more responses after injury. Rats showed no recovery during the four weeks of post-injury testing. These results stand in contrast to prior findings within our lab in which impulsive deficits were the largest change after injury. This suggests that the post-TBI phenotype may be more generalized than previously believed, particularly in light of the number of omitted responses. However, further study will be needed to understand why impulsive deficits emerge in some cases but not others.

Title: The effect of experimental brain trauma on sustained and flexible attention in female rats

Authors: *A. IOUCHMANOV, L. KUTASH, T. CRAINE, C. SUNLEAF, J. CHENG, A. KLINE, C. BONDI;
Physical Med. and Rehabil., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Impaired attention is central to the cognitive deficits associated with long-term sequelae for many traumatic brain injury (TBI) survivors. We previously demonstrated, for the first time, higher-order attentional impairments after moderate TBI, by using two frontal cortex-dependent ‘attentional tasks’, the operant 3-choice serial reaction time task (3-CSRT) and the digging attentional set-shifting (dAST) paradigms in male rats. Given that over 40% of TBIs occur in female patients, we hypothesized that adult female rats subjected to TBI will also exhibit attentional deficits seen as reduced accuracy and increased impulsivity. The 3-CSRT, a modified version of the five-choice serial reaction time task, requires the animal to orient toward and divide attention between three nose poke holes in an operant chamber, in which brief (300

ms) cues are randomly presented, to obtain a sucrose pellet reward. Upon reaching baseline of greater than 70% accuracy, which takes approximately 4-5 months using incrementally decreasing cue durations, adult female normal-cycling Sprague-Dawley rats were subjected to a controlled cortical impact (2.8 mm cortical tissue deformation depth at 4 m/sec) or sham injury over the parietal cortex in the right hemisphere. After two weeks of recovery, they were re-tested on 3-CSRT for ten days and then trained and tested on dAST, which involves a series of increasingly difficult stages, including simple and compound discriminations, stimulus reversals, and intra/extradimensional set-shifts, at approximately 28-29 days post-surgery. Dependent measures for the attention tasks include accuracy, omissions, trials to reach criterion, as well as total and perseverative errors. Results suggest that TBI females display reduced percent accuracy, particularly when the cue was presented on the Left side, suggesting a rodent analog of spatial hemi-neglect. Females alone exhibited partial recovery of function after ten days of re-testing, paralleling visual scanning therapy in the clinic. They also displayed increased omissions on 3-CSRT compared to Sham rats (n=3/group), which was similar in males. Ongoing analyses include dAST performance (total trials and errors), as well as within-subject correlations between attention test modalities. Statistical analyses will employ repeated-measures ANOVA followed by Newman-Keuls post hoc for individual test days when appropriate. Assessing attention post-TBI via multimodal testing is clinically-relevant and may provide reliable avenues towards developing therapeutic and rehabilitation targets in both males and females.

Title: Environmental enrichment enhances spatial learning in a pediatric model of asphyxial cardiac arrest

Authors: *M. NICHOLAS[1], C. O. BONDI[2], S. SEPPI[1], M. HOOK[6], A. E. KLINE[3], A. ROWLEY[1], H. ALEXANDER[4], J. CHENG[5], M. MANOLE[1];

Resuscitation Res., [4]Critical Care Med., [5]Physical Med. and Rehabil., Univ. of Pittsburgh, Pittsburgh, PA; [6]Univ. of Bath, Somerset, United Kingdom

Abstract: Every year, approximately 16,000 children suffer from a cardiac arrest (CA), with asphyxia accounting for most pediatric insults. After successful resuscitation from CA, hypoxic ischemic brain injury manifests as cognitive dysfunction and is present in most patients. Multiple studies have ascertained the role of environmental enrichment (EE) in reducing cognitive dysfunction after traumatic brain injury. To date, no studies have evaluated the effect of EE after CA. Hence, we sought to analyze the efficacy of EE in a pediatric model of asphyxia CA (ACA). It was hypothesized that EE would attenuate ACA-induced cognitive deficits in pediatric rats. Post-natal day16-18 rat pups received either a 9.5-minute ACA or sham injury. The rats were immediately placed in either standard housing (STD, 6-8 pups with the mother for 3 days, then weaned to single caging) or EE (6-8 pups with the mother for 3 days, then the mother was removed, and the pups remained). Four groups were studied: sham-STD, sham-EE, ACA-STD, and ACA-EE, n=8-10/group. Behavioral assessments included beam balance, days 1-5, novel object recognition (NOR) and open field, days 5-6, and Morris water maze, days 6-14. Both the ACA-STD and ACA-EE groups performed worse on the beam-balance task vs. sham controls ($p<0.05$) but did not differ from one another ($p>0.05$). Open field behavior did not differ among any of the groups ($p>0.05$), but there was a trend for the ACA-EE to perform better than the ACA-STD ($p = 0.06$). Spatial learning was improved in the ACA rats receiving EE vs. STD housing. ($p<0.05$). The EE-mediated improvement in the acquisition of spatial learning suggests that EE promotes beneficial effects after pediatric ACA and supports the hypothesis. The study supports the plethora of evidence showing that EE confers robust cognitive benefits after CNS injury and further validates it as a preclinical model of neurorehabilitation.

Title: Instrumental learning and behavioral flexibility in adolescent rats following pediatric brain trauma

Authors: *C. SUNLEAF, K. GROBENGIESER, A. TUROCY, A. PATEL, S. SHA, L. KUTASH, J. CHENG, A. KLINE, C. BONDI;
Physical Med. and Rehabil., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: With 500,000 yearly emergency room visits being attributed to childhood-acquired brain trauma (under 14 years of age), patients endure long-lasting cognitive, physical, or behavioral effects. Thus, it is vital to consider the effect brain trauma has on executive processes, such as learning, motivation, and behavioral flexibility, as one transitions from childhood to adolescence. We hypothesized that rats subjected to pediatric traumatic brain injury (TBI) will display task-dependent impairments in instrumental learning task (ILT) behavior and behavioral flexibility during adolescence. We employed a multimodal behavioral approach after moderate parietal lobe (2.2 mm tissue deformation depth at 4 m/sec) controlled cortical impact or sham injury to the right hemisphere in pediatric Sprague-Dawley male rats (postnatal day, PND 17). After ten days of recovery, they were trained on a fixed-ratio schedule of 1 for 12 consecutive days in operant chambers fitted with three nose-poke holes and a food trough, by learning to poke for sucrose pellet reinforcement in the center when illuminated. Outcome measures included the number of total trials completed, task-irrelevant pokes (left or right), and latency for pellet retrieval following instrumental nose-poking. Rats were then trained/tested on the attentional set-shifting test (AST) at PND 42-43, which involves simple and compound discriminations, stimulus reversals, and intra/extradimensional set-shifts. Dependent measures included the number of trials to reach criterion, as well as total and perseverative errors. Statistical analyses employed repeated-measures ANOVA followed by Newman-Keuls post hoc for individual test days when appropriate. ILT data (n=8/group) paradoxically demonstrate increased total trial rates and reduced task-irrelevant pokes, suggesting attenuated exploratory drive but also reduced impulsivity in adolescent rats after pediatric TBI ($p<0.05$). These effects were not due to motivation changes, as latency from poke to pellet was in fact shorter in TBI rats. Moreover, no group differences were detected in AST, possibly a result of higher baseline behavior in Sham adolescent rats, as previously reported. In summary, adolescent instrumental learning is affected by pediatric TBI in a divergent manner, reflecting reduced exploratory drive without affecting motivation. Executive function was not impaired, albeit adolescent rats naturally display enhanced cognitive rigidity compared to adults. These findings will advance our understanding of long-term higher-order cognitive and motivational deficits in adolescent survivors of childhood brain trauma.

Title: Amantadine as a bridge-therapy prior to neurorehabilitation after experimental traumatic brain injury

Authors: *K. GRIMM, C. LOMAHAN, D. BROOKS, I. BLEIMEISTER, M. HELKOWSKI, C. O. BONDI, A. E. KLINE;
Physical Med. & Rehabil. and Safar Ctr. for Resuscitation Res., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Traumatic brain injury (TBI) is a significant health care issue with limited treatment options. Environmental enrichment (EE), which consists of a complex living space and is vastly different from standard (STD) housing, is considered a preclinical model of neurorehabilitation because it improves cognition after experimental TBI. However, initiating EE immediately after TBI does not parallel the real world where patients will likely not receive rehabilitation until after critical care. Yet, treating TBI early is important for recovery. Hence, the goal of the current study was to evaluate amantadine (AMT) as a bridge therapy between critical care and rehabilitation. It was *hypothesized that AMT followed by EE would confer greater motor and cognitive recovery after TBI than either treatment alone.* Anesthetized adult male rats received a cortical impact of moderate severity (2.8 mm tissue deformation at 4 m/s) or sham injury and then were randomly assigned to enriched or STD housing where AMT (10 mg/kg) or vehicle (VEH; 1 mL/kg) were administered intraperitoneally beginning 24-hr after injury and daily for 7 days (AMT bridge) or every day for 26 days (daily treatments). Motor function (beam-balance/beam-walk) and spatial learning/memory (Morris water maze) were assessed on post-operative days 8-12 and 21-26, respectively. All TBI groups receiving EE performed significantly better than the AMT and VEH treated STD-housed groups on motor and cognition ($p<0.05$). No other comparisons were significant ($p>0.05$). The lack of an additive effect with AMT and EE does not support the hypothesis. Future studies should include abbreviated EE as neurorehabilitation as continuous EE may be too robust to afford additional benefits.

Title: Intranasal zinc remediates behavioral deficits following stress and traumatic brain injury

Authors: *E. N. DOHERTY[1], W. R. KOCHEN[1], T. T. DIMOPOULOS[1], D. D. CERRI[1], J. M. FLINN[2];
[2]Psychology, [1]George Mason Univ., Fairfax, VA

Abstract: Mild traumatic brain injury (mTBI) has become the "signature wound" of the military population in recent combat operations. Repeated mTBI (rmTBI) produce long-term cognitive and behavioral deficits, which can be exacerbated by the high-stress environment experienced by service members. This study employed a mouse model to examine the effects of chronic variable stress (CVS) on rmTBI, and how these may be ameliorated by intranasal zinc. Six-week old mice received two varied stressors (e.g., food deprivation, physical restraint, ice bath, predator urine) each day for seven days. A second week of CVS was administered concurrently with four closed-head mTBIs. Each injury was immediately followed by either intranasal zinc treatment or a vehicle control (water). A subset of mice was removed for analysis of acute protein changes in the brain and alterations in ionic zinc. The remaining mice were subjected to behavioral testing that assessed a) spatial memory via Morris water maze (MWM) and b) circadian rhythm via wheel-running activity. A significant interaction between stress and zinc was found in MWM testing; post-injury zinc treatment led to a significant *increase*, $p = .047$, in platform crossings for stressed mice when compared to the non-stressed controls. Circadian rhythm testing measured 24-hour performance and yielded a similar interaction. Stressed mice given vehicle treatment showed a significant deficit in activity at the beginning of the dark cycle, but when zinc was administered, the deficit was corrected and activity for stressed mice nearly doubled. These findings suggest that zinc had a therapeutic effect on behavioral deficits associated with rmTBI, with chronic stress increasing zinc efficacy. Western blots are currently being performed to investigate the biological mechanism underlying this interaction between stress and zinc on rmTBI.

Title: Omega-3 fatty acid deficiency increases neurological impairments in a rat model of combined blast-traumatic brain injury and traumatic stress

Authors: *J. C. DEMAR, J. G. ROSENBERGER, A. B. BATUURE, R. T. URIOSTE, O. D. EKEN, L. ZHILIN, D. M. WILDER, J. B. LONG;
Blast-Induced Neurotrauma Br., Walter Reed Army Inst. of Res., Silver Spring, MD

Abstract: BACKGROUND: US Soldiers suffer a high incidence of traumatic brain injuries from bomb explosions (blast-TBI). There is a high co-morbidity of blast-TBI with post-traumatic stress disorder (PTSD) development. Dietary long chain omega-3 polyunsaturated fatty acids (omega-3s) are building blocks of neuronal cell membranes and are converted to anti-inflammatory metabolites. Omega-3 deficiency is a risk factor for cognitive and psychiatric disorders. Providing dietary omega-3s improves outcomes in many models of brain trauma. Thus, we explored if an omega-3 poor diet increases vulnerability to blast-TBI and PTSD, and if combining these insults has an additive deleterious effect. **METHODS**: Adult male rats (n = 24 / group) were maintained for 6 weeks on diets devoid of omega-3s and increased in pro-inflammatory omega-6 content. Anesthetized animals were then exposed once to a blast over pressure wave (18 psi) in an advanced blast simulator, followed immediately by a weight drop skull concussion (500 g from 125 cm), to induce TBI symptoms. After 3 days of recovery, the rats were subjected once to a traumatic stressor, i.e., forced immersion underwater (30 sec), to induce “PTSD” behaviors. Shams were subjected to anesthesia, recovery, and free swimming. Diets were continued and the animal’s neurobehavioral function was evaluated out to 28 days, using rotarod, rotary pole, elevated plus maze, Y-maze, and open field tests. **RESULTS**: Our results showed that blast-TBI plus traumatic stress leads to minor increases in behavioral impairments, compared to each insult alone, e.g. coordination, “anxiety”, and hyperactivity disturbances. Omega-3 deprivation, however, markedly perturbed behaviors of both shams and injured rats to a similar degree. **CONCLUSIONS:** Our findings, in showing little impact on behavior of combining the brain insults, may indicate that their underlying pathophysiological processes can mask each other. Nevertheless, omega-3 deficiency caused a worsening of the outcomes. Future studies will examine the neuronal cell injury status of the animal’s brains, e.g. histopathology and cytokine assays. **DISCLAIMER:** Research was conducted under an institutionally approved animal care and use protocol in compliance with the Animal Welfare Act, and all other Federal requirements. Title: Long-term cognitive benefits from abbreviated environmental enrichment after cortical impact injury

Authors: *C. LOMAHAN[1], K. GRIMM[2], M. ALVAREZ[2], M. WOLFF[2], H. RADABAUGH[2], C. O. BONDI[2], A. E. KLINE[2];
[2]Physical Med. & Rehabil. and Safar Ctr. for Resuscitation Res., [1]Univ. of Pittsburgh, Pittsburgh, PA

Abstract: It is well established that a relatively brief exposure to environmental enrichment (EE) enhances motor and cognitive performance after experimental traumatic brain injury (TBI). It has also been shown that the EE-induced benefits can be sustained for up to six months. What is not known is whether rats that received EE and then transferred to standard (STD) housing would benefit further from "refresher rehabilitation." To address this rehabilitation-relevant concern, anesthetized rats received a cortical impact or sham injury, and for phase 1 of the experiment were randomly assigned to either 3 weeks of EE (6 hr/day) or STD housing. Neurobehavioral outcome was assessed by established motor and cognitive tests on postoperative days 1-5 and 14-18, respectively. Motor, spatial learning, and memory retention were facilitated in TBI+EE vs. TBI+STD ($p<0.05$). In phase 2, half of the EE rats were transferred to STD (TBI+EE+STD) and half of the STD went to EE (TBI+STD+EE). Cognition was re-assessed once per month for 6 months. TBI+EE performed better vs. TBI+STD continuous and TBI+STD+EE ($p<0.05$). Also, TBI+EE+STD performed better than TBI+STD+EE ($p<0.05$). In phase 3, the TBI+EE+STD group was provided an additional week of EE (i.e., refresher). The data showed continued improvement in the refresher rehabilitation group vs. the TBI+STD+EE group ($p<0.05$). These data replicate those of several studies from our laboratory showing that EE enhances recovery after CCI injury and extend those findings by demonstrating that the cognitive benefits are maintained for at least 6 months post-rehabilitation with abbreviated EE and that providing "refresher" EE further improves benefits. The persistent benefits shown with this paradigm provide further support for EE as a pre-clinical model of neurorehabilitation.

Title: Inhibition of microglia using chemogenetics reduced proinflammatory cytokine levels after traumatic brain injury

Authors: *K. M. PECHACEK, K. M. MARTENS, B. ZHU, C. VONDER HAAR;
West Virginia Univ., Morgantown, WV

Abstract: Traumatic brain injury (TBI) often results in chronic neuroinflammation and is associated with cognitive deficits and psychiatric disorders. One of the major mediators of this process are microglia cells through the production of proinflammatory cytokines. The current study examined the effects of chemogenetic microglia inhibition on the neuroinflammatory response after TBI. Rats (N = 36) first underwent stereotaxic surgery to deliver the virus containing the Designer Receptor Exclusively Activated by Designer Drug (DREADD) construct pAAV CD68-hm4D-(Gi) to the four sites surrounding what would become the injury periphery (AP: -0.9/-3.9, ML:-1.0/-4.0, DV: -1.4). After allowing three weeks for protein expression, animals were trained for two sessions on the accelerating rotarod task, a measure of motor coordination. Rats then received a unilateral controlled cortical impact to the location of DREADD infusion (AP: -2.4, ML: -2.4, DV: -2.5) or sham procedures (craniotomy only). Subgroups were then given the DREADD-activating agent, clozapine N-oxide, starting at time points of 0, 4, 8, or 24 h after injury and every six hours thereafter. At 72 h post-injury, animals were re-tested on the rotarod and then sacrificed immediately after. Brain tissue was collected for multiplex ELISA of cytokine levels. Performance on rotarod revealed an effect of TBI that was not recovered by the DREADD in any groups. TBI increased proinflammatory cytokines IL-1β and IFN-γ but this response was attenuated in the perilesion by the DREADD at time points 0 and 4 h. The DREADD had no effect on inflammatory cytokines IL-6, TNF-α, and IL-10. Inhibition of microglia after unilateral TBI affected the proinflammatory response in the perilesion but yielded no functional improvements. Future work should consider the time sensitive nature of microglia inhibition as they development treatments for TBI.

Title: Bioactive scaffolds of mobile molecules to repair the injured spinal cord

Authors: *Z. ALVAREZ PINTO, A. N. EDELBROCK, J. ORTEGA, I. R. SASSELLI, E. KISKINIS, S. I. STUPP;
Northwestern Univ., Chicago, IL

Abstract: Developing reliable therapeutic methods to treat spinal cord injuries (SCI) has been a major challenge due to the complex and dynamic cellular microenvironment during the disease progression. While several current therapeutic approaches have aimed to restore neural signaling, reduce neuroinflammation and prevent subsequent damage to the injured area, to date, there is no single biological intervention that can address all of the physiological events that damage the spinal cord. Self-assembling supramolecular systems have been identified as an important class of biomaterials given their ability to generate dynamic structures. Peptide amphiphiles (PAs) that self-assemble in water into high aspect ratio nanofibers and form hydrogel networks in the presence of physiological electrolytes have emerged as attractive supramolecular candidates for regenerative medicine. Inspired by the highly mobile environment at cell-extracellular matrix (ECM) interfaces, we investigate here supramolecular scaffolds formed by molecules with identical chemical bioactivity but drastically different mobility within the supramolecular fibers they form and their effect on neural regeneration, vascularization and glial scar formation. This was accomplished by designing and testing fibroblast growth factor 2 (FGF-2) mimetic molecules that self-assemble into nanostructures as an angiogenic and neurogenic biomaterial platform for treating SCI. The growth factor mimetic PA co-assembled with a known PA that presents the neuroactive pentapeptide epitope from laminin alpha-1, IKVAV, promoted vascularization, nerve regeneration, functional recovery, and limit the glial scar formation. Overall, our PA technology highlights the importance of the ECM in recapitulating in vivo conditions and offers a more physiological and translational platform to study the dysfunction of the CNS after injury.

Title: Enhancing endogenous reprogramming for neurogenesis after spinal cord injury

Authors: *W. TAI, L.-L. WANG, H. NI, C.-L. ZHANG;
UT Southwestern Med. Ctr., Dallas, TX

Abstract: Spinal cord injury (SCI) induces pathological changes that frequently lead to functional impairments. Whereas endogenous neurogenesis is associated with innate cognitive recovery following brain injury, it is still unclear whether SCI induces neurogenesis. In the present study, we find that doublecortin-positive (DCX+) cells could be robustly detected surrounding the injury sites 7 days after a diverse SCI models including contusion, crush, hemi-section, and stab-wound injury. These cells co-express markers for NG2 glia but not astrocytes. However, the number of DCX+ cells declines rapidly with time and very few becomes neurons. Since our mouse genetics showed that SOX2 is essential for DCX-induction in NG2 glia, we then examined whether ectopic SOX2 in these cells could enhance their fate reprogramming. Indeed, ectopic SOX2 robustly induces DCX+ cells from NG2 glia. These NG2-derived DCX+ cells pass through an ASCL1+ progenitor stage and can become mature neurons. Rabies virus-mediated synaptic mapping showed that these NG2-derived neurons can integrate into the existing neural network. Together, our results indicate that SCI induces partial reprogramming of NG2 glia and ectopic SOX2 can enhance such reprogramming towards neurogenesis.

Title: Sensorimotor improvement following dorsal root repair with PRP and human embryonic stem cells

Authors: *M. V. DE CASTRO[1], M. SILVA[1], G. CHIAROTTO[1], S. KYRYLENKO[2], M. H. SANTANA[1], A. LUZO[1], A. L. OLIVEIRA[1];
[1]Univ. of Campinas (UNICAMP), Campinas, Brazil; [2]Med. Inst. - Sumy State Univ., Sumy, Ukraine

Abstract: Spinal dorsal roots can be affected by lesions to the brachial and lumbosacral plexuses, leading to loss of proprioceptive inputs to motoneurons, greatly hampering motor coordination. The loss of afferents greatly affects spinal circuits, and to date, there is no effective therapy to overcome such deficits. Reimplantation of roots, combined with stem cells therapy, have been proposed to mitigate the degenerative effects of dorsal rhizotomy. In this sense, the present study evaluated the motor and sensory improvement following dorsal root reimplantation with platelet-rich plasma (PRP) after dorsal rhizotomy. We also combined such scaffold with modified human embryonic stem cells (hESCs) overexpressing fibroblast growth factor 2 (FGF-2). hESC were used to enhance the repair process. For that, female adult Lewis rats (LEW/HsdUnib; n=5 per group) were subjected to unilateral dorsal rhizotomy (DRZ) of the L4-L6 roots and divided into the following groups: (1) Unlesioned/Control; (2) DRZ without reimplantation (DRZ); (3) DRZ followed by root reimplantation with PRP (DRZ+PRP); (4) RZ followed by root reimplantation with PRP associated with modified human embryonic stem cells (RZ+PRP+hESC). PRP was obtained from human blood subjected to centrifugation steps. It was characterized regarding platelet concentration, integrity, and viability. For cell therapy, hESCs were bioengineered to overexpress a human fibroblast growth factor 2 (FGF-2). qRT-PCR was used to assess gene expression of TNFα, TGFb, IL4, IL6 and IL13 in the spinal cord, and FGF2, BDNF, GDNF, VEGFA and IGF mRNA levels in hESC *in vitro*. We also evaluated glutamatergic pre-synaptic terminals (VGLUT1) and glial reaction (GFAP and Iba-1) immunolabeling in the spinal cord, eight weeks post-lesion. The results indicate that the combination of hESC overexpressing FGF2 with PRP induces regeneration of afferent fibers after dorsal rhizotomy, restoring the paw withdrawal reflex, significantly enhancing VGLUT1 immunoreactivity in deeper spinal cord laminae. Also, PRP+hESC therapy does not exacerbate glial reactivity. We hypothesize that local hESC+PRP immunomodulation at the site of injury overcomes the effects of inhibitory molecules that hamper the growth of regenerating primary afferent fibers within the spinal cord. Overall, the present data suggest that repair of dorsal roots with PRP application combined with cell therapy is efficient and may be considered as an approach to improve sensory-motor recovery following dorsal rhizotomy.

Title: Modulation of microenvironment by iron oxide nanoparticles embedded in gelatin-genipin hydrogel along with magnetic field stimulation in contused spinal cord injury rats

Authors: *S. B. BHATTACHARYYA[1], S. JAIN[2], A. K. DINDA[3];
[2]Physiol., [3]Pathology, [1]AIIMS, New Delhi, New Delhi, India

Abstract: Traumatic spinal cord injury (SCI) is a great challenge for therapeutic management considering its high morbidity. It initiates cascade of events that creates an inhibitory milieu for axonal growth and repair. Thus to modulate this microenvironment there is a need to develop a biocompatible growth enhancing material which can fill the cysts, bridge the gap and act as conduit for axonal guidance. To formulate an effective therapeutic strategy with translational potential and understand its mechanism, we fabricated gelatin-genipin hydrogel (GGH) system which was impregnated with IONPs and injected at the lesion site in a clinically relevant contusion rat model of SCI. The rats were concomitantly exposed to electromagnetic fields 2h/day for 5 weeks. A significant improvement in behavioral, electrophysiological and morphological parameters was observed which was due to alteration in neurotrophin levels and reduction in activated microglia. The intervention thereby made the microenvironment conducive and facilitated neural repair and regeneration.

Title: A comparative study of human-derived UCMSC, ADMSC and iPSC-induced progenitor transplants in the treatment of spinal cord injury

Authors: *A. LIU, P. YU, L. SHI, K.-F. SO, L. ZHOU;
Jinan Univ., Guangzhou, China

Abstract: Spinal cord injury (SCI) is still a worldwide problem, and recent studies show stem cells transplantation provides a promising treatment in animal experiments and clinic trials. However, which type of stem cells should be considered for use remains unknown. In this study, we prepared human umbilical cord-derived mesenchymal stem cells (UCMSCs), human adipose-derived mesenchymal stem cells (ADMSCs) and human iPSC-induced neural progenitor cells (NPCs), and carried out cell transplantation 1 week after SCI using a T10 moderate contusion rat model. Most transplanted UCMSCs and ADMSCs survived up to 4 weeks and failed to further differentiate into neurons or glial cells, in contrast, about 30% transplanted NPCs could survive for 4 weeks and differentiate into a few neurons (7.9%) and astrocytes (1.8%). Both UCMSC and ADMSC transplants significantly improved motor and sensory function assessed by BBB scores, CatWalk tests, footslip tests, motor-evoked potential and sensation tests. However, NPC transplants were much less efficient for functional recovery. After SCI, UCMSC and ADMSC transplants indiscriminatingly contributed to spinal neuron survival and axonal regeneration, decreased the glial scar formation, lesion cavity and the number of active macrophages. However, NPC transplants displayed much less effect on improving spinal micro-environment after SCI compared to UCMSC and ADMSC transplants. Bioplex analysis with Spinal samples 3 and 7 days after cell transplantation showed IL-10, IL-13 were significantly increased and TNF-α were significantly decreased in the UCMSC and ADMSC groups. NPC transplants induced the decrease of MCP-1, IL-2 and IFN-γ. Seven days after cell transplantation, iTRAQ proteomics analysis of spinal samples showed there were 101 common proteins changed in the UCMSC and the ADMSC, 117 changed proteins particularly in the UCMSC group.Many common changed proteins with more than 1.5 fold increase were benificial for axon growth, including Fez1, Tnpo1, Dclk2, Cnpy2, Stat3, Ctss, Sort1 and Yes. However, in the NPC group, most changed proteins were different from two other groups. In conclusions, UCMSC and ADMSC transplants similarly contributes to motor and sensory function recovery after SCI probably via anti-inflammation, improving axonal growth and neurotrophic effect; transplanted NPCs can differentiate into some neurons, which number of neurons do not significantly improve functional recovery; short survival time of transplanted UCMSC and ADMSC suggests multiple transplantations should be considered in the clinic.

Abstract: [Introduction]Cell-based therapy targeting spinal cord injury (SCI) is an attractive approach to promote functional recovery by replacing damaged tissue. We have previously shown effectiveness of transplantation of human-induced pluripotent stem cell-derived oligodendrocyte precursor cell-enriched neural stem/progenitor cells (hiPSC-OPC-enriched-NS/PCs) in SCI animal model, regarding robust remyelination to the demyelinated axons and motor functional recovery. For clinical application, the NS/PCs should be generated from feeder-free iPS cells cultured under xeno-free conditions. Here, the aim of this study is to examine therapeutic efficacy and safety of feeder-free hiPSC-OPC-enriched-NS/PCs (ff-hiPSC-OPC-enriched-NS/PCs).[Method]OPC-enriched NS/PCs were generated from feeder-free iPSCs. Contusive SCI was induced at the Th10 level in adult female NOD-SCID mice, and the ff-hiPSC-OPC-enriched NS/PCs were transplanted into the lesion epicenter 9 days after the injury. An equal volume of phosphate buffered saline was injected for the control groups. Motor function of injured mice was assessed by the Basso Mouse Scale score, Rota-rod test and DigiGait analysis. Histological analyses were performed to examine the survival and differentiation of the grafted cells.[Results]Histological analyses revealed that the transplanted cells well survived and migrated far into the host spinal cord without any tumor formation. The transplanted cells differentiated into three neural lineages including neurons, astrocytes and oligodendrocytes. In particular, the differentiation rate of oligodendrocytes evaluated by expression of APC was 36.6±2.8%. The myelinated positive area of the spinal cord was evaluated by Luxol fast blue staining at cross section, and it was significantly larger from the epicenter to +1.0 mm rostral and caudal sites in the transplanted group rather than in the vehicle control group. Furthermore, the active remyelination on damaged axon in injured spinal cord was observed in the transplanted group by immunoelectron microscopy. Importantly, hindlimb motor function was significantly improved in the transplanted group one week following transplantation and thereafter.In addition, both Digigait analysis and rotarod tests revealed a significant motor functional improvement in the transplanted group at 12 weeks after transplantation.[Conclusion]Feeder free-hiPS-OPC-enriched NS/PCs showed therapeutic potency similar to the conventional ones. These cells would be potential sources of therapeutic application for SCI patients in the clinical settings.

Abstract: Activity-dependent spinal stimulation has shown promise as a therapy following spinal cord injury (SCI). To improve volitional control of reaching and grasping movements in rats with cervical SCI, we facilitate spike-timing dependent plasticity (STDP) in descending pathways by triggering spinal stimulation on single motor unit action potentials from muscles of the impaired forelimb. To deliver this therapy more effectively, we have developed a small, fully implantable, wireless device that delivers robust activity-dependent stimulation with minimal stimulus artifacts, which can interfere with closed-loop performance. The device uses an Intan Technologies chip for recording, an ARM Cortex-M4 microprocessor for signal processing, and a custom-designed stimulation circuit. In this study, the device was implanted subcutaneously in injured rats and connected to electrodes implanted in 3 forelimb muscles and in spinal segments C6-C8. Electromyographic activity (EMG) was recorded differentially, sampled at 6.5 kHz, and transmitted wirelessly to a nearby laptop computer. The signals had low noise and high signal-to-noise ratios. Parameters to identify single motor unit action potentials with a dual time-amplitude window discriminator were determined offline and uploaded wirelessly to the implanted device. Motor unit action potentials from each muscle triggered delivery of a subthreshold, biphasic, electrical pulse to an intraspinal microwire from which contraction of that muscle could be evoked with higher currents. The delay between generation of a trigger and delivery of a stimulus was ~1.2 msec, well within the required window for STDP. Stimulus pulses of 150 usec width can be adjusted in 256 steps from -18 V to 18 V depending on therapy conditions. Recorded stimulus artifacts were brief and small in all EMG channels due to: a) a switching circuit that reduces the amplifier input gain during stimulation; b) reduction of charge build-up

on parasitic capacitances due to shielding of the system by the animal's body; c) low impedance EMG electrodes. These results demonstrate robust performance of a novel, fully implantable neuroprosthetic device that can deliver closed-loop electrical stimulation with dual time-amplitude window discrimination and wireless communication. The device enables implementation of real-time, activity-dependent stimulation for treatment of SCI in freely moving, untethered animals.

Title: Significant heterogeneity in neural stem cell populations for transplantation

Authors: T. N. G. ADAMS, S. TIWARI, C. RO, H. X. NGUYEN, R. NISHI, D. L. HAUS, B. J. CUMMINGS, A. J. ANDERSON, ***L. A. FLANAGAN**;
Neurol., Univ. of California, Irvine, Irvine, CA

Abstract: As clinical trials of human neural stem and progenitor cells (HuNSPCs) develop for neurological applications such as spinal cord injury (SCI), it will be imperative to ensure equivalent potency of each line of cells prior to transplantation. We hypothesized that multimodal profiling of HuNSPCs prior to transplant will enable quantitative detection of population composition and prediction of cell potency. We measured the following parameters: cell size, whole cell electrophysiological properties, cell proliferation, and marker expression. We discovered significant heterogeneity in HuNSPCs expanded for SCI transplant in all measures of the multimodal profile, creating problems for ensuring transplant reproducibility. We sorted HuNSPCs to reduce heterogeneity using markers (CD133+, CD34-). Sorted HuNSPCs differed from unsorted cells in cell size, electrophysiological properties, and proliferative ability, which is critical for cell expansion prior to transplant. Sorted cells also significantly differed from unsorted controls in expression of cell surface markers, which can indicate cell phenotype and predict ability of cells to interact with molecules in the transplantation niche. Thus, multimodal profiling identified several significant quantifiable differences between control and sorted HuNSPCs prior to transplantation.
Despite differences in the sorted and unsorted cells, randomized, blinded assessment of locomotor recovery using ladder beam showed that although animals receiving the sorted cells

had slightly higher performance values there was not significant improvement over controls. However, animals treated with sorted cells showed reduced heterogeneity in functional recovery, showing a tighter range of responses than those of animals treated with unsorted cells or vehicle controls. Importantly, animals treated with the sorted cells did not show evidence of increased allodynia, suggesting that enriching proliferative cells for transplant did not cause harm. Future studies of HuNSPCs that elicit a robust increase in locomotor recovery post-transplant will help to identify which quantifiable cellular characteristics most closely associate with the ability of HuNSPCs to repair the CNS.

Title: The relationship between frequency of acute intermittent hypoxia treatment, spinal plasticity, and functional improvements in chronic cervical spinal cord injury

Authors: *A. E. HAGGERTY[1], N. DE LA OLIVA[2], M. OUDEGA[3];
[1]The Miami Project to Cure Paralysis, Univ. of Miami, Miami, FL; [2]Miami Project To Cure Paralysis, Univ. of Mia, Miami, FL; [3]Dept. of Neurolog. Surgery, The Miami Project to Cure Paralysis, Univ. of Miami Dept. of Neurolog. Surgery, Miami, FL

Abstract: Spinal cord injury (SCI) results in nervous tissue loss and functional impairments. Acute intermittent hypoxia (AIH), a relative non-invasive exposure to cycles of normal and hypoxic oxygen levels, has been investigated as a potential therapy for spinal cord injury in both animal and human studies. It was shown that AIH treatment result in partial functional recovery in adult rats and in humans with SCI, especially when paired with exercise training. Currently, the mechanisms underlying these effects are largely unknown. One possibility is AIH leads to increased presence of growth factors that mediate axon sprouting in spared circuitries and/or damaged axons leading to the strengthening and/or formation of synaptic connections. The dose of AIH can be measured in terms of both frequency and duration. The previously defined “safe” range of hypoxia dose, i.e. one that has been shown to not elicit negative physiological consequences, is fairly wide (Navarrete-Opazo and Mitchell, 2014). Optimizing dose within this

“safe” range to maximize synaptic plasticity and improve functional recovery after SCI has not previously been reported. Here, we evaluated a range of frequencies of hypoxia/normoxia-cycles paired with neuronal tracing techniques and clinically relevant functional outcome measures including reach/grasp and grip strength using an adult rat model of chronic contusive cervical spinal cord injury. Optimizing AIH in our model may lead to a better understanding of the mechanisms of AIH and inform clinical implementations of AIH in studies involving SCI patients. Preliminary data suggests that the dose of AIH is correlated with synaptic plasticity at and around the injury and that spared connections within the chronic SCI environment can be engaged in new circuitry for improvements in function.

Children's Hosp Boston, Boston, MA

Abstract: After spinal cord injury (SCI), most patients have anatomically incomplete injuries with spared axons around the lesion. How to maximally utilize the spared axonal connections surviving after SCI presents a new direction for the treatment of SCI. Our previous data showed that reactivating KCC2, via its agonist CLP290 or viral strategy-based KCC2 over-expression is sufficient to revive the dormant circuitry rendered by injury and restores stepping ability in staggered bilateral hemi-section mice. In order to test the translational potential of KCC2 related treatments, we used contusion injury which could model the wide spectrum of SCI patients. Our preliminary data showed that after contusion injury, KCC2 over-expression by tail vein injected AAV-PHP.B vectors led to significant functional recovery according to the score on the Basso mouse scale (BMS). Furthermore, kinematic analysis indicated that KCC2 treatment mice had significantly increased quality of hindlimbs standing (body weight support) and stepping (step height and step frequency). We are performing additional kinematics, electrophysiology, and histological analysis in contused mice with the treatment of AAV-KCC2 or CLP290. In conclusion, our data will indicate if KCC2 related treatments could support functional recovery in a clinically relevant, spinal cord contusion model.

Abstract: Neural stem cell (NSC) is a promising therapeutic approach for many neurodegenerative and neurological disorders including spinal cord injury (SCI). NSCs replace and reestablish neuronal cells in damaged brain areas. We recently showed that adult human multipotent neural cells (ahMNCs) have significant therapeutic efficacy in animals with SCI, which is partly mediated by trophic and pro-angiogenic paracrine effects. In this study, we further investigated cytokines of ahMNCs that attenuate apoptosis of spinal cord neurons (SCNs). The treatment of ahMNC-conditioned media (CM) significantly reduced H_2O_2-induced cell death of primarily cultured SCNs. ahMNC-CM treatment significantly reduced expression of pro-apoptotic genes such as cleaved caspase3 and BAX in SCN cells. These data identified cytokines of ahMNCs that have significant neuroprotective effects in SCN cells, which could be utilized to enhance the paracrine effects of stem cell therapeutics for neurodegenerative diseases.

Title: GDF10 promotes axonal regeneration and functional recovery: A novel gene therapy strategy for spinal cord injury

Authors: *P. M. ABDUL-MUNEER, S. BHOWMICK, V. D'MELLO;
Hackensack Meridian Hlth. JFK Med. Ctr., Edison, NJ

Abstract: Spinal cord injury (SCI) occurs when there is damage from trauma, loss of normal blood supply, or a mass effect due to compression from tumor or infection. Unlike other parts of the body, the regenerative ability of the spinal cord is relatively poor. The inability of axons to regenerate after SCI is attributable to a combination of effects of the non-permissive extrinsic factors including myelin proteins and chondroitin sulfate proteoglycans (CSPGs), and cell-autonomous intrinsic factors including cAMP, RhoA, Krüppel-like factors, mammalian target of rapamycin (mTOR) and phosphatase and tensin homolog (PTEN). However, the factor(s) that may be triggered to promote the initiation of a molecular growth program and axonal sprouting in SCI are largely unknown. In this project, we developed a novel therapeutic approach to treat SCI by exploiting the neuronal growth-promoting potential of growth differentiation factor 10 (GDF10), a potential gene belongs to the transforming growth factor beta (TGF-β) superfamily. GDF10 regulates several molecular signaling systems to induce a neuronal growth state. Our focus on GDF10 as a therapeutic target after SCI is based on the observation that GDF10 regulates major axonal regenerative cues including PTEN, phosphoinositide 3-kinase (PI3K) and suppressor of cytokine signaling 3 (SOCS3). Thus, we hypothesize that up-regulation of GDF10 mitigates PTEN-mediated inhibition of axonal regeneration. We examined the specific effects of GDF10 on other major regulatory signaling cascades of axonal regeneration, the PI3K, and SOCS3 pathways *in vitro* and *in vivo*. In order to up-regulate GDF10 in experimental animals, we delivered GDF10 gene via adeno-associated virus into the sensory-motor cortical area of the brain and into the spinal cord rostral to the SCI lesion, and evaluate the subsequent progress of axonal regeneration and functional recovery after SCI. To validate the role of GDF10 in axonal regeneration, we used the CRISPR/Cas9 gene deletion technology to remove GDF10 gene. Findings from this project would help to clarify the specific role of GDF10 in axonal regeneration and functional recovery after SCI and establish a basis for pursuing GDF10 as a therapeutic strategy for spinal cord injured patients.

Title: The effects of 6-aminonicotinamide (6-AN) treatment on migration of Schwann cells transplanted in the contused spinal cord in adult rats

Authors: *T. MIHARA[1], A. HAGGERTY[1], K. YAMANE[1], Y. PRESSMAN[1], S. CERQUEIRA[1], M. B. BUNGE[1,2], M. OUDEGA[1,2,3,4];

Abstract: In different models of spinal cord injury (SCI), transplantation of Schwann cells (SCs) into the injury elicits anatomical repair, which often is accompanied by some improvements in functional outcomes. Currently, SC transplantation for spinal cord repair is being tested in a clinical trial. One of the hallmark effects of SC transplantation is the promotion of axon regeneration. However, the responding axons remain 'trapped' within the SC environment; they do not grow beyond the transplant into the adjacent spinal cord nervous tissue. This failure has been a longstanding hurdle for achieving larger repair effects by intraspinal SC transplants. It is thought that the astrocytic scar in the spinal cord adjacent to the SC transplant arrests the growth of the axons. Treatment of SCs and reactive astrocytes in a confrontation assay with 6-aminonicotinamide (6-AN), an antimetabolite that interferes in the pentose phosphate metabolic pathway, promotes mingling of SCs within the astrocytic milieu. Moreover, in this confrontation assay, axons from dorsal root sensory neurons seeded on the SCs were growing across the SC-astrocyte border with 6-AN treatment but not in controls. We argued that 6-AN treatment could promote transplanted SC-astrocyte mingling in the injured spinal cord, thereby facilitating axon growth beyond the SC transplant further into the spinal cord. We tested different 6-AN concentrations and different treatment times and locations for eliciting SC-astrocyte mingling in the contused spinal cord in adult rats. SCs were transplanted at one week after impact into the contusion epicenter. We found that an injection of 6-AN at different concentrations into the spinal cord parenchyma caudal to the SC transplant caused damage. The degree of damage related to the amount of 6-AN and was especially visible in gray matter. An injection of 0.02 M

6-AN injected 1 mm caudal to the contusion epicenter, within the SC transplant did not affected SC survival and resulted in SC migration into the adjacent astrocyte-rich environment one week after injections. Long-term effects on SC migration using the latter treatment paradigm and associated axon growth responses will be discussed. Our data suggest that 6-AN treatment may support SC migration into astrocyte-rich terrain which modifies the axon growth obstructive astrocytic scar in the injured spinal cord.

Abstract: Clinical trials striving to improve neurological outcomes following spinal cord injury (SCI) have yet to identify an intervention that maintains the current medical standard of care while effectively improving neurological outcomes beyond initial surgical stabilization and comprehensive rehabilitation. Regenerative therapy with stem cells for SCI has recently attracted interest from scientists and clinicians alike for a variety of conditions, including neuronal degeneration and traumatic SCI. Adipose-derived MSCs (AD-MSCs) represent a readily accessible cell source with high proliferative capacity that overcome limitations of previously studied cell lines. We are currently enrolling patients in our CELLTOP trial which is a Phase I/II clinical trial investigating safety and efficacy of intrathecal autologous AD-MSCs in a patient with blunt, traumatic SCI. In the present report, we describe the outcome of the first subject, a 53 year old survivor from a surfing accident who sustained an ASIA A/B cervical SCI with subsequent neurologic improvement which plateaued at 7 months following injury. He was enrolled with ASIA C neurologic status, at 9 months post injury. An adipose biopsy was

performed and MSCs were isolated, expanded and cryopreserved in the Mayo Clinic Immune, Progenitor, and Cell Therapeutics (IMPACT) Lab. He received an intrathecal injection of 100 million AD-MSCs suspended in Lactated Ringer's solution and infused after a standard lumbar puncture at the L3-L4 level, 11 months after the injury. Significant improvement in International Standards for Neurologic Classification of Spinal Cord Injury (ISNCSCI) motor and sensory scores was recorded at 1 year following intrathecal administration. Significant improvement in Capability of Upper Extremity score (measured using Capabilities of Upper Extremity Instrument) and global health (measured using PROMIS-10) was also documented. AD-MSCs may be a promising candidate for improving, rather than stabilizing, neurologic impairment after SCI.

Title: Allogeneic umbilical cord derived mesenchymal stem cells transplantation improves motor function in spinal cord injured rats

Authors: *F. MOINUDDIN[1], K. PETRUCCI[2], G. YEH[2], A. SIDDIQUI[1], Y. YOLCU[1], W. WAHOOD[1], A. GOYAL[1], M. ALI ALVI[1], S. GONCALVES[1], N. MADIGAN[1], A. WINDEBANK[1], B. MOHAMAD[1];
[1]Mayo Clin., Rochester, MN; [2]Animal Cell Therapies, Inc, San Diego, CA

Abstract: ***Introduction****:* Spinal cord injury (SCI) is one of the most devastating forms of trauma resulting in severe functional loss. The injury induces a cascade of secondary insults that limits spontaneous neural tissue regeneration. In recent years, stem cell treatment for SCI has been extensively investigated. Human umbilical cord derived mesenchymal stem cells (UCMSCs) are easier to isolate and expand, and exhibit greater proliferative activity. Using allogeneic UCMSC in spinal cord injured rats could be an appropriate preclinical representation of functional improvement. ***Methods****:* Twelve female Sprague-Dawley rats were randomly divided into two groups: control group (n=6), and rat UCMSC group (n=6). Both groups were subjected to T9 moderate spinal cord contusion injury using a Horizon Impactor machine with 150 kilodynes force. The control group received ringer lactate (RL) injections, whereas the UCMSC group were infused with cells through tail vein 7days after SCI. All rats were examined for motor function by Basso, Beattie, and Bresnahan (BBB) open field locomotion score. The contents of

axonal regeneration, cavity volume and glial scar were also explored by immunohistochemistry. ***Results****:* Recovery of hind-limb locomotor function was significantly enhanced in the UCMSC infused animals from 2nd week to 14th week after injection. BBB scores in UCMSCs- infused animals were 11.1, 11.9, and 14.1 at 2, 3, and 14 weeks after infusion, respectively, which were significantly higher than those of the RL-infused group (8.5, 9.1, and 10.1). Damaged lesions cavity area were lesser in the UCMSCs treated rats compared to the control group. ***Conclusion****:* Our results demonstrated that treatment with allogeneic UCMSC can facilitate functional recovery after SCI in rats. This will support that intravenous human-UCMSCs will be a useful translational therapeutic strategy that could improve the functional capacity among patients with SCI.

Title: Tacc3 is a therapeutic target for axon regeneration in adult CNS

Authors: *S. WANG, X. JIANG, Y. OHTAKE, S. LI;
Lewis Katz SOM, Shriners Hosp. Pediatric Res. Ctr., Temple Univ., Philadelphia, PA

Abstract: Severed axons fail to regenerate in adult mammalian CNS and currently there are no treatments for patients with CNS injuries. Microtubules (MT) are critical cytoskeleton proteins during axon elongation and regulation of their dynamics may affect axon regeneration of mature neurons. Transforming Acidic Coiled-Coil Containing Protein 3 (TACC3) is a MT plus-end-tracking protein and is essential for regulating axon extension during development. Here, we study the role of TACC3 for regulating regenerative capacity of mature neurons in adult mammals by a viral vector approach. We designed adeno-associated virus (AAV) vectors for TACC3 using synapsin I promoter to target neuron populations specially. We delivered AAV2-

Syn-TACC3 intravitreally to adult mice with optic nerve crush injury and demonstrated that upregulation of TACC3 in retina ganglion cell (RGCs) promotes robust axon regeneration past the lesion site of optic nerve (> 2 mm in length), in contrast to no regrowth in controls treated with AAV2-synapsin-GFP. Most regenerated axons display a linear trajectory growth towards the optic chiasm. Currently, we are studying whether treatments with our viral vectors that target TACC3 increase survival of RGCs after optic nerve injury and whether upregulation of this gene by a systemic delivery approach achieve the similar outcomes. We conclude that overexpression of TACC3 promotes dramatic axon regeneration in adult CNS neurons and that TACC3 is an important therapeutic target for CNS lesions, including axon injury along the visual system.

Title: The effect of a glycosaminoglycan mimetic on Schwann cell-mediated repair of a severely injured spinal cord in adult rats

Authors: *A. OKUDA[1], T. MIHARA[1], S. HASHEMI[2], T. L. ARINZEH[2], M. OUDEGA[1,3,4,5]; [1]The Miami Project To Cure Paralysis, Miami, FL; [2]Biomed. Engin., New Jersey Inst. of Technol., Newark, NJ; [3]Dept. of Neurolog. Surgery, Univ. of Miami Miller Sch. of Med., Miami, FL; [4]Affiliated Cancer Hosp. & Inst. of Guangzhou Med. Univ., Guangzhou Med. Univ., Guangzhou, China; [5]Bruce W. Carter Dept. of Veterans Affairs Med. Ctr., Miami, FL

Abstract: Spinal cord injury (SCI) results in nervous tissue damage and functional impairments. Current repair approaches have limited effect on functional recovery, especially in the severely damaged spinal cord. Schwann cells (SCs) are explored for SCI due to their ability to promote axon growth and myelination and elicit numerous other repair-supporting events, which often result in functional recovery. Glycosaminoglycans (GAGs) are sulfated polysaccharides that can elicit axon growth depending on the position and degree of sulfation. Fully sulfated cellulose (fCelS), with three sulfate groups per glucose monomer unit, is a GAG mimetic that elicits axon growth (Menezes et al., 2019) and SC myelination *in vitro*. We argued that combining SC transplantation with fCelS treatment would enhance the overall axon growth response and elicit repair and recovery after severely injured spinal cord. To address this idea, we first evaluated the design of the scaffold, which was prepared in a spiral form containing aligned fibers for axonal

growth. After implantation into the completely transected adult rat spinal cord, we found that axons were abundant and growing into the rostral-caudal direction in the scaffold. Then, we evaluated the fCelS-containing scaffold in the same SCI model with or without SCs. We investigated the effects on SC survival, axon growth and myelination, inflammation, and vascularization in the scaffold, and on tissue sparing and scar presence in the spinal cord adjacent to the scaffold. We also discuss the presence of axons that regenerated from the scaffold into the caudal spinal cord and on behavioral outcomes.

Abstract: Spinal cord injury (SCI) results in nervous tissue loss and so far untreatable functional impairments. A transplant of bone marrow-derived mesenchymal stem cells (MSCs) can elicit anatomical repair resulting in partial functional recovery, likely through paracrine actions. Previously, we showed that repair by a MSC transplant is limited by their poor survival in damaged spinal cord nervous tissue (Ritfeld et al., 2014). Angiogenesis in the injured spinal cord influences cell transplant survival, neuroprotection, and functional outcome (Ritfeld et al., 2015). Hydrogels are used as a matrix for cell transplants. Here, we tested the utility of a nanofiber hydrogel composite (NHC) engineered to resemble spinal cord nervous tissue in stiffness while providing a porosity that enables cell infiltration as a transplant matrix for MSCs. The effects of MSCs on SCI repair is in large part due to their ability to improve angiogenesis, growth factor secretion, neuroprotection, and immunomodulation. MSC transplants have limited effects on axon regeneration. Our quantitative data indicate that the NHC-MSC combination modulates the immune response in the injured spinal cord segment and elicits a robust axon regeneration response. These effects were found at later, rather than earlier, time points after implementation of the combinatorial treatment.

Title: Retrograde AAV transduction and 3D microscopy enable rapid assessment of axon sparing and regeneration after spinal injury

Authors: *Z. WANG[1], P. TSOULFAS[2], M. G. BLACKMORE[1];
[1]Biomed. Sci., Marquette Univ., Milwaukee, WI; [2]Pope Life Ctr., Univ. of Miami Sch. of Med., Miami, FL

Abstract: White matter in the spinal cord is comprised of discrete axon tracts that arise from diverse sets of supraspinal neurons. Injuries to the spinal cord are often quite variable, even in controlled research settings, resulting in subject-to-subject differences in the number of surviving axons in each population. In addition, as researchers test strategies to promote axon regeneration after injury, there is inevitable variability in response between subjects (i.e. “responders” and “non-responders”) and differences in the response from neuronal sub-types. Thus, to evaluate

pro-regenerative treatments, and to meaningfully interpret behavioral outcomes, there is a pressing need to quantify the number and location of neurons whose axons were initially spared by injury, and to survey the neuronal populations that subsequently regenerated. To do so we have developed a method that combines viral delivery of retrograde fluorophores with optical clearing of brain tissue. In initial experiments adult mice received of Retro-AAV-H2B-mScarlet or H2B-mNeongreen to C6 spinal cord, in the presence or absence of unilateral dorsal wireknife injury at C4. Two weeks later, various 3DISCO-based clearing methods and 3D imaging revealed extensive label in supraspinal populations throughout the brainstem, midbrain, and cortex. Bright fluorescent signal and nuclear localization facilitated semi-automated quantification. As expected, the dorsal injury reduced cortical labeling by more than 99% while largely maintaining brainstem labeling, reflecting the dorsal versus ventral trajectory of axons. Thus, quantification of labeled nuclei throughout the brain can compare the degree of axon sparing between individual animals and between various injury models. In ongoing work, we are combining immediate H2B-mNeongreen injections with delayed H2B-mScarlet injections, in order to distinguish axon sparing and subsequent regeneration. Our current data indicate that retrograde transduction and 3D imaging provides a practical tool to examine CNS-wide axon maintenance and regrowth after spinal injury.

Abstract: Hand function is the highest priority to regain for people with cervical SCI. We are developing translational therapeutic neuromodulation approaches using brain and spinal cord stimulation that activate key motor pathways to promote recovery of hand function. We use

patterned cortical electrical stimulation (intermittent theta burst stimulation; iTBS), shown in the rat to strongly activate the corticospinal system (CS), the principal pathway for hand control, to promote recovery of skill and dexterity. We combine this with transcutaneous spinal direct current stimulation (tsDCS) to further strengthen connections and improve function after SCI. We determined if combined stimulation augments the efficacy of CS activation of muscle. In separate sessions we compared the motor evoked potential (MEP) before, during, and after iTBS or tsDCS alone, and in combination. The dose of tsDCS was based on algorithms to steer the direct current to influence corticomuscular output. In line with the findings in the rat studies, iTBS alone, tsDCS alone, and the combination, augmented the period of post-stimulation MEP facilitation.

To evaluate stimulation therapy after SCI we developed a pre-clinical large animal model of contusion injury, informed by modeling the tissue strain to the C4 spinal segment and pilot experiments (3.5 mm spherical indentor at 800 kDyn force with a 1-15 s dwell). MR-scans and histopathology indicate the lesion was incomplete and asymmetric, analogous to most human cases. The chronic motor deficits were asymmetric and associated with injury size. We tailored the delivery of iTBS to primarily activate the impaired CS, with tsDCS (4 mA cathodal), and for 30 min/day on 10 consecutive days in the chronic phase 1-2 months, after spontaneous recovery had plateaued.

We observed improved reach control following stimulation therapy. We also found augmented MEP recruitment that suggests CS strengthening. The behavioral and physiological improvements persisted beyond several weeks after therapy.

These encouraging results show a strengthening of motor cortex-to-muscle activation, facilitation of motor cortex-mediated MEP potentiation, and an improvement in distal motor skill. These preliminary findings point to a neuromodulatory strengthening of the corticospinal system for improved motor control after cervical injury.

Title: Effects of different single-bout AIH protocols on LUT function in adult naïve and SCI rats

Authors: *W. F. COLLINS, III[1], I. C. SOLOMON[2];
[1]Neurobio. & Behavior, [2]Physiol. & Biophysics, Stony Brook Univ., Stony Brook, NY

Abstract: We have previously demonstrated that a single bout of acute intermittent hypoxia (AIH) produces sustained increases in reflex bladder inter-contraction interval (ICI) and micturition volume in both naïve rats and rats with moderate spinal cord injury (SCI) as well a sustained decrease in the frequency of non-voiding contractions in SCI rats. In the present study, we extend these observations on lower urinary tract (LUT) function in naïve and SCI rats by comparing different single-bout AIH protocols that keep the total duration of hypoxia (15 min; 12% O_2, balance N_2) constant but differ in timing and number of hypoxic episodes. To this end, adult female Sprague-Dawley rats were randomly assigned to either the naïve or SCI (moderate contusion (200 kilodynes) mid-thoracic SCI, 4-weeks survival) groups. In each rat, bladder intravesical pressure and void volume were recorded under urethane anesthesia (1.4 g/kg, spontaneous breathing) during continuous infusion of saline (0.04 ml/min) into the bladder to elicit reflex micturition events. Following >60 min of baseline recording, rats were exposed to a single bout of AIH with one of the following three protocols: (1) three 5-min episodes of hypoxia each separated by 5-min exposures to room air, (2) five 3-min episodes of hypoxia each separated by 3-min exposures to room air, or (3) ten 1.5-min episodes of hypoxia each separated by 1.5-min exposures to room air. Following AIH exposure, data acquisition continued for up to 120 minutes while the rats continued to breathe room air. Each of the single-bout AIH protocols produced comparable sustained (up to 120 min post-AIH) increases in bladder inter-contraction interval and micturition volume both in naïve and SCI rats. Moreover, each of the protocols appeared to be equally effective in reducing the ratio of non-voiding/voiding bladder contractions in SCI rats. Single-bout AIH exposure also produced transient increases in both bladder contraction threshold pressure and minimum bladder pressure. Modulation of LUT behavior during individual exposures to hypoxia and immediately following each hypoxic episode ("off effect") were also observed, with the intensity of the "off effect" tending to be lower following short duration (e.g., 10 x 1.5-min) hypoxic exposures. Our observations suggest that each single-bout AIH protocol is effective in reducing non-voiding bladder contractions and increasing micturition in SCI rats albeit subtle differences in magnitude and/or timing were noted across the protocols.

Title: Effect of oral ketone esters use on motor function recovery alter cervical hemicontusion in rats

Authors: *O. SEIRA[1], K. KOLEHMAINEN[1], J. LIU[1], W. PLUNET[1], J. NICOLE[1], S. KAMAKARI[1], L. RAFFAELE[1], K. CLARKE[2], W. TETZLAFF[1];

Abstract: Our laboratory has previously shown that treatment with ketogenic diet (KD) improves forelimb motor control after cervical spinal cord injury (SCI) in rodents. KD is a high fat, low carbohydrate diet and as such perceived as unpalatable, which could reduce compliance in acute SCI patients. Consumption of KD results in increased liver production and release of ketone bodies like β-hydroxybutyrate (βHB). Our objective in this study is to evaluate the effect of an alternative ketogenic dietary approach. Here, we administered exogenous βHB in form of an oral ketone ester (ΔG®) as an alternative treatment that can be easily administered as an oral supplement. Beginning 4 hours following a C5 hemi-contusion injury, male Sprague-Dawley rats were treated with ΔG® or water via oral gavage, and fed *ad libitum* with either a standard control diet (SD) or KD resulting in 3 treatment groups: Ctrl+SD; ΔG®+SD & ΔG®+KD. Animals were orally gavaged with ΔG® during the first 2 weeks, followed by a gradual addition of ΔG® into their drinking water until the end of the experiment. We observed significant improvements in fine control of the forelimbs and digits after cervical SCI, such as the Irvine, Beattie and Bresnahan (IBB) Forelimb recovery score, digital extension test and the Montoya staircase in the group treated with ΔG®+SD but not with the ΔG®+KD group. The latter treatment resulted in βHB levels exceeding 6-8 mM while βHB levels in the ΔG®+SD group fluctuated in the 1-4 mM range. The spinal cords were harvested at the 8 weeks endpoint for histological analysis Our data indicate that and excessive amount of ketone bodies ΔG®+KD no longer have beneficial effects on behavioural outcomes after SCI. Further analyses to determine the mechanisms behind these behavioural improvements (and their losses) are needed. The oral administration of ΔG® might be a realistic translatable alternative to the KD. Supported by the Craig H Nielsen Foundation

Title: Impact of severity and duration of acute hypoxic exposure on lower urinary tract (LUT) function in urethane-anesthetized adult female rats

Authors: *I. C. SOLOMON[1], W. F. COLLINS, III[2];
[1]Physiol. & Biophysics, [2]Neurobio. & Behavior, Stony Brook Univ., Stony Brook, NY

Abstract: Acute hypoxia is a common occurrence in cardiovascular and pulmonary diseases, and while hypoxia-induced changes in respiratory drive/function are well documented, the effects of acute hypoxia on non-respiratory somatic motor systems are less well understood. Ongoing work in our laboratory has been examining the effects acute hypoxia on lower urinary tract (LUT) function, and these experiments have revealed that exposure to an acute episode of hypoxia modifies LUT function with the hypoxia-induced modulation being present both during hypoxia and transiently after the hypoxic stimulus is removed in both intact and SCI rats. To better understand the influence of acute hypoxia on LUT function, the present study evaluated the impact of the severity and duration of an acute hypoxic episode on LUT behaviors in urethane-anesthetized, spontaneously breathing, intact adult female Sprague-Dawley rats. For this study, reflex micturition events (rME) were elicited by continuous infusion of saline into the bladder, with the rate of infusion set to achieve a baseline (BL) bladder inter-contraction interval (ICI) of ~4.5 min. Following ~30 min of normoxic BL recording, a single episode of hypoxia (10% or 12% O_2) was initiated at approximately the midpoint of BL ICI and maintained for 90 s, 3 min, 5 min, or 15 min, after which the rat was returned to normoxia and allowed to recover. In a subset of rats, 2 hypoxic exposures (*e.g.*, 2x 90s; 2x 3 min; 90 s and 5 min; separated by at least 30 min) were used. Bladder intravesical pressure (BP) and void volume were recorded, and peak BP, minimum BP, threshold BP, ICI, and void volume of individual ME were determined. Consistent with our prior observations, exposure to hypoxia elicited a premature rME (reduced ICI), which exhibited reduced peak and threshold BP, decreased void volume, and variable effects on minimum BP. With return to normoxia, the initial rME was delayed (increased ICI) and it exhibited a marked increase in threshold BP, variable increase in both minimum BP and void volume, and negligible effects on peak BP. The hypoxia-induced LUT behaviors were reproducible in the individual rats that had 2 similar hypoxic exposures (*e.g.*, 2x 90s; 2x 3 min). The magnitude of hypoxia-induced effects was minimally affected by the severity of hypoxia, but strongly influenced by exposure duration, with longer exposures (*i.e.*, 5 and 15 min) producing progressively greater or sustained magnitude changes during hypoxia and more robust effects during the initial stages of recovery. These data demonstrate that the duration of acute hypoxic exposure can impact the magnitude and duration of hypoxia-induced alterations in LUT function.

Abstract: Spinal cord injury (SCI) affects over 80 000 people in Canada and significantly impacts quality of life. Previous findings in our lab demonstrated that the ketogenic diet (KD) may be a promising SCI treatment as rats fed with KD acutely after cervical SCI showed behavioural improvement in forelimb function. KD is a high fat, low carbohydrate diet and is clinically used in drug-resistant epilepsy in children. A hallmark of KD is the increased levels of ketone bodies, particularly β-hydroxybutyrate (BHB), which is formed through the metabolism of fatty acids. BHB can be used as an alternate energy source by cells but is also the only known endogenous ligand of the G protein-coupled receptor HCA2 (also known as the niacin receptor). Given our positive results with acute KD treatment, we were interested to see if administering exogenous BHB could provide similar benefits after SCI. To provide exogenous BHB we used the commercially available ketone ester, ΔG®, which can be administered as an oral treatment and produces a rapid and transient increase in plasma BHB. Sprague-Dawley rats were given a C5 hemi-contusion then gavaged with the ΔG® ketone ester (KE) starting 4 hours after injury. Gavage treatment continued for two weeks at which point rats were sacrificed and the spinal cord lesion site was prepared for mass spectrometry analysis. We performed a global proteomic analysis of the injury site. As expected we found multiple metabolic proteins upregulated by KE. Specifically, those involved in the TCA cycle and glycogen synthesis. As well we found upregulation of cytoskeletal components and proteins involved in neural outgrowth and differentiation. Overall, our results identify multiple pathways affected by BHB and we are following up on our proteomic analysis with specific *in vitro* and *in vivo* manipulation of candidate pathways.

Abstract: The ability to manipulate specific neuronal populations of the spinal cord following spinal cord injury (SCI) could potentially prove highly beneficial for rehabilitation in patients through maintaining and strengthening still existing neuronal connections and/or facilitating the formation of new connections. A non-invasive and highly specific approach to neuronal stimulation is bioluminescent-optogenetics, where genetically expressed light emitting luciferases are tethered to light sensitive channelrhodopsins (luminopsins, LMO); neurons are activated by the addition of the luciferase substrate coelenterazine (CTZ). This approach takes advantage of utilizing ion channels for current conduction while activating the channels through application of a small chemical compound, thus allowing non-invasive stimulation and recruitment of all targeted neurons. We previously showed the efficacy of this approach in improving locomotor recovery following severe spinal cord injury in rats expressing the excitatory LMO3 under control of a pan-neuronal and motor neuron specific promoter; CTZ was applied through a lateral ventricle cannula. Here we transduced spinal cord neurons with a synapsin-driven step function LMO, SFLMO(CS). In this construct the Gaussia luciferase variant sbGLuc is fused to the step function opsin ChR2(CS). As SFOs are significantly more light sensitive than other opsins, we stimulated transduced lumbar neurons by intraperitoneal application of CTZ, allowing for a less invasive treatment.

Title: Repeated transspinal stimulation reorganizes neural circuitries in spinal cord injured rat

Authors: *D. C. MALLOY, M.-P. CÔTÉ;
Neurobio. and Anat., Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: Electrical stimulation is commonly used to promote recovery of motor function in upper motoneuron lesions. After spinal cord injury (SCI), stimulation delivered over muscle(s), mixed or sensory nerves, primary motor cortex, and spinal cord transcutaneously or epidurally have all been employed with the aim to promote functional recovery. In this study, we probed spinal neuroplasticity after repeated cathodal transspinal stimulation via the plantar H-reflex, a well-established neurophysiological biomarker of hyperreflexia and spasticity in rodents. We also assessed changes in motor output via the transspinal stimulation induced muscle responses (transspinal evoked potentials; TEPs). Adult female Sprague Dawley rats underwent a severe T9 contusion SCI (250 kdyn) and were randomly assigned to sham or transspinal stimulation groups that was delivered three times per week for 5-6 weeks on awake animals, starting five days post-SCI. Animals laid prone with the cathode electrode placed over the lumbar enlargement and the anode electrodes placed over the abdomen. Stimulation was delivered at sub- (0.8T) and suprathreshold TEP intensity (1.2T) in alternating 3-minute bouts (1 ms pulses, 0.2 Hz) for 18 minutes. Terminal experiments were performed at 6-weeks post-injury to establish changes on the recruitment of flexor and extensor motoneurons, H-reflex frequency dependent depression, and H-reflex modulation profile following transspinal conditioning stimulation. We found that repeated transspinal stimulation increased the amplitude of TEPs recorded from hindlimb muscles in the experimental and not in the sham group. Lower recruitment threshold, steeper slope, and larger maximal responses were observed in the plantar muscle. In addition, the H-reflex excitability was decreased and frequency-dependent depression was potentiated. Lastly, repeated transspinal stimulation decreased the H-reflex when preceded by a TEP, a phenomenon that was not observed in the sham group. These results provide strong evidence that transspinal stimulation can be used as a neuromodulation tool to concomitantly decrease spinal reflex hyperexcitability and increase motor output after SCI.

Title: The co-occurrence of Alice in Wonderland syndrome and autonomous sensory meridian response

Authors: *S. BEDWELL[1], I. BUTCHER[2];
[1]Birmingham City Univ., Birmingham, United Kingdom; [2]Univ. of Manchester, Manchester, United Kingdom

Abstract: Alice in Wonderland Syndrome and Autonomous Sensory Meridian Response are both terms used to describe specific neurophysiological responses to external stimuli. Although different in their presentation and symptomatic descriptions, there are many commonalities in terms of symptoms of perception and of theories of aetiology. In the present study, we sought to establish the link between symptoms associated with Alice in Wonderland Syndrome and those described in Autonomous Sensory Meridian Response. In an online questionnaire study, participants known to experience Autonomous Sensory Meridian Response self-reported their specific experiences of the phenomena, along with experiences associated with symptoms of Alice in Wonderland Syndrome. Our findings show a striking high presence of Alice in Wonderland Syndrome symptoms amongst a population who are aware of experiencing Autonomous Sensory Meridian Response. Additionally, we observed a significant predictive relationship ($p = .036$) between the visual symptoms of Alice in Wonderland Syndrome in childhood and the age of onset of Autonomous Sensory Meridian Response. These findings provide a valuable insight into the possible underpinnings of two little understood neurophysiological phenomena and offer the foundation for gaining a further understanding of the possible therapeutic and neuroprotective effects of Autonomous Sensory Meridian Response.

Title: Components of the cochlear mechanoelectrical transduction machinery involved in auditory cortex development

Authors: M. D. MORAIS, M. GAGLIARDINI, O. POSTAL, P. JEAN, T. DUPONT, B. GOURÉVITCH, C. PETIT, *N. MICHALSKI;
Unite Genetique & Physiologie Audition, Paris Cedex 15, France

Abstract: The genetic approach, based on inherited forms of deafness, has proved particularly effective for deciphering the molecular physiology of the auditory sensory organ, the cochlea. Since the discovery of the first gene responsible for deafness in both humans and mice, the gene encoding myosin-VIIa, about 110 genes responsible for non-syndromic forms of deafness and about 300 genes responsible for syndromic forms have been reported in humans and/or mice. By contrast, the genetic approach has provided little information about the central auditory system, even though central auditory system dysfunctions are thought to affect ~5% of children and more than ~25% of elderly people. One possible explanation for this discrepancy is that intrinsic auditory central deficits may be concealed by peripheral deficits in genetic forms of deafness. Indeed, we have recently revealed that the genes encoding cdhr15 and cdhr23, the cadherin-related proteins forming the tip-link, the heart of the auditory transduction machinery in auditory sensory cells, are also expressed by precursors of many GABAergic inhibitory parvalbumin interneurons. We have shown that these interneuron precursors are specifically targeted to the auditory cortex in a process requiring these two cadherins. Therefore, these results have opened the possibility that the other proteins of the mechanoelectrical transduction machinery, in addition to cdhr15 and cdhr23, could be involved in the development of cortical interneurons and other cell types of the auditory cortex. To gain insight into other deafness genes that may have roles in the auditory cortex and more generally in the central auditory pathways, we have produced new cre genetic tools for the fluorescent tracing of Cdhr15/Cdhr23-expressing interneurons. Here, we will present these new genetic tools and the first insights they provided on the expression of other deafness genes in the auditory cortex. By characterizing cortical deficits in mouse models of previously identified forms of peripheral human deafness, our work should pave the way for future studies of intrinsic cortical defects in patients and improvements in auditory rehabilitation.

Title: Long-term NAD^+ supplementation rescues high-frequency age-related hearing loss in mice

Authors: *R. KIMURA, M. N. OKUR, D. L. CROTEAU, V. A. BOHR;
Natl. Inst. on Aging, NIH, Baltimore, MD

Abstract: Hearing loss is the most common sensory impairment in elderly adults, affecting over one-third of adults beyond age 60. Age-related hearing loss (ARHL) is characterized by a progressive loss of sensitivity to sounds, starting with high-frequency stimuli. Our group previously showed that mouse models of Cockayne Syndrome (CS), a premature aging disease with a major symptom resembling an accelerated form of ARHL, display high metabolic activity and mitochondrial dysfunction. Given the importance of mitochondrial integrity in healthy hearing, interventions targeting mitochondrial homeostasis may prove beneficial for ARHL. Our current study shows that a short-term 4-week intervention of nicotinamide riboside (NR), a precursor of a key metabolite nicotinamide adenine dinucleotide (NAD+), in drinking water has preventative effects for high-frequency hearing loss in CS mice. Interestingly, our results show that NR also has a beneficial effect on wild type mice, which led to further inquiries assessing the efficacy of long-term NR treatment under non-diseased conditions. In our subsequent study, we subjected mice (N=48) to a prolonged 6-month NR treatment starting at 8 weeks of age. We used auditory brainstem response (ABR), a measure of auditory transduction and neural pathway integrity, and distortion product otoacoustic emissions (DPOAE), a measure of outer hair cell function, to characterize the hearing ability of our mice. Remarkably, our data shows that NR treatment dramatically reduces ($p<0.0001$) high-frequency hearing loss in aging mice, with 8-month-old treated cohorts displaying ABR thresholds statistically similar to that at 8 weeks. These results collectively support a model of metabolic deficit in ARHL and offer NAD+ supplementation as a promising therapeutic for this condition.

Title: Behavioral phenotyping of a novel Wolfram syndrome zebrafish model

Authors: *B. DELPRAT[1], L. CROUZIER[1], C. DELETTRE[2], T. MAURICE[1];
[1]MMDN, Univ. Montpellier, EPHE, INSERM, U1198, Montpellier, France; [2]Inserm U1051, Montpellier, France

Abstract: Wolfram syndrome (WS) is a rare multisystem neurodegenerative disorder also known as DIDMOAD (diabetes insipidus, insulin-deficient diabetes mellitus, optic atrophy and deafness). WS is an autosomal recessive disease causing degeneration of beta cells in the pancreas, ganglion cells in the retina and hair cells in the inner ear. The syndrome is due to mutations in *WFS1*, coding Wolframin, a MAM protein involved in regulation of ER Ca^{2+} homeostasis. We previously characterized a novel $Wfs1^{Exon8del}$ knock out mouse and analyzed their auditory and visual abilities. Mice developed a progressive optic atrophy at 3 months and a moderate hearing loss at 6 months. Since those mice do not recapitulate the human's symptoms, we used a zebrafish model system, which is a valuable animal model for studying development and function of the vertebrate inner ear and retina. In zebrafish, two Wfs1 gene were expressed, *Wfs1a* and *Wfs1b*. Wfs1a shares 45% identity with human WFS1 and *Wfs1b* shares 53% identify. Interestingly, several *Wfs1a* and *Wfs1b* mutations were identified and we chose $Wfs1a^{L692X}$ and $Wfs1b^{W493X}$ to reproduce WS in two zebrafish models. Preliminary results indicated that loss of *Wfs1b* decreases visual motor response and the number of eye's saccade/min in 5dpf zebrafish. In addition, acoustic startle response is also decreased in *Wfs1b* deficient zebrafish compared to controls. Therefore, this model will be useful to decipher the molecular mechanism leading to optic atrophy and hearing loss.

Title: Drug screening utilizing the visual behavior of a night blindness zebrafish model

Authors: *L. GANZEN, Y. LEUNG;
Purdue Univ., West Lafayette, IN

Abstract: Retinitis Pigmentosa (RP) is an incurable retinal degeneration disease which affects approximately 1 in 4000 individuals globally, and the purpose of our work is to discover drugs for patients suffering from the disease. To accomplish this goal, we utilized a visual-motor response (VMR) assay to assess the diminished vision of a transgenic zebrafish RP model carrying a human Rhodopsin transgene with Q344X truncation mutation (Tg(rho:Hsa.RH1_Q344X)), and used this line to screen compound libraries. The Q344X larvae experiences significant rod degeneration by 7 days post-fertilization (dpf) and also carries a Tg(-3.7rho:EGFP) reporter for rod visualization (Nakao et al., 2012). To assess the extent of visual deficit in the Q344X zebrafish, larvae were acclimated to a scotopic light source (0.01 lux) for 1 hour. Their VMR was quantified at light-offset. Wildtype larvae exhibited an average distance travelled of 0.275 ± 0.043cm whereas Q344X larvae exhibited a significantly attenuated VMR only travelling 0.128 ± 0.038cm (Welch's Two-Sample T-test; p-value=2.124e-12, N=18 biological replicates of 48 larvae per group). This VMR assay was then utilized to screen drug compounds to identify novel drugs that can improve the visual behavior of the Q344X model. A pilot screen of SCREEN-WELL® REDOX library was performed to identify drugs that may alleviate excessive oxidative stress in the retina. The FDA-approved drug Carvedilol was identified from this screen due to its ameliorating effects on the Q344X VMR. To determine the cause of this improved behavior, the rod-containing area in the larval retina was quantified. Treated larvae had a larger average area of fluorescent signal near the marginal zone (3610±2841 μm ; N = 24)compared to the untreated larvae (1112±1305 μm ; N = 24) (Welch's Two-sample T-test, T=3.9; df=32.3; p-value= 0.0004). Treated larvae also had a larger average area of fluorescent signal in the ventral patch(2728±2468 μm ; N = 24) compared to untreated larvae (529±537 μm ; N = 24) (Welch's Two-sample T-test;T=4.2; df=25.2; p-value = 0.0002). We conclude that Carvedilol is a beneficial drug to the Q344X RP model. Fluorescent imaging indicates that rod-positive area near the marginal zone area and ventral patch were expanded by the drug treatment. This finding implies that the drug potentially increased rod numbers and in turn improved the vision of the Q344X RP model.

Title: The role of GDF6A in the early development of hearing in zebrafish

Authors: M. RICHMOND[1], M. TEKIN[2], *Z. LU[1];
[1]Dept. of Biol., Univ. Miami, Coral Gables, FL; [2]Dr. John T. Macdonald Fndn. Dept. of Human Genet. and John P. Hussman Inst. for Huma, Univ. of Miami Miller Sch. of Med., Miami, FL

Abstract: Hearing loss is the most common congenital sensory disorder with 2-3 in every 1,000 individuals born with hearing defects. Myriad genes are responsible for establishing a proper environment for the development of the hearing system. Precise control of physical structures is needed for proper conduction of vibrations, and sensory epithelia must be properly established in order for an individual to hear. Bone morphogenetic proteins (BMPs) have been extensively studied for their role in the structuring of many tissue types important to the auditory system including bone, cartilaginous, and neural tissue. Mutations in Growth Differentiation Factor 6 (GDF6), otherwise known as Bone Morphogenetic Protein 13 (BMP13), cause several developmental disorders, such as Klippel-Feil Syndrome Type 1 and Multiple Syntosis Syndrome. Patients with these disorders display an increased likelihood of having hearing loss. However, there is little published clinical evidence relating the gene to sensorineural hearing loss directly. In this study, we used zebrafish as a model to investigate the role that *gdf6a*, a paralog of human *GDF6*, plays on the early development of the inner ear using electrophysiological and confocal imaging techniques. We used *radar*^{s327}mutants (*gdf*6a$^{-/-}$) created by the Baier lab with a C to A substitution in *gdf6a*, leading to a premature stop codon early in the ORF. The mutants have a truncated Gdf6a protein lacking the functional signaling domain. We observed that *gdf6a*$^{-/-}$ mutants display cellular and functional differences with their non-mutant siblings though there was no significant difference in gross anatomy of the inner ear. To assess the auditory function of the mutants, microphonic potential recordings were made from hair cells in the otic vesicle of 3- and 7-dpf zebrafish larvae. We found that the mutants had an increased hearing threshold and reduced microphonic amplitude compared to non-mutant larvae. Then we examined the sensory epithelium in the saccule, the major hearing organ in larval zebrafish, using *Et(krt4:GFP)*^{sqet4}

transgenics expressing cytosolic GFP in hair cells. Inspection of the saccular epithelium revealed that the overall hair cell count for the mutants is normal, but the orientation of hair cells in the anterior epithelium is obstructed, which likely results in a decrease in mechanotransduction efficiency. These results demonstrate that *gdf6a* most likely plays a novel role in the development of the zebrafish inner ear during the first-week post-fertilization.

Title: What white matter plasticity can tell us about the associations between hearing loss and tinnitus

Authors: *R. A. KHAN, S. SCHMIDT, Y. TAI, S. SHAHSAVARANI, F. HUSAIN;
Univ. of Illinois At Urbana-Champaign, Urbana, IL

Abstract: Tinnitus, the perception of sound in the absence of an external source, has been attributed to changes in both the periphery (e.g. hearing loss) and the cortex. It is unclear, however, what specific neuroanatomical and functional changes co-occur with tinnitus. More confusing still is the nature of the association between hearing loss and tinnitus – most tinnitus patients have decreased hearing sensitivity, but half of those with hearing loss do not have tinnitus. The goal of the current study was to parse out the relationship between hearing loss and tinnitus by examining white matter (WM) tracts in the brain. Diffusion tensor imaging (DTI) data were collected from 76 participants across 4 groups – controls with normal hearing (n=17), controls with hearing loss (n=11), tinnitus subjects with normal hearing (n=11) and tinnitus subjects with hearing loss (n=37). Diffusion was measured along 60 directions using a 3T Siemens Prisma scanner. Fractional anisotropy (FA) analysis was conducted using FSL FMRIB and TBSS libraries. Whole brain analysis focusing on the two tinnitus groups revealed six major tracts that showed diminished integrity in the hearing loss group compared to the normal hearing group, using a FWE correction of $p<0.05$ - the left anterior thalamic radiation (ATR), bilateral anterior corona radiata (ACR), bilateral inferior longitudinal fasciculi (IF-OF), right uncincate fasciculus, right inferior longitudinal fasciculus, and bilateral superior longitudinal fasciculi (SLF). To parse out the association of observed changes with tinnitus and hearing loss, supplementary ROI analysis was conducted, with individual FA values being extracted from all 4 groups from each of the regions described above. FA values in the left ATR, ACR, IF-OF, and

SLF showed an inverse relationship with pure-tone average hearing loss (measured at 2,4,6,8 kHz frequencies), suggesting that these regions may be associated with the degree of hearing loss, regardless of tinnitus status. No strong associations were seen with the scores of Tinnitus Functional Index, which may be attributed to the relative homogeneity of tinnitus severity amongst our participants. With the collection of additional data, we hope to elucidate the neural correlates of these two associated disorders.

Title: An allele independent gene therapy strategy induces rod function in a transgenic swine model of autosomal dominant retinitis pigmentosa

Authors: A. JALLIGAMPALA[1], G. PANGENI[1], M. H. JABBAR[1], W. WANG[1], F. EFRAT[1], A. RISING[3], W. HAUSWIRTH[4], A. LEWIN[5], M. A. MCCALL[2];
[1]Ophthalmology and Visual Sci., [2]Ophthalmology & Visual Sci. and Anatom. Sci. and Neurobio., Univ. of Louisville, Louisville, KY; [3]Natl. Eye Inst., Natl. Inst. of Hlth., Bethesda, MD; [4]Ophthalmology Res., [5]Mol. Genet. and Microbiology, Univ. of Florida, Gainesville, FL

Abstract: Introduction- Retinitis pigmentosa (RP) is an inherited neurodegenerative disease. The general phenotype is characterized by an initial loss of rod photoreceptors followed by the loss of cone photoreceptors, leading to irreversible vision loss. 30% of RP cases are autosomal dominant (adRP) and mutations in the rhodopsin (RHO) gene account for about 25% of these although there is significant allelic heterogeneity. Therefore an attractive approach is one that could be broadly applied across all rhodopsin mutations. In this study, we applied a gene therapy approach in a transgenic human P23H Rho swine model of adRP, using a dual rAAV vector that combines and short hairpin RNA (shRNA) to eliminate expression of both mutant human and WT pig rhodopsin protein and augment WT rhodopsin with a shRNA resistant Rho gene.
Methods- The rAAV dual vector contains both a short hairpin RNA (shRNA820) and a WT, shRNA-resistant, replacement *RHO* gene (*RHO820*). We injected 50ul of the rAAV dual vector

at titers between 5 x 10^{11} and 1 x 10^{12}vg/ml subretinally in Tg hP23H Rho piglets between postnatal day (P)3 and 7. The structural and functional integrity of the retinas were assessed non-invasively monthly through ~20 weeks post injection (wpi), using optical coherence tomography (OCT), and full-field electroretinograms (ffERG). After the terminal assessment, the animals were euthanized, their eyes enucleated and retinas processed for morphological analyses.
Results- The Tg hP23H pig retina has a large complement of rod photoreceptors in the first postnatal month, although a rod isolated retinal response is not evident. By P60, most rods have degenerated. In contrast, AAV shRNA820/RHO820 induced a scotopic ffERG b-wave in 4 out of 6 eyes that extended through 20 wpi. Consistent with the induction of rod function, these retinas retained rod photoreceptors that express normally localized rhodopsin and, the inner laminar integrity of the OCT. Additionally, the photopic ffERG of treated Tg hP23H pig responses remain unaltered over the period analyzed. Scotopic and photopic function weres not altered in control WT piglets treated with the same vector and retinal morphology also was not affected.
Conclusion- Our results show that the AAV shRNA820/RHO820 reduces rod degeneration and induces rod function in this adRP swine model. This suggests that this therapy should potentially be useful for patients with *RHO*-linked RP.

Title: Behavioral and mechanistic study of tinnitus induced by sustained optogenetic activation of inhibitory neurons in the mouse inferior colliculus

Authors: X. LIU, ***F. LI**, H. TANG, X. LIANG, G. BI, P. LAU, L. CHEN;
Building of Life Sci., Univ. of Sci. and Technol. of China, Hefei, China

Abstract: The inferior colliculus (IC) plays an important role in the transduction of auditory signals. In animal models of tinnitus, neural activity in the IC undergoes plastic changes, but it is still debated whether tinnitus can originate from a central source such as the IC without peripheral malfunction. To address this issue, we first designed a two-way choice paradigm for tinnitus detection and built an automated system for behavioral training and testing. The effectiveness of this approach was verified using established tinnitus model with induction by

sodium salicylate. We then directly manipulated the activity of the IC using optogenetic methods to chronically activate inhibitory neurons in the IC in VGAT-ChR2-EYFP transgenic mice. Interestingly, the transgenic mice exhibited strong tinnitus-like behavior within two hours after the optogenetic stimulation, and this behavior lasted for 1-2 days. Using multi-channel recordings, we found that after 2 days of optogenetic activation in VGAT-ChR2 animals, some IC neurons showed remarkable changes in their frequency tuning, indicating weakened lateral inhibition. Meanwhile, IC neurons showed increased synchrony in their spontaneous activity. These results suggest a neural plastic change in the IC induced by chronic optogenetic activation of the inhibitory neural circuits, which led to tinnitus-like behavior, thus supporting a central origin of tinnitus.

Title: Voxel-based morphometry in age-associated hearing loss: A preliminary study

Authors: *S. SHENDE, S. SHAHSAVARANI, Y. TAI, R. MUDAR, F. HUSAIN;
Univ. of Illinois at Urbana-Champaign, Champaign, IL

Abstract: Objective and rationale: Emerging evidence suggests gray matter (GM) volume alterations in auditory and a few non-auditory regions in individuals with age-associated hearing loss. Specifically, studies report that poorer peripheral hearing acuity is correlated with reduced GM volume in the auditory cortices and parahippocampal gyrus. However, a number of these studies have failed to include an older normal hearing control group, suggesting a need to further examine whether GM alterations observed in this population are due to age or hearing loss, or both. Methods: Data from seven older adults with mild to moderate age-associated hearing loss (age: 71.5 ± 1.29 years, better ear speech-frequency pure tone average [sp-PTA]: 29.69 ± 3.28 dB HL) and four older normal hearing controls (age: 63.5 ± 4.35 years, better ear sp-PTA: 15.53 ± 4.83 dB HL) were examined. Using magnetic resonance imaging, T1 weighted structural images were obtained from all participants. GM volume was assessed using whole-brain and region-of-interest (ROI) voxel-based morphometry in both groups using the Computational Anatomy Toolbox (CAT12) with Statistical Parametric Mapping (SPM12). The ROIs located in auditory regions including the inferior colliculus, medial geniculate nucleus, superior temporal

gyrus, and middle temporal gyrus; and in non-auditory regions including anterior cingulate cortex and parahippocampal gyrus were examined. The WFU Pick Atlas toolbox in SPM12 was used to generate bilateral 8-mm radius spheres for each ROI centered at MNI coordinates. Age, sex, and total intracranial volume were used as covariates of no interest. Results: Whole brain analysis using FWE corrected ($p<0.05$) at cluster level revealed reduced GM volume in the left and right cerebellum in older adults with age-associated hearing loss as compared to older normal hearing controls. Additionally, using a less stringent threshold, reduced GM volume in the right middle temporal gyrus was observed in the hearing loss group compared to the normal hearing group (uncorrected p-value; $p<0.001$ at voxel level). ROI analysis did not show any significant group differences. Conclusion: Our preliminary findings suggest GM alterations in auditory and non-auditory regions in older adults with age-associated hearing loss, echoing the results reported in younger and middle aged adults with hearing loss. However, given that our sample size was low, further examination is needed. We are currently collecting more data to better characterize GM changes in age-associated hearing loss.

Title: Synaptic zinc regulates cochlear resilience to noise-induced hearing loss

Authors: *B. B. BIZUP[1], A. THATHIAH[1], T. TZOUNOPOULOS[2];
[2]Otolaryngology and Neurobio., [1]Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Exposure to loud noise results in a degenerative cascade involving ribbon synapse loss, hair cell death, or even shearing of the basilar membrane. The capacity of the cochlea and spiral ganglion to be repaired following damage is limited and thus noise-induced hearing loss (NIHL) is often permanent. While some treatments, like growth factor application, have been shown to alleviate NIHL in certain circumstances, there are not any clinical strategies for curing NIHL, suggesting a need for novel insights into the mechanisms of NIHL.
Zinc is involved in neurodegeneration and is modulated by noise exposure within the central auditory system, but little is known regarding its contribution to NIHL in the cochlea. Vesicular (synaptic) zinc is involved in neurodegeneration following ischemic injury and nerve crush in the visual system. Synaptic zinc is dependent on ZnT3—the protein that loads zinc into synaptic

vesicles. ZnT3 is expressed in the cochlea, and while its precise location and roles in cochlear function are unknown, it may have a similar pathological role in NIHL.
To determine if ZnT3-dependent synaptic zinc is involved in NIHL, we measured auditory brain stem response (ABR) thresholds and wave 1 amplitudes—which represent auditory nerve activity--and performed cochlear whole mount histological analysis in wild-type (WT) and ZnT3-knockout (KO) mice following sham or noise exposure. After noise exposure, KO mice display better recovery of both ABR thresholds and ABR wave 1 amplitude relative to wild-type mice, indicating that KO mice have resilience to and better recovery of cochlear function from NIHL compared to WT mice. Furthermore, this protection in KO mice is associated with higher number of ribbon synapses than WT mice 1 day after NE. To evaluate whether synaptic zinc is involved in cochlear degeneration, we treated wild-type mice systemically with the zinc chelator, TPEN, prior to and following noise exposure. We found that chelating zinc results in improved cochlear physiological function and increased ribbon synapse density in noise-exposed mice. Together, these data suggest that ZnT3-dependent synaptic zinc contributes to vulnerability to NIHL, and that zinc may be a novel target in treating NIHL.

Title: Inner ear exposure of SENS-401 is not altered by severe acoustic trauma in a rat model

Authors: C. ROMANET, C. TRAN VAN BA, P. LIAUDET, M. PETREMANN, ***J. DYHRFJELD-JOHNSEN**;
Sensorion SA, Montpellier, France

Abstract: The blood-labyrinth barrier (BLB) plays a role analogous to the blood-brain barrier, forming a selective protective barrier between the inner ear and the circulatory system. Damage to the inner ear has been demonstrated to increase BLB permeability for systemically administered macromolecules, however, the impact of this on systemically administered small molecules is unknown. Significant impact of BLB permeabilization on drug candidate local exposure of s in animal models would need to be accounted for in the translation of preclinically effective drug doses to the clinical setting for inner ear disease drug development.
SENS-401 is a small molecule otoprotectant currently in phase 2 clinical trials for the treatment of Sudden Sensorineural Hearing Loss (SSNHL). Preclinical otoprotectant efficacy with significant improvement of hearing outcomes by SENS-401 treatment vs placebo has been demonstrated in an animal model of SSNHL caused by acoustic trauma (Petremann et al., 2019),

one of many potential causes in the clinical setting.
The effect of acoustic trauma-induced damage to the BLB on SENS-401 local exposure was evaluated in a rat model. Male Wistar rats underwent severe acoustic trauma (120 dB SPL, 2 hours) or a sham equivalent exposure. A single oral dose of 13.2 mg/kg SENS-401 was administered orally either immediately after (n=4/group) or 24h after (n=16/group) end of acoustic trauma or sham trauma. In the 24h administration groups, hearing status was confirmed by auditory brainstem response (ABR) evaluations pre-trauma (all animals) and 24 hours post-trauma (acoustic trauma animals). Drug concentrations were measured in the blood and temporal bone (n=4/time-point) from 0.5 to 4 hours after administration using LC-MS/MS.
At 24h after acoustic trauma, ABR recordings confirmed an acute hearing loss with mean threshold shifts in the range of 53-58 dB across test frequencies of 8/16/25/32 kHz. Following administration immediately after severe acoustic trauma or with a 24h delay, no significant differences in SENS-401 concentration profiles of sham trauma versus acoustic trauma animals were found either locally or systemically.
In conclusion, while local exposure of macromolecular agents has been demonstrated to be significantly impacted following damage to the BLB for example by acoustic overexposure, a severe acoustic trauma had a minimal effect on local exposure of SENS-401 in the inner ear after oral administration. This supports the use of animal pharmacokinetics and local exposure data for clinical trial dose selection, without a potential impact of difference between etiologies of SSNHL in the preclinical model and the clinical setting.

Title: Neurosensory changes following low-level repeated blast exposure

Authors: *S. SAJJA[1], J. C. DEMAR, JR[2], L. HEYBURN[3], R. URIOSTE[4], A. BATUURE[4], D. WILDER[4], Y. WANG[3], A. PEETHAMBARAM[4], J. LONG[4];
[1]Walter Reed Army Insitute of Res., SilverSpring, MD; [2]Blast-Induced Neurotrauma Br., [3]Walter Reed Army Inst. of Res., Silver Spring, MD; [4]Walter Reed Army Inst. of Res., SilverSpring, MD

Abstract: Introduction: Multiple low-level blast exposures have been linked to impairment of neurosensory systems, prompting concern over the cumulative deleterious effects of blast and the need to define standards to mitigate this risk among Warfighters. There are no set guidelines establishing cumulative limits for number and intensity of blast exposures for training and operations of the Warfighter. Our objective in this study is to conduct a comprehensive assessment of auditory, visual and neurological outcomes using a rodent model of repeated low-level blast exposures.
Methods: Anesthetized rats (n=6/ group) were frontally positioned in an advanced blast simulator, which closely mimics "free-field" blast, and subjected to 1, 4 or 14 daily exposures at 4 or 6psi. Functional assessments were conducted with electroretinogram (ERG) for vision and distortion product otoacoustic emissions (DPOAE) and auditory brainstem response (ABR) for the auditory system. Assessments were made either 7 or 28 days following final exposure. Structural integrity of cochlea was evaluated using myosin VIIa and phalloidin markers and otoscopy determined the integrity of tympanic membrane.
Results: At 4psi (1, 4 or 14 exposures), significant decrements in DPOAE thresholds and impaired ABR response were observed at 7 and 28 days following blast, while significant reduction in ERG A- and B-waves were observed only in 6psi (14 exposure) groups at 28 days following blast. Outer hair cells were completely lost at the base and middle of cochlea but remained intact at the apex. Analyses for retinal damage are ongoing.
Discussion/conclusion: We identified in these preliminary findings that the ear is most susceptible to single or repeated blast exposures. Functional assessment of the visual system also shows vulnerability to low level repeated blast like that occurring in training and operations of Soldiers, which provides a first step towards identifying tolerable thresholds of blast exposure.

Abstract: Efficient and targeted gene delivery is fundamental to experimental interrogation of the nervous system, as well as for the success of gene therapies. Sufficient levels of gene expression in the affected cell type are essential, while at the same time, off-target expression must be minimized for precisely targeted gene delivery. Here we create a complete atlas of viral vectors enabling efficient and specific expression of proteins across retinal cell types. Using single-cell RNA-Seq based methods, we have identified cell types by their transcriptome profiles and simultaneously quantified the performance of a library of viral vector variants, including naturally occurring serotypes and engineered variants selected for their ability to deliver transgenes across physical barriers to specific cell types. These methods are an unbiased and quantitative method by which viral variants can be compared across every cell type simultaneously, based on their ability to drive gene expression. This approach exponentially increases the rate by which new viral vectors can be developed. The experiments have been performed in primates, in order to create vectors with maximum potential to be translated for use in humans.

Abstract: Noise-induced hearing loss (NIHL) is one of the most prevalent disabilities for which there is no effective therapeutic treatment. Auditory insult via noise exposure damages the sensory elements of the ear, leading to metabolic and/or mechanical damage to hair cells and degeneration of spiral ganglion neurons (SGN). To improve hearing in NIHL patients, the inner hair cell-SGN synapses must be maintained or regenerated. Though effective compounds for the treatment of NIHL have been suggested, challenges in delivery hinder the progress of these therapies to a clinical setting. In this study, we examined the efficacy of different AAV viral vectors and promoters, administered via different injection routes, in targeting the IHCs and SGNs. AAV vectors carrying a GFP transgene were delivered via different delivery routes. Vector transduction efficacy was compared in the presence or absence of noise injury. To induce auditory injury, mice were exposed to 100 dB sound pressure level (SPL) octave band noise for 2 hours. Five adult mice, both male and female, were used for each injection route and vector. Injections were performed at various time points pre and post noise exposure to determine whether noise exposure influenced vector transduction. Age-matched, uninjected mice were processed alongside experimental mice. Mice were sacrificed at varying time points post injection and cochleae were assigned a random number by a member of the lab to blind the processing and analysis of GFP expression in samples. Our results demonstrate that AAV vectors are effective in targeting cells in both healthy and noise damaged cochleae via multiple injection routes. Using gene therapy techniques, transgenes or therapeutic compounds can be efficiently delivered to the cochlea. Our findings open a novel avenue of therapeutic treatment for auditory injury and cochlear disorders.

Title: Assessing the integrity of eye-brain communication in a mouse model of pediatric glaucoma

Authors: N. AMIRMOKHTARI[1], R. A. BOUHENNI[2], *M. A. SMITH[1];
[1]Northeast Ohio Med. Univ., Rootstown, OH; [2]Rebecca D. Considine Res. Inst., Akron Children's Hosp., Akron, OH

Abstract: Glaucoma is a group of eye conditions affecting both very young children and older adults where a buildup of eye fluid leads to an increase in eye pressure can stress/damage neurons in the retina of the eye-- causing them to die. New research in adult glaucoma suggests, retinal neurons lose their ability to transmit visual information via electrical signals to neurons in the brain long before retinal neurons themselves actually die. These findings suggest that eye-brain diseases like glaucoma may actually be preventable and/or treatable where restoring function to these “sick” retinal neurons may prevent/reverse vision loss, as opposed to replacing dead neurons with new ones---a more arduous task that has yet to be accomplished. Unfortunately, most glaucoma research is focused on adult rather than childhood manifestation of the disease, therefore, commonality of risk factors, timing, and etiologies of the disease between the developing and developed visual systems continues to be resolved. While elevated ocular pressure remains the primary modifiable risk factor for both childhood and adult glaucoma, the role of recessive pathogenic variants in the CYP1B1 gene continues to be a focus in pediatric glaucoma etiology. However, by what mechanisms and to what degree CYP1B1 variants contribute to disease onset and progression particularly regarding the relationship with elevated intraocular pressure remains to be determined. We set out to determine whether a predisposition to lack of CYP1B1 expression modulates timing, severity, and presentation of retinal ganglion cell structural and functional deficits when ocular pressure is artificially elevated. Using intracameral cannulation and microbead injection techniques we induced ocular hypertension in transgenic CYP1B1-knockout mice. Our data indicate additional alterations in CYP1B1KO RGC axons pertaining to the myelin sheath and nodes of Ranvier after induced ocular hypertension that are not seen in hypertensive RGC axons with normal CYP1B1 expression. Similar changes are seen to occur in naturally occurring glaucoma mouse models and have been suggested contribute to early changes in axon physiology. We conclude that CYP1B1 genetic variance may predispose developing RGC axons to factors that make them more susceptible for modification when ocular pressure is elevated.

Title: Ocular amyloid triggers signaling dysfunction in retinal ganglion cells

Authors: *E. S. PLYLER, M. A. SMITH, C. M. DENGLER-CRISH, S. D. CRISH; Pharmaceut. Sci., Northeast Ohio Med. Univ., Rootstown, OH

Abstract: Amyloid-beta (Aβ) is a major neuropathology of Alzheimer's disease (AD) that has also been implicated in age-related visual disorders such as glaucoma, macular degeneration, and diabetic retinopathy. In AD, retinal accumulation of Aβ appears prior to overt brain degeneration- likely contributing to visual defects seen in this disease. While early retinal amyloidosis shows promise as a biomarker, the effects of Aβ on visual function are not well understood. Previously, we found that ocular amyloidosis produces neuroinflammation in the primary visual pathway of mice, and caused retinal ganglion cell (RGC) death. However, the mechanisms of pathology remain unknown. Recently, our lab reported early neuronal signaling deficits between the eye and brain in glaucoma. These deficits occur in RGCs that remain connected to their postsynaptic targets in the brain and may drive later axon and cell body loss. As Aβ has also been implicated in glaucomatous neurodegeneration, we hypothesized that similar dysfunctions may precede RGC loss after retinal exposure to Aβ. We tested this hypothesis by assessing RGC activity in a validated model of induced ocular amyloidosis by measuring pattern electroretinogram (PERG) responses *in vivo* after visual stimulation. PERG is a minimally invasive approach that can be used to longitudinally screen mice for emerging functional deficits in the visual system, as well as to monitor disease progression. To induce ocular amyloidosis, we injected fibrillized $A\beta_{1\text{-}42}$ into the vitreal chamber of the left eyes of 6-8 mo. mixed-sex C57BL/6J mice. Control mice received comparable injections of saline vehicle. We measured PERG in these mice at post-induction time-points of 24 hours, 1 week, and 2 weeks. Our results indicated that Aβ-injected eyes had reduced RGC response to visual stimulation (i.e. reduced P1 amplitude) compared to baseline, and this signal worsened over the 2-week period. Control mice had reduced P1 amplitude at 24 hours post-injection, but recovered by 2-weeks post-injection. These results suggest that Aβ exposure may cause early RGC dysfunction, potentially contributing to visual deficits in glaucoma and AD. These functional deficits may provide a therapeutic window for rescuing cells by restoring function prior to overt RGC loss.

Title: Primary-afferent-driven presynaptic inhibition of the C-fiber inputs to spinal lamina I projection and local-circuit neurons

Authors: E. FERNANDES[1], C. PECHINCHA[2], ***B. V. SAFRONOV**[2];
[1]IBMC, Porto, Portugal; [2]IBMC 503828360, Porto, Portugal

Abstract: Spinal lamina I neurons play a key role in the nociceptive processing. They receive numerous inputs from unmyelinated C-afferents, which are processed and relayed to the specific areas of the brainstem and thalamus. Presynaptic inhibition of the primary afferents is critically important for the control of pain. Here we studied whether the afferent-driven presynaptic inhibition affects the C-fiber inputs to anatomically classified lamina I neurons. An isolated spinal cord preparation with attached dorsal roots was used for the whole-cell patch-clamp recording from biocytin- or retrogradely-labelled lamina I neurons. We have developed a novel method of the inverted current pulse stimulation to selectively evoke the pure C-afferent volley in the dorsal root. The degree of the presynaptic block was estimated by comparing the amplitudes of the monosynaptic C-fiber-mediated EPSCs evoked in a lamina I neuron by the pure C-fiber volley, and under conditions when arrival of the C-fiber volley was preceded by arrival of the Aβ-, Aδ- and C-volleys from the same or adjacent root. These results show that the homo- and/or heterosegmental Aβ-, Aδ- and C-afferents can mediate a complete or partial presynaptic block of the C-fiber inputs to the lamina I local-circuit and projection neurons. Thus, we present the first functional evidence for the primary afferent-driven GABAergic presynaptic inhibition of the direct C-fiber inputs to lamina I neurons. Our data suggest that, not only the low-threshold afferents, but also the high-threshold afferents mediate presynaptic inhibition of the primary nociceptors, and thus regulate the nociceptive information flow into the spinal cord.

Title: Gucy2d is a novel and selective marker of a subset of dynorphin-expressing neurons in the spinal dorsal horn

Authors: *E. K. SERAFIN, J. LI, M. L. BACCEI;
Anesthesiol, Univ. of Cincinnati Dept. of Anesthesiol., Cincinnati, OH

Abstract: Recent work has identified discrete subpopulations of inhibitory interneurons within the spinal dorsal horn (DH), defined by their expression of neurochemical markers such as parvalbumin, NPY and dynorphin, which modulate distinct modalities of somatosensory processing. However, none of the markers identified thus far are selectively expressed within DH neurons, instead showing widespread distribution across the peripheral and central nervous systems, thereby necessitating the use of complex intersectional genetic strategies to manipulate the function of a given neuronal population of interest. Here we identify the gene *Gucy2d*, encoding the membrane-bound guanylate cyclase GC-D, as a novel and highly selective marker of a subset of inhibitory DH interneurons derived from the dynorphin (*Pdyn*) lineage. An unbiased transcriptional analysis of dynorphin-lineage DH neurons revealed dramatic enrichment for *Gucy2d* within this population. *In situ* hybridization demonstrated that nearly all (~94%) of *Gucy2d*-expressing DH neurons also expressed *Pdyn*, although only ~54% of *Pdyn* neurons exhibited *Gucy2d* expression. The vast majority (~96%) of *Pdyn*-expressing neurons were located in laminae I-II with the remainder localized to lamina III. Furthermore, most *Gucy2d*-expressing neurons are inhibitory, as determined by co-expression of *Pax2* mRNA. Virtually all of these neurons (~99%) also co-express the transcription factor *Bhlhb5*, previously reported to be necessary for the development of dynorphin-lineage DH neurons which suppress chemical itch, as well as *Pde2a*, a phosphodiesterase previously used as a selective marker for *Gucy2d*-expressing neurons within the olfactory epithelium. The degree to which *Gucy2d* is expressed at the protein level in DH neurons remains unclear, as *in vitro* patch clamp recordings suggest that the application of the putative GC-D ligand uroguanylin (UG) fails to alter resting membrane potential or induce action potential firing in dynorphin-lineage spinal neurons. Importantly, within the brain, strong expression of *Gucy2d* mRNA was restricted to the olfactory bulb, with a very weak and diffuse signal visible in the hindbrain and an absence of detectable expression in all other brain regions. *Gucy2d* mRNA was also absent from the dorsal root ganglia (DRG), raising the possibility that utilization of the *Gucy2d* promoter could provide a novel means to

selectively manipulate dynorphin-expressing neurons at the level of the spinal dorsal horn. Future studies will investigate the role of the *Gucy2d*-expressing population in the regulation of pain and itch signaling within the DH.

Title: Movement gating of cutaneous signals in the cuneate nucleus

Authors: *Q. HE[1], A. K. SURESH[1], C. VERSTEEG[2], J. M. ROSENOW[3], L. E. MILLER[4], S. J. BENSMAIA[1];
[1]Organismal Biol. and Anat., Univ. of Chicago, Chicago, IL; [2]Biomed. Engin., [4]Dept. of Physiol., [3]Northwestern Univ., Chicago, IL

Abstract: The cuneate nucleus (CN), located in the medulla, is the first recipient of tactile signals along the medial lemniscal pathway. This neural structure is known to receive top down signals from cortex, and these signals have been implicated in modulating bottom up input. Indeed, sensitivity to cutaneous stimulation is reduced during movement or force generation, and this reduced sensitivity has been traced down to the CN. In the present study, we seek to characterize the spatial structure and temporal dynamics of this modulating. Specifically, we investigate whether the gating is spatially uniform, and affects the entire body surface equally, or sculpted to reduce sensitivity in body regions where cutaneous signals are expected to be behaviorally irrelevant. We also investigate the time course over which this gating occurs: Does it precede movement or force generation? If so, to what extent? To address these questions, we trained Rhesus macaques to perform a reach to grasp task while we measure the neural activity evoked by tactors placed over the receptive fields of CN neurons. Tactors are activated periodically before, during, and after movement and before, during, and after force generation. We then assess the degree to which the cutaneous response is modulated in the various task epochs.

Title: Comparison of dorsal and ventral sensory afferent involvement in crossed reflex

Authors: *O. D. LAFLAMME, M. IBRAHIM, T. AKAY;
Dept. of Med. Neurosci., Dalhousie Univ., Halifax, NS, Canada

Abstract: Sensory afferent feedback is important for coordinating the movement of multiple joints within and between the legs during locomotion, as removal of sensory feedback severely impairs movement. It has been established in humans and cats that sensory information from one leg influences the motor neuron (MN) activity of the contralateral leg (crossed reflex) through spinal commissural interneurons (CINs). More recently, *in vivo* crossed reflexes in mice have been shown to modulate the contralateral motor responses through excitatory and inhibitory pathways (Laflamme and Akay, 2018; *J Neurophysiol*). In this previous study, crossed reflex responses were recorded by stimulating either the proprioceptive afferents from extensor muscles or the cutaneous afferents from the posterior surface of the leg. Crossed reflexes transduced by different sources of sensory afferents have not been shown. Our goal in this study is to determine if proprioceptive feedback from flexor muscles or cutaneous feedback from the anterior surface of the leg elicits similar crossed reflex responses. We describe crossed reflex responses elicited by the stimulation of the contralateral cutaneous afferents from the anterior surface of the leg, and from the proprioceptive afferents of flexor muscles (peroneal nerve stimulation). These results were compared to the stimulation of contralateral cutaneous afferents from the posterior surface and proprioceptive afferents from extensor muscles (tibial nerve stimulation). Our data show two findings. First, that peroneal nerve stimulation evokes crossed reflex motor responses, but no clear motor pattern could be detected, in contrast to tibial nerve stimulation. Second, that inhibitory crossed reflex effects are present when the peroneal nerve is stimulated; however, the inhibitory effect is only found in a subset of flexor and extensor muscles. This contrasts with our previous data involving tibial nerve stimulation where the inhibitory crossed reflex was observed in all recorded muscles. The patterned muscle activation resulting from crossed reflexes depends on the source of the afferent feedback. These outcomes provide the groundwork for our future aim to describe the spinal network that controls crossed reflexes in mice.

Title: Supraspinal and segmental contribution to the effects of systemic and local injections of picrotoxin on the patterns of functional connectivity between dorsal horn neurons

Authors: *L. MORENO[1], N. PLAMENOV DONCHEV[1], D. CHÁVEZ[1], E. HERNÁNDEZ[1], S. GLUSMAN[2], P. RUDOMIN[1,3];
[1]CINVESTAV, Mexico City, Mexico; [2]Stroger Cook County Hosp., Chicago, IL; [3]El Colegio Nacional, Mexico City, Mexico

Abstract: In the anesthetized cat, the patterns of functional connectivity between the dorsal horn neurons are not random but rather structured (Contreras et al, 2015). During low levels of neuronal synchronization this ensemble generates negative cord dorsum potentials (nCDPs) and there is a concurrent activation of the pathways mediating non-reciprocal postsynaptic inhibition. In contrast, during higher synchronization, the same neuronal network generates negative-positive cord dorsum potentials (npCDPs) as well as dorsal root potentials (DRPs), a sign of PAD. So far we assumed that this PAD was GABAergic. Yet, Hochman et al., (2010) suggested that a fraction of the DRPs could be of a non-GABAergic origin. The present studies were aimed to disclose the role played by $GABA_A$ mechanisms in the generation of the npCDPs and DRPs. This seemed a relevant issue because we have used different classes of CDPs selected according to their shape and amplitude to infer the changes in the global state of neuronal connectivity induced by nociception (Chávez et al., 2012; Martin et al., 2016). In pentobarbital anesthetized, paralyzed and artificially ventilated cats, we examined the changes produced by picrotoxin (PTX, a $GABA_A$ antagonist) on the ongoing correlation between CDPs recorded on the L4-L7 spinal segments. PTX was administered either systemically (0.5 mg/kg) or through a glass micropipette inserted in the deep L6 dorsal horn (4 μg/10 μL). In preparations with intact neuroaxis, systemic PTX induced slow synchronized “epileptic like” CDPs in the recorded segments. The participation of spinal and/or supraspinal mechanisms in the generation of this synchronized activity was elucidated by testing the effects of systemic PTX in a preparation with a spinal transection between L5 and L6. We found that PTX induced epileptiform activity and increased the occurrence of npCDPs only in those spinal segments that remained connected to supraspinal structures. In contrast, the segments below the lesion showed no epileptiform activity while there was a significant reduction in the occurrence of npCDPs. In another series of experiments the PTX microinjection decreased the number of npCDPs without inducing

epileptiform activity, that was however generated by a subsequent systemic injection of PTX, both in the rostral ventromedial medulla and in the dorsal horn. The present observations indicate that the PAD associated with the generation of the npCDPs and DRPs has a significant $GABA_A$ component that is blocked by PTX. They also provide evidence of a functional coupling between supraspinal and spinal neurons, a process of relevance in the shaping of sensory information (Plamenov et al., 2018).

Title: Phox2a defines a developmental origin of the anterolateral system and is required for supraspinal nociception

Authors: *R. B. ROOME[1], S. RASTEGAR-POUYANI[1], C. SALESSE[1], B. MONA[2], K. LISTER[3], S. FERLAND[4], W. S. THOMPSON[1], S. SOTOCINAL[3], A. DUMOUCHEL[1], J. E. JOHNSON[2], M. KMITA[1], J. S. MOGIL[3], Y. DE KONINCK[4], A. KANIA[1];

Abstract: The mammalian anterolateral system (ALT) is the main pathway relaying pain, itch and temperature information from the spinal cord to the brain. Classical anatomical and physiological experiments suggest a functional diversity of the spinal projection neuron (PN) subpopulations that give rise to this pathway. However, without molecular handles, their relative contribution to somatosensation remains unknown.
The Paired-like homeobox 2A (Phox2a) transcription factor is expressed in the dI5 spinal neuron lineage hypothesised to give rise to PNs. Using mouse genetic anterograde and retrograde labelling, we show that virtually all spinal neurons of the Phox2a lineage give rise to PNs that innervate ALT nociceptive targets, such as the parabrachial nucleus, peri-aqueductal grey, nucleus of the solitary tract and the thalamus. Nearly half of spinal PNs innervating the

parabrachial nucleus and the thalamus express Phox2a, revealing it as the first exclusive molecular handle of a major spinofugal PN population. Phoxa2 PNs are born concurrently with motor neurons, constituting the earliest spinal postmitotic population. The spinal dI lineage determinants Ascl1 and Ptf1a control the early aspects of Phox2a PNs specification, directing them to develop into all anterolateral system spinal PN types, first populating laminae I, then the deeper laminae II/III and V. A developmental loss of spinal Phox2a function does not affect nociceptive spinal reflexive behaviours. In contrast, behaviours that involve supraspinal relay of nociceptive information are impaired in these mutants, arguing that normal ALT development requires Phox2a.
Our experiments provide a molecular handle on a major constituent PN population of the ALT, allowing us to probe its precise adult function. Currently, we are determining whether Phox2a PNs encode noxious stimulus modality, location, intensity and/or its emotive dimension.

Title: Feature extraction by muscle proprioceptors using machine learning

Authors: *S. N. HOUSLEY[1], T. C. COPE[2];
[2]Applied Physiol. and Engin., [1]Georgia Inst. of Technol., Atlanta, GA

Abstract: Spike train encoding of muscle stretch by muscle proprioceptors is altered in animals treated with chemotherapy. We find great variability in the magnitude of change expressed among the multiple measures used to paramaterize spike trains responding to dynamic and static mechanical stimuli. Interest in the behavioral consequences of spike train corruption led us to ask how neurotoxic effects of chemotherapy affect mechanical feature extraction by muscle proprioceptors. To answer this question, we applied modern machine learning techniques, including long short-term memory neural networks, to test what features of position and dynamics are preferentially decoded from spiking activity of physiologically identified proprioceptors. We first trained neural networks on populations of recorded mechanosensory responses from three classes of physiologically identified proprioceptors in healthy adult rats

anesthetized with isoflurane. Neurons were classified as muscle spindle group Ia or II or as tendon organ group Ib afferents. Trained models successfully predicted both stereotyped and pseudorandom movements with individual neuron classes preferentially contributing unique feature information during decoding. We then employed our trained models to test how feature extraction is impaired following a neurologic insult known to impair sensory encoding, chemotherapy.
Upstream consequences of these neural deficits are unknown but could provide valuable insight to understand and assist in predicting behavioral deficits in humans treated with chemotherapy. Population spiking activity of the three classes of proprioceptors recorded from animals treated with chemotherapy were used to generate predictions. Preliminary results indicate significantly corrupt feature extraction. We show both under and over estimation of stimulus features. For example, static positions are consistently under predicted. Our results suggest that unpredictable sensorimotor integration may contribute to lasting behavioral deficits documented in patients treated with chemotherapy.

Title: Reward and force modulation of neurons in the primate primary somatosensory cortex (S1)

Authors: *M. U. ATIQUE[1], J. T. FRANCIS[2];
[1]Biomed. Engin., [2]Univ. of Houston, Houston, TX

Abstract: Sensorimotor cortices play an important role during movement and action observation. Previous work has introduced the fact that reward level can modulate activity in S1 (McNiel et al 2016). In this study, we show that force related activity in S1 is also modulated by the cued level of possible reward. We analyzed data from two monkeys, one male (Macaca radiata, Monkey S) and one female (Macaca Mulatta, Monkey P). Trials consisted of a psychophysical task where the monkey had to apply an appropriate amount of grip force to a force transducer to enable a simulated robotic manipulator to grasp and transport an object to a targeted location. For each of these monkeys, we used two different blocks of manual trials. One

block consisted of trials where the monkeys were given a cue for the level of reward while the other block was uncued. We used the spiking activity of units from S1 for our analysis. We measured the significance (F-test, p-value < 0.05) between the spike rate of the units and applied grip force. Additionally, a separate analysis was performed to calculate the significance (t-test, a p-value < 0.05) for the reward level using the post reward spiking activity (500ms for each trial). The units that are common to both force and reward significance tests were collected. For Monkey S we have found 53 units that are significant for both force and reward. For monkey P the significant unit number was 22. The raster plots during the cue presentation and reward delivery periods showed the difference in activities of the same unit between rewarding and non-rewarding trials. The spiking activity of neurons during the grasping period represents a similar variation to the applied force. We used Multiple Linear Regression (MLR) on spike rate to predict force from manual cued and uncued blocks. The correlation coefficient (R-square) between the predicted force and the actual applied force for Monkey S was 0.86 and 0.83 for cued and uncued blocks respectively. For Monkey P the correlation coefficient was 0.83 and 0.82. We computed the linear tuning curves for the force during rewarding and non-rewarding trials and measured if they are significantly different for each individual units (F-test, p-value < 0.05). For Monkey S, in the cued manual block, there were 21 units that showed a significant difference between tuning curves of rewarding and non-rewarding trials whereas the number of significant units were 30 for Monkey P. The results we have presented here demonstrate that units from S1 have a representation of grip force and this representation is modulated by the reward expectation.

Title: Is this a vibration evoked potential? Preliminary study in healthy subjects

Authors: F. OVAK BITTAR[1], ***M. M. SABBAHI**[2];
[1]Texas Physical Therapy and Electrophysiology Services, Houston, TX; [2]Texas Electrophysiology and Physical Therapy, Houston, TX

Abstract: Vibration has long been known to be a strong and specific stimulus to muscle spindle afferents. Its effect on Ia afferents with its transmission to the cerebellum via spinocerebellar tracts has been a central neural information for most neurological testing. Its dysfunction in spinal cord injuries and other spinal disorders such as Tabes dorsalis, transvers myelitis and dorsal spinal column pathologies provide the clinical utility for a large array of neurological

disorders. Despite all these possibilities for clinical application, to our knowledge, vibration evokes potential has not been recorded or reported in the current literature. The purpose of this study is to present preliminary results to record Vibration Evoked potential in healthy subjects. Peroneal stimulation at the ankle level was electrically stimulated using 0.5 ms. Pulses at 0.5 pps at zero intensity. This was used to trigger the sweeps of a peroneal somatosensory evoked potential. The vibration potential was recorded using bipolar surface electrodes applied on T11-12 and C7 vertebral spinal levels with the ground electrode applied on the iliac crest. Subject stood on the surface of Whole-Body Vibration unit operated for 90 sec. at 50 Hz of low amplitude. Vibration electrical signal was averaged and recorded for the 90 sec. period. Three trials were recorded and analyzed. This is an exploratory descriptive study. Results showed a Vibration evoked potential after 11 msec. from the electric signal artifact. Signal for the T11-12 location, showed a peak to peak amplitude was 50 uv. Biphasic in shape. Vibration signal was smaller for the C7 vertebral location and was recorded at 14msec). Modulation of these Vibration Evoked potentials will be the focus of future studies. In a parallel study an attempt was carried out to record the current vibration potential via stimulation of the tibial nerve at the popliteal fossa. Vibration evoked potential could not be recorded using tibial nerve pathways. These vibration potentials can be useful testing method for patients with central spinal disorders and pathologies.

Title: Electrophysiological and morphological characterisation of excitatory interneurons in the dorsal horn of the spinal cord

Authors: *A. C. DICKIE[1], A. M. BELL[1], N. IWAGAKI[1], E. POLGÁR[1], M. GUTIÉRREZ MECINAS[1], R. KELLY[1], H. LYON[1], K. TURNBULL[1], S. J. WEST[2], A. ETLIN[3], J. M. BRAZ[3], M. WATANABE[4], D. L. H. BENNETT[2], A. I. BASBAUM[3], J. S. RIDDELL[1], A. J. TODD[1]; [1]Spinal Cord Group, Univ. of Glasgow, Glasgow, United Kingdom; [2]The Nuffield Dept. of Clin. Neurosciences, Univ. of Oxford, Oxford, United Kingdom; [3]Dept. of Anat., Univ. of California San Francisco, San Francisco, CA; [4]Hokkaido Univ. Sch. of Med., Sapporo, Japan

Abstract: Excitatory interneurons (eINs) account for the majority of neurons in the superficial dorsal horn, but despite their presumed roles in pain and itch, our knowledge of their organisation and function is limited. We have shown that eINs can be assigned to several distinct populations based on the expression of neurochemical markers, and this broadly agrees with recent transcriptomic studies. We have used anatomical and electrophysiological techniques to characterise eINs that express Substance P (SP), Gastrin-releasing peptide (GRP), or the GRP receptor (GRPR), to determine whether they are functionally distinct. Transgenic mouse lines used to identify these eINs include; GRP::eGFP (GRP), $Tac1^{Cre}$ (SP) and $GRPR^{CreERT2}$;Ai9 (GRPR). $Tac1^{Cre}$ mice were intraspinally injected with AAV.Flex.tdTom or AAV.Flex.eGFP. In $Tac1^{Cre}$;GRP::eGFP mice intraspinally injected with AAV.Flex.tdTom there was minimal overlap between GFP+ (GRP) and tdTom+ (SP) cells, showing that they are distinct populations. This was confirmed with in situ hybridisation. Similarly, we found that GRPR cells are a distinct group. Patch-clamp electrophysiology in spinal cord slices, was used to study the eINs. Action potential firing patterns in GRP cells were mainly transient or single spike. This differed from SP cells, which mostly showed delayed firing, and GRPR cells, which showed delayed or single spike firing. EPSC frequency was higher in SP and GRPR cells, suggesting they have a greater excitatory drive than GRP cells. Almost all GRP cells responded to the MOR agonist, DAMGO, but were largely unresponsive to NA or 5-HT. In contrast most SP cells were sensitive to NA and 5-HT, but not DAMGO. Morphology was assessed in GRP cells filled with neurobiotin during patch-clamp recordings, and SP and GRPR cells in perfusion fixed tissue from mice injected with Brainbow AAVs. This demonstrated that these eINs were morphologically distinct. Although GRP cells were heterogeneous, some could be classified as central cells. In contrast, many SP cells resembled radial cells. GRPR cells exhibited vertical cell morphology. Our findings demonstrate that SP, GRP and GRPR eINs show major differences in their morphological, electrophysiological and pharmacological properties. Based on somatodendritic morphology and firing patterns, we propose that SP cells correspond to a population known as radial cells, while GRP cells are likely to overlap extensively with a population previously classified as transient central cells, and GRPR cells are a type of vertical cell. Our findings indicate that SP, GRP and GRPR cells are functionally distinct, and presumably have different roles in somatosensory processing.

Title: Connectivity and molecular identity of neurons expressing gastrin-releasing peptide in the superficial dorsal horn in a GRPeGFP transgenic mouse line

Authors: *A. BELL, M. GUTIERREZ-MECINAS, E. POLGAR, A. DICKIE, A. TODD;
Univ. of Glasgow, Glasgow, United Kingdom

Abstract: Gastrin releasing-peptide (GRP) released in the superficial dorsal horn (SDH) of the spinal cord has an important role in itch sensation. This peptide is released by a distinct population of excitatory interneurons which have been shown to have roles as secondary pruritoceptors. In BAC transgenic mice that express enhanced green fluorescent protein (eGFP) under control of the GRP promotor, these cells have been shown to be functionally and morphologically homogeneous and show little neurochemical overlap with other defined classes of SDH interneuron. However recent transcriptomic studies report that Grp mRNA is widely distributed in the dorsal horn among several excitatory interneuron clusters.To resolve this apparent discrepancy, here we aim to define the molecular identity of specifically those GRP cells expressing eGFP. Additionally, the complex neuronal circuits that they engage have not been fully elucidated and using anatomical techniques we aim to identify both the source of input and synaptic targets of these cells.Multiplex *in situ* hybridisation was performed on spinal cord tissue using RNAScope with probes against both GRP and eGFP and other markers of interneuron populations. Virtually all eGFP mRNA+ cells in this mouse line contain GRP mRNA however eGFP expression was only evident in 20-30% of GRP mRNA+ cells. While GRP mRNA+ cells were present throughout lamina I and II, eGFP+ cells tended to form a tighter band in mid lamina II. GRP transcripts overlapped with markers for several excitatory interneuron clusters (Glut5-12 i.e Tac1, Tac2, Npff & Nmur2) but eGFP did not with the exception of Nmur2 where moderate overlap was evident.To investigate neuronal circuits involving GRP-eGFP cells, confocal microscopy was used to reveal excitatory synaptic inputs on dendritic trees using immunostaining for the postsynaptic protein Homer. This allows estimation of the amount of synaptic input to and from GRP-eGFP cells in an unbiased manner. Compared to SP-expressing excitatory interneurons, GRP-eGFP receive a higher proportion of their inputs (90% vs 40%) from primary afferent nerve fibres. These include non-peptidergic nociceptors and low threshold c-fibres. The axons of GRP-eGFP cells selectively innervate lamina II SP-expressing radial cells but do not target lamina I projection neurons directly.GRP-eGFP cells appear to represent a discrete functional population, even though GRP message is far more widely expressed. This discrete functional role is evident as GRP-eGFP cells form part of a neuronal circuit relaying convergent input from different classes of primary afferent to other specific interneuron populations with dendrites in lamina II.

Abstract: Inhibitory interneurons in the spinal dorsal horn play a crucial role in controlling transmission of somatosensory information to the brain. Spinal inhibition is diminished in some chronic pain states, and inhibitory interneurons therefore represent a potential target for therapeutic intervention. Previous studies have identified a population of inhibitory interneurons in lamina II that express the calcium binding protein calretinin, and have shown that these are islet cells. We have identified a subpopulation of these cells that co-express the RAR-related orphan receptor beta (RorB), and the RorB-creERT2 mouse line provides a means of identifying and manipulating the function of these cells. We have used a combination of anatomical and electrophysiological approaches with genetically modified mice in which fluorescent proteins are expressed in RorB interneurons. We show that the dendritic trees of the RorB cells overlap extensively with central arbors of C-fibre mechano-nociceptors (defined by expression of Mas-related G-protein coupled receptor D; C-MrgD) and that they receive extensive synaptic input from these afferents. We also find that RorB-expressing axons form axo-axonic synapses onto central terminals of type I glomeruli, which originate from C-MrgD afferents. Peripheral stimulation under terminal anaesthesia revealed that RorB cells are preferentially activated by noxious mechanical stimulation, rather than noxious chemical (capsaicin) or noxious heat stimulation. A recent transcriptomic study assigned inhibitory calretinin cells to two subpopulations, Gaba8 and Gaba9, and reported that the Gaba9 population expressed mRNA for Tac1, the gene that encodes substance P. We had previously identified an inhibitory Tac1-expressing population and shown that these cells co-express calretinin, corresponding to the Gaba9 subpopulation. We find that the inhibitory Tac1 population includes RorB-expressing interneurons and accounts for approximately 40% of all inhibitory calretinin cells. The recent development of viral vectors coding for transgenes that depend on co-expression of two recombinases means that these cells can be targeted by crossing VGAT-Flpo mice with either calretinin-Cre or Tac1-Cre lines. This will allow studies of their role in pain behaviour.

Title: Characterisation of gastrin-releasing peptide receptor-expressing neurons in the mouse spinal dorsal horn

Authors: *E. POLGAR, M. GUTIERREZ-MECINAS, A. BELL, A. C. DICKIE, R. CLARK, E. AB RASHID, A. J. TODD;

Abstract: The spinal dorsal horn receives information from somatosensory afferents, including those that relay nociceptive and pruritic stimuli. Signals from these terminals are transmitted to a complex network of local interneurons. In lamina I-II of the spinal cord (SDH), excitatory interneurons account for ~75% of all neurons. Recently, among these cells we have identified five non-overlapping populations based on their neuropeptide content. In addition, transcriptomic studies identified a separate cluster of neurons, those that express the gastrin-releasing peptide (GRP) receptor (GRPR). While several lines of evidence implicate GRP-GRPR signalling in itch but not pain, our knowledge about the characteristics of GRPR expressing neurons remains elusive. We aimed to characterise the GRPR-expressing neurons in the mouse SDH. To study their morphology we performed intraspinal injection of Brainbow adeno-associated virus (AAV) in $GRPR^{CreERT2}$ mice. To determine whether GRPR cells form a distinct neuronal population we performed cluster analysis - based on morphometric dendritic parameters - and carried out co-localisation studies using various neuronal markers. We looked for phosphorylated ERK expression to test whether GRPR cells selectively respond to pruritic stimuli following intradermal injection of pruritogens and various noxious stimuli applied on the hind limb. In all of the above experiments bar the AAV-Brainbow injections, we used $GRPR^{CreERT2}$ mice crossed with the Ai9 reporter line, in which after tamoxifen treatment Cre^{+} cells are expected to be labelled with tdTomato. In order to confirm the recombination efficiency of the Cre we also injected AAV.flex.GFP into the spinal cord of $GRPR^{CreERT2}$;Ai9 mice. Our main findings are: (i) GRPR cells have specific morphological characteristics that correspond to vertical cells. (ii) The lack of co-localisation with other neuronal markers and cluster analysis data confirm that GRPR cells represent a distinct neuronal population within the superficial dorsal horn. (ii) Contrary to previous suggestions that these cells are required for mediation of itch sensation rather than pain,

we find that they also respond to various types of noxious stimuli. (iv) While there was a considerable overlap between viral labelled and tdTomato expressing cells, there were numerous GFP-only-labelled cells. This suggests that the intraspinal injection method is more efficient to capture GRPR-expressing interneurons. Since vertical cells have been shown to be presynaptic to lamina I projection neurons, our results suggest that GRPR cells may be an integral part of the itch circuit and are involved in spinal pain mechanisms.

Title: Neuropeptide y-expressing dorsal horn inhibitory interneurons in spinal pain and itch circuits

Authors: *K. A. BOYLE, M. GUTIERREZ-MECINAS, A. C. DICKIE, E. POLGAR, A. M. BELL, D. I. HUGHES, A. J. TODD;
Inst. of Neurosci. & Psychology, Univ. of Glasgow, Glasgow, United Kingdom

Abstract: Previous work from our laboratory has identified neuropeptide Y (NPY)-expressing neurons of the dorsal horn as a population of inhibitory interneurons (INs) that are well placed to modulate spinal nociceptive circuits through connections with nociceptive projection neurons and other dorsal horn interneurons (Iwagaki et al. 2016). The aims of the current study were 1) to use intraspinal injection of adeno-associated viruses (AAVs) in adult RH26 NPY::Cre mice to allow targeted manipulation of the activity of dorsal horn INs that express NPY in the adult (NPY-INs), 2) to assess the effects of NPY-IN activity manipulation on dorsal horn nociceptive and pruriceptive circuit activity and associated behavioural output, and 3) to test the hypothesis that activation of NPY-INs will supress the pathological pain phenotypes observed in the plantar Complete Freund's Adjuvant (CFA) model of inflammatory pain and the spare nerve injury (SNI) model of neuropathic pain.
To achieve these aims, we unilaterally injected a Cre-dependent AAV construct that expresses the excitatory DREADD hM3Dq fused to mCherry (AAV.hM3Dq.mCherry), into the L3-5 dorsal horn of young adult RH26 mice. Systemic administration of the hM3Dq agonist CNO induced Fos expression (a marker of neuronal activation) in the vast majority of mCherry-expressing neurons in laminae I-III, and this was largely restricted to NPY-immunoreactive cells.

However the proportion of mCherry-negative neurons in laminae I-II that expressed Fos following noxious heat or a pruritic stimulus was significantly lower in CNO-treated animals compared to vehicle-treated controls, suggesting that NPY-IN activation can inhibit spinal neurons normally activated by these stimuli. Consistent with this conclusion, NPY-IN activation increased the noxious heat withdrawal threshold and markedly reduced chloroquine-induced itch behaviour, as well as increasing noxious mechanical and cold withdrawal thresholds. NPY-IN activation also reversed mechanical and thermal hypersensitivity in the plantar CFA inflammatory pain and SNI neuropathic pain models.
Based on these findings, we draw the following conclusions: 1) Intraspinal injections of AAV.DREADDs into adult RH26 mice allows the specific manipulation of dorsal horn NPY-IN activity, 2) NPY-IN activation supresses activity in dorsal horn circuits that process pain- and itch-related information, resulting in reductions in acute pain- and itch-related behaviours and 3) recruitment of NPY-INs reduces inflammatory and nerve injury-induced pain. Dorsal horn NPY-INs therefore represent a potential target for treatment of acute and/or pathological pain and itch.

Title: Relationship of severity of sensory impairments and balance strategies in individuals with lower-limb amputation

Authors: *B. A. PETERSEN[1], P. J. SPARTO[2], L. E. FISHER[3];
[1]Dept. of Bioengineering, [2]Dept. of Bioengineering, Dept. of Physical Therapy, [3]Physical Med. and Rehabil., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: People with lower-limb amputations often exhibit gait and balance impairments, with 52.4% reporting a recent fall. Amputees rely more heavily on vision than healthy controls, likely due to lack of somatosensory feedback. Additionally, most lower-limb amputations occur after chronic dysvascular disease, which can also impair sensation in the contralateral intact limb. However, there has been little research to date to correlate severity of sensory impairments and measures of postural control in this population. We evaluated sensation and postural control in eight people with lower-limb amputations (5 traumatic, 3 dysvascular). Somatosensory integrity of both the residual limb and intact limb was assessed by a physical therapist. Assessments

included monofilament testing, light touch sensation, protective (pinprick) sensation, two-point discrimination, and joint position sense. Participants' standing balance was assessed with the sensory organization test (SOT). In the SOT, participants stand on a force platform during altered visual (eyes closed, surround sway) or somatosensory feedback (platform rotation). Each of six feedback conditions consists of three 30-second trials. Standard measures of postural control (excursion, velocity, and 95% confidence interval ellipse) were collected in addition to equilibrium scores. Equilibrium scores indicate a participant's ability to stay within a normative 12° anteroposterior sway envelope. Sway area increased for all participants without vision. However, this decrease in performance was more substantial for those with lower-limb amputation compared with healthy controls. In the stable platform condition without vision, all subjects had lower equilibrium scores (76$\pm$16) than normative controls (92$\pm$ 3). Six subjects weight shifted toward the intact limb, however one subject lacking any sensation on the intact limb weight shifted to the prosthetic limb. Additionally, increased sway area without vision (indicating a higher reliance on visual feedback) was correlated with decreased sensation on the residual limb only. These results suggest that the degree of sensory impairment, primarily in the residual limb, may predict balance ability, particularly in cases where visual feedback is unreliable.

Title: Non-uniform recruitment of lower limb muscles by epidural stimulation of lumbosacral spinal cord in trans-tibial amputees

Authors: *D. SARMA[1], A. C. NANIVADEKAR[2], B. A. PETERSEN[2], M. LIU[2], E. R. HELM[1], M. L. BONINGER[1], L. E. FISHER[1], D. J. WEBER[2];

Abstract: In the lower limbs, bilaterally coordinated spinal reflexes play an important role when responding to unexpected perturbations like slips and trips. These reflexes, responses to sensory inputs from the foot and ankle, also largely mediate the transitions between phases of gait. To restore proper ambulation to lower limb amputees, the ability to evoke and precisely control patterns of reflexive activity will be critical. Lumbar epidural spinal cord stimulation (eSCS) is an intervention that can modify dysregulated lower-limb sensorimotor functions and augment

residual motor capacity. In an ongoing study, we aim to improve balance and gait by electrically stimulating lateral structures in the lumbosacral spinal cord to generate sensations appearing to emanate from the missing limb, in turn evoking coordinated bilateral reflexive muscle activity. In addition to characterizing the conscious sensory percepts evoked by stimulation, a significant effort is being made to understand evoked reflex responses as stimulation engages spinal and subcortical reflex pathways. In one subject, epidural stimulation was delivered through percutaneously implanted (< 30 days) commercial SCS leads (Boston Scientific) to the L4-S1 spinal cord and dorsal roots. Stimulation was delivered at various pulse widths (0.2 to 1ms) at 1Hz across amplitudes ranging from 0.1mA to 6mA. Bipolar surface EMG was recorded bilaterally from 16 muscles, with reflex responses observed most robustly in the biceps femoris and semitendinosus in response to stimulation. The evoked reflexes (onset of 30±5ms) grew proportionally with stimulation amplitude, and were observed to be an order of magnitude larger during standing than sitting. Higher amplitude stimulation also recruited the residual gastrocnemius. These preliminary results suggest that laterally-targeted spinal cord stimulation can engage reflex pathways, which might be effective for restoring gait and balance adaptation after lower-limb amputation. Further studies will evaluate modulating and controlling these responses during active ambulation.

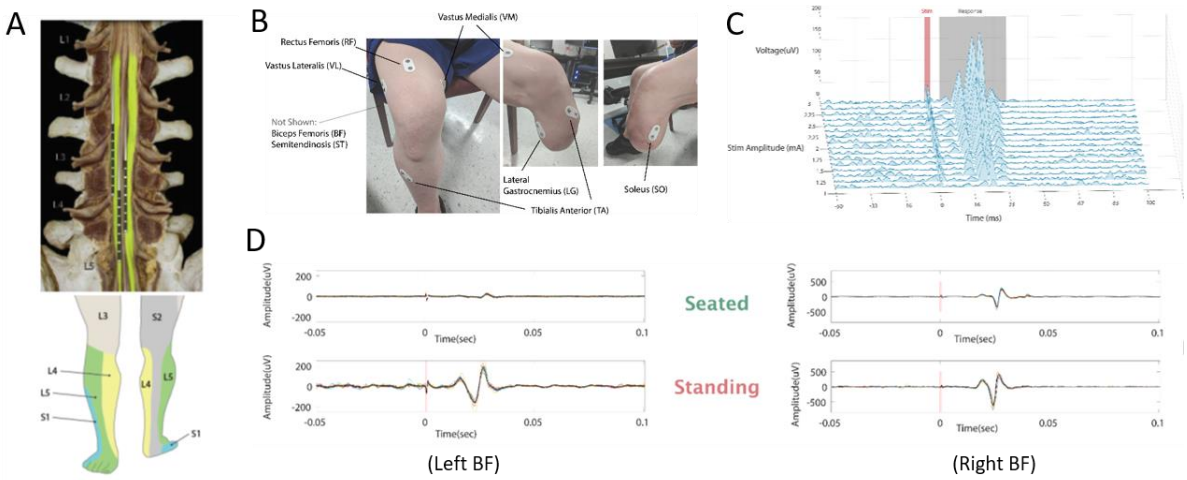

Figure 1 - Characterizing myoelectric responses to epidural spinal stimulation in a transtibial amputee. (A) Commercial spinal cord stimulation leads are implanted percutaneously to evoke sensory and myoelectric responses in the residual limb. (B) Bipolar sEMG recorded bilaterally. (C) Stim-evoked reflex responses grow with increased stimulation amplitude. (D) Reflex responses observed most robustly in hamstring muscles, bi- & uni- laterally, with responses during standing an order of magnitude larger than when sitting.

Title: Effect of stimulus parameters on perceived sensation and phantom limb pain during stimulation of lumbosacral spinal cord in lower-limb amputees

Authors: *A. C. NANIVADEKAR[1], E. OKOROKOVA[4], B. PETERSEN[1], D. SARMA[1], S. J. BENSMAIA[5], E. HELM[1], M. BONINGER[1], D. J. WEBER[2], L. E. FISHER[3];

Abstract: Numerous studies indicate that sensory feedback may enhance the embodiment and ease of use of prosthetic limbs and potentially alleviate phantom limb pain (PLP). Here, we present observations from human psychophysics experiments performed while stimulating the L4-S1 spinal cord to provide sensory feedback in an individual with trans-tibial amputation using FDA-approved spinal cord stimulation leads. Using percutaneous implantation techniques, we placed three 16-contact leads in the lateral epidural space near the lumbosacral spinal cord. Stimulation was delivered using a custom external stimulator during 15 in-lab sessions across 4 weeks, after which the electrodes were removed. Most evoked percepts (74%) were described as a ‘vibration’ or ‘buzz’ originating in the residual limb and in some instances extending down into the phantom limb. For all electrodes, the amplitude of stimulation had a strong positive correlation with the intensity of the reported sensation. As stimulation amplitude was increased the subject described the evoked percepts as feeling less natural. Stimulus frequency strongly affected the perceptual modality as well as the location of the evoked percept. For a subset of electrodes, stimulation frequencies above 200 Hz resulted in sensations exclusively in the phantom limb at the calf, ankle, toes and sole of the foot. At threshold, these sensations were described as faint ‘tickle’, ‘itch’ or ‘numbness’ that became more salient upon repeated stimulation. Additionally, a two-alternative forced choice task was administered to quantify the sensitivity to stimulation. The average detection thresholds across 4 electrodes was 1.33 ± 0.32 mA. Just-noticeable differences varied from 0.07 mA to 0.10 mA. To assess PLP, we administered the McGill Pain Questionnaire (MPQ) once before implantation, weekly during the 29-day study and one month after explant. We observed a 29-point decrease in MPQ score over the course of the implant period. These results suggest that stimulation of the dorsal spinal cord is a promising technique for providing sensory feedback and reducing PLP in individuals with lower-limb amputation.

Abstract: Neuropathic pain has been associated with maladaptive remodeling within the spinal cord pain circuitry. Specifically, our previous work has indicated a structure-function link between dendritic spine dysgenesis within the spinal cord and models of neuropathic pain. However, these prior studies relied on Golgi-stained post-mortem tissue, thereby limiting this analysis to static snap shots of a dynamic process.
To overcome this technical limitation, we have assessed the utility of implanting “glass windows” over the exposed spinal cord of living animals and applied the use multi-photon imaging technology to visualize neurons at the cellular level *in vivo.* Implanting a window over the lumbar spinal cord of thy1-YFP mice allows repeat imaging of dorsal horn neurons at a depth of 300-350um. At this depth we can visually document morphological (thin/mushroom) changes in dendritic spines within the superficial dorsal horn of the spinal cord. In uninjured animals, repeatedly imaging YFP expressing dorsal horn neurons reveals that fluctuations in dendritic spine morphology can be detected after 4 hours. Animals with implanted glass windows can survive for one month allowing us to track dendritic spines over an extended period.
To determine whether *in vivo* spinal cord imaging could detect neuropathic pain associated changes in dendritic spines, we repeatedly imaged animals after inducing a spared nerve injury (SNI). Seven days after injury, SNI animals displayed significant mechanical hypersensitivity that was associated with an increased number and stability of mushroom spines and increased turnover of thin shaped spines. Together, these results indicate that this technique can be used to monitor fluctuations in dendritic spines within the spinal cord pain circuitry. This provides a powerful tool to assess the efficacy of therapeutic interventions designed to modify structural and functional correlates of pain associated with injury.

Title: Prefrontal circuit dysfunction in a mouse model of neuropathic pain

Authors: *M. LI[1], S. TENG[2], G. YANG[1];
[1]Dept. of Anesthesiol., [2]Columbia Univ. Irving Med. Ctr., New York, NY

Abstract: The prefrontal cortex is important for top-down regulation of sensory inputs. Recent *in vivo* electrophysiological studies in rodents suggest a decrease of neuronal firing rates in this region in chronic pain. However, the precise changes of prefrontal circuits underlying the development of chronic pain remain unclear. Here, using *in vivo* two-photon microscopy, we examined the Ca^{2+} activity of pyramidal neurons in different layers and regions of the medial prefrontal cortex (mPFC) in a spared nerve injury mouse model of neuropathic pain. In both prelimbic and secondary motor cortices, we observed a substantial reduction of pyramidal neuron activity across cortical layers. This reduction of prefrontal neuron activity occurred within days after peripheral neve injury and persisted for weeks. Using optogenetic manipulation in freely moving mice, we further showed that activation of prefrontal circuits in neuropathic pain ameliorated the animals' touch sensitivity and aversive quality of pain. Together, these results reveal prefrontal dysfunction in neuropathic pain and highlight mPFC as a potential therapeutic target for pain treatment.

Abstract: In mammalian females the pelvic floor provides a base to support the viscera of the pelvic cavity and allows reproductive and non-reproductive physiological functions. The complex innervation comes from different nerves such as the Levator ani and the pudendal. One branch of the sensory pudendal nerve innervates to bulbospongiosus muscles. Mainly, the afferents to travel to the dorsal horn of the spinal cord and are distributing transversely around the lateral and medial edge of the dorsal horn. The afferent and efferent information that carries bulbospongiosus nerve (Bsn) is important to regulate the contraction of its muscle and other functions of the urogenital system, as the micturition. Is very important to determine the distribution of Bsn cord dorsum potentials (Bsn CDPs) to identify the relevant structures, for instance pudendal afferents within dorsal sacral roots, which should be spared during rhizotomy procedures for treatment of spasticity or to establish treating lower urinary tract dysfunction by 'neuromodulation'. The aim of the study was determine the organization of these aferences across the Bsn CDPs activated by electrostimulation of the Bsn. We used young virgin rabbits (n = 8), the aged was between 6 ± 8 months and anesthetized with urethane, the Bsn was located and mounted in a silver electrodes. The organism in a spinal unit record was fixed in prone position and a laminectomy of the lumbosacral dorsal region (L5-S3) was performed. The dura mater was partially removed and the CDPs were recorded in response to the electrical stimulation of the Bsn. The signals were amplified with a Grass 7P511 amplifier and visualized with a Tektronix TDS2024C oscilloscope. Was analized the amplitude, latency, peak latency, duration and the number of components. Each registers obtained was average of 16 events. The Bsn CDPs showed differences in the number of components and their amplitude. The mayor CDPs amplitude was obtained in S1 lever and lowered to rostral and caudal spinal cord. This results showed the afferent information of perineal muscles is not limited to a single spinal segment, and could help to explain the regulation of micturition, deliver or other physiological processes in the pelvic floor components.

Title: Tac1-expressing neurons in the periaqueductal gray facilitate the itch-scratching cycle via descending regulation

Authors: *W.-Z. CHEN, Z.-R. GAO, M.-Z. LIU, X.-J. CHEN, X.-Y. ZHANG, L. YUAN, Y.-G. SUN;
Inst. of Neurosci., Shanghai, China

Abstract: Uncontrollable itch-scratching cycles lead to serious skin damage in patients with chronic itch. However, the neural mechanism promoting the itch-scratching cycle remains elusive. Here, we report that tachykinin 1 (Tac1)-expressing glutamatergic neurons in the lateral and ventrolateral periaqueductal gray (l/vlPAG) facilitate the itch-scratching cycle. We found that l/vlPAG neurons exhibited scratching-behaviorrelated neural activity and that itch-evoked scratching behavior was impaired after suppressing the activity of l/vlPAG neurons. Furthermore, we showed that the activity of Tac1-expressing glutamatergic neurons in the l/vlPAG was elevated during itchinduced scratching behavior and that ablating or suppressing the activity of these neurons decreased itch-induced scratching behavior. Importantly, activation of Tac1-expressing neurons induced robust spontaneous scratching and grooming behaviors. The scratching behavior evoked by Tac1-expressing neuron activation was suppressed by ablation of spinal neurons expressing gastrin-releasing peptide receptor (GRPR), the key relay neurons for itch. These results suggest that Tac1-expressing neurons in the l/vlPAG promote itch-scratching cycles.

Abstract: Atopic dermatitis is a chronic inflammatory skin disease with severe itching. In atopic dermatitis patients, itch control is very important for improving quality of life and treating atopic dermatitis. However, the underlying mechanisms of itching still unclear. Alpha melanocyte stimulating hormone (alpha MSH) is an endogenous peptide hormone involved in cutaneous pigmentation and our recent study showed that an intradermal injection of alpha MSH elicited itch related responses in mice. In this study, we therefore investigated whether alpha MSH was involved in itching in AD. In the skin of AD patients and mice with atopy like dermatitis (dermatitis mice), alpha MSH was distributed mainly in epidermis, especially keratinocytes. In the skin of mice with dermatitis, alpha MSH receptors (MC1R and MC5R) were expressed at the mRNA level and were distributed in the dermis. In the dorsal root ganglion (DRG) of mice with dermatitis, mRNAs encoding MC1 and MC3~5 were also expressed. MC1R antagonist agouti signaling protein inhibited spontaneous scratching in mice with dermatitis. Our previous study has shown that TXA_2 is an itch mediator and is involved in spontaneous scratching in mice with dermatitis. In healthy mice, intradermal alpha MSH elicited itch-associated responses, which were inhibited by TP thromboxane (TX) receptor antagonist. In mouse keratinocytes, alpha MSH increased the production of TXA_2. alpha MSH increased intracellular Ca^{2+} ion concentration in DRG neurons and keratinocytes. In addition, U46619, a TXA_2 stable analogue, also increased intracellular Ca^{2+} ion concentration in DRG neurons. These results suggest that alpha MSH is involved in itching in AD and elicits itching through the direct activation of primary sensory neurons and the indirect activation of the neurons through TXA_2, which is produced in keratinocytes.

Abstract: Much progress has been made in the neuronal mechanisms of somatosensory processing, particularly at the spinal and subcortical regions. Electrophysiological recording and macroscopic brain imaging studies have characterized neuronal responses in the primary somatosensory cortex (S1) activated by itch, thermal, and mechanical stimuli, but how somatosensory information of multiple modalities is processed by S1 at the level of single neurons remains largely unknown. Here, we report that itch, thermal, and mechanical stimuli activate largely overlapping neuronal population in S1, with modality-specific patterns but not spatial distinct clustering. Using and *in vivo* two-photon calcium imaging that simultaneously monitor hundreds of layer 2/3 neurons in S1 of awake mice, we observed neuronal responses reliably triggered by thermal and mechanical stimuli. To achieve precisely-timed itch sensation, we performed precisely timed optogenetic stimulation of spinal itch-selective neurons that elicited reliable responses in S1 neurons. We found that the same S1 neuronal population showed responses to all three modalities of stimuli, with the reliability and amplitude of responses variable among neurons within the population. Inter-neuronal distance analysis of neurons with similar modality preference revealed no evidence for spatial clustering. Further decoding analysis showed that the recorded population of a few hundred S1 neurons allowed discrimination of the modality and intensity of the somatosensory stimuli. These findings pave the way for further understanding the processing and integration of multimodal somatosensory information in the cortex.
