Title: Mutations in protocadherins impact neural circuit assembly

Authors: *S. LIGHT, J. JONTES;
Neurosci., The Ohio State Univ., Columbus, OH

Abstract: Protocadherins (pcdhs) belong to a diverse family of homophilic cell adhesion molecules involved in a variety of developmental processes that are critical for establishing appropriate brain structure and function. Mutations in pcdhs are associated with neurodevelopmental diseases including autism spectrum disorder, schizophrenia, and epilepsy. Our lab has previously shown that zebrafish with mutations in various pcdhs display subtle defects in neurogenesis, neuronal organization of the optic tectum, and visually-guided behaviors. To further characterize individual pcdh mutants, we employed *in vivo* imaging of spontaneous neuronal activity to investigate the development of network architecture and neuronal connectivity. We performed whole-brain multiplane two-photon calcium imaging of wild type, pcdh19 mutant, and pcdh1a mutant larvae during the first developmental week, which represents a critical period of circuit assembly and structural maturation. The evolution of network topology was evaluated with graph theory, which allowed us to easily compare wild type and mutant networks. This novel approach proved to be an efficient and reliable way to quantify dynamic network properties over time. In both pcdh mutants, we observed robust alterations in the trajectory of network development, as measured by clustering, transitivity, and small world organization. These changes in complex network measures reflect a dysregulation in neuronal architecture and synaptic maturation at the circuit level that leads to altered activity patterns across the brain. Using transient BAC injections, truncation constructs, and non-adhesive pcdh mutants in conjunction with time-lapse imaging, we are investigating the cellular roles of pcdhs that contribute to the altered network phenotypes we observe. Additionally, using proteomics, we have identified interactomes for pcdhs that have suggested relevant molecular pathways for future exploration. Ultimately, we theorize that pcdh function influences brain architecture by locally regulating and coordinating developmental processes, such as neurogenesis and axon outgrowth.

Title: Altered cortical development and neural excitability in the medial prefrontal cortex of B-cell CLL/lymphoma 9 mutant mice

Authors: *Y. KUANG[1], B. YANG[2], S. CHEN[3], W. LI[4];
[1]Shanghai Jiaotong Univ., Shanghai, China; [2]Bio-X Inst., Shanghai, China; [3]Bio-X Institutes, Shanghai Jiao Tong Univ., Shanghai, China; [4]Shanghai Jiao Tong Univ., Shanghai City, China

Abstract: B-cell CLL/lymphoma 9 (*BCL9*), located on the human chromosome locus 1q21.1, has been implicated in tumor progression through the Wnt signaling pathway. Human genetic studies have suggested that common *BCL9* variants confer a risk of schizophrenia, bipolar disorder, and autism development. However, the function of BCL9 in central nervous system remains poorly understood. We used in utero electroporation mice and BCL9 mutant mice in our study. Here, we demonstrated BCL9 is highly expressed in mouse brain during the embryonic and early postnatal period. Knockdown BCL9 in E13.5 could severely disturb the migration of cortical neurons and down regulation of Wnt target genes. Knockdown of BCL9 increased ultrasonic vocalization in pups. Interestingly, we identify BCL9 expression level change voltage-dependent sodium channels expression, leading to abnormal neuronal excitability. We also noted that the common BCL9 variants regulate the brain structural volume and psychotic-like symptoms in adolescents. In conclusion, our findings indicate a possible role of BCL9 in the pathogenesis of neurodevelopmental disorders.

Title: Early fast frequency activity sculpts functional and behavioral maturation of prefrontal networks

Authors: *J. A. PÖPPLAU[1], S. H. BITZENHOFER[2], M. CHINI[1], A. MARQUARDT[1], I. L. HANGANU-OPATZ[1];
[1]Developmental Neurophysiology, Inst. of Neuroanatomy, Univ. Med. Ctr. Hamburg-Eppendorf, Hamburg, Germany; [2]Dept. of Neurosciences, Univ. of California San Diego, San Diego, CA

Abstract: Rhythmic fast frequency oscillations in prefrontal cortex (PFC) are the neural network attribute of cognitive processing. Recently we showed that they already emerge at neonatal age entrained by local synchronized firing of layer 2/3 pyramidal neurons. However, the contribution of early rhythmic activity to cortical circuit formation and their maturation across development is still largely unknown. To fill this knowledge gap we combine in vivo and in vitro electrophysiology with chronic and acute optogenetic stimulations of prefrontal neurons during awake and anesthetized state, as well as morphological and behavioral investigations of postnatal day (P) 5-40 mice. First, we show that layer 2/3 pyramidal neurons in the prelimbic subdivision of PFC entrain local circuits in fast oscillatory rhythms with increasing frequency and amplitude that relate to the progressive embedding of parvalbumin-positive interneurons into developing networks. Next, we directly test the functional engagement of early activity in shaping cortical network refinement by manipulating neonatal oscillations. Mild chronic optogenetic boosting of fast rhythmic activity in PFC during a defined period of neonatal development results in reversible neuronal morphological alterations, such as premature dendritic growth of layer 2/3 pyramidal neurons and reduced interneuronal density. These transient morphological changes are accompanied by permanent circuit dysfunction, reflected by abnormal gamma entrainment at adult age. Mice with manipulated neonatal activity show impaired social interactions and poorer recognition and working memory at juvenile and adult age. Our results indicate that early patterns of coordinated oscillatory activity are relevant for network function and behavioral performance of adults.

Title: Chronic exposure to delta9-THC during adolescence alters muscarinic M2 receptor distribution in adult prefrontal cortical neurons contacted by CB1 terminals

Authors: M. GARZON[1], K. MACKIE[2], *V. M. PICKEL[3];
[1]Dpt Anat, Histol and Neurosci. Fac Med. UAM, Madrid, Spain; [2]Psychol & Brain Sci., Indiana Univ. Bloomington Dept. of Psychological and Brain Sci., Bloomington, IN; [3]Brain and Mind Res. Inst., Weill Cornell Med., New York, NY

Abstract: Chronic intermittent administration of marijuana's major psychoactive compound, Δ9-tetrahydro-cannabinol (THC) results in adaptive changes in adult social and cognitive functions that are dependent on activity of output neurons in the prelimbic prefrontal cortex (PL-PFC). Memory and learning processes in PL-PFC neurons can be regulated by cholinergic transmission through muscarinic-2 -like receptors (M2R) and modulated by activation of cannabinoid-1 receptors (CB1Rs) that are targeted by THC. This learning is a key contributor to the experience-dependent plasticity ongoing in the PL-PFC during the vulnerable stage of adolescence, which suggests that chronic exposure to THC during adolescence may alter the expression and/or distribution of M2Rs in PL-PFC neurons receptive to CB1R terminals. We used high resolution electron microscopic dual CB1R and M2R immunolabeling in adult C57BL/6J male mice (postnatal day, PD70) that had received vehicle or escalating dose (2.5-10mg/kg/ip) of THC through adolescence (PD 29-43) to test this hypothesis. In **vehicle controls** CB1R-immunolabeling was mainly localized to small unmyelinated axons and axon terminals almost none of which contained M2R but often apposed M2R-immunoreactive profiles. M2-labeling was also localized to axons, but it was more often seen in the cytoplasm or on extrasynaptic plasma membrane of varying sized dendrites and dendritic spines. The dendritic profiles receive input from CB1R-labeled or unlabeled terminals, whereas the dendritic spines received asymmetric synapses exclusively from axon terminals lacking CB1Rs. **Adolescent THC** produced a significant increase in M2R-immunogold density exclusively in large dendrites receiving input from CB1R-labeled terminals. In contrast, the cytoplasmic M2R-immunogold density was decreased in small spines of the THC-treated adult mice. We conclude that THC occupancy of presynaptic CB1R receptors during adolescence produces increased plasmalemmal accumulation of M2R in large proximal dendrites and decreased cytoplasmic expression in small spines influenced by CB1R regulated modulators in PL-PFC. They have implications for understanding and treating psychiatric disorders worsened by teenage marijuana use.

Title: Connectivity profiling and single-cell RNA sequencing to study homeostatic plasticity in hippocampal neuronal networks *in vitro*

Authors: *T. KIM, J. BARTRAM, M. SCHROETER, A. HIERLEMANN;
D-BSSE Bioengineering Lab., ETH Zurich, Basel, Switzerland

Abstract: Homeostatic plasticity represents an important set of regulatory mechanism to help maintaining stable neuronal circuit function and to flexibly adapt firing rates to changes in external drive (Turrigiano and Nelson 2004; Turrigiano 2008). Moreover, deficits in the ability to homeostatically regulate neuronal activity have been linked to a series of neurological and neuropsychiatric diseases (Frere and Slutsky 2018; Roselli and Caroni 2015). Although the intrinsic and synaptic mechanisms underlying homeostatic responses have been an area of active research (Turrigiano 2012), only few studies have attempted to link the electrophysiological properties of individual neurons to their gene-expression profiles following up- or down regulation of activity (Schanzenbächer et al. 2018; Schanzenbächer et al. 2016; Schaukowitch et al. 2017).
We sought to gain a more integrated understanding of how the homeostatic firing-rate regulation of single neurons correlates to their functional connectivity in the network and their transcriptomic changes, respectively. To track the development and spontaneous activity of primary rodent hippocampal networks *in vitro*, we used high-density microelectrode arrays (HD-MEAs) (Müller et al. 2015). HD-MEAs enable studying of neuronal function both at the network and subcellular scale (Obien et al. 2014) and, futhermore, provide the means for tracking extracellular multi-channel footprints of single neurons over extended developmental periods (Gong et al. 2016). Finally, combined with simultaneous patch clamp recordings, HD-MEAs are a suitable tool to map the synaptic connectivity of individual neurons (Jäckel et al., 2017).
Here, we tracked the emerging spontaneous activity of hippocampal neuronal networks across development and inferred their functional connectivity. Once the network had reached a mature devlopmental stage, we applied bicuculline and followed the homeostatic response of the full network and a subset of pre-selected neurons at high resolution. In a second step, we applied the Patch-seq protocol (Cadwell et al. 2017) to extract cellular content from cells of interest and to combine the identification of the electrophysiological phenotype of neurons with post-hoc single-cell RNA sequencing. We demonstrate that the response dynamics of individual neurons

to perturbation are heterogeneous, which is also reflected in the mRNA extracted from these neurons. We propose that a combined analysis of neuronal activity, synaptic connectivity and gene expression patterns is a promising approach to study the mechanisms underlying neuronal homeostasis.

Title: A synaptic switch gates developmentally-regulated homeostatic plasticity in parvalbumin interneurons of the visual cortex

Authors: ***M. DRUART**[1,2], M. SOIZA-REILLY[3], M. QUAGGETTO[1,2], M. GARCIA[1,2], I. MOUTKINE[1,2], C. LE MAGUERESSE[1,2];

Abstract: Brain development is shaped by synaptic plasticity, which contributes to the formation of mature neuronal networks. Critical periods (CP) of brain development are specific time windows characterized by high plasticity in neural networks in response to environmental perturbations. A specific CP has been well characterized in the developing visual cortex where permanent changes in ocular dominance (OD) occur after monocular deprivation (MD) during CP. Converging evidence implicates glutamatergic inputs onto parvalbumin-expressing (PV) interneurons in the onset of the CP for OD plasticity. However, the underlying molecular and synaptic mechanisms remain largely unknown. Using patch-clamp recordings in acute slices from mice at different developmental stages, we studied the development of the glutamatergic input onto PV interneurons. Our results revealed a transient decrease in the AMPA-receptor (AMPAR) rectification index during CP. This suggests a transient loss of AMPAR subunit GluA2 at excitatory synapses onto PV interneurons during CP. Interestingly expression of GRIP1, a protein involved in GluA2 trafficking, has been shown to be transiently downregulated in cortical PV interneurons at P25. Furthermore, the interaction between GRIP1 and GluA2

mediates homeostatic plasticity at glutamatergic synapses. To assess homeostatic plasticity in PV neurons, we sutured one eye for 3 days before recording miniature excitatory postsynaptic currents (mEPSCs) in PV neurons of the contralateral visual cortex. We observed an increase in mEPSC frequency before and after CP but not during CP. This result suggests an absence of homeostatic plasticity at excitatory synapses onto PV interneurons selectively during CP, thus potentially allowing profound changes in visual cortex connectivity at this crucial developmental stage. We hypothesized that the downregulation of GRIP1 during CP prevents the trafficking of GluA2 subunit to the synapse and homeostatic plasticity in PV interneurons during CP. To test this hypothesis, we generated PV-Cre::GRIP1lox/lox mice in which GRIP1 is ablated specifically in PV neurons and then recorded PV neurons in the visual cortex of adult (P50) mice after MD. The rectification index of AMPAR was decreased in adult mice lacking GRIP1 in PV neurons. In addition, MD in KO mice did not elicit the increase in mEPSC frequency observed in WT mice, indicating that GRIP1 is necessary for homeostatic synaptic plasticity in PV neurons. Taken together, our results suggest that the transient downregulation of GRIP1 prevents the homeostatic plasticity of glutamatergic inputs onto PV interneurons in visual cortex selectively during CP.

Title: Multiplexing rhythmic information by spike timing dependent plasticity

Authors: *M. SHAMIR[1], N. SHERF[2];
[1]Ben-Gurion Univ., Be'er Sheva, Israel; [2]Ben-Gurion Univ. of the Negev, Be'er-Sheva, Israel

Abstract: Rhythmic activity has been associated with a wide range of cognitive processes including the encoding of sensory information, navigation, the transfer of emotional information and more. Past studies have shown that spike timing dependent plasticity (STDP) can facilitate the transfer of rhythmic activity downstream along the information processing pathway. However, STDP has also been known to generate strong winner-take-all like competition between subgroups of correlated synaptic inputs. Consequently, one might expect that STDP will induce strong competition between different rhythmicity channels; thus, preventing the multiplexing of information across the different frequency channels. Here we ask: **Can STDP**

facilitate the multiplexing of information across different frequency channels, and if so, under what conditions? This question was addressed using the framework of a modelling study. We investigated the STDP dynamics of two competing sub-populations of neurons that synapse in a feedforward manner into a single post-synaptic neuron. Each sub-population was assumed to oscillate in an independent manner and in a different frequency band. To investigate the STDP dynamics, a mean field Fokker-Planck theory was developed in the limit of slow learning rate. Surprisingly, our theory predicted limited interaction between the different sub-groups. Our analysis further reveals that the interaction between those channels is mainly mediated by the shared component of mean (DC) activity. Next, we generalized our results beyond the simplistic model using numerical simulations. We found that, for a wide range of parameters, the system converges to a dynamic solution, in which the post-synaptic neuron responds to both rhythms. However, all of the synaptic weights remain dynamic and do not converge to a fixed point. Thus, we find that STDP can support multiplexing of rhythmic information, depending on the temporal structure of the STDP rule. This work demonstrates how functionality (multiplexing of information) is retained in the face of continuous remodelling of all of the synaptic weights.

Title: Mechanism by which perineuronal nets promote hardwiring of vestibular circuits for sensori-motor behaviors

Authors: *Y.-S. CHAN, T. KWAN, A. TAM, C.-W. MA, K. WU, D. SHUM;
Sch. of Biomedic. Sci., Fac. Med., Univ. Hong Kong, Hong Kong, China

Abstract: Chondroitin sulphate (CS)-rich perineuronal nets (PN) have emerged as a powerful regulator of plasticity. We asked how PN governs early brain development. Consolidation of PN around GABAergic neurons in the VN coincides with emergence of vestibular-dependent negative geotaxis behavior at P9 in rats. Treatment of the VN at P6 with chondroitinase ABC (ChABC) to delay consolidation of PN resulted in shift of negative geotaxis to P13. To elucidate the effect of ChABC treatment at the cellular level, we performed whole-cell patch-clamp recordings on VN interneurons in brainstem slice preparations at P9 and P14 when PN-CS underwent consolidation. Pre-treatment of the VN with ChABC decreased inhibition but

promoted excitatory neurotransmission in VN neurons. We found that ChABC treatment increased excitability of VN neurons due to increase in membrane potential. Apart from this direct effect, we further showed that the PN-CS associated plasticity-inducing factor semaphorin 3A (Sema3A) was liberated with treatment of ChABC. In vitro tests confirmed that Sema3A promoted neurite growth and branching of VN neurons. To reveal the behavioral consequence, we compared Sema3a treatment alone with combined ChABC and Sema3A delivery to the VN at P6. Sema3A delayed the emergence of another graviceptive reflex air-righting from P15 to P16, while combined treatment further delayed it to P18. Taken together, our results suggest that retention of Sema3A by PN-CS moieties limits dendritic/synaptic plasticity of VN interneurons, thereby contributing to developmental hardwiring of the central circuitry for vestibular behavior.

Title: Genetic disruption of DCC and Ntn1 expression in adult midbrain dopamine neurons produces significant behavioral changes

Authors: *M. M. CLINE[1], A. HUNKER[2], B. JUAREZ[2], L. S. ZWEIFEL[2];
[1]Psychiatry and Behavioral Sci., [2]Pharmacol., Univ. of Washington, Seattle, WA

Abstract: Netrin1 signaling through the netrin receptor deleted in colorectal cancer (DCC) promotes growth cone attraction, axon elongation and branching, and synaptic development during embryogenesis. Emerging evidence suggests DCC and secreted netrins may play an additional role in maintaining excitatory synaptic connections in the adult brain. Both netrin1 and DCC are highly expressed in the adult ventral tegmental area (VTA) and substantia nigra (SN), and co-label with TH expression, but their function in these cells remains unclear. To explore the function of netrin1 and DCC in adult dopamine neurons, we used a combination of viral-mediated, cre-inducible CRISPR/Cas9 technologies and transgenic mice to selectively disrupt *Ntn1* and *Dcc* expression exclusively in midbrain dopamine neurons of adult mice. Eight-week old DAT-IRES$^{Cre/+}$ mice were injected bilaterally into the VTA with AAV-FLEX-SaCas9-HA-sg*Ntn1*, or -sg*Dcc*, and AAV-FLEX-YFP. Control DAT-IRES$^{Cre/+}$ mice received bilateral injections of AAV-FLEX-YFP. Four weeks following viral injections, mice were screened for alterations in dopamine-mediated behaviors. Open field testing revealed *Ntn1* and *Dcc*

conditional knockout (cKO) mice spent significantly less time in the arena center (Mean±SEM; *Ntn1* cKO 34.58s ± 4.375, *Dcc* cKO 30.21s ± 6.117) compared to YFP controls (66.67s ± 8.030, $p<0.001$), and significantly more time on the arena edge ($p=0.0015$, *Ntn1* cKO 425.8s ± 13.15, *Dcc* cKO 427.6s ± 12.65, YFP 360.2s ± 14.41). Locomotion measured across three nights and two days showed significantly reduced day distance traveled in *Ntn1* and *Dcc* cKOs compared to controls ($p<0.05$, *Ntn1* cKO 1867cm ± 152.3, *Dcc* cKO 1416cm ± 142.5, YFP 2635cm ± 383.8) on day one. Curiously, *Dcc* cKO, but not *Ntn1* cKO, mice displayed significant impairment in novel object recognition and social recognition. These data suggest that both *Ntn1* and *Dcc* play an important role in regulating specific aspects of dopamine-regulated behaviors through their actions in dopamine neurons of the adult midbrain. Future experiments will be aimed at establishing a role for these proteins in maintaining excitatory synaptic connectivity in dopaminergic midbrain neurons in the adult brain.

Title: Humanization of SRGAP2C expression increases cortico-cortical connectivity and alters cortical neural responses in the mouse brain

Authors: *E. SCHMIDT[1], H. T. ZHAO[2], C. KIM[2], E. HILLMAN[2], F. POLLEUX[1];
[1]Neurosci., [2]Biomed. Engin. and Radiology, Columbia University, Mortimer B. Zuckerman Mind Brain Behavior Inst., New York, NY

Abstract: Little is known about the molecular changes that have led to the emergence of human-specific traits of brain development and function. Recently, we have focused our attention on human-specific gene duplications as potential genetic modifiers of human brain development.

One such gene is SRGAP2: the ancestral copy SRGAP2A, which is present in all mammals, promotes maturation and limits the density of both excitatory (E) and inhibitory (I) synapses received by cortical pyramidal neurons (PNs). Partial duplication of SRGAP2A resulted in a human-specific paralog, SRGAP2C, which inhibits all known functions of SRGAP2A. Expression of SRGAP2C in mouse PNs leads to the emergence of phenotypic traits characterizing human cortical PNs, including increased E and I synapse density and delayed synapse maturation. However, how these changes in synapse number and maturation affect the structure and function of cortical circuits remains unknown. We explored how humanization of SRGAP2C expression affects the structural organization of mouse cortical circuits by using monosynaptic rabies tracing from sparse populations of cortical layer 2/3 PNs in the primary somatosensory cortex (S1). Using a novel method for reconstruction and mapping of traced neurons, we found that humanization of SRGAP2C expression causes a significant increase in local connectivity, as well as long-range feedback connections from other cortical areas, including M2 and contralateral S1. Interestingly, we did not detect any quantitative changes in inputs for subcortical neurons, showing humanization of SRGAP2C expression selectively increases cortico-cortical connectivity of layer 2/3 PNs. These results suggest that developmental mechanisms that control synaptic connectivity, like SRGAP2, represent suitable evolutionary substrates through which increased complexity of cortical circuit wiring has emerged during human brain evolution. We now investigate how this increased cortico-cortical connectivity impacts circuit performance related to sensory processing and behavior. Using multiple *in vivo* imaging approaches, including wide-field optical imaging, we are testing how SRGAP2C expression alters cortical circuit function and modifies sensory evoked neuronal responses across the entire dorsal cortex. Our work aims to uncover the mechanisms whereby human-specific genetic modifiers altered synaptic development and neuronal connectivity and how these changes in circuit architecture affected cortical function and might have allowed the emergence of human-specific features of brain function during evolution.

Title: Distinct roles of TrkB and p75NTR signaling in neural circuit refinement in the developing visual system

Authors: *E. KUTSAROVA[1], A. SCHOHL[1], M. MUNZ[2], O. BILASH[3], Y. ZHANG[1], A. WANG[4], E. S. RUTHAZER[1];
[1]Montreal Neurolog. Inst., McGill Univ., Montreal, QC, Canada; [2]Friedrich Miescher Inst. for Biomed. Resear, Basel, Switzerland; [3]Neurosci. Inst., New York Univ. Sch. of Med., New York, NY; [4]Interdepartmental Neurosci., Yale Univ., New Haven, CT

Abstract: Building a brain which contains properly connected neurons is essential for the survival of an animal in the surrounding world. Sensory experience translated into patterned neuronal activity instructs various aspects of topographic map refinement, crucial for orderly representation in the brain of the outside world. Forming and refining proper brain connectivity relies on the communication between a projecting neuron and its future postsynaptic partners. Brain-derived neurotrophic factor (BDNF) was identified as one of the prominent molecular candidates that underlies activity-dependent neural circuit refinement. BDNF is synthesized as a precursor protein proBDNF which has been shown to play a role in facilitating synaptic weakening through p75 neurotrophin receptor (p75NTR) signaling, whereas the post-cleavage mature form (mBDNF) signals through p75NTR and tropomyosin-related kinase B (TrkB) and is crucial for synaptic strengthening. Overall, BDNF signaling is crucial for structural remodeling of dendrites and axons during development. We used multiphoton imaging of retinal ganglion cells (RGCs) projecting into the optic tectum in the albino Xenopus laevis tadpole to observe their structural remodeling in vivo. A single ectopic ipsilaterally projecting RGC axon was visually stimulated either synchronously or asynchronously with its neighboring inputs, while blocking BDNF signaling with TrkB-Fc, or knocking down its receptors TrkB or p75NTR in RGCs. We showed that acute BDNF signaling is necessary for suppression of axonal branch addition in response to correlated firing. p75NTR in RGCs is required for asynchrony-induced branch addition, while TrkB signaling in RGCs acts as an activity-dependent suppressor of branch elimination. p75NTR in the RGCs is crucial for exploratory growth over days. p75NTR and TrkB appear to have distinct signaling in darkness compared to during visually evoked activity. These results provide cellular structural details for BDNF, TrkB and p75NTR signaling as mechanisms underlying specific aspects of activity-dependent structural remodeling during development.

Title: Family nurture intervention (FNI) which increases EEG power of preterm infants at term age does so through mechanisms other than FNI effects on delta brushes, effectors of early brain development

Authors: P. G. GRIEVE[1], M. M. MYERS[1], J. L. BARONE[1], R. J. LUDWIG[1], R. I. STARK[1], J. R. ISLER[1], ***M. G. WELCH**[2];
[1]Columbia Univ., New York, NY; [2]Pediatrics, Columbia Univ. Med. Ctr., New York, NY

Abstract: The Nurture Science Program (NSP) at Columbia University (nurturescienceprogram.org) conducted an RCT of Family Nurture Intervention (FNI) in the NICU. Prior results showed that FNI, which facilitates emotional connection (EC) and physiological co-regulation between preterm infants and their mothers, has positive physiological and neurobehavioral effects including robust increases in frontal brain activity (EEG power, 19-21Hz) at term age. Prominent features of preterm EEG activity are bursts known as delta brushes (DB) which appear at 28-30 wks and which are largely gone by 42 wks. It is thought that early bursting activity plays a key role in shaping brain development. Here we characterize FNI effects on early EEG bursting activity and ask if they mediate effects of FNI on term EEG activity. Results from 31 SC and 33 FNI infants (~30 wks GA at birth) show that FNI alters two aspects of DBs: 1) FNI infants have more rapid increases in amplitudes of the brush component of DBs from ~35 to ~40wks, and 2) DBs in FNI infants have longer durations, especially during quiet sleep (QS). Consistent with the hypothesis that DBs shape subsequent brain activity we found, pooling data from both SC and FNI, four parameters of DBs at ~35 weeks were correlated with term power: active sleep (AS) rate, $r=0.30$, $p<0.05$; AS brush amplitude, $r=0.32$, $p<0.05$; QS brush amplitude, $r=0.28$, $p<0.05$; QS brush oscillation frequency, $r=0.36$, $p<0.05$. However, results from mediator analyses found no evidence that effects of FNI on early burst parameters mediate effects of FNI on term power. This finding is also illustrated in the figure. Thus, while early bursting activity can have important effects on shaping later brain activity, facilitating EC through FNI results in maturation of brain activity being less dependent on early bursting activity. Mechanisms underlying how co-regulation and EC embedded in FNI alter brain development are not clear but ongoing NSP research in human infants and animal models are exploring autonomic conditioning as key to understanding these important effects of nurture.

Title: Maturation of prefrontal cortex responses to basolateral amygdala inputs during adolescence: Frequency-dependent regulation by local excitatory & inhibitory signaling

Authors: *M. AUGER[1], K.-Y. TSENG[2];
[1]Anat. & Cell Biol., Univ. of Illinois at Chicago-College of Med., Chicago, IL; [2]Anat. and Cell Biol. / Neurosci., Univ. of Illinois at Chicago - Col. of Med., Chicago, IL

Abstract: Basolateral amygdala (BLA) inputs to the prefrontal cortex (PFC) are involved in the regulation of decision-making, impulse control and affective processing. Past research has suggested that BLA innervation of the PFC is remodeled during adolescence, which may

contribute to the adolescent maturation of these cognitive faculties. If so, the functional refinement of BLA-PFC circuitry is expected to occur during adolescence to impact how the PFC processes inputs from the BLA. To address this issue, we conducted local field potential recordings in the PFC and changes in the pattern of responses elicited from the BLA using different frequencies of train stimulation were compared across 4 age groups of rats (postnatal day): P30-37, P40-47, P50-57, and P65-80. Reduced facilitation of PFC responses to 15 Hz BLA stimulation was observed during adolescence in comparison to adults, an effect that was most prevalent within the P30-37 and P40-47 age groups. In contrast, adolescents showed blunted suppression of responses to 30-40 Hz BLA stimulation, an effect that was most obvious in the P50-57 age group. These results suggest BLA recruitment of excitatory and inhibitory components in the PFC mature over adolescence, which may display distinct developmental trajectories in a frequency-dependent manner. Future studies will elucidate how variations in BLA output transmission and local PFC signaling regulate the distinct frequency-dependent responses observed during the transition from adolescence to adulthood. Collectively, these findings point to a novel feature of PFC development during adolescence that may support the dynamic cognitive and emotional changes that occur during this time.

Title: Maturation of cFos expression in cortical circuits

Authors: *M. POMPEIANO, M. T. COLONNESE;
Pharmacol. and Physiol., The George Washington Univ. Sch. of Med., Washington, DC

Abstract: Wakefulness in cortical circuits is accompanied by robust expression of the activity-induced gene cFos, which is driven by a combination of neuronal activity and noradrenergic release (Pompeiano et al 1994). During development, circuit formation in the cerebral cortex is accompanied by unique patterns of activity whose similarities with adult cortical activities are not fully understood (Colonnese and Phillips 2018). Early background activity is discontinuous (long silent periods) and poorly modulated by arousal state. The switch to adult-like patterns of background activity occurs, with some regional heterogeneity, during the second week postnatally in mice, first in somatosensory cortex and last in visual cortex. Here we investigated when cFos expression matures in the cerebral cortex in order to determine its relationship with

the maturation of cortical activity patterns and potentially validate its use as a marker to predict developmental activity patterns throughout the brain. C57BL/6 mouse pups were killed at 5 (P5), 9, 13, and 17 days of age or as adults (n=4, 2 males and 2 females for each age) after manual stimulation to keep them awake for 1-2 hours. At P5, cFos staining was limited to layer 6b in somatosensory, motor and auditory cortex. These cells co-labeled with Nurr1 indicating they are subplate neurons. The only structure with adult-like, widespread staining at this age was the piriform cortex, consistent the early development of olfaction to cue suckling (Al Aïn et al 2013). Dense, multi-layer adult-like staining was observed in somatosensory, motor, and auditory cortex by P13 and in visual cortex by P17 in line with the timing of whisking, ear-opening and eye-opening respectively (Colonnese and Phillips 2018). cFos staining was very low or absent in sleeping animals of the same ages. These observations show that immature spontaneous activity bursts do not drive cFos expression beyond the subplate. Robust cFos expression is instead correlated with the onset of mature, continuous, background activity. cFos is therefore a potential marker for the maturation of cortical activity patterns.

Title: Microglia-mediated remodelling of the medial pulvinar connectivity: New insights for schizophrenia

Authors: *J. HOMMAN-LUDIYE, J. A. BOURNE;
Australian Regenerative Med. Inst., Monash Univ., Clayton, Australia

Abstract: Uniquely evolved in primates, the medial pulvinar (PM) is a multimodal thalamic nucleus, responsible for coordinating the simultaneous processing of many elements of information and the modulation of selective directed attention. Anatomical and structural evidence of abnormal PM architecture and activity in patients suggest that the cognitive and behavioural symptoms associated with schizophrenia result from abnormal PM connectivity. To address this hypothesis, we mapped the extensive connectivity between the PM and neocortex in the adult marmoset monkey (*Callithrix jacchus*) using MRI-guided bidirectional tracer injections (n=3; > 2yo; sex was not a selection criterion). Whilst we confirmed previous connections with the temporal, parietal and prefrontal cortices, we identified 20 additional cortices connected with the PM. Based on our previous evidence that connectivity between the inferior pulvinar and neocortex is profoundly remodelled during development, we investigated if this principle is conserved in the PM. Using the same tracing paradigm applied to neonatal (postnatal day (PD)

14); juvenile (PD90) and adolescent (PD300; n=2/ stage) monkeys, we observed a more extensive PM connectivity in the juvenile brain, in terms of both density and spatial distribution, which is refined during adolescence to make place for the adult profile. Co-labelling with the microglial marker Iba1 enabled the identification of tracer-labelled PM terminals internalised within the phagocytic cells, suggesting that the microglia participate in sculpting PM efferents in the neocortex. Dysregulation of the microglia-mediated synapse elimination has been associated with the excessive pruning and loss of grey matter characteristic of schizophrenia. Therefore, abnormal PM connectivity in patients is potentially a consequence of dysfunctional developmental processes. To further investigate the role of PM in neocortical maturation, we performed chemical lesions of PM in neonatal animals (n=2, PD14). Analysis in adulthood revealed abnormal expression of maturation markers in neocortical areas connected to PM, akin to observations in schizophrenia patients. Therefore, we conclude that the PM plays an instructive role on cortical development and is central in the aetiology of schizophrenia.

Title: Death of Cajal-Retzius cells regulates the wiring of upper cortical layers

Authors: *M. RIVA[1,2,3], I. GENESCU[4], C. HABERMACHER[1], D. ORDUZ[5], F. LEDONNE[3], F. RIJLI[6], G. LOPEZ BENDITO[7], E. COPPOLA[1,2,3], S. GAREL[4], M. C. ANGULO[1,5], A. PIERANI[1,2,3];

Res., Basel, Switzerland; [7]Inst. de Neurosciencias de Alicante, Alicante, Spain

Abstract: Programmed cell death (PCD) is emerging as a key player in the wiring of cortical circuits.

Cajal-Retzius cells (CRs) are among the first born cortical neurons and reside in the most superficial layer of the developing cerebral cortex from where they coordinate multiple crucial steps in the construction of functional circuits. At embryonic stages CRs comprise at least three distinct subtypes which differ for their generation site (septum, ventral pallium and hem), molecular signature, distribution at the cortical surface and function. The vast majority of CRs are thought to be transient as they disappear during early postnatal life in mice as well as in primates and their abnormal persistence is associated with pathological conditions in humans. Here we show that subtype-specific features persist at postnatal stages. Using genetic fate mapping our work revealed that CR subtype-specific differences exist in the distribution and timing of disappearance in the postnatal mouse brain. We showed that all CR subtypes undergo cell death although, surprisingly, through at least two molecularly distinct pathways. Conditional inactivation of the pro-apoptotic factor *Bax* prevented death of septum but not hem-derived CRs. Surviving CRs are integrated in neural circuits and keep the electrophysiological properties of immature CRs. Furthermore, we found that CRs survival promotes exuberance of dendrites and spine density in upper layers pyramidal neurons. This results in imbalanced Excitatory/Inhibitory (E/I) ratio due to an increase in excitatory drive in the network. These changes are activity-dependent as hyperpolarization of CRs by Kir2.1-dependent expression promoted their survival in the absence of any differences in pyramidal neuron morphology, number of spines or electrophysiological properties.
These results strongly suggest that CRs demise is a novel player in developmental remodeling and maturation of dendrites and synapses and provide the first mouse model to test the relevance of altered PCD in human pathologies. We will discuss the effects of maintaining immature neurons in the mature cortex, the role of a subtype-specific control of CR programmed cell death in the construction of cortical functional and dysfunctional circuits.

Title: Early life adversity and maturation of dorsal raphe synapses

Authors: *A. KISNER, C. GOMEZ, M. CAMACHO, A. M. POLTER;
Pharmacol. and Physiol., The George Washington Univ., Washington, DC

Abstract: Early life is a critical period in the development and refinement of the central nervous system. Experience during this early life period plays an important role in shaping the maturation of the brain. Exposure to early life adversity is implicated in increased susceptibility to many neuropsychiatric disorders such as depression, anxiety and addiction. These processes are themselves linked to dysfunction of neuromodulatory systems. In particular, the serotonergic neurons of the dorsal raphe nucleus (DRN) exert widespread and complex neuromodulatory effects that are necessary for fine-tuning neural circuit formation. While it is known that serotonin regulates a wide range of brain functions and behavior, it is not clear how their circuits regulating serotonergic function are modulated by development and early-life experience. Here, we used slice electrophysiology to characterize the maturation of synaptic inputs received by serotonergic and GABAergic neurons in the DRN from juvenile to adult developmental stages in mice. We found that the strength of excitatory transmission increased over the course of the juvenile and adolescent period and was maintained through early adulthood. Additionally, we determined that within the juvenile (PND15) and adolescent (PND35) developmental stages the AMPA/NMDA receptor-mediated current ratio in serotonergic neurons is higher than that found in GABAergic neurons, suggesting differential patterns of synaptic maturation in DRN serotonergic and GABAergic neurons. To better understand the impact of early life experience on maturation of DRN synapses, we implemented a limited bedding model to induce early life stress (ELS) from PND4 to PND11. We then used slice electrophysiology to assess the maturation of DRN synaptic inputs. Our results indicate a decrease in excitatory neurotransmission (mean spontaneous excitatory postsynaptic current frequency ELS 1.11 Hz ± 0.1, n = 3 cells vs control 2.43 Hz ± 0.1, n = 3 cells) onto DR serotonergic neurons immediately following stress that persists into adulthood. Thus, our results demonstrate that adverse experience during early life can cause persistent alterations in the synaptic architecture of the DRN. We anticipate that our findings will be a starting point to understand the impact of adverse experiences on synaptic maturation of the DRN highlight targets for novel treatments for stress-related disorders.

Title: Developmental divergence of sensory stimulus representation in cortical VIP and SST interneurons

Authors: *R. KASTLI[1], R. VIGHAGEN[1], A. VAN DER BOURG[2], A. ARGUNSAH[1], A. IQBAL[1], F. F. VOIGT[3], D. KIRSCHENBAUM[4], A. AGUZZI[4], F. HELMCHEN[5], T. KARAYANNIS[6];

Abstract: Inhibitory interneurons play an important role in sensory processing in the rodent whisker somatosensory cortex (wS1). In wS1 of adult mice the VIP^+ and SST^+ interneurons have been shown to be critically involved in modulating network activity during active whisking. However, little is known about the activity of these cells in the early post-natal brain before the mouse pup starts to actively whisk. Using *in vivo* two-photon calcium imaging, we investigated the activation of VIP^+ and SST^+ interneurons in response to two different whisker stimulation paradigms (single- and multi-whisker), before and after the onset of active whisking (P14). We found that before P14 both interneuron types respond stronger to the multi- compared to the single-whisker stimulation. In contrast, after the onset of active whisking the activation profiles diverge and only the SST^+ interneurons retain the ability to differentiate between the two stimuli while the VIP^+ cells do not. In order to get at the potential circuit mechanisms underlying the diverging response profiles we used monosynaptic rabies virus tracings followed by CLARITY based tissue-clearing, as well as photostimulation-coupled electrophysiology to investigate the cortico-cortical and thalamo-cortical inputs onto the two interneuron types. We found that, both before and after P14, SST^+ interneurons receive cortical inputs from further away within wS1 compared to VIP^+ cells, pointing at one route for cross-whisker sampling by SST^+ cells. In addition, we also found that a second route for SST^+ cells to sample multiple whiskers before P14 was the robust inputs from the somatosensory thalamus, which was also true for VIP^+ cells of that age. Nevertheless, the thalamic inputs onto the two cell types significantly re-arrange after P14, with those onto SST^+ interneurons shifting to nuclei associated with the motor thalamus. These results show that wS1 VIP^+ and SST^+ interneurons undergo impactful changes around the time the animal starts actively whisking, potentially to diversify their role and allow the refined processing of multiple aspects of the environment.

Title: Development of cortical AMPA and GABA-A receptor mediated connections in the absence of NMDA receptors

Authors: *R. DENG, P. O. KANOLD;
Biol., Univ. of Maryland, College Park, MD

Abstract: Fast neurotransmissions mediated by ionotropic receptors are essential for interneuronal communication and neural computation. Our understanding of the mechanisms underlying the development of synaptic connections in the brain is still incomplete. Synaptic inputs to developing cortical neurons are mostly supplied via glutamatergic and GABAergic synapses. In early development glutamatergic synapses are mostly composed of NMDA receptors while AMPA receptors emerge later. NMDA receptors are thought to play a crucial role in the development of AMPA receptor mediated connections. Since GABA can be depolarizing in immature neurons it has been hypothesized that GABAergic signaling activates NMDA receptors to facilitate the maturation of AMPA receptor containing glutamatergic synapses during early development. This scenario suggests that activation of NMDA receptors is required for the development of glutamatergic connections. However, in the hippocampus NMDA receptors are not required for the formation of AMPA and GABA-A receptors mediated connections received by excitatory neurons, raising the question if indeed NMDA receptors are required for the maturation of synaptic connections in the cerebral cortex. Moreover, it is unknown if the development of spatially specific inter- and intra-laminar cortical synaptic connections depend on NMDA receptors. To test if the development of synaptic connections to cortical excitatory neurons requires NMDA receptors, we sparsely eliminated NMDA receptors in cortical neurons through *in utero* electroporation of *Cre* plasmid driven by *Cdk5r* gene promoter in *Grin1*$^{fl/fl}$ mice at embryonic day 12.5 or 13.5. Consequently, in post-mitotic neurons expressing the electroporated plasmid the obligatory NMDA-R1 subunit was eliminated and NMDA currents were absent. The development of AMPA and GABA-A connections in the cortex was subsequently investigated through *in vitro* whole-cell patch clamp recordings coupled with laser-scanning photostimulation via glutamate uncaging at the end of the second postnatal week. We found that the amount and the spatial distribution of AMPA and GABA-A receptor mediated connections received by neurons lacking NMDA receptors are comparable to those received by control neurons. We thus conclude that NMDA receptors are not required for the

formation of AMPA and GABA-A receptors mediated neurotransmission in cortical excitatory neurons.

Title: Establishment of clustered protocadherin-regulated high reciprocal connectivity between clonal cortical neurons requires sensory experience in mouse barrel cortex

Authors: *E. TARUSAWA[1,2], M. SANBO[2], M. HIRABAYASHI[2], T. YAGI[1], Y. YOSHIMURA[2];
[1]Osaka university, Suita, Japan; [2]NIPS, Okazaki, Japan

Abstract: The specificity of neural connections in the sensory cortex is fundamental for the proper processing of sensory information. We previously have shown that high reciprocal connectivity is established between clonal cortical neurons and the establishment is regulated by clustered protocadherins in mouse barrel cortex. In this study, we analyzed the effect of sensory deprivation on the establishment of the cell-lineage-dependent reciprocal connectivity. To visualize clonal neurons, we generated chimeric mice by injecting a small number of induced pluripotent stem cells (iPS cells) marked with GFP into blastocysts. We conducted dual whole-cell recordings from GFP-positive excitatory neuron pairs (presumed clonal pairs) or GFP-positive and negative excitatory neuron pairs (non-clonal pairs) within a layer 4 barrel in acute cortical slices prepared from the chimeric mice. In naïve chimeric mice at postnatal day 9 (P9) to P11, almost all connected neuron pairs showed one-way connections in both clonal and non-clonal neuron pairs. After that, high reciprocal connectivity in clonal neuron pairs was established by two sequential processes, an initial formation of reciprocal connections from P9-11 to P13-16, and a selective elimination of one-way connections from P13-16 to P18-20. As a result, 83% of connected neuron pairs showed reciprocal connections. This high reciprocity was not observed in non-clonal neuron pairs.To reveal the influence of sensory deprivation on the development of high reciprocal connectivity, whisker trimming was performed on the chimeric mice from P13 to the day before recording. In clonal neuron pairs after whisker-trimming, the formation of reciprocal connections at P15-16 was strongly suppressed and the lower reciprocity was kept at P18-20. The elimination of one-way connections from P15-16 to P18-20 was also prevented by the whisker trimming. Consequently, only 20% of connected neuron pairs showed reciprocal connections after deprivation. Surprisingly, the effect of sensory deprivation on the neural connections was not observed in non-clonal neuron pairs, suggesting that cell-lineage-

specific neural connections are selectively modified by sensory experience. Our previous and current findings suggest that the sensory inputs and clustered protocadherins are required for the establishment of reciprocal connections between clonal neurons, and further investigations into the signaling pathways to link neural activity and clustered protocadherins may shed light on the mechanisms underlying cell-lineage-dependent connection specificity in neocortex.

Title: Transgenerational transmission of behavioral phenotypes in a paternal aspartame exposure mouse model

Authors: *S. K. JONES, D. M. MC CARTHY, P. G. BHIDE;
Biomed. Sci., Florida State Univ. Col. of Med., Tallahassee, FL

Abstract: The use of low-calorie sweeteners as weight loss tools is highly prevalent. In the US, 25% of children and 41% of adults report using low-calorie sweeteners, which represents a 54% increase since 1999. Aspartame is among the most widely used low-calorie sweeteners worldwide. We examined whether aspartame exposure results in adverse behavioral consequences for male mice, and if offspring derived from the aspartame-exposed males display behavioral alterations. We exposed adult (6-8 week) male C57BL/6 mice to aspartame in drinking water (0.03% or 0.015% - doses equivalent to 50% and 25%, respectively, of FDA's acceptable daily intake). We used a two-bottle choice paradigm in which mice had continuous access to aspartame containing or plain drinking water. Following 12 weeks of such exposure, we analyzed spontaneous locomotor activity (home-cage activity), anxiety-like behavior (elevated zero maze), and spatial working memory (Y-maze). The mice exposed to 0.015% aspartame did not show significant changes in any of the behavioral measurements. However, mice exposed to 0.03% aspartame displayed significant reduction in spontaneous locomotor activity, as well as significant anxiety-like behavior, and spatial working memory deficit (ANOVA, $p < 0.05$; followed by Dunnett's multiple comparisons test). The aspartame-exposed and control mice were bred with drug-naïve females. Male offspring derived from the aspartame-exposed males displayed anxiety-like behavior and spatial working memory deficit whereas the

female offspring displayed anxiety-like behavior only (ANOVA, $p < 0.05$; followed by Bonferroni multiple comparisons test). These data suggest that aspartame exposure produces significant behavioral changes in male mice and their offspring. Thus, aspartame exposure at levels equivalent to 50% of the FDA recommended human daily intake, carries the risk of adverse behavioral outcomes not only in individuals exposed to the aspartame but also their descendants. The molecular mechanisms underlying the "transgenerational transmission" are not known. We suggest that aspartame-induced epigenetic modification of spermatozoa is a likely mechanism.

Title: Distraction processing in adults with ADHD: An ERP study

Authors: *E. T. MARCELLE, Y. ZHAO, N. KARIMI, J. W. KAM, S. P. HINSHAW; Univ. of California, Berkeley, Berkeley, CA

Abstract: Attention-Deficit/Hyperactivity Disorder (ADHD) is one of the most commonly occurring and impairing neurodevelopmental disorders across the lifespan. Although ADHD has traditionally been conceptualized as a deficit in one's ability to sustain attention, replicated evidence of ability to sustain attention in reduced distraction environments for such individuals has challenged this accepted framework. That is, ADHD may be best viewed as a disorder of attention regulation. Furthermore, as conceptualization moves toward a focus on distractibility as a key feature of the disorder, examining neural differences in distraction processing between adults with and without ADHD is an important area of focus. Although preliminary studies have begun to investigate associated neural processes in children, adult investigations are warranted. Therefore, the present study seeks to examine the neural correlates of distraction processing in adults with ADHD using EEG. To accomplish this goal, adults with and without ADHD completed a three-stimulus auditory oddball task using Standard (500Hz tone, probability P = 0.80); Target (1000Hz tone, P = 0.10); or Distractor (e.g., bell, whistle, tone sweep, P = 0.10) sounds. Participants were instructed to respond by (green) button press to target sounds, vs. (red) button press to standard and distractor sounds. A button press for each tone, as opposed to only target tones, was required to minimize motor-related confounds between target, distractor, and standard sounds. EEG data were collected by a 128-channel BioSemi ActiveTwo system with a

sampling rate of 250 Hz. Participants were recruited from a larger pool of 70 subjects with and without ADHD participating in a completed study of sustained attention in ADHD at UC Berkeley. Event-related potentials (ERPs) examined included Mismatch Negativity (MMN), P3a, P3b, and Reorienting Negativity (RON). Behavioral measures included response time and discrimination/accuracy. Preliminary behavioral findings in pilot testing were consistent with existing literature: response times to distractor sounds were significantly longer than response times to target and standard tones, indicating the attentional cost of distraction processing. Implications of behavioral and EEG findings for future conceptualization of adult ADHD are discussed.

Abstract: Recent experiments have shown that weak learning can be enhanced by unrelated salient events like reward, stress or novelty, if those events occur during a vulnerable phase of consolidation. According to the Behavioral Tagging theory (Moncada & Viola, 2007), this memory mechanism is associated with an interaction between a synaptic tag set by the learning event and the synthesis of plasticity related proteins (PRPs) triggered by the salient event. In animal research, Behavioral Tagging is often operationalized by letting animals explore a novel open field before or after learning a certain task. In this case, memory modulation is supposedly mediated by an enhanced release of dopamine in the hippocampus triggered by the novel experience. Translating from animal to human research, the novelty induced surplus of dopamine could be potentially used to tackle the learning difficulties observed in children with attention deficit hyperactivity disorder (ADHD), who often exhibit a hypofunction of the dopaminergic system.

In the current experiment, we asked 30 children with ADHD and 30 healthy control children (age 9-15) to explore either a previously familiarized or a novel virtual environment 45 minutes after they had learned a list of 20 words. During immediate free recall, patients with ADHD remembered significantly less words than healthy control children. When measured 24 hours later, the ADHD patients who explored a novel environment showed a free recall performance similar to the level of healthy control children, while ADHD patients who explored a familiar environment did not show any improvement. Contrary to previous studies, this beneficial effect of novelty was only present for patients and not for healthy control children, indicating that Behavioral Tagging with novel virtual environments might be especially useful to promote memory consolidation in children with ADHD.

Title: Overexpression of the ataxin 7 gene in the prefrontal cortex and striatum leads to the development of hyperactive phenotype in mice: Involvement of the noradrenergic and dopaminergic systems

Authors: *L. L. SAYSON, C. BOTANAS, R. CUSTODIO, A. ABIERO, M. KIM, H. LEE, H. KIM, J. CHEONG;
Uimyung Res. Inst. For Neurosci., Seoul, Korea, Republic of

Abstract: Attention deficit hyperactivity disorder (ADHD) is a neurodevelopmental disorder marked by excessive levels of hyperactivity, impulsivity, and/or inattention. To identify the potential genetic underpinnings of ADHD, we previously identified a number of common differentially expressed genes in the prefrontal cortex of the hyperactive spontaneously hypertensive rat (SHR), the most validated animal model for ADHD. This included Ataxin 7 (Atxn7), a gene that codes the Atxn7 protein, which is implicated in gene transcription. Then, we established a line of mice overexpressing the Atxn7 gene (Atxn7 OE) and found them to be hyperactive and impulsive. Treatment with atomoxetine (ATO), a common drug for ADHD, normalized their behaviors and the Atxn7 gene expression in the prefrontal cortex and striatum. However, there is still a need to elucidate the underlying mechanism of the observed behaviors

of the Atxn7 OE mice. Thus, in this study, we determined the involvement of the noradrenergic and dopaminergic systems in the ADHD symptoms of the Atxn7 OE mice, considering the effects of ATO, by measuring the mRNA expressions of noradrenergic and dopaminergic-related genes in the prefrontal cortex. We also examined the brain electrical activity of the Atxn7 OE mice. Furthermore, protein levels of ubiquitinated histone H2B (Ub-H2B) in the prefrontal cortex of the Atxn7 OE mice were measured. Atxn7 has been suggested to affect H2B ubiquitination, a necessary process for gene transcription. Our results show that the Atxn7 OE mice have altered noradrenergic and dopaminergic-related gene expressions in the prefrontal cortex. Atxn7 OE mice showed decreased delta, theta, alpha, and beta waves, and were normalized by ATO treatment. Furthermore, Ub-H2B protein levels were decreased in the Atxn7 OE mice. Taken together, we suggest that the noradrenergic and dopaminergic systems are involved in the ADHD-like symptoms exhibited by the Atxn7 OE mice.

Title: Brain-derived neurotrophic factor improves neurite development and mitochondrial activity of dopaminergic neurons differentiated from exfoliated deciduous tooth-derived pulp stem cells of children with ADHD

Authors: *H. T. NGUYEN, H. KATO, H. SATO, H. YAMAZA, K. MASUDA;
Fac. of Dent. Science, Kyushu Univ., Section of Oral Med. for Children, Div. of Oral Health, Growth & Develop., Fukuoka, Japan

Abstract: Attention deficit hyperactivity disorder (ADHD)—the most common neurodevelopmental disorder—is characterized by impaired attention, hyperactivity, and impulsivity. While multiple factors have been implicated in the pathogenesis of ADHD, the underlying mechanism remains unclear. Dysregulation of dopaminergic signals, mitochondria, or brain-derived neurotrophic factor (BDNF) have been hypothesized to explain the mechanism of ADHD pathogenesis in children; however, only a few reports have demonstrated these associations. Stem cells from human exfoliated deciduous teeth (SHED) are neural crest-derived mesenchymal stem cells, and they are present in the dental pulp of exfoliated deciduous teeth; these cells can efficiently differentiate into dopaminergic neurons (DNs). SHED are associated with few ethical limitations in research; they can be obtained using minimally invasive methods. Thus, SHED are useful as a disease-specific cellular model for studying a neurodevelopmental

disorder associated with DN dysfunction. The purpose of this study was to elucidate the association between DNs, mitochondria, and BDNF in ADHD by analyzing DNs differentiated from SHED obtained from three boys with ADHD compared with those from three typically developing boys. Without exogenous BDNF, the DNs derived from the boys with ADHD (ADHD-DNs) showed impaired neurite outgrowth and branching, which is associated with decreased mitochondrial activity, i.e., reductions in mitochondrial membrane potential, number of mitochondria within the neurites, number of mitochondria/cell area, and ATP production. In addition, we found that BDNF mRNA expression was significantly lower in ADHD-DNs. Exogenous BDNF supplementation significantly enhanced neurite outgrowth and branching and mitochondrial function in ADHD-DNs. In conclusion, ADHD-DNs may show impaired neurite development and mitochondrial function associated with an impaired BDNF expression, and the consequent BDNF deficiency can be improved by exogenous BDNF supplementation. This ADHD-derived SHED-based study may contribute to the development of treatment strategies for aberrant dopaminergic signaling, mitochondrial function, and BDNF levels in patients with ADHD, in future.

Title: Hand performance asymmetry as a motor phenotype of children with fetal alcohol spectrum disorder

Authors: *D. E. LIDSTONE[1], *F. Z. MIAH[2], J. F. BEASLEY[2], J. S. DUFEK[1];
[1]Kinesiology and Nutr. Sci., [2]UNLV Med. Ackerman Autism Ctr., Univ. of Nevada, Las Vegas, Las Vegas, NV

Abstract: Fetal Alcohol Spectrum Disorder (FASD) is a common neurodevelopmental disorder characterized by neurological, developmental, and neurobehavioral deficits caused by prenatal alcohol exposure. Neuroimaging studies of children with FASD have identified hypoplasia of the Corpus Callosum (CC) as the most frequently observed structural abnormality. Reduced size of the CC is a neurophenotype of FASD and the size of the CC is associated with the strength of handedness. Therefore, reduced hand performance asymmetry may be a motor phenotype of FASD. In the current study, we examined whether hand performance asymmetry could differentiate a group of children (7-17 years old) with a clinical diagnosis of FASD (N = 16; 15 right-handed; 6 males; age = 12.6±3.0 years; full-scale intelligence quotient (FSIQ) = 90.6±11.3)

from a clinical control group with a diagnosis of Autism Spectrum Disorder (ASD) (N = 23; 21 right-handed; 18 males; age = 12.2±2.8 years; FSIQ = 93.7±13.8) and a typically developing (TD) control group (N = 12; 12 right-handed; 5 males; age = 11.6±2.8 years; FSIQ = 116.7±7.5). To examine manual dexterity performance, the 9-hole pegboard test was completed on the dominant and non-dominant hand with the order of hand assessed randomized. Manual dexterity performance for the dominant-hand and non-dominant hand was assessed as the fastest time (in sec) of three attempts. Hand performance asymmetry was defined as the percent difference between dominant and non-dominant hand manual dexterity performance. Results showed that hand performance asymmetry was significantly greater in the ASD group (-15.70±19.76%) compared to the FASD group (-3.77±8.31%; p=0.02). Hand performance asymmetry was also significantly greater in the TD group (-14.78±15.89%) compared to the FASD group (p=0.02). In conclusion, our results show that hand performance asymmetry differentiated a group of children with FASD from children with ASD and TD controls. Therefore, reduced hand performance asymmetry may be a motor phenotype of FASD and an indirect measure of CC hypoplasia. A larger sample of children should be examined to determine the robustness of our findings. Discovery of motor phenotypes in children with FASD may improve diagnostic practices in clinical settings.

Title: Altered anatomic and functional connectivity in Tourette syndrome

Authors: *S. W. WU[1], H. S. JACKSON[1], D. A. HUDDLESTON[1], W. YUAN[2];
[1]Neurol., [2]Radiology, Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH

Abstract: OBJECTIVE Tics are the hallmark symptoms in Tourette Syndrome (TS). Prior diffusion tensor imaging (DTI) studies have revealed white matter alterations in the cortico-striato-thalamo-cortical (CSTC) circuit. In adult controls, dual-site Transcranial Magnetic Stimulation (TMS) has shown that right frontal stimulation can reduce primary motor cortex (M1) excitability. Here we used DTI and TMS to examine CSTC network connectivity in Tourette Syndrome children and controls.
METHOD Twenty-three right handed subjects (12 controls, 11 TS; average ages 11.5, 12.6 years

respectively, p=0.7) participated in the study. Brain MRI was obtained using 3T Phillips MR scanner. DTI indices, including fractional anisotropy (FA), mean, axial, and radial diffusivity (MD, AD, and RD, respectively), were calculated and analyzed using the Tract Based Spatial Statistics approach in FSL software. DTI group difference was tested using 2-sample t-test with age adjusted as a covariate and Threshold Free Cluster Enhancement method to correct for multiple comparison. DTI data in the region with significant group difference was extracted and fitted with age with a linear model. These residual values that are free of age effect was used in correlation analysis. Left M1 resting motor thresholds (RMT) were measured using the right 1st dorsal interosseous muscle. Figure-8 coil was navigated to the right pre-supplementary motor area (pre-SMA), identified as the gyrus anterior to the Vertical Commissure Anterior line, using BrainSight to perform dual-site TMS. The pre-SMA conditioning pulse (110%*RMT) preceded the M1 pulse (120%*RMT) by 6, 8 and 10ms. A mixed, repeated-measures regression model (age included as a covariate) was used to analyze motor-evoked potential (MEP) amplitudes, using False Discovery Rate to correct for multiple comparison.
RESULT DTI analysis showed TS participants had increased FA and decreased RD in the right superior corona radiata when compared to controls ($p<0.05$). Diagnosis*pulse condition interaction was significant ($p=0.02$), with post-hoc analysis showing that controls had ~20% inhibition while this inhibition was not present in TS children. FA residual ($\rho = -0.68$, $p = 0.04$) and 6ms TMS data ($\rho = -0.78$, $p = 0.008$) correlated with clinical rating of tic suppressibility, suggesting that those who are more efficient at suppressing tics had DTI/TMS data more similar to controls.
CONCLUSION Using DTI and dual-site TMS, we showed that anatomic and functional connectivity within the right frontal region in TS children are different from typically-developing children. This multi-modal approach may help to further understand TS pathophysiology.

Title: Brain and behavioural changes in mice colonized with human ADHD gut microbiota

Authors: *S. DAM[1], A. TENGELER[2], M. WIESMANN[2], C. BELZER[3], B. FRANKE[1], T. KOZICZ[2], A. KILIAAN[2], A. ARIAS VASQUEZ[1];
[1]Donders Inst. for Brain, Cogniton & Behaviour, Nijmegen, Netherlands; [2]Radboudumc, Nijmegen, Netherlands; [3]Lab. of Microbiology, Wageningen Univ. & Res., Wageningen, Netherlands

Abstract: Microbes inhabiting our gastrointestinal tracts, the gut microbiota, are involved in regulation of the gastrointestinal system, modulation of the immune, endocrine as well as nervous systems by influencing the brain, mood and stress regulation. The microbiota can stimulate the release of serotonin from specific cells located in the gastrointestinal tract. Some members of the microbiota can also independently synthesize neurotransmitters or precursors of neurotransmitters, that can communicate bidirectionally with the brain (gut-brain axis). A growing body of research recognizes the role of gut microbiota in behaviour and neurodevelopment in which an imbalance in microbiota has been observed in patients and animal models of several neurodevelopmental disorders, especially in attention-deficit /hyperactivity disorder (ADHD). Therefore, the current study was designed in which we implanted gut microbiota of anonymous human donors of the NeuroIMAGE cohort with and without ADHD into germ-free mice. We hypothesized that the microbiota from humans with ADHD would differentially affect mouse behaviour and brain structure and function compared to that from controls. To test our hypothesis, we performed behavioural tests (Open Field, Marble Burying and Novel Object Recognition), did brain scanning with an 11.7 T MR scanner (DTI and resting-state fMRI) and collected fecal samples after colonization and sequenced the 16s rRNA genes to measure bacterial composition (α & β-diversity and relative abundance). Mice colonized with ADHD microbiota (i) were more anxious in the open field test, (ii) showed decreased resting-state fMRI-based functional connectivity between right motor and visual cortices and (iii) showed gray and white matter integrity loss in hippocampus and right internal capsule. Structural brain changes found in mice colonized with ADHD microbiota occurred in regions corresponding to those reported to be altered in human ADHD. Mice colonized with ADHD and control microbiota showed a global difference in microbiome composition (β-diversity). Moreover, we found 22 genera overlapping with the microbiota in our human cohort, predominantly from *Ruminococcaceae* family, showing different relative abundance between the mice groups. Similar changes in this family have been observed in multiple psychiatric and neurodevelopmental disorders including ADHD, which highlights the relevance the gut microbiome plays at the brain level, through the gut-brain-axis. While further research is needed, our findings might open a window of opportunity for potential treatment strategies targeting the microbiota in disorders such as ADHD.

Title: Motivation is deficient in the spontaneously hypertensive rat (SHR), a rodent model of ADHD: Evidence from an operant breakpoint paradigm

Authors: *A. S. NAZARIO, M. E. STEVENSON, Y. S. GREENBERG, B. S. LARSON, C. C. MILLER, R. A. SWAIN;
Univ. of Wisconsin-Milwaukee, Milwaukee, WI

Abstract: Attention Deficit Hyperactivity Disorder (ADHD) is one of the most commonly diagnosed childhood neurobehavioral disorders. ADHD is characterized by three core behavioral deficits (hyperactivity, inattention, and impulsivity) that significantly hinder the daily functioning of those diagnosed. Furthermore, children with ADHD have problems with motivation and often require larger, more frequent rewards in order to complete a task. While the etiology of the disorder is largely unknown, we do know that various areas of the brain, including the cerebellum, have abnormalities and warrant further investigation. In this study, we used the Spontaneously Hypertensive Rat (SHR), a rodent model of ADHD that exhibits all of the core deficits of the disorder. The goal of the current study was to further validate the SHR as a model of ADHD by training rats in an operant conditioning breakpoint paradigm, which is commonly used to assess motivation. Twelve male SHR and 12 male Wistar Kyoto (WKY) control rats were trained on a Progressive Ratio (PR-20) schedule that increased in difficulty until the rats reached their breakpoint, which was defined as the point at which the animals stopped working. The breakpoint served as a measure of motivation and the higher the breakpoint, the more motivated the animal was. Results show that the SHR animals display a significantly lower breakpoint compared to the control animals, indicating that the SHR animals gave up working on the task much sooner. Furthermore, we found that during the operant session, the SHR animals spent significantly more time off task, engaged in significantly more off-task behaviors, and pressed the lever significantly less times consecutively in a row compared to the WKY. Open field analyses indicated that the SHR animals crossed significantly more squares and spent significantly more time in the inner zone. Elevated plus maze results indicated that the SHR animals appeared to be less anxious compared to the controls as the SHR animals entered into and spent significantly more time in the open arms of the maze. Future analyses include an examination of cerebellar anatomy that may provide an explanation for why the motivational behavior is altered in the SHR model. Together, our behavioral findings from the operant chamber, open field, and elevated plus maze indicate that the SHR rat displays

motivational deficits in addition to the core ADHD symptoms of hyperactivity, inattention, and impulsivity.

Title: The cerebello-thalamo-prefrontal pathway in ADHD

Authors: *E. M. ALLISON, T. IKUTA;
The Univ. of Mississippi, Oxford, MS

Abstract: The cerebellum has been repeatedly implicated in ADHD. Smaller cerebellar volume has long been known and white matter reduction has also been found in ADHD. However, it is not quite well understood how cerebellar deficits relate to attentional functions that are considered to be prefrontal. In this study, we isolated the cerebello-thalamo-prefrontal (CTP) white matter pathway and tested the association between its integrity and Conners Adult ADHD Rating Scale (CAARS) total score in 440 individuals. There was significant association between the white matter integrity of the CTP pathway and CAARS total score. A significant regression equation was found ($F(2,438)=7.07$, $p=0.00096$) with an $R2$ of 0.027. The predicted CAARS total score is equal to 5.47 + 26.19 (CTP FA) – 0.062 (age). The CTP FA significantly predicted the CAARS total score ($p=0.028$). Our results suggest that the integrity of the CTP pathway is positively associated with ADHD spectrum, suggesting that the CTP pathway may contribute to ADHD. This may not be consistent with previous findings. Volume reductions in cerebellar white matter has been repeatedly reported (van Ewijk et al 2012). It has been reported that disrupted functional connectivity is found between the cerebellum and default mode network in ADHD (Kucyi et al 2015).

Title: Shared and unique neural correlates of reading and attention

Authors: ***M. E. MARKO**[1], R. F. SLOMOWITZ[2], B. C. DRURY[1], L. M. MCGRATH[2], C. J. STOODLEY[1];
[1]Psychology, American Univ., Washington, DC; [2]Univ. of Denver, Denver, CO

Abstract: Neurodevelopmental disorders of reading (i.e. developmental dyslexia) and attention (i.e. ADHD) are highly prevalent (5-10%) with a high rate of comorbidity (25-40%). While prior studies have found overlapping risk factors at the cognitive and genetic levels, little is known about the neural underpinnings of this comorbidity. To identify potential neural correlates of comorbid reading and attention problems, we used voxel based morphometry (VBM) to investigate the shared and unique brain regions associated with reading and attention in 330 children (156 males, 174 females; age=8-18 years, M=13.4, SD=3.1) drawn from a publicly-available, population-based sample, the Philadelphia Neurodevelopmental Cohort (PNC). For inclusion, participants were required to have a T1-weighted MRI scan that passed quality control and behavioral measures of both reading and attention. Participants were excluded if they had any genetic or major health condition that would impact the CNS. Word reading was assessed with the Wide Range Achievement Test-4 (WRAT-4) and attention was measured by clinical interview of parents using 6 inattention symptoms from the DSM-IV ADHD criteria. Data were preprocessed using the CAT12 toolbox, and SPM12 multiple regression analyses were used to determine regions of the brain where grey matter (GM) volume was related to reading or attention scores ($p<0.001$, cluster FDR<0.05). Covariates included age, age^2, sex, handedness, and total intracranial volume. Better attention scores correlated with increased GM in the left precuneus. Higher reading scores were associated with increased GM in the bilateral thalamus. A conjunction analysis ($p<0.05$, $k>100$, uncorrected) was performed to determine regions associated with both reading and attention, and revealed overlap in the bilateral caudate and bilateral precuneus. These results are consistent with a recent meta-analysis of VBM studies of developmental dyslexia and ADHD which found shared GM reductions in the caudate. It is possible that caudate dysfunction may contribute to the shared deficits in executive dysfunction

in both disorders and partially explain their high rates of comorbidity. Future work will investigate the roles of the caudate and precuneus in dyslexia and ADHD.

Title: Differences in social behaviors as reflected by parental judgement in school age children with perinatal stroke and school age children with high functioning autism

Authors: *E. M. BEAVER, M. MEYER, S. EDWARDS, P. LAI;
Dept. of Commnication Disorders, Univ. of Nebraska at Kearney, Kearney, NE

Abstract: Social behavior affects all aspects of one's life. Lacking the ability to process and effectively convey social information can lead to deficits in maintaining peer and family relationships, in addition to academic failure in school. Individuals with neurodevelopmental disorders often have significant impairments in social communication that impact their relationships with others. In this study, two groups of children were assessed, children with High Functioning Autism (HFA) and children with Perinatal Stroke (PS). This study included 43 children in total between 7 to 14 years of age, 23 children with HFA, 20 children with PS. Individuals with HFA are characterized by deficits in core areas such as: social interaction, social communication, and restricted repetitive and stereotyped patterns of behavior, interests, and activities. This disorder affects an estimated 1 in 68 children in the United States. Children with PS experience a cerebrovascular event around the perinatal period. The estimated prevalence rate is 1 in 4,000 births. In this study, the Social Responsiveness Scale (SRS) was distributed to caregivers to complete. The SRS assesses children's social and affective impairments. The results of these items on the SRS questionnaire allows us to analyze the similarities and differences between these groups to gain a deeper understanding of each group's social phenotype from the caretaker's perspective. Results from the one-way analysis of variance (ANOVA) showed a significant difference between the two groups when it came to the item of "staring off into space" (SRS #65). The HFA group was rated as producing more of this particular behavior and this was rarely observed in children with PS ($p=0.004$). There was also a trend ($p=0.13$) for children with HFA not matching their expressed emotions on their face (SRS

#2). Once again, this behavior was not observed in children with PS. Taken together, even at school age, children with HFA are continuing to show social deficits, while, children with PS are not displaying these behaviors. These results in school age children provide clinical value as strengths and weaknesses of social behavior can be observed with the goal of constructing more targeted treatment methods for the future.

Title: The progression of white matter abnormalities in phenylketonuria

Authors: *H. E. CLOCKSIN[1], D. A. WHITE[2], Z. HAWKS[2], S. E. CHRIST[1];
[1]Univ. of Missouri, Columbia, MO; [2]Washington Univ. in St. Louis, St. Louis, MO

Abstract: Phenylketonuria (PKU) is a rare autosomal recessive disorder characterized by an inability to metabolize phenylalanine (phe) to tyrosine, a precursor for dopamine and other catecholamines. Despite early and continuous treatment, individuals with PKU experience cognitive and neurological sequelae. The most common neurological finding is abnormalities of the cortical white matter (WM). Past findings suggest that generally posterior regions may be more affected than anterior regions, but little is known regarding the potential impact on individual WM tracts. The aim of the present study is to further characterize the progression of WM abnormalities in early-treated PKU (ETPKU) by investigating the interaction between spatial locations along established WM tracts using Automated Fiber-Tract Quantification (AFQ). DTI neuroimaging data from a group of 22 individuals with ETPKU between the ages of 9 to 35 (*M*=23.8, *SD*=7.0) and 22 individuals without PKU between the ages of 9 to 33 (*M*=23, *SD*=6.9) was analyzed using AFQ. Results revealed significant reductions in mean diffusivity (MD) in our ETPKU group compared to our non-PKU group in several WM tracts including the callosum forceps minor (p=.001) and the left arcuate fasciculus (p =.013). Among those with ETPKU, higher plasma phe levels (associated with poorer treatment adherence) was associated with greater reductions in MD. Additionally, the within-tract pattern of disruptions appeared to differ based on the orientation of the tracts. For tracts (e.g., arcuate fasciculus) with a primary anterior-to-posterior orientation, PKU-related differences were more apparent in the posterior as compared to anterior aspects of the pathway. For other tracts (e.g., callosum forceps minor) with

a more dorsal-ventral or left-right orientation, PKU-related differences were relatively equivalent across the spatial extent of the tracts. Overall, these findings can be taken to suggest that WM integrity worsens overall as individuals with ETPKU age and their phe levels increase. Furthermore, the progression of WM disruptions in ETPKU seems to vary along the spatial location of WM tracts such that tracts extending in an anterior-to-posterior direction are differentially affected while tracts with different directionality experience a main effect of phe.

Title: Caffeine via adenosine A2A receptors recovers neuronal outgrowth in attention deficit and hyperactivity disorder (ADHD) rat model

Authors: C. B. ALVES, A. S. ALMEIDA, D. M. MARQUES, A. FAÉ, A. L. MACHADO, **L. O. PORCIÚNCULA**;
Biochem., Univ. Federal do Rio Grande do Sul, Porto Alegre, Brazil

Abstract: Attention deficit and hyperactivity disorder (ADHD) is the most prevalent psychiatric disorder in children and adolescent, which is characterized primarily by a triad of symptoms that include hyperactivity, inattention and impulsivity. Experimental studies have evidenced the potential of caffeine in counteracting cognitive and inattention deficits in Spontaneoulsy hypertensive rats (SHR, the most validated ADHD rat model). Studies about the development *in vitro* of cortical neurons from this ADHD model were not performed yet; the effects of caffeine at cellular levels were not investigated. In this study, we sought to find morphological

differences between in cultured frontal cortical neurons from SHR and Wistar-Kyoto rats (WKY, control strain). In addition, we investigated the effects of caffeine and adenosine receptors signaling in these morphological alterations. The percentage of neurons with less branch points was higher in SHR neurons (76 ±3.83% vs 57.86 ±5.29, n=7), while it was decreased for neurons with more branch points (17.75 ±2.85 vs 29.61 ±4.21, n=7). The maximal neurite length was also decreased in SHR neurons (21 %, $P < 0.05$, n=7). Tau immunoreactivity was also decreased in SHR neurons (117.4 ±11.03 vs 206.7 ±31.67 a.u., n = 9). The percentage of neurons with less branch points decreased after 24 h of exposure to 30 μM caffeine [$F_{(1, 20)}= 11.77$; $P = 0.0026$, n=6]and the selective adenosine A_{2A} receptors ($A_{2A}R$) antagonist [$F_{(1,20)}= 8.560$; $P = 0.0084$, n= 6]. A trend toward recovering Tau immunoreactivity was observed after 24 h of incubation with $A_{2A}R$ antagonist[$F_{(1, 25)}= 3.639$; $P = 0.0680$, n = 7-8], which was further confirmed when PI3K inhibitor blocked its effects in recovering Tau immunoreactivity [$F_{(1,30)}= 5.32$, $P = 0.0281$, n = 8-9]. Likewise, PI3K inhibitor blocked the effects of caffeine in increasing the number of branch points [$F_{(1,12)}= 7.159$; $P = 0.0202$, n = 4], maximal neurite length [$F_{(1,12)}= 18.35$; $P = 0.0011$, n = 4]. Similar findings were found for PKA inhibitor, which also blocked the effects of caffeine in recovering total [$F_{(1,12)}= 31.17$; $P = 0.0001$, n = 4]and maximal neurite length [$F_{(1, 12)}= 16.45$; $P = 0.0016$, n = 4]from SHR neurons. Our findings showed for the first time impaired neuronal differentiation in cultured frontal cortical neurons from ADHD model. In addition, our data revealed that the benefits of caffeine against memory and attentional disturbances in ADHD model may involve its ability in recover neuronal outgrowth.

Title: Effects of repeated tDCS over the right IFG in children and adolescents with ADHD

Authors: *C. BREITLING[1], T. ZAEHLE[2,3], V. BAUMANN[1], J. TEGELBECKERS[1,4], H.-H. FLECHTNER[1], K. KRAUEL[1,3];
[1]Child and Adolescent Psychiatry, [2]Neurol., [3]Ctr. for Behavioral Brain Sci., Otto-von-Guericke Univ., Magdeburg, Germany; [4]Dept. of Neurol., Northwestern Univ., Chicago, IL

Abstract: ADHD related deficits in response inhibition and working memory are associated with an underactivation of the right inferior frontal gyrus (IFG). Repeated applications of tDCS could induce long-lasting increase in activity of this area and therefore enhance cognitive functions. 33 ADHD patients in the age between 10 and 16 years underwent five sessions of HD-tDCS over the right IFG on consecutive days. Participants received either sham (n=13), 500 µA or 250 µA stimulation depending on individual dermal sensitivity. During tDCS patients solved a combined working memory and response inhibition paradigm (n-back/Go-Nogo). Pre, post and in a 3-months follow up EEG was recorded during the task and performance in transfer tasks of visuo-spatial working memory (span board task) and interference control (flanker task) was assessed. ADHD patients who received 500 µA tDCS showed no change in performance of the n-back/Go-Nogo task from pre to post tDCS. But amplitudes of P2, N2 and P3 were increased at frontal sites post tDCS during nogo trials compared to the sham group. Furthermore, accuracy in the flanker task was improved post tDCS. In contrast, patients who received 250 µA tDCS made more nogo commission errors post tDCS than patients who received sham stimulation. This effect occurred not in the first session, but started from the second tDCS session and increased throughout the course of the five-day stimulation. P3 was reduced at frontal sites and accuracy in the flanker task was reduced post tDCS. In both groups, effects of tDCS were not significant in the 3-month follow up. The increase of nogo related ERP amplitudes and enhanced flanker task accuracy indicates that consecutive tDCS sessions of the right IFG with 500 µA are suitable for modulating inhibitory processes. It is therefore a promising approach for inducing cognitive improvement in ADHD patients. This study demonstrated the outstanding importance of current intensity for the success of stimulation. Furthermore, it is remarkable that performance decline manifested only from the second tDCS session showing the importance of studies investigating of not only one but several applications of tDCS.

Title: Reduced sensitivity to auditory statistics in dyslexia is associated with a reversed activation pattern in the default mode network

Authors: *A. GERTSOVSKI, M. AHISSAR;
The Hebrew Univ. of Jerusalem, Jerusalem, Israel

Abstract: Developmental dyslexia is an impairment in the acquisition of expert reading skills. It is associated with a difficulty in efficient use of long-term statistics of both speech and simple sounds (the 'anchoring deficit' hypothesis; Ahissar et. al, 2006; Lieder et al., 2019), which can reduce load from online processing. We now asked how these deficits in utilizing sound statistics are manifested in the pattern of brain activity during performance of a 2-tone pitch discrimination task. We administered two conditions, with and without a fixed cross-trial reference tone, which differ in the advantage afforded by efficient utilization of tone repetition. For good readers the reference condition enables much better discrimination, whereas individuals with dyslexia do not use this regularity efficiently. Thus, to create equal levels of difficulty across conditions (for the good readers), the acoustic distance between the two tones was smaller in the reference condition. Adult participants with and without dyslexia (N=21,20) performed the task during fMRI scanning (protocol of Daikhin & Ahissar, 2015). As expected, good readers benefited more than individuals with dyslexia from stimulus repetition. This successful fast learning was associated with reduced activity in the primary auditory cortex, suggesting that repetition was detected there. No such reduction was observed in the primary auditory cortex of individuals with dyslexia. Importantly, individuals with dyslexia had higher activation in the reference compared with the no-reference condition in a network of higher-level cortical areas, including the inferior frontal gyrus, medial prefrontal cortex, posterior cingulate cortex, angular gyrus and middle temporal gyrus. This network is similar to the previously identified default mode network. Contrasting the conditions between the two groups, we found an opposite pattern of activation in the temporo-parietal areas of the network, and in the hippocampus, where individuals with dyslexia activated the high-level network more in the easier-by-regularity reference condition. We propose that controls' auditory-cortex based improved ability to utilize stimulus repetition allows them to perform the reference condition as a lower-level task compared to the no-reference condition, increasing their task signal to noise ratio. In contrast, for the dyslexia group the reference condition is substantially more difficult perceptually, hence it is noisier. This results in the two groups using different and even opposite strategies for the two task conditions. Surprisingly, this also determines the relative activation of the default mode network.

Title: Delayed neuronal outgrowth and alterations in synaptic proteins in cultured cortical neurons from attention deficit and hyperactivity disorder (ADHD) rat model

Authors: *D. M. MARQUES, A. S. ALMEIDA, C. B. ALVES, L. O. PORCIÚNCULA; Biochem., Federal Univ. of Rio Grande Do Sul, Porto Alegre, Brazil

Abstract: Attention deficit hyperactivity disorder (ADHD) is a heterogeneous and phenotypically complex neurobehavioral disorder with unknown etiology, characterized by symptoms of inattention, hyperactivity and impulsivity. Spontaneously hypertensive rats (SHR) are considered the most validated model for ADHD studies. However, cultured neurons from this animal model and alterations in synaptic proteins at neuronal level were not assessed yet. In this study, we sought to characterize neuronal course development of cortical neurons from SHR and whether these neurons could present alterations in synaptic proteins over time. Based on polymorphisms found in ADHD patients whose genes encode synaptosomal-associated protein 25 (SNAP-25), synaptophysin and brain-derived neurotrophic factor (BDNF), we also evaluated the immunocontent of these proteins in primary cortical neuron culture from SHR and Wistar-Kyoto rats (WKY, control strain). As revealed by MAP-2 staining, SHR neurons presented decreased maximal neurite length over days *in vitro* (DIV) ($n = 5$; $F_{(3, 12)} = 12.21$; $p = 0.0006$). Percentage of WKY neurons with zero branch points was different from 1 and 5 DIV and from 1 and 8 DIV within subjects ($n = 5$; $F_{(3, 24)} = 10.82$; $p = 0.0001$). SHR presented a lower percentage of neurons with one branch point at 2 DIV in relation to WKY ($n = 5$; $p < 0.05$). WKY presented different percentage of neurons with two branch points from 1 and 5 DIV, from 1 and 8 DIV and from 2 and 5 DIV within subjects ($n = 5$; $F_{(3, 24)} = 8.831$; $p = 0.0004$). Percentage of WKY neurons three branch points was different from 1 and 5 DIV and from 5 and 8 DIV within subjects ($n = 5$; $F_{(3, 24)} = 6.958$; $p = 0.0016$). Percentage of SHR neurons with zero and four branch points was different from 1 and 5 DIV within subjects ($n = 5$; $F_{(3, 24)} = 10.82$; $p = 0.0001$; $F_{(3, 24)} = 3.633$; $p = 0.0272$). Compared to WKY neurons, SHR neurons presented increased synaptophysin immunocontent at 1 DIV ($n = 6$; $p = 0.0313$), decreased both SNAP-25 at 5 DIV ($n = 8$; $p = 0.0078$) and CREB at 1 DIV ($n = 7$; $p = 0.0169$). While BDNF and phospho-TrkB and TrkB immunocontent were not altered over time, a trend towards decreasing proBDNF was detected at 5 DIV ($n = 7$; $p = 0.06$). Cortical neurons from both strains did not change their morphology after 24 h of BDNF treatment ($n = 6$). Altogether, our findings suggest that changes at protein level may be associated to the alterations in neuronal development of SHR neurons. These changes found in the neuronal outgrowth and dendritic arborization from ADHD model may contribute to understand the neurobiological basis of ADHD. Ethical committed CEUA/UFRGS (Proc. 29196).

Title: Sex differences in impulsivity, cognition, proteins involved in brain maturation and response to caffeine in a rat model of attention deficit and hyperactivity disorder (ADHD)

Authors: *A. S. ALMEIDA, F. NUNES, D. M. MARQUES, L. O. PORCIÚNCULA;
Biochem., Federal Univ. of Rio Grande Do Sul, Porto Alegre, Brazil

Abstract: Attention Deficit and Hyperactivity Disorder (ADHD) is a neurodevelopmental disorder characterized by hyperactivity, inattention and impulsivity, whose symptomatology varies according to sex. We aimed at investigating the influence of sex differences on behavioral outcomes and on proteins involved in brain maturation of Spontaneous Hypertensive Rats (SHR, the most validated rat model of ADHD). Our data revealed that infant SHR females showed recognition [$t = 1.733$; $p = 0.1138$, $n = 7$ litters] and olfactory [$t = 1.214$; $p = 0.2423$, $n = 7$ litters] memory impairment, when compared to control strain (Wistar Kyoto rats) and to their male counterparts. In the delay discounting task (a learning and impulse control task), adolescent SHR from both sexes required more sessions in order to complete the training phase, but females presented a worse performance [$F_{(1, 26)} = 28.42$; $p < 0.05$, $n = 4$ litters]. Impulsivity was observed in male SHR, which chose larger food rewards (to which they had to wait longer) less often than the smaller ones compared to the control strain [$F_{(1, 28)} = 7.622$; $p < 0.05$ $n = 4$ litters]. When we evaluated Growth Associated Protein 43 (GAP-43) and Sonic Hedhehog (SHH) immunocontent, SHH equally increased over time (from 8º to 22º postnatal day) in both strains and sexes in the hippocampus [$F_{(1,48)} = 19.50$; $p < 0.05$, $n = 7$ litters]. Although GAP-43 increased over time in the frontal cortex (FC) and in the olfactory bulb (OB), this increase was more pronounced in SHR from both sexes in FC [$F_{(1,48)} = 235.1$; $p < 0.05$, FC; $F_{(1,23)} = 4.527$; $P < 0,05$, OB. $n= 7$ litters]. Based on previous findings, caffeine has been able to improve cognitive and attention deficits in ADHD model, we also investigated the effects of caffeine in the delay discounting task. Our data revealed that both sexes of SHR treated with caffeine improved their performance in the task, as evidenced by the decrease in the number of sessions required to finish the training phase [$F_{(1, 22)} = 2,998$; $p = 0.09$, $n = 2$ litters]. Besides, an attenuation in the impulsivity was observed in male SHR treated with caffeine [$F_{(1, 25)} = 0,9252$; $p = 0.3453$, $n = 2$ litters]. Our findings revealed significant sex differences in ADHD model, with females presenting more cognitive deficits while male SHR showed evident signs of impulsivity. GAP-43 remained

increased over time in SHR frontal cortex, which might suggest impairments in neural networks. These data may contribute for better understanding of the neurobiological basis of ADHD**.** Moreover, caffeine was able to attenuate impulsivity, a characteristic symptom of ADHD, and thus such results extend its potential as an alternative for ADHD treatment. Ethical committed CEUA/UFRGS (Proc. nº29196).

Title: Methylphenidate ameliorates hyperlocomotion in CDKL5 deficient mice

Authors: *W.-L. LIAO[1,2], Y. LUO[1], C.-L. JHANG[1];
[1]Inst. of Neuroscience, Natl. Cheng-Chi Univ., Taipei, Taiwan; [2]Res. Ctr. for Mind, Brain and Learning, Natl. Cheng-Chi Univ., Taipei, Taiwan

Abstract: Cyclin-dependent kinase-like 5 (CDKL5), a serine-threonine kinase encoded by an X-linked gene, is highly expressed in mammalian forebrain. Mutations in this gene cause CDKL5 deficiency disorder (CDD), a neurodevelopmental encephalopathy characterized by early-onset seizures, motor dysfunction and intellectual disability. We previously found that mice lacking CDKL5 exhibit hyperlocomotion and increased impulsivity, resembling the core symptoms present in attention-deficit hyperactivity disorder (ADHD). The underlying neuronal mechanisms remain poorly understood. Here, we report that hyperlocomotion in *Cdkl5* null mice was recapitulated in mice carrying *Cdkl5* deletion selectively in dopaminergic neurons those express dopamine transporters (DAT). The phosphorylation of DAT and extracellular dopamine levels were altered in the striatum differently along the rostocaudal axis in hyperactive *Cdkl5* null mice. Moreover, administration of methylphenidate (MPH), a DAT inhibitor commonly used for treating ADHD, significantly alleviated hyperlocomotion in *Cdkl5* null mice. The behavioral effects of MPH were accompanied by region-specific normalization of phosphorylation of dopamine- and cAMP-regulated phosphoprotein Mr 32 kDa, a phosphoprotein enriched in the striatal neurons. Together, our findings uncover the CDKL5-mediated motor control through

region-specific regulation of dopamine transmission proteins that may serve as potential therapeutic targets to ameliorate the shared symptoms in CDD and ADHD.

Title: Decoding dyslexia: Early identification of reading impairment

Authors: ***L. A. GABEL**[1], E. JOHNSON[3], D. T. TRUONG[5], S. PANIAGUA[5], B. E. SHELTON[4], J.-L. HUNG[4], E. MURRAY[2], K. VOSS[2], O. GRIGAUX[2], M. SCHIAZZA[2], M. DENBLEYKER[2], W. DUNCAN[2], J. R. GRUEN[6];
[1]Psychology & Neurosci., [2]Neurosci., Lafayette Col., Easton, PA; [3]Special Educ., [4]Educational Technol., Boise State Univ., Boise, ID; [5]Pediatrics, Yale Univ., New Haven, CT; [6]Pediatrics & Genet., Yale Sch. of Med., New Haven, CT

Abstract: Reading disorder (RD, a.k.a. Dyslexia) is a specific learning disability affecting children across language orthographies, despite adequate intelligence and educational opportunity. If learning disabilities remain untreated, a child may experience long-term social and emotional problems, which may influence future success in all aspects of their lives. Early detection and intervention will help to close the gap between typically developing and reading impaired children in acquiring reading skills. Recently we demonstrated that animal models of dyslexia (i.e. genetic models based on candidate dyslexia susceptibility genes) and children with specific reading impairment show a common deficit on a virtual Hebb-Williams maze. In addition, we have demonstrated that this deficit is consistent across language orthographies (i.e. transparent and non-transparent languages). In this study we examined phonological awareness, genetic risk factors and virtual Hebb-Willimas maze performance in pre-school (4-5 years of age) and school-aged (5-6 years of age) children to determine if maze performance correlated with risk of future reading impairment. In addition, a subset of children were re-examined on maze performance and reading measures in second grade, in order to determine if their ability to complete the task was a strong predictor of future reading ability. Since virtual maze task does not require oral reporting (i.e. rapid access to phonological processing), or rely on text, performance is not influenced by a potential difference in reading experience between groups. Using computational modeling of students' actions using maze locations and latency values,

prediction results can be integrated into the test for real-time feedback of the performance in the form of at-risk percentages for reading. Initial computational modeling exceeded 80% accuracy in identifying known reading outcomes based on these predictors. New modeling techniques that include auto-encoding, a deep learning framework, holds promise for even higher identification successes. If performance on the maze task is a strong predictor of future reading ability, then the maze task may be effective in the early identification of children at risk for reading impairment.

Title: Chronic exposure to the psychostimulants Ritalin and Adderall during adolescence alters brainstructure and function

Authors: ***J. L. DEMAREE**[1], D. AGGARWAL[1], I. SENTHILKUMAR[1], C. LAWSON[1], X. CAI[2], P. P. KULKARNI[3], C. F. FERRIS[4];

Abstract: Attention Deficient Hyperactivity Disorder (ADHD), commonly diagnosed in children and adolescence, is routinely treated with the psychostimulants Ritalin and Adderall. It has been argued, ADHD is over diagnosed resulting in “normal” individuals being exposed to psychostimulants for prolonged periods of time during adolescence, a critical development period in brain maturation. This study used non-invasive multimodal magnetic resonance imaging (MRI) to examine the changes in brain structure and function in healthy rats following chronic exposure to d-amphetamine (Adderall ®) and methylphenidate (Ritalin®) during adolescence. On postnatal day 21 (PND 21), 30 male rats were divided into three groups of 10 animal each. At the same time each day, for three weeks, rats were given intraperitoneal injections of either saline vehicle, Ritalin (10mg/kg) or Adderall (5 mg/kg) assigned to one of the

three groups. At the cessation of treatment on PND 45, rats were imaged for changes in brain volumes, gray matter microarchitecture and function connectivity. Images were acquired using a 7.0T MRI scanner.The imaging modalities included T1 weighted voxel-based morphology, diffusion weighted imaging with quantitative anisotropy and resting state BOLD functional connectivity. All images for each modality were registered to a 3D MRI Rat Atlas with 171 segmented and annotated brain areas used to generate an unbiased computational analysis of all data. Changes in measures of anisotropy, often used in clinical studies to identify areas of potential inflammation or injury, were not significantly different between experimental groups. There were only 14/171 brain areas that showed a significant increase in brain volume between treatments and only in response to Ritalin. Interestingly, Ritalin's effect on brain volume was primarily localized to the cerebellum, particularly the deep cerebellar nuclei. These same cerebellar nuclei showed a significant increase in connectivity to the rest of the cerebellum and the brainstem that was not observed with vehicle or Adderall treatments. Ritalin treatment also showed a significant increase in functional connectivity across the midbrain dopaminergic system but not the anticipated connectivity between the prefrontal cortex and striatum. These data suggest a reorganization of neural circuitry around the brainstem/cerebellum and midbrain dopaminergic system in response to chronic exposure to psychostimulants during adolescence. Behavioral studies assessingchanges in cognition, motivation and emotion in these animals were ongoing at the time of this submission.

Abstract: Angelman syndrome (AS) is a neuro-developmental disorder caused by neuronal loss of E3 Ubiquitin ligase UBE3A leading to a plethora of severe intellectual disabilities. Although neuronal loss of UBE3A causes AS, there is a paucity of knowledge of downstream molecular and cellular dysfunction, ultimately hampering drug discovery. To this end, protein and RNA

expression profiling was performed on AS patient and healthy control human induced pluripotent stem cell (iPSC)-derived neurons. UBE3A and proteins and pathways were deregulated across patient lines. Using RNAi molecules, reducing UBE3A protein in control lines or restoring it in patient lines, by knocking down the sense or anti-sense transcript respectively, reciprocally modulated a subset of these proteins. This included a subset of LTR retrotransposon-derived genes containing GAG capsid domains. UBE3A formed a complex with these Gag proteins and regulated its ubiquitination to modulate proteosomal degradation. These proteins share similarities to retroviruses and by virtue of their expression in AS cells, modulate extracellular vesicle content and RNA granule assembly. Thus, we identify a novel proteins modulated by UBE3A and demonstrate their role in regulating extracellular vesicle content and RNA granules. This work is expected to ultimately lead to a better understanding of Angelman pathophysiology and potentially enable target engagement biomarker discovery for therapies currently under development for Angelman syndrome.

Abstract: Williams Syndrome (WS) is a genetic neurodevelopmental disorder with a wide spectrum of symptoms, including hypersociability. Although the disorder is known to be caused by 7q11.23 deletions, the molecular basis of phenotypic variability remains unclear. Thus, we systematically investigated the relationship between DNA methylation and WS phenotypes. Genome-wide DNA methylation analysis was performed using Illumina DNA methylation arrays with blood samples. WS-associated modules were identified at the systems level by weighted

gene co-methylation network analysis. DNA methylation profiles were validated by pyrosequencing and integrated with gene expression profiles. The effects of age on methylation of the most promising candidate gene were examined in 90 WS patients. Differential DNA methylation associated with WS was detected throughout the genome. Systems-level network analysis revealed that multiple co-methylation modules were significantly correlated with intermediate phenotypes of WS, with the top-scoring module linked to neurogenesis and development of the central nervous system. Notably, *ANKRD30B*, a promising hub gene, was found to be significantly hypermethylated in WS patients, regardless of age. Furthermore, potential master regulator transcription factors associated with WS, including *BCL11A*, were identified by the integration of methylome and transcriptome profiles. To our knowledge, this is the largest epigenetic study of WS, as assessed at the systems-level, providing a possible explanation for complex phenotypes among patients. Our findings could help to further understand not only WS but other neuropsychiatric disorders.

Title: Magnetic resonance assessment of learning deficiency induced by neonatal exposure to isoflurane

Authors: *D. P. AKSENOV, P. VENKATASUBRAMANIAN, C. DIXON, L. LI, M. MILLER, A. WYRWICZ;
NorthShore Univ. HealthSystem, Evanston, IL

Abstract: Each year approximately 6 million children in the USA alone undergo anesthesia in the course of surgeries, imaging and other diagnostic procedures. Multiple studies have indicated that early exposure to general anesthesia can affect neuronal development, leading to deficits in learning and memory. It was found, for example, that children who underwent anesthesia were more than twice as likely to exhibit behavioral/developmental deficits in young adulthood. Animal studies provide a more well-controlled analysis of anesthesia-related effects and allow for more precise comparisons between anesthetized subjects and controls. A variety of animal models have been used to study the effects of inhaled anesthetics and have revealed associations

between early anesthesia exposure and developmental pathologies including increased cell apoptosis, defects in myelination, hippocampal and cortical cell loss and disruption of associative learning in adult subjects. Changes in the brain associated with such impairments have not been directly characterized using MRI. Previously, we have used blood oxygen level dependent (BOLD) functional magnetic resonance imaging (fMRI) to examine the learning-related functional changes that occur during eyeblink classical conditioning (ECC) in awake rabbits. fMRI allowed us to evaluate the functional state of the sensory system before learning, and together with ECC provided a non-invasive, easily quantifiable approach for characterizing the impact of anesthesia on learning. Our findings demonstrated learning impairment fore trace ECC and changes in BOLD activation induced by the CS after training in anesthesia-exposed subjects. In this study we evaluated the effects of anesthesia exposure during infancy with and without supplemental oxygen using MR volumetry, spectroscopy (MRS), and diffusion tensor imaging (DTI) during young adulthood. Infant rabbits were exposed to isoflurane anesthesia using a common surgical protocol and then received training with a trace ECC paradigm at three months of age. MRI experiments were performed in adolescent rabbits to measure the BOLD response to the whisker vibration CS as well as the hippocampal volume before and after learning. The awake rabbit model allowed us to compare directly the results in anesthesia-exposed animals versus controls. MRS and DTI data were also acquired from anesthesia-exposed rabbits as well as controls during final stage of the experiments. Our MRI findings revealed a variety of significant changes in the brain associated with learning impairment on the trace ECC paradigm.

Title: Chronic metabolic effects of anesthesia on the developing brain

Authors: *P. N. VENKATASUBRAMANIAN, L. LI, A. M. WYRWICZ, D. P. AKSENOV; Ctr. for Basic MR Res., NorthShore Univ. HealthSystem, Evanston, IL

Abstract: Millions of children undergo general anesthesia each year and a growing body of literature suggests that exposure to anesthesia at an early age can impact neuronal development, leading to learning and memory impairments later in childhood. Although behavioural and structural effects of anesthesia exposure during infancy have been reported, long-term metabolic

effects of anesthesia have not been examined. In this study we have investigated metabolic changes in the dentate gyrus (DG) of rabbits exposed to volatile anesthetics when they were pups. Dutch-belted rabbits were anesthetized at postnatal days 8, 11, and 14. Kits were anesthetized with either sevoflurane (SVF) or isoflurane (ISF) in air or in 80% O_2. At 3 months of age, animals were given eyeblink classical conditioning. After the learning sessions, localized proton MR spectra were acquired from voxels located in the left and right DG of awake rabbits on a 9.4T imager. N-Acetyl aspartate (NAA), glutamate (Glu), glutamine (Gln), GABA, creatine/phosphocreatine (Cr/PCr), choline (Cho), taurine (Tau), and myo-Inositol (Ins) were seen in the DG. In the left DG of the *SVF+air* group, NAA, Glu+Gln, and GABA were significantly lower than controls. In the left DG of *SVF+O_2* group GABA and Tau were lower than controls. ISF treated groups did not show many differences from the control group, with only Ins being elevated in the left DG of *ISF+air* group. Metabolite levels in the right DG revealed a different pattern. The *SVF+O_2* group showed significant decreases in Glu and Cho, which were also significantly lower in the *SVF+air* group. In contrast, no significant changes in metabolite levels were detected in the *ISF+air* and *ISF+O_2* groups. MR spectroscopy of the DG showed differential effects of exposure to sevoflurane and isoflurane in rabbit pups nearly 4 months after anesthesia. Decreases in NAA, Glu+Gln, GABA and Tau in the pups exposed to SVF mixed with air or O_2 suggest that SVF has long-term effects on neurons, both excitatory and inhibitory neurotransmitters, and brain osmolyte. In contrast, ISF causes minimal long-term neuronal effects in the DG. Increases in Ins in the *ISF+air* group indicates glial metabolic effect of anesthesia. The difference in the metabolic patterns between left and right DG in anesthetic-exposed animals suggests that the effects of anesthesia might be modulated by behavioural training, with the side involved in learning showing changes in fewer metabolites. Exposure to volatile anesthetics in infancy has chronic adverse effects on the metabolism of the developing brain. SVF causes greater metabolic impairment than ISF. The metabolic effects of anesthesia may be modulated by behavioural training.

Title: Sex differences in blood-brain barrier permeability during lipopolysaccharide-induced sickness

Authors: *D. KOLMOGOROVA[1], E. AH-YEN[1], K. B. SMITH[2], B. C. TAYLOR[4], R. CHANDRASEGARAM[4], N. ISMAIL[3];
[2]Sch. of Psychology, [3]Dept. of Psychology, [1]Univ. of Ottawa, Ottawa, ON, Canada; [4]Cardiff Univ., Cardiff, United Kingdom

Abstract: Puberty is a critical period with extensive neurodevelopmental changes that render it vulnerable to immune challenges. In CD-1 mice, a peripheral immune challenge during the stress-sensitive period of puberty (i.e., 6 weeks of age) alters various brain processes and behaviours in a sex-specific manner. For example, six-week-old CD-1 mice show a female-biased increase in neuroinflammation and neuronal cell death during sickness induced by intraperitoneal (*ip*) lipopolysaccharide (LPS) exposure. However, the mechanisms underlying such sex differences in how peripheral immune events influence the central nervous system is unclear. One promising explanation lies in how systemic pathogens affect substance exchange at the blood-brain barrier (BBB) in males and females. This study examined sex differences in the effects of a systemic immune challenge on BBB permeability during puberty. Male and female CD-1 mice were treated with either LPS (1.5 mg/kg body weight, *ip*) or .9% sterile saline (LPS-matched volume, *ip*) at six weeks of age (i.e., stress-sensitive pubertal period). BBB disruption (whole brain) was measured using ^{14}C-sucrose (1 x 10^6 *dpm*) at 24 hours (i.e., during sickness) post-treatment. Regional differences in BBB permeability during sickness were also examined in the prefrontal cortex, hippocampus, hypothalamus, and the cerebellum. Treatment and sex differences in BBB permeability were assessed with a 2x2 analysis of variance. As expected, systemic LPS induced more sickness behaviours and body weight loss than saline treatment in all mice, with LPS-treated females showing a quicker symptomatic recovery than LPS-treated males (all $p < .05$). BBB disruption was present among females but not males treated systemically with LPS during puberty (all $p < .05$). Sex differences in BBB permeability were not observed among the saline-treated mice. These BBB-mediated sex differences during sickness may explain some sex differences in brain and behaviour outcomes of a systemic immune challenge during puberty.

Title: Enriching experiences during adolescence affect enrichment evoked activity in entorhinal cortex in late adolescence and early adulthood

Authors: *H. GODFREY, C. H. GODFREY, D. E. DRURY, D. D. WRIGHT, E. M. BUNCICK-ROAKES, M. C. ZRULL;
Appalachian State Univ., Boone, NC

Abstract: Environmental enrichment (EE) provides opportunity for stimulation with and learning about spatial, object, and social cues within some environment and can have both immediate and lasting impact on brain structures and circuits. With its role in processing spatial information, we examined neural activity in medial and lateral entorhinal cortex (MEC, LEC) neurons evoked by a single enriching experience in rats with and without a history of EE during adolescence (EE+EE, No+EE, respectively) in two experiments. Control groups with and without EE history did not have a final EE experience (EE+No, No+No), and EE+EE and EE+No groups of Long-Evans rats experienced periodic EE sessions through adolescence in both experiments. For Experiment 1 (groups of 5), EE+EE and No+EE rats experienced a final EE session immediately following periodic EE on postnatal day (pnd) 49 and were then sacrificed; however, for Experiment 2 (groups of 7), the final EE session for EE+EE and No+EE occurred about 20 days after periodic EE ended. Periodic and final EE sessions occurred in the same environment but objects, object locations, and rats varied session-to-session. In both experiments, controls were sacrificed on the same schedule as evoked activity rats, and neural activity was quantified using tissue processed for c-FOS and digital light microscopy with stereological techniques. Experiment 1 provided insight about the immediate effects of an EE history, and Experiment 2 showed persisting effects of EE history. When the final EE session was novel (No+EE), superficial MEC (sMEC) exhibited more c-FOS+ neurons than for all other groups (EE+EE, EE+No, No+No) tested at pnd 49 (+334%, $p<.030$) and at pnd 75 (+382%, $p<.001$) suggesting enhanced neural activity reflecting novelty of the EE space for only the No+EE rats. In contrast, deep MEC (dMEC) and superficial and deep LEC (sLEC, dLEC) of EE+EE and No+EE rats showed more c-FOS+ neurons than rats not experiencing a final EE session at pnd 49 (dMEC, +215%, $p<.001$; sLEC, +89%, $p<.002$; dLEC, +272%, $p<.001$) and pnd 75 (dMEC, +200%, $p<.001$; sLEC, +119%, $p<.010$; dLEC, +142%, $p<.003$) suggesting enhanced neural activity evoked by being in a novel or familiar space with new or newly located objects. Our results support the idea that MEC neurons represent information about global cues or the overall spatial scene of an organism's environment, and LEC neurons respond to more local cues within a space or, perhaps, what is where in an environment. Further, enriching experiences during adolescence seem to influence, at least to some degree, how MEC and LEC neurons respond to some aspects of novelty at least until early adulthood.

Title: Constant innervation despite pubertal growth of the mouse constant innervation despite pubertal growth of the mouse constant innervation despite pubertal growth of the mouse penis

Authors: *L. PURKART, J. SIGL-GLÖCKNER, M. BRECHT;
Bernstein Ctr. for Computat. Neurroscience, Humboldt-Universität Zu Berlin, Berlin, Germany

Abstract: It has long been recognized that the sexual characteristics of the vertebrate body change under the control of sex hormones (Berthold, 1849). Hence, in mammals the genitals undergo major changes in puberty. While such bodily changes have been well documented, the associated changes in the nervous system are still poorly understood. To address this issue we studied the growth and innervation of the mouse penis throughout puberty. To this end we measured length and thickness of the mouse penis in prepubertal (P21) and adult (P56-77) mice and performed fiber counts of the dorsal penile nerve. We obtained dorsal penile nerve fiber counts by confocal microscopy of thin proximal sections of the mouse penis after paraffin embedding, antibody staining with antibody Neurofilament H in combination with antigen retrieval procedures. We find that the mouse penis grows roughly 1,4 times in both, thickness and length. Fiber counts in the dorsal penile nerve were not different in prepubertal (1596 ± 188 fibers per penis) and adult (1569 ± 384 fibers per penis) mice, however. The number of nerve fibers on the left and right side of the penis was bilaterally symmetric. The constant innervation of mouse penis through puberty suggests that changes in central representation of the rodent penis (Lauer, Lenschow, & Brecht, 2017; Lenschow, Sigl-Glöckner, & Brecht, 2017) are probably not simply a reflection of peripheral change.

Title: Treatment with the PDE9 inhibitor BI409306 during adolescence mitigates social interaction and dopaminergic deficits in adult offspring of the poly(I:C) based maternal immune activation neurodevelopmental mouse model

Authors: J. RICETTO[1], J. SCARBOROUGH[1], R. ARBAN[2], ***C. DORNER-CIOSSEK**[2], H. ROSENBROCK[2], U. MEYER[1];
[1]Inst. of Pharmacol. and Toxicology, Univ. of Zurich-Vetsuisse, Zurich, Switzerland; [2]CNS-DR, Boehringer Ingelheim Pharma GmbH & Co KG, Biberach an der Riss, Germany

Abstract: Rodent models of maternal immune activation (MIA) are used to study neurodevelopmental disorders such as schizophrenia by analyzing the neuronal and behavioral dysfunctions of the offspring. Injection of the viral mimic poly(I:C) in pregnant mice causes disruption of neuronal development of the offspring leading in adulthood in particular to deficits in social behavior and the dopaminergic system. BI 409306 is a selective phosphodiesterase-9 (PDE9) inhibitor [1] currently investigated for intervention in patients with Attenuated Psychosis Syndrome (APS) (NCT03230097). PDE9 inhibition is hypothesized to improve the NMDA-receptor signaling cascade by increasing cGMP levels which subsequently leads to strengthening of synaptic plasticity. Abnormalities in the excitatory/inhibitory network related to NMDA-receptor hypofunction at adolescent age, along with dopaminergic dysfunction, are hypothesized to occur in individuals with APS. In this study, we have investigated the effect of BI 409306 administered during adolescent age on the behavioral deficits of the adult offspring from the poly(I:C)-based MIA mouse model. Pregnant C57BL6/N mice were treated with poly(I:C) (5 mg/kg, i.v.) or control (saline, i.v.) solution on gestation day 12. All offspring (n=21-22/group) were administered orally once daily with BI 409306 (1 mg/kg) or vehicle starting at post-natal day (PND) 30 for 4 weeks or until subjected to a battery of consecutive behavioral tests social interaction to assess social behavior, pre-pulse inhibition (PPI) for sensorimotor processing and amphetamine-induced hyperlocomotion to assess the dopaminergic system at PND 72-114. Statistical analyses used one-way ANOVA followed by Fisher's LSD post-hoc. Maternal poly(I:C)-induced immune challenge led to a significant decrease in social interaction ($p<0.01$) in the adolescent and adult offspring, and to a significant potentiation of amphetamine-induced hyperlocomotion at adulthood. PPI was not affected. Treatment with BI 409306 during adolescence significantly mitigated the social interaction deficits ($p<0.005$) and amphetamine hyper-responsiveness ($p<0.05$) at adult age of the offspring. Plasma exposure of BI 409306 determined in satellite mice was in the range as expected for the doses used in the clinical trial.

For the first time, we could show that treatment with the PDE9 inhibitor BI 409306 during adolescence offsets social behavior and dopaminergic deficits observed in adult offspring in this model. Therefore, our findings support the test of BI 409306 for early intervention in patients with APS. [1] Moschetti et al. (2017), Br. J. Clin. Pharmacol., 82(5):1315-1324.

Title: Dosage sensitivity intolerance of VIPR2 duplication is causative in manifestation of schizophrenia-like striatal dopamine abnormality, cognitive, social, and developmental deficits in a novel bacterial artificial chromosome transgenic mouse model

Authors: *X. TIAN[1], M. REN[1], A. D. RICHARD[1], M. ELSAADI[1], D. S. DWYER[2], R. L. KLEIN[1], N. E. GOEDERS[1], X. W. YANG[3], X.-H. LU[1];
[1]Dept. of Pharmacology, Toxicology & Neurosci., [2]Psychiatry, Louisiana State Univ. Hlth. Sci. Ctr., Shreveport, LA; [3]Dept Psych, UCLA, Los Angeles, CA

Abstract: Recent genome-wide association studies (GWAS) have identified copy number variations (CNVs) at chromosomal locus 7q36.3 that significantly contribute to the risk of schizophrenia, with all of the microduplications occurring within a single gene: Vasoactive intestinal peptide receptor 2 (VIPR2). To confirm disease causality and translate such a genetic vulnerability into mechanistic and pathophysiological insights, we have developed a series of conditional VIPR2 Bacterial Artificial Chromosome (BAC) transgenic mouse models of VIPR2 CNV with one extra copy (microduplication) or four extra copies of human VIPR2, and one fully

humanized model in the murine Vipr2 null background. The conditional design of the BAC allows switching-off the transgene expression in desired spatiotemporal patterns, thus facilitating the dissection of the inflicted neurocircuits. VIPR2 CNV mouse model recapitulates gene expression and signaling deficits seen in human CNV carriers. VIPR2 duplication in mice elicits prominent dorsal striatal dopamine dysfunction, consistent with recent human neuroimaging reporting dopamine abnormalities in schizophrenia are the greatest within dorsal striatum. VIPR2 CNV mice manifest cognitive, sensorimotor gating and social behavioral deficits preceded by an increase of striatal cAMP/PKA signaling and the disrupted early postnatal striatal development. Genetic removal of VIPR2 transgene expression via crossing with Drd1a-Cre BAC transgenic mice rescued the dopamine dysfunction and multiple behavioral deficits, implicating a pathogenic role of VPAC2 overexpression in dopaminoceptive neurons. Thus, our results provide further evidence to support the GWAS studies that the dosage sensitivity intolerance of VIPR2 is causative in the manifestation of schizophrenia-like dopamine, cognitive, and social behavioral deficits. The conditional BAC transgenesis offers a novel strategy to model CNVs with a gain-of -copies and facilitate the genetic dissection of when/where/how the genetic vulnerabilities affect development, structure, and function of neural circuits. Our findings have important implications for therapeutic development, and the etiology-relevant mouse model provides a useful preclinical platform for drug discovery.

Title: Feminized digit ratios in androgen insensitive rats

Authors: *V. DI RITA, S. M. BREEDLOVE, C. L. JORDAN;
Neurosci. Program, Michigan State Univ., East Lansing, MI

Abstract: The ratio of the length of the second digit to the fourth digit (2D:4D) is often used as a statistical indicator of prenatal androgen exposure in both human and non-human subjects. The ratio is sexually dimorphic in humans beginning before birth; males - on average - have lower ratios than females. Additionally, masculinized ratios have been identified in both men and women with congenital adrenal hyperplasia (CAH), in self-identified “butch” lesbians, and in male and female rats whose mothers received testosterone enhancements during gestation. Prior to this study, the 2D:4D had not been investigated in the testicular feminized (Tfm) rat, which expresses a dysfunctional androgen receptor (AR) gene on the X chromosome, giving rise to a

female external phenotype in XY rats. Because testosterone plays essentially no role in the development of these animals in utero, they offer a unique model to study the relationship between fetal testosterone and 2D:4D. We hypothesized that male Sprague Dawley Tfm rats would show feminine digit ratios compared to their wildtype (wt) brothers. Examining the hind paws of 21 male Tfm rats and 13 wt male rats at six weeks of age revealed a more feminine (larger) 2D:4D in the Tfm group, with an average ratio of 0.997 (SEM = 0.010) in the right hind paw, compared to male wt rats which showed an average 2D:4D of 0.951 (SEM = 0.014) in the right hind paw ($p = 0.01$, $d' = 0.95$). We did not find a significant difference between the mean digit ratios of wt male and female (N =13) rats, perhaps due to greater variance among females. Nevertheless, the more feminine digit ratio in Tfm males compared to males with a wt AR demonstrates that androgen activity plays a role in the development masculine digit ratios in rats, as has been shown in mice with limb AR deletions. Our study supports the theory that 2D:4D is inversely related to prenatal androgen stimulation in both human and non-human animals, validating efforts to link statistical trends in human behavior to digit ratios as a proxy of prenatal hormone influence.

Title: The effects of an adenosine A(2a) agonist on the rewarding associative properties of nicotine and neural plasticity in a rodent model of schizophrenia

Authors: *W. D. GILL, H. W. SHELTON, K. C. BURGESS, R. W. BROWN;
Dept. of Biomed. Sci., East Tennessee State Univ., Johnson City, TN

Abstract: A neurobiological hallmark of schizophrenia (SZ) is increased dopamine D_2 receptor sensitivity. Additionally, nicotine abuse is greatly increased in individuals diagnosed with SZ compared to the normal population. The adenosine system has been identified as a potential novel target for both SZ treatment and nicotine abuse, because adenosine A_{2a} receptors form a heteromeric complex with dopamine D_2 receptors that is mutually inhibitory. This relationship means each receptor exhibits lower sensitivity to its agonist after the opposing receptor agonist is bound, thus, adenosine A_{2a} agonists have been suggested to treat both psychosis and nicotine abuse. This study investigated the efficacy of an adenosine A_{2a} agonist, CGS 21680, in alleviating the rewarding aspects of nicotine in the neonatal quinpirole rodent model of SZ. Rats

were treated neonatally from postnatal (P)day 1 through 21 with the dopamine D_2/D_3 agonist quinpirole, raised to P41, and tested on conditioned place preference (CPP). Rats were conditioned to saline or nicotine (0.6 mg/kg base) from P43-51. Groups receiving CGS 21680 (0.03 or 0.09 mg/kg) were given the agonist 15 min before nicotine was administered. A drug-free post-conditioning test was administered on P52 to determine preference. The following day, brain tissue was analyzed for brain-derived neurotrophic factor (BDNF) and glial cell-lined neurotrophic factor (GDNF). Results revealed that neonatal quinpirole enhanced nicotine CPP, replicating previous work, and both doses of CGS 21680 alleviated this enhancement. Nicotine resulted in a CPP in controls, and both doses of CGS 21680 also alleviated this preference. BDNF analyses in the nucleus accumbens (Nacc) revealed that CGS 21680 alleviated the enhancement in Nacc BDNF in neonatal quinpirole-treated animals, and eliminated the increase in Nacc BDNF produced by nicotine in controls, much like CPP results. GDNF analyses revealed that neonatal quinpirole animals conditioned to nicotine resulted in an increase of GDNF in the NAacc, but this was eliminated by CGS 21680. This project revealed that an adenosine agonist with antispsychotic properties may have utility towards decreasing the rewarding aspects of nicotine and its accompanying neural plasticity changes in a model of SZ.

Title: The effect of early-life fluoxetine administration on binge eating behavior in adulthood in male and female rats

Authors: *A. L. CASTRO[1], Y. TREESUKOSOL[2];
[2]Dept. of Psychology, [1]California State Univ. Long Beach, Long Beach, CA

Abstract: Fluoxetine (Prozac), a selective serotonin reuptake inhibitor (SSRI) is a commonly prescribed antidepressant for adolescents. Recommendations for adolescent-use are based on findings from data collected from adult samples which raises the question of how SSRIs affect the developing brain. Fluoxetine administration in adolescent rats has been shown to affect responses to reward and aversive stimuli in adulthood (Iñiguez et al., 2010). In the current study,

male and female rats (n=46) were treated daily (i.p.) with 20 mg/kg fluoxetine (FLX) or saline (control) during adolescence (postnatal day PND 35-49). In adulthood (from PND 72) rats were exposed to a binge access eating paradigm twice a week for six consecutive weeks. Each session began with 23-h food restriction followed by a 30-minute presentation of chow (3.43 kcal/g) and sweetened fat (8.6 kcal/g). This experimental design allows us to ask whether fluoxetine treatment in early life will lead to increased response to sweetened fat compared to controls. Here, FLX and control rats did not significantly differ in preference for sweetened fat versus chow or total caloric intake across the test session. Whereas juvenile fluoxetine administration results in enduring changes in mood-related measures, here, no long-term changes in preference for a palatable stimulus are observed. Both males and females preferred sweetened fat during the first 2 sessions but whereas females maintained this preference, preference in male rats decreased over time thus providing evidence for sex differences.

Title: Investigation of GLuR1 and GLuR2 AMPA receptor subtype distribution in the hippocampus of long evans rats during a sensitive developmental period

Authors: *N. TZAKIS, M. R. HOLAHAN;
Neurosci., Carleton Univ., Ottawa, ON, Canada

Abstract: Understanding the development of spatial memory abilities requires insight about the development of cellular underpinnings that mediate the transition from juvenile-like to adult-like spatial processing capabilities. We reported that the hippocampus shows morphological adjustments from postnatal days 18 - 24 (p18 - p24) that predicted the emergence of spatial memory function. Examination of axonal and dendritic processes (structural changes) and c-Fos labeling (functional changes) in the hippocampus revealed improved connectivity patterns and developmentally-dependent increases in c-Fos positive cells that predicted the emergence of spatial behavior. From this, we hypothesized that p16 - p24 (pre-adolescent) represented a sensitive period for hippocampal development and modification. The effect of AMPAr blockade during this time revealed an important role of AMPA receptor-mediated function in the organization and long-term storage of spatial memories acquired during the juvenile period. AMPAr are made up of 4 subunits, of which GluR1 and GluR2 have been shown to play the

most prominent role in cognitive processes. While their function in adults has been well documented, their developmental expression in juveniles is less understood. To study this, Western blotting and immunohistochemistry were performed on the hippocampus in preadolescent rats (P18-30) and compared to postadolescent rats (P50) to determine the quantitative and cellular distribution of GluR1 and GluR2 through development. Western blot results showed that both GluR1 and GluR2 expression peaked during late hippocampal modification then reached adult levels after P30. Immunohistochemical staining of the GluR1 subunit showed a pattern of cellular labeling that peaked in the CA3 and dentate gyrus at p20 and declined thereafter. Further studies will be carried out to determine if these cells are immature neurons or interneurons. Within all hippocampal regions, immunohistochemical localization of GluR2 stained cells remained constant. These results indicate that this period of hippocampal modification is a crucial transitionary period, whereby the cellular processes that mediate spatial memory capabilities shift from juvenile- to adult-like.

Title: Stress in adolescence enhances the use of dorsolateral striatum-dependent habit learning in adulthood

Authors: *T. M. GADBERRY, C. A. BOLANOS-GUZMAN, M. G. PACKARD; Psychological and Brain Sci., Texas A&M Univ., College Station, TX

Abstract: Previous research indicates that anxiety and stress can influence the relative use of hippocampal-dependent cognitive and dorsolateral striatal-dependent habit memory systems. Specifically, stress/anxiety biases both lower animals and humans towards the use of habit memory. These results have been observed primarily in adult organisms. Early life stress in humans has been associated with predisposition to various psychopathologies that involve the development and expression of maladaptive habitual behaviors (e.g. OCD, addiction, PTSD). However, the effect of early life stress during adolescence on the later use of DLS-dependent habit memory in adulthood has not been extensively investigated. Accordingly, in the present study adolescent male Long-Evans rats were injected with either 5mg/kg corticosterone (CORT) or sesame oil vehicle (VEH) once daily for 5 days beginning PND 37(±4) and then allowed to mature into adulthood (>PND 60) undisturbed. Subjects were then trained over 7 days (6 trials/day) in a single-solution water plus-maze task that requires the use of DLS-dependent response learning. In this task, rats were released from different starting positions (i.e. north or

south) and were required to make a consistently reinforced body turn response (i.e. always turn right) at the maze choice point to mount a hidden escape platform. Relative to VEH-subjects, adolescent animals injected with CORT were significantly enhanced in the later acquisition of response learning in the plus-maze during adulthood. These findings suggest that activation of stress pathways in adolescence may have a long-term effect on the use of memory systems in adulthood. The present findings suggest that an enhancing effect on habit memory functions may potentially be part of the mechanism by which early life stress influences later habitual behavior.

Title: Age-dependent voluntary ethanol consumption and escalation in a rat model using alcohol vapor self-administration

Authors: *M.-L. RISHER[1,2], H. G. SEXTON[1];
[1]Joan C. Edwards Sch. of Medicine, Marshall Univ., Huntington, WV; [2]Duke Univ. Med. Ctr., Durham, NC

Abstract: Introduction: Binge drinking typically begins in adolescence and is associated with increased risk of developing an alcohol use disorder later in life. The adolescent alcohol research field models binge drinking using number of rat involuntary ethanol (EtOH) administration techniques. However, these methods not provide an opportunity to assess self-initiated EtOH consumption, subsequent escalation, and dependence. Rat self-administration models typically use methods such as sucrose fading to mask the aversive taste of EtOH, however very few result in binge-level consumption within the adolescent timeframe. To address this, we used nose-poke initiated, EtOH inhalation vapor chambers to elucidate how age influences voluntary consumption and escalation. Methods: Adult (PND70) and adolescent (PND30) male Sprague Dawley rats were placed in the vapor chambers every other day for 30 sessions and had the choice of water (H2O) and/or ethanol (EtOH) vapor for 8 HR/day. Blood alcohol levels and general signs of withdrawal were assessed. Anxiety was assessed in the light/dark box after the final EtOH exposure. Results: Across the first 3 sessions, adolescent rats showed equal preference for H2O and EtOH. Throughout the following sessions, adolescent rats showed repeated, self-initiated escalation and de-escalation of EtOH consumption, indicative of binge-

like drinking behavior followed by bouts of withdrawal. Adult rats demonstrated a 70% preference for H2O across the first 4 sessions. Beginning on session 5, adult rats showed a gradual escalation in EtOH preference, plateauing at 70% EtOH preference. Data from the following 20 sessions, impulsivity, anxiety, and withdrawal will also be presented. Conclusion: These data demonstrate that by eliminating the aversive taste of ethanol, adolescent and adult male Sprague Dawely rats will self-administer ethanol. Adolescent rats demonstrate bouts of heavy drinking that may be reminiscent of drinking patterns commonly observed in adolescent and college-age students. Adult rats demonstrate a slower initiation of EtOH consumption and progressive escalation. Ongoing work will continue to dissect the nuances of age-dependent patterns of EtOH consumption and consequences on brain function.

Title: Galantamine prevents adolescent binge ethanol-induced loss of cholinergic neurons, neuroimmune activation, and epigenetic modifications in the adult basal forebrain

Authors: *R. P. VETRENO, F. T. CREWS;
Dept. of Psychiatry, Univ. of North Carolina at Chapel Hill, Chapel Hill, NC

Abstract: Binge drinking and alcohol abuse are common during adolescence, and cause lasting cholinergic pathology. Using the preclinical adolescent intermittent ethanol (AIE; 5.0 g/kg, i.g., 2-day on/2-day off from postnatal day [P]25 to P55) model of human adolescent binge drinking, we tested the hypothesis that treatment with the acetylcholinesterase inhibitor galantamine (4.0 mg/kg, i.p. 30-min prior to each EtOH administration) would prevent AIE-induced cholinergic pathology. We report that galantamine treatment from P25-P55 prevented the loss of cholinergic neuron markers (i.e., ChAT, TrkA, and NGFR) and cholinergic neuron shrinkage in the adult (P70) basal forebrain. Recent studies from our laboratory link AIE-induced neuroimmune activation and epigenetic histone methylation modifications to the persistent cholinergic pathology. In the present study, we found increased expression of the proinflammatory nuclear

transcription factor pNF-kB p65 in the adult AIE-treated basal forebrain, which colocalized with ChAT+IR cells, an effect that was prevented in galantamine-treated AIE animals. Further, AIE is associated with increased histone 3 lysine 9 dimethylation (H3K9me2) and trimethylation in the adult basal forebrain, which was prevented with galantamine treatment. Together, these data suggest AIE-induced neuroimmune and epigenetic mechanisms may contribute to the loss of cholinergic neurons in the adult basal forebrain. Galantamine prevention of the persistent AIE-induced loss of cholinergic neurons is a novel therapeutic intervention to ameliorate the persistent adolescent binge ethanol-induced cholinergic pathology. Title: Effects of WIN 55,212-2 on inhibitory control in adolescent mice

Authors: A. LAUER, ***T. K. LAFFERTY**, R. HALE;
Shippensburg Univ., Shippensburg, PA

Abstract: The purpose of this research was to examine the effect of the synthetic cannabinoid receptor agonist WIN 55,212-2 (WIN) exposure during adolescence on the development of inhibitory control among mice (*Mus musculus*). A total of 40 CD-1 IGS outbred mice were included in the study. Mice in the experimental group received a solution containing 3 mg of WIN per kg of body weight through subcutaneous injection each day, from postnatal day 30 to postnatal day 50. Mice in the control group received a saline solution of a comparable volume. Mice in both the experimental and control conditions were examined on the detour paradigm of animal cognition starting at postnatal day 70. The results revealed a significant difference in weight between groups, with those exposed to WIN weighing less than the control group. On the detour paradigm, the group exposed to WIN performed significantly worse on the habituation phase of the paradigm. During testing of the paradigm, no significant differences were noted between groups on either measures of latency and perseveration. However, significant differences in body weight were present which suggests appropriate dosage techniques.

Title: The behavioural effects of early adolescent lipopolysaccharide administration on adolescent and adult male and female rats

Authors: *I. BISHNOI, M. KAVALIERS, K.-P. OSSENKOPP;
Psychology, Western Univ., London, ON, Canada

Abstract: There is accumulating evidence for sex differences in the behavioural, physiological, and immunological effects of infection. Lipopolysaccharide (LPS), a cell wall component of Gram-negative bacteria, has been effectively used to examine these differences. Generally, males are more susceptible to infection than females. However, age-related changes are a contributing factor to the sex differences. As such, it is important to examine sex differences in the susceptibility to infection within the context of various developmental periods. A number of rodent studies have found several behavioural effects upon prenatal and neonatal administration of LPS, particularly in males. Yet, there have been limited investigations of: (1) the impact of adolescent infection, (2) the long-term effects in later adolescence compared to adulthood, and (3) whether or not there are sex differences in these long-term effects. The present exploratory study was designed to examine sex differences in the long-term behavioural effects of LPS measured in late adolescence and adulthood following early adolescent LPS exposure. Thus far, a standard sample size of eight male Charles River rats were assigned to each of the LPS (0.2 mg/kg dissolved in 0.9% NaCl) and vehicle control (0.9% NaCl) groups. The rats received early adolescent intraperitoneal injections on postnatal days 30 and 32. After a five-day washout period, (1) general locomotor activity; (2) anxiety; (3) social behavior; (4) memory; (5) acoustic startle response (ASR); and (6) sensorimotor gating were examined in late adolescence and adulthood. The behavioural tasks were organized from least to most stressful and a single day gap between each task was used to buffer against the stressful effects of the previous behavioural task(s). Physiological tolerance to LPS was established. Early adolescent LPS administration increased locomotor activity in adolescence, decreased anxiety and social initiations in adolescence and adulthood, and had no significant effects on memory, ASR, and sensorimotor gating in male rats. Upon completion of this project through early adolescent LPS exposure in female rats, variations in age and sex will be accounted for to better our understanding of differences in the behavioural effects of LPS in late adolescence and adulthood.

Abstract: In humans, obesity is one of the most important health problems due to its considerable increase and tends to remain from childhood to adulthood, producing alterations in metabolism, mainly carbohydrates. Diet rich in carbohydrates, induces endocrine disorders and metabolic syndrome. For instance, leptin levels increase with sucrose consumption in rats and are inversely correlated with testosterone levels. In contrast, increase of lactate levels favors increase of testosterone, this has been poorly studied in reproduction. Obese animals present a deterioration of sexual behavior associated with infertility. It has been described that the pubococcygeus muscle (Pcm) participates in sexual function. In male rats, Pcm participates in micturition and ejaculation. This muscle has a heterogeneous proportion of slow oxidative fibers (type I), rapid oxidative-glycolytic (type IIa/d) and rapid glycolytic (type IIb) fibers. It has been shown that androgens affect muscle weight, muscle fibers size and cross-sectional area of their fibers. These morphological changes correlate with an increase in speed of contraction of the muscle fibers. Moreover, it has been said that this muscle can change its metabolism, since it stores a large amount of testosterone-dependent glycogen. In the present study we explore sugared water consumption effect in early age animals concerning morphological changes through basic ATPase and NADH-TR techniques, and also determine expression of LDH in male rats Pcm. Wistar rats of 21 days-old were divided into 2 experimental groups: Control and experimental (S30). The S30 animals showed an increase in glycolytic fibers but a decrease the oxidative fibers, associated with an increase in leptin levels without affecting testosterone concentration. In addition, they showed a higher expression of LDH. A sucrose rich diet, at young age, has a greater impact on the Pcm, affecting the number of both oxidative and glycolytic fibers. This, may have an impact on male sexual behavior.

Title: Gestational diabetes mellitus results in cerebral vascular remodeling in the developing brain of offspring

Authors: T. ROGERS, Q. LIU, K. RARICK, *S. S. COHEN;
Med. Col. of Wisconsin, Milwaukee, WI

Abstract: Background Diabetes mellitus during pregnancy (GDM) results in fetal exposure to hyperglycemia and a subsequent relative hypoxia. The cerebral cortex undergoes vascular remodeling to support neuronal function in response to hypoxia. There appear to be two major pathways by which brain angiogenesis occurs: hypoxia-inducible factor-1α (HIF-1α) dependent upregulation of vascular endothelial growth factor (VEGF) and a HIF-1α independent process with upregulation of angiopoietin (Ang)-1 and 2 and tyrosine-protein kinase receptor (TIE)-2. **Objective** To investigate the cortical vascular development in offspring of GDM mothers at infancy and adolescence and measure key proteins that regulate brain angiogenesis. **Design/Methods** Sprague Dawley rats were injected with citrate buffer or streptozotocin (STZ) to induce GDM on gestational day 14. Subsequent maternal glucose was monitored to maintain serum glucose of diabetic rats within 200-400 mg/dl resulting in offspring exposed to hyperglycemic or control conditions. All pups were naturally born and raised by control foster dams. Offspring were sacrificed at postnatal day (P)1 (infancy) and 21 (adolescence). Cerebral cortexes were collected for histology and protein quantification. Frozen sections were processed with lectin to evaluate cerebral vasculature. Protein expression of HIF-1α, VEGF, Ang-1, Ang-2, TIE-2 proteins were measured by Western blot in cortical tissue lysates. Results were compared using student's T-test with significance set at $p < 0.05$. **Results** GDM-exposed offspring rats had higher quantified number of vessels within the cerebral cortex, smaller average size of visualized vessels, yet equivalent total area of vessels compared to controls at P1 (n=1 slide per 8 litters, $p<0.05$). GDM-exposed offspring rats had less number of vessels within the cortex, comparable average size of visualized vessels, and smaller total area of vessels compared to the controls at P21 (n=1 slide per 3 litters, $p<0.05$). Western blot results from P1 show no significant difference in HIF-1α dependent or independent pathway proteins for angiogenesis, but at P21 there were significant decreases in HIF-1α and VEGF protein levels in whole cell lysate from cerebral

cortex (n=8, per age, p<0.05). **Conclusions** This study is among the first to demonstrate that GDM can affect the cortical vascular development of the developing infant brain and suggests that alterations in angiogenesis may persist into adolescence. It also demonstrated these changes are associated with decrease of key angiogenic proteins at adolescence.

Informatics and Clin. Epidemiology, Oregon Hlth. & Sci. Univ., Portland, OR

Abstract: Studies investigating the drastic social, emotional, hormonal and neural changes during adolescence are crucial to understand the emergence of psychopathology during this developmental phase. Increases in pubertal hormones may be responsible for neural remodeling and maturation during adolescence, including reports of increased amygdala (AMY) activity and changes in its connectivity with the prefrontal cortex (PFC). The goal of this study was to investigate changes in emotional responses toward stressors from pre- to peri-puberty, and underlying changes in PFC-AMY circuitry in a translational non-human primate model.Data were collected from 3 male macaques during pre-puberty (~24 months) and early adolescence (~32 months). Testicular volume was used to establish pubertal stage, while the Human Intruder Task (HIT) was used as an acute stressor to measure emotional reactivity. Structural and resting-state functional MRI (rsfMRI) scans were acquired at both ages using a 3T MRI scanner to examine developmental changes in functional connectivity (FC) between AMY and medial PFC across pubertal stage. We hypothesized that pubertal status would be associated with the

developmental changes in emotional reactivity and in underlying PFC-AMY FC.Testicular volumes increased from pre- to peri-puberty, but the magnitude of increase showed high individual variability. The results showed that increased testicular volumes from pre- to peri-puberty were associated with (1) enhanced fear (freezing) and declined hostile behaviors, and (2) increased FC between medial PFC and AMY and between right and left AMY. Thus, despite individual variability in behavioral reactivity and PFC-AMY FC at each age, pubertal status seemed to better account for the individual differences than chronological age. As our sample size increases with the addition of a second cohort of 7 animals, and more longitudinal timepoints are collected from peri-puberty to adulthood, stronger statistical power will allow to formally test the effect of pubertal maturation on emotional regulation and neural development. We expect that as neural circuits critical for emotional and stress regulation (PFC-AMY) become more mature and show stronger connectivity during late adolescence, behavioral reactivity (e.g. freezing) will be reduced due to top-down modulation of AMY reactivity by the PFC. To further understand the role of pubertal stage on stress reactivity and emotion regulation, future studies will also examine the relationship between gonadal hormone concentration (Testosterone) and cortisol release during HIT.

Title: Adolescent binge ethanol slows oligodendrocyte maturation through regulation of histone methylation in the PFC

Authors: E. BLAY, R. E. STEVENSON, A. C. PAIS, *J. T. WOLSTENHOLME;
Pharmacol. and Toxicology, Virginia Commonwealth Univ., Richmond, VA

Abstract: Alcohol use in teens primarily occurs in binges, often begins at a young age, and is associated with cognitive impairments, decreased white matter content, and structural changes in the brain. Ongoing frontal cortex myelination during this developmental period may make these adolescent drinkers particularly vulnerable to long-term consequences of binge ethanol. However, the molecular mechanisms underlying ethanol-induced myelin deficits in prefrontal cortex (PFC) development are not fully understood. Recently, we reported immediate and long-

lasting transcript changes in the PFC following adolescent binge ethanol; myelin-related genes and genes that regulate H3K9 methylation were decreased in the PFC. H3K9 tri-methylation (H3K9me3) is a stable repressive mark primarily found in heterochromatin and is associated with the development of oligodendrocyte precursors into mature, myelin-forming oligodendrocytes. Given that binge ethanol decreased lysine demethyases specific for H3K9 methylation, this may be a potential mechanism through which ethanol decreases myelin expression in the frontal cortex. To uncover the immediate adaptive and maladaptive responses during the course of adolescent binge ethanol, we dosed male and female DBA2/J mice with binge-levels of ethanol (4g/kg, i.g.) intermittently from PND 29-42. Tissue from the frontal cortex was collected at four time points during the course of binge ethanol administration: 24 hours after 1 binge at PND 30, after 4 binges at PND 35, after 8 binges at PND 43 and 3 weeks after the last binge to assess persistence of these transcriptional changes. Oligodendrocytes were enriched from frontal cortex and compared to bulk PFC for expression of oligodendrocyte maturation markers at each age by qPCR. We also tracked changes in genes responsible for depositing and removing methyl groups from H3K9me3 during the course of binge ethanol treatments. Together, these results will be the first to quantify changes in oligodendrocyte maturation during adolescent ethanol binges in male and female mice and link these changes to an epigenetic mechanism for how ethanol disrupts oligodendrocyte maturation in the frontal cortex. *Supported by NIAAA R01AA026347 to JTW.*

Title: Reduction of litter size induces overweight, depressive-like behavior, and increases IL-1β plasma levels in juvenile rats

Authors: *A. S. SAMPAIO, T. M. LIMA, P. S. RODRIGUES, N. A. SANTOS, L. M. SILVA, M. C. GALVÃO, K. E. KIATAQUI, T. M. REIS-SILVA, N. MOREIRA, I. B. SUFFREDINI, T. B. KIRSTEN, M. M. BERNARDI;
Envrn. and Exptl. Pathology, Paulista Univ., Sao Paulo, Brazil

Abstract: Overweight and obesity disorders are considered worldwide epidemics, which predispose the individual to numerous diseases. In the last three decades, its incidence has

increased intensively among the population, however, this growth has been greater among children. The objective of this study was to evaluate the effects of overnutrition during lactation on weight gain, depressive-like behavior, and immune mediators of juvenile male Wistar rats. On postnatal day (PND) 2, the experimental group (EG) litters were reduced to 3 males and 1 female, whereas the control group (CG) remain with its standard distribution of 4 males and 4 females per litters of. Body weight during the PND 2, 9, 21, and 31 was collected to calculate the weight gain. On PND 31 the rats were submitted to the forced swimming test and immediately euthanized for blood samples collection for pro-inflammatory cytokines and corticosterone evaluation. For the statistical analysis with more than two variables, a two-way ANOVA was performed followed by the Tukey post hoc test when pertinent. Student's t test was used for analysis with only one variable. The behavioral results indicate that the EG presented increased weight gain [$F(1.30) = 5.074$, $p = 0.03$] between PNDs 9 and 21, increased immobility ($p=0.0497$) and climbing time ($p=0.0319$) as well as increased latency for first immobility ($p=0.0003$) in the forced swimming test. The EG also presented increased IL-1β levels compared to CG ($p=0.0390$). In conclusion, reduction of litter size induced overweight, depressive-like behavior, and increased IL-1β plasma levels in juvenile rats. Together, these results may indicate a possible inflammatory process induced by the overnutrition during lactation, which resulted in behavioral and immune impairments in juvenile rats. This study was financed in part by the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior - Brasil (CAPES/PROSUP) - Finance Code 001

Title: Reorganization of dynamic connectivity patterns during brain development in awake rats

Authors: *Z. MA, Y. MA, N. ZHANG;
The Penn State Univ., University Park, PA

Abstract: Childhood and adolescence are both phases characterized by rapid social, emotional, and cognitive growth. During these transition periods, the brain undergoes a complex and dynamic maturational process that contains multiple stages. These stages are marked by notable neuronal changes such as myelination of axons, synaptic pruning. In addition, cell morphology, neural transmitter and receptor density also change drastically during early brain development. Protracted development during childhood and adolescence makes the brain particularly vulnerable to adverse early-life experience. In fact, neuropsychiatric disorders often emerge during childhood and persist across the lifespan. Therefore, understanding postnatal brain development is crucial for uncovering brain function in health and disease. Recent work and literature in our lab has demonstrated characteristics of brain functional connectivity change during development. However, brain connectivity undergoes dynamic changes during development. However, how dynamic patterns of functional connectivity links with maturation process of brain at system level remains unclear. To bridge this gap, we further investigated our resting state fMRI data.
To comprehensively trace the developmental changes of dynamic functional connectivity pattern, we longitudinally acquired rsfMRI data in awake rats during five developmental stages: juvenile (P30-P31), early adolescence (P34-P35), adolescence (P41-P42), late adolescence (P48-P49) and adulthood (P70-P90). We analyzed data using a dynamic approach that combines sliding window method and k-means clustering. We discovered that the whole brain connectivity architecture contains several patterns that occurs across several age groups. Specifically, patterns that involves stronger connections between polymodal association areas are strongly biased toward older ages, as well as patterns involves stronger within-system connections have a higher occurrence rate at younger age.

Title: Adolescent morphine exposure has long term, sex-specific effects on social behavior

Authors: *C. FIGUEROA[1], S. D. BILBO[2], A. M. KOPEC[1];
[1]Neurosci. and Exptl. Therapeut., Albany Med. Col., Albany, NY; [2]Pediatrics, Harvard Med. School/MGH, Charlestown, MA

Abstract: Brain regions involved with reward processing undergo sex-specific development during adolescence, which contributes to social behavior development in rats (Kopec et al. 2018). Morphine exposure during adolescence has long term effects on addiction-related behaviors in male rats (Schwarz et al. 2012), but the effects of adolescent morphine exposure on social behavior in adulthood, and whether they are sex-specific, are largely unstudied. To investigate this, we exposed male and female rats to morphine during different stages of adolescent development, early adolescence (postnatal day (P)31-35), mid-adolescence (P39-43), or late adolescence (P55-59), and then assessed social and anxiety-like behaviors in mature adulthood (~P90). In the sociability task (novel social vs. novel object stimulus), there were no differences in time spent in either the social or object chambers. However, male rats exposed to early and mid-adolescent morphine had significantly decreased exploration of the novel social stimulus compared to drug-naïve age-matched control rats. In the social novelty preference task (novel social vs. familiar social stimulus), early adolescent morphine-treated males demonstrated a trend toward ($p=0.056$) decreased exploration of the novel stimulus, but no differences in time exploring the familiar stimulus nor in time spent in either chamber. These preliminary data suggest that early adolescent morphine exposure may cause anxiety-like behaviors in male rats, but interestingly no differences were observed for these behaviors in open field. Females showed no behavioral differences in any task assessed. Altogether, our data suggest that early adolescent morphine exposure causes avoidance of novel social stimuli without affecting overall preference for social interaction, specifically in male rats. Social avoidance is a common symptom of social anxiety disorder (SAD), which is often comorbid with other anxiety and affective disorders (Toth et al. 2013). Lack of treatment effects in open field behavior indicates that anxiety may be induced specifically by novel social stimuli as opposed to generalized anxiety. In male rats, the nucleus accumbens reward region undergoes dopamine 1 receptor (D1r) pruning during early adolescence, while female D1r regulation occurs at a different developmental stage and via different mechanisms (Kopec et al. 2018). Since dopamine signaling is a key regulator of social behavior in rats (Steinman et al. 2018), in future studies we will explore the possibility that early adolescent morphine exposure alters D1r pruning in males, but not females, potentially producing SAD-related behaviors in adulthood.

Title: Interactions of sex and reduced dopamine transporter expression on social play

Authors: *H. T. TRAN[1], B. DEMARCO[1], F. S. HALL[2];
[1]Univ. of Toledo, Toledo, OH; [2]Pharmacol., Univ. of Toledo Col. of Pharm. and Pharmaceut. Sci., Toledo, OH

Abstract: Social isolation during adolescence leads to long-term behavioral deficits in adulthood. Many of these behavioral changes have been described as pathological in nature and include symptoms that resemble aspects of mood disorders, anxiety disorders, and autism spectrum disorders (ASD). These outcomes are neurodevelopmental in nature, resulting only from social isolation at this age, and are not reversed by later socialization. Other factors that influence social play may impact the consequences of social isolation. Dopamine has a role in social play, and the dopamine transporter (DAT) regulates extra-synaptic dopamine levels. Sex differences in social play may also influence the developmental consequences of social experiences. A 24-hr period of social isolation increases motivation for play and was used to study play in DAT +/+ and DAT +/- knockout mice. Methods: Male and female, DAT +/+ and DAT +/- mice were isolated for a 24-hr period, between 28 and 35 days of age, or remained in social housing. After this time, socially-housed mice were introduced to a novel cage for 10 min before a novel, non-sibling isolated mouse was introduced to the cage. Social and non-social behaviors were scored by an observer, and ultrasonic vocalizations (USV) were recorded. Results: Effects on Social behavior were observed to result from isolation, sex and genotype. Isolation: Grooming was increased by isolation, indicative of anxiety. Withdrawal (abrupt leap away from an approaching mouse) was observed only in isolated female WT Mice. Following was increased in isolated mice, but only in females. Rearing was reduced by isolation, except in female DAT +/- mice. Sex: Nose-to nose sniffing and anogenital sniffing was lower in females. Genotype: dorsal pins were reduced in male DAT +/- mice, but females showed a complex interaction between sex, genotype, and isolation. Increased USV was associated with social behavior. Conclusions: Social isolation increased social approach, but simultaneously induced anxiety, particularly in female mice. Distinct sex differences were particularly seen in certain behaviors as well, while other affected by reduced DAT expression in a sex dependent manner. These data suggest that sex and genotypic differences in the long-term effects of social isolation may result from alterations in social behavior tendencies, and consequent differences neural activation resulting from the altered experiences. Ongoing studies examine the initial neural responses to social experiences after a short period of isolation. It is thought that understanding of these neurodevelopmental processes will provide insight into ASD and associated conditions.

Title: Female adolescent Sprague Dawley rats display blunted central and peripheral cytokine responses following an acute stress challenge

Authors: *P. MARSLAND[1], A. PARRELLA[1], A. S. VORE[1], T. DEAK[2];
[1]Binghamton Univ., Binghamton, NY; [2]Behavioral Neurosci. Program, Dept. of Psychology, Binghamton University-SUNY, Binghamton, NY

Abstract: Adolescence is a unique developmental stage in which extensive physiological and cognitive development occurs, creating a critical period of developmental vulnerability. Recent studies in adolescent rodent models have demonstrated that adolescents demonstrate reduced reactivity to pharmacological challenges that evoke a substantial neuroimmune response, including acute alcohol (ethanol) and lipopolysaccharide administration (Doremus-Fitzwater et al., 2015). Furthermore, repeated ethanol administration during adolescence produced long-lasting changes in neuroimmune function, reminiscent of a “locking-in-like” effect of the adolescent neuroimmune phenotype (Vore et al., 2017; Gano et al., 2019). The goals of the present experiment were to (a) test whether reduced neuroimmune reactivity among adolescents would be observed in female rats; and (b) assess whether this neuroimmune insensitivity would generalize to a (non-pharmacological) stress challenge (footshock). To do this, female adolescent (P29-33) and adult (P70-80) Sprague Dawley rats were exposed to intermittent footshock (1 mA, 5 sec each, 90 sec variable inter-trial interval) for 1 hour, 2 hours, or 2 hours and a 2-hour recovery period to assess the kinetics of cytokine induction by stress. Cytokine gene expression was analyzed in the paraventricular nucleus of the hypothalamus (PVN), the medial amygdala (MeA), and the ventral hippocampus (vHPC) using RT-PCR. In addition, spleens were analyzed for cytokine protein expression via multiplex protein analysis. As expected, adolescent females displayed evidence for functionally reduced cytokine expression evoked by footshock. IL-1β was significantly increased in adult females following 1- and 2-hours of footshock in the PVN and MeA, but not in adolescent females. c-FOS gene expression was also elevated in both adolescent and adult females in the PVN during 1- and 2-hours of footshock, but adolescents displayed blunted expression when compared to adults. Protein analysis in the spleens revealed that adult females, but not adolescents, display increased IL-1α following 1- and 2-hours footshock. Similarly, IL-1β protein expression was elevated in adult females following 2-hours of footshock, but not in adolescents. Taken together, these results indicate that reduced

neuroimmune reactivity appears to be a common feature of adolescents that generalizes to non-pharmacological challenges such as footshock. This functionally immature immune response to stress among adolescents may contribute to later development of stress-related pathology.

Title: Individual differences in brain activation following ethanol-induced social facilitation and inhibition among cFos-LacZ transgenic rats

Authors: *T. T. TOWNER[1], E. I. VARLINSKAYA[2], D. F. WERNER[3], L. P. SPEAR[4];

[4]Ctr. For Develop. and Behavioral Neurosci., Binghamton, NY

Abstract: Adolescence is a developmental period during which increases in risk taking, novelty seeking, and drug experimentation occur. In adolescence, alcohol consumption typically takes place in a social setting, with the subjective feeling of alcohol's stimulant and sedative effects in such social contexts likely contributing to drinking behavior. Individual differences in both the physiological and subjective responses to alcohol impact vulnerabilities to later alcohol abuse, and have been recently assessed in animal models of social behavior. Previous work has shown that adolescent rats acutely challenged with ethanol display individual differences in their response to 0.75 g/kg ethanol ranging from marked increases in social behavior evident in some and inhibition in others. The aim of the current study was to examine ethanol-induced changes in social behavior following escalating doses of ethanol and differences in brain activation between animals that respond to ethanol via increases in social behavior versus social inhibition. Thirty-four adolescent male transgenic cFos-LacZ rats on a Sprague-Dawley background (postnatal day [P] 30 at beginning of testing) were assessed in a modified social interaction test. Social testing occurred under baseline no-injection conditions (P30), following a saline injection (P32), as well as after injection of 0.5 g/kg (P34) and 0.75 g/kg (P36) ethanol. Changes in social behavior following administration of the 0.75 g/kg ethanol dose relative to saline were calculated, and a tertile split was used to distinguish animals that responded to ethanol with social facilitation from those that were socially inhibited by the same ethanol dose. Following the final social interaction test on P36, animals were perfused and brains collected for beta-galactosidase staining. Brain

regions examined were the prefrontal and orbitofrontal cortices, nucleus accumbens, lateral septum, and amygdala. Social behavior was increased by 0.5 g/kg dose, whereas following the dose of 0.75 g/kg ethanol, some animals were socially facilitated and others were inhibited socially. Beta-galactosidase staining, a proxy for cFos activation, revealed significant increases in the nucleus accumbens shell as well as decreases in the prefrontal cortex among socially facilitated animals relative to their socially-inhibited counterparts. These findings demonstrate that individual behavioral differences in responding to ethanol indexed by the notable split between ethanol-induced social facilitation and inhibition are accompanied by differences in neural ensemble activation in the prefrontal cortex and accumbens shell.

Title: Influence of developmental nicotine exposure on cholinergic circuits engaged in fear/threat memory

Authors: *J. A. WILKING[1], N. S. DESAI[4], D. A. TALMAGE[2], L. W. ROLE[3];
[1]Neurobio., [2]Pharmacol. Sci., [3]Neurobio. & Behavior, Stony Brook Univ., Stony Brook, NY;
[4]Circuits, Synapses, and Mol. Signaling Section, NINDS, Bethesda, MD

Abstract: Nicotine use during pregnancy is the most preventable risk factor associated with adverse fetal outcomes including cognitive deficits and later increased substance abuse. Additionally, approximately 80% of smokers initiate tobacco use during adolescence, suggesting the age of nicotine exposure plays a critical role in the developing brain and the cholinergic system. Further prior smoking history is a predictor of increased vulnerability to post traumatic stress (PTSD) and panic disorder following a traumatic event, and smoking rates increase after a trauma. The cholinergic system has been implicated in attention, learning, and memory processes. One key brain region that is highly involved in fear/threat learning is the amygdala. Part of the amygdala, the basolateral amygdala (BLA) receives abundant cholinergic innervation which is critical for establishing emotionally salient memories. Our laboratory has demonstrated that cholinergic input from the basal forebrain is critical for BLA dependent learning and memory, endogenous acetylcholine (ACh) induces synaptic plasticity in the BLA, and this effect requires nicotinic acetylcholine receptors (nAChRs). We predict nicotine exposure during

development increases fear learning which is long lasting. To test this prediction, we exposed (a) pregnant C57BL/6J dams from embryonic day 14 (E14) to postnatal day 21 (P21); (b) adolescent C57BL/6J animals from P21 - P42 to 200 µg/ml nicotine (plus Splenda in their drinking water), Splenda alone, or water. Animals were then tested for cued conditioned fear/threat learning. To date when animals are tested immediately after prenatal exposure the Splenda only animals exhibit decreased freezing compared to water controls and nicotine + Splenda treated animals. When animals were tested 21 days after cessation of nicotine and/or Splenda treatment, the nicotine + Splenda group showed a sustained increase in cue conditioned freezing. The surprising short term effects of Splenda will be explored further. Additional treatment x sex interactions are present during both training and recall. We have not seen effects of adolescent nicotine (or Splenda) exposure on threat learning. To determine potential cholinergic circuit modifications following early chronic nicotine exposure we are assessing intrinsic excitability and synaptic transmission using whole cell patch recordings from BLA principal neurons in slices following recall.

Title: Isolation stress during adolescence on anxiety-like behavior and conditioned place preference to cocaine

Authors: *E. U. PÉREZ-CARDONA, A. C. SEGARRA;
Dept. of Physiol., Univ. of Puerto Rico, Med. Sci. Campus, San Juan, PR

Abstract: Adolescence is a sensitive developmental period in human beings characterized by sexual maturation and continuing brain development. Chronic stress during adolescence, as abandonment and social isolation, interferes with maturation of higher brain functions such as decision making, learning and memory; leading to behavioral alterations and mental illness. Rats are social animals, and thus serve as an animal model to investigate the consequences of isolation during adolescence on the development of anxiety-like behaviors and the rewarding response to cocaine. Male and female rats were either housed in groups of the same sex or single housed from weaning (postnatal day 21) until the end of the experiments. At day 34 rats were tested for anxiety-like behavior with the Elevated Plus Maze. From day 35 to day 48 their contextual

associated memory to cocaine (15 mg/kg) was assessed using the Conditioned Place Preference (CPP) paradigm. Our results indicate that male rats reared in isolation during adolescence spend more time in the closed arm than grouped housed rats. A similar trend was observed in the females. Grouped housed and isolated rats (females and males) showed CPP to cocaine when tested during days 35 to 48, however, no differences were observed between isolated and grouped housed rats. These results show that isolation increases anxiety in adolescent male rats, and that does not alter the rewarding properties of cocaine.

Title: Mapping prefrontal cortical development over adolescence in mouse

Authors: *K. J. MASTRO[1,3,4], C. WILLING[1], W. WANG[4], L. STANWICKS[3], B. SABATINI[4,5], B. A. STEVENS[2,5];
[2]Harvard Med. Sch. Neurobio., [1]Boston Children's Hosp., Boston, MA; [3]Broad Inst., Cambridge, MA; [4]Harvard Med. Sch., Boston, MA; [5]Howard Hughes Med. Inst., Chevy Chase, MD

Abstract: The prefrontal cortex (PFC) is critical for cognitive functions, like working memory and flexibility, and has been implicated in the pathogenesis of cognitive dysfunction in psychiatric disease. Onset for many psychiatric disorders occurs during adolescence and suggests alterations to the development of PFC, but our understanding of how PFC matures remains unclear. Unlike that of sensory cortices, data from human imaging and human post mortem tissue suggests that the development of PFC extends through adolescence, a developmental critical period that parallels the development of cognitive control. To understand how psychiatric disease risk genes and environment shape this developmental trajectory, we must first establish what is normal. Here, we employ a range of anatomic and electrophysiological techniques to map spatiotemporal changes to PFC inputs in the mouse. To track the development of excitatory synapses, we performed slice electrophysiology and recorded miniature excitatory postsynaptic currents across weeks of postnatal development. We found that the frequency and amplitude of these excitatory events undergo a prolonged change until reaching their stable state in adulthood.

To understand how different sources of excitatory inputs are changing over the same period, we used immunohistochemical approaches to track the density and localization of inputs across cortical layers. Consistent with our physiology results, we found that excitatory inputs are increasing dramatically during the early phases of postnatal prefrontal development, but greater subcircuit resolution is necessary. Currently, we are using virally delivered optogenetics to parse the distinct developmental timelines of specific prefrontal subcircuits. In doing so, we are examining how specific components of synaptic connectivity, including strength and impact on the local microcircuitry (e.g. feedforward inhibition) are changing over the course of adolescence. Together, these results provide a detailed timeline of how excitatory inputs to the PFC mature across the full adolescent window, and provide both the baseline and targets for perturbations to genes and environment.

Title: Photoreception in Lumbriculus variegatus, an aquatic annelid

Authors: *M. VARGAS[1], J. SCOTTY[2], C. L. BAER[3], C. R. FLORES[3], E. L. CAIN[3], V. G. MARTINEZ ACOSTA[1];
[2]Rosenberg Sch. of Optometry, [1]Univ. of the Incarnate Word, San Antonio, TX; [3]Northeast Lakeview Col., San Antonio, TX

Abstract: *Lumbriculus variegatus,* an aquatic annelid, is capable of complete regeneration from a few body segments (Martinez et al., 2006). In this study, we present an investigation of photoreception in Lumbriculus. In annelids, there are three different types of photoreceptors: rhabdomeric, ciliary, and phaosomous sensory cells. Photoreceptors are present in cerebral ocelli, in ectopic ocelli, and eyes situated in different places in photoreceptor-like sense organs. *Lumbriculus* is thought to possess photoreceptors within its posterior-most segments, as rapid tail withdrawals are evoked when a shadow is cast over the water column. Initial studies describe that Lumbriculus possesses large phaosomal photoreceptors that lie directly below the epithelial layer (Drewes and Fourtner 1989). Using a simple phototactic assay we set out to determine the range of wavelengths that result in a behavioral response. Preliminary data suggest that Lumbriculus negatively phototaxis away more strongly from red light when compared to that of

white, UV, green, or blue light respectively (*n=25; UV 36±15.01s, G: 43.6 ±29.3s, B: 48.4±24.6s, R: 31.2±12.1s, W: 34.3±12.07s*). Candidate sensory receptor cells identified at present include cells with low concentration pigmentation that are found adjacent to axonal connections that project to cell bodies found within the muscle wall. Further characterization of the photoreceptor system using transmission electron microscopy will elucidate more clearly the ultrastructural arrangement of the photoreceptors within the posterior-most segments that mediate the rapid escape tail responses previously detected. Candidate opsin sequences were determined using a newly synthesized Lumbriculid transcriptome. Phylogenetic analysis comparing two different r-opsin sequences from *Platynereis dumerilii* and *Homo sapien*s resulted in a predicted r-opsin sequence for Lumbriculid Opsin 4 (LumVa Opsin 4). Primers developed against the LumVa r-opsin successfully amplified a 1332 bp pcr product. TOPO-TA cloning step has been performed and colonies are currently being screened to isolate clones containing the most complete LumVa Opsin 4 product. Lastly, immunohistochemical analysis of the G-protein-alpha subunit, G-α q/11/14, previously described to be involved in phototransduction in other annelids and invertebrates, will be utilized to elucidate the structural arrangement of the receptors within the tail segments and subsequent mechanism of their phototransduction. Overall, this research will add to the body knowledge we currently understand regarding the evolution of photoreception in metazoans.

Title: Nervous system evolution: A molecular genetic characterization of neural cell types in S. kowalevskii

Authors: *J. M. ANDRADE LOPEZ[1], A. M. PANI[2], P. J. MINOR[1], C. J. LOWE[1];
[1]Biol., Stanford Univ., Stanford, CA; [2]Biol., Univ. of North Carolina, Chapel Hill, Chapel Hill, NC

Abstract: Hemichordates are a key deuterostome phylum for understanding the evolution of the chordate CNS. Their nervous system is organized around two elements; a pervasive nerve plexus concentrated anteriorly, and two nerve cords; one dorsal and one ventral. Despite the major organizational differences between the nervous system of hemichordates and vertebrates, they

share a well-conserved gene regulatory network for anterior-posterior patterning. It is still unclear whether any of this conserved pattern regulates fundamental similarities in neural cell type specification. I will present data on the spatiotemporal expression of neural markers, including genes involved in neurotransmitter synthesis and transport by in situ hybridization, to determine the level of regional specialization of the neural plexus and nerve cords in juvenile *S. kowalevskii*. These data also facilitate more direct neural comparisons with chordates. I will also present data using a meganuclease, a transposon-mediated approach, to generate transgenic animals expressing GPF in a subset of neurons. These experiments facilitate an analysis of the identity and location of specific neural cell bodies, and also neuronal morphology and connectivity, to better understand the structure and function of this nervous system. We have generated constructs to label neurons using pan-neural (synapsin, elaV, Syt1), cell type specific markers (GAT, TH), and an endogenous synaptic vesicle protein, synaptotagmin, to label synapses. I will present a preliminary analysis of these data and their impact on our understanding of the comparative relevance of hemichordate nervous systems to broader questions of nervous system evolution. This work will give insights into the evolution of deuterostomes and the origins of the vertebrate brain, but also the evolution of bilaterian nervous systems.

Title: Radial glial cells coexpress DCX and GFAP in the adult turtle brain and early embryonic mouse brain

Authors: *A. J. NAPOLI[1], A. S. POWERS[1], S. GE[2];
[2]Neurobio. and Behavior, [1]State Univ. of New York at Stony Brook, Stony Brook, NY

Abstract: Radial glial cells (RGCs), a population of neural stem cells, disappear from the cortex of mammals after development, enduring in adult neurogenic niches. However, in vertebrates that exhibit pervasive adult neurogenesis (AN), such as reptiles, RGCs persist in all regions of the telencephalon throughout life, providing a source of neural stem cells and a mechanism for migration and integration. As RGCs also give rise to glial progeny, the mechanism underlying the fate specification remains largely unknown.
Non-mammalian vertebrates are capable of pervasive AN, and many have demonstrated the ability to repair injury to the telencephalon. These vertebrates may retain, as adults, molecular

processes thought to be exclusively developmental in mammals, and which may allow for rebuilding of the brain. Some mechanistic studies have revealed that glial fibrillary acidic protein (GFAP) is expressed in RGCs. Doublecortin (DCX) is thought to be expressed exclusively in immature neurons. The expression profiles of GFAP and DCX in RGCs and their progeny have been mostly described based on mammalian adult neurogenic niches, in which sequential, not concurrent, expression has been shown. GFAP is expressed in RGC, followed by DCX expression in neuroblasts. However, whether the unique circumstances of adult mammalian AN are reflective of the developmental state is unknown.
In this study we first assessed the expression of GFAP and DCX in RGCs in the telencephalon of adult turtles (*Chrysemys picta*) using immunohistochemistry. Surprisingly, GFAP and DCX were robustly co-expressed in the RGCs, suggesting their potential role in cell fate specification. Importantly, after telencephalic lesions, we found elevated expression of both GFAP and DCX, further suggesting their regulatory roles in differentiation. We extended the investigation to the developing mammalian brain and found that, at mouse embryonic day 13, RGCs also coexpress GFAP and DCX in the cortex, but this co-expression is lost by embryonic day 15.
DCX has traditionally been thought of as a marker of immature neurons, although recent work has demonstrated its expression in putative astrocytes during ischemic injury, which may harken back to their RGC ancestry and RGC responsiveness to injury signals. Although temporal and spatial co-expression of GFAP and DCX in RGCs had not been previously demonstrated, current work may help elucidate their molecular mechanisms in the developing cortex and subsequent implications for neural regeneration and repair.

Abstract: An increase in the neural progenitor pool, present almost exclusively during fetal development, is a well-described mechanism that can lead to expansion of neocortical surface

area. Numerous autism-linked mutations affect genes involved in Wnt signaling, a pathway that regulates neural progenitor proliferation. In addition, common genetic variants near Wnt-pathway genes are associated with changes in cortical surface area in adults. Here, we test the hypothesis that common genetic variation modulates proliferation and Wnt signaling in human NPCs, and assess the degree of overlap with variants contributing to brain structures and autism risk. To achieve this, we utilize a library of 94 human neural progenitor cell lines derived from developing cortical tissue, which have previously undergone genome-wide genotyping, RNA-seq, and ATAC-seq. In these lines, we quantify sensitivity to three Wnt modulators (CT99021 - a highly selective GSK3B inhibitor, lithium chloride, valproic acid) at several concentrations using a Wnt sensitive transcriptional reporter (beta-catenin activated reporter). We also measure how these compounds effect proliferation rates using a DNA dye and EdU incorporation assay followed by flow cytometry. We observe dose dependent increases in Wnt signaling and proliferation in response to CT99021 and LiCl. In contrast, less than 5% of NPC lines responded to valproic acid using the reporter assay. VPA also decreased proliferation in all lines. We observe significant variation in inter-individual responsiveness to Wnt activation. Responsiveness also correlates to expression levels of key Wnt genes, including beta-catenin and Wnt ligands. While biological factors, such as gestational age and sex, do not detectably influence Wnt sensitivity, we do detect an effect of gestational age on proliferation. Ongoing experiments include, completing an association study for the remaining drugs and assays, identifying caQTLs that correlate with Wnt responsiveness, and assessing pleiotropy between variants that alter these cellular phenotypes, cortical surface area, and autism risk. Overall, this approach is designed to draw mechanistic connections from common genetic variants to molecular and cellular phenotypes to adult brain structure and disease relevant loci.

Abstract: Von Economo neurons (VENs) are bipolar, spindle-shaped neurons restricted to layer 5 of human frontoinsula and anterior cingulate cortex that appear to be selectively vulnerable to neuropsychiatric and neurodegenerative diseases, although little is known about other VEN cellular phenotypes. Single nucleus RNA-sequencing of frontoinsula layer 5 identified a transcriptomically defined cell cluster that contained all VENs and fork cells, but also a subset of neurons with pyramidal morphologies. Cross-species alignment of this cell cluster with a well-annotated mouse classification shows strong homology to subcortically projecting extratelencephalic (ET) excitatory neurons. This cluster also shows strong homology to a putative ET cluster in human temporal cortex, but with a strikingly specific regional signature. Together these results predict VENs are a regionally distinctive type of ET neuron, and we additionally describe the first patch clamp recordings of VENs from neurosurgically resected tissue that show distinctive intrinsic membrane properties from neighboring pyramidal neurons.

Title: Identification of mouse and human Ppp1r1b/DARPP-32 striatal-specific enhancers

Authors: *M. D. CIRNARU[1], C. CORWIN[1], **J. CREUS-MUNCUNILL**[1], M. AUDRAIN[1], J. FULLARD[2], P. ROUSSOS[2], M. E. EHRLICH[1];
[1]Neurol., [2]Psychiatry, Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract: Background: DARPP-32 (dopamine and cyclic AMP-regulated phosphoprotein, 32 kDa), encoded by the PPP1R1B gene, is expressed in almost all medium spiny neurons (MSN), where it is a key modulator of neurotransmitter signal transduction, particularly dopamine. Enhancer sequences which contribute to cell-specific transcription specify cell identity and differentiation, may contribute to disease, e.g. Huntington's disease. We sought to identify Ppp1r1b MSN-specific cis-regulatory elements (CREs) in mouse and human. **Method:** We used transgenic deletion analysis to identify the Ppp1r1b mouse enhancer and ATAC-seq to identify the human enhancer (Fullard et al., 2018). The activity of the human enhancer was also validated via transgenesis in mouse. The activity of both was assayed in MSN-like neurons derived from mouse and human stem cells.**Results:** We identified mouse and human CREs which restrict transgene expression to MSNs in the forebrain. There was significant divergence between mouse and human enhancers in their location relative to the transcription starting site, expression in cerebellar Purkinje cells, a site of endogenous DARPP-32 expression, and in response to BDNF, a known inducer of DARPP-32 expression in mouse. **Conclusion:** This study highlights divergence of CREs between species, which could be disease-relevant. In addition, the enhancer sequences will provide useful tools for MSN specific gene delivery and for the study of MSN maturation.

Abstract: Recent discussions of human brain evolution have largely focused on increased neuron numbers and changes in their connectivity and expression. However, it is increasingly appreciated that oligodendrocytes play important roles in cognitive function and disease. Whether both cell-types follow similar or distinctive evolutionary trajectories is not known. Here, we examined the transcriptomes of neurons and oligodendrocytes in the frontal cortex of humans, chimpanzees, and rhesus macaques. We identified human-specific trajectories of gene expression in neurons and oligodendrocytes and show that both cell-types exhibit human-specific upregulation. Moreover, oligodendrocytes have undergone accelerated gene expression evolution in the human lineage compared to neurons. In addition, oligodendrocytes human-specific signatures are enriched for variants associated with neuropsychiatric disorders. These results provide insight into the role of oligodendrocytes in human brain evolution and neuropsychiatric disorders.

Title: Characterization of a neoblast population in the regenerating model system, Lumbriculus variegatus

Authors: B. A. SALVADOR, *V. G. MARTINEZ ACOSTA;
Biol., Univ. of the Incarnate Word, San Antonio, TX

Abstract: Members of the annelid phyla demonstrate varying capabilities of regeneration however the processes are similar, including three phases: wound healing, blastema formation,

growth, and differentiation (epimorphosis). In Lumbriculus, it had been hypothesized that differentiation occurs via proliferation of a stem cell population termed ‘neoblasts’ (Dubois, 1956). Neoblasts are small populations of mesenchymal cells that are found in worms and are described as a cellular source of regeneration. Despite efforts taken to determine the molecular mechanisms that may be involved during regeneration in Lumbriculus, little work has been done to fully characterize stem cell populations which are involved in this process. Using worm fragments 24hr and 11d post-amputation, we describe a small population of cells that are labeled by 5-ethynyl-2’-deoxyuridine (Click-iT® EdU) and readily mobilize to the wound blastema. A sub-population of these EdU-positive cells are also labeled with a neoblast-specific marker (Ross et. al., 2015), 1D9-E11. Immunohistochemical analysis demonstrates 1D9 positive cells within regenerating blastema of anterior and posterior ends of a regenerating fragment. 1D9 cells are detected 24hr post-amputation and are increased in number at 1wk post-amputation. Increased localization of 1D9-cells is noted within anterior segments in comparison to posterior segments. Immunoblot analysis of protein epitopes labeled by 1D9 in Lumbriculus blastemal tissue detected 2 protein bands that measure 214 kDa and 137 kDa. Total worm lysates were then purified using an immunoaffinity column method with 1D9 antibody conjugated sephadex beads and then sent for mass spectrometry analysis using the MALDI-TOF method. This work will ultimately determine the protein identity of 1D9 immunoreactive protein epitopes involved in regeneration in Lumbriculus. We believe that the 1D9 labled proteins may be important contributors to stem cell differentiation and, as reported in other regenerative models, may be the cellular source of regeneration in Lumbriculid worms. Overall, understanding the mechanisms of regeneration utilized by Lumbriculus will further our understanding of these complex processes and the knowledge gained will expand the regeneration literature.

Title: Conserved and divergent expression dynamics during early patterning of the telencephalon in mouse and in chick embryos

Authors: *V. Y. MULEY[1], C. J. LOPEZ-VICTORIO[1], J. T. AYALA-SUMUANO[1], A. GONZÁLEZ-GALLARDO[1], B. FARIAS-SERRATOS[1], L. GONZÁLEZ-SANTOS[1], G. WRAY[2], M. HERNÁNDEZ[3], A. VARELA-ECHAVARRÍA[1];

Abstract: The telencephalon differs dramatically in the mammals and the reptiles, in various aspects, including the presence of a laminated cortex and a corpus callosum in the former and a dorsoventral ridge in the latter. The early embryonic vesicle that develops into telencephalon has similar morphology, but the pallium of these animals diverges morphologically in their adult form. The extent to which common and lineage-specific gene regulatory programs control the ontogenetic divergence of the pallium in these animal taxa is currently unknown. To address this issue, we studied the global gene expression dynamics in mouse and chick telencephalon at early patterning stages. Our findings indicate that early telencephalic patterning in mouse and chick is governed by less than 3,000 genes, with subtle differences in the regulation of common signaling and transcriptional regulatory networks. The differential expression of Gata6, Neurod2, Foxf2, Nr1h4, Elk3 transcription factors determines telencephalon development. Epigenetic factors such as Atrx, Cbx3, and Cbx5 seems to modulate global gene expression in species specific manner. Impaired telencephalon development is likely to results in autism spectrum disorders.

Title: Widespread neuronal expression of class I major histocompatibility complex isotypes in the adult human brain

Authors: M. T. C. MOU[1], S. M. CLARK[2], M. L. LANE[1], ***L. H. TONELLI**[3];
[2]Psychiatry, [1]Univ. of Maryland Sch. of Med., Baltimore, MD; [3]Univ. of Maryland Baltimore, Baltimore, MD

Abstract: Class I major histocompatibility complex (MHC-I) molecules have been implicated in developmental processes of the central nervous system (CNS), specifically in activity dependent

synapse elimination and refinement of neural circuitries. In the adult brain, they are believed to participate in neural plasticity in several regions including the hippocampus. However, the expression of these molecules in the adult human brain has been minimally studied. Here, high-sensitive radioactive in situ hybridization and RNAscope technology were used to examine MHC-I A, B & C transcripts and beta-2 microglobulin in neurons of several brain regions of the adult human brain and to compare their expression with that of the adult rat brain. Postmortem samples containing area 45 or 11 of the prefrontal cortex (PFC), dorsal thalamus (Thal), dorsal striatum and corpus callosum were obtained from the NIH NeuroBioBank's brain and tissue repository at the University of Maryland and from the Maryland Psychiatric Research Center. Strong MHC-I expression signals were identified in both gray and white matter of the PFC and dorsal striatum and in the corpus callosum, choroid plexus and ependymal cell layer of the subventricular zone. Low or no specific signals were identified in the Thal. Examination of MHC-I in the PFC showed stronger and wider expression in human compared to rat. Analysis of cellular expression revealed a widespread distribution in different types of cells in which perivascular cells were the most abundant types of cells expressing MHC-I isotypes. RNAscope analysis confirmed neuronal expression of beta-2 microglobulin in the PFC and dorsal striatum of the adult human brain. MHC-I expression was also localized to NG2 positive cells using RNAscope. These studies provide strong evidence of a widespread expression of MHC-I isotypes in neurons of the adult human PFC, as well as in cells of the brain vasculature. These results suggest a role for MHC-I molecules in neurons of the adult human brain beyond those shown during circuit formation and maturation. Moreover, expression in perivascular cells provides the neuroanatomical basis for direct interactions with CD8+ and natural killer T cells of the immune system in normal non-inflammatory conditions.

Abstract: Despite our close genetic relationship with chimpanzees, there are notable differences between chimpanzee and human social behavior. Oxytocin and vasopressin are two neuropeptides known to regulate social behavior across mammalian species. Moreover, the distribution of their receptors has been shown to contribute to species-specific social behavior in several taxa. Yet little is known about the neuroanatomy of these systems in primates, and virtually nothing in great apes. Here, we used receptor autoradiography with a competitive binding protocol to localize oxytocin and vasopressin v1a receptors in seven chimpanzee brains. Oxytocin receptors were found in the lateral septum, hypothalamus, corticomedial amygdala, nucleus basalis, and substantia nigra. Vasopressin v1a receptors were observed in the cortex, lateral septum, hypothalamus, entire amygdala, dentate gyrus, and substantia nigra. These findings suggest continuity with other primate species in several areas, including those important for social visual attention. They also suggest potential differences between humans and chimpanzees in neuropeptide receptor expression in the reward system as well as areas important for threat.

Title: Immediate early gene expression demonstrates ocular dominance columns in V1 of squirrel monkeys

Authors: *S. LI, S. YAO, Q. ZHOU, T. TAKAHATA;
Zhejiang University, Interdisciplinary Inst. of Neurosci. and Technol. (ZIINT), Hangzhou, China

Abstract: The squirrel monkey is regarded as the only one anthropoid primate species which is lack of ocular dominance columns (ODCs). Although previous studies have demonstrated that strabismus can induce formation of ODCs in the striate cortex (V1) of squirrel monkeys, many

individuals of the squirrel monkey with normal vision are lack of ODCs, when they tested it by cytochrome oxidase (CO) histochemistry. On the other hand, all individuals of the squirrel monkey are shown to be capable of stereoscopic 3D vision. Hence, ODCs are considered as a byproduct of cortical development. Moreover, this paradigm has been generalized to all cortical columns of other species as well, urging researchers to discuss that cortical columns are functionally unimportant trait. However, the observation of lack of ODCs in normal squirrel monkeys may be due to technical limitation. Immediate-early genes (IEGs) are a group of genes whose expression level is up-regulated or down-regulated immediately after the onset or offset of neuronal activity, respectively, and the sensitivity of their expression change to neuronal activity is much greater than that of CO expression. Our Previous study has revealed that ODCs exist in V1 of owl monkeys by IEG expression patterns after monocular inactivation, whereas conventional CO method failed to reveal. Therefore, in this research two kinds of immediate-early genes, *ZIF268* and *c-FOS*, are used to show ODCs in squirrel monkeys. Five normally reared adult squirrel monkeys were monocularly inactivated by TTX injection or eye enucleation. As a result, ODC-like patches were seen in V1 of all cases by *ZIF268* and *c-FOS* expression pattern, although they were not as evident as that in other anthropoid primate species. Thus, it is not compelling that squirrel monkeys are lack of ODCs as previous studies have shown solely by CO staining method. This research reveals universal existence of ODCs across primate species and suggests researchers to reconsider about the functional importance of cortical columns in general.

Title: Distribution of the calcium binding proteins calbindin-D28k, calretinin, and parvalbumin in the naked mole-rat brain

Authors: *R. J. EMBALABALA, J. L. CHEATWOOD, D. K. SARKO;
Anat., Southern Illinois Univ. Med. Sch., Carbondale, IL

Abstract: The naked mole-rat (*Heterocephalus glaber)* is a small, poikilothermic rodent endemic to hot, dry regions of east Africa, such as those found in Somalia, central Ethiopia and parts of northeastern Kenya. *H. glaber* are eusocial animals that tend to live in hypoxic, hypercapnic subterranean colonies which has ultimately led to anatomical and physiological adaptions specific to *H. glaber*. These adaptions include: longevity, resistance to cancer, and unique sensory specializations such as a significant representation in the somatosensory cortex

dedicated to tactile inputs from the incisors. Because of these specializations, the use of *H. glaber* as a research animal model is becoming increasingly more common, enhancing the need for a more comprehensive understanding of its brain architecture. In this study, three significant calcium binding proteins were selected and used to characterize major structures in the brain based on previous analyses of other rodent species. Cresyl Violet (Nissl) was used along with immunohistochemistry techniques for calbindin-D28k, calretinin, and parvalbumin. Characterization of the distribution of these calcium binding proteins are being used to construct portions of a chemoarchitectonic atlas to facilitate brain-related studies involving *H. glaber*. Typical immunoreactivity in major regions of the brain will be shown and discussed for each protein, with comparisons made to other rodent species.

Title: Neuron-specific protein-coding genes are evolutionarily more conserved than genes specific to other brain cell types

Authors: *L. XU, S. DOS SANTOS, T. CAPRA, S. HERCULANO-HOUZEL;
Vanderbilt Univ., Nashville, TN

Abstract: There is high diversity in the morphologies and sizes of neurons across mammalian species and brain structures compared to other brain cell types such as glial cells. However, little is known about the potential genetic drivers of this diversity over evolutionary time scales. Could it be that protein-coding genes expressed in neurons are evolving more rapidly than the genes expressed by glial cells? To test this hypothesis, we quantified the evidence for natural selection on the sequence of ~2’000 brain cell type specific mouse genes, including genes specific to neurons, glial cells, glial subtypes, and endothelial cells. In particular, we computed the ratio of the rate of non-synonymous substitutions to the rate of synonymous substitutions (dN/dS) between mouse and 61 other species. If the diversityin neuronal sizes and morphologies is due to adaptive changes in protein-coding sequences, we would expect to see higher dN/dS scores for neuron-specific genes across a wide range of species in comparison with glial cell and endothelial cell-specific genes. Contrary to our expectation, neuron-specific genes are significantly more conserved than genes specific to endothelial cells, glial cells, and glial subtypes. We also found that neuron-specific genes are more conserved than glial cell-specific genes and endothelial cell-specific genes across a range of functional categories defined by Gene Ontology annotations. The abundance of microglia-specific immune system process related

genes, which have higher dN/dS scores, contributes to glial cell-specific genes' higher rate of evolution. Thus, other factors must explain why neuron-specific genes are more conserved while neurons are diverse in size and morphology, such as the important yet meticulous restoration of resting potential in neurons likely involving highly conserved genes, or the regulatory regions of neuron-specific genes being responsible for the diversity in neuronal morphology and size.

Title: Energy availability in the rat brain related to constrained capillary supply, not neuronal demand

Authors: *L. VENTURA-ANTUNES, M. DASGUPTA, L. WESOLOSKI, S. HERCULANO-HOUZEL;
Dept. of Psychology, Vanderbilt Univ., Nashville, TN

Abstract: What determines the metabolic rate of brain tissue: neuronal demand, blood availability, or both? To address this question, we use high-resolution confocal microscopy of sections through the entire rat brain to examine the relationship between local densities of neurons, of glial cells, and of capillary-associated cells (endothelial cells and pericytes) with measurements of the local rate of glucose use and blood flow in matching structures in the rat brain found in the literature. Previous results showed that local capillary density is linearly correlated with local rate of glucose utilization and blood flow across brain structures in the rat brain. However, those analyses did not examine whether glucose utilization and capillary density correlate with local density of neurons and glial cells, which would indicate demand-supply matching between the vascular bed and brain neurons. We find that local rates of glucose use and blood flow are linearly correlated with local densities of capillary-associated cells. Remarkably, local glucose utilization does not correlate with local density of neurons nor glial cells. Within an individual brain, neuronal density is highly variable across structures, whereas densities of glial cells and capillary-associated cells vary little across structures. As a consequence of the stable density of the capillary bed, the ratio of capillary-associated cells per neuron varies inversely across sites with the local density of neurons, such that neurons compete more intensely for a constant blood supply where there are more of them locally (i.e. where neuronal density is higher). We thus propose that it is not that larger neurons *require* more energy, but rather that they have more energy available to them because of decreased competition for limited blood

supply. Our results further suggest that the density of the capillary network is determined independently of neuronal activity, such that within the brain, neurons must adjust their metabolism according to the energy available. Consequently, the emergence of larger neurons, at lower neuronal densities, would result in fewer, larger neurons competing locally for energy, which might provide an evolutionary advantage to tissue function.

Title: Mosaic scaling of numbers of neurons in subcortical structures of bird and mammalian brains

Authors: *S. HERCULANO-HOUZEL;
Vanderbilt Univ., Nashville, TN

Abstract: Uncovering the mechanisms that led to the emergence of the large diversity of vertebrate brains requires examining brains of extant species for patterns that reveal the rules behind the origins of diversity. Comparative analyses of brain structure were for decades based on volumetric measurements. Analyses focusing on absolute structure size variation over several orders of magnitude emphasized similarities, and culminated with the influential concept of linked regularities in brain development and evolution. Later re-analyses of the same datasets, focusing instead on relative volumes, revealed that there are clade-specific variations in the relative size of certain structures, as if they had become uncoupled from others in those linked regularities, in what was termed mosaic evolution. Strikingly, the recent availability of data on the numbers of neurons that compose brain structures in a wealth of species has shown that the scaling of absolute or relative structure volume is a poor predictor of the scaling of numbers of neurons in the structure. So far, those data have focused on the cerebral cortex (pallium) and cerebellum, lumping together all other structures in the "rest of brain". Here I analyze the scaling of numbers of neurons in the subpallium, diencephalon, mesencephalon and hindbrain of 15 mammalian species (artiodactyls, marsupials and one afrotherian) and 24 bird species spanning a similar 100-fold range of numbers of neurons in the "rest of brain". Across mammals, the mesencephalon gains neurons more slowly than the hindbrain; the subpallium and diencephalon gain neurons slightly faster than the hindbrain; and in marsupials, but not in artiodactyls, the pallium has the fastest expanding population of neurons. This is strikingly different from birds: the bird mesencephalon gains neurons rapidly over the hindbrain, and the subpallium gains

neurons even more rapidly, faster even than the pallium. As a consequence, the subpallium of some parrots holds more neurons than even the elephant subpallium. This study reveals an unprecedented mosaicism of brain structure composition that is missed by volumetric analyses, and cautions strongly against evolutionary inferences made on the basis of brain structure volume across species.

Abstract: GABA is the main inhibitory neurotransmitter in the vertebrate brain. It binds to two sites on the $GABA_A$ receptors, causing channel opening and influx of chloride ions, and thereby leads to hyperpolarization. Benzodiazepines, used to treat insomnia and anxiety among other conditions, bind at a different site and enhance the effect of GABA. The $GABA_A$ receptors are pentamers whose subunits belong to the superfamily of cysteine-loop ion channels along with the nicotinic acetylcholine, glycine and 5-HT_3 receptor subunits. We have analyzed the $GABA_A$ gene family in the jawed vertebrates by combining phylogenetic and sequence-based analyses with comparisons of chromosomal synteny. The results show that the vertebrate ancestor had 7 subunit genes: two α and one each of β, δ, γ, π and ρ. The two rounds of genome doubling (1R and 2R) in early vertebrate evolution, as well as a local duplication of ρ after 2R, resulted in 20 genes in the gnathostome ancestor. One of these, which we have named π_2, has not been previously reported. This gene was lost in the mammalian ancestor. The teleost fish genome doubling (3R) resulted in 29 subunit genes in the teleost ancestor. Three of these were lost in zebrafish, resulting in 26 subunit genes in this experimentally important species. The θ and the ε genes in placental mammals that have undergone rapid evolutionary change, were found to be orthologous to β_4 and γ_4 respectively. We therefore suggest that they are renamed accordingly. A number of chromosomal translocations were resolved in these analyses. We also identified extra exons that may introduce additional sites of phosphorylation, if incorporated into the subunit in the M3-M4 intracellular loop, and compared these across species. We also provide an analysis of

key residues in the ion channel pore as well as at the GABA and benzodiazepine binding sites. These analyses indicate the ion channel pore is highly conserved and that the benzodiazepine binding site was formed gradually by changes that began after the split of the β/δ/π/ρ ancestor from the α/γ ancestor and continued in the γ_2 gene until the split of lobe-finned and ray-finned fishes. These results will serve as a framework for understanding the functional specialization of the many $GABA_A$ subunits.

Title: Distribution of $GABA_A$ receptor subunits in the monkey fore brain

Authors: ***G. SPERK**[1], E. KIRCHMAIR[1], I. KONDOVA[2];
[1]Dept. of Pharmacol., Med. Univ. Innsbruck, Innsbruck, Austria; [2]Div. of Pathology and Microbiology, Biomed. Primate Res. Ctr., Rijswijk, Netherlands

Abstract: $GABA_A$ receptors are composed of five subunits arranged around a central chloride channel. Their subunits originate from different genes or gene families. The majority of $GABA_A$ receptors in the brain consist of two α-, two β-subunits and one γ- or δ-subunit. This subunit constitution crucially determines the physiological and pharmacological properties of the $GABA_A$ receptors. Using immunhistochemistry we investigated the distribution of 10 $GABA_A$ receptor subunits (α1, α2, α3, α4, α5, β1, β2, β3, γ2 and δ) in the fore brain of three female Rhesus macaques. Within the cerebral cortex subunits α1, α5, β2, β3 and γ2 were abundant and distributed through all layers, whereas α2, α3 and β1 were more concentrated in the inner and outer layers of the cortex. The caudate/putamen was rich in α1, α2, α5, all three β subunits notably β2 and β3 and γ2 and δ. Subunits α3 and α5 were considerably more concentrated in the caudate than in the putamen. In contrast, subunits α3, α4, α5, β1, β2 (notably not β3), γ2 and δ were the most abundant ones in the globus pallidus. Subunits α1, α5, β1 and γ2 were the most abundant ones in the substantia nigra. In most thalamic nuclei α1, α2, β3 and γ2 were highly expressed. Within the amygdala, high concentrations of subunits α1, α2, α3, β1 and γ2 were found in the cortical nucleus, whereas in the lateral, basal and basolateral amygdala α1, α2, α5, β1, β2, β3 and δ, and in the central amygdala α1, α2, α3, and γ2 were most abundant. Interestingly, subunit α3-IR outlined intercalated nuclei of the amygdala. In the hippocampus, subunits α1, α2, α4, β2, β3, γ2 and δ were highly expressed in the molecular layer of the dentate

gyrus. Subunits α1, α2, α3, α5, β2, β3, γ2 were most abundant in sector CA1 and the subiculum. The distribution of $GABA_A$ receptor subunits in the monkey was similar as the one in the rat and mouse. Overall subunit α4 was only expressed at low concentrations. We did not detect subunit γ1 e.g. in the substantia nigra. We thank Karoline Fuchs and Werner Sieghart from the Medical University Vienna for supplying the antibodies.

Title: Glycine alpha2-containing receptors in de the developing striatum of mice

Authors: *J.-M. RIGO[1], J. COMHAIR[1], J. DEVOGHT[1], S. N. SCHIFFMANN[2], G. MORELLI[1], R. J. HARVEY[3], D. GALL[2], B. BRÔNE[1];
[1]Hasselt Univ., Hasselt, Belgium; [2]Univ. libre De Bruxelles (ULB), Brussels, Belgium; [3]UCL Sch. of Pharm., London, United Kingdom

Abstract: In this research, we set out to find the presence of the glycine receptor in the early developing striatum and more specifically within the MSN population. We found that the glycine receptor alpha 2 ligand binding subunit (GlyRα2) is already present at E13.5. The GlyRα2 is also seen in neuronal precursors that are still proliferating. The number of postnatal MSNs is reduced in GlyRα2KO mice compared to wild-types, which could be potentially explained by altered mitotic profile at E13.5 and unsuccessful compensation at E16.5. The two important CCCs are also affected it the absence of embryonic glycinergic signalling. At E13.5, we can hypothesize that the chloride driving force is higher in the WT embryos, which could potentially explain, via calcium-related excitability, the increased activation of CREB. This is opposite at E16.5 where we found an increase in the inward chloride transporter NKCC1 that occurs concurrently with an increase in CREB activation in the GlyRα2KO LGE. Furthermore, relatively mild phenotypic changes were observed in the GlyRα2KO mice at early postnatal ages that could be of multifactorial nature.

Title: Influence of the N265M mutation on intrinsic kinetics of α5β2γ2L GABAA receptors

Authors: *S. KLEIN, C. LOR, R. A. PEARCE;
Anesthesiol., Univ. of Wisconsin-Madison, Madison, WI

Abstract: Background: GABAA receptors containing α5 subunits (α5-GABAARs) are essential for etomidate-induced amnesia. This subunit partners with β2 or β3 subunits, and mice carrying mutations in these subunits have been used to study mechanisms of general anesthetic action. A mutation of the β-subunit, N265M, has been found to eliminate the effect of etomidate on the receptor. However, we (SFN abstracts 2019) and others have found that even under drug-free conditions these mutant mice exhibit impaired memory. Therefore, we sought to characterize changes in intrinsic receptor properties caused by the β2(N265M) mutation. Additionally, we sought to confirm that the β2N265M mutation does confer insensitivity to etomidate.
Methods: HEK293 cells were transfected with cDNA encoding α5β2γ2L (WT) or α5β2(N265M)γ2L (MUT) at a ratio of 1α:1β:3γ with eGFP co-transfected to identify cells with successful transfection. A brief pulse of GABA (10 mM, 10 ms) was applied to outside-out patches via a multibarrel pipette mounted on a piezoelectric stage. Several responses (5-10) were averaged for analysis. Activation and deactivation were characterized by 10-90% rise time and fits to a biexponential decay function.
Results: MUT receptors deactivated more rapidly than WT, with a weighted time constant (tau-wt) of 60 ± 7.0 ms (MUT, mean ± SE) vs. 107 ± 9.6 ms (WT; p=0.002). This difference reflected an increase in the relative fraction of the fast component of biexponential decay (WT 0.60 ± 0.02 vs. MUT 0.68 ± 0.02; p=0.025) as well as the time constants (WT 41 ± 3.4 vs MUT 22 ± 2.1 tau-fast; p=0.0007, WT 211 ± 22 vs MUT 137 ± 14 tau-slow; p=0.02). In addition, the rise time was faster in the WT (1.20 ± 0.13 ms) than the MUT receptor (1.6 ± 0.7 ms; p=0.019). As expected, etomidate (1 uM) slowed deactivation of WT (tau-wt ETOM/CTRL = 267.8 ± 14.1%; p=0.000021) but not MUT receptors (111.9 ± 13.5%, p=0.4684).
Conclusion: Our findings show that the N265M mutation in the β2 subunit substantially affects the kinetics of the GABAA receptor by increasing the rate at which the receptor deactivates and decreasing the rate of activation. These alterations in intrinsic kinetics may be sufficient to significantly impair memory in mutant mice (SFN abstracts 2019) even in drug-free conditions.

Title: Feedback signaling from horizontal cells to cone photoreceptors in mammalian retina mediated by GABA-induced pH changes

Authors: ***S. A. BARNES**[1,2], J. C. R. GROVE[3], A. A. HIRANO[2], N. C. BRECHA[2]; [1]Doheny Eye Inst., Los Angeles, CA; [2]UCLA, Los Angeles, CA; [3]Univ. of California, San Francisco, San Francisco, CA

Abstract: Hybrid actions of GABA pit a classical neurotransmitter system together with proteins that change the alkaline milieu within the photoreceptor synaptic cleft to mediate horizontal cell feedback signaling to photoreceptors. This mechanism is responsible for enhancing key features of temporal and spatial contrast adaption (e.g., synaptic gain control and receptive field antagonism). It has been shown that mammalian horizontal cells respond via rho-subunit containing GABA receptors to their own persistent GABA release, and that the results of this autaptic action affect cone Ca channel gating through changes in pH as a result of the high bicarbonate permeability of the GABA receptor anion channels. The magnitude of bicarbonate efflux is dictated by the driving force on this anion, which has an equilibrium potential near -15 mV. The rate of efflux changes rapidly in response to horizontal cell membrane potential, with depolarization causing reduced efflux, which increases acidity, and hyperpolarization causing greater bicarbonate efflux, which increases cleft alkalinity. In addition, steady-state activation of these GABA receptors can contribute to depolarization of horizontal cells, which increases cleft acidity via sodium/hydrogen exchanger proton extrusion, an action resulting in cone Ca channel inhibition via surface charge effects. But this inhibition is effectively counteracted during broad field illumination when horizontal cells are sufficiently hyperpolarized, which increases bicarbonate efflux that alkalinizes the cleft and disinhibits cone Ca channels. **System Modulation:** The hybrid actions of GABA operate in parallel to effect voltage-dependent pH changes, a novel mechanism for regulating presynaptic output. In addition, the GABA-pH hybrid system is modified by the adaptation signal, dopamine. Whereas under fully dark-adapted light levels, application of the GABA agonist muscimol disinhibits calcium channel activation in cones, when the slices are incubated in dopamine (5 µM), the polarity of this response is

reversed. Several likely sites of action may account for the dopamine-induced sign change: D1 receptor and D2 receptor activation modulates calcium channels, glutamate receptors, and GABA receptors, as well as other membrane proteins. This means that signaling from horizontal cells to photoreceptors is dependent on modifiable parameters that regulate feedback properties, enabling the system to be adjusted for different states of light adaptation.

Title: Regulation of tonic and phasic inhibition by phosphorylation of α5-$GABA_A$ Receptors

Authors: *C. KIVISILD, D. P. BRIGHT, T. G. SMART;
Neuroscience, Physiol. & Pharmacol., Univ. Col. London, London, United Kingdom

Abstract: In the adult brain, the main role for γ-aminobutyric acid receptors ($GABA_ARs$) is to control neural excitability via a combination of transient phasic and persistent tonic inhibition. Phasic inhibition is mediated by receptors located at inhibitory synapses, while extrasynaptic receptors give rise to tonic inhibition. These two forms of inhibition are known to have distinct functional characteristics that differentially impact upon their control of neuronal excitation. Receptors containing the α5 subunit (α5-$GABA_ARs$) exhibit properties that associate with both forms of inhibition and due to their predominant location in the hippocampus, these receptors are thought to play a significant role in learning and memory. Several selective negative and positive allosteric modulators (NAM/PAMs) of α5-$GABA_ARs$ have been proposed as therapeutic targets for cognitive dysfunction associated with disorders such as Down syndrome, Alzheimer's disease, schizophrenia and autistic spectrum disorder. However, it is unclear how phasic and tonic inhibition, mediated by α5-$GABA_ARs$ in the hippocampus are proportionately regulated. Using whole-cell patch clamp recording and structured illumination microscopy (SIM) in cultured hippocampal neurons, we show that phosphorylation of the α5 subunits can alter the cell surface location of these receptors and thus regulate distinct forms of GABA-mediated inhibition. We propose that the underlying molecular mechanism behind these changes is altered binding between phosphorylated α5-$GABA_ARs$ and inhibitory synapse scaffold proteins. Although there are several drugs that target α5-$GABA_ARs$, a greater understanding of the molecular mechanisms by which neurons control the accumulation of $GABA_ARs$ at synaptic or

extrasynaptic sites and thus regulate phasic and tonic inhibition respectively, is needed in order to elucidate the role of α5-$GABA_A$Rs in cognition.

Title: Targeting extrasynaptic gammaaminobutyric acid receptors to prevent and reverse opioid antinociceptive tolerance in mice

Authors: K. GENARO, R. F. YOSHIMURA, D. HOGENKAMP, T. B. C. JOHNSTONE, *K. W. GEE;
Pharmacol., Univ. of California Irvine, Irvine, CA

Abstract: Tolerance to the analgesic effect is the main side effect of chronic administration of opioids. Several drugs have been studied to try to find agents to prevent the development of this phenomenon. Research on a relatively new class of agents known as neurosteroids has revealed novel modulatory sites and mechanisms of action that are providing insights into the pathophysiology of pain. In the present study we aimed to evaluate the effect of different compounds targeting α4β3δ $GABA_A$ receptors on morphine-induced tolerance to its analgesic effect. Groups of male mice were randomly assigned to groups that received daily morphine (10 mg/kg, subcutaneously) in combination with enaminone 2-261 (10 mg/kg, intraperitoneally) or 2-261 vehicle twice daily. 2-261 is a non-steroidal positive allosteric modulator of extrasynaptic receptors with similar efficacy as the prototypical neurosteroids allopregnanolone and ganaxolone. Nociception was measured using the warm water tail immersion test and the tail flick latency was recorded. Treatments and evaluations continued (15 days) until tolerance developed to the analgesic effect of morphine. The second aim of this study was to investigate the acute effect of compounds that modulate α4β3δ $GABA_A$ receptors on morphine antinociceptive tolerance including 2-261 (3 mg/kg), ganaxolone (10 mg/kg), etifoxine (50 mg/kg; modulates $GABA_A$ receptors via stimulation of neurosteroid production) and 2-301 (20 mg/kg), a compound that has negligible efficacy at α4β3δ $GABA_A$ receptors relative to 2-261. Our findings indicated that full tolerance was achieved following 9 days of morphine administration, while 2-261 pre-treatment (chronic) was able to prevent tolerance. Moreover, acute administration of 2-261 on day 9 reversed the morphine-induced tolerance. Similarly,

etifoxine reversed morphine tolerance on a different time course compared to 2-261; ganaxolone attenuated the analgesic tolerance to morphine but did not restore full analgesia; and 2-301 treatment did not significantly affect morphine-induced tolerance. Our findings suggest that α4β3δ $GABA_A$ receptors may be a promising pharmacological target to prevent or reverse morphine-induced tolerance to its analgesic effect.

Title: MicroRNA regulation of inhibitory synaptic plasticity

Authors: *D. RAJGOR[1], A. M. PURKEY[1], T. M. WELLE[1], J. D. GARCIA[2], M. DELL'ACQUA[1], K. R. SMITH[1];
[1]Pharmacol., Univ. of Colorado, Denver, Aurora, CO; [2]Pharmacol., Univ. of Colorado, Anchutz, Aurora, CO

Abstract: The molecular mechanisms underlying the long-term post-synaptic plasticity of inhibitory synapses is poorly characterized. Recruitment and clustering of $GABA_AR$s at the inhibitory post-synaptic domain is a major mechanism which rapidly increases inhibition in the brain during inhibitory Long-Term Potentiation (iLTP). However, it is unclear how $GABA_AR$s are maintained at the surface in a manner which sustains iLTP. We show protein synthesis via miRNA regulation is important for maintaining persistent iLTP. We identify novel roles for miRNAs in silencing *GABRA1* and *GABRG2*, which encode for the important synaptic $GABA_AR$ sub-units $GABA_AR\alpha1$ and $GABA_AR\gamma2$ respectively. During chemical-iLTP, miRNA down-regulation promotes increased translation and maintenance of surface $GABA_AR\alpha1$ and $GABA_AR\gamma2$. This pathway is essential for chemical-iLTP and can be blocked by miRNA overexpression which impairs inhibitory neurotransmission. Finally, we show *de novo* synthesis of $GABA_AR\alpha1$ occurs exclusively in dendrites during chemical-iLTP, which supports plasticity-induced local translation of $GABA_AR$s.

Title: GABAergic interneurons in mice excite neonatal hippocampus but inhibit isocortex

Authors: Y. MURATA[1], ***M. T. COLONNESE**[2];
[1]Pharmacol. and Physiol., George Washington Univ., Washington, DC; [2]Pharmacol. and Physiol., The George Washington Univ. Sch. of Med., Washington, DC

Abstract: Low expression of the neuronal K-Cl co-transporter KCC2 during development renders $GABA_A$ receptors depolarizing and sometimes excitatory in excised tissue preparations. Recent studies in mice suggest that GABA and GABAergic interneurons are inhibitory in isocortex and hippocampus *in vivo* during the first postnatal week. However, the role of local interneurons in regulating excitability of cortical circuits *in vivo* has not been directly examined. Here we investigated the role of GABAergic neurons in early cortical and hippocampal network activity using chemogenetics and *in vivo* electrophysiology. Chemogenetic receptors (KORD for suppression of activity and hM3Dq for its enhancement), were expressed in GABAergic neurons by locally injecting Cre-dependent AAVs into the visual cortex or hippocampus of GAD2-Cre mice on postnatal day (P) 0-1. This approach allowed us to bi-directionally manipulate activity of GABAergic neurons in un-anesthetized mice as early as P3, while simultaneously monitoring LFP and neuronal firing using multi-electrode recordings. In the hippocampus, suppressing GABAergic neuron activity on P3 *decreased* multi-unit firing rates in the pyramidal cell layer of CA1 by ~50% and reduced the amplitude of early sharp waves. Enhancing GABAergic neuron activity *increased* firing rates by ~150% with no effect on sharp wave amplitude. On P7, this 'excitatory' effect of GABAergic neurons was no longer observed: suppression of GABAergic neurons increased firing rates in the pyramidal cell layer ~200%, while increasing GABAergic activity reduced firing by ~75%. By contrast, in the visual cortex, suppressing GABAergic neuron activity on P3 increased cortical multi-unit firing rates by ~300% without substantially altering the frequency of spontaneous spindle-burst oscillations. Enhancing GABAergic neuron firing decreased network firing by ~60%. This inhibitory effect of interneurons was also present at P7. An excitatory effect of hippocampal interneurons was observed in CA1 only when viral expression was restricted to hippocampus. Widespread expression within cortex in addition to hippocampus resulted in and 'inhibitory' interneuron action at P3, suggesting that reduced activity in cortex, which provides the major input to neonatal hippocampus, can swamp local excitation by interneurons in CA1 on P3. Our results reveal regionally diverse roles for

GABAergic interneurons in modulating excitability in cortical structures during development. They further suggest that regardless of their inhibitory or excitatory effect, interneurons are not critical for the normal patterning of spontaneous activity during circuit formation.

Title: Anesthetic drug activation of $GABA_A$ receptors in astrocytes drives a persistent increase in extrasynaptic $GABA_A$ receptor function in neurons

Authors: *A. PINGUELO[1], K. KANESHWARAN[1], G. LEI[1], D.-S. WANG[1], B. A. ORSER[1,2,3];
[1]Physiol., [2]Anesthesia, Univ. of Toronto, Toronto, ON, Canada; [3]Anesthesia, Sunnybrook Hlth. Sci. Ctr., Toronto, ON, Canada

Abstract: We have previously shown that a brief exposure to commonly used general anesthetic drugs triggers a sustained increase in cell-surface expression of extrasynaptic $GABA_A$ receptors ($GABA_ARs$) in hippocampal neurons. The resulting increase in inhibition causes subtle, yet sustained postanesthetic cognitive deficits. Interestingly, astrocytes are necessary to trigger this overexpression of $GABA_ARs$; however, the mechanisms underlying this cross-talk with neurons are unknown. In addition, the proinflammatory cytokine IL-1β also increases cell-surface expression of extrasynaptic $GABA_ARs$ via a p38 mitogen-activated protein kinase (p38 MAPK) signaling pathway. Further, anchoring of extrasynaptic $GABA_ARs$ to the cell membrane is regulated by the phosphorylation of radixin. As astrocytes express anesthetic-sensitive $GABA_ARs$, we hypothesize that anesthetic drugs activate $GABA_ARs$ in astrocytes and stimulate the release of IL-1β, which acts via a p38 MAPK- and radixin-dependent signaling pathway to increase cell-surface expression of extrasynaptic $GABA_ARs$ in neurons. Cultured hippocampal neurons and cortical astrocytes were prepared from fetal mice. Whole-cell voltage clamp recording was used to measure tonic inhibitory current mediated by extrasynaptic $GABA_ARs$ in neurons. Astrocyte cultures were treated with the anesthetic etomidate (1 μM) +/- the $GABA_AR$ antagonist bicuculline (20 μM) for 1 h, then washed. Two hours later, the astrocyte-conditioned media was applied to the neurons and 24 h later, tonic current was recorded in neurons. In further

experiments, conditioned media from etomidate-treated astrocytes was applied to neurons +/- an IL-1 receptor antagonist (IL-1ra, 100 ng/ml) or an inhibitor of p38 MAPK (SB203,580, 20 μM). Also, mice were injected with etomidate (8 mg/kg, i.p.) or vehicle then IL-1β, p38 MAPK, and radixin levels in the hippocampus were studied 24 h later through Western blot. The results showed that bicuculline prevented the etomidate-induced increase in tonic current in neurons (n=10-12). Furthermore, IL-1ra and SB203,580 also prevented this effect of etomidate (n=9-13). Etomidate increased the levels of IL-1β, phosphorylated p38 MAPK, and phosphorylated radixin (n=3-4). Thus, anesthetic activation of $GABA_A$Rs in astrocytes triggers a sustained increase in extrasynaptic $GABA_A$R function in hippocampal neurons via a pathway of IL-1β, p38 MAPK and radixin. Our results identify a novel cross-talk mechanism between astrocytic $GABA_A$Rs and neuronal $GABA_A$Rs that might be targeted to mitigate postanesthetic cognitive deficits.

Title: Mis-trafficking of $GABA_A$ receptor subunits in mouse models of autism spectrum disorder

Authors: C. CHOI, J. L. SMALLEY, Q. REN, S. J. MOSS, ***P. A. DAVIES**;
Neurosci., Tufts Univ. Sch. of Med., Boston, MA

Abstract: Tonic and phasic inhibition arise from activation of extrasynaptic and synaptic $GABA_A$Rs respectively. Extrasynaptic and synaptic $GABA_A$Rs are comprised of different subunit combinations which instills unique biophysical and pharmacological properties upon the receptors. While tonic inhibition controls overall excitation of the neurons, phasic inhibition is important for information processing. Because of their distinct functions, tonic and phasic

inhibition requires precise trafficking of $GABA_A$Rs to their discrete locations. The trafficking of α4-containing extrasynaptic $GABA_A$Rs in healthy and pathological states remains unknown. We have examined the Fragile X model, *Fmr1 KO,* and the autistic model, β3 S408/9A, and found that compared to wild-type (WT) mice, *Fmr1 KO* and β3 S408/9A mice had a deficit in tonic current while phasic inhibition has increased amplitude and decay time. We hypothesized that in ASD α4-containing $GABA_A$Rs can be mis-trafficked from the extrasynaptic space to synaptic regions *Methods*. We used whole-cell patch-clamp to measure phasic and tonic currents from dentate gyrus granule cells (DGGCs) in hippocampal slices from male WT, Fmr1 *KO*, and β3 S408/9A mice. We also isolated native α4 and α1 subunit-containing $GABA_A$Rs from the cortex and hippocampus of *Fmr1 KO,* β3 S408/9A and WT mice and analyzed their subunit composition, and the associated proteins these $GABA_A$Rs are associated with using liquid chromatography coupled with mass spectroscopy (LC-MS/MS). *Results.* Using the α4βγ2 specific benzodiazepine Ro15-4513, phasic currents from Fmr1 KO mice were modulated whereas those from WT remained unaltered. Additionally, we observed an increase in α4 subunit immunoreactivity at gephyrin positive structures in hippocampal slices from brains of *Fmr1 KO* mice. Results from the LC-MS/MS studies demonstrate that in WT mice α1 and α4 $GABA_A$Rs are mutually exclusive, however they form mixed receptors in *Fmr1 KO* mice causing an association of the α4 subunit with synaptic proteins. *Conclusion.* Pathological mis-trafficking of α4 subunits to GABAergic synapses depletes extrasynaptic GABAARs to reduce tonic inhibition, alters phasic inhibition, causing an increase in neuronal activity. Aberrant trafficked GABAARs are a potential novel therapeutic target that could reverse excessive circuit excitation by reversing tonic inhibition deficits.

Title: δ-subunit containing $GABA_A$ IPSCs are driven by both synaptic and diffusional GABA in mouse dentate granule neurons

Authors: *M.-Y. SUN[1], L. ZIOLKOWSKI[1], A. BENZ[1], S. MENNERICK[1,2];
[1]Psychiatry, [2]Taylor Family Inst. for Innovative Psychiatric Res., Washington Univ. in St. Louis, St. Louis, MO

Abstract: $GABA_A$ receptors are the major inhibitory neurotransmitter receptors in the central nervous system. Two distinct $GABA_AR$ classes are those containing a δ subunit (δ receptors) and those with a γ2 subunit. The decay time constants from δ IPSCs are slower than those from γ2 IPSCs, but the reasons are unclear. Slower δ IPSCs could represent transmitter diffusion, rebinding, or slow deactivation kinetics of channels. We used gene editing to confer picrotoxin resistance on the δ subunit in mice, and pharmacologically isolated δ receptors in dentate granule cells to explore IPSCs. We also used rapid application of GABA onto nucleated patches from dentate granule cells to explore deactivation kinetics. To differentiate the effects of diffusion vs local/synaptic GABA on δ IPSCs, we applied 5% dextran to reduce GABA diffusion, thereby enhancing local synaptic [GABA] and slowing/reducing access to extrasynaptic receptors. Dextran accelerated the decay and increased the peak amplitude of evoked δ IPSCs, suggesting that the peak amplitude is driven by non-saturating synaptic GABA, while the decay may normally be driven by some GABA escape to distal extrasynaptic δ receptors. Dextran also increased the peak amplitude of evoked γ2 IPSCs but did not alter γ2 IPSC decay, suggesting peak amplitude of evoked γ2 IPSCs is also driven by unsaturating synaptic GABA, with little or no GABA diffusional effects on the decay. Dextran had no effect on spontaneous γ2 or δ IPSC decay or peak amplitude, suggesting that GABA actions during spontaneous IPSCs (sIPSCs) are local for both receptor types, although frequency of δ sIPSCs is low, suggesting that many synapses may not contain appreciable δ. The slower decay of δ sIPSCs compared with γ2 sIPSCs might result from slower deactivation of δ receptors. To examine this, we used rapid iontophoretic application of varied [GABA] onto nucleated patches. PTX-isolated δ currents activated by either iontophoresis or by theta-tube application exhibited a deactivation rate equivalent to that of sIPSCs, consistent with the idea that deactivation and local GABA actions drive sIPSCs. Overall, our results indicate that δ IPSCs are driven by both synaptic and diffusional GABA, and are only slightly more sensitive to altered GABA diffusion than γ2 IPSCs. Our results are consistent with a relationship between δ and γ2 $GABA_A$ receptors akin to that of NMDA and AMPA receptors at glutamate synapses.

Title: Neurosteroids, $GABA_A$ receptors, and neuronal synchrony

Authors: *X. LU[1], P. LAMBERT[1], A. BENZ[1], C. F. ZORUMSKI[1], J. H. STEINBACH[2], S. J. MENNERICK[1];

Abstract: Electrical oscillations reflecting the synchronized activity of large numbers of neurons play key roles in learning, memory, and cognition. Abnormal synchrony underlies seizures. In rodent hippocampal slices, electrical oscillations are chemically induced by activating kainate receptors or muscarinic acetylcholine receptors. Nevertheless, the oscillations are eliminated by the application of $GABA_A$ receptor antagonists, indicating an essential role of inhibitory neurotransmission in neuronal synchrony. The role of subsets of $GABA_A$ receptors in generating neuronal synchrony in hippocampus represents an attractive object for study, given the role of oscillations in normal and abnormal brain function. We introduced a mutation in the mouse $GABA_A$ receptor γ2 subunit gene that slightly accelerates IPSC decays. The γ2 mutation in fact entirely prevented oscillations induced by kainate (200 nM) and blocked by picrotoxin/gabazine in WT CA3 region of slices. To test whether the deficit directly results from faster IPSCs, we prolonged IPSCs pharmacologically with allopregnanolone (3α5αP, 100 nM). As expected, 3α5αP increased the power of oscillations in WT tissue. By contrast, 3α5αP did not restore kainate induced oscillations in γ2 mutant hippocampus. We conclude that yet-to-be defined developmental changes may contribute to the deficits in synchrony observed in γ2 mutant animals. Overall, our results likely have relevance the impact of inhibition in abnormalities of brain function, including epilepsy.

Title: Subtle changes to IPSC kinetics have profound implications on larger scale brain activity

Authors: *P. M. LAMBERT, M. KEISER, M.-Y. SUN, L. ZIOLKOWSKI, H. SHU, A. BENZ, S. MENNERICK;
Washington Univ. in St Louis, St Louis, MO

Abstract: We have generated a mouse line carrying a point mutation (T6'Y) in the γ2 subunit of $GABA_A$ receptors (γ2*) to precisely alter synaptic inhibition. The presence of the γ2* subunit renders the receptor resistant to the nonselective antagonist picrotoxin allowing for the confirmation of the presence of the mutant receptors in a recording. We observe that the γ2* mutation speeds up the decay kinetics of $GABA_A$ responses in N2A cells as well as the decay kinetics of dentate granule cell and CA1 pyramidal cell IPSCs in γ2* homozygote mice. While the effects of γ2* seem limited to receptor deactivation kinetics on the cellular level, we find large changes in the EEG of γ2* mice. When compared to wild-type littermates, γ2* homozygotes exhibit a significant increase in total spectral power, slowing of the theta rhythm, and suppression of gamma power during active exploration. Additionally, γ2* mice show a lack of normal theta-gamma phase amplitude coupling, indicating that these mice have significant deficits in producing coordinated neural activity. Finally, γ2* mice exhibit severe deficits in prepulse-inhibition of the startle response. Taken together, these results show that even slight perturbations of synaptic inhibition can have a significant impact on larger scale brain activity.

Abstract: In the mammalian central nervous system $GABA_A$ receptors ($GABA_A$Rs) mediate the majority of fast inhibitory transmission and serve as major targets for the treatment of a number of neurological and psychiatric disorders, including epilepsy, anxiety and sleep disorders. In addition, impaired GABAergic transmission has been implicated in the pathogenesis of many neurological/psychiatric illnesses and modulating inhibitory tone through the benzodiazepine-binding site of $GABA_A$Rs is an effective therapeutic strategy for several mood disorders. Thus, it

is important to understand the molecular mechanisms underlying the regulation of $GABA_AR$ trafficking, function and pharmacology in the brain. We have characterized a $GABA_AR$ associated protein and examined its regulation of $GABA_AR$ synaptic abundance, channel kinetic properties, and pharmacology. Functional investigations in gene knockout mice, including synaptic physiology and behavioral analysis, indicate the importance of this molecule in controlling inhibitory transmission and benzodiazepine-induced sleep.

Title: Mannitol decreases neocortical epileptiform activity during early brain development via co-transport of chloride and water

Authors: E. DUQUETTE[1], N. RAHMATI[1], K. DUQUETTE[1], K. J. STALEY[1], ***J. GLYKYS**[2]; [1]Massachusetts Gen. Hosp., Boston, MA; [2]Univ. of Iowa. Carver Col. of Med., Iowa City, IA

Abstract: Seizures and brain injury result in water and Cl^- accumulation in neurons. Neocortical neuronal membranes have a low water permeability as they lack aquaporins necessary to move free water. Instead, neurons use cotransport of ions including Cl^- to move water. Thus, increasing the extracellular osmolarity during seizures should result in an outward movement of water and salt, reducing $[Cl^-]_i$ and improving $GABA_A$ receptor-mediated inhibition. We tested the effects of hyperosmotic therapy with a clinically relevant dose of mannitol (20 mM) on epileptiform activity, spontaneous multiunit activity (sIPSCs), $[Cl^-]_i$, and neuronal volume in layer IV/V of the developing neocortex of C57BL/6 and Clomeleon mice. Using electrophysiological techniques and multiphoton imaging in acute brain slices (post-natal day 7-12) and organotypic neocortical slice cultures, we observed that mannitol: 1) decreased epileptiform activity, 2) decreased neuronal volume and $[Cl^-]_i$ through CCCs, 3) decreased spontaneous multi-unit activity frequency but not amplitude, and 4) restored the anticonvulsant efficacy of the $GABA_A$ receptor modulator diazepam. We conclude that an increase in extracellular osmolarity by mannitol mediates the efflux of $[Cl^-]_i$ and water through CCCs, which results in a decrease in epileptiform activity and enhances benzodiazepine actions in the developing neocortex in vitro.

Novel treatments aimed to decrease neuronal volume may concomitantly decrease $[Cl^-]_i$ and improve seizure control.

Title: Potassium chloride cotransporter-2 is an important facilitator for epileptogenesis

Authors: *Y. WANG;
State Key Lab. of Med. Neurobio. and MOE Frontiers Ctr. for Brain Sci., Fudan Univ., Shanghai, China

Abstract: $GABA_A$ receptor-mediated inhibition depends on the maintenance of low level intracellular $[Cl^-]$ concentration, which in adult depends on neuron specific K^+-Cl^- cotransporter-2 (KCC2). Previous studies have shown that KCC2 was downregulated in both epileptic patients and various epileptic animal models. However, the temporal relationship between KCC2 downregulation and epileptogenesis is still unclear. In this study, we explored the relationship and the influence of KCC2 downregulation on epileptogenesis. Both pilocarpine and cyclothezide induced *in vivo* and *in vitro* epilepsy models were used in this study. Patch clamp electrophysiology, western blotting and immunohistochemistry were used to detect the structure and functional change of hippocampal neurons during epileptogenesis. Our results showed that significant downregulation of plasma membrane KCC2 was directly associated with severe (Racine Score III and above) behavioral seizures *in vivo*, and interestingly, occurred before the epileptiform bursting activities. Suppression of membrane KCC2 expression by $shRNA_{KCC2}$ both *in vitro* and *in vivo*, induced spontaneous epileptiform bursting activities and seizure behavior. Furthermore, either overexpression of KCC2 using KCC2 plasmid or blockade of KCC2 down regulation with Frusemide, a KCC2 inhibitor, effectively enhanced the resistance to convulsant stimulation induced epileptiform activities. In addition, blockade of KCC2 down regulation both in acute and silent period prevented the occurrence of chronic seizure. In conclusion, our findings demonstrated that altered expression of KCC2 is not the consequence, but likely is the contributing factor for both induction and progression of chronic seizure.

Abstract: NKCC1 is the primary transporter mediating chloride uptake in immature principal neurons, but its role for network dynamics in the developing brain remains controversial. To address this question, we generated mice lacking NKCC1 in the vast majority of forebrain glutamatergic cells. Using a combination of electrophysiological and optical approaches *in vitro* and *in vivo*, we demonstrate that NKCC1-dependent GABAergic depolarization promotes spontaneous network activity during early postnatal development in a model-, event type- and region-specific manner. Unexpectedly, long-term effects of a chronic absence of NKCC1 on synaptic development, network dynamics and behavioral performance are subtle or absent. Our data provide evidence for a neural network function of NKCC1 in the immature hippocampus *in vivo* and, at the same time, challenge the idea that NKCC1 expression by cortical principal neurons is indispensable for major aspects of hippocampal development.

Title: Role of psychosine in cognitive deficits in the Krabbe brain (KD)

Authors: *R. REBIAI[1], M. MARSHALL[1], M. PERGANDE[2], D. NGUYEN[1], S. COLOGNA[2], M. I. GIVOGRI[1], E. R. BONGARZONE[1];
[1]Anat. and Cell Biol., [2]Dept. of Chem., Univ. of Illinois At Chicago (UIC), Chicago, IL

Abstract: The abnormal assembly and loss of synaptic components cause synapses to fail maintaining cell-to-cell communication. This synaptic failure usually leads to synaptic death, largely irreversible, which is the basic contributor to cognitive impairment in neurological diseases. In Krabbe disease (KD), a lysosomal deficiency of galactosylceramidase that causes toxic accumulation of psychosine in membranes, severe cognitive impairment is observed. However, it is unknown whether synaptic dysfunction contributes to cognitive problems in KD. We hypothesize that the gradual accumulation of psychosine in the membrane of Krabbe synapses disrupts lipid rafts, altering the assembly of synaptic components and signaling, and lead to synaptic failure and cognitive decline. Using Golgi Cox staining, we found a significant decrease in the number of dendritic spines in cortical neurons of sick twitcher mice, the natural mouse model for KD. Electron microscopy data confirmed ultrastructural alterations in KD synapses, with reduced contact area and lower number of synaptic vesicles, in parallel to increased levels of psychosine in the pre and post-synaptic membrane. Western blotting also showed altered levels and subcellular localization of the synaptic scaffolding protein, PSD-95, suggesting abnormal assembly of synaptic components. These results provide direct evidence that synapses are structurally disrupted in KD, which may contribute to the severe cognitive impairment observed in Krabbe patients. Ongoing studies are evaluating how psychosine accumulation may involve local changes in the stability and fluidity of synaptic membranes, altering lipid raft synaptic function and promoting some of the ultrastructural changes observed in our experiments.

Title: Human glycine receptor autoantibodies disrupt inhibitory neurotransmission

Authors: *S. J. CRISP[1,2], C. L. DIXON[2], L. JACOBSON[3], E. CHABROL[2], A. VINCENT[3], D. M. KULLMANN[2];
[1]Univ. of Cambridge, Cambridge, United Kingdom; [2]Dept. of Clin. and Exptl. Epilepsy, Inst. of Neurol., London, United Kingdom; [3]Nuffield Dept. of Clin. Neurosciences, Univ. of Oxford, Oxford, United Kingdom

Abstract: Chloride-permeable glycine receptors have an important role in fast inhibitory neurotransmission in the spinal cord and brainstem. Human autoantibodies to glycine receptors are found in a substantial proportion of patients with progressive encephalomyelitis with rigidity and myoclonus (PERM), and in other variants of stiff person syndrome (SPS). The symptoms of PERM/SPS could be explained by a failure of inhibitory neurotransmission, and at least some patients respond to immunotherapies. However, it remains unknown whether and how glycinergic neurotransmission is impacted by autoantibody binding. We purified immunoglobulin G (IgG) antibodies from four PERM/SPS patients with glycine receptor autoantibodies and four control subjects. We incubated cultured rat spinal motoneurons in each IgG sample, then recorded 'miniature' synaptic currents by whole cell patch clamp to assess the consequences of autoantibody binding on glycinergic neurotransmission. Glycinergic synaptic currents were almost completely abolished following incubation in all four patient IgGs (100.0% after 16 h incubation ($p = 0.003$)). Human autoantibodies targeting other CNS neurotransmitter receptors, such as NMDA receptors, only affect whole cell currents after several hours' incubation and this effect depends on divalency of the antibodies suggesting that a predominant pathogenic mechanism is antibody-mediated crosslinking and internalisation of receptors. In contrast, we observed substantial reductions in glycinergic currents within 15 minutes of exposure to patient IgGs ($75.3 \pm 14.1\%$ ($p = 0.021$)). When monovalent Fab fragments were generated from patient IgG samples, these also profoundly reduced glycinergic currents in three out of four cases. We conclude that human glycine receptor autoantibodies disrupt glycinergic neurotransmission, demonstrating a pathogenic role for these autoantibodies in PERM/SPS.

Furthermore our results suggest that the pathogenic mechanisms include direct antagonistic actions on glycine receptors, which has important implications for therapeutic strategies.

Title: A computational model of two-photon calcium imaging with GCaMP6 in dendrites and spines

Authors: *B. B. SCHNEIDERS[1], M. ADOFF[2], A. ABOUZEID[1], D. A. DOMBECK[2], W. L. KATH[1];
[1]Engin. Sci. and Applied Mathematics, [2]Neurobio., Northwestern Univ., Evanston, IL

Abstract: Recent *in vitro* uncaging experiments (Sheffield 2017) in CA1 pyramidal neurons investigated the spatiotemporal patterns of calcium influx, measured with GCaMP6f, resulting from different stimulation patterns of multiple dendritic spines. Spines were stimulated over 10-20 micron stretches, first individually, typically resulting in no detectable calcium transients, and then near-simultaneously until a local, branch-isolated calcium transient was generated. Depending on the laser power this often occurred with stimulation of 3-8 spines. We developed a morphologically detailed computational model of GCaMP6f fluorescence, calibrated to these *in vitro* experiments. The model features a reconstructed CA1 morphology with morphologically realistic dendritic spines, calcium influx from voltage-gated calcium channels (R-type, T-type and L-type), calcium buffering, calcium-induced calcium release, AMPA and NMDA receptors, and calcium transmembrane pumps.
We verify that the model reproduces a number of results from these uncaging experiments. In particular, dendritic and spine compartments exhibit appropriate changes in indicator fluorescence in response to simulated synaptic stimulation. A unitary event, with a depolarization of 20-25 mV in the spinehead and 10-15 mV in the local dendrite, evokes a fluorescence change that is sub-visible ($dF/F < 10\%$), as observed in the experiments. We also reproduce fluorescence changes between 40-600% in dendrite and spine for multiple and nearly coincident spine stimulations, with a larger fluorescence increase in the spinehead than dendrite for coincident synaptic input.
With the model calibrated to *in vitro* conditions, we are now employing it to understand *in vivo*

observations, mechanisms underlying the generation of local dendritic calcium transients (~5-15 microns in length), for example. Thus far it seems clear that clustered and coactive inputs are a requirement to generate such calcium transients. With sufficient clustered and co-activated synaptic input, the local dendritic calcium transients appear to result from the generation of a local regenerative nonlinear event. The model also allows us to explore what factors lead to the observation of a transient in a single spine. When we implement smaller spinehead geometries (as reported in Harris 1989), early indications are that we can generate observable transients from single spine stimulations. This takes into account that smaller spines are found to have less PSD area, and therefore fewer NMDA channels.

Title: Geometric effects on the electrochemical activity in dendritic spines

Authors: *M. BELL, P. RANGAMANI;
Univ. of California San Diego, La Jolla, CA

Abstract: Dendritic spines are centers of synaptic communication and are hotspots of electrical and chemical activity in neurons. These spines are known to have characteristic shapes that are related to their function and indicative of aging, diseases, and learning. However, this shape-function relationship is not well understood. In particular, how the shape of the dendritic spine affects the propagation of electrical activity in response to activation of glutamatergic receptors has not been well studied. This electrical activity and depolarization of the membrane causes calcium influx that triggers downstream signaling cascades that lead to long term potential and depression, and synaptic weight changes. Here we propose a spatial continuum model of calcium influx dependent on membrane voltage based on explicit ion concentration and ion influx including sodium, potassium, chloride, and calcium ion channels and AMPAR. We predict that i) the size and shape of the spine head can modify the propagation of membrane voltage, ii) internal organelles can modulate the membrane voltage through the creation of nanodomains,

and iii) the spine apparatus can potentially play a role in electrical communication through its own membrane potential changes.

Title: Optogenetic induction of long term potentiation at somatostatin interneuron excitatory synapses causes metaplasticity in pyramidal cell afferent pathways in hippocampus

Authors: *A. ASGARIHAFSHEJANI, I. LAPLANTE, J.-C. LACAILLE;
Univ. De Montreal, Montreal, QC, Canada

Abstract: Somatostatin-expressing cells in CA1 hippocampus (SOM-INs) are dendrite-projecting inhibitory interneurons. SOM-INs, particularly O-LM cells, differentially regulate afferents onto pyramidal cells: via distal dendritic inhibition, they downregulate activity and long-term potentiation (LTP) in the temporo-ammonic pathway (TA); via proximal dendritic disinhibition, they upregulate activity and LTP in the CA3-CA1 Schaffer collateral pathway (SC). The main excitatory inputs onto SOM-INs are from pyramidal cells and these synapses show mGluR1a-mediated LTP. This plasticity at SOM-IN input synapses results in metaplasticity in the CA1 pyramidal cell network and contributes to spatial and contextual memory consolidation. Here we aimed to establish conditions to induce synaptic plasticity in SOM-INs by optogenetics in slices and determine if optogenetically induced SOM-IN plasticity differentially affects metaplasticity in pyramidal cell SC and TA pathways. For optogenetic activation of pyramidal cell excitatory inputs to SOM-INs, we injected AAV-CaMK2a-ChR2 (E123T/T159C)-mCherry in CA1 of SOM-Cre-eYFP mice. Whole-cell recordings showed that single optogenetic stimulation locally in oriens-alveus (Polygon 400; 5mW, 470nm) elicited EPSPs ($EPSP_{opto}$) in SOM-INs in slices. Optogenetic theta burst stimulation (TBS_{opto}) produced LTP of $EPSP_{opto}$. LTP was absent with low frequency TBS_{opto} or in untetanized cells. LTP of $EPSP_{opto}$ was mediated by mGluR1a (blocked by LY367385) and mTORC1 (absent in conditional SOM;$Rptor^{-/-}$ mice). Optogenetically-induced LTP is thus analogous to electrically-evoked LTP in SOM-INs. In addition, TBS_{opto} produced LTP of electrically-evoked EPSPs ($EPSP_{elect}$) via mGluR1a and mTORC1. Furthermore, TBS_{opto} using whole field fiber illumination (300 µm diameter; Thorlabs) elicited similar LTP of $EPSP_{opto}$. Next we tested if

whole field TBS_{opto}, that produce mGluR1a- and mTORC1-mediated LTP at SOM-IN synapses, would result in a differential regulation of SC- and TA-LTP using field potential recordings in slices. 25 min after TBS_{opto}, LTP of fEPSPs induced by weak theta burst electrical stimulation was enhanced in the SC and depressed in the TA pathway. Thus, optogenetic stimulation induces mGluR1a- and mTORC1-mediated LTP at CA1 pyramidal cell excitatory synapses onto SOM-INs and is sufficient to result in differential metaplasticity in SC and TA pathways onto CA1 pyramidal cells. The optogenetic protocol for induction of LTP in SOM-INs provides a tool to determine in vivo the role of SOM-IN synaptic plasticity in hippocampal-dependent learning and memory.

Title: A biochemical mechanism for time-encoding memory formation within individual synapses of Purkinje cells

Authors: *A. MANDWAL, J. ORLANDI, C. SIMON, J. DAVIDSEN;
Univ. of Calgary, Calgary, AB, Canada

Abstract: Within the classical eye-blink conditioning, Purkinje cells (PCs) in the Cerebellum suppress their tonic firing rates for a well defined time period in response to a conditioned stimulus after training. Recent experiments have shown that metabotropic glutamate-based receptor type 7 (mGluR7), which resides on the PC synapses, is responsible for the initiation of the suppression of firing rate, suggesting an intrinsic mechanism within the PC for the temporal learning. These receptors activate G-protein coupled Inward Rectifier Potassium (GIRK) ion channels at the PC's synapses which causes the pause in the tonic firing rate of the cell. However, the mechanism by which the PC encodes the time-memory signature is not fully understood. We propose a biomolecular model which explains how the cell learns, stores and alters any specific time-duration memory at synapes depending upon training conditions. According to the proposed mechanism, the learning process involves trafficking of mGluR7 receptors to the PC's synapses. mGluR7 receptor opens the GIRK ion channel, while Protein Kinase A and Protein Phosphatase 1 closes the GIRK ion channel via a G-protein with the help of RGS8 proteins. The pause duration is encoded within effective rate constants of their biochemical interactions. In addition, all these proteins form together a protein complex consisting of one GIRK ion channel. We propose that such protein complex can bind more receptors which results in slower GIRK gating dynamics. As there are several such protein

complexes present at the synapse, their collective dynamics allow the PC to produce any pause duration just by changing the total amount of receptors at the synapse. While the learning process involves placing of receptors at synapses, their removal causes memory loss. To validate the mechanism, we implement a mathematical model focussing on biomolecule interactions governing GIRK ion channels gating dynamics and combined it with a realistic biophysical model of the PC. With this, we are able to reproduce the ensemble of pause durations, consistent with experimental results. This implies that individual PC's synapses can also store more complex memories such as time-duration memory within itself than simply synaptic strengths.

Title: Variance analysis on synaptic currents predicts the source of plasticity at hippocampal synapses

Authors: *A. N. VAN HUIJSTEE[1,2], C. A. P. SILVA[2], C. LOHMANN[2], H. W. KESSELS[1,2]; [1]Swammerdam Inst. for Life Sci., Univ. of Amsterdam, Amsterdam, Netherlands; [2]Netherlands Inst. for Neurosci., Amsterdam, Netherlands

Abstract: Experiences can remodel neural circuitries by strengthening some synapses and weakening others. The strength of synaptic transmission onto a neuron largely depends on three parameters: the number of functional release sites (N), the presynaptic probability of vesicle release (P_r), and the quantal size (Q), defined as the amplitude of the postsynaptic response to the release of a single vesicle of neurotransmitter. Current electrophysiological techniques cannot directly assess which of these parameters is altered when a change in synaptic strength is observed. Instead, statistical tools based on the quantal model of synaptic transmission can be used to acquire information about which of the three parameters is the source of plasticity by analyzing the variance in the amplitude of stimulus-evoked excitatory postsynaptic currents (EPSCs) before and after a synaptic modulation using binomial statistics. We show that the Variance-to-Mean Ratio (VMR) is determined by P_r and Q, but is independent of N. Combining this tool with the conventional quantal measure of $1/CV^2$ (CV = coefficient of variation), which is not dependent on Q but instead on P_r and N, allows for a simple and reliable prediction of the mechanisms underlying synaptic plasticity. We used this variance analysis to assess the subunit-

specific distribution of AMPA- and NMDA-receptors at synapses. Our analysis suggests that while AMPA-receptors are evenly distributed across synapses, GluN2A- and GluN2B-containing NMDA-receptors appear to be largely segregated from each other at different synapses.

Abstract: The highly polygenic nature of psychiatric diseases is one of the major challenges in the study of the mechanisms underlying the etiology of these disorders. To address this challenge we took advantage of unbiased proteomic and phosphoproteomic analysis to uncover the specific biochemical signaling pathways of synaptic plasticity controlled by disease-associated genetic perturbations. We identify novel readouts for synaptic plasticity signaling using chemical LTP in neuronal cultures: 9370 proteins and 13904 phosphosites with statistically significant phopshorylation changes at >60 sites. Interestingly, calcineurin A subunit alpha isoform (CNAα), one of the first phosphatases activated by calcium influx downstream NMDAR, showed over 5-fold increase at 5min post-chemical LTP in the phosphorylation of a novel serine residue associated for first time to synaptic plasticity. Crystal structure analysis and biochemical studies indicated that phosphorylation of this site enhance CNAα activity. We generated phosphospecific antibodies to CNAα and verified increased CNAα phosphorylation at the serine site in vitro and in hippocampal slices. Moreover, using high-content imaging we observed this phosphorylation event increased under multiple stimuli inducing network activity but was blocked by network activity inhibition with TTX suggesting a key role as neuronal activity marker. In addition, mapping of the signaling pathways resulting in this phosphorylation were performed using a library of siRNA in combination with in vivo disease-relevant perturbations. Our findings point to a novel role of calcineurin phosphorylation in synaptic function and

highlight the power of unbiased phosphoproteomics for defining the signaling pathways of synaptic plasticity

Abstract: The role of the pro-inflammatory cytokine tumor necrosis factor (TNF) in synaptic plasticity has been extensively studied. Nevertheless, it remains unclear how TNF asserts its effects on neural plasticity. Although TNF mediated effects on glial cells are well-described, the neuronal targets through which TNF modulates the ability of neurons to express plasticity remain unknown. Here, we used organotypic entorhino-hippocampal tissue cultures to test for TNF-induced modulation of Schaffer-collateral CA1 synapses. Using extracellular recordings, whole-cell patch-clamp recordings and immunostainings we show that TNF modulates neural circuits in a dose-dependent manner: high concentrations of TNF impair synaptic plasticity, whereas low concentrations of TNF improve the ability of neurons to express plasticity. These metaplastic effects of TNF are accompanied by changes in the actin-associated protein synaptopodin which has been firmly linked to the expression of associative and homeostatic plasticity. In line with

these findings, 24 h TNF-treatment (6nM) causes changes in synaptopodin expression. These results further elucidate the role of TNF in modulating synaptic plasticity, here by acting through synaptopodin-associated intracellular calcium stores.

Title: The role of AnkyrinR in perineuronal nets in parvalbumin-positive inhibitory interneurons

Authors: *S. R. HA[1], J. OSES-PRIETO[2], A. L. BURLINGAME[2], M. N. RASBAND[1]; [1]Dept. of Neurosci., Baylor Col. of Med., Houston, TX; [2]Dept. of Pharmaceut. Chem., Univ. of California, San Francisco, CA

Abstract: The ankyrin family of proteins, AnkR, AnkB and AnkG, corresponding to the genes *ANK1-3*, respectively, are critical for membrane domain organization and protein stabilization in many cell types throughout the body. In the nervous system, AnkG and AnkB are known to function as important domain organizers; however, AnkR's role in the nervous system is poorly understood. Intriguingly, several large independent epigenome-wide association studies (EWAS) identified differentially methylated regions of the *ANK1* gene, in which hypermethylation was correlated with onset and neuropathology of Alzheimer's disease. Moreover, AnkR has been linked to de novo mutations in schizophrenia. Our expression analyses show AnkR is highly expressed in the somatodendritic domain of a subset of neurons, including forebrain parvalbumin-positive (Pv^+) interneurons with 94 ± 1.2% and 93 ± 0.9% of Pv^+ cells expressing AnkR in the cortex and hippocampus, respectively. Interestingly, AnkR's spatial expression overlaps with that of perineuronal nets (PNNs), preferentially surrounding Pv^+ cells. Moreover, AnkR increases expression levels during postnatal development, following a similar temporal expression pattern as PNNs. To elucidate the role of AnkR in these cells, we used the Cre/Lox system to create AnkR conditional knockout mice (AnkR cKOs). AnkR floxed animals were crossed with Nestin-Cre and Dlx5/6-Cre to investigate the role of AnkR in the nervous system as a whole and specifically in forebrain GABAergic neurons, respectively. To identify the molecular mechanisms underlying these changes, we performed mass spectrometry screens and biochemical analysis yielding AnkR's interactors, including PNN proteins brevican, versican, and tenascin-R. Furthermore, our data show AnkR has multiple spectrin binding partners in the

brain, including beta-I spectrin that is also highly expressed in the somatodendritic domain of Pv^+ cells. Both *in vitro* and *in vivo* immunoprecipitation protein interaction assays show AnkR interacts with Neuropilin-1, PlexinA1, and PlexinA4. These proteins function as signal transduction receptors for Semaphorin3A previously shown to be enriched in PNNs. Taken together, these data suggest AnkR is important for tethering somatodendritic molecules, including membrane proteins interacting with PNNs, to the spectrin cytoskeleton in specific neuronal membrane domains. Future work will focus on increasing our understanding AnkR's role in PNN function, which may enable further characterization of the molecular mechanisms underlying altered cortical excitability observed in neurodegenerative and neurodevelopmental disorders.

Title: Characterization of perineuronal nets in human entorhinal cortex, hippocampus and ventromedial prefrontal cortex

Authors: *C. BELLIVEAU[1,2], A. TANTI[1], A. MCFARQUHAR[2], F. DENUX[1], M. DAVOLI[1], N. MECHAWAR[1,2];

Abstract: Background: Childhood and adolescence are marked by profound changes in functional cortical connectivity and a period of heightened plasticity. One of the major mechanisms involved in shutting down these critical windows of plasticity is the development of perineuronal nets (PNNs), a lattice-like condensed extracellular matrix structure that forms around various types of neurons in the brain, most notably parvalbumin-positive (PV) inhibitory interneurons and pyramidal cells. By acting as a mechanical and chemorepellent barrier around neurons, PNNs restrict axonal and dendritic growth and limit the mobility of neurotransmitter receptors playing an important role in modulating functional neural networks. Our work aims to further characterize the cellular and molecular features of PNNs in the post-mortem human brain. **Methods**: Blocks of frozen post-mortem human entorhinal cortex (EC), hippocampal and ventromedial prefrontal cortex (vmPFC) samples (Douglas-Bell Canada Brain Bank) were dissected, shortly fixed in formalin, cut on a cryostat and free-floating sections were processed

for immunohistochemistry (PV and NeuN). PNNs were visualized using biotin-conjugated Wisteria Floribunda Lectin followed by immunofluorescent detection using fluorophore-conjugated streptavidin. Whole slide images were analyzed using QuPath and ImageJ. **Results**: We show that we can reliably label PNNs in combination with neuronal markers using immunofluorescence in human postmortem samples, warranting that we can apply this procedure to further characterize cellular and molecular features of PNN formation during normal and pathological development. Our preliminary observations show that PNNs display region-specific quantitative and qualitative features in the different subfields of the hippocampus, the EC and the vmPFC. **Conclusions**: Our exploratory results suggest that PNNs display region-specific features that are likely to be associated with differences in information processing. Further understanding the cellular and molecular properties of these structures in different regions of the human brain will allow better appreciation of the nature of the PNN changes that have been associated with various CNS disorders.

Title: Subanaesthetic ketamine reactivates adult visual cortical plasticity to restore vision from amblyopia

Authors: *S. F. GRIECO[1], Q. QIAO[1], X. ZHENG[1], T. HOLMES[1], S. P. GANDHI[2], X. XU[3]; [1]UCI, Irvine, CA; [2]Neurobio. and Behavior, Univ. of California Irvine Dept. of Neurobio. and Behavior, Irvine, CA; [3]Anat. and Neurobio., Univ. California, Irvine, Irvine, CA

Abstract: A low dose of ketamine can elicit rapid and long-lasting antidepressant effects in patients for up to 2 weeks, well beyond ketamine's chemical half-life time of ~2 hours. This suggests that ketamine modulates adult brain plasticity. Here we show that subanaesthetic ketamine reactivates visual cortical plasticity. We subjected mice (P90-P120) to monocular deprivation (MD) for four days, which is known not to induce ocular dominance plasticity. Robust ocular dominance plasticity is induced after MD and ketamine treatment (administered at the start of 4-day MD). We further tested if ketamine can restore visual perception from critical-period amblyopia, using the visual water task. This shows a restoration of acuity with ketamine. We identify that in vivo single-dose ketamine treatment results in sustained down-regulation of

neuregulin-1 (*nrg1*) expression in parvalbumin-expressing (PV) inhibitory interneurons in mouse primary visual cortex (V1), at 24, 48 and 72 hours post treatment. Translating ribosome affinity purification was employed to measure cell-specific mRNAs under different conditions. In contrast, there is no significant change of NRG1 expression in excitatory neurons while there is sustained enhancement of pCREB activity in excitatory neurons following ketamine treatment. To test if subanaesthetic ketamine increases cortical excitability by attenuating inhibitory inputs onto pyramidal neurons (disinhibition), we performed whole-cell recording of electrically-evoked inhibitory postsynaptic currents (IPSCs) in pyramidal neurons in V1 cortical layer 2/3. Single-dose ketamine treatment evokes sustained reduction in synaptic inhibition to excitatory neurons up to a week. To test if PV neurons are the initial circuit locus for ketamine's action, we mapped excitatory inputs (EPSCs) to PV inhibitory neurons in L2/3 of the visual cortex using laser scanning photostimulation (LSPS). Correlating with cortical disinhibition, single-dose ketamine treatment evokes sustained reduction in excitatory inputs to PV neurons. PV-specific ErbB4 ablation abolishes ketamine-induced plasticity. Reciprocally, exogenous NRG1 rapidly restores excitatory inputs onto PV neurons in ketamine-treated cortex to enhance cortical inhibition. Thus, ketamine effects on cortical plasticity are mediated by sustained cortical disinhibition via downregulation of neuregulin-1 (NRG1) signaling in parvalbumin-expressing (PV) inhibitory interneurons. Our findings reveal molecular, cellular and circuit mechanisms of ketamine-mediated induction of cortical plasticity to promote functional recovery from amblyopia.

Title: Role of GirK channels in long-term potentiation of synaptic inhibition in an *in vivo* mouse model of early amyloid-β pathology

Authors: *J. NAVARRO-LOPEZ[1], I. SÁNCHEZ-RODRÍGUEZ[2], A. GRUART[3], J. DELGADO-GARCIA[4], L. JIMENEZ-DIAZ[5];

Abstract: Imbalances of excitatory/inhibitory synaptic transmission occur early in the pathogenesis of Alzheimer's disease (AD), leading to hippocampal hyperexcitability and causing synaptic, network, and cognitive dysfunctions. G-protein-gated potassium (GirK) channels play a key role in the control of neuronal excitability, contributing to inhibitory signaling. Here, we evaluate the relationship between GirK channel activity and inhibitory hippocampal functionality in vivo. In a non-transgenic mouse model of AD, field postsynaptic potentials (fPSPs) from the CA3-CA1 synapse in the dorsal hippocampus were recorded in freely moving mice. Intracerebroventricular (ICV) injections of amyloid-β (Aβ) or GirK channel modulators impaired ionotropic ($GABA_A$-mediated fPSPs) and metabotropic (GirK-mediated fPSPs) inhibitory signaling and disrupted the potentiation of synaptic inhibition. However, the activation of GirK channels prevented Aβ-induced changes in $GABA_A$ components. Our data shows, for the first time, the presence of long-term potentiation (LTP) for both the $GABA_A$ and GirK-mediated inhibitory postsynaptic responses in vivo. In addition, our results support the importance of an accurate level of GirK-dependent signaling for dorsal hippocampal performance in early amyloid pathology models by controlling the excess of excitation that disrupts synaptic plasticity processes.

Title: Inhibition of G9a/GLP complex rescues synaptic plasticity deficits in the hippocampal area CA1 in APP/PS1 mouse model of Alzheimer's disease

Authors: *K. PANG[1,2], J. LEE[1,2], S. SAJIKUMAR[1,2];
[1]Dept. of Physiol., Natl. Univ. of Singapore, Singapore, Singapore; [2]Neurobiology/Aging Programme, Life Sci. Institute, Ctr. for Life Sci., Singapore, Singapore

Abstract: Memory impairments are characteristic symptoms of Alzheimer's disease (AD), a progressive neurodegenerative disorder. Synaptic dysfunction has been widely considered to contribute to the cognitive deficits, especially in the early stages, in AD. Characterizing such synaptic impairments and the underlying molecular mechanisms could aid in the development of therapeutic interventions. Using *in vitro* field electrophysiological recordings, we examined long-term potentiation (LTP) and synaptic tagging and capture (STC), the cellular correlates of long-term memory and associative memory, in three- to five-months-old male APP/PS1 mice, a mouse model of AD. In particular, we investigated the role of G9a/GLP complex, a histone methyltransferase implicated in learning and memory, in regulating the expression of synaptic plasticity-related proteins in AD conditions. Our data suggest that short-term pharmacological inhibition of the G9a/GLP complex ameliorated LTP and STC impairments in CA3-CA1 synapses in acute hippocampal slices of APP/PS1 mice. This rescue of synaptic plasticity was dependent on *de novo* protein synthesis. In addition, biochemical analysis results shed light on some of the molecular mechanisms that mediated this restoration of synaptic plasticity by G9a/GLP blockade. All electrophysiology experiments were conducted in at least seven hippocampal slices from at least five animals per series. And data were subjected to statistical tests including Wilcoxon signed-rank test, Mann-Whitney U-test and ANOVA as appropriate. Our study not only suggests that G9a/GLP could be a potential therapeutic target for early stage AD-related dementia, but it also delineates the role of G9a/GLP complex in mediating transcription and translation in synaptic plasticity.

Title: Extended amygdala circuits in alcohol use disorder

Authors: *N. D. WINTERS, S. PATEL;
Vanderbilt Univ., Nashville, TN

Abstract: Alcohol use disorder (AUD) is characterized by compulsive alcohol consumption and a shift from use to dependence. Negative affective states during withdrawal, such as anxiety, are major drivers of relapse and are intractable to current therapies for these conditions. Given a prevalence of approximately 30% of the US population and the lack of effective therapies for AUD, these challenges warrant investigation into novel treatment mechanisms for AUD. Chronic alcohol consumption and withdrawal have been shown to alter synaptic function in the central amygdala (CeA), a heterogeneous brain structure critical in the regulation of fear and anxiety. The CeA has been consistently demonstrated to be a critical locus in the generation of alcohol dependence and anxiety disorders, however, the cell type- and circuit-specific mechanisms mediating these effects have not been determined. Preliminary data from our lab demonstrate that in an animal model of AUD, chronic alcohol self-administration and withdrawal in mice results in an enhancement of spontaneous glutamatergic drive selectively onto somatostatin-expressing neurons in the CeA, an effect that persists 2 weeks into abstinence. Future studies will employ optogenetic projection-targeting strategies aimed at systematically interrogating excitatory inputs to the CeA in order to identify the source input for this enhanced glutamate release, as well as retrograde-tracing techniques to probe the effects of chronic alcohol on distinct CeA efferent projections. Additionally, the efficacies of many inputs onto CeA neurons are regulated by endocannabinoids (eCBs), bioactive signaling lipids that are released by neurons as retrograde messengers that act to reduce presynaptic neurotransmitter release probability. The eCB system has been consistently implicated in the regulation of stress and anxiety-like states, and pharmacological augmentation of eCB signaling *in vivo* has been demonstrated to be anxiolytic in animal models of AUD. The proposed studies are aimed at identifying the cell type- and circuit-specific mechanisms by which chronic alcohol consumption and protracted withdrawal result in maladaptive synaptic remodeling within the CeA to produce heightened states of anxiety, and the role of eCBs in modulating these effects. Collectively, these studies will provide novel insight into the neurobiological mechanisms underlying negative affect generation associated with AUD, as well as explore the therapeutic potential of developing eCB-based therapies for treating this disorder.

Title: Phrenic evoked response is enhanced after daily acute intermittent hypoxia in rats

Authors: *R. RODRIGUES PERIM, M. D. SUNSHINE, A. HOLLAND, J. SANTIAGO, G. S. MITCHELL, E. GONZALEZ-ROTHI;
Physical Therapy, Univ. of Florida, Gainesville, FL

Abstract: Plasticity is a hallmark of the respiratory system controlling breathing. A long-lasting increase in phrenic nerve activity is observed following acute intermittent hypoxia (AIH), known as phrenic long-term facilitation (pLTF). AIH induces cell signaling cascades within phrenic motor neurons, activating serotonin type 2 receptors and initiating new synthesis of BDNF protein. However, there is no direct evidence that pLTF arises via increased strength of monosynaptic inputs to phrenic motor neurons. Thus, we tested the hypothesis that AIH enhances short-latency evoked phrenic responses elicited by ventrolateral funiculus (VLF) stimulation. Respiratory cycle-triggered VLF stimulation was performed while recording phrenic nerve activity in anesthetized, paralyzed, mechanically ventilated rats, with the stimulating electrode placed 2mm below the C2 dorsal root entry zone. During baseline conditions and 60 min post-AIH, 10 bipolar pulses (1ms) of progressively increasing intensity (100 to 700μA) were applied during either the inspiratory or post-inspiratory phase of successive breaths defined by a threshold of 50% of peak activity. Although robust pLTF (~60% above baseline) was observed after AIH (3 x 5 min, PaO_2: 35-55 mmHg), there was no significant change in amplitude of evoked phrenic responses during inspiration or post-inspiration, contrary to our hypothesis. In an additional set of rats, which were treated with two weeks of daily AIH preconditioning, both baseline phrenic nerve activity and the amplitude of evoked phrenic responses were increased (during both inspiratory and post-inspiratory phase), suggesting longer duration treatment may be required to enhance synaptic strength. Further studies are needed to understand the impact of AIH and daily AIH preconditioning on synaptic inputs to phrenic motor neurons.

Title: Molecular mechanism of non associative learning in earthworms

Authors: *Y. KITAMURA, D. SOUDA, H. FUJITA;
Kanto Gakuin Univ., Yokohama, Japan

Abstract: Molecular mechanism of non-associative learning in the earthworm *Eisenia fetida* is investigated. Electrophysiological recording from the ventral nerve cord of the earthworm revealed that repeated tactile stimulus to the body wall gradually decreases number of action potential. We previously reported that habituation by repeated tactile stimulus to the body wall in the earthworm is induced assumedly due to via nitric oxide (NO)-cGMP signaling, because relatively high concentration of NO or cGMP accelerated decrease of number of action potentials by single tactile stimulus. In this study, for clarifying molecular mechanism and recovery process of habituation in the earthworm, we investigated effect of 5-HT receptor antagonists and cyclic nucleotide analogues on establishment of habituation. From these results, it is revealed that 5-HT receptor antagonist delayed establishment of habituation, and only cGMP but not cAMP induced habituation. After establishment of habituation, action potential generation by tactile stimulus fully recovered after 120 min. In summary, non-associative learning such as habituation in the earthworm is short term memory and is due to via 5-HT-NO-cGMP signaling.

Title: Automated quantitative assessment and classification of neuromuscular junctions

Authors: *A. MEJIA MAZA[1], C. SUDRE[3], J. N. SLEIGH[2], E. M. FISHER[4];
[2]Sobell Dept. of Motor Neurosci. and Movement Disorders, [1]Univ. Col. London, London, United Kingdom; [3]Kings Col. London, London, United Kingdom; [4]Inst. of Neurology, Univ. Col. London, London, United Kingdom

Abstract: The neuromuscular junction (NMJ) is a peripheral synapse between the axon terminal of a lower motor neuron and a muscle fibre. In motor neuron diseases (MNDs), NMJ denervation may be concomitant with either muscle wasting, motor neuron death or both, but the underlying mechanisms leading this process are largely unknown. Studies on NMJ pathology and the morphological changes driving denervation have not been carried out across all MND mouse models. Moreover, mouse NMJ denervation is most often assessed visually. The high inter-rater variability makes such an assessment difficult to reproduce and limits further analyses on association with NMJ morphological characteristics. To overcome these limitations, in this study, morphological characteristics among which volume, surface, shape factor, length and diameter, compactness and fragmentation of pre- and post-synaptic NMJ components, were

automatically extracted and used as input of a support vector machine (SVM) learning algorithm trained in a 10-fold cross-validation setting for classification purposes. Here, we used hindlimb lumbrical muscles of Charcot-Marie-Tooth disease (CMT) type 2D ('Gars') (1-month old males) and amyotrophic lateral sclerosis (ALS, SOD1-*G93A*) (1- and 3-month old males) mouse models to follow the morphological changes of the pre- and post-synaptic NMJ components. For both mouse models, more than 5000 NMJs were manually studied and automatically characterised. Both volume and surface of CMT2D-NMJ pre- and post-synaptic components were smaller than wild-type littermates, whereas in SOD1-*G93A* the size of motor endplate remained similar at 1- and 3-months old. However, the presynaptic volume of SOD1-*G93A* was significantly smaller at 3-months old. 'Coverage', defined as the percentage of motor endplate with overlapping pre-synaptic volume staining, is reduced in both CMT2D and SOD1-*G93A* at 3 months, but not at 1 month. NMJs of SOD1-*G93A* at 1-month of age were visually classified as fully innervated in 98.6% of the cases vs 99.6% in wild-type littermates; at 3-months, only 49.8% of NMJs remained fully innervated vs 94.3% in wild-type littermates. Quantitative measurements were compared to existing licensed software output for validation of the analysis. Taken together, we confirmed the validity of our method for automated characterisation of NMJ morphology in two MND mouse models. Volume, coverage and surface appeared to be highly relevant for the distinction between disease states of NMJs and were successfully used for the automated classification of the different subtypes with an accuracy of 95%. Future work will further investigate the patterns of these pathological changes.

Title: Resurgent sodium and high threshold potassium currents underlie the maturation of a zebra finch vocal motor nucleus

Authors: *B. ZEMEL[1], A. A. DAGOSTIN[2], P. V. LOVELL[3], S. R. FRIEDRICH[4], C. V. MELLO[3], H. P. VON GERSDORFF[5];
[2]Vollum Inst., [1]Oregon Hlth. and Sci. Univ., Portland, OR; [3]Dept. of Behavioral Neurosci., Oregon Hlth. and Sci. Univ. Sch. of Med., Portland, OR; [4]Behavioral Neurosci., [5]Vollum Inst., Oregon Hlth. & Sci. Univ., Portland, OR

Abstract: Zebra Finches develop learned vocalizations that are refined from unstructured notes known as subsong, to increasingly structured songs that become stable and reproducible in a process known as crystallization. The songbird brain possesses interconnected nuclei utilized for acquisition and production of learned song. Nucleus RA integrates and relays signals from the HVC and the lateral magnocellular nucleus of the nidopallium (LMAN) via its descending projections out of the telencephalon onto motor neurons innervating the finch's vocal organ, the syrinx. Its function is analogous to laryngeal motor cortex neurons that project to brainstem nucleus ambiguus in human speech circuitry, components of which are absent in non-vocal learners. RA neurons develop temporally precise, high-frequency action potential (AP) firing during the song learning period that define the acoustic structure of song syllables. The molecular determinants underlying this development are unknown. We studied developmental changes within RA of the voltage-gated sodium channel beta 4 subunit, Navβ4, and the voltage gated potassium channel alpha subunit, Kv3.1. Navβ4 acts as a fast open channel blocker that reduces the ability of Nav channels to accumulate in the inactivated state and produces resurgent currents (I_{NaR}). Kv3 subunits provide the repolarizing force needed to initiate Nav channel recovery from inactivation before the next AP. Both Navβ4 and Kv3.1 are implicated in high frequency AP firing in other systems, thus we hypothesized they might be critical for maintaining high frequency and reliable firing in RA neurons. *In situ* hybridizations at various ages during the critical period for song learning revealed expression of Navβ4 and Kv3.1 mRNA in RA, but not in the surrounding arcopallium of adult male finches or in the RA of non-vocal 20 day old juveniles. Whole-cell voltage clamp recordings in slices showed an increase in I_{NaR}, decrease in AP half-width, and increase in AP number during a current stimulus in projection neurons within RA during development. Intracellular administration of a peptide containing the Navβ4 C-terminal blocking sequence was sufficient to make juvenile RA neurons appear developmentally mature by increasing both I_{NaR} and AP firing frequency. Injection and subtraction of *in silico* I_{NaR} via dynamic clamp was sufficient to decrease and increase AP interspike intervals in juvenile and adult neurons respectively. Together, these findings reveal the developmental regulation of novel molecular determinants of neuronal excitability in a zebra finch song nucleus that plays critical roles in the production and acquisition of learned vocalizations.

Abstract: Visual neurons in many brain areas show non-linear response profiles as a function of the stimulus shown inside their receptive fields. These can be fit with different non-linear functions to obtain the tuning curve of the neuron for a particular feature. One example is the contrast response function, e.g., increases in the contrast of a stimulus inside a neuron's receptive field produce changes in its response profile that can be fitted by a sigmoid function. Such properties have been attributed to lateral inhibition and normalization within a network of interconnected neurons. Here we test the hypothesis that non-linearities in response functions of single neurons during *in vivo* recordings can be at least in part attributed to their intrinsic (not network dependent) response properties. To address this issue, we first obtained response functions from single neuron recordings in the lateral prefrontal cortex (LPFC areas 8A/9/46) of two macaques to gratings of varying contrast inside their receptive fields. We then conducted patch clamp *in vitro* recordings in slices extracted from the same LPFC area of 4 macaques using square current pulses of varying intensities that attempted to simulate increases in input strength when increasing contrast. In both datasets we convert spikes trains to firing rates over 250ms of stimulus presentation (*in vivo*) or pulse duration (*in vitro*) and fit the data with a sigmoid and a linear function. From 27 *in vivo* neurons, 52% were best fitted by the sigmoid and 48% were best fitted by a line. From 31 *in vitro* neurons 45% were best fitted by the sigmoid and 55% by a line. The proportions of neurons fitted with either function was not significantly different between areas ($p>0.1$, Chi-Square test) suggesting that non-linearities in the responses of visual neurons can be explained to a large degree by intrinsic cell properties.

Title: Intermittent access to alcohol enhances the intrinsic excitability of lateral orbitofrontal cortex neurons

Authors: *S. N. ROBERTS[1], R. D. CANNADY[1], P. J. MULHOLLAND[3], J. J. WOODWARD[2];
[2]Neurosciences, [1]Med. Univ. of South Carolina, Charleston, SC; [3]Neurosciences, MUSC, Charleston, SC

Abstract: In humans, chronic consumption of alcohol is often associated with dysfunction of frontal cortical areas including the orbitofrontal cortex (OFC). Recent findings from this laboratory have demonstrated that mice exposed to repeated cycles of chronic intermittent ethanol (CIE) vapor also show deficits in OFC-mediated behaviors. This was accompanied by an increase in the intrinsic excitability of lateral OFC (lOFC) neurons, reduced sensitivity to ethanol inhibition of firing and altered spontaneous synaptic transmission. In the current study, a two-bottle choice intermittent alcohol access (IAA) paradigm was used to examine whether voluntary ethanol consumption would also alter the intrinsic excitability of lOFC neurons in C57BL/6J male mice. Mice were given 24 hr access to alcohol (20% v/v) every other day for 1-day, 1-week, 4-week or 7-week. Water was provided each day and the location of the alcohol bottle was alternated each session. Mice were sacrificed 24 hr following the final day of the drinking paradigm and brain slices containing the lOFC were prepared for whole-cell patch-clamp electrophysiology recording. While no difference in spike number was noted between controls and 1-day IAA mice; mice that received 1-week, 4-week and 7-week IAA showed a significant increase in current-evoked action potential (AP) spiking as compared to their water-drinking counterparts. In particular, neurons from the 4-week IAA group showed a near doubling in APs as compared to their water-drinking counterparts. We then tested whether IAA would also alter the inhibition of firing during bath application of ethanol. Ethanol (11, 33 and 66 mM) produced a significant reduction in AP spiking in 1-day, 1-week, 4-week and 7-week water-drinking groups in a concentration-dependent manner. Similarly, significant decreases in spike firing by acute ethanol were observed in 1-day, 1-week and 7-week IAA drinkers. However, there was a total loss of ethanol inhibition in lOFC neurons from the 4-week IAA mice. Unlike CIE-induced increases in sEPSCs and sIPSCs, no change in amplitude and frequency of sEPSCs and sIPSCs in IAA animals. Overall, these results suggest that similar to that reported in mice following

chronic ethanol vapor exposure, voluntary ethanol consumption leads to enhanced intrinsic excitability of lOFC neurons and blunted responsiveness to acute ethanol. These alterations may contribute to the impairment of OFC-dependent behaviors often observed in alcohol-dependent individuals. Supported by P50AA10761.

Title: Impact of a novel slow afterhyperpolarization (sAHP) on spike encoding by serotonergic (5-HT) dorsal raphe (DR) neurons

Authors: M. ISHIBASHI[1], E. A. BERRY[2], N. E. MOLINA[2], T. SATO[2], A. FUKUDA[1], *C. S. LEONARD[2];
[1]Dept. of Neurophysiol., Hamamatsu Univ. Sch. of Med., Hamamatsu, Japan; [2]New York Med. Coll, Valhalla, NY

Abstract: Serotonergic dorsal raphe neurons regulate numerous functions including behavioral state, reward and mood and are themselves regulated by orexin peptide inputs. Indeed, orexin receptor signaling at these neurons rescues cataplexy in the sleep disorder narcolepsy. We recently reported that in addition to activating a depolarizing cation current, orexin-A strongly enhances the post-spike afterhyperpolarization in 5-HT DR neurons. This orexin-enhanced AHP (oeAHP) requires Ca^{2+} influx and has two distinct components: a shorter one (tau ~ 0.5s), mediated by enhanced SK channel activation; and a longer one (tau ~ 5s), that is apamin-insensitive (ai-oeAHP). The ai-oeAHP is a novel sAHP since it not blocked by internal cesium but is blocked by flufenamic acid or NMDG substituted for Na^+ in the ACSF and is accompanied by a reduced membrane noise and conductance suggesting it results from transient Ca^{2+}-mediated inhibition of the depolarizing orexin cation current. Here we have utilized current clamp and dynamic clamp recordings in mouse brain slices to investigate the role of the ai-oeAHP in regulating 5-HT DR neuron firing. Apamin increased excitability of 5-HT DR neurons but orexin-A still reduced steady-state repetitive firing without reducing initial firing indicating the ai-oeAHP enhances spike-frequency adaptation. Since membrane conductance is decreased

during the ai-oeAHP, we postulated that synaptic responsiveness might be preserved during the ai-oeAHP, rather than shunted as expected from the classical sAHP. To test this, we delivered either a virtual ai-oeAHP or virtual classical sAHP conductance by dynamic clamp and compared their effects on responsiveness to a virtual EPSP burst. Preliminary findings indicate that both virtual sAHPs slowed firing produced by either a constant driving current or virtual noisy orexin current, but that spike induction by the virtual EPSP burst was better preserved during the ai-oeAHP. This supports the idea that in addition to the high-pass filtering of inputs conferred by the oeAHP, the novel mechanism underlying the ai-oeAHP functions to preserve spike encoding of transient synaptic signals. Thus, the loss of orexin in narcolepsy would be expected to degrade this function and interfere with the ability of 5-HT neurons to adequately encoding synaptic signals which thereby may contribute to the expression of cataplexy.

Title: Pathophysiological concentrations of acetic acid from ethanol metabolism increases excitability of medium spiny neurons in the nucleus accumbens shell

Authors: *A. D. CHAPP[1], P. G. MERMELSTEIN[2], M. THOMAS[3];
[1]Neurosci., [2]Univ. of Minnesota, Minneapolis, MN; [3]Dept. of Neurosci., Univ. of Minnesota Syst., Minneapolis, MN

Abstract: Ethanol metabolism leads to increased concentrations of acetic acid in both the peripheral system and brain. In brain, peak acetic acid concentrations can reach 2-5 mM and remain elevated for several hours following metabolism and clearance of a modest dose of ethanol ingestion. Given the biological activity of acetic acid *in vivo* and *in vitro*, and the limited degree to which it has been explored in alcohol research, we investigated whether acetic acid is capable of altering neuronal function. As the nucleus accumbens is a key node in the mammalian reward circuit that contributes to the rewarding aspects of alcohol use, we focused our study on medium spiny neurons (MSN) of the nucleus accumbens shell (NAcSh). We performed a time-course (pre acetic acid, 1 min post acetic acid and 3 min post acetic acid), of whole-cell miniature excitatory postsynaptic current (mEPSC) recordings of MSNs within the NAcSh in the presence and absence of acetic acid. Bath application of a pathophysiological acetic acid

concentration (4 mM) significantly ($p < 0.05$) increased mEPSC frequency (Hz) in a time-dependent manner (3.6 ± 0.95, 5.3 ± 1.3 and 6.1 ± 1.1 respectively, n=4). Time-course control displayed no significant ($p = 0.91$) alterations in mEPSC frequency (2.4 ± 0.7, 2.7 ± 0.6 and 2.6 ± 0.6, n=3). mEPSC amplitudes (pA) were unaltered in acetic acid treated cells (15.2 ± 1.6, 15.9 ± 2.5 and 15.6 ± 2.2 respectively) or time-course control cells (15.2 ± 1.5, 14.8 ± 1.5 and 14.3 ± 1.3). In current-clamp, we performed a current injection response curve with both time-course (pre, 5 min and 10 min) and dose response of acetic acid (0, 2 and 4 mM). Acetic acid (2 and 4 mM) produced a left shift in the stimulus response curve compared to pre-acetic acid application ($p < 0.05$). Likewise, acetic acid (4 mM) significantly ($p = 0.002$) increased E_{max} firing frequency compared to pre-acetic acid (19.69 ± 3.24 Hz vs 14.69 ± 3.32 Hz, n=4). Time course control displayed no significant changes ($p = 0.84$) in E_{max} (15.00 ± 0.51 Hz vs 14.69 ± 1.07 Hz, n=4) or stimulus response curve. These data suggest that the generation of acetic acid through ethanol metabolism is capable of increasing glutamatergic activity and excitability in MSNs of the NAcSh. Future studies will be needed to determine the extent to which this modulation may contribute to the rewarding effects of alcohol consumption.

Title: Oxytocin modulates the electrical properties of liver-projecting DMV neurons

Authors: *K. M. SANTOS[1], D. J. MORAES[2], V. R. ANTUNES[1], M. P. D. SILVA[2];
[1]Dept. of Physiol. and Biophysics, Inst. of Biomed. Sci., Sao Paulo, Brazil; [2]Dept. of Physiol., Sch. of Med. of Ribeirao Preto, Ribeirao Preto, Brazil

Abstract: The dorsal motor of vagus nucleus (DMV) is the main parasympathetic output of central nervous system to the periphery, including to gastrointestinal tract, such as liver, with the involvement of the paraventricular nucleus oh hypothalamus (PVN) in this neuronal circuit, through a PVN-DMV-liver communication, to control hepatic glucose production (HGP). Previous studies from our laboratory have shown that after i.c.v injection of insulin, Wistar rats presents a decrease on HGP, an effect not observed in an animal model of sympatho-vagal

imbalance, the spontaneously hypertensive rats (SHR). However, when SHR are subjected to aerobic exercise training on treadmill for 4 weeks, the response was similar to Wistar rats. Based on literature that there is an oxytocin (OT) secretion, coming from PVN to DMV and that physical exercise may improves this signaling, herein we analyzed the OT effects on liver-projecting DMV neurons electrical properties from Wistar (W), SHR (SHRs) and trained SHR (SHRt) using the whole-cell patch-clamp technique.
We observed that: a) OT produced a depolarization of the resting membrane potential in W (-59,4 ± 0,748 mV vs -56,2 ± 1,209 mV, n = 10, p < 0,05) and SHRt (-61,33 ± 1,283 mV vs -59,61 ± 1,453 mV, n = 18, p < 0,05), reflecting increases in the firing frequency of these cells (W = 1,86 ± 0857Hz vs 3.044 ± 0,97Hz, n = 10, p < 0,001, and SHRt = 3.924 ± 0.67Hz vs 4.762 ± 0.645Hz, n = 18, p < 0,01). However, these changes were not observed in SHRs (Vm = -59.0 ± 1.267mV vs -57.75 ± 1.175 mV, n = 12, p = 0,1007; Frequency= 2.856 ± 0.638 Hz vs 4.144 ± 0,607Hz, n = 12, p = 0,159); b) no changes were found in excitability and in the input resistance in all groups analyzed.
These findings contribute for a better understanding of how an imbalance of sympathetic and parasympathetic nervous system could affect the central nervous system control of hepatic glucose production.

Title: Spontaneous spike homeostasis as a protective mechanism against reactive oxygen species (ROS) saturation

Authors: *C. CHINTALURI, T. VOGELS;
Univ. of Oxford, Oxford, United Kingdom

Abstract: The spontaneous firing rate of neurons varies according to cell-type, but it's also affected by nutrient levels, fatigue, and circadian phase. Spontaneous firing often persists in the absence (and even deprivation) of synaptic input. This seems perplexing, especially given that action potentials are metabolically expensive, and the majority of neuronal energy resources are allocated to maintain sodium (Na) and potassium (K) gradients. In line with recent results on the involvement of mitochondrial respiration in homeostatic firing-rate regulation, we propose a

model that links the metabolic creation of reactive oxygen species (ROS) with the regulation of spontaneous firing rates, so to serve as a protective mechanism against ROS saturation.
The majority of cellular ROS --- which is toxic to many cellular processes --- is generated in the mitochondria under two well-established conditions. Firstly, in situations nearing ATP-depletion, the high mitochondrial respiration rates necessary to replenish ATP levels also generate excessive ROS. Neurons are especially vulnerable to this "exhaustive-ROS" saturation under conditions that also lead to excitotoxicity. Secondly, in situations of low ATP demand, ATP production is stalled and electrons taxiing in the transport chain jump the production line to combine with intracellular oxygen to produce ROS. We postulate that quiescent neurons in the absence of sensory inputs are ATP saturated and thus vulnerable to this second type of "energetic-ROS" saturation. Using a conductance-based neuron model that includes mitochondrial ATP production and ROS generation we can explore the interaction of well-established ROS-driven changes in voltage-gated Na, K and Ca channels and ATP-sensitive K channels. In our model, cellular processes act to minimize ROS either through ROS-mediated ion-channel changes that lead to ATP-consuming spikes which relieve the cell of energetic-ROS, or by making spikes less frequent that allow replenishment from ATP depletion during exhaustive-ROS. We thus propose a direct and self-regulating negative feedback mechanism between spontaneous neuronal firing and ROS concentration.

Title: Electrophysiological properties of genetically distinct nociceptive neurons in the central amygdala

Authors: *A. ADKE[1], A. KHAN[1], H. H. AHN[1], Y. K. SUGIMURA[2], T. WILSON[1], Y. CARRASQUILLO[1];
[1]Natl. Ctr. for Complementary and Integrative Hlth., NIH, Bethesda, MD; [2]Dept. of Neurosci., Jikei Univ. Sch. of Med., Minato, Japan

Abstract: Despite the high incidence of chronic pain, therapeutic options are limited and much of the underlying neurobiology is unknown. Recently, the central nucleus of the amygdala (CeA) emerged as a critical center for pain processing, receiving direct nociceptive input from the parabrachial nucleus (PBN). Research in our lab found that distinct GABAergic CeA cell types

contribute differently to pain-related behaviors in mice. For example, during pain states, cells expressing Protein Kinase C delta (CeA-PKCδ) display increased excitability and promote hypersensitivity while somatostatin-expressing (CeA-Som) neurons suppress excitability and promote hyposensitivity. The cellular mechanisms driving this dual and opposing modulation of pain-related behaviors remain unknown. To begin to address this, we aim to determine whether intrinsic membrane properties of and PB inputs to CeA neurons are cell-type-specific. Using optogenetically-assisted circuit mapping of PBN-CeA circuits, we found that both CeA-PKCδ and CeA-Som cells receive PBN inputs and respond to PB terminal stimulation with similar magnitude. Interestingly, experiments using whole-cell patch-clamp recordings in acute slices demonstrated that CeA-PKCδ cells, which are more excitable in pain states, are less excitable than CeA-Som neurons at baseline. In contrast, CeA-Som cells are more excitable in baseline states but show decreases in excitability following nerve injury. Further analyses of firing properties and action potential waveforms demonstrated that in pain states, CeA-PKCδ cells have increased input resistances, decreased latencies to fire, and longer action potential durations. These results are consistent with decreased transient A-type potassium currents (I_A) following nerve injury. Ongoing experiments aim to establish a causal relationship between nerve injury, changed I_A current density, and behavioral hypersensitivity. Altogether, our results characterize firing properties of genetically distinct cells and suggest that pain-related hyperexcitability in CeA-PKCδ cells is due, at least in part, to alterations at the intrinsic level, thus identifying a potential source of pain plasticity and therapeutic target.

Title: Microglia-triggered plasticity of intrinsic excitability modulates psychomotor behaviors in acute cerebellar inflammation

Authors: *G. OHTSUKI[1], M. YAMAMOTO[2], M. KIM[1], H. IMAI[3], Y. ITAKURA[4];
[1]The Hakubi Ctr. for Advanced Res., [2]Dept. of Nephrology, [3]Dept. of Systems Sci., [4]Dept. of Biophysics, Kyoto Univ., Kyoto, Japan

Abstract: Cerebellar dysfunction is involved in various psychiatric disorders, including autism-spectrum and depressive disorders. However, the physiological aspect is less-advanced. We have previously reported the induction of intrinsic plasticity of the cerebellar Purkinje cells and its associated plasticity of the dendrite excitability (Belmeguenai et al. 2010, J. Neurosci.; Ohtsuki et al., 2012, Neuron; Ohtsuki and Hansel, 2018, iScience). Here, we comprehensively investigated the immune-triggered hyperexcitability in the cerebellum. Activated microglia via exposure to bacterial endotoxin lipopolysaccharide or heat-killed Gram-negative bacteria induced a potentiation of the intrinsic excitability in Purkinje neurons, which was suppressed by microglia-activity inhibitor and microglia-depletion. An inflammatory cytokine, tumor necrosis factor-<alpha> (TNF-<alpha>) released from microglia via toll-like receptor 4 triggered this plasticity. While our two-photon FRET ATP-imaging showed an increase in ATP concentration following endotoxin exposure, both TNF-<alpha> and ATP secretion facilitated synaptic transmission. Region-specific inflammation in the cerebellum in vivo showed depression- and autistic-like behaviors. Such behavioral modulation was reverted by both TNF-<alpha>-inhibition and microglia-depletion. Resting-state functional MRI revealed overconnectivity between the inflamed cerebellum and prefrontal neocortical regions. Thus, immune activity in the cerebellum induces neuronal hyperexcitability and disruption of psychomotor behaviors in animals (Yamamoto et al., Cell Reports, 2019).

Title: Cholinergic modulation of intrinsic plasticity in layer 2/3 pyramidal neurons of the mouse barrel cortex

Authors: D. F. GILL, ***C. HANSEL**;
Neurobio., Univ. of Chicago, Chicago, IL

Abstract: Long-term potentiation of synaptic inputs is widely considered the cellular mechanism underlying learning and memory. However, the degree to which EPSPs generated in the distal dendrite control spike output depends on intrinsic excitability that regulates EPSP propagation toward the soma (Larkum et al., *J. Physiol.* 533, 2001). Here, we sought to examine the mechanisms by which cortical pyramidal neurons can modify their excitability to enhance spike output. Using whole-cell patch-clamp recordings from layer II/III pyramidal neurons in slices prepared from the mouse (P28-40) primary somatosensory cortex (S1), we studied mechanisms underlying plasticity of membrane excitability ('intrinsic plasticity', IP). Measuring spiking responses (spike count) elicited by depolarizing current injection in wild-type (WT) mice, we could induce an average change in excitability of 148 ± 13% compared to baseline spiking (n=14). After this finding, we hypothesized this change was due to internalization of SK2 channels. SK2 channels are small-conductance, calcium-gated potassium channels, which serve to hyperpolarize the cell in response to burst activity. When the somatic protocol was tested in SK2-KO mice, we could no longer elicit changes in excitability (105 ± 8% in comparison to baseline, n=8) suggesting IP occlusion. We went on to test for the involvement of protein kinases in this SK2-dependent excitability regulation. Using an adapted synaptic protocol, we attempted to induce IP in a mouse with a mutant CaMKII which is permanently inhibited, the CaMKII 305D line (Elgersma et al., *Neuron* 36, 2002). However, changes in IP were CaMKII independent with a 165 ± 27% and 148 ± 21% change in excitability for WT and CaMKII 305D neurons, respectively (n=7 and 13). We then tested if SK2 channels were internalized (PKA-dependent) using the PKA inhibitor H89, and we could not induce IP under these conditions (82 ± 9%, n=6). Lastly, we sought to understand the role and convergence of muscarinic signaling on IP. To test this, we bath applied oxotremorine-m (oxo-m, muscarinic agonist) alone and during the somatic depolarization protocol. Oxo-m was able to increase excitability 147 ± 14% and showed enhancement to 212 ± 20% when paired with somatic stimulation (n=7 and 8). When oxo-m was applied to SK2-KO neurons, it no longer had an effect on the excitability of the cell (105 ± 9%; n=5). These findings demonstrate that cholinergic signaling enhances spike output in layer II/III pyramidal neurons, which may promote the integration of these neurons into cortical memory engrams (see Titley et al., *Neuron* 95, 2017).

Title: Increased excitability and decreased inhibition in layer 5 primary somatosensory cortex pyramidal neurons of aged mice

Authors: *I. R. POPESCU[1], K. Q. LE[2], A. E. LELAND[2], R. MOSTANY[3];
[1]Pharmacol., [2]Tulane Brain Inst., [3]Pharmacol. and Tulane Brain Inst., Tulane Univ., New Orleans, LA

Abstract: Increased excitability and decreased inhibition in the principal cortical neurons are hypothesized to contribute to expanded receptive fields and increased seizure susceptibility in aged humans and rodents. Here we asked whether age-related changes in excitability and inhibition are evident in layer 5 (L5) pyramidal neurons. Our strategy built on the differential expression of synaptic and intrinsic properties in pyramidal neuron subtypes, and age comparisons were made accordingly. We recorded intrinsic active properties enabling pyramidal type classification, and spontaneous IPSCs, in primary somatosensory cortex neurons, in acute mouse brain slices. L5 pyramidal neurons can be classified by co-varying active properties. “Adapting” neurons display larger adaptation of action potential (AP) frequency, larger slow afterhyperpolarization (sAHP), smaller sag and slower APs than “non-adapting” neurons. Cluster analysis of two active properties unaffected by age, AP duration and sAHP, yielded two neuron groups. Active properties and IPSC frequency co-varied in these groups in agreement with previous reports. Aged adapting neurons (18-29 months) had a more negative AP threshold, and strong trends towards decreased rheobase and adaptation compared with young adapting neurons (2-6 months). Non-adapting neurons displayed an age-dependent increase in sag, a decrease in rheobase and adaptation, and a decrease in IPSC frequency. Both neuron types exhibited age-dependent increases in AP frequency, but at different current step amplitudes. We conclude that aging causes an increase in excitability and a decrease in synaptic inhibition in L5 primary somatosensory cortex pyramidal neurons. However, changes were specific to adapting and non-adapting neuronal subtypes.

Title: Non-thermal modulation of neuronal signaling by electromagnetic mid-infrared stimulation

Authors: *X. LIU[1], Y. XIAO[1], C. CHANG[2], B. SONG[3], Y. SHU[1];
[1]Sch. of Brain and Cognitive Sci., Beijing Normal Univ., Beijing, China; [2]Advanced Interdisciplinary Technol. Res. Ctr., Natl. Innovation Inst. of Def. Technol., Beijing, China; [3]Sch. of Optical-Electrical Computer Engin., Univ. of Shanghai for Sci. and Technol., Shanghai, China

Abstract: Selective manipulation of activities in certain brain regions through neuromodulation approaches is a highly effective strategy to regulate brain functions and treat brain disorders. Most of these approaches exert their effects mainly though electrical stimulation of the neural tissue. Optogenetic stimulation is now a potential neuromodulation method, but the expression of exogenous genes hampers its use in human subjects. Here we show that mid-infrared stimulation (MIRS) with a specific wavelength provides non-thermal and reversibly regulatory effects on neuronal properties. To exclude the thermal effect of MIRS, we measured the temperature increase surrounding the tip of MIRS fiber and performed whole-cell recording from mouse (aged P14 to P25) neocortical pyramidal cells outside the region with temperature increase. We found that MIRS reversibly inhibits neuronal spiking responses to weak current injections but enhances those to strong current injections, indicating a gain modulation. Moreover, MIRS shapes the AP waveform by dramatically shortening its voltage integral by ~26% (from 131.7 ± 9.4 to 97.8 ± 5.7 mV·ms, $t_8 = 22.9$, $P = 0.1 \times 10^{-7}$, paired Student's *t*-test). MIRS also reduces the input resistance (from 194 ± 17 to 169 ± 14 MΩ, $t_8 = -6.91$, $P = 0.1 \times 10^{-3}$, paired Student's *t*-test) and the membrane time constant (from 38.5 ± 1.5 to 34.9 ± 0.9 ms, $t_8 = 2.78$, $P = 0.024$, paired Student's *t*-test). We then performed dynamic clamp experiments and found that a similar decrease in the input resistance (though adding leak conductance) only impedes spiking activities but has no effect on AP waveform. In dual soma-axon recording experiments, MIRS substantially accelerates AP conduction velocity along the axon by ~15% (from 0.24 ± 0.02 to 0.27 ± 0.02 m/s, $t_5 = -8.85$, $P = 0.3 \times 10^{-3}$, paired Student's *t*-test). Considering the crucial roles of voltage-gated sodium channels and potassium channels in AP generation and conduction, we examined whether MIRS exerts its effects via the regulation of activities of these channels. Consistent with AP waveform changes, MIRS selectively augments potassium currents (from 555 ± 54 to 651 ± 69 pA, $t_6 = -4.71$, $P = 0.003$, paired Student's *t*-test) and accelerates the gating kinetics. Together, our results indicate that MIRS represents a novel neuromodulation approach that can effectively regulate neuronal spiking activities, AP waveform and conduction velocity. Because there is no need to express exogenous genes, MIRS could be a potential optical neuromodulation method for clinical use.

Title: A biophysical mechanism for epigenetic inheritance of enhanced complex learning capabilities

Authors: *S. ZIDAN, E. BARKAI;
Univ. of Haifa, Haifa, Israel

Abstract: Training rats in a difficult olfactory discrimination (OD) task initiates a period of accelerated learning of other odors, manifested as a dramatic increase in the rats' capacity to acquire memories for new odors once they have learned the first discrimination task, implying that rule learning has taken place. Here we show that the acquired superb learning capability is transferred to descendants epigenetically.
We found that exposure of parents to OD task affects learning abilities of their offspring; Regardless which parent went through the training, or whether they have interacted with the offspring or not, trained rats' offspring (males and females) learned the same OD task significantly faster compared to pseudo-trained' offspring even when training odors differed from those used to train the FO generation. Such enhanced learning capabilities extended well beyond the OD task: descendants of OD trained parents, showed a remarkably enhanced learning capabilities in Morris water maze (MWM) as well. Showing a general enhancement in learning capabilities.
At the cellular level, intracellular recordings with sharp electrodes show that the biophysical properties of CA1 pyramidal neurons of trained rats' descendants differ significantly from neurons taken from control rats' descendant's, their intrinsic excitability is higher and they are capable of generating repetitive spike firing at a higher frequency than neurons taken from controls, such enhanced excitability is mediated by reduction in the post-burst AHP, presumably generated by the slow calcium-dependent potassium current (sI_{AHP}). Our previous studies show that these are the exact changes that are induced in the brains of rats after they acquire the rule, all experiments were performed blindly and replicated.
Together, the observed changes, which occur simultaneously at the behavioral and single cell levels, suggest that acquired enhanced learning capabilities of complex tasks may be transferred to the next generation(s) via an epigenetic mechanism. Trained rats' descendants are superb learners, since they are born with neurons that are intrinsically more excitable than neurons from control rats. This change occurs in their ancestors brains only after the rule learning and is transferred to them at birth, so they need less training to acquire new rules.

Title: Mitf links neuronal activity and intrinsic plasticity in olfactory bulb projection neurons

Authors: ***P. H. PETERSEN**, D. ATACHO, H. REYNISSON, T. EYSTEINSSON, E. STEINGRÍMSSON;
Biomed. Ctr., Univ. of Iceland, Reykjavik, Iceland

Abstract: The Microphthalmia associated transcription factor (MITF) is a basic helix-loop-helix-leucine zipper transcription factor essential for the development of melanocytes and mast cells. *Mitf* is also expressed in the glutamatergic projection neurons of the mouse olfactory bulb. Using the $Mitf^{mi\text{-}vga9}$ mouse model, we have determined that lack of Mitf leads to an increase in the ability of the $Mitf^{mi\text{-}vga9}$ mouse to distinguish between odors, while its capacity to detect odor is similar to the wild type mice. However, the ability of the mutant mice to adapt to odors over a period of hours is changed. We have identified tentative target genes of MITF in the projection neurons of the OB, including the potassium channels subunit Kcnd3, which is important for type A potassium current. *Mitf* has been shown in melanocytes to be regulated by glutamate signaling. As the nervous system is shaped and regulated by glutamate signaling, we determined whether MITF takes part in activity-induced responses at the transcriptional level. Expression of both Mitf and Kcnd3 is activity-dependent and expression of Kcnd3 is Mitf dependent. MITF binds to a strong enhancer of the Kcnd3 gene, suggesting that MITF regulates Kcnd3 expression directly. A decrease in Type A- potassium current in $Mitf^{mi\text{-}vga9}$ mouse M/T neurons is also observed, and a concomitant increase in neuronal activity of the M/T neurons of the $Mitf^{mi\text{-}vga9}$ mouse. Function of other putative target genes of MITF in OB projection neurons, suggest a general role of MITF as a negative regulator of neuronal activity. We propose a model, where MITF regulates intrinsic plasticity in the olfactory bulb projection neurons. The role of MITF in neuronal homeostasis following activity suggests that MITF plays a major role in long-term selective olfactory habituation and homestatic plasticity.

Title: Hyperexcitability of pyramidal neurons caused by BRAFV600E is partially rescued by dominant negative REST

Authors: *G. AKGÜL, J. DUNNACK, J. J. LOTURCO;
Physiol. and Neurobio., Univ. of Connecticut, Storrs, CT

Abstract: BRAF V600E mutation is the cause of up to 70 % of low grade neuroepithelial tumor cases. Intractable focal epilepsy is comorbid with 25-80 % of these cases. The mechanisms of epileptogenesis in low grade brain tumors is poorly understood. However, BRAF V600E mutation harboring mouse brain tumor tissue has been recently reported to exhibit differential expression profile of REST (RE1-silencing transcription factor) mRNA. Therefore, we investigated the hyperexcitability of BRAF V600E expressing neurons and the role of REST as a mediator. By using *in utero* electroporation, we introduced BRAF V600E mutation to radial glia cells in mouse embryos at E13-15, to generate a mouse model for BRAF V600E carrying low grade brain tumors. We delivered the recombinant DNA in a *piggybac* vector along with *piggybac* transposase expressing vector to ensure stable expression of BRAF V600E in mouse brain. To study the role of REST in neuronal hyperexcitability, we delivered dominant negative REST (dnREST) alone (as control) or with BRAF V600E (to test REST rescue of hyperexcitability). We probed brain sections of mice transfected with BRAF V600E and dnREST with a GFP antibody to confirm dnREST expression due to low expression of YFP. Confocal images showed that dnREST expressing neurons exist in cortex. Interestingly, focal cortical dyplasia (FCD) is also apparent in those brains. Whole cell electrophysiology recordings from neurons expressing BRAF V600E alone (V600E), BRAF V600E and dnREST (V600E+dnREST), dnREST alone and nonfluorescent neighbors in acute brain slices of mice at P17-24 showed that the frequency of action potentials fired from V600E and V600E+dnREST are the same with each other and significantly different from AP frequency of dnREST expressing or nonfluorescent neighbor neurons, over the period of the incremental increase in injected current [-80 - +300 pA]. V600E or V600E+dnREST expressing neurons had also high SAG ratio at hyperpolarizing current injections (calculated at -40 pA step) (V600E: 27.4 ± 13.3 %; V600E+dnREST: 20.3 ± 11.6 %) compared to dnREST (5.8 ± 5.8 %) or nonfluorescent neurons (5.5 ± 2.8 %). However, the waveform of the first action potential fired from the neurons displayed significant differences that could be implicated hyperexcitability, across groups. For

example, action potential threshold was significantly higher in V600E+dnREST (-47.6 ± 1.3 mV) compared to V600E (-42.6 ± 3.2 mV; p=0.004). These results show that, V600E expressing neurons go through multiple changes that make them hyperexcitable and REST is involved in some of the molecular mechanisms in this process.

Title: Fibronectin is heterogeneously expressed in the mouse subiculim

Authors: *T. KASHIMA, A. NOGUCHI, Y. IKEGAYA, N. MATSUMOTO;
The Univ. of Tokyo, Tokyo, Japan

Abstract: The subiculum is anatomically and physiologically heterogeneous at the single neuron level. Recent studies have investigated the diversity of the dorsal subiculum in terms of gene and mRNA expression. However, few studies have investigated the heterogeneity of the entire subiculum. To reveal the heterogeneity of the whole subiculum, we examined fibronectin protein because its mRNA (FN1 mRNA) is known to be expressed in the subiculum. We horizontally sectioned the mouse brains, performed immunohistochemistry against fibronectin and NeuN, and characterized the expression pattern of fibronectin protein in the entire subiculum along three axes (i.e., the dorsoventral, proximodistal, and superficial-deep axes). We first found that FN1 mRNA is translated into protein inside cells although fibronectin is generally distributed in extracellular regions. Based on the immunofluorescence pattern of NeuN-positive cells, we defined the pyramidal cell layer of the subiculum and transformed the pyramidal field into a virtual rectangle. Unexpectedly, we found that the fibronectin protein was widely distributed in the pyramidal cell layer of the dorsal subiculum, whereas in the ventral subicular pyramidal field, fibronectin was concentrated around more superficial and distal corner. To exclude the possibility that this heterogeneous expression pattern of fibronectin was totally dependent on the plane of sectioning, we performed the same immunohistochemistry with coronally sectioned slices. In coronal sections, we found almost the same expression pattern of fibronectin as shown in the horizontal sections. Moreover, we investigated the functional relevance of fibronectin-positive cells in the subiculum. A previous study reported that vesicular glutamate transporter 2

(VGluT2) functions as a specific marker protein for bursting neurons in the subiculum (Wozny *et al*., 2018). Thus, we immunostained VGluT2 as well as fibronectin and consequently found that the expression of fibronectin and VGluT2 did not overlap. These results suggest that fibronectin-positive excitatory neurons exist more locally in the ventral subiculum than in the dorsal subiculum and might exhibit a regular-spiking firing pattern. Therefore, fibronectin may be useful as a marker protein for investigating the heterogeneity of principal cells in the entire subiculum.

Title: Which cellular mechanism yields compatibility between brain states, synaptic plasticity and neuromodulation?

Authors: *K. COUTISSE, G. DRION;
Electrical Engin. and Computer Sci., Univ. of Liege, Liege, Belgium

Abstract: Learning and memory are attributed to the ability of neurons to modify their connections with other cells based on experience, a property called *synaptic plasticity*. On the other hand, brain information processing is shaped by fluctuations in neuronal rhythms at the cellular and population levels, each defining distinctive *brain states*. Switches between these brain states, driven by *neuromodulation*, can be fast and localized, such as those observed in Parkinson disease patients stopping, almost instantaneously, tremor symptoms when deep-brain stimulation is turned on. Switches can also be global and long lasting, such as those observed during the wake-sleep transition. The coexistence of these two mechanisms raises challenging questions: how can switches in brain states remain reliable despite constant rewiring of neuron connectivity and how is synaptic plasticity affected by switches in brain states?
Here, we highlight the role of *slow regenerativity*, a cellular dynamical property, in the generation of brain state switches that are robust to cellular heterogeneity, independent from network connectivity, and thus compatible with synaptic plasticity. This key mechanism is accessible by all neurons that embed *slowly activating voltage-gated calcium channels or slowly inactivating potassium channels* in their membrane. Yet, in computational neuron models, this channel dynamics is often considered as an instantaneous event and it is absent from all available hybrid models.
To demonstrate this point, we compare the robustness of 6 published thalamic neuron conductance-based models at the cellular, circuit and population levels [Destexhe, 1996;

Destexhe, 1998; Drion, 2018; Huguenard and McCormick, 1992; Rush and Rinzel, 1994; Wang, 1994]. We show that the robustness of rhythms at the population level correlates with the presence of slow regenerativity at the cellular level. We extend our results to 3 subthalamic nuclei neuron (STN) conductance-based models [Terman et al, 2002; Kubota et al, 2011; Santaniello et al, 2007]. It confirms that this key dynamical property is also required to reproduce switches in STN neuron activity robust to variability. Our work highlights that slow regenerativity is independent on the type of neurons, the intrinsic frequency of the firing pattern and valid for global and lasting brain state switches as well as local and fast. Second, we show that this mechanism can be embedded in simple hybrid neuron models without increasing the model complexity. These results open the possibility to study the interactions between switches in network rhythmic activity and synaptic plasticity in large neuronal populations.

Title: Differential effect of oxytocin on cell types in medial prefrontal cortex: A comparison between single and pair fear-exposed adolescent rats

Authors: *J. TAESUB;
Dankook Univ., Young-in si, Korea, Republic of

Abstract: The prosocial hormone oxytocin activates the medial prefrontal cortex (mPFC) and fear-related behaviors during pair exposure are under tight control of the mPFC, but the underlying cellular mechanism of oxytocin action for mPFC in pair-exposed condition is poorly understood. To determine this issue, we performed a slice current-clamp patch recording in single- and pair-exposed electric shocked rats. Here we distinguished two types of cells, pyramidal neurons and interneurons, in mPFC with their morphologic and electrophysiologic characteristics. There were not significant differences of resting membrane potential alteration in both cell types between single and pair rats. We found that the treatment of oxytocin in interneurons induced the increase of neuronal spikes in single rats compared with pair rats, whereas the oxytocin exposure in pyramidal neurons decreased the spikes in both single and pair rats, suggesting that the activity of mPFC in single rats is reduced by oxytocin compared to that in the pair rats. These results reveal oxytocin-mediated interneuronal activity reduction in mPFC of pair-exposed shocked rats represents a reinforcement of mPFC activity and induces a reduction of fear-related behavior compared with single-exposed shocked rats. Abstract: Epilepsy is a common neurological disease with the highest incidence occurring in the youngest and oldest segments of the population. Genetic mouse models have led to important clues regarding the etiology of epilepsy; however, the phenotypes of known mouse mutants that exhibit spontaneous, recurring seizures emerge early in life, generally by one month of age. Prior work at Thomas Jefferson University established a colony of inbred mice that exhibited recurring generalized tonic-clonic seizures beginning between 6-18 months of age. The index case was a male mouse that was the offspring from a cohort of the Collaborative Cross strain CC039/Unc. The pedigree has been expanded to 5 generations with the epilepsy phenotype segregating according to an apparent autosomal dominant or semi-dominant mode of transmission. Males from the founder family develop epilepsy significantly earlier than females, and seizure episodes become more frequent with advancing age. Whole-genome analysis of single nucleotide polymorphisms was performed in epilepsy (N = 6) and non-epilepsy (N = 5) mice from the founder family. Several chromosomal deletions were identified; however, none segregated with the epilepsy phenotype. An F1 generation (N = 99) was created by mating CC039 epilepsy mice with DBA/2J (D2) mice. Currently, F1 mice range in age from 70-140 weeks with only approximately 10% of the population exhibiting epilepsy, i.e. spontaneous seizures. This result suggests incomplete penetrance of the mutation on the D2 genetic background. An N2 backcross generation (N = 115) was created by mating F1 epilepsy mice with D2 mice. As observed in the F1 generation, about 10% of the N2 population over 1 year of age have demonstrated spontaneous seizures to date. Production and phenotyping of F1 and N2 mice remains ongoing.

Complete genetic dissection of this novel mouse model may lead to important insight into the mechanisms of adult-onset epilepsy in humans.

Title: Targeted deletion of mitochondrial cyclophilin D mediates neuroprotection in epileptic brain

Authors: *B. R. VILLA[1], C. N. GAVRILOVICI[2], G. TESKEY[1], J. M. RHO[3];
[1]Cell Biol. & Anat., [2]Paediatrics, Univ. of Calgary, Calgary, AB, Canada; [3]Alberta Children's Hospital, Univ. of Calgary, Calgary, AB, Canada

Abstract: Epilepsy is a chronic neurological disease affecting over 50 million people worldwide. It is characterized by spontaneous recurrent seizures (SRS) arising from hyperexcitable and hypersynchronous brain activity. Seizure activity leads to debilitating co-morbid problems (e.g. cognitive impairments) that ultimately impair quality of life. Current therapies fail to control seizures in one-third of people with epilepsy. There is a strong need to develop new treatments that block seizures and the progression of the disease, thus preventing deleterious consequences. Mitochondria are critically important for cell energy homeostasis and survival. Recently, it has been shown that a mitochondrial protein known as cyclophilin D (CypD) - which regulates the mitochondrial permeability transition pore (mPTP) - a determinant of cell death - when inhibited, significantly reduces seizures in a mouse model of human epilepsy. Despite this intriguing observation, it is unclear how CypD regulates seizure activity.
We used immunohistochemistry and confocal microscopy techniques to show that hippocampal parvalbumin (PV)-positive GABAergic interneurons, which are fast-spiking and thus very energy-consuming, express high levels of mitochondrial CypD in a clinically relevant model of developmental epilepsy (*Kcna1*-null mouse). We proposed that this elevated expression increases the sensitivity of these interneurons to mPT and subsequent cell loss. As PV-positive interneurons project onto hundreds to thousands pyramidal cells, any decrease in interneuron firing may contribute to seizure generation.

We found that most neurons with high immunoreactivity to CypD in the dorsal CA1 hippocampal area of wild-type mice express parvalbumin. *Kcna1*-null mice showed significant PV-positive cell loss, which was prevented by specific deletion of CypD in those mice. In addition, targeted deletion of CypD in wild-type mice is itself neuroprotective by increasing the survival of PV-positive cells. Furthermore, we observed that GAD67 interneurons in wild-type, *Kcna1*-null, CypD-deficient *Kcna1*-null, and CypD-deficient wild-type mice are unchanged, indicating that the vast majority of interneurons survive in epileptic *Kcna1*-null mice, but that only a subpopulation of (most likely PV) interneurons are reduced in CA1 hippocampus. Further studies will detail the role of CypD in GABAergic interneurons and in modulation of the hippocampal inhibitory network. Collectively, our results will provide further evidence for a direct link between metabolism and seizures genesis, and will establish CypD as a promising therapeutic target for medically intractable epilepsy.

Title: Leveraging intrinsic ion channel plasticity in the hippocampus to dampen seizure susceptibility

Authors: *C. M. CARVER, M. S. SHAPIRO;
Univ. of Texas Hlth. San Antonio, San Antonio, TX

Abstract: M-type (KCNQ2/3) K+ channels have important roles in neuronal regulation of resting potential, spike-frequency adaptation, and hyper-excitatory states. We have previously shown M channel transcription to be upregulated in sympathetic ganglia and in hippocampus after a seizure. In a model of hyperactivity that does not provoke epileptogenesis, we monitored activity-dependent KCNQ2 transcription in the hippocampus. We used transgenic mice with a KCNQ2-EGFP reporter to detect region-specific mRNA expression maps, in which transcription of KCNQ2 mRNA occurs concomitantly with EGFP protein expression. Mice were challenged with pilocarpine (230 mg/kg) or pentylenetetrazole (60 mg/kg) and brain tissue was examined 48

hours later. We observed significant increases in KCNQ2 transcription in CA1 and CA3 pyramidal neurons 48 hours after hyperexcitability, which dissipated after 7 days, but no significant change was observed in the dentate gyrus (DG) due to moderate hyperexcitability. In response to status epilepticus (300 mg/kg pilocarpine), DG granule cells exhibited robust upregulation of KCNQ2, whereas CA1 and CA3 expression was reduced. *In situ* hybridization paralleled fluorescent experiments investigating KCNQ2, however KCNQ3 was not upregulated in hippocampus.
Using brain-slice electrophysiology, CA1 pyramidal neurons demonstrated increased M-current amplitudes after hyperexcitability; there were no significant changes in DG granule cell M-current amplitudes between control and pilocarpine challenged mice. In current-clamp recordings of action potential firing properties, DG granule cells demonstrated hyperexcitability, along with cFos activity, despite no significant change to M-current. We examined *in vivo* seizure susceptibility 48 hour after an initial hyperexcitability challenge, at which time heightened KCNQ2 transcription and protein expression was observed. After a secondary challenge with pentylenetetrazole, mice were highly susceptible to tonic-clonic seizures and death, whereas mice given the M-channel opener retigabine were protected from seizures. This study demonstrates that independent of the mechanism of hyperexcitability, activity-dependent excitation promotes KCNQ2 upregulation in the hippocampus in a cell-type specific manner, and may serve as a compensatory mechanism after a hyperexcitable event. The transient upregulation we describe may serve as a protective mechanism against the deleterious cascade of hyperexcitability, which could be potentially leveraged in anticonvulsant enhancement of KCNQ2 channels as therapeutic target for preventing onset of seizures.

Title: Prediction of seizures by active probing neurostimulation

Authors: *C. KREMPP[1], S. EBRAHIM[2], E. ROGGE[2], B. F. COUGHLIN[3], A. AZMI[2], N. F. FUMEAUX[2], A. KADAMBI[2], M. F. MORAES[4], S. S. CASH[5];

Abstract: Objective: Seizure prediction by analyzing continuous EEG has been a long-term therapeutic goal for closed loop seizure preemption. Yet, current approaches remain suboptimal. An alternative approach is to examine responses to active perturbation of the system instead of spontaneous activity. In this work, we explored both spontaneous data over long time periods and the use of single pulse electrical stimulation (SPES) to actively probe the ictogenic neural circuitry and examined neural responses between and before seizures with an eye toward seizure forecasting. **Methods:** Young male SD rats (2-3 mo, n = 18) were implanted with surface electrodes, EMG pads and intrahippocampal depth electrodes bilaterally. Unilateral intrahippocampal injections of kainic acid were administered to induce chronic epilepsy, while video and EEG recordings were recorded continuously for 3 months. Multichannel EEG data was analyzed by computing standardized features in time and frequency domains for 5-second windows, and seizure segments were also manually labelled by an expert. In two animals, SPES was delivered at 0.5 mA every three to five seconds for active probing. We developed pooled and individualized predictors using multiple methods applied to passive and active data, including support vector machines (SVM). **Results:** SVM analysis of the spontaneous data without stimulation yielded an AUROC of 0.70 on our pooled dataset of 1012 rodent seizures across 16 animals. From the active data, we identified multiple features across time and frequency domains, including evoked HFOs that significantly change in preictal periods. In the two subjects with active probing via SPES, we trained individualized SVM classifiers that perform at AUROCs of 0.94 and 0.98.
Conclusions: We predicted seizures in a rodent epilepsy models with a high degree of sensitivity and specificity, with a significant improvement in AUROC relative to the state of the art. These results offer new insights into the mechanisms underlying seizure initiation, and may help improve diagnostic and therapeutic approaches for patients suffering from focal epilepsy.

Title: The effect of inflammation on behavioral outcome and seizure susceptibility after experimental traumatic brain injury

Authors: *Y. LIN[1], C. WU[2], J. LIU[2], A. Y. REID[3];
[1]Inst. of Med. Sci., Univ. of Toronto, Toronto, ON, Canada; [2]Univ. Hlth. Network, Toronto, ON, Canada; [3]Neurol., Univ. Hlth. Network, Univ. of Toronto, Toronto, ON, Canada

Abstract: Objective and Rationale: Traumatic brain injury (TBI) can lead to cognitive impairment, motor abnormalities and post-traumatic epilepsy, which can significantly impact quality of life. The inflammatory response mounted after TBI has both beneficial and detrimental consequences. A direct comparison between pro- and anti-inflammatory strategies after TBI has not been performed. Our goal was to investigate the effect of post-TBI inflammation on behavioral outcome and seizure susceptibility. We hypothesized increased inflammation would lead to more severe behavioral deficits and increased seizure susceptibility, while decreased inflammation would lead to milder behavioral deficits and lower seizure susceptibility.
Methods: Experiments were performed in four groups of young adult male Sprague-Dawley rats: Group 1) sham injury; Group 2) severe TBI via fluid percussion injury; Group 3) TBI plus minocycline (45 mg/kg ip twice on day of injury and daily thereafter for 18 days); Group 4) TBI plus lipopolysaccharide (LPS; 100 ug/kg ip immediately pre-injury) (n=7-18 rats/group). A battery of behavioral tests consisting of a composite neuroscore, rotarod, novel object recognition (NOR), and Barnes maze was performed at various time points within one month post-TBI. Rats were later implanted with intracranial recording electrodes, and approximately nine months post-injury a subset of rats from each group were injected with a single dose of 30 mg/kg pentylenetetrazol (PTZ) to determine seizure susceptibility.
Results: Similar levels of neuromotor deficits were seen in all TBI groups early after injury as compared to sham controls. Barnes maze testing showed the TBI+mino group had better spatial memory than the TBI and TBI+LPS groups ($p<0.05$). No difference between groups was found in NOR testing. The TBI+mino group had shorter seizure duration in response to PTZ compared to the TBI group, comparable to the sham group. The TBI+LPS group had longer seizure duration than all other groups. However, the sham and TBI+mino groups had a higher number of interictal spikes after PTZ than the TBI and TBI+LPS groups.
Conclusions: These results suggest certain TBI-related dysfunctions, such as spatial memory disturbance and increased seizure susceptibility, can be ameliorated by decreasing inflammation in the acute post-injury period. Heightened levels of post-TBI inflammation did not appear to affect many behavioral outcomes, but did further increase susceptibility to PTZ-induced seizures. Further work is needed to understand the complex effects of pro- and anti-inflammatory therapies on post-TBI behaviors in order to develop potential therapeutic strategies.

Title: Effects of the testicular androgens in absence seizures in the myelin mutant taiep male rat

Authors: *C. CORTES, E. GRADOS, J. R. EGUIBAR;
B. Univ. Autonoma de Puebla, Puebla, Mexico

Abstract: Absence seizure is a type of generalized type of epilepsy and it is most frequent during childhood. Importantly, the major proportion of children with this type of epilepsy develop the absence crisis during childhood and most of them change after puberty. The availability of animal models in which it is possible to do a long-term electroencephalography (EEG) recordings are limited, the two available absence seizure rat models are Genetic Absence Epilepsy Rat from Strasbourg (GAERS) and Wistar Albino Glaxo rats from Rijswijk (WAG/Rij). The *taiep* rat is as myelin mutant rat with a recessive trait inheritance. *Taiep* is an acronym of tremor, ataxia, immobility episodes, epilepsy and paralysis. Recently, we characterized this abnormal waves as an absence seizure that affects differentially male and female rats, being the male more susceptible with respect to female *taiep* rats. Thus, the aim of this study was to analyze the susceptibility to have in adulthood absence seizures with different hormonal conditions male *taiep* rats. Adult sham-operated rats and adult orchiectomized males (n=8 per group) were used. Stereotaxic surgery was performed to implant a bipolar of electrode in the CA1 region of the hippocampus, and also stainless-steel electrodes in the frontal and occipital cortex and in the muscles of the neck and ocular orbit in order to analyze absence seizures. A 24-hour video-EEG recording was used to analyze the absence seizures every 2-hour bias. Our results show that adult orchiectomy increased significantly the frequency of absence seizures, being the MESOR value 187.875 ± 69.974 with respect to just 86.142 ± 30.422 (*t student,* T=0.052, $p<0.02$) in the control group. There was also a significant increase in the mean duration of the absence seizures in adult orchiectomized males with the highest peak in duration of orchiectomized rats at 11:00 of 2.3175 ± 01.2271 S.E.M (*t student, T*=-15.095, $p<0.001$) and a MESOR of 2.08 ± 0.029 sec ($F(2104) = 85.94$, $p<0.001$). Meanwhile, MESOR value of seizures for control male rats was of 1.77 ± 0.027 sec (t student, $F(2104) = 85.94$, $p<0.001$). This is the first demonstration absence seizures depend on testicular androgens and with different effects

depending on time of castration and then in the modulation of thalamo-cortical circuit that support that absence seizures increased in non-androgen condition.

Title: Electrophysiological characterization of CA1 neurons in a mouse model of Dravet syndrome

Authors: *M. MARTINA[1], S. SCHOCK[2], D. DYMENT[2];
[1]Human Hlth. Therapeut. Res. Ctr., Natl. Res. Council of Canada, Ottawa, ON, Canada;
[2]Children's Hosp. of Eastern Ontario Res. Inst., Ottawa, ON, Canada

Abstract: Dravet Syndrome (DS) is the archetypal Early-onset Infantile Epileptic Encephalopathy (EIEE) which affects 1-2 per 10,000 individuals and are heterogeneous both in their underlying genetic etiologies and clinical presentation. DS often manifests in the first year, with characteristic clinical and EEG findings. The seizures are typically refractory to anti-epileptic medications and, possibly, as a result of this, are associated with mild to profound cognitive and developmental deficits. It is estimated that 85% of individuals with a clinical diagnosis of DS have a mutation in the voltage gated sodium channel ($Na_v1.1$) encoding gene SCN1A. SCN1A mutations are thought to operate through different mechanisms with both altered function of the channel and complete loss-of-function mutations observed. To gain insight into these mechanisms, a mouse model of DS based on a Canadian patient was created (Care4Rare Consortium) in collaboration with The Centre for Phenogenomics (TCP) in Toronto, Canada. The mouse was generated by microinjection of Cas9 RNA guided nuclease (Cas9-RGN) and guide RNAs (gRNAs) that specify the target site into the zygotes. The patient specific mutation (p.H939R) mice were bred on a C57BL/6N background. We have characterized the mouse seizures and overall behavior. We found that heterozygous mice carrying the Nav1.1 substitution displayed seizures. To study the neuronal network makeup causing seizures in these mice and to gain insight on the possible effects of any future therapeutic intervention, we have studied the electrophysiological properties of pyramidal neurons and interneurons of the CA1 region of the mouse hippocampus and compared them with wild type (WT), using whole cell patch clamp recording in brain slices. We found that pyramidal neurons and interneurons in DS had a significantly more depolarized resting membrane potential compared to WT. In addition, DS interneurons showed a reduced firing frequency compared to WT. These features could be

responsible for the hyper-excitability of the CA1 circuit under certain conditions, such as temperature, which can trigger seizures.

Title: Severe, refractory status epilepticus following cortical injury

Authors: *T. SINGH, S. JOSHI, J. WILLIAMSON, J. KAPUR;
Dept. of Neurol., Univ. of Virginia, Charlottesville, VA

Abstract: Status epilepticus (SE) is a common complication of cortical injury. However, there are no animal models. Therefore, our goal was to develop a model of SE resulting from neocortical injury. Cobalt was implanted (2.1 mg) in the supplementary motor cortex and 18h later homocysteine (845 mg/kg i.p.) was administered. Seizures were evaluated using video, and EEG recorded from bilateral frontal and parietal electrodes. Focal seizures commenced 13.5 ± 1.5 min following homocysteine administration which manifested as focal dystonia with clonus. During these seizures, frontal onset rhythmic spike wave discharges were observed. The focal seizures then evolved into generalized continuous convulsive activity. Continuous behavioral seizures lasted 1-2 h and consisted of generalized tonic stiffening, bilateral limb clonus, and generalized tonic clonic activity. There were generalized rhythmic spike wave discharges, generalized polyspikes discharges, and generalized high frequency (β and γ) low amplitude activity during this phase. After prolonged seizures, animals became still with intermittent bilateral myoclonic seizures or jerks. EEG at this time evolved to seizures interspersed with generalized period discharges on a suppressed background. This evolved to burst suppression and then to profound and persistent suppression. Following SE animal were stuporous, comatose and then died. Seizures were refractory to diazepam (10, and 30 mg/kg i.p.) administered 10 min after onset of continuous seizures. Blood brain barrier was disrupted as evident from Evan's blue staining and presence of albumin in the ipsilateral and frontal part of the brain. We have developed an animal model of severe, refractory SE which began in the frontal cortex. SE ended in coma, burst suppression and death. We will study mechanism underlying this form of SE.

Title: Seizure susceptibility in a PCDH19 epilepsy mouse model

Authors: *N. SABETFAKHRI[1], A. D. GUEMEZ-GAMBOA[2];
[1]Physiol., Northwestern Univ. Feinberg Sch. of Med., Chicago, IL; [2]Physiol., Nortwestern Univ., Chicago, IL

Abstract: PCDH19-related epilepsy is an early-onset epileptic encephalopathy characterized by short and repeated seizure clusters. Patients present with predominantly focal seizures, which are often followed by developmental decline and intellectual disability. PCDH19-related epilepsy is caused by heterozygous loss-of-function mutations in the X-linked gene, *Protocadherin 19* (*PCDH19*). Pathogenic *PCDH19* variants are inherited in an atypical X-linked dominant pattern in which heterozygous females present with seizures, while hemizygous carrier males are asymptomatic. It is hypothesized that this unusual pattern of inheritance results from cellular interference, a mechanism in which the co-existence of neurons expressing wild-type or mutant *PCDH19* disrupts cell-cell interactions. Recent cases of affected males with somatic mosaicism for *PCDH19* mutations provide further support for cellular interference as the disease mechanism. To investigate seizure susceptibility in a PCDH19 epilepsy mouse model, we induced generalized and focal seizures in female *PCDH19* heterozygous and knock-out mice, male *PCDH19* hemizygous mice, and their wild-type littermates. All genotypes showed comparable levels of seizure susceptibility to induced generalized seizures. However, female *PCDH19* heterozygous and knock-out mice showed significantly increased susceptibility to induced focal seizures. Interestingly, they displayed comparable levels of increased seizure susceptibility and severity. These results suggest that a pathogenic mechanism in addition to cellular interference may contribute to the PCDH19 seizure phenotype.

Title: Endogenous activation of cannabinoid receptor type 1 (CB1R) is required for survival and neuroprotection in rats exposed to the organophosphate nerve agent soman

Authors: *S. O'BRIEN, B. WINNER, S. WOLFE, K. KELLY, C. PHUNG, K. PAGARIGAN, M. EISEN, P. BODNER, M. NELSON, P. MCNUTT;
MRICD, Gunpowder, MD

Abstract: The endocannabinoid (eCB) system is one of the most important and least understood endogenous on-demand neuroprotective pathways. Overstimulation of glutamatergic, cholinergic, or GABAergic receptors results in rapid biosynthesis of eCBs in the postsynaptic neuron, resulting in their retrograde transport to activate presynaptic cannabinoid receptor type 1 (CB1R) in neurons and astrocytes and reduce presynaptic release probability. Exposure to the organophosphate nerve agent soman overstimulates central muscarinic acetylcholine receptors, causing status epilepticus (SE) and eliciting excitotoxicity in several brain regions. We have previously shown in hippocampal slices that perfusion with organophosphate nerve agents elicits long-term depression at Schaffer collateral synapses that is dependent on group 1 muscarinic receptors and CB1R activation, suggesting that eCB signaling may reduce excitatory neurotransmission under conditions of cholinergic overstimulation. Here we tested the clinically used CB1R antagonist SR141716A (Rimonabant) in a rat survival model of soman exposure to determine the systemic effects of CB1R inhibition on soman-induced neuropathology and survival. In contrast to vehicle controls, which exhibited 100% survival through 10 d after soman exposure, only 25% of rats treated with Rimonabant survived through the course of the study ($p = 0.0039$). Furthermore, neuropathological scoring revealed significant increases in neuronal loss and gliosis in the hippocampus of Rimonabant-treated rats versus vehicle controls. Taken together, these data demonstrate that endogenous CB1R signaling decreases neurotoxicity and improves survival following exposure to organophosphate nerve agents. We are currently determining if positive modulation of CB1R can enhance neuroprotection in response to lethal organophosphate nerve agent exposure.

Title: Zebrafish model of post-traumatic epilepsy

Authors: *S.-J. CHO[1], E. PARK[2], A. BAKER[2], A. REID[1];
[1]Univ. Hlth. Network, Toronto, ON, Canada; [2]St. Michael's Hosp., Toronto, ON, Canada

Abstract: Background: Post-traumatic epilepsy (PTE) is a complication from traumatic brain injury (TBI). PTE is defined as recurrent and unprovoked seizures occurring more than one week after TBI. Animal studies of PTE are lengthy and expensive. Zebrafish are an emerging model organism for studying disease and development due to their ease of use and require less maintenance than rodents. In this study, we developed a cost-effective PTE model using zebrafish to bridge the gap between *in vitro* studies and low-throughput animal studies.
Methods: Severe closed-head TBI was induced in AB strain wild-type zebrafish (6-12 months old) using pulsed high-intensity focused ultrasound, with naïve zebrafish as controls. We used an automated behavioral tracking system to evaluate locomotor/psychological deficits, and spontaneous behavioral seizure activity was manually scored for 21 days post-injury (DPI). A behavioral seizure susceptibility test was also performed using a sub-convulsive dose of 2.5 mM pentylenetetrazole (PTZ) on day 7, 14, and 21. In addition, we recorded forebrain electrophysiological signals to confirm seizure activity.
Results: The severe closed-head TBI model resulted in mortality in 25% of the injured zebrafish. Locomotor activity was disrupted post-injury and never fully recovered by 21 DPI. Also, the TBI group had heightened anxiety for 21 days. 100% of the TBI group showed spontaneous myoclonic-like jerking behavior for 21 days. 44% of the TBI group developed clonic-like prolonged jerking behavior at 3 DPI (n=15), which increased to 80% at 21 DPI (n=15). Such activities were not detected in the naïve group (n=10). After the administration of 2.5 mM PTZ, 90% of injured ZF had clonic-like seizures at 7 DPI (n=10), increasing to 100% at 14 DPI and 21 DPI (n=10), versus 30% of the naïve group. Of those progressing to clonic seizures, the average seizure onset time was significantly longer in the naïve group at 750±50s versus 258±46.5s in the TBI group at 7 DPI, 217±41.2s at 14 DPI and 298±45.2s at 21 DPI. Lastly, we demonstrated interictal epileptiform discharges and electrographic seizure activity in the TBI group, which were not detected in the naïve controls.
Conclusion: We have demonstrated increased PTZ-induced seizure susceptibility as well as spontaneous behavioral and electrographic seizure activity, after TBI in zebrafish. These changes endured for at least 21 DPI, suggesting this may be a useful model that can accelerate research in PTE.

Title: Vasoactive intestinal peptide-expressing interneurons are impaired in a mouse model of Dravet syndrome

Authors: *K. M. GOFF[1], E. M. GOLDBERG[2];
[1]MSTP, Univ. of Pennsylvania, Philadelphia, PA; [2]Neurol., The Children's Hosp. of Philadelphia, Philadelphia, PA

Abstract: Dravet syndrome (DS) is the most common early infantile epileptic encephalopathy, caused primarily by *de novo* mutations in *SCN1A* which codes for the voltage gated sodium (Na+) channel alpha subunit Nav1.1. This channel is prominently expressed in GABAergic interneurons, and it is therefore hypothesized that selective dysfunction of interneurons leads to impaired inhibition in the developing brain, which in turn underlies the epilepsy and other cognitive comorbidities found in DS. Both parvalbumin (PV) and somatostatin (SST) expressing interneurons have been shown to be impaired in DS; however, the function of the third major group of interneurons - the vasoactive intestinal peptide (VIP) expressing interneurons - have not been specifically investigated. Here, we used *Scn1a*$^{+/-}$ mice crossed to VIP-Cre.tdTomato reporter mice to perform targeted whole cell recordings from VIP interneurons in layer 2/3 primary somatosensory and visual cortex of acute brain slices prepared from male and female mice across development. We demonstrated that VIP interneurons have impaired excitability, with depolarized action potential thresholds, reduced steady state firing frequencies, and prominent spike height attenuation in *Scn1a*$^{+/-}$ mice at both post-natal day (P) 18-21 and P35-56 age groups relative to age-matched wildtype littermate controls. Immunohistochemistry confirmed expression of Nav1.1 on VIP interneuron axons, and selectively activating Nav1.1 with the toxin Hm1a was able to rescue the cellular phenotype of VIP cells in *Scn1a*$^{+/-}$ mice. These deficits were found to primarily affect a large (50%) subgroup of VIP interneurons which show a prominent irregular spiking (IS) firing pattern. We then showed that, while IS VIP interneurons do not colocalize with other putative VIP subtype markers such as calretinin and cholecystokinin, the presence of M current in VIP interneurons largely accounts for their IS phenotype. We further explored the interaction between loss of Nav1.1 and the presence of M current with detailed biophysical modelling. Our results indicate that VIP-positive interneurons

express Nav1.1 and, along with PV and SST interneurons, are dysfunctional in DS. As the canonical VIP circuit is disinhibitory rather than inhibitory, these findings suggest that VIP cell dysfunction could relate to non-epilepsy comorbid conditions in DS. Title: Compensatory contralateral hippocampal neurogênesis in the absence of cognitive impairment following experimental hippocampectomy in adult rats

Authors: *W. GOMES-LEAL[1], G. T. M. CARDOSO[2], E. C. S. FRANCO[3], A. PEREIRA[4], F. L. GOMES[5], A. F. BRINO[6], S. M. A. LIMA[7];

Abstract: Temporal lobe epilepsy (TLE) is the most common type of focal epilepsy in adult humans and hippocampal sclerosis (HE) is its main pathological finding. In TLE refractory cases, patients are indicated for unilateral resection surgery of the affected hippocampus (hippocampectomy), which generally does not cause any additional cognitive impairment in patients. Adult hippocampus is a region of endogenous neurogenesis even in elderly people. We have hypothesized that a compensatory increase in hippocampal neurogenesis might occur in the remaining hippocampus after surgery to treat TLE. To test this hypothesis, we performed hippocampectomy in adult Wistar rats to investigate possible compensatory neurogenic events in the contralateral hippocampus as well as whether the surgical procedures induce any kind of cognitive impairment. Animals (n=6 per group) were randomically allocated to the following experimental groups: control (no surgery), G15 and G30. Animals were deeply anesthetized with a mixture of ketamine (80 mg / kg) and xylazine (10 mg / kg) until complete absence of corneal

and paw withdraw reflexes. Adjacent cortex and hippocampus of the left hemisphere were completely removed. The G15 and G30 animals were perfused at 15 and 30 days, respectively, post-surgery. Behavioral tests were undertaken to address possible cognitive impairments using eight arms radial maze for 7 days. After this period, animals were perfused with 0.9% saline and 4% paraformaldehyde in 0.1M phosphate buffer and processed for histological analysis. Gross histopathology was performed using cresyl violet staining. Cell bodies of mature neurons and migratory neuroblasts were immunolabeled using anti-NeuN and anti-double courtin (DCX) antibodies, respectively. There was no cognitive impairment in the animals after hippocampal removal. The remaining hippocampus presented a higher number of DCX positive cells compared to control. The results suggest that unilateral hippocampectomy did not cause any cognitive impairment and there is a compensatory increase in endogenous neurogenesis in the contralateral hippocampus at both 15 and 30 days post-surgery. Further studies must test this hypothesis in hippocampectomized TLE patients using high-resolution magnetic resonance imaging.

Title: Validation of a single-channel murine seizure and interictal event detection algorithm in multi-channel rat and human EEG

Authors: *R. A. BERGSTROM[1], R. J. KOTLOSKI[2];
[1]Biol., Beloit Col., Beloit, WI; [2]Neurol., Univ. of Wisconsin Sch. of Med. and Pub, Madison, WI

Abstract: Seizures and interictal events in humans and rodents share the same fundamental cellular basis, but analysis of electroencephalogram (EEG) signals across the species require different but equally time-consuming considerations for analysis. A seizure- and interictal event-detection algorithm originally validated in murine intracranial EEG may not, therefore, be easily applied to human or rat EEG. Here we analyze and optimize the performance of a published murine wavelet- and line-length-based EEG analysis algorithm (Bergstrom et al. 2013) on human data. This algorithm can identify and quantify ictal and interictal epileptiform EEG signal using a single algorithm. We obtained multi-channel human intracranial EEG data from ieeg.org and multi-channel rat EEG from a traumatic brain injury model and analyzed the signals to establish seizure onset and locus and to identify relevant interictal events such as spikes. We compared the algorithm output to visual scoring to determine algorithm performance. Using

published algorithm parameters optimized for murine seizure detection does not reliably quantify seizure activity in human intracranial EEG or rat EEG, even though the EEG signals of humans, rats, and mice share similar characteristics under seizure conditions. However, with slight modifications to event thresholding and definitions, we found that the algorithm was able to correctly identify and quantify seizure, spike, and other abnormal content in human and rat records with high reliability. That the algorithm is flexible for use in multiple patient and species settings suggests that the combination of line length and wavelet analysis is a robust method for seizure identification and quantification in basic and translational research and clinical settings. Further, the multi-event detection capabilities of this algorithm provide the opportunity to consider the relationships among ictal and interictal events as a part of a unified workflow.

Title: Changes in neural activity associated with different gad gene mutations in larval zebrafish

Authors: *J. D. LAUDERDALE[1], Y. LIU[2], J. B. BYERS[1], H. C. SCHRIEVER[1], A. J. VANLEUVEN[1], J. M. CARPENTER[3], C. E. GUNDERSON[1], N. M. FILIPOV[4], S. QUINN[5], P. KNER[2];

Abstract: Our group is investigating how GABAergic interneurons act to maintain homeostasis between excitation and inhibition in the intact live vertebrate brain. Under normal conditions, an increase in excitatory activity results in an increase in inhibitory activity. A focal imbalance of this response causes aberrant levels of excitation, which can be held in check by the feedforward inhibitory surround. Failure of the inhibitory surround allows coherent excitation to propagate to adjacent neural tissue. The underlying basis of this phenomenon has been difficult to study *in vivo*. We hypothesize that altered synaptic depression in interneuron populations will be a significant contributing factor to the generation and propagation of runaway coherent excitation. As a test of this hypothesis, we have generated using CRISPR-cas9 a series of zebrafish lines null for glutamic acid decarboxylase (gad) genes, *gad1a*, *gad1b*, or *gad2*. In the central nervous system, *gad1a* and *gad1b* typically exhibit differential expression, but both co-express with

gad2. Zebrafish homozygous mutant for each gad gene are viable, but exhibit seizure behavior. Loss-of-function mutations in the different gad genes differentially reduce the overall amount of GABA in the brains of larval and adult zebrafish as measured by HPLC. Electrographic recordings obtained from the tecta of larvae (5 to 7 dpf) harboring mutations in *gad1a* or *gad1b* exhibited an increase in high frequency, low-amplitude discharges compared to wild-type fish. Optical imaging of calcium activity in the tecta of larvae (5 to 7 dpf) harboring mutations in the *gad* genes revealed a spatiotemporal pattern of neural activity that was distinguishable from wild-type fish or wild-type fish exposed to the GABAA receptor antagonist pentylenetetrazol. Optical imaging experiments were performed using a custom-built, high speed light sheet microscope and wild-type or *gad* mutant zebrafish transgenic for *elavl3:GCaMP5g* on a *mitfa*$^{w2/w2}$ background. For some experiments, zebrafish also harbored a *gad1b:RFP* reporter transgene. Our results indicate that zebrafish harboring mutations in *gad1a*, *gad1b*, and *gad2* are useful animal models for understanding the impact of genetically reduced inhibition on overall network activity in the brain.

Title: Behavioral characterization of a new temporal lobe epilepsy model induced by 4-aminopyridine in rats

Authors: B. NUÑEZ-IBARRA, A. X. LÓPEZ, ***C. VENTURA**, L. MEDINA-CEJA;
Univ. De Guadalajara, Guadalajara Jalisco, Mexico

Abstract: Epilepsy is a syndrome of cerebral dysfunction characterized by the abnormal synchronic discharge of a group of cerebral neurons. The Temporal Lobe Epilepsy (ELT) is the most frequent and resistant to drugs. To study the basic mechanism of induction, maintenance and extinction of seizures and epilepsy, animal models are greatly used to simulate some of the characteristics of the TLE. These models are acute or chronic and 4-aminopyridine (4-AP) is a drug that when is administrated by intraperitoneal (i.p.) or intracerebral (i.c.) routes is capable of inducing convulsive seizures in different animal species. The pattern of convulsive seizures induced by the administration i.p. of 4-AP in the rat, is very similar to that produced by the

administration i.c. of kainic acid. For this reasons, in the present work 4-AP was used to induce a new model of TLE and some parameters such as latency to the first spontaneous seizure and severity of the convulsive behavior according the Racine scale were analyzed. For that purpose, male rats were used from the Wistar strain (200-250 g), which were divided in five groups, two groups were injected with 4-AP i.c. with doses of 10 and 20 mM and the rest of the groups were injected with 4-AP i.p. with doses of 5, 7 and 9 mg/kg of weight. The results showed that animals injected with a dose of 20 mM (i.c.) presented spontaneous and recurrent seizures between 15 to 112 days after 4-AP administration (2/3 animals) with a scale of 4 and 5 which are the most severe; it is important to point out that once administrated the 4-AP the *status epilepticus* of the animals was not blocked by any other drug and the animals did not receive special care. We conclude that 4-AP administration by i.c. route at a dose of 20 mM induced spontaneous and recurrent seizures associated with scales 4 and 5 with the advantages of no other pharmacological intervention was used and special take care of animals was not necessary.

Title: Characterization of interictal spike (IIS) morphologies important in the mouse kainate and rat pilocarpine models of epilepsy

Authors: R. A. BERGSTROM[1], J. A. PFAMMATTER[2], D. SUBRAMANIAN[3], V. SANTHAKUMAR[3], ***M. V. JONES**[2];

Abstract: Interictal spikes are a potential clinical biomarker for epilepsy, but their detection, quantification, and classification in EEG is overly time-intensive and subject to significant interobserver variability. We have developed a probability-based algorithm for the detection and classification of interictal spikes (IIS) from long (24-hour) EEG records to differentiate mice with kainate (KA) model of epilepsy from saline-treated (SA) controls. (Pfammatter et al. 2018). Briefly, our algorithm detects potential spike-like events from EEG. These event waveforms are projected into principal components (PC) space using only the first three PCs and then are clustered using a Gaussian mixture model. A probability score (P(e)) based on the odds-ratio of

observing events from KA versus SA animals within that cluster is assigned to each of the resultant event clusters. We create an index that predicts risk of epilepsy by assigning each event in an EEG record its cluster-based prediction score, summing these values, then dividing by the record duration to yield an index with units of "epileptiform spikes per second". This score effectively predicts whether an animal received an epileptogenic insult even in the absence of ever observing either convulsive or electrographic seizures. Here we test and validate the utility of our algorithm to differentiate between epileptic and control EEG in the rat pilocarpine model of epilepsy. We also characterize the frequency and temporal relationships between the individual IIS morphologies and convulsive seizures in the kainate and pilocarpine models of epilepsy, which indicate that some IIS morphologies and not others may be predictive of seizure activity. Finally, we investigate the utility of a wavelet-based event detection method for spikes and other interictal events as an alternative to our previous two-threshold event detection method and find in our preliminary results that wavelet-based event detection methods provide a unique and important view of IISs regarding their potential contribution to epileptogenesis.

Title: Neurochemical changes in the hippocampus of a prenatal model of epilepsy

Authors: *S. T. PERUZZARO, N. MORISOT, L. YU, A. MALIK, S. HSIEH, H. B. JANSSENS, A. RASSOULPOUR;
Charles River Labs., South San Francisco, CA

Abstract: Abnormalities in brain development have been associated with epilepsy. Yet, little is known about the functional underpinnings of epileptic episodes in patients with abnormal brain development. Recent research has shown that toxic exposure to the DNA alkylating agent, methylazoxymethanol (MAM), in pregnant rats disrupts brain formation in the offspring, resulting in abnormalities that resemble the human condition, including epileptic spasms. The aim of the present study was to investigate the neurochemical changes in the hippocampus of prenatally MAM-exposed rats. To produce malformation in brain development, dams were administered with MAM during gestation. Control dams received saline administration. Adult rats were all administered pilocarpine to induce seizures. Adult animals that were prenatally exposed to MAM or saline underwent microdialysis in the hippocampus. Spontaneous epileptic spasms were observed in MAM-exposed rats during the course of the experiment. Microdialysis

samples were analyzed by LC/MS-MS for levels of up to 14 neurotransmitters, neuromodulators and metabolites. Results revealed drastic changes in hippocampal neurochemistry in MAM-exposed rats. We observed increased levels of tryptophan, kynurenine, 3-hydroxy kynurenine, kynurenic and anthranilic acid in the MAM model compared to the control group. MAM-exposed rats also displayed elevated glutamate, dopamine, serotonin and glycine levels compared to controls. In contrast, GABA and acetylcholine concentrations were lower in MAM- compared to saline-exposed animals. Our set of data suggests that upregulation in kynurenine pathway and excitatory signaling together with GABA downregulation in the MAM-exposed rats may contribute to their epileptic phenotype. The prenatal MAM model may help understanding the neuronal mechanisms underlying epilepsy associated with abnormal brain development. In addition, the prenatal MAM model could be used to advance drug development for the treatment of epilepsy.

Title: Impaired GABAergic inhibition and seizure susceptibility in a mouse model of SLC13A5 deficiency

Authors: *J. J. LAWRENCE[1,2,3], R. WANG[1], F. SELINA[1], T. ANDERSON[1], X. LIU[1], M. HAYES[1], S. RAMCHANDRAN[4], V. GANAPATHY[4,2];
[1]Pharmacol. and Neurosci., [2]Ctr. for Translational Neurosci. and Therapeut., [3]Garrison Inst. for Aging, [4]Cell Biol. and Biochem., Texas Tech. Univ. Hlth. Sci. Ctr., Lubbock, TX

Abstract: SLC13A5 loss-of-function mutations cause Early-onset Infantile Epileptic Encephalopathy type 25 (EIEE-25), a condition where seizures are refractory to treatment. Human SLC13A5 and mouse Slc13a5 encode the sodium-dependent plasma membrane citrate transporter. In neurons, cytoplasmic citrate is a substrate for synthesis of ATP and the neurotransmitters GABA, glutamate, and acetylcholine. Although the precise mechanisms by which SLC13A5 deficiency causes EIEE-25 remain poorly understood, growing evidence implicates GABAergic dysfunction. Reduced cytoplasmic citrate availability could impair downstream metabolic pathways, leading to impaired synaptic function and excitation/inhibition imbalance by weakening GABAergic function. In this study, using an acute low-dosing

paradigm of consecutive intraperitoneal (IP) injections on Slc13a5 knockout (KO) and wild-type (WT) mice, we tested the hypothesis that SLC13A5 KO mice exhibit a lower seizure threshold to the chemoconvulsants pilocarpine **(**PILO) and pentylenetetrazole **(**PTZ). Seizures were scored manually using a Racine scale (RS, 0-7 index of seizure severity). In PILO experiments (1 mg/kg atropine applied 30 min preceding a sequence of 50 mg/kg PILO every 10 min), KO mice exhibited more time in RS2 (KO: 441.8 ± 24.9 sec vs. WT: 144.4 ± 45.9 sec, n=4, $p<0.001$) over the course of the first 10 min. In PTZ experiments (15 mg/kg PTZ IP every 10 min), PTZ KO mice exhibited shorter latency to seizure onset than age-matched WT mice (KO: 24.8 ± 1.4 min (n=3), WT: 44.6 ± 6.6 min (n=3), $p<0.05$). KO mice also exhibited increased seizure severity to PTZ at earlier time points relative to WT mice (time in RS3; KO:13.3 ± 2.9 sec vs. WT:0.4 ± 0.4 sec, $p<0.05$). Because cFos permits the visualization of neuronal excitability, seizure location was investigated using cFos immunocytochemistry on KO and WT mice that had undergone PILO and PTZ-induced seizures. Preliminary results indicate that high cFos activation was present in the hippocampus, cortex and hypothalamus of both WT and KO mice. However, cFos activation was highest in the hippocampal dentate gyrus (DG) of KO mice that had undergone PTZ-induced seizures, suggesting that the DG was the seizure focus in SLC13A5 KO mice. Our preliminary results from both PTZ and PILO experiments converge on the finding that KO mice have lower seizure threshold compared to WT mice. In conclusion, these results are consistent with the hypothesis that SLC13A5 deficiency impairs GABAergic signaling.

Title: *In vivo* unanesthetized mapping of glutamate neurotransmission during acute interictal spikes in the mouse neocortex using a genetically encoded sensor

Authors: *M. Z. ZHAO[1,2], J. LI[1,3], F. YANG[1,3], J. NIEMEYER[1], H. MA[1,2,3], T. H. SCHWARTZ[1,2];
[1]1Department of Neurolog. Surgery, [2]Brain and Mind Res. Inst., Weill Cornell Med. of Cornell Univ., New York, NY; [3]Dept. of Neurol., The First Hosp. of Jilin Univ., Changchun, China

Abstract: Epilepsy is a neurological disorder characterized by aberrant neuronal excitability. Glutamate is the major excitatory neurotransmitter in the brain and plays an important role in the initiation and spread of epileptic activity. However, little data exists on the utility of in vivo real-time glutamate neurotransmission mapping of epileptic activity and the impact of anesthesia on glutamate concentration and release. Furthermore, glutamate has been hypothesized to play a role in neurovascular coupling. We performed in vivo real time imaging of interictal spikes using local field potential, glutamate, blood flow and oxygenation imaging in unanaesthetized and anesthetized transgenic mice. We generated Emx-CaMKII-iGluSnFR transgenic mice to produce expression of iGluSnFR within all excitatory neurons across all layers of the cortex, but not in GABAergic neurons. For the anesthetized experiments, 1.5% isoflurane was used. We induced acute focal interictal discharges in the neocortex by injection of bicuculline methiodide (BMI, 5mM, 0.5µl). Glutamate fluorescence imaging and intrinsic optical imaging including 530nm and 617nm wavelengths were used to measure glutamate transmission and hemodynamic signals. The local field potential was recorded to identify the epileptic discharges. Single interictal spike induced a strong change in iGlu fluorescence in the area of the interictal spike focus. The maximum amplitudes of fluorescence changes in anesthetized and awake mice were 17.1±5.7% (n=178 spikes, n=3 animals) and 42.7±9.9% (n=284 spikes, n=3 animals; p=0.044) at 0.033±0.010s and 0.027±0.006s (p=0.322), respectively. The intrinsic optical imaging showed that Hbt concentration increase peaks at 0.57±0.13 µm and 1.56±0.45µm (p=0.049) with latencies of 1.95±0.32 s and 1.21±0.02s (p=0.042) in anesthetized and awake mice, respectively, whilst Hbr concentration decreases by 0.37±0.15 µm and 0.51±0.19 µm (p=0.304) and at 0.37±0.31 s and 1.07±0.63 s (p=0.148). Our data suggests that genetically encoded glutamate sensor imaging might provide a powerful tool to map neuronal activity in neocortical epilepsy. The glutamate neurotransmission and hemodynamic responses measured in awake mice are substantially different from anaesthetized animals. These results may have important implications for the neuroimaging research in awake epileptic humans and animals.

Title: Behavioral state tracking using intracranial electrophysiology in an implantable system

Authors: *V. KREMEN, Jr[1], V. SLADKY[2], P. NEJEDLY[2], I. KIM[1], T. PAL ATTIA[1], B. H. BRINKMANN[1], B. K. STURGES[3], C. M. CROWE[4], G. A. WORRELL[2];
[1]Neurol., [2]Mayo Clin., Rochester, MN; [3]Dept. of Surgical and Radiological Sci., [4]Vet. Med. Teaching Hosp., Univ. of California at Davis, Davis, CA

Abstract: Electrical brain stimulation (EBS) is an emerging therapeutic option for patients with neurological and psychiatric diseases. The FDA approved indications include epilepsy, obsessive compulsive disorder, Parkinson's disease, and tremor. Sleep disorders are common comorbidities of brain disease and accurate automated sleep staging is needed for long-term objective assessment of sleep and to help guide chronic EBS therapy.
We developed a system for the automated sleep scoring using machine learning and narrow artificial intelligence applied to intracranial EEG recordings acquired from a chronic brain implant. The investigational Medtronic Summit RC+S system (bilateral hippocampus & anterior thalamic nucleus (ATN) or cortical electrodes) was implanted in canines with naturally occurring epilepsy. The system provides streaming iEEG and bi-directional connectivity between the implant and a tablet computer enabling large-scale data management and analytics for real-time, remote tracking of behavioral state and adaptive stimulation. We developed classifiers for different behavioral states with both passive and active probing paradigms using hippocampal iEEG and evoked potentials during ATN stimulation.
We verified the automated system for real-time, remote behavioral state tracking using a single hippocampal electrode and one electrode pair (bilateral hippocampus). Our results suggest that the observed iEEG dynamics in hippocampal electrodes can be used to assess the brain state of subjects receiving chronic EBS. The iEEG-based behavioral state classification developed here is efficient and could feasibly be incorporated into implantable devices for quantifying patient sleep patterns, administering behavioral state-specific therapies, and adjust other iEEG-based classifiers.

Title: A novel epileptic mouse model to better understand pathogenic mechanisms: mTOR-repressor DEPDC5 deficient mouse

Authors: *A. BACQ, T. RIBIERRE, D. ROUSSEL, S. BAULAC;
Inst. Du Cerveau Et De La Moelle Epiniere (ICM), Paris, France

Abstract: *DEPDC5* gene (Dishevelled, Egl-10, and Pleckstrin Domain Containing 5) is so far the most frequently mutated gene in familial focal epilepsies. Patients often have drug-resistant seizures requiring neurosurgery. Moreover, recent observations from the clinics suggested that

DEPDC5 mutations might confer a higher risk to sudden unexplained death in epilepsy (SUDEP). DEPDC5 is part of the GATOR1 (Gap Activity Towards Rags complex 1) complex, which functions as a repressor of the recently recognized amino acid-sensing branch of the mTORC1 pathway (mechanistic Target Of Rapamycin Complex 1). To date, the specific function of DEPDC5 in the brain and how mutations leads to seizures remain unknown. We have developed a novel mouse model with both a tagged-version of Depdc5 and lox sites for subsequent deletion (unpublished data). Using the tagged mouse, we were able to describe the spatio-temporal profile of Depdc5 expression in the mouse brain. We then generated a neuronal synapsin 1 KO (Syn1cKO) and unveiled the occurrence of spontaneous seizures, premature death resembling SUDEP, and comorbid psychiatric features. We further explored the pathomechanism of SUDEP, by investigating cardiorespiratory functions and their cerebral origin. We show alterations in limbic system and their connexions to brain stem that may sustain the SUDEP phenotype. To further investigate the underlying pathogenic mechanisms, we performed RNA-sequencing from the somatosensory cortex of adult animals (before the age of seizure onset). We found ~ 600 differentially expressed genes in the cKO mice compared to WT littermates. New pathways, independent of mTORC1 signaling cascade, were altered, highlighting dysregulation of genes involved in the regulation of neuronal excitability. Investigation of the functional consequences of these molecular alterations are ongoing to better understand how Depdc5-deficiency cause epilepsy.

Abstract: Background In the central nervous system, the mTOR signaling cascade is involved in normal neuronal homeostasis by promoting neuronal differentiation, neurite elongation and branching, synaptic formation during development and regulation of excitability in mature

synapses. DEPDC5 protein is a member of GATOR1, a negative regulator of mTOR complex 1 (mTORC1). Recently, mutations in *DEPDC5* have been associated with various focal epileptic syndromes, both lesional and non-lesional, even within the same family. **Aims** Our aim is to characterize morphologically and physiologically the epileptogenic mutants belonging to the mammalian target of rapamycin (mTOR) pathway, in particular *Depdc5*. Since it has been demonstrated that the complete knockout is embryonically lethal in rodents, we decided to compare a constitutive condition of haploinsufficiency (*Depdc5*$^{+/-}$) with the acute silencing of *Depdc5* obtained by RNA interference, in order to unveil new aspects of GATOR1-related epileptogenesis. **Methods** We employ a combination of Real-Time PCR, Western Blot, Immunofluorescence and Patch-Clamp recordings to evaluate the effect of Depdc5 deficiency in both *Depdc5*$^{+/-}$ and *Depdc5* acutely silenced cortical primary neurons. **Results** While we do not observe a strong epileptogenic phenotype in *Depdc5*$^{+/-}$ primary cortical neurons compared to wild type neurons, *Depdc5* silenced neurons show mTOR pathway hyperactivation associated with increased soma size and dendritic arborization and coupled with increased excitatory synaptic transmission and intrinsic excitability. **Conclusions** This study shows novel aspects of GATOR1-related epileptogenesis due to Depdc5 deficiency resulting in increased excitatory synaptic connectivity and intrinsic excitability and confirming its role in epileptogenic process.

Title: Oligodendrocyte involvement in adapter-protein 4 deficient hereditary spastic paraplegia

Authors: *J. BELGRAD, E. SANTOS, R. DE PACE, J. BONIFACINO, R. FIELDS;
NIH, Bethesda, MD

Abstract: Hereditary spastic paraplegia (HSP) is a rare genetic disorder characterized by lower extremity weakness and stiffness, with symptoms arising in children as early as the first year of life. With over 80 genetic subtypes, one of the more severe forms of HSP is adaptor protein 4 (AP-4)-deficient HSP. In addition to the typical features of spastic paraplegia, children with AP-4-deficient HSP present additional symptoms, including thinning of the corpus callosum, nonspecific periventricular white matter loss, impaired speech development and early onset seizures. AP-4 is a heterotetrameric complex that sorts the autophagy-related protein 9A

(ATG9A) from the trans-Golgi network (TGN) to pre-autophagosomal structures to promote autophagosome formation. Autophagy has recently emerged as an essential process in many cells, particularly neurons, but the role of autophagy in myelinating glia, particularly in oligodendrocytes, remains largely unknown. Our studies show that components of the autophagy machinery are expressed in oligodendrocytes across development and are activated during hypoxia and starvation. Using an AP-4-epsilon (*AP4E1*) knockout mouse, we characterize the spinal cord white matter, and test the hypotheses that autophagy is necessary for white matter maturation and that oligodendrocytes contribute to the motor and cellular phenotypes that hallmark the pathophysiology of AP-4-deficient HSP.

Title: The function of tuberous sclerosis complex in oligodendrocytes and myelin

Authors: *A. V. EVANGELOU[1], J. N. BOURNE[2], W. B. MACKLIN[2], T. L. WOOD[1];
[1]Dept. of Pharmacology, Physiol. and Neurosci., Rutgers Univ., Newark, NJ; [2]Dept. of Cell and Developmental Biol., Univ. of Colorado, Aurora, CO

Abstract: A number of investigators have provided evidence that the mechanistic target of rapamycin (mTOR) has an important role in oligodendrocyte development and CNS myelination. Our prior studies demonstrated that deleting mTOR from the oligodendrocyte lineage leads to hypomyelination in the spinal cord (Wahl et al., 2014). In contrast, other groups have reported results from experiments designed to upregulate mTOR signaling in oligodendroglia through disrupting tuberous sclerosis complex (TSC), a negative upstream regulator of the mTOR complex 1 (mTORC1). Surprisingly, these studies showed that mice with constitutive activation of the mTORC1 pathway displayed a hypomyelination phenotype, instead of hypermyelination as originally predicted (Lebrun-Julien et al., 2014; Carson et al., 2015; Jiang et al., 2016). However, in these prior reports, the deletion of *Tsc1* or *Tsc2* was introduced early in development, during specification or differentiation of the oligodendrocyte lineage. These early deletions led to decreased number of oligodendrocytes and thus, myelination independent of

differentiation was not evaluated.
The goal of this study is to assess how myelin production is altered when mTORC1 signaling is upregulated exclusively in mature oligodendrocytes so that the differentiation process remains unperturbed. We have generated an inducible conditional knock-out mouse model carrying Tsc1 floxed alleles and the tamoxifen inducible proteolipid protein promoter (*Tsc1* cKO). We induced *Tsc1* deletion in premyelinating oligodendrocytes at postnatal day (PND) 7-10, at the peak of oligodendrocyte differentiation in spinal cord. Our data suggest that loss of TSC in maturing oligodendrocytes in spinal cord has no effect on oligodendrocyte survival or differentiation as assessed at PND17 and PND49. Interestingly, electron microscopy analysis at PND25 showed normal myelin thickness indicating no effect of *Tsc1* loss on developmental myelination in spinal cord. Surprisingly, myelin thickness was significantly decreased at PND49, supporting a cell intrinsic function for TSC in myelin maintenance. Very unexpectedly, we also observed that Tsc1 cKO mice had epileptic episodes beginning at 3-4 months of age. Myelin in the corpus callosum of these mice showed normal thickness. This seizure phenotype is likely due to a subset of neurons showing recombination, in line with previous reports of PLP promoter activity in areas outside the white matter in the early postnatal brain. Follow up studies are designed to further investigate this unexpected brain phenotype, as well as to define the mechanism underlying the defect in myelin maintenance in the *Tsc1* cKO spinal cord.

Abstract: Autism Spectrum Disorder (ASD) is genetically heterogeneous in nature with convergent symptomatology, suggesting dysregulation of common molecular pathways. We analyzed transcriptional changes in the brains of five independent mouse models of Pitt-Hopkins Syndrome (PTHS), a syndromic ASD caused by autosomal dominant mutation in *TCF4*, and identified considerable overlap in differentially expressed genes (DEGs). Gene and cell-type enrichment analyses of these DEGs highlighted oligodendrocyte dysregulation and we confirmed the myelin-associated transcriptional signature in two additional mouse models of syndromic ASD (*Pten*$^{m3m4/m3m4}$, *Mecp2*$^{tm1.1Bird}$). We subsequently validated oligodendrocyte deficits in our *Tcf4* mouse model which showed inefficient oligodendrocyte maturation in both an isolated oligodendrocyte *in vitro* cell culture system and *ex vivo* at day 24 (P24) and day 42 (P42). Furthermore, we used transmission electron microscopy (TEM) to visualize myelination in the corpus callosum (CC) of *Tcf4*$^{+/tr}$ and *Tcf4*$^{+/+}$ littermates, observing a significant decrease in the proportion of myelinated axons in the CC of *Tcf4*$^{+/tr}$ mice compared to *Tcf4*$^{+/+}$ littermates. Similar to our *ex vivo* IHC results, we observed a significant reduction in the number of CNP-positive oligodendrocytes in primary cultures derived from *Tcf4*$^{+/tr}$ mice compared to *Tcf4*$^{+/+}$ littermates. When comparing compound action potentials (CAP) using electrophysiology, we show the ratio of N1/N2 is significantly reduced in the *Tcf4*$^{+/tr}$ mice compared to *Tcf4*$^{+/+}$ littermates, indicative of a greater proportion of CAP traveling down unmyelinated axons. Moreover, we integrated syndromic PTHS mouse model DEGs with human ASD genes (SFARI) and human idiopathic ASD postmortem brain RNA-seq, and found significant enrichment of overlapping DEGs and common biological pathways associated with myelination. Remarkably, we show that DEGs from syndromic ASD mouse models can be used to identify human idiopathic ASD cases from controls. These results from seven independent mouse models of ASD are validated in human brain, implicating disruptions in oligodendrocyte biology as shared mechanisms in ASD pathology.

Title: Nanostructured surfaces for oligodendrocyte differentiation

Authors: *K. D. SHARMA[1], K. M. ALGHAZALI[2], A. B. RANGUMAGAR[3], J. TRINGALI[4], A. GHOSH[3], A. S. BIRIS[2], J. Y. XIE[4];

Abstract: In regenerative medicine, replenishing lesioned cells through the implantation of differentiated cells has been proposed to reduce the tumorigenic risk of stem cells. “On-demand” generation of functional oligodendrocytes (ODCs) represents a better therapeutic option in restoration of the signal transduction and axonal functions in demyelinating diseases than the undifferentiated stem cells. However, current methods used to create ODCs from neural stem cells (NSCs) fail to result in sufficient differentiations. Mounting evidence suggests that rigidity and composition of the extracellular matrix (ECM) play a pivotal role in determining the fate of the stem cells. Advances in biocompatible material development provide several options for fabrication of ECM to promote NSCs differentiated to the desired cell types. Nanostructured surfaces have been shown to best mimic the cell-environment interactions and facilitate cell adhesion, migration and differentiation. In this study, we have tested the efficiency of a couple of fabricated surfaces, i.e., (i) covalently modified crystalline nanocellulose with lysine molecule (CNC-Ly) and (ii) gold nanorods (AuNRs) functionalized with amine (NH_2^+) group, on the differentiation of NSCs to ODCs. Both materials are biocompatible and have been used as novel and advanced nanomaterials in biomedical sciences. Lysine and amine molecules confer positive charges to the nanomaterials and thus promotes the attachment of NSCs, which have negatively charged plasma membranes. Cortical NSCs from E14 rat embryos were differentiated on CNC-Ly or AuNRs substrate for one week. The differentiation of NSCs on these surfaces were compared to that of traditional poly-D-lysine (PDL) surface. Markers of ODCs (Rip) and astrocytes (GFAP) were identified by immunocytochemical methods and the quantification was done via Gen5 3.05 program. Our results showed that by one week 55±1.82% and 33±2.76% of cells were Rip^+ ODCs on AuNR and nanocellulose substrates, respectively, compared to 21±5.36% on PDL. While 66±9.33% (PDL) and 50±1.86% (CNC-Ly) of NSCs remained undifferentiated, such cells were very few on AuNR substrate. 18±0.45% and 45±2.32% of differentiated NSCs were $GFAP^+$ astrocytes on CNC-Ly and AuNR substrates, respectively, compared to 15.68±4.6% on PDL. Additionally, the survival rate and the morphology of the ODCs differentiated on AuNR and CNC-Ly substrates were better than those on PDL. The results from CNC-Ly and AuNR surfaces indicate that the design and properties of the plasmonic surfaces are advantageous for tissue engineering in respect to neural regeneration.

Title: mTOR regulation of differentiation, myelination, and maintenance in brain and spinal cord oligodendroglia

Authors: *L. KHANDKER[1], M. A. JEFFRIES[1], T. L. WOOD[2];
[1]Rutgers Univ., Newark, NJ; [2]Dept Pharmacology, Physiol. & Neurosci., New Jersey Med. Sch, Rutgers Univ., Newark, NJ

Abstract: Myelin deficits during development can result in diseases such as leukodystrophies, and loss of myelin after development leads to demyelinating diseases such as Multiple Sclerosis. The process of myelination is highly regulated through multiple signaling pathways, including the PI3K/Akt/mTOR pathway. Disruption of this pathway in mice compromises developmental myelination and may affect long-term myelin integrity. Loss of mTOR in the oligodendrocyte lineage by CNP-Cre deletion of mTOR floxed alleles (mTOR cKO) results in a delay in oligodendrocyte differentiation and initiation of myelination as well as long-term hypomyelination of the spinal cord. In contrast, these mice exhibit normal developmental myelination of the brain up until 8 weeks of age, suggesting heterogeneity in cellular response to loss of mTOR. By flow cytometry, we have determined that at postnatal day 10 there is an increase in PDGFRα+ early-stage precursors in mTOR cKO spinal cords, and a decrease in O4+ late-stage progenitors/immature oligodendrocytes, suggesting an accumulation of early precursors that are unable to or delayed in progress to the O4+ stage when mTOR is deleted. In contrast, oligodendroglia from mTOR cKO brains exhibit normal proportions of early and late-stage OPCs. In order to define molecular pathways downstream of mTOR that promote myelination, we have undertaken single-cell mRNA transcriptome analysis of oligodendroglia from mTOR cKO animals. We isolated O4+ oligodendroglia from mTOR cKO and control animals and used 10x Genomics to simultaneously analyze mRNA transcripts of thousands of individually identifiable cells. Sequencing data reveal alterations in several key cellular pathways, including oxidative phosphorylation which is the most significantly downregulated pathway in mTOR cKO. Interestingly, analysis of O4+ OPCs from mTOR cKO brains reveal that despite the lack of a developmental phenotype, mTOR cKO brain oligodendroglia also exhibit a downregulation of mitochondrial function and oxidative phosphorylation. We measured mitochondrial function in isolated O4+ cells and confirmed that loss of mTOR results in a deficit in oxidative phosphorylation in both the brain and spinal cord. Consistent with these findings, we

observe hypomyelination in the brains of mTOR cKO mice at 12 weeks of age, suggesting compromised myelin maintenance. As the mice age, this myelin deficit persists in both the spinal cord and brain. Understanding the molecular regulators of myelination and oligodendrocyte stability, along with heterogeneity, will promote better understanding of human myelin diseases and potential therapeutic targets.

Title: Zinc storage proteins and zinc transporters are developmentally regulated in oligodendrocytes

Authors: *C. M. ELITT[1,2], C. E. R. RICHARDSON[3], J. WANG[1], S. J. LIPPARD[4], M. D. SHOULDERS[3], P. A. ROSENBERG[1,2];
[1]Neurol., Boston Children's Hosp., Boston, MA; [2]Harvard Med. Sch., Boston, MA; [3]Chem., [4]MIT, Cambridge, MA

Abstract: Zinc is abundant in the central nervous system and required for proper function of a variety of enzymes, proteins and transcription factors, including many important in myelination. Increases in free ionic zinc (Zn^{2+}) play a critical role in neuronal and oligodendrocyte (OL) injury. Little is known about mechanisms of zinc regulation in developing or mature OLs. We have previously shown that concentrations of free zinc are downregulated as OLs mature using Chromis-1, a novel Zn(II)-selective ratiometric fluorescent probe optimized for two-photon excitation fluorescence microscopy (TPEM) (Bourassa and Elitt et al., *ACS Sensors,* 2018). The objective of the current study was to understand molecular mechanisms that might contribute to these developmental changes in intracellular free zinc concentrations. Mixed glia cultures were isolated from postnatal day 2 (P2) rat forebrains and grown for 10-17 days. Developing OLs were separated from microglia and astrocytes using selective detachment. Cells were maintained

in the presence of platelet-derived growth factor (PDGF) and basic fibroblast growth factor (FGF) for 6 days prior to harvesting RNA or protein for analysis. To produce mature OLs, PDGF and FGF were replaced by triiodothyronine (T3) and ciliary neurotrophic factor (CNTF) and harvested at 16 days. We used qPCR to evaluate mRNA expression of metallothioneins, the metal regulatory transcription factor 1 (MTF-1) as well as zinc influx proteins (ZIPs) and zinc exporters (ZnTs). MT-1, MT-2 and MTF-1 were all increased 4-6 fold in mature OLs compared to developing OLs. Initial evaluation of zinc transporters by qPCR and immunoblot have shown similar increases as OLs differentiate. Taken together, these results raise the possibility that a zinc influx is required for OL differentiation to proceed. To study zinc transport across oligodendrocyte cell membranes, we measured $^{65}Zn^{2+}$ uptake in the two cells types and both robustly take up zinc. We are currently correlating changes in uptake with changes in zinc storage proteins and transporters. With an improved understanding of zinc homeostasis in oligodendrocytes, additional studies into zinc dyshomeostasis in white matter disorders will be warranted.

Title: Oligodendrocyte progenitor cells during development and upon sensory loss in mouse visual cortex

Authors: *H. SHIN[1], H. D. KAWAI[2];
[1]Dept. of Bioinformatics, [2]Dept. of Sci. and Engin. for Sustainable Innovation, Soka Univ., Tokyo, Japan

Abstract: Oligodendrocyte progenitor cells (OPCs) are widely distributed as the principal proliferative cells in the postnatal cortex and continue to proliferate to produce newly myelinating cells throughout the lifetime. It is unclear how OPCs self-renew or differentiate into oligodendrocytes (OLs) and how sensory deprivation affects them in primary visual cortex (V1). We examined developmental changes in the distribution of OPCs and the effects of binocular enucleation (BE) starting at postnatal day (P) 15. 3-day BrdU injection from P22 to P25 (i.e., around the onset of the critical period for ocular dominance plasticity, ODP), but not from P19 to P22 nor from P25 to P28, resulted in increased proliferative cells. BE notably increased

proliferative cycling OPCs particularly in lower layer 6 at P25. The visual deprivation increased OPC progeny in the lower layer due mainly to the shift of the symmetric cell division from the differentiated to the undifferentiated states. We then examined possible signaling mechanism underlying the BE-induced shift and found that sonic hedgehog (Shh) signaling pathway is involved. At P30, most, if not all, of P22-25 BrdU-labeled proliferated cells exited the cell cycle and mostly became differentiated cells in control mice. Meanwhile, BE increased the formation of quiescent OPCs rather than the formation of differentiated cells. The difference in the elevated undifferentiated cells at P25 between BE and control mice was maintained at P30. Further, many of the BrdU-labeled proliferated OPCs differentiated into mature OLs at P50. At this age, BE mice had an elevated number of mature OLs and an increased expression of CNPase particularly near the white matter. Overall, our study suggests that V1 has a sensitive period of OPC proliferation and differentiation around the ODP critical period, in which sensory loss promotes undifferentiation via a shift in symmetric cell division in lower layer 6, but later resulting in an increase in quiescent OPCs and the subsequent formation of mature OLs.

Title: Myelinating glial connexin deficiency within the central nervous system results in an increased inflammatory response and decreased oligodendrocyte development

Authors: *S. KEIL[1], M. FREIDIN[2], C. K. ABRAMS[3];
[1]Neurol. and Rehabil., Univ. of Illinois Chicago, Chicago, IL; [2]Neurol. & Rehabil., [3]Dept of Neurol. & Rehabil., Univ. of Illinois at Chicago, Chicago, IL

Abstract: Central nervous system (CNS) glia rely on a dynamic network of communication to maintain effective function and homeostasis throughout the brain. Their interactions are dependent, in part, on several transmembrane proteins called connexins (Cxs). Through the formation of low resistance gap junctions or hemichannels, Cxs provide a pathway for small signaling molecules and ions between the cells or the external environment. These channels transmit the signals necessary for a variety of functions involved in cellular development, synchronization, and immune response. Alterations in Cx function hinders this communication, causing a wide range of cell and tissue-specific disease states in the brain and throughout the body. In the CNS, the role of oligodendritic connexins in overall glial function is highlighted by human diseases; mutation of oligodendrocyte Cx32 causes X-linked Charcot-Marie-Tooth disease (CMT1X) while mutation in Cx47 causes Pelizaeus-Merzbacher-Like disease 1

(PMLD1). Using mixed glial cultures and tissue sections from Cx32KO, Cx47KO and WT mice, we evaluated the effect of Cx loss on the CNS glia. In both KO models, there is a significantly lower presence of $O4^+$ cells, with a decrease in proliferation in both mature oligodendrocytes and oligo progenitor cells. There is a significant increase in activation and presence of $Iba1^+$ cells, and a significant increase in proliferation and fluorescence intensity in $GFAP^+$ cells, suggesting an increased inflammatory state at baseline. This baseline inflammatory state within mutant CNS tissue could make it difficult to manage additional neurologic stress, resulting in the inability to remyelinate injured nervous tissue, as has been seen in previous experiments.

Title: Oligodendrocyte progenitor cell fate after white matter stroke

Authors: *N. M. SHIH[1], I. L. LLORENTE[2], M. MACHNICKI[2], S. T. CARMICHAEL[3]; [2]Neurol., [1]UCLA, Los Angeles, CA; [3]UCLA Sch. Med., Los Angeles, CA

Abstract: White matter stroke is a progressive vascular disease that leads to neurological deficits and accumulates to cause dementia. It accounts for approximately 30% of all stroke subtypes and damages the cellular constituents of subcortical white matter: oligodendrocytes, myelinated and unmyelinated axons, astrocytes, microglia and blood vessels. In clinical studies, new white matter strokes develop within pre-existing lesions and also generate adjacent lesions in 70% of cases. This indicates a vulnerable peri-infarct region which can progress to further damage and disrupt neuronal connections to cause substantial disability. Sozmen *et. al* previously showed that an oligodendrocyte progenitor cell (OPC) response is triggered after a focal lesion is induced in white matter of mice. OPC proliferation occurs acutely after stroke but an OPC differentiation block prevents OPCs from maturing into myelinating oligodendrocytes. Additionally, other studies have demonstrated that OPCs have the ability to become other glial cells (Zhang L *et. al*, 2016). To understand how OPCs in the white matter respond to later stages of white matter stroke and initiate a process of repair, we are utilizing a model of white matter stroke that mimics more advanced stages of white matter stroke and vascular dementia. To study cell fate changes of proliferating OPCs after stroke, we are labeling proliferating OPCs by brief pulses of the S phase marker 5-ethynyl-2′-deoxyuridine (EdU) given at multiple timepoints after stroke. EdU is administered at acute and chronic timepoints to compare levels of OPC proliferation post-stroke

as well as cell identity changes of these labeled OPCs at later timepoints. We are examining if proliferating OPCs induced after injury remain as OPCs, differentiate into oligodendrocytes and/or other cell types, or dying at a later time. By understanding OPC cell fate following white matter stroke, we can investigate what repair mechanisms exist to remyelinate damaged axons at different phases post-stroke and what disease mechanisms are preventing the brain from undergoing full recovery.

Title: Oxygen tension regulates the phenotype of oligodendrocyte precursor cells

Authors: *K. YASUDA, T. MAKI, H. KINOSHITA, R. TAKAHASHI;
Neurol., Kyoto Univ. Grad. Sch. of Med., Kyoto, Japan

Abstract: Background: Oligodendrocyte precursor cells (OPCs) regulate the neuronal system in various ways, and play crucial roles in brain homeostasis besides their well-known role as a major reservoir for mature oligodendrocytes (OLGs). Recent studies have reported that some OPCs exposed to severe hypoxia gain ability of promoting angiogenesis during developmental stage[1] and post-stroke[2] at the expense of OPC differentiation arrest. However, how different oxygen tension affects the phenotype of OPCs remains unclear.
Object: The purpose of present study was to investigate the phenotypic changes of OPCs under different levels of oxygen concentration.
Methods: For *in vitro* experiments, we prepared primary culture of oligodendrocyte lineage cells obtained from neonatal rats. During OPC differentiation induction, cultured OPCs were maintained under normoxic (FiO_2=21%) or different levels of hypoxic (FiO_2=3, 5, 7 and 10%) conditions in a multi-gas incubator. Six days after differentiation induction, immunocytochemistry, western blot analysis, and quantitative RT-PCR analysis were performed to examine the effects of different oxygen tension on the phenotype of OPCs.
Results: Immunocytochemistry demonstrated that the number of myelin basic protein (MBP) positive cells was significantly increased under mild hypoxic condition (FiO_2=5%) compared to normoxic condition. Western blot analysis confirmed that the expression of MBP level was significantly increased under different levels of hypoxic conditions (FiO2=3, 5, 7 and 10%) compared to normoxic condition. Quantitative RT-PCR analysis revealed the gene expressions of OPC differentiation-related factors such as *Sox10*, *Olig2*, and *Myrf* were higher in

oligodendrocyte lineage cells under mild hypoxic condition (FiO_2=5%).
Conclusion: The present study indicated that mild hypoxia promotes OPC differentiation and different oxygen tension may regulate the phenotype of OPCs.

Title: The role of neuron-derived connective tissue growth factor in cuprizone-induced intoxication of mature oligodendrocytes

Authors: *L.-J. LEE, C.-Y. CHEN;
Anat. and Cell Biol., Natl. Taiwan Univ., Taipei, Taiwan

Abstract: Connective tissue growth factor (CTGF) is a matricellular protein which is involved in many physiological processes. In the nervous system, CTGF is expressed in some distinct brain areas, such as the cortical subplate, a layer just above the white matter which contain great amount of oligodendrocytes. In the present study, we aimed to evaluate the role of subplate neuron-derived CTGF in the maturation of oligodendrocytes using a cuprizone (CPZ) intoxication paradigm. Eight-week old female forebrain-specific *Ctgf* knockout (Fb*Ctgf* KO) and control mice were fed with CPZ-containing chow (0.25% w/w) for 4 weeks. Afterwards, some mice were returned to normal chow for another 1 or 2 weeks. Mature oligodendrocytes were labeled by GST-pi immunohistochemistry and quantified in six brain regions, including the genu of corpus callosum, the upper (layer II/III), lower (layer V) and subplate (layer VIb) regions of the somatosensory cortex, the underneath external capsule and the striatum. After 4 weeks of CPZ treatment, compared with controls, greater number of GST-pi-positive mature oligodendrocytes was noted in the cortical subplate as well as the two regions in close proximity, the external capsule and lower cortex in Fb*Ctgf* KO mice. In the rest of examined regions, the numbers were comparable between genotypes. In the genu of corpus callosum, interestingly, greater number of mature oligodendrocyte was counted in CPZ-treated Fb*Ctgf* KO mice after 1

week of normal chow compared with CPZ-treated controls. Our results suggested a suppressive role of CTGF in the maturation of oligodendrocyte.

Title: Remyelination leads to new myelination patterns in the cerebral cortex

Authors: *C. L. CALL[1], J. L. ORTHMANN-MURPHY[2], G. C. MOLINA-CASTRO[1], Y.-C. HSIEH[3], M. N. RASBAND[4], P. A. CALABRESI[1], D. E. BERGLES[1];
[1]Johns Hopkins Univ., Baltimore, MD; [2]Neurol., Perelman Sch. of Medicine, Univ. of Pennsyl, Philadelphia, PA; [3]Harvard Univ., Boston, MA; [4]Neurosci., Baylor Col. of Med., Houston, TX

Abstract: Myelination patterns in the cerebral cortex are highly variable, with sheath number and length varying among different types of neurons and even along individual axons. Although discontinuous, we find that myelin is allocated preferentially to a small subset of the diverse array of axons available. This sparse, but specific, pattern of cortical myelination has been shown in recent *in vivo* imaging studies to be remarkably stable, suggesting that maintaining sheath placement is important for cortical function. In people with multiple sclerosis, and the cuprizone model of toxic demyelination in mice, the cortex is capable of spontaneous remyelination after demyelination. However, it is unknown whether precise myelination patterns or overall myelin coverage of particular axons are restored following oligodendrocyte regeneration. To determine the specificity of myelin repair in the cortex, we performed longitudinal *in vivo* two-photon microscopy to follow individual oligodendrocytes and their myelin sheaths through de- and remyelination in MOBP-EGFP mice fed 0.2% cuprizone diet for 3 weeks. This protocol sufficiently induced near-complete loss of oligodendrocytes within the cortex, with complete restoration of layer I oligodendrocytes by 5 weeks recovery. Regenerated oligodendrocytes were formed in different locations, but had similar overall morphologies and comparable sheath production, despite the larger axonal territory available, suggesting oligodendrocyte size is primarily determined by cell-autonomous mechanisms. Unexpectedly, myelin sheaths from regenerated oligodendrocytes overlapped weakly with the territories of previous

oligodendrocytes, suggesting that inhibitory factors may prevent new oligodendrocytes from differentiating within the territories of degenerated cells. As a result, just over half of baseline sheaths were restored and many novel sheaths were formed along previously unmyelinated axon segments. For instances where sheaths were replaced, their position along axons was remarkably conserved, suggesting that demyelinated axons retain molecular marks that dictate sheath location. Indeed, in prolonged cuprizone experiments, nodal structural proteins persisted even after complete demyelination, indicating that axonal nodal molecular architecture may serve as a guidepost for remyelinating sheaths. These studies suggest that despite efficient oligodendrocyte regeneration, overall myelination patterns are not preserved during remyelination, which may have consequences for sensory processing and cognitive function.

Title: The DYT6 dystonia protein THAP1 regulates glycosaminoglycan metabolism during oligodendrocyte maturation

Authors: *D. YELLAJOSHYULA[1], M. R. COOKSON[2], W. DAUER[1];
[1]Univ. Of Michigan, Ann Arbor, MI; [2]Lab. Neurogenetics, Natl. Inst. Aging, NIH, Bethesda, MD

Abstract: Dystonia is a common neurological movement disorder characterized by debilitating prolonged involuntary movements. The neuropathology of one form of inherited dystonia (DYT6), caused by loss-of-function mutations in the THAP1 gene encoding the transcription factor THAP1 appears to stem from myelination deficits in the CNS. Our prior studies demonstrate that THAP1 plays a critical role in myelination during CNS maturation in a cell autonomous manner. Conditional deletion of THAP1 in the CNS retards maturation of the oligodendrocyte (OL) lineage, delaying myelination and causing persistent motor deficits. To develop mechanistic insight into the THAP1-regulated OL lineage progression we conducted RNA-seq analyses in differentiating OL from control and THAP1 null OPCs. Glycosaminoglycan (GAG) metabolism and extracellular matrix (ECM) signaling pathways

were the most-represented and significant THAP1 dependent biological pathways that are persistently dysregulated in differentiating OL. Consistent with gene expression studies, we observed abnormal accumulation of GAGs in differentiating THAP1 null OL and CNS, resulting from deficits in their catabolism. We present a model where THAP1 loss-of-function impedes OL lineage maturation by disrupting GAG metabolism. GAGs have significant influence on the development of OL lineage, however mechanisms regulating GAG metabolism and biology in various cell types of CNS are complex and poorly understood. Our studies on THAP1 function in the CNS illuminates the cell-autonomous role and regulation of GAG in the OL lineage.

Title: Loss of oligodendrocyte monocarboxylate transporter 1 expression causes late onset axonal degeneration

Authors: *T. PHILIPS[1], Y. MIRONOVA[1], Y. JOUROUKHIN[3], M. V. PLETNIKOV[4], D. E. BERGLES[5], J. D. ROTHSTEIN[2];

Abstract: In the CNS neuronal energy homeostasis is highly dependent on the metabolic support by glia. Apart from forming the myelin that ensheats the axons, oligodendrocytes play an essential role in fueling neuronal energy metabolism. Our earlier work has identified the lactate/pyruvate transporter monocarboxylate transporter 1 (MCT1) as a key mediator of oligodendrocyte metabolic support: acute oligodendroglial knock-down of MCT1 by virally delivered MCT1shRNAs causes neuronal degeneration. Still unexplored to date is the developmental and long-term consequences of loss of MCT1 metabolic support in oligodendrocytes. Our preliminary data has indicated that oligodendrocyte MCT1 expression is gradually decreasing with aging, which could contribute to subtle neuronal metabolic alterations in older mice. In order to understand the full importance of oligodendrocyte MCT1, we have recently generated MCT1 conditional null mice that allow for Cre mediated deletion of MCT1 expression in specific cell types. We crossed our conditional MCT1 null mice with Cre mice targeting either mature oligodendrocytes only (MogiCre) or both oligodendrocytes as well as

oligodendrocyte progenitor cells (Sox10Cre). We observed that mice with oligodendroglial loss of MCT1 using either Cre line develop indistinguishable from their littermate controls: P90 old oligodendrocyte conditional null mice were behaviorally normal and did not develop any signs of axonal or myelin pathology as assessed with either light or electron microscopy (EM). On the other hand, EM analysis of aged nerves of oligodendroglial MCT1 null mice (P360-P700) revealed specific pathological hallmarks of metabolic disturbances with full blown axonopathy: At P360, mitochondria in the axons had significantly increased in size and were often found to have a dysmorphic, enlarged christae structure strongly suggestive of axonal metabolic dysregulation. In addition, we observed an increase in intra-axonal mitochondrial aggregation in the null mice as compared to littermate controls. At a later time point, (~P700) the pathology had further progressed into a full-blown axonopathy with axonal swellings with intra-axonal organelle accumulations and significant myelin debris accumulation. We are now looking to further characterize these alterations either metabolically (ie changes in ATP or ROS production) as well as with electrophysiology on acutely isolated optic nerves. In summary, loss of oligodendrocyte MCT1 is well tolerated in early development and early adulthood but causes a progressive, late onset axonopathy characterized by severe metabolic alterations.

Abstract: The exact molecular mechanisms involved in oligodendrocyte lineage progression remain unclear. Emerging studies have shown that N6-methyladenosine (m6A), the most common internal RNA modification of mammalian mRNA, plays a critical role in various

developmental processes. In this study, we demonstrate that oligodendrocyte lineage progression is accompanied by changes in m6A modification on numerous transcripts. *In vivo* conditional inactivation in oligodendrocyte lineage cells of an essential m6A writer component, METTL14, results in decreased oligodendrocyte numbers and CNS hypomyelination, although oligodendrocyte precursor cell (OPC) numbers are not altered. *In vitro* Mettl14 ablation disrupts post-mitotic oligodendrocyte maturation. In addition, Mettl14 ablation has distinct effects on OPC and oligodendrocyte transcriptomes. Together, our findings indicate that dynamic RNA methylation plays a critical regulatory role in oligodendrocyte development and CNS myelination.

Title: Developmental myelination and the nuclear progesterone receptor

Authors: *P. WINOKUR[1], B. ZHAO[2], Y. MA[2], T. VARTANIAN[2];
[1]The Rockefeller Univ., New York, NY; [2]Weill Cornell Med. Col. of Cornell Univ., New York, NY

Abstract: Steroid hormones synthesis within the CNS is evolutionarily conserved and thought to play important roles in development, homeostasis, and response to injury. Progesterone stimulates remyelination in experimental models of CNS demyelination through unknown molecular mechanisms. We developed an *ex vivo* mouse cerebellar explant system ideally suited to investigate both developmental myelination and remyelination. Oligodendrocyte maturation in cerebellar slices mimics physiological development in terms of temporal and cytoarchitectural patterns. To induce demyelination, cerebellar explants were treated with epsilon toxin, which induced highly specific and reproducible demyelination in a dose- and time-dependent fashion. To address the effect of progestins on myelination, cerebellar slices from P7 mouse pups were cultured for 7 or 14 days in the presence or absence of Nestorone, a potent, synthetic progesterone analog. Administration of 20 or 50 μM Nestorone significantly enhanced myelination as assessed by fluorescent staining intensity of the mature myelin protein, myelin basic protein (MBP). The most striking effects were seen at the 7-day timepoint, with 20 and 50

uM Nestorone treatment resulting in 96% and 81% increases in MBP fluorescence intensity, respectively, compared to that in vehicle-treated control slices. This trend was more modest at the 14-day timepoint, with 20 uM Nestorone treatment leading to a 35% increase in MBP fluorescence intensity. Interestingly, no effect was apparent with 50 uM treatment. This data suggests progesterone impacts myelination at an early postnatal age. To determine if the classical nuclear receptor is required for the effects of Nestorone on myelination, we conducted cerebellar explant experiments as described above in slices from mice carrying a germline loss-of-function mutation at the nuclear progesterone receptor locus.

Title: Activity-induced release of a neuropeptide promotes oligodendrocyte precursor cell differentiation and myelination

Authors: *L. A. OSSO, K. A. RANKIN, J. R. CHAN;
Weill Neurosci. Grad. Program and Dept. of Neurol., Univ. of California, San Francisco, San Francisco, CA

Abstract: Evidence of activity-dependent myelination has been rapidly accumulating, generating substantial excitement in recent years. Yet, the mechanisms through which neuronal activity regulates myelination remain unknown. Using an unbiased screen, we previously identified a cluster of kappa opioid receptor agonists - including the neuropeptide class dynorphins - that promote oligodendrocyte precursor cell (OPC) differentiation and myelination *in vitro* and *in vivo* (Mei et al., 2016). These neuropeptides are released from neurons following high levels of neuronal activity, leading us to investigate whether the activity-dependent release of these neuropeptides is an underlying mechanism of activity-dependent myelination. Combining behavioral, genetic, pharmacological, and chemogenetic techniques to manipulate neuropeptide release in adult mice *in vivo*, we demonstrate that activity-induced neuronal release of these

neuropeptides promotes OPC differentiation and myelination. These data demonstrate a novel mechanism of activity-dependent myelination.

Title: Electrophysiological and genetic profiling of single oligodendrocyte lineage cells

Authors: *E. GOULD[1], J. KIM[2];
[1]Univ. of Texas San Antonio Hlth. Sci., San Antonio, TX; [2]Physiol., Univ. of Texas Hlth. Sci. Ctr. San Antonio Sch. of Nursing, San Antonio, TX

Abstract: The oligodendrocyte lineage consists of distinct states and subpopulations as defined by morphology, physiology, and transcriptional profile. Physiological characteristics of oligodendrocytes are shaped by their transcriptional profile. How the molecular profile of specific oligodendrocyte populations confers different physiological profiles is not known. Oligodendrocyte lineage cells have the capacity to sense neuronal activity because these cells express neurotransmitter receptors and can receive synaptic input. Our previous study showed a subpopulation of pre-myelinating oligodendrocytes display spikes in response to neuronal input. Not all oligodendrocyte lineage cells demonstrate a spiking response to neuronal input and the significance of this excitability is still undetermined. It is hypothesized that the electrophysiological properties of oligodendrocytes depend on the expression of specific voltage-gated ion channels, such as voltage-gated sodium channels. This study aims to better understand the role of electrical excitability in oligodendrocytes in the developing brain. Utilizing the whole-cell patch-clamp recording paired with single-cell transcript profiling, we identified the molecular profile of single oligodendrocytes and their distinct physiological characteristics. Following whole cell recording, oligodendrocyte was collected for single-cell quantitative polymerase chain reaction to quantify the expression of 45 key genes. All cells (n=62) isolated after electrophysiological recordings show optimal levels of housekeeping genes (e.g. *Actin*), indicating consistent and reliable collection of mRNA. Individual oligodendrocytes showed a distinct molecular profile with consistent expression of oligodendrocyte markers (e.g. *Olig1*), which differentiated them from neurons. Oligodendrocyte lineage markers (e.g. *Pdgfra*) were expressed in a gradient across the cell population and correlated with the distinct physiological characteristics. Isolated oligodendrocytes expressed multiple voltage-gated sodium channel

subunits, indicating each cell contains multiple sodium channel types. Intriguingly, *Scn2a*, encoding Nav1.2 channel, expression was restricted to oligodendrocytes with distinct spikes. This electrophysiological and genetic profile of a single oligodendrocyte strongly supports that Nav1.2 is expressed in a unique subpopulation of excitable oligodendrocytes, as has been described in our previous work. Understanding the molecular diversity of oligodendrocytes will further our understanding of how the molecular profile shapes their physiology and function.

Title: Using patient-derived hiPSCs to model white matter changes in autism spectrum disorder

Authors: *J. LI, S. CHETTY;
Stanford Univ., Stanford, CA

Abstract: Autism Spectrum Disorder (ASD) is defined as a group of neurodevelopmental disorders associated with impaired social communication, repetitive behaviors, and intellectual deficits. However, early diagnosis of ASD remains challenging due to its complexity and heterogeneity. In some subtypes of ASD, an increase in brain size precedes the first clinical signs, suggesting that understanding the mechanisms leading to brain overgrowth could provide important insights in disease onset. Here, we use human induced pluripotent stem cell (hiPSC) technology to model ASD associated with disproportionate megalencephaly (ASD-DM) and investigate the cellular and molecular mechanisms involved. While an overall enlargement in brain size has been shown through brain imaging of autistic children with megalencephaly, the iPSC models to date have primarily focused on modeling neurons in ASD. In this study, we investigate changes in glial cells by differentiating hiPSCs to brain-derived glia from control subjects and ASD-DM subjects. Changes in morphology, including the cell body size and the number of processes, and proliferation rates were compared across control and patient-derived hiPSCs. Preliminary data shows that the ASD-DM-derived glia have more processes. Also, increases in proliferation could be observed in glia from ASD-DM compared to the controls. We also investigate and compare changes in gene expression associated with the cell cycle. Overall, these data indicate that ASD with megalencephaly is possibly a result of enhanced proliferation. While prior studies have focused on changes in neurons, this study is the first to systematically investigate changes in glial cells in ASD-DM.

Title: Regulation of oligodendrocyte exploratory behavior and sampling of axons by neural activity

Authors: J. R. GRONSETH[1], T. A. MALLON[1], M. R. MARTELL[1], B. B. DUXBURY[1], A. J. TREICHEL[1], J. T. HENKE[1], E. S. MENGES[1], H. N. NELSON[1], T. L. HOBBS[2], *J. H. HINES[1]; [1]Dept. of Biol., [2]Winona State Univ., Winona, MN

Abstract: Oligodendrocytes (OLs), the myelinating cell type of the CNS, interact with a plethora of diverse neuronal subtypes but only wrap a select subset with myelin sheaths. Prior to initiating axon wrapping, OLs dynamically extend and retract membrane processes in order to contact and sample numerous axons. Whether neural activity-dependent mechanisms regulate exploratory axon sampling, target axon recognition, and stabilization of OL-axon interactions prior to initial axon wrapping is unknown. To test this, we directly observed interactions between pre-myelinating OL processes and individually labeled target axons in larval zebrafish using time-lapse confocal microscopy. In control larvae anesthetized with the neuromuscular blocker pancuronium bromide, we observed dynamic axon sampling characterized by frequent formation and turnover of OL-axon interactions. In contrast, treatment with the neural activity blocker tricaine methanesulfonate (MS-222) caused reduced frequency of new interaction formation, increased interaction duration, and reduced frequency of interaction retraction. Time-lapse imaging revealed differential effects on OL-axon interactions at axon varicosities and thin, intervening segments. Specifically, the destabilizing effects of neural activity on OL-axon interactions were heightened at axon varicosities. MS-222 increased contact durations at varicosities but not at neighboring intervening segments. Neural activity manipulations also influenced the dynamics of axon varicosity formation, lifetime, and turnover, raising the possibility that changes to axon morphology or local properties could direct OL-axon interactions and subsequent myelination. Taken together, we conclude that neural activity negatively regulates the duration of OL-axon interactions prior to initial axon wrapping and myelination. These findings support a mechanism whereby neural activity plays opposing roles on OL-axon interactions before and after initial myelin ensheathment. Prior to ensheathment,

neural activity destabilizes interactions, which may serve to facilitate increased overall sampling of potential wrapping sites. After successful ensheathment, neural activity stabilizes OL-axon adhesion in order to promote continued growth and maturation of the myelin sheath. Current and future studies aim to understand the reciprocal effects between OL processes and axon morphology, and the effects of synaptic vesicle release during initial OL-axon interactions.

Title: Axon determination of subtype specific myelin ensheathment and pruning

Authors: *H. N. NELSON, A. J. TREICHEL, E. DANKERT, M. MARTELL, A. KAISER, A. TRUDEL, J. R. GRONSETH, S. LANG, J. H. HINES;
Biol., Winona State Univ., Winona, MN

Abstract: In the developing central nervous system, pre-myelinating oligodendrocytes contact and sample candidate nerve axons by extending and retracting process extensions. Some contacts stabilize and mature, leading to the initiation of axon wrapping, myelin sheath formation, and sheath elongation by oligodendrocytes. Although axonal signals influence the overall process of myelination, which precise steps and oligodendrocyte cell behaviors require signaling from axons is incompletely understood. In this study, we investigated whether cell behaviors during the early events of myelination involve input from axons or are mediated by an oligodendrocyte-autonomous myelination program. To address this, we utilized *in vivo* time-lapse imaging in embryonic and larval zebrafish during the initial hours and days of axon wrapping and myelination. Transgenic reporter lines marked individual axon subtypes or oligodendrocyte membranes. In the larval zebrafish spinal cord, individual axon subtypes supported distinct nascent sheath growth rates and pruning frequencies. Oligodendrocytes ensheathed individual axon subtypes at different rates during a two-day period after initial axon wrapping. When the ratio of oligodendrocytes to target axons was increased by ablating spinal projection axons, local

spinal neuron axons supported a constant ensheathment rate despite the increased ratio of oligodendrocytes to target axons. We conclude that properties of individual axon subtypes instruct oligodendrocyte behaviors during initial stages of myelination by differentially controlling nascent sheath growth and stabilization.

Abstract: Glioblastoma multiforme (GBM) is the most malignant, aggressive and common form of gliomas. Despite extensive research this situation has not changed significantly during the past decade. Currently, GBM is considered to be a homogenous mass histologically and all its margins are treated equally at the time of resection. However, it is not known whether radiologically distinct regions of GBM are also distinct at cellular level? We conducted this study to see if 4 radiologically distinct regions of 20 GBM patients, identified using MRI Apparent Diffusion Coefficient (ADC) and Contrast Enhancement (CE), i.e. 1) high ADC and high CE, 2) high ADC and low CE, 3) low ADC and low CE and 4) low ADC and high CE were also different at cellular level. Hematoxylin and Eosin staining showed markedly increased nuclear pleomorphism, cellularity, vascularity and necrosis in Region 2. Oncogene IDH was expressed in all regions, however, it was highest in Region 4. Stem cell marker, CD44 expression was highest in Region 1 and lowest in Region 4. Interestingly, expression of another stem cell marker, CD133, was highest in Region 4. This study shows that MRI characteristics of an area within GBM can indicate the type cells that populate it.

Title: From tumor growth to invasiveness: Morpho-molecular dynamics of the glial-immune-vascular unit in the GL261-C57/Bl6J mouse model of glioblastoma

Authors: A. VIRTUOSO[1,2], G. CIRILLO[1], M. RIVA[2,3], A. BENTIVEGNA[2], C. GIUSSANI[2], M. LAVITRANO[2], *M. PAPA[1], R. GIOVANNONI[4];

Abstract: Glioblastoma multiforme (GBM) is the most aggressive brain tumor with ineffective treatments, bad prognosis, and poor survival. Recent studies have attributed the tumor growth and invasiveness to the ability of the GBM in converting the activity of the brain elements to its benefits. Moreover, the broad genetic-epigenetic heterogeneity of the GBM and the lack of suitable experimental models have limited the translation of the results to humans. Hence, targeting both the tumor and the microenvironment in a reliable model represents a more valuable approach for translational studies. In the present work, we aimed to describe the kinetics of the tumor progression in parallel with its landscape using an immuno-competent mouse model of primary GBM. GL261 glioma cells were implanted in the right striatum of syngeneic C57Bl6J mice and animals were sacrificed at 7, 14 and 21 days (7D, 14D, 21D) after the cell implants. Brains were then processed for immunohistochemistry, immunofluorescence and western blotting analyses. Our preliminary results showed a definite tumoral bulk at 14D, with no expression of the glial fibrillary acidic protein (GFAP) by GL261 cells and fibrous GFAP+ astrocytes surrounding the malignancy. GBM invasiveness prevailed at 21D: we observed a partially necrotic GBM-lesion in most of the tumor-injected hemispheres, causing tissue compression while a secondary cancerous mass developed in the contralateral hemisphere. We found that the "growth to go" decision of the malignancy was associated to an inhibition of the tumor immuno-escape as observed from the microglia/macrophages (Iba1+, Ionized calcium binding adaptor molecule 1) dynamic. The resident immune system exploited only in the late stage of the disease while peritumoral astrocytes density gradually increased with time. Changes in the extracellular matrix (tenascin-C; metalloproteases) as well as in the vascular pericytes

(platelet-derived growth factor receptor-β, PDGFR-β+) and in the antigen presenting functions were correlated to the GBM switch towards the invasive mode. By combining morpho-molecular features, our study offers a picture of the alterations in the glial-immune-vascular unit leading the GBM from the growth to the invasiveness, gaining hints for the development of novel multi-targeted therapies in an experimental model expected to be analogous to the human system.

Abstract: Malignant brain tumors are the most common cause of solid cancer death in children. Innovative therapies are vital to improve treatment outcomes, but must be developed to enable trafficking across the blood brain barrier (BBB). For this advent, animal models provide important information prior to clinical studies. Among the different in vivo models orthotopic patient-derived xenograft (PDX) models represent the diversity seen in patient tumors and hence replicate response rates in the clinical trials better as compared to other more simplistic models. Especially in the brain tumor field, imaging has a central role in clinical diagnosis and as a prognostic factor to monitor therapy response. It enables longitudinal patient monitoring in a fully translational manner. Magnetic resonance imaging (MRI) and positron emission tomography (PET) are widely used for clinical diagnosis and disease follow up. Choosing the most suitable imaging application depends of the target of interest or mechanism of action. MRI offers unprecedented soft tissue contrast, high spatial resolution and non-invasive nature renders MRI in rodents a perfect tool for preclinical work in oncological applications. In case of orthotopic brain tumor models, MRI offers the state-of-the-art quantitative volumetric tumor size analysis over disease progression. PET is an excellent tool to study tumor proliferation, metabolism, metastasis as well biodistribution of novel antibodies.

The purpose of this work was to analyze volumetric, metabolic and functional changes in orthotopic PDX brain tumor model using MRI, MRS and PET imaging. During the course of the experiment, volume, perfusion within the tumor as well proliferation and metastasis were monitored. Perfusion measurement indicates angiogenesis in tumor, one hallmark of most malignant gliomas. Also, alterations in glucose and amino acid metabolism between tumor and healthy tissue has been previously identified. By direct comparison of the imaging data derived from the preclinical mouse model with similar data-sets from the donor patient the translational value of the model as well as the read-out system will be achieved.
As a conclusion, translational in vivo imaging techniques were applied to study orthotopic tumor progression. These readouts provide a powerful and translational research tool together with oncological disease animal models allowing comprehensive evaluation of disease progression and treatment interventions for in vivo studies.

Title: Comparative RNA-seq analyses of mouse IUE-induced gangliogliomas and human counterparts

Authors: ***S. CASES-CUNILLERA**[1], H. VATTER[2], S. SIVALINGAM[3], S. SCHOCH[4], A. J. BECKER[1];
[1]Section for Translational Epilepsy Research, Dept. of Neuropathology, Neuropathology; Univ. Bonn Med. Ctr., Bonn, Germany; [2]Dept. of Neurosurg., [3]Dept. of Human Genet., [4]Dept. of Epileptology, Univ. Bonn Med. Ctr., Bonn, Germany

Abstract: Gangliogliomas are the most common entity in the glioneuronal neoplasm spectrum. Their pathogenetic basis is only insufficiently understood and their neuropathological phenotype

composed from an admixture of dysplastic neuronal and neoplastic glial cells appears peculiar. Recently, frequent $BRAF^{V600E}$ mutations and increased mTOR pathway signaling were observed in ganglioglioma biopsy tissue obtained from patients generally undergoing epilepsy surgery for seizure relief. Neoplasms reflecting key ganglioglioma features have been recently induced by intraventricular in-utero electroporation of the murine equivalent of $BRAF^{V600E}$ to mice. Here, we aimed to scrutinize whether $BRAF^{V600E}$ mutations and mTOR pathway activation may act synergistically to induce ganglioglioma like tumors. Ethical approval was obtained for animal experiments (Nr. 84.02.04.2013.A307). We induced gangliogliomas by IUE of $BRAF^{V600E}$ (n = 5) as well as co-IUE of a piggyBac vector containing the sequence encoding $BRAF^{V600E}$ and constitutively active Akt kinase (*p*Akt) under the control of the ubiquitous (CAG-) promoter at the embryonic day 14 (E14) in CD1/ C57BL6 mice (n = 4). Both experimental approaches resulted in brain lesions with a glioneuronal phenotype resembling neuropathological features of gangliogliomas. With respect to survival, we did not find any statistical difference between the both groups of mice with gangliogliomas and long-term survival. We performed mRNA sequencing in order to analyze the transcript signatures of mouse ganglioglioma-like tumors compared to human GGs (n = 4), from patients of whom informed written consent was obtained for these experiments. GO enrichment analysis of abundant RNAs revealed growth related transcripts, whereas low expression of mRNAs was related to synaptic transmission, nervous system development and ion transport. Overall, our data indicate that $BRAF^{V600E}$ and active mTOR pathway signaling elicits tumor in mice recapitulating all characteristic features of GGs.

Title: Androgens stimulate glioblastoma derived U87 cell metabolism and proliferation while steroid enzymes inhibitors and androgen antagonists reduced their metabolic capacity

Authors: M. A. OROZCO[1], R. A. VALDEZ[2], J. V. SEGOVIA-VILA[3], *M. C. ROMANO[4]; [2]Fisiología, Biofísica y Neurociencias, [1]Cinvestav IPN, Ciudad de México, Mexico; [3]Cinvestav-IPN, Mexico 07300 DF, Mexico; [4]Fisiología, Biofísica y Neurociencias, Ctr. De Investigación Y De Estudios Avanzados De, Ciudad de México, Mexico

Abstract: Glioblastoma (GBM) is the most frequent and aggressive primary brain tumor in adult humans. Therapeutic resistance and tumor recurrence after surgical resection results in poor prognosis. The incidence of GBM in the adult population is 50% higher in men than in women, which suggest a significant role of steroid hormones in its development. It has been shown that U87 cells synthesize a number of androgens, express several steroidogenic enzymes involved in androgen synthesis, and have androgen receptors. These data strongly suggest that androgens may have a role in tumor pathogenesis. The aims of this study were to investigate: 1.The effect of three androgens on U87 metabolism and proliferation. 2. The consequence of 5α-reductase inhibitors and androgen receptor antagonists in the growth and survival of GBM derived cells. To perform the experiments U87 human glioma derived cells were cultured in DMEM plus antibiotics in the absence or presence of different doses of androstenedione (A4), testosterone (T4), or dehydrotestosterone (DHT). The competitive inhibitor of 5α-reductase, dutasteride, or the androgen receptor antagonist's ciproterone and flutamide, alone or in combination with androgens, were also assayed with different concentrations and periods in culture. Cells were processed to investigate metabolism by MTT and proliferation by BrdU. Results showed that T4 and DHT, but not A4 increased U87 cell metabolism and proliferation. DHT was more efficient than T4. The 5α-reductase inhibitor dutasteride significantly decreased the cell metabolism. In addition, ciproterone and flutamide significantly reduced the metabolism of U87 cells after 72h of exposure to the drugs. These results showed that testosterone ad DHT enhance glioblastoma derived cells metabolism and proliferation, and that a 5α-reductase inhibitor that interferes with androgen synthesis significantly reduced their metabolic activity. Furthermore, drugs that inhibit androgen binding to the receptor also affected their metabolism. Therefore, the use of drugs related to androgen synthesis or receptors could be an adjuvant tool for the treatment of glioblastoma.

Title: Osmr controls cellular respiration and resistance to stress in glioma stem cells and post mitotic neurons

Authors: *A. JAHANI-ASL, A. SHARANEK, A. BURBAN;
McGill Univ., Montreal, QC, Canada

Abstract: Cytokines and their receptors play important roles in the regulation of cell fate, inflammation and immunity. Oncostatin M receptor (OSMR) is a plasma membrane receptor that is activated by Oncostatin M (OSM) ligand. OSM/OSMR signaling (OSMR) plays important roles in the nervous system. For example, OSM confers neuroprotection against ischemic stroke and protects against demyelination via modifying microglia function. On the other hand, OSMR promotes the self-renewal of brain tumour stem cells (BTSCs), a rare population of multipotent stem cells in the bulk of the tumor, that are responsible for the tumor growth and exhibit resistance to therapy. BTSCs possess a unique metabolic phonotype, with a distinct upregulation of oxidative phosphorylation (OXPHOS) and a low glycolytic rate. Thus, BTSCs more closely resemble neurons as opposed to the majority of cells in the bulk of the tumor relying on aerobic glycolysis. Here we report a novel role for OSMR in the control of cellular respiration in BTSCs and primary neurons. OSMR promotes mitochondrial biogenesis via MAPK/PGC1 signaling. Knockdown of OSMR in BTSCs sensitizes BTSCs and patient derived xenografts to DNA damage-induced ionizing radiation. OSMR knockout mice exhibit metabolic defects and a decrease in oxygen consumption rate (OCR). Furthermore, OSMR and its ligand OSM, upregulate maximal respiration in primary neurons, induce mitochondrial fusion, and protect against camptothecin induced DNA damage. Our data suggests that OSMR is targeted to peroxisomes to induce conversion of long fatty acid to provide substrates to the mitochondria to enhance oxidative phosphorylation. Thus, we have identified a novel mechanism by which OSMR regulates respiration and confers resistance to DNA-damage induced cell death.

Title: Diffuse intrinsic pontine glioma invasion mediated by the Nogo pathway

Authors: *R. AZIZ-BOSE, K. R. TAYLOR, A. C. HUI, H. ZHANG, A. PONNUSWAMI, M. MONJE;
Stanford Univ., Stanford, CA

Abstract: Diffuse intrinsic pontine glioma (DIPG) is a devastating childhood brain cancer, in part due to its characteristic diffuse infiltration of brain that prevents the option of surgical resection. DIPG is thought to arise from early oligodendrocyte precursor cells (OPCs or pre-OPCs) and peaks in incidence during a specific developmental timepoint in mid-childhood, suggesting that the tumor may be influenced by dysregulated signaling cues in the environment of the developing childhood brain. However, the microenvironmental signaling that regulates DIPG invasion and migration is incompletely understood. An emerging principle is that signaling pathways classically involved in axon guidance during neural development are repurposed in malignancy to regulate cancer invasion. Early studies in adult glioblastoma indicate that inhibition of the Nogo receptor (NgR), important for axon pathfinding and neurite outgrowth, may increase tumor cell migration *in vitro*. Our RNA sequencing studies of patient-derived DIPG samples demonstrate that NgR is also expressed in pediatric DIPG tumors. To evaluate the role of NgR in DIPG migration, CRISPR/Cas9 technology was used to delete NgR from a patient-derived DIPG culture derived from a frontal lobe DIPG metastasis, SU-DIPGXIII-FL. Loss of NgR, confirmed by qPCR and by Western blot, significantly enhanced DIPG tumor cell migration at 72 hours in a 2D spheroid migration assay ($p < 0.05$). NSG mice xenografted with SU-DIPGXIII NgR-null cells exhibited a 33% increased extent of tumor invasion through the brain at 8 weeks compared to mice xenografted with wild-type SU-DIPGXIII control cells ($p < 0.05$). Additionally, the endogenous Nogo pathway antagonist Crtac1 is sufficient to promote tumor cell migration at 72 hours in the 2D spheroid migration assay ($p < 0.005$). Ongoing DIPG pontine xenografts into a newly established Crtac1 knock-out mouse line will demonstrate the contribution of Crtac1 to tumor spread *in vivo*. This work elucidates the importance of Nogo pathway signaling in diffuse intrinsic pontine glioma, which may be targeted therapeutically to limit tumor spread.

Title: Capsaicin effects on glioma cell cultures

Authors: A. SANGAMI, A. TORRES, T. GRAY, *E. E. SERRANO;
New Mexico State University, Biol., Las Cruces, NM

Abstract: The high cost and prolonged time frame of the drug discovery pipeline have fueled interest in drug repositioning. Capsaicinoids have emerged as a class of alkaloid compounds with potential therapeutic effects that extend beyond analgesia to include neuroprotective and antineoplastic activity. Previous reports have suggested that capsaicin can serve as an inhibitor of the survival of human glioma cells in culture, a finding we seek to confirm as a prelude to mechanistic studies of capsaicinoid action on cells of the nervous system. In this pilot study we compared the effect of capsaicin exposure on the proliferation of the CCF-STTG1 glioblastoma cell line (RRID:CVCL_1118) with that of the antimalarial drug, chloroquine. Cells were purchased from a vendor (ATCC CRL-1718) and used within the first five passages of cell line stock preparation. A blinded-experimental design was undertaken by preparing and anonymizing treatment and control solutions and unmasking treatment identity after completion of all data analysis. Cultures were continuously exposed to chloroquine (Sigma 12084-10MG-F; Lot #: BCBS7557V) and capsaicin (Sigma C6628-25G; Lot#: 085M4098V) for 96 hours. Drug effects were evaluated by using Hoechst 33342 (Invitrogen H3570; Lot#: 1387197) to label nuclei, then capturing images, and quantifying cells per unit with the open access program, ImageJ. Analysis from replicate experiments uncovered that chloroquine was effective at preventing cell survival ($p < .01$; 200 uM) but capsaicin showed modest potential to reduce glioma proliferation ($p < 0.10$; 200 uM). These outcomes underscore the need to evaluate drug action on multiple cell lines and suggest that capsaicin may be useful in conjunction with other antineoplastic agents. Future experiments will extend the analysis to include additional cell lines and evaluate the potential of other capsaicinoids to serve as antineoplastic agents.

Abstract: Glioblastoma multiforme (GBM) are tumors composed of several types of cells, such as: progenitor cells, glial cells, neurons & GBM tumor stem cells (GSC); In addition, tumors of the central nervous system are most aggressive & have a worse prognosis, being the type of primary brain tumor more common in adults, with a survival rate of 15 months. Temozolomide (TMZ) is currently administered as a chemotherapeutic treatment; however, some tumors have drug-resistance mechanisms against the cytotoxic effects of TMZ; Although, the main cause of this drug resistance is not yet clear, it can be pointed out to the GSC as possible culprits of this characteristic. It has been proven that coumaric compounds have the potential to attack tumor stem cells, reducing their capacity for proliferation, self-renewal & resistance in gliomas. The objective of this work is to evaluate the therapeutic potential of coumaric derivatives such as propyl, iso-butyl & ethyl-o-coumaric, since they have cytotoxic & antiproliferative capacity in GBM cells, in addition to reducing self-renewal & inhibiting the expression of stem markers in GSC. The GBM U-87 cell line, was used as a study model; In previous studies in our laboratory the LC50 was determined by MTT, for each compound, covering a range between 200μM & 300μM. Spheroid formation assay & Clonogenic assay were performed to determine the decrease in the proliferative capacity & self-renewal of the GSC, for which the neurospheres generated in the culture were collected & cultured with the LC50 of each compound for 24 hours, for 15 days; A decrease was observed not only in the capacity of formation of secondary spheroids, but also in the number of spheres & the number of colonies generated by individual cells in culture. The cells were also exposed to the compounds for 3 days, to determine the inhibition of the stem & induction of neuronal & astrocyte differentiation by immunofluorescence, using the antibodies CD133, GFAP, NeuN & Nestin; where we observed the constant expression of differentiation markers such as GFAP & NeuN, & the inhibition of stem markers such as CD133 & Nestin. This can allow the development of joint therapies with coumaric derivatives for cases of chemoresistant GBM, having the faculty to act on the GSC & the malignant properties that confer to the tumors of GBM.

Title: The chemokine receptor CXCR7 modulates numerous signaling pathways in glioblastoma stem cells

Authors: *G. F. TAPSALL[1], A. CALINESCU[3], S. AKULA[2];
[1]Dept. of Neurosurg., [2]Univ. of Michigan Med. Sch., Ann Arbor, MI; [3]Neurosurg., Univ. of Michigan, Ann Arbor, MI

Abstract: Glioblastoma is one of the deadliest and most common forms of primary malignant brain cancer. The resilience of glioblastoma stem cells (GSCs) may account for resistance to treatment of GBM. Studies demonstrate that the chemokine CXCL12 promotes the growth of GSCs, resistance to hypoxia and disease progression. CXCL12 and its signaling receptor CXCR4 have been the focus of much interest, due to important roles in cancer biology. CXCR7 is an alternate receptor for CXCL12, that binds CXCL12 with higher affinity than CXCR4, targets the chemokine for degradation and prevents signaling through CXCR4. Studies of CXCR7 in various cancers present conflicting results; CXCR7 appears to either promote or inhibit cancer progression. Previous studies have demonstrated that blocking CXCR4 decreases viability of GSCs, suggesting that CXCL12 is necessary for continued growth of GSCs. We reasoned that overexpression of CXCR7 will decrease CXCL12 and render GSCs more sensitive to CXCR4 blockade. Surprisingly, we found decreased sensitivity of CXCR7-GSCs to AMD3100 and AMD070. To test if the presence of CXCR7 on alternate cells in the environment alter viability of GSCs, these were cultured with neural stem cells (NSCS) overexpressing or not CXCR7. No change in GSC viability was observed. Interestingly, the tumor cells decreased viability of NSCs and this decrease was less pronounced in the presence of CXCR7-GSCs. Analysis of CXCL12 in GSCs and NSCs revealed increased expression in CXCR7 cells, accompanied by a decrease in expression of CXCR4. This suggested that CXCR7 modulates transcriptional activity in GSCs to adapt to the surrounding environment. RNA-Seq analysis identified 706 differentially expressed genes between GSCs and CXCR7-GSCs, majority of the genes (555) being downregulated, among them numerous growth factors and cytokines, such as FGF1, FGF21, TGFb2, TGFbi, VEGFa, VEGFb, PGF, PTN, GDF15, CXCL1 and CXCL10. Pathway analysis revealed 58 significantly impacted pathways, with decreased MAPK, cAMP, and TNF pathways and activation of the Wnt and Hippo pathways. Current experiments are dissecting the contribution of these genotypic alterations on the malignant phenotype of GSCs using *in vitro* assays and an *in vivo* orthotopic mouse model of GBM.

Title: Neuronal-activity regulated BDNF secretion promotes pediatric glioma growth

Authors: *K. TAYLOR, R. AZIZ-BOSE, H. ZHANG, A. HUI, A. BLANK, A. C. GERAGHTY, M. MONJE;
Stanford Univ., Stanford, CA

Abstract: Pediatric high-grade gliomas (pHGG) are a devastating group of diseases that critically require novel therapeutic options. We have previously demonstrated that pHGGs hijack mechanisms of brain development and plasticity to their advantage. One key process, neuronal activity, robustly drives proliferation of pHGG via the secretion of the synaptic protein neuroligin-3 (NLGN3) and the neurotrophin brain-derived neurotrophic factor (BDNF) into the tumor microenvironment. The relative contribution of BDNF signaling to pHGG progression and therapeutic utility of targeting the BDNF receptor remains to be defined. Here, we investigated the role of microenvironmental BDNF on pediatric gliomas, independent of the NTRK fusion events commonly identified in infant HGG. We found spatio-temporal patterns of BDNF expression in normal brain during the postnatal developmental period that highlight this growth factor as particularly relevant to childhood gliomas. Primary pediatric glioma single-cell RNA-Seq confirms expression of the canonical BDNF receptor TrkB, without expression of the BDNF ligand. Conditioned media (CM) collected from optogenetically stimulated acute cortical slices robustly increases patient-derived DIPG cell proliferation, an effect that is abrogated with CM collected from mice deficient of activity-regulated BDNF expression. The BDNF ligand increases patient-derived pediatric glioma cell proliferation and activates the canonical downstream MAPK signaling pathway. CRISPR deletion of the TrkB receptor, *NTRK2*,in glioma cells abrogates the proliferative response to BDNF ligand exposure, subsequent p42/44 MAPK pathway activation and increases survival in an orthotopic cortical GBM xenograft model (SU-pcGBM2, p=0.0032). Small molecule pan-TrkB antagonists, entrectinib and LOXO-101, abrogate the tumor cell proliferative response to BDNF ligand stimulation. Entrectinib treatment reduces *in vivo* tumor proliferation of a brainstem glioma xenograft model (SU-DIPGXIIIFL,

p<0.05). Disrupting pediatric glioma responses to microenvironmental cues such as BDNF may contribute to effective therapeutic strategies for these lethal childhood brain cancers.Funding: Abbie's Army Foundation

Title: Altered neurotrophin receptor expression and signalling by histone deacetylase inhibitors in human neuroblastoma cells

Authors: S. DEDONI[1], L. MARRAS[2], M. C. OLIANAS[3], A. INGIANNI[2], *P. ONALI[2]; [1]Univ. of Cagliari, Dept Biomed. Sci., Cagliari, Italy; [2]Univ. of Cagliari, Dept.Biomedical Sci., Cagliari, Italy; [3]Biomed. Sciences, Sect. Neurosci., Univ. of Cagliari, Monserrato, Italy

Abstract: Neurotrophin receptors, including TrkA, TrkB, TrkC and p75NTR, have been shown to play a critical role in the biology of human neuroblastoma. Preclinical and clinical studies have demonstrated that the expression of TrkB, the receptor of brain-derived neurotrophic factor (BDNF), is associated with tumour aggressiveness and resistance to chemotherapy. On the other hand, enhanced expression of the common neurotrophin receptor p75NTR has been reported to induce neuroblastoma cell apoptosis. In the present study we investigated the effects of various histone deacetylase (HDAC) inhibitors on the expression and functional activity of Trk and p75NTR receptors in human neuroblastoma cell lines. We found that in retinoic acid (RA)-differentiated SH-SY5Y cells the HDAC inhibitor valproic acid reduced the expression of TrkB at the protein and mRNA levels, and inhibited the intracellular signalling, neurotrophic activity, and pro-survival function of BDNF. VPA down-regulated TrkB and curtailed BDNF-induced signalling also in RA-differentiated MYCN-amplified LAN-1 and Kelly cells. The class I HDAC inhibitors entinostat and romidepsin mimicked the VPA effect, whereas the class II HDAC inhibitor MC1568, the HDAC 6 inhibitor tubacin and the HDAC 8 inhibitor PCI 34051 were inactive. VPA and entinostat increased the cellular levels of the transcription factor RUNX3, a suppressor of TrkB gene expression. Exposure to VPA enhanced the protein and transcript levels of p75NTR and its co-receptor sortilin in SH-SY5Y and LAN-1 cells. In both cell lines, this

effect was associated with a potentiation of VPA-induced apoptosis in response to proNGF. Collectively, these data indicate that some HDAC inhibitors alter neurotrophin receptor expression to promote apoptotic cell death and suggest that this action may contribute to the anti-neuroblastoma activity of these agents.

Abstract: Glioblastoma (GBM), a grade IV glioma, is a very aggressive tumor, that promotes vascularization, necrosis and is resistant to chemotherapy and radiotherapy. There is currently no effective therapy for its treatment. This means that new therapeutic approaches are needed. AZD5363 is an inhibitor of AKT and its isoforms; AZD8542 is a SMO inhibitor (AstraZeneca) and both have antitumor activity *in vivo* and *in vitro* in breast, prostate and pancreatic cancer cells. Curcumin (CCR) is a polyphenolic compound extracted from the root of the turmeric plant, native to Asia, it is used as a spice and dye in the food industry. CCR decreases the activity of PI3K / AKT and SHH signaling pathways in human GBM cells. Resveratrol (RV) is a phytoalexin, an antimicrobial agent that accumulates in some plants and is also a molecule with anticancer and chemoprotective effects. RV decreases AKT phosphorylation and activates p53 in human GBM cells, moreover it decreases the activity for the SHH pathway in pancreatic, colon and gastric cancers. A current experimental approach for the treatment of GBM is to use combined therapies that affect different signaling pathways, to increase their efficacy and decrease secondary effects. In this work, we propose the use four anticancer agents (AZD5363, AZD8542, RV and CCR) to develop an alternative or adjuvant combination therapy against

GBM. For these experiments we employed human GBM cells lines U87-MG and A-172. Each of the agents tested was shown to have a cytotoxic effect. Using the IC50 of each agent, 10 combinations were tried in each cell line and MTT and Trypan Blue cell viability assays were performed. We found that the combination of AZD8542 and CCR is the most effective to decrease the growth of human GBM cell lines, presumably by inhibiting both the PI3K/AKT and SHH signaling pathways. The action of this combined therapy reduces cellular metabolic activity, induces plasma membrane damage and produces 70%-80% cell death in the lines tested.

Title: Identification and characterization of the role played by the neuronal Na^{+}/Ca^{2+} exchanger in glioblastoma progression and malignity

Authors: L. CALABRESE[1], ***P. MOLINARO**[1], A. SERANI[1], B. SEVERINO[2], S. NATALE[1], F. FRECENTESE[2], F. FIORINO[2], G. DI RENZO[1], L. ANNUNZIATO[3];
[1]Neurosci., [2]Pharm., "Federico II" Univ. of Naples, Naples, Italy; [3]IRCCS SDN, Naples, Italy

Abstract: Glioblastoma multiforme (GBM) is the most lethal and recidivist brain tumor in adults and it is characterized by an aggressive phenotype, with a progressive invasion of brain parenchyma, that is resistant to chemo- and radio-therapy. Furthermore, GBM shows the alteration of several transcription factors involved in genetic and epigenetic mechanisms of control a large number of target genes including *Slc8a2*, encoding for Sodium Calcium Exchanger 2 (NCX2). In fact, NCX2 is physiologically expressed in neuronal and glial cells of CNS, but it is selectively silenced in all glioma subtypes, including GBM, suggesting that this gene might represent a tumor suppressor gene for this disease. To explore the genetic and epigenetic mechanisms leading to NCX2 downregulation, we identified and cloned both rat and human *slc8a2* promoters. Furthermore, we analyzed the promoter regions and the binding sites involved in the regulation of NCX2 transcription. The transfection of several transcription factors, whose expression is altered in a GBM cell line (U87), modified the promoter activity and the mRNA expression of NCX2 in PC12 cells, whereas they were ineffective in U87 cell line suggesting the presence of an epigenetic upstream mechanism that turns off *Slc8a2* gene in

GBM. Indeed, we found that the genomic DNA demethylation of U87 cell line, induced by 5-aza-2′-deoxycytidine treatment, increased NCX2 mRNA expression levels. In addition, the stably transfection of NCX2, or the other isoform NCX1, in U87 cells hampered cell growth. In a prospective therapeutic approach, we also analyzed the effect of two compounds, namely neurounina-1 and CN-PYB2, on the vitality and cell growth of U87 cell line. Neurounina-1 is a stimulator of NCX1 and NCX2 activity, whereas CN-PYB2 is a selective stimulator of NCX1 activity. Results showed that these compounds hampered in a concentration- and time-dependent manner cell growth of U87 cell line, whereas they were ineffective in BHK, SH-SH5Y and PC12 cell lines. Altogether, these data suggest that NCX1 and NCX2 expression/activity slows-down glioblastoma cell growth and thus might exert a tumor suppressor effect in glioblastoma.

Title: Adora2a inhibition as novel therapeutic target for cisplatin-induced cognitive dysfunction

Authors: *A. OLIVEROS, K.-H. YOO, A. M. CORUJO, J. TANG, D. BROGREN, M.-H. JANG;
Neurolog. Surgery, Mayo Clin. Col. of Med., Rochester, MN

Abstract: Cisplatin chemotherapy, although efficacious in positive resolution of cancer, adversely potentiates off-target cognitive dysfunction and affects approximately 14 million cancer survivors in the United States alone. Despite the high prevalence of chemotherapy induced cognitive impairments (referred to as chemobrain), there is little information on how memory and learning are impaired and no known cure. In order to elucidate the mechanisms by which chemobrain impairs cognition, we implement a novel experimental mouse model resembling clinical cisplatin-chemotherapy. Our results reveal that repeated cisplatin administration impairs hippocampal neuronal functional morphology, while inducing significant emotional and memory deficits. Although the molecular targets and pathways vulnerable to

cisplatin in the central nervous system (CNS) are currently unknown, RNA-sequencing derived from mice administered cisplatin or vehicle revealed the adenosine A_{2A} receptor (Adora2a), a G-protein coupled receptor critical for synaptic plasticity and memory, as a promising therapeutic target for chemobrain. Bioinformatic analysis and qRT-PCR validation revealed significant induction of Adora2a mRNA expression by cisplatin in the adult hippocampus, a brain structure critical for learning and memory. Interestingly, while Adora2a is known to be expressed by various CNS cell types, including neurons and astrocytes, confocal microscopy analysis demonstrates that cisplatin specifically increases Adora2a expression in hippocampal neurons without affecting astrocytes in this structure, indicating that Adora2a expressing neurons are particularly vulnerable to cisplatin. To mechanistically determine whether elevated neuronal Adora2a functionality are implicated in cisplatin-induced chemobrain, we assessed the efficacy of Istradefylline (KW-6002), a selective Adora2a inhibitor, in preventing cisplatin-induced chemobrain. Our results indicate that selective pharmacological inhibition of Adora2a prevented cisplatin induced anxiety and cognitive impairments in the elevated plus maze, the Morris water maze and novel object recognition test. Therefore, our results suggest a critical role for Adora2a in cisplatin-induced cognitive dysfunction. Given that Adora2a antagonists are proven to be safe and neuroprotective in neurodegeneration as well as in enhancing anti-tumor activity, inhibiting Adora2a may have far-reaching synergistic effects on cancer treatment and chemobrain.

Title: Harnessing redox homeostasis as a therapeutic modality in glioblastoma

Authors: J. SUN[1], S. NAGPAL[1], C. PATEL[1], M. MERCHANT[1], T. JANG[1], A. R. DIERS[2], S. KAZEROUNIAN[2], *S. GESTA[2], N. R. NARAIN[2], R. SARANGARAJAN[2], L. RECHT[1]; [1]Dept. of Neurol., Stanford Med., Palo Alto, CA; [2]BERG LLC, Framingham, MA

Abstract: A potential clinical application of targeting cancer metabolic reprogramming (i.e. the Warburg effect) is the ability to capitalize on the differences in oxidative stress levels; with specific disruption in cancer cells without damaging (or perhaps even benefitting) non-tumor cells. Coenzyme Q_{10} (CoQ_{10}) represents a prototypical agent for this approach due to its primary role in electron transfer reactions in mitochondria and its capacity to form toxic free radicals

when present in high concentrations, leading to generation of oxidative stress. BPM31510 is a novel ubidecarenone (oxidized CoQ_{10}) - lipid formulation that facilitates delivery of supraphysiologic concentrations of this quinone to cells and their mitochondria. In this study, we assessed the effects of BPM31510 on comparative viability and redox homeostasis in rodent and human derived *in vitro* cocultures of glioma and non-cancerous cells (rodent C6 glioma and NIH3T3 cells or human U251 glioma and primary human astrocytes, respectively). Sensitivity to increasing doses of BPM31510 was initially assessed in the rodent coculture model. After 6 days of treatment, the percentage of C6 relative to NIH3T3 cells within the coculture was lowest at doses of BPM31510 between 115 and 230 μM, providing evidence of greater sensitivity to BPM31510-induced cytotoxicity in the C6 glioma cells in this dose range. The differential effects on cell viability were less evident at higher doses of BPM31510. Interestingly, the peak effect of differences in superoxide levels and cell growth occurred at the same dosage (230 μM). A similar differential (glioma selective) sensitivity to BPM31510 was observed in a human derived model. Basal superoxide levels for U251 cells were 1.5-fold higher compared to the astrocytes, and this difference increased to over 4-fold upon treatment with BPM31510, suggesting BPM31510 exploits differential redox vulnerabilities between U251 and astrocytes to mediate its anti-cancer activity. In summary, the data indicate that cellular delivery of ubidecarenone differentially affects cell growth via increasing intramitochondrial superoxide in tumor cells, when compared to non-transformed cells. The results also suggest that dosing of agents inducing oxidative stress is crucial to enhance cancer-selective effects and that clinical application will be bolstered by the development of a measurement tool for real-time, *in situ* measures of oxidative stress.

Title: Vitamin C induces glioblastoma invasiveness by increasing perivascular satellitosis and bystander effect

Authors: *E. RAMIREZ[1], N. A. JARA[3], F. A. MARTINEZ ACUÑA[2], L. E. FERRADA[4], K. A. SALAZAR[6], A. WOLLMANN-ZWERENZ[7], P. HAU[7], F. J. NUALART[5];

De Concepción, Concepcion, Chile; [7]Dept. of Neurol. and Wilhelm Sander-Neurooncology Unit, Univ. Hosp. Regensburg, Regensburg, Germany

Abstract: Introduction: Glioblastoma, a highly aggressive astrocytic tumor, expresses both vitamin C transporters, SVCT2 and GLUT1/3, but preferentially uptakes oxidized dehydroascorbic acid (DHA) by GLUT1. It is well accepted that reduced ascorbic acid (AA) plays an important role in the biosynthesis of collagen, which is essential for tumor progression; its disruption reduces invasiveness. We propose that DHA confers antioxidant protection to glioblastoma cells by its reduction to AA and increasing collagen deposition. **Materials and Methods:** U87MG, HSVT-C3, and RAV27 human glioblastoma cells were used to characterize SVCT2, GLUT1, and GLUT3 expression. Cell viability was evaluated by the XTT-method. Migration assays were performed using *in vitro* and *in situ* (Organotypic Brain Slice Culture, OBSC) spheroid strategies. A guinea pig orthotopic xenograft model and human tumor samples were analyzed by immunohistochemistry. Picrosirius-Red staining (PRS) and second harmonic generation (SHG) were used to analyze collagen deposition.**Results:** Glioblastoma cells express intracellular SVCT2 while GLUT1 is found in the cell membrane. Radiolabeled assays confirm functional DHA uptake. XTT experiments show that DHA protects glioblastoma cells against H_2O_2-induced oxidative stress. AA and DHA increase *in vitro* RAV27 cell migration. *In situ* analysis using the OBSC assay confirms that migration was associated with collagen IV. U87MG xenografts and human tumor samples express collagens. Xenografts also show augmented blood vessel invasion that is reduced during scurvy.**Conclusions:** Glioblastoma cells functionally uptake DHA, which protects them against oxidative stress. Vitamin C could enhance perivascular satellitosis associated with collagen deposition.

Title: A new class of inhibitors of HuR multimerization is identified

Authors: *N. FILIPPOVA[1], J. A. CALANO[1], X. YANG[1], S. ANANTHAN[2], E. OFORI[2], P. VIBHA[2], L. B. NABORS[1];
[1]Neurol., Univ. of Alabama at Birmingham, Birmingham, AL; [2]Southern Res. Inst., Birmingham, AL

Abstract: HuR is an mRNA binding protein (ELAV family), and it is overexpressed in different types of cancer, including brain tumors. In normal non-proliferating cells, HuR exhibits mostly nuclear localization; however, in proliferating and tumor cells, HuR localizes in both the nucleus and cytoplasm. HuR strong cytoplasmic localization and multimerization are associated with a rise of the tumor grade and poor patient outcome. We identified a new class of inhibitors of HuR multimerization and evaluated the outcome of the disruption of HuR multimerization on HuR function and glioma progression. We utilized a split Firefly Luciferase-HuR assay (HuR molecules were attached to the N and C parts of Firefly Luciferase in living glioma cells) to search for new compounds, which interfere with HuR multimerization. The cell lines expressing a full-length luciferase without HuR or co-expressing N and C parts of luciferase were utilized as a control. New inhibitors of HuR multimerization (with IC50s ranging from 0.3 uM to 5 uM in glioma cells) were identified. We observed a significant reduction of the expression of the anti-apoptotic Bcl-2 family molecules on mRNA and protein levels after cell treatment with newly identified inhibitors of HuR. The average decreases of Bcl2/18S and Mcl1/18S mRNA ratios were 96$\pm$2% and 95$\pm$3%, 95$\pm$2% and 86$\pm$7%, 95$\pm$2% and 87$\pm$8%, 96$\pm$2% and 90$\pm$9% based on three experiments for the established U251, U87, LN229, and the primary XD456 cell lines, respectively, after cell treatment with compound #2 compared to the control. We confirmed that the identified inhibitors of HuR multimerization reduce proliferation and evoke cell cycle arrest with significant cell accumulation in the G1 phase and a dramatic reduction in the S phase of the cell cycle. The spheroid viability of primary GBMs was decreased by compound #2 with the IC50s ranging from 1.5 to 8 uM (48 hours of treatment). The global Illumina RNA-Sequencing workflow and proteomic analysis are on the way for the identification of the pathways involved in the tumor spheroids' sensitivity to the compound #2. In the intracranial athymic mice glioma model, we observed a decrease of primary XD456 tumor growth by an average of 5-7 folds after treatment with compound #2 compared to the control. The mice were treated with compound #2

by intraperitoneal injection (15mg/kg, twice a day for 15 days) or with the corresponding vehicle as a control. We conclude that the disruption of HuR multimerization in glioma cells by a new class of HuR inhibitors results in a decrease of anti-apoptotic Bcl2 family molecules in mRNA and protein levels, the arrest of cell cycle progression, and, therefore, reduces tumor cell viability and proliferation.

Title: Identifying small molecules that specifically inhibit glioma stem cells

Authors: S. E. LAYE[1], R. SPINA[2], A. SLOAN[2], D. M. VOSS[2], *B. J. HOFFER[3], E. E. BAR[2]; [1]Hathaway Brown Sch., Shaker Heights, OH; [2]Case Western Reserve Univ., Cleveland, OH; [3]Scientist Emeritus, NIDA/NIH, Lyndhurst, OH

Abstract: Glioblastoma (GBM) are a highly malignant form of brain tumor which proliferate rapidly throughout the brain and are incredibly difficult to treat. The median survival time is approximately 15 months with the combined treatment of maximal surgical resection followed by concomitant radiation and temozolomide (TMZ) chemotherapy. Glioblastoma stem cells (GSC) are shown to play a role in tumor growth and survival due to their tumor initiation and propagation abilities as well as their link to GBM resistance to current treatment. Due to these poor clinical outcomes and resistance to current treatments, more potent and preferably more specific pharmacological therapies are needed in order to target cellular-molecular pathways to eradicate GSCs and effectively treat GBM. Small-molecule drug library including over 3,000 compounds was screened in an effort to identify agents that effectively and specifically target GBM patient derived neurospheres. HSR020913 patient derived neurospheres were treated for 72 hours with library agents at a concentration of 10 µM and cell growth was observed for a period of 5 days. We identified twelve highly potent compounds in the primary screen that inhibited the growth of HSR020913 neurospheres by over 50%. Subsequently, the potency of these compounds was tested on five additional GBM patient derived neurosphere lines (HSR040622, HSR040822, CCF3691, CCF3832, and CCF08-387), immortalized human neural stem cells (v-Myc hNSCs) and normal human astrocytes (NHA) at concentrations ranging from 10 µM to 0.001 µM. Collectively, these efforts yielded three drugs: AGSC9, AGSC11, and AGSC12 all capable of inhibiting GBM cells but show no effect against normal neural stem cells (NSC and NHA). The respective half maximal inhibitory concentration (IC50) was determined

for all the neurosphere lines utilized. Future studies will help to determine the effect of these drugs on self-renewal *in vitro*, to elucidate the molecular mechanisms involved and also to shed light on the effect on tumorigenicity and survival *in vivo*.

Title: Identifying safe and effective pharmacologic agents for use with neural stem cell therapy in glioblastoma

Authors: *M. KAUSS, A. CALINESCU;
Neurosurg., Univ. of Michigan, Ann Arbor, MI

Abstract: There is no known cure for glioblastoma multiforme (GBM), the deadliest and most common form of malignant brain tumor in adults. Although current therapies slow progression, the median survival for patients with GBM is less than two years. Glioma stem cells (GSCs), which are resistant to chemo- and radiotherapy, are a main contributor to treatment failure and recurrence of GBM. Neural Stem Cells (NSCs) can naturally migrate towards the tumor and represent a promising new alternative as vehicles for GBM targeted therapy. No single therapy has been shown effective in the treatment of GBM. To identify pharmacological agents effective in killing tumor cells, but safe to use in combination with NSC therapy, we first tested a panel of chemotherapeutics commonly used in the treatment of GBM, in murine NSCs and in GSCs derived from an aggressive model of mouse GBM. Results so far indicate that all tested drugs severely affect the viability of both GSCs and NSCs, with NSCs being more sensitive to Temozolomide, Cisplatin and Erlotinib and less sensitive to Imatinib and SU-6668 than GSCs. To identify specific molecules to target GSCs we compared gene expression between NSCs and GSCs using high throughput RNA-Seq. This analysis identified 2951 differentially expressed genes. Among these, SIX1, a transcription factor member of the PAX-SIX-EYA-DACH developmental transcriptionally regulatory network had a 64-fold higher expression in GSCs than in NSCs (2^{nd} hit on the list). Overexpression of SIX1 has been documented to correlate with increased aggressiveness and poor prognosis in multiple human cancers, including GBM. It has been shown that SIX1 increases cancer stem cell numbers and promotes malignancy by regulation of cell proliferation, apoptosis, genome stability, and energy metabolism. Current

experiments are focused on testing strategies to inhibit SIX1 expression and activity with specific siRNAs and/or phosphatase inhibitors targeting its EYA cofactors and activators. Results from this study will enhance our understanding of glioma stem cell biology and may identify strategies for optimal use of therapeutic NSCs in combined treatment strategies for GBM.

Title: Lateral ventricle infiltrating glioblastoma disrupts the ventricular-subventricular zone neurogenic niche

Authors: *E. S. NORTON[1], C. DE LA ROSA PRIETO[3], S. JEANNERET[4,2], K. BELTRAN[2], N. ZARCO[2], M. A. LARA VELAZQUEZ[2,5], A. CARRANO[2], A. QUINONES-HINOJOSA[2], J. GARCIA-VERDUGO[6], H. GUERRERO CAZARES[2];

Abstract: Glioblastoma (GBM) is the most common and devastating primary brain tumor in adults, with an average survival of only 15 months and a recurrence rate of nearly 100%. This is largely due to the high invasive capacity of GBM cells into distal regions of the brain parenchyma, leading to recurrence despite standard of care therapy of combinatorial surgical resection, chemotherapy, and radiation. Tumor location has a strong effect on patient outcome, as association of GBM with the lateral ventricles (LV) results in a lower survival rate and an increased rate of distal tumor recurrence. Although the reason for this worse prognosis is unknown, it may be due in part to the interaction of tumor cells with the neurogenic niche in the ventricular-subventricular zone (V-SVZ). This niche is highly organized, with characteristic

pinwheel structures of ependymal cells and neural stem cell process centers. This organization forms a barrier on the LV surface that separates the cerebrospinal fluid (CSF) from the rest of the brain parenchyma. Disruption of the V-SVZ may lead to the interaction of GBM with growth factors and chemokines contained in the CSF. Using patient-derived primary lines of GBM brain tumor initiating cells (BTICs), we evaluated the effect of tumor proximity on the integrity of the V-SVZ niche and survival using immunosuppressed mice. GFP-labeled BTICs were implanted into immunosuppressed mice at locations proximal and distal to the LV. The organization of the V-SVZ was evaluated by wholemount preparations of the V-SVZ, as well as coronal sections followed by immunofluorescence or transmission electron microscopy. In agreement with patient retrospective studies, mice with LV-proximal GBM displayed a more proliferative tumor phenotype and shorter survival rate than mice with LV-distal tumors. We observed that LV-proximal GBM interrupts the characteristic pinwheel cytoarchitecture of the V-SVZ. GFP+ tumor cells disrupt the ependymal barrier and integrate into the LV surface. By electron microscopy, we found that LV-proximal GBM induces an accumulation of lipid droplets in ependymal cells and that V-SVZ fractones are smaller and less dense when compared to controls. Our observations demonstrate that the typically organized V-SVZ becomes severely disrupted by invading GBM, potentially implicating the normal function of this niche. The mechanisms utilized by GBM cells to disrupt the neurogenic niche as well as the effect on neurogenic function remain to be studied.

Title: *In vivo* circadian rhythms in glioblastoma multiforme presents opportunities for chronotherapy and personalized medicine

Authors: *A. R. DAMATO[1], J. B. RUBIN[2], E. D. HERZOG[1];
[1]Biol., Washington Univ. in St. Louis, St. Louis, MO; [2]Pediatrics, Washington Univ. Sch. of Med., St. Louis, MO

Abstract: Glioblastoma multiforme (GBM) is the most common primary adult brain tumor diagnosed, with a 15-month prognosis using current standard of care treatment which includes chemotherapy with Temozolomide (Temodar, TMZ). Previous work on a cultured murine mesenchymal GBM cell line showed a time-of-day dependent maximum in DNA double-strand breaks, activation of the apoptotic pathway, and cell death corresponding with the peak of *Bmal1* and trough of *Per2* expression, two core clock genes. However, tumor circadian rhythms *in vivo* have not been shown to exist. We hypothesized that circadian rhythms exist in GBM tumors *in vivo* and that TMZ treatment would reduce tumor size in our GBM mouse model. We implanted murine GBM expressing a real-time luciferase reporter of either *Bmal1* or *Per2* transcription into the basal ganglia of 10 ten-week-old male nude (CrTac:NCr-*Foxn1*^{nu}) mice and recorded bioluminescence for 6 weeks, as well as locomotor data. Mice were maintained in a light-dark cycle and imaged in darkness. We found that GBM tumors had daily rhythms in gene expression with high *Per2* and low *Bmal1* at ZT9. The phase of expression corresponded to host daily rhythms as measured by locomotor activity, showing a two-fold change between peak and trough, which decreased to no change in amplitude by week 6 when the experiment was concluded. In a second group of 10 mice, tumor size was measured over 10 weeks via a fluorescent reporter. At 6 weeks post-implant, mice were treated with the standard dose of 21mg/kg/day TMZ for 5 days at either ZT2 or ZT9. Tumor fluorescent intensity was reduced following treatment with TMZ in both groups. Follow-up histology confirms successful implantation and proliferation of the xenograft. The time of day difference in clock gene expression in GBM cells, which corresponds to daily onset and offset of activity in mice, indicates that GBM tumors have circadian rhythms that synchronize to the host *in vivo*. The decrease in amplitude of bioluminescent signal could be due to the development of a hypoxic environment in the solid tumor mass, which can disrupt clock gene function. The decrease in fluorescence intensity following TMZ treatment indicates that TMZ is effective in killing tumor cells in this xenograft mouse model of GBM. This work establishes a foundation for testing whether chemotherapy timed according to circadian time in the host and tumor could be used to maximize tumor killing and minimize side effects.

Title: Treatment of glioblastoma using superparamagnetic iron oxide nanoparticles with modified surface

Authors: *P. JENDELOVA[1], Z. PLICHTA[2], D. MAREKOVA[1], K. TURNOVCOVA[1], D. HORAK[2];
[1]Inst. of Exptl. Medicine, CAS, Prague, Czech Republic; [2]Inst. of Macromolecular Chem., Prague, Czech Republic

Abstract: Glioblastoma multiforme (GBM) is a frequent brain tumor, representing 80% of malignant primary central nervous system tumors. The life span of patients with treatment is about 12 months. The aim of our study was to develop multifunctional superparamagnetic iron oxide (SPIO) nanoparticles suitable for magnetic resonance imaging (MRI), hyperthermia in high frequency electromagnetic field and drug delivery [carrying poly[*N*-(2-hydroxypropyl)methacrylamide-*co*-*N*-(2-hydrazinyl-2-oxoethyl)methacrylamide] [P(HP-MAH)] with conjugated doxorubicin (Dox)].
We used human glioblastoma line (GAMG), and primary cultures isolated from solid patient GBM tumors, which were characterized by flow cytometry. As a model of healthy cells, human mesenchymal cells (hMSC) were utilized. To evaluate the therapeutic effect, SPIO- P(HP-MAH)-Dox nanoparticles were incubated with all types of used cells and cell growth was assessed using real time proliferation assay (XCELigence). SPIO nanoparticles alone did not affect the viability of any of the tested cells and transmission electron microscopy confirmed the uptake of SPIO nanoparticles into the cell cytoplasm. SPIO nanoparticle-labeled cells were visualized by MRI. Due to hydrolysis of the hydrazone bond in acid milieu of tumor cells and Dox release, the SPIO-P(HP-MAH)-Dox nanoparticles significantly decreased the GAMG and GBM cell growth compared to free Dox and P(HP-MAH)-Dox in low concentration (10 nM), whereas free Dox was effective only up to 50 nM. Moreover, SPIO P(HP-MAH)-Dox nanoparticles did not affect growth of hMSC. Hypothermia was effective only in cells mixed with SPIO nanoparticles in concentration of 16-32mM, in which temperature reached 50°C. On contrary, the exposure to high frequency magnetic field did not affect cells that contained SPIO nanoparticles only in the cytoplasm. The temperature of these samples did not exceed 30°C. In conclusion, SPIO-P(HP-MAH)-dox nanoparticles can offer enhanced cell permeation, increased cell death and reduced nonspecific toxicity, however, their hyperthermic effect has to be enhanced.

Title: Interactions between immune microenvironment, stem cells, and cell proliferation in pediatric embryonal central nervous system [CNS] tumors

Authors: *K. T. SCHAFERNAK[1], E. C. UTAGAWA[2], S. V. MEHTA[2], T. DI MODICA[1], E. J. MUFSON[3], S. E. PEREZ[4];
[1]Phoenix Children's Hosp., Phoenix, AZ; [3]Neurobio., [4]Dept Neurobio., [2]Barrow Neurolog. Inst., Phoenix, AZ

Abstract: Mounting evidence suggests that the brain's own immune cells, microglia, and perivascular macrophages play important roles in immune surveillance/inflammation and response to injury, but also support proliferation and growth of gliomas, possibly through interactions with tumor stem cells. Immune cells are increasingly regarded as potential targets for cancer therapy, however, the immune microenvironment has not been well studied in embryonal CNS tumors [i.e., medulloblastomas (MBLs), primitive neuroectodermal tumors (PNETs) and atypical teratoid-rhabdoid tumors (ATRTs)], the most common malignant pediatric brain tumors. To characterize the tumor-associated immune microenvironment of a series of pediatric brain tumors (13 MBLs, 7 PNETs and 6 ATRTs) we quantified the number of cells immunopositive for macrophage/microglia Ionizing calcium binding adaptor molecule 1 [Iba1], CD68 (expressed on both "M1" antitumor/proinflammatory macrophages and "M2" protumor/anti-inflammatory macrophages), CD163 ("M2" macrophages), CD3 (T-cell marker), CD4 (helper T cell), CD8 (cytotoxic T cell) and CD20 (B-cell marker) and correlated these findings with the stem-cell marker nestin and the Ki67/MIB1 proliferation index. Significant results were as follows: Across groups, CD68 showed a strong Spearman rank-order correlation with both CD163 (r=0.610, p=0.0007) and nestin (r=0.577, p=0.0017), while CD3 correlated strongly with CD8 (r=0.601, p=0.004), CD4 (r=0.526, p=0.005) and CD20 (r=0.499, p=0.008). Between groups, the number of CD163-positive cells was significantly higher in PNETs compared to MBLs (p=0.035). Within the MBL group, CD68 showed a significant relationship with nestin (r=0.595, p=0.0387) and Ki67 (r=0.606, p=0.0333), and there was a robust correlation between CD4 and CD8 values (r=0.846, p=0.0000002), less so with CD20 and CD3 (r=0.793, p=0.001) and CD20 and CD4 (r=0.756, p=0.003). Within the PNETs, there was a strong negative correlation between CD163 and nestin (r=-0.883, p=0.0000002), while CD68 correlated with CD4 (r=0.803, p=0.006). Within ATRTs, nestin and Ki67 were strongly correlated (r=1.000, p=0.0028) as were CD68 and CD163 (r=0.943, p=0.017). These data suggest a role for blocking embryonal CNS tumor-associated macrophages by inhibiting the CSF1R pathway (perhaps in conjunction with CD8-positive T cells which could antagonize the immunosuppressive function of tumor-associated macrophages) or reprogramming them from an M2 to an M1 phenotype (particularly in PNETs, which had the highest number of CD163-positive cells).

Title: Gliobalstoma invades by co-opting healthy astrocytes via gap junctional communication

Authors: S. MCCUTCHEON, ***D. C. SPRAY**;
Neurosci., Albert Einstein Col. Med., Bronx, NY, NY

Abstract: Glioblastoma multiforme (GBM) is the deadliest CNS cancer. Its dismal prognosis is due to difficulty of resection, chemotherapeutic resistance, and invasion along vasculature. Elucidating how GBM invades is critical for development of effective resection and adjuvant therapies. GBM invasion involves change of non-cancerous cells, including astrocytes, in the tumor microenvironment toward a cancer-friendly phenotype. Evidence suggests post-transcriptional regulation by miRNAs may be the culprit. Past studies have highlighted transfer of miRNAs from GBM to astrocytes by means of Cx43 channels, however it is known that gap junctions have a size exclusion of 1 kDa, and miRNAs are about 14 kDa. We seek to address how gap junctions are implicated in the expression or transfer of miRNAs whether by direct passage through Cx43 junctions or other pathways. Invasion assays were done using coated transwell inserts, using 10% fetal bovine serum as the chemoattractant. Invasion index was quantified for GL261, U87, primary astrocytes, immortalized astrocytes, and Cx43 knockout astrocytes individually, in cocultures, and treated with 100µM carbenoxolone. An ex vivo slice culture invasion model was used to measure invasion in a pseudo-3D environment with native astrocytes. 350µm whole brain coronal slices were injected with 250 µm diameter U87 spheroids (150-200 Cells), cultured for 0-3 days, then quantified for tumor outgrowth. miRNA sequencing on cocultures of U87 cells with immortalized wild type or Cx43 knockout astrocytes, utilizing genetic GFP labeling, FACS, and small RNA isolation identified targets for miRNA trafficking studies. Functional Cx43 homotypic gap junctions form between GBM and astrocytes *in vitro*. Presence and functionality of astrocyte-GBM Cx43 channels alter the invasion potential of GBM *in vitro* and *ex vivo*. GBM-GBM Cx43 junctions limit invasion and promote tumor cohesion, while astrocyte-GBM junctions promote invasion and of GBM along vascular tracts. Presence of GBM-astrocyte Cx43 junctions causes a shift in miRNA profile for cells cocultured with the GBM cell line U87-MG, such that miRNA found in GBM pre-coculture appeared in wild type but not Cx43 knockout astrocytes post-coculture. Future work seeks to pursue the mechanism for miRNA transfer.

Title: Xenotransplantation of human glioblastoma y neuroblastoma in zebrafish larvae: *In vivo* imaging and proliferation assessment

Authors: *V. AKLE[1], J. A. VENEGAS[1], M. A. FORERO-SHELTON[2], J. M. GONZALEZ[1]; [1]Sch. of Med., [2]Fac. of Sci., Univ. de los Andes, Bogota, Colombia

Abstract: Neuroblastoma (NBM) and glioblastoma (GBM) have completely different backgrounds with respect to their ontogeny. Treatment options include maximal surgical resection and drug-radiotherapy combination for GBM, while there are many more treatment options for NBM. However, chemotherapy continues to be an important option treatment with significant side effects, prompting the search for new models for drug discovery and testing, especially those that allow assessment of *in vivo* responses to treatment. Here, it is introduced an *in vivo* imaging and proliferation assessment method of human NBM and GBM xenograft in zebrafish larvae. Zebrafish larvae microinjected with fluorescently labeled human tumor cells were screened daily using a stereomicroscope and imaged by Light Sheet Fluorescence Microscopy (LSFM); volumetric modeling and composite reconstructions was done in single individuals. Larvae containing tumors were enzymatically dissociated, and the proliferation of human cancer cells was measured using dye dilution by flow cytometry. GBM microtumors formed mainly in the zebrafish yolk sac and perivitelline space following injection in the yolk sac. Daily image analysis suggested cellular division, as microtumors progressively grew with differentiated fluorescence intensity signals. At least three division cycles for human GBM cells were identified in the dye dilution assay by flow cytometry. Human cancer cells proliferate in zebrafish larvae, making it possible to assess cell divisions and tumor growth, and the interference by chemotherapy agents. With this approach, it should be possible to better predict the clinical efficacy of different anticancer treatments and contribute to individualize patient treatment.

Title: Intratumoral modulation therapy enhances multi-modality treatment platforms for pediatric and adult high grade gliomas

Authors: *A. DEWEYERT[1], E. IREDALE[2], H. XU[3], E. WONG[2], S. SCHMID[2], M. HEBB[2]; [1]Univ. of Western Ontario, London, ON, Canada; [2]Western Univ., London, ON, Canada; [3]London Hlth. Sci. Ctr., London, ON, Canada

Abstract: Introduction: Intratumoral modulation therapy (IMT) is a putative new treatment modality that delivers non-ablative electrical stimulation directly into tumor-affected brain regions to induce tumor cell death. We have previously shown that low amplitude, intermediate frequency IMT reduces glioblastoma burden [Di Sebastiano et al 2018] and now aim to assess IMTs therapeutic potential for the pediatric brain tumor diffuse intrinsic pontine glioma (DIPG).
Hypothesis: We hypothesize that targeted IMT in combination with chemoradiotherapy will provide an effective means to increase drug sensitivity and reduce viability of patient-derived high grade-gliomas in monolayer and spheroid cultures.
Methods: Spheroids were generated by implanting $1x10^4$ patient-derived cells into extracellular matrices and allowed to grow for 3 days. DIPG cells or spheroids were treated with either 72 hours IMT using a continuous sinusoidal waveform (200 kHz, ±2V), temozolomide (TMZ), radiation (RT) or the combination of IMT, TMZ, and RT. DIPG cell monolayer viability was assessed with the MTT assay, and flow cytometry with Annexin V and zombie red detection. Spheroid viability was evaluated with bioluminescence imaging (BLI), confocal microscopy and stereology. Computer-generated electric field modeling was performed using COMSOL software to predict field strength and dimensions and to reconstruct IMT treatment fields using various electrode configurations. To validate mathematical predictions, *in vitro* measurements within our IMT models were taken using an oscilloscope.
Results: MTT revealed a significant loss of metabolic viability in DIPG cells treated with IMT compared to sham conditions *in vitro* (<40% vs. sham; n=4, p<0.01). TMZ and RT revealed a modest 19% and 28% reduction in cell viability respectively but increased significantly to 80% with concomitant IMT (<80% vs. sham; n=3, p<0.001). BLI revealed a significant loss of metabolic viability in spheroids treated with IMT compared to sham conditions. To date measurements within our IMT models have corroborated mathematical predictions of field intensity by COMSOL allowing for accurate mapping of electric fields and determination of IMT therapeutic coverage.
Conclusion: This study provides first-time evidence of DIPG cell susceptibility to a non-ablative

electrical therapy and demonstrates the potential of IMT to effectively enhance multi-modality treatment platforms for high grade-glioma both in 2D and 3D model systems. Continued advances in this technology, has the potential to facilitate clinical translation of IMT as a critically-needed therapy for these devastating brain cancers.

Title: Predisposition for neoplasia in progenitors for horizontal and cone photoreceptor cells in the developing chicken retina

Authors: *D. KONJUSHA, M. BLIXT, M. HELLSAND, F. HALLBÖÖK;
Dept. of Neurosci., Uppsala Univ., Uppsala, Sweden

Abstract: The intra-ocular child tumor retinoblastoma originates in the neural retina. The tumors arise mainly as a result of biallelic RB1 gene loss-of-function mutations, although other mutations such as MYCN amplification have been found in a subset of cases. The cell-of-origin in human retinoblastoma is mainly from the horizontal cells (HC)/cone photoreceptors (PR) cell type lineage. The variation in mutations causing the tumor, together with previous studies indicating a p53-insensitivty in the HC/cone PR progenitors in the developing chicken retina, indicate a cell type-specific predisposition for neoplastic growth.
PiggyBac genome-integrating over expression vectors with variants of MYC (MYCN, MYCN T58A, cMYC or cMYC T58A) and a GFP reporter were injected subretinally in embryonic day 3.5 (E3.5)/Hamburger & Hamilton stage 22 (st22) White-Leghorn chicken embryos and electroporated *in ovo*. Expression was driven from the ubiquitous actin promotor. Eyes were analyzed at ages E8-P43 by immunohistochemistry. Cells from GFP+ regions were dissected, dissociated, cultured and were orthotopically transplanted to E18 eyes for analysis of tumor formation.
Initially GFP (MYC) expression was observed in all retinal cell types. By E14, GFP+ clusters with HC and cone PR markers were observed while cells with amacrine and ganglion cell markers had disappeared (by E10-12). A similar result was seen by E18 and in post-hatch chickens. Similar results were obtained regardless of the MYC-construct used. Transformed cells

were grown *in vitro* for 6 months while maintaining this phenotype. Orthotopic transplantation of these GFP+ cells to E18 embryo eyes generated clusters of proliferating cells in various parts of the eye with maintained phenotype. Cells had increased expression of Ki67 and decreased expression of p21.
We show that MYCN over expression is sufficient to transform the chicken HC/cone PR progenitor cells, while the amacrine and ganglion cells die. This effect was observed regardless of the MYC variant, implying a cell type and developmental stage-specific intrinsic predisposition for neoplastic transformation. Tentatively, the low p21 expression indicates that the tumor suppressor protein p53 may be involved and urge for further investigation of the mechanistic basis. This potential chicken model for neoplastic transformation in retina shows similarity to the human cancer and allows for further investigation of early carcinogenesis both *in vitro* and *in vivo*.

Title: Generation of a porcine experimental model of spinal cord glioma

Authors: *M. S. TORA, P. TEXAKALIDIS, J. WETZEL, N. HARDCASTLE, T. FEDERICI, N. M. BOULIS;
Neurosurg., Emory Univ. Sch. of Med., Atlanta, GA

Abstract: Background: SC Glioma (SCG) is an orphan disease which accounts for 8-10% of all primary SC (SC) tumors. High-grade lesions result in survival as low as 11% and a clinical picture of untenable morbidity and mortality. The failure of numerous therapeutic strategies has highlighted the importance of novel disease models in rodents and large animals as pre-clinical platforms. In the interest of developing putative novel-models in the spinal cord for pre-clinical study, our group utilized orthotopic, thoracolumbar, intraparenchymal injections of retroviral vectors expressing combinations of Platelet-Derived Growth Factor Beta (PDGF-B), HRASG12V, and shRNA-P53. Here we report our initial behavioral, immunohistochemical, and histologic data in 12 Sprague Dawley rats and 3 Göttingen-Minipigs.**Methods**: Sprague Dawley Rats and Göttingen Mini-pigs received thoracolumbar laminectomies followed by stereotactic injection targeting the lateral white matter. Retroviral vectors expressing oncogenic transgenes were infused at a volume of 2ul in rats and 25 ul in pigs. Animals underwent were monitored for

motor deficits until IACUC defined endpoint with subsequent imaging and histology.**Results:** Our results demonstrate the growth of high-grade gliomas in wild-type rats within 60 days of inoculation with PDGF-B (11 of 12 rats, 91%), resulting in complete hind-limb paralysis. H&E staining demonstrated infiltrative lesions consistent with high-grade gliomas (N = 11/12). 1 pilot pig inoculated with PDGFB-IRES-DsRED (N = 1) resulted in a hypercellular region with immunohistochemical findings consistent with glioma markers (GFAP-, NG2+, Olig2+, Nestin+, N= 5/5 sections). Most notably, 2/2 pigs receiving retroviral PDGF-B, HRASG12V, and shRNA-P53 developed market motor deficits and mass forming lesions on MRI consistent with high-grade gliomas in 21 days. **Conclusion:** Oncogenic transgene expression generates high-grade SCGs in the spinal cord of rats and pigs, warranting further study as putative candidates for immunocompetent, orthotopic, and reproducible models of SCG.

Title: Sex-specific effects of maternal separation on cognition and LPS-induced accumulation of amyloid beta in adult C57BL6/J mice

Authors: *J. L. PETERMAN, J. D. WHITE, S. LOPEZ, M. JOHNSON, M. CHUMLEY, G. BOEHM;
Texas Christian Univ., Fort Worth, TX

Abstract: Alzheimer’s Disease (AD) is the most common form of dementia, with an incidence expected to drastically increase as our population grows older. AD is characterized by the accumulation of amyloid-beta (AB) plaques and neurofibrillary tangles. Our laboratory has previously demonstrated that 7 consecutive daily injections of LPS (250 ug/kg; i.p.) result in increased inflammation and significant elevation of amyloid-beta within the hippocampus of C57BL6/J mice. Given the relationship between stress, inflammation, and AD pathology, we sought to explore how an early life stressor, maternal separation, could impact AD-like markers in adulthood. Mouse pups were separated from their mothers for three hours daily from post-natal day 2 (PND2) to PND21 and then were allowed to age in standard housing conditions into adulthood. At 4-6 months of age, mice received LPS or Saline injections and cognition was assessed utilizing a contextual fear conditioning (CFC) paradigm. Tissue was collected and hippocampal AB levels were quantified via ELISA, while western blotting was utilized to explore potential mechanisms behind AB alterations. Maternal separation significantly impaired

cognitive function, and exacerbated LPS-induced accumulation of AB in a sex-specific manner. Maternal separation also resulted in decreased hippocampal BDNF expression in males and females. Overall, the results suggest that early-life stress can exacerbate inflammation-induced AD-like pathologies in adulthood. Understanding how the interaction of stress and immune function may increase one's potential risk for AD, as well as impact AD pathologenesis, are some of the first steps in developing effective interventions.

Title: Cystatin F derived from blood borne monocyte ameliorates cognitive impairment of APP/PS1 transgenic mice

Authors: *K. ZHANG, Y.-H. CHEN, X. CHEN;
Developmental Cell Biol., China Med. Univ., Shenyang, China

Abstract: Alzheimer's disease (AD) is the most common form of age-related dementia. One important pathological hallmarks of AD is the activated microglia. Two different types microglia exist in the brain, the resident and newly differentiated microglia originates in part from hematopoietic cells, and more particularly from monocytes, called bone marrow-derived microglia (BMDM). BMDM are more efficient in restricting amyloid burden and preventing the formation or eliminating amyloid beta (Aβ) plaques deposition than resident counterparts. In an attempt to identify the determinants that associated with AD in BMDM, we first performed microarray analysis of mRNA isolated from monocytes of AD patients. Compared with aged-matched controls, the transcription of cystatin F were up-regulated significantly, which was then verified by qRT-PCR. In order to investigate the function of cystatin F in AD monocytes, we knocked down the level of cystatin F in U937 cells by using a lentiviral-based RNAi technique. Results showed that RNAi-cystatin F U937 cells had an impaired ability to degrade exogenous Aβ. In contrast, cystatin F-overexpressing monocytic THP-1 cells line displayed enhanced ability in degradation of Aβ. Furthermore, over-expressing of cystatin F in THP-1 cells markedly increased the clearance of Aβ plaque in the APP/PS1 mouse brain slices. These data indicated that cystatin F in monocytes was associated with the metabolism of Aβ. We tried to explore the molecular mechanism on cystatin F-related degradation of Aβ in monocytes. We found that

cystatin F could bind Aβ directly in vitro. Furthermore, GST-pull down assay showed that endogenous cystatin F interacted with GST-Aβ 1-40, GST-Aβ 1-42,or GST-C99 in U937 cells. To further detect how cystatin F worked in vivo, we generated a monocyte-derived human cystatin F transgenic mouse which was then crossed with the APP/PS1 transgenic mouse. Immunofluorescence staining images showed that cystatin F^+/APP^+ double transgenic mice had decreased Aβ plaques in brain. In additional, cystatin F^+/APP^+ mice had an increased cognitive function than APP/PS1 mice in morris water maze test. These data suggested that cystatin F exhibited a protective role in AD through increasing the degradation of Aβ and ameliorating cognitive impairment of APP/PS1 transgenic mice. Further study will focus on determine whether cystatin F promotes degradation of Aβ through a lysosomal-dependent pathway in monocytes and analyzing the binding sites between cystatin F and Aβ. Our study will provide a potential therapeutic strategy by adjusting the level of cystatin F in monocyte and promoting the clearance of Aβ by BMDM.

Title: Effect of humanin on streptozotocin-induced cognitive deficit in mice

Authors: T. TANAKA[1], *Y. KITA[2], T. NIIKURA[1];
[1]Sophia Univ., Tokyo, Japan; [2]Alliance Protein Labs., San Diego, CA

Abstract: Humanin (HN) is a 24-residue neuroprotective peptide. HN with a substitution of glycine for serine 14 (HNG) is a highly potent HN derivative and protects neurons from amyloid beta-induced cell death at nano M levels in vitro. In a mouse model of Alzheimer's disease (AD), HNG suppressed cognitive impairment and reduced amyloid burden. HNG also ameliorated amnesia induced by a muscarinic receptor antagonist and a $GABA_A$receptor agonist in normal mice. In addition, HNG reduced gliosis and cognitive deficit induced by short-period treatment of cuprizone, a copper chelator, suggesting that HN has anti-inflammatory function. To further understand the effects of HN on cognitive deficit related to AD, we used an AD-like mouse model using streptozotocin (STZ). STZ is a glucosamine-nitrosourea and the systemic administration of STZ is commonly used to induce long-lasting model of diabetes mellitus. Intraventricular (icv) injection of STZ triggers some features of sporadic AD, such as disturbance in learning and memory, neuroinflammation, and dysregulation of insulin signal. As a model of

early stage of AD, we used lower dose of STZ and longer treatment period comparing with a frequently used model (3 mg/kg STZ, 3 weeks treatment). To test the effect of HNG, we injected HNG intraperitoneally. After 9 weeks of treatment, we performed a series of behavioral tests to evaluate cognitive function. We found that STZ induced cognitive deficit in object recognition memory and social recognition memory. HNG attenuated the effects of STZ. These findings suggest that HN can rescue memory impairment in a sporadic AD model.

Title: Effects of docosahexaenoic acid and its peroxidation product on amyloid-β peptide-stimulated microglia

Authors: ***X. GENG**[1], B. YANG[2], R. LI[3], M. LADU[4], G. Y. SUN[3], C. GREENLIEF[2], J. C. LEE[1];
[1]Bioengineering, Univ. of Illinois at Chicago, Chicago, IL; [2]Chem., [3]Biochem., Univ. of Missouri-Columbia, Columbia, MO; [4]Anat. and Cell Biol., Univ. of Illinois, Chicago, Chicago, IL

Abstract: Growing evidence suggests that docosahexaenoic acid (DHA) exerts neuroprotective effects, although the mechanism(s) underlying these beneficial effects has not been fully understood. Here we demonstrate that DHA, but not arachidonic acid (ARA), suppressed oligomeric amyloid-β peptide (oAβ)-induced reactive oxygen species (ROS) production in primary mouse microglia and immortalized mouse microglia (BV2). Similarly, DHA but not ARA suppressed oA-induced increases in phosphorylated cytosolic phospholipase A_2 (cPLA_2), inducible nitric oxide synthase (iNOS), and tumor necrosis factor-α (TNFα) in BV2 cells. LC-MS/MS assay indicated the ability for DHA to cause an increase in 4-hydroxyhexenal (4-HHE) as well as suppressing oAβ-induced increase in 4-hydroxynonenal (4-HNE). Although oAβ did not alter the nuclear factor erythroid 2–related factor 2 (Nrf2) pathway, exogenous DHA, ARA as well as low concentrations of 4-HHE and 4-HNE upregulated this pathway and increased production of heme oxygenase-1 (HO-1) in microglial cells. These results suggest that DHA modulates ARA metabolism in oAβ-stimulated microglia through its actions to suppress oxidative and inflammatory pathways, and upregulates the antioxidative stress pathway involving Nrf2/HO-1. Understanding the mechanism(s) underlying the beneficial effects of DHA

on microglia should shed light into nutraceutical therapy for the prevention and treatment of Alzheimer's disease.

Title: Neonatal infection leads to increased susceptibility to amyloid-βoligomer-induced brain inflammation, synapse loss and cognitive impairment in mice

Authors: P. S. FROST[1], R. T. DA SILVA[1], A. VENANCIO[2], I. MATIAS[1], N. LYRA E SILVA[1], G. KINCHESKI[1], P. M. PIMENTEL-COELHO[1], F. G. DE FELICE[1], F. C. A. GOMES[1], S. T. FERREIRA[1], C. P. FIGUEIREDO[1], ***J. R. CLARKE**[3];

Abstract: Harmful environmental stimuli during critical stages of development can profoundly affect behavior and susceptibility to diseases. Alzheimer disease (AD) is the most frequent neurodegenerative disease, and evidence suggest that inflammatory conditions act cumulatively, contributing to disease onset. Here we investigated whether infection early in life can contribute to synapse damage and cognitive impairment induced by amyloid-β oligomers (AβOs), neurotoxins found in AD brains. To this end, wild-type mice were subjected to neonatal (post-natal day 4) infection by *Escherichia coli* (1 x 10^4 CFU/g), the main cause of infection in low-birth-weight premature infants in the US. *E. coli* infection caused a transient inflammatory response in the mouse brain starting shortly after infection. Although infected mice performed normally in behavioral tasks in adulthood, they showed increased susceptibility to synapse damage and memory impairment induced by low doses of AβOs (1 pmol; intracerebroventricular) in the novel object recognition paradigm. Using *in vitro* and *in vivo* approaches, we show that microglial cells from *E. coli*-infected mice undergo exacerbated activation when exposed to low doses of AβOs. In addition, treatment of infected pups with minocycline, an antibiotic that inhibits microglial pro-inflammatory polarization, normalized microglial response to AβOs and restored normal susceptibility of mice to oligomer-induced cognitive impairment. Interestingly, mice infected with by *E. coli* (1 x 10^4 CFU/g) during adolescence (post-natal day 21) or adulthood (post-natal day 60) showed normal cognitive performance even in the presence of AβOs (1 pmol), suggesting that only infections at critical stages of development may lead to increased susceptibility to amyloid-β-induced toxicity.

Altogether, our findings suggest that neonatal infections can modulate microglial response to AβOs into adulthood, thus contributing to amyloid-β-induced synapse damage and cognitive impairment.

Title: Systemic long-term inflammation promotes spatial memory impairment

Authors: *G. H. SCHIRMBECK, C. F. DA RÉ, M. SEADY, F. FRÓES, S. G. SILVA, J. H. TADAY, C. S. GONÇALVES, M. C. LEITE;
Dept. of Biochem., Federal Univ. of Rio Grande Do Sul, Porto Alegre, Brazil

Abstract: Long-term inflammation is a major player in the progression of neurodegenerative diseases such as dementia, although is not its main initiator. Its been demonstrated that inflammatory activation of microglia and astrocytes promotes aggregation of amyloid plaques and tau tangles, leading to neuronal death through other mechanisms, such as excitotoxicity. Although some studies investigated the effect of systemic inflammatory insult on the progression of dementia and amyloid plaques in genetic mouse models of Alzheimer's disease, is not clear if systemic inflammation *per se* for an extended period of time can induce cognitive impairment observed in dementia models. **Methods:** 90-day Wistar rats were exposed to chronic inflammatory challenges with intraperitoneal injections of LPS in two doses (500 μg/kg and 250 μg/kg) or saline once a week, for a 16-week period. Rats were euthanasied 24 h after last LPS injection. Behavioral evaluation was conducted through Open Field (OF) and Object Location Memory-Test (OLM) for spatial memory assessment. Hippocampal S100B content was measured by ELISA, nuclear Nf-κB was measured by western blot, and L-[^{3}H] glutamate uptake was analyzed. **Results:** Both groups receiving LPS presented impaired spatial memory in the 24 h OLM, which is characteristic of hippocampal degeneration in animal models of dementia, while OF shown no locomotor impairment. S100B protein remained unchanged between groups,

and glutamate uptake was reduced only in LPS 500 μ/kg group. Nuclear fraction of Nf-κB was increased in both LPS groups. Discussion: Here, we demonstrate that chronic peripheral inflammatory stimuli promote cognitive impairment in the absence of other underlying neurodegenerative causes, such as genetic background. Increased Nf-κB in nucleus indicates hippocampal neuroinflammation, despite LPS challenge being peripheral. Besides, glutamate uptake was reduced in the higher dose of LPS, indicating a possible excitotoxic damage. Conversely, S100B content, which is an important biomolecule in inflammatory signaling, was not affected by LPS.

Title: Metabolic dysregulation induces early-onset Alzheimer's disease in a high-fat diet mouse model

Authors: *M.-H. JO[1], R. ULLAH[1], M.-W. KIM[1], B. P. F. RUTTEN[2], *M.-O. KIM[1]; [1]Gyeongsang Natl. Univ., Jinju, Korea, Republic of; [2]Maastricht Univ. Med. Ctr., Maastricht, Netherlands

Abstract: Obesity-related metabolic dysfunction is a risk factor for cognitive decline and is concomitant with early-onset Alzheimer’s disease. A high-fat diet induces obesity-associated microglial activation, neuroinflammation, and neuronal insulin resistance, which are considered important risk factors for neurodegeneration. However, the molecular mechanism underlying HFD-induced neuropathy remains unclear. The present study aimed to elucidate whether chronic consumption of HFD (24 weeks) can induce neuroinflammation, insulin resistance, amyloid deposition and, most importantly, plaque formation in mouse brains. HFD-fed mice showed abnormal metabolic parameters and insulin resistance compared with their age-matched littermates fed with normal chow diet. Similarly, HFD increased neuroinflammation, as indicated by an increased expression of inflammatory markers (NF K B, IL-1β and TNFα) and astrocyte and microglial activation (Iba-1 and GFAP) in the cortex and hippocampus region in the brains of HFD mice. Furthermore, HFD mouse brains exhibited early signs of amyloid pathology, as evident by the minor accumulation of deposited amyloid plaques, decreased expression of markers of synaptic plasticity (SNAP-23 and PSD95) and subsequent behavioral deficits observed in the HFD mouse brains compared with the normal chow-fed mouse brains. Taken together, our findings suggest that the consumption of an HFD has a profound impact on brain

activity, which involves the acceleration of cognitive impairment due to increased insulin resistance and neuroinflammation that ultimately leads to early-onset of Alzheimer's-like pathology.

Title: Human TREM2 gene dosage-mediated microglia reprogramming is impaired by the R47H variant *in vivo*

Authors: *C. LEE[1,2], A. DAGGETT[1], K. INOUYE[1], P. LANGFELDER[1,2], R. KAWAGUCHI[1,2], N. WANG[1,2], X. GU[1,2], G. COPPOLA[1,3,4], H. XU[5], X. W. Inst., [4]Dept. Neurology, David Geffen Sch. of Med., UCLA, Los Angeles, CA; [5]Neurosci. and Aging Res. Ctr., Sanford Burnham Prebys Med. Discovery Institutu, La Jolla, CA

Abstract: Whole-genome and exome sequencing studies identified a rare R47H variant of Triggering Receptor Expressed on Myeloid Cells 2 (TREM2) linking to 2-4 fold higher risk for developing late-onset Alzheimer's disease (AD). In the brain, TREM2 is expressed exclusively by microglia. The human genetic findings led to a plethora of discoveries on the *in vivo* function of TREM2 (e.g. promoting microglia survival and enabling microglia to cluster around and remove amyloid plaques). Recently, we showed that elevated TREM2 gene-dosage exerts multiple beneficial effects in amyloid-depositing AD mouse models, which are likely due to a molecular and functional reprogramming of the microglia responsivity in the disease brains (Lee et al., Neuron 97:1032-1048, 2018). In the current study, we applied the same human TREM2 genomic transgenic model system to address whether the AD risk-associated R47H variant could alter TREM2 function *in vivo* by modifying microglia responsivity in the disease brains. We created BAC transgenic mice carrying TREM2 with R47H variant (BAC-TREM2-R47H), and crossed them to 5xFAD, an accelerated Aβ-depositing mouse model of AD. By comparing the pathology and behavioral phenotypes of 5xFAD mice with or without the BAC-TREM2 or BAC-TREM2-R47H transgenes, we found that the TREM2-R47H variant appears hypofunctional compared to the wildtype TREM2 allele in reducing the amyloid pathology, and

is minimally effective in altering the morphology of the activated, plaque-associated microglia. Moreover, RNA-sequencing studies showed the transcriptomic signatures of TREM2-mediated microglial reprogramming are also absent in the 5xFAD/TREM2-R47H mice. Finally, we were able to examine the effect of R47H SNP on the splicing of human TREM2 exons. Together, our study demonstrates the important utility of a human genomic transgenic model system to study disease-associated TREM2 variants in the mammalian brain.

Title: Tissue inhibitor of matrix metalloproteinase-1, a cytokine secreted rapidly from amyloid-β induced reactivated astrocytes, ameliorate disease pathology and cognitive impairments in models of Alzheimer’s disease

Authors: S. SARKAR, P. SAHA, P. KUMAR, *S. C. BISWAS;
CSIR-Indian Inst. of Chem. Biol., Kolkata, India

Abstract: Reactivation of astrocytes is an integral part of Alzheimer’s disease (AD) however its role in disease pathogenesis is poorly understood. It is hypothesized that at initial stages of AD progression reactive astrocytes act in a protective manner. In this study, we aim to identify the key players in reactive astrocytes at the early phase of AD that contribute to their neuroprotective potential in disease models. We used primary cortical neuron culture from Sprague Dawley (SD) rat and performed a time-dependent cytokine array of astrocyte-conditioned medium (ACM) to find the secretion status of proteins from astrocytes in response to oligomeric Aβ1-42 (Aβ) treatment in vitro. Among the differentially expressed cytokines in response to Aβ, extracellular levels of tissue inhibitor of metalloproteinase-1 (TIMP-1) was rapidly elevated at 6h. We then tested the effect of 6h Aβ-treated ACM (Aβ-ACM) on neuronal health by a combination of immunocytochemistry and cell viability assay and found that Aβ-ACM induced morphological protection and approximately 100% (mean 101.4% SD 8.0) survival of neurons against Aβ toxicity (55.6% ± 8.3) where TIMP-1 played a key role since its neutralization reduced the viability to 53.8% ± 6.9. Moreover, rat recombinant TIMP-1 (rrTIMP-1) recovered neuronal viability to 100.9% ± 7.2 against Aβ toxicity (50.8% ± 6.2). Akt, a central kinase in survival

signaling, was triggered profoundly upon rrTIMP-1 treatment to neurons denoting its role in cellular survival. To understand TIMP-1 function in vivo, we used stereotaxic rat model (bilaterally infusing Aβ into hippocampus of SD rat brain, 280-320 g) and 5XFAD mice model where TIMP-1 was injected intracerebroventricularly. We used coronal brain sections to follow Aβ deposition and apoptosis by Aβ-immunohistochemistry and TUNEL assay respectively and found that TIMP-1 reduced Aβ load and apoptosis in hippocampus. We also got evidence of cognitive recovery by TIMP-1 from Aβ-induced impairment in both models by behavioral studies. For example, in cue-dependent fear conditioning test, associative memory was assessed where animals previously exposed to a shock following light and sound cues were checked for freezing response following cues but without shock. Aβ-induced rat showed 55% ± 10 freezing as compared to 69% ± 9 of control which was significantly recovered by TIMP-1 to 74% ± 8 (1-way ANOVA, tukey's post hoc, n=6). Hence, it was evident that TIMP-1 infusion protected against Aβ induced cognitive impairments. Thus, TIMP-1 is an important cytokine secreted from reactivated astrocytes with neuroprotective function at early AD stage and can be developed into a potentially good therapeutic agent.

Title: The impact of high sucrose diet on the cortical pathogenesis and insulin sensitivity of APPswe/PS1dE9 mice

Authors: *H.-H. YAO, P.-C. KAO, L.-M. CHEN, L.-J. CHAO, H.-J. TSAY;
Neurosci., Natl. Yang-Ming Univ., Taipei, Taiwan

Abstract: The high fat and sugar-containing diet contributes to the prevalence of type II diabetes and Alzheimer's disease (AD). High fat diet (HFD) or high sugar-containing diet is known to increase the risk of AD. Our previous studies have suggested that the reciprocal augmentation between the HFD-induced metabolic stresses and AD central pathogenesis leads to accelerated cognitive impairments and fatty liver in HFD-fed APP/PS1d9E transgenic mice. Our previous studies demonstrate the deleterious effects of high fat diets on AD-related pathology; however, the impacts of a high sugar-containing diet on the AD pathogenesis remain unclear. Like HFD, the use of sugars and high fructose corn syrup in modern human diet also cause the epidemic of obesity and metabolic disorders. This study is focused at whether the high sucrose diet (HSD) accelerates APP/PS1 pathology and the impact of AD pathology on HSD-induced metabolic stresses. The peripheral metabolic index, daily capabilities, and neuroinflammation of HSD WT

and APP/PS1 mice were compared. These results will shed light on the deleterious effects of HSD on the pathology of APP/PS1 mice and the underlying mechanism. APPswe/PS1dE9 (APP/PS1) transgenic mice and wildtype mice were fed with HSD, and their biochemical index and cognitive behaviors were compared. The result showed that HSD increased the level of cortical and serum Aβ and cortical inflammation in APP/PS1 mice. HSD aggravated obesity, hyperinsulinemia, insulin resistance without inducing hyperphagia in APP/PS1 mice. The nesting capability was attenuated by HSD and APP/PS1 genetic background. Our study demonstrated that HSD exacerbated the cognitive dysfunction in APP/PS1 mice.

Title: Elucidating the role of heat shock protein 27 in vascular cognitive impairment and dementia

Authors: A. E. WOOLUMS[1], B. R. PRICE[2], *T. L. SUDDUTH[1], C. A. DICKEY[4], D. M. WILCOCK[3];
[1]Sanders-Brown Ctr. on Aging, [2]Physiol., [3]Univ. of Kentucky, Lexington, KY; [4]Mol. Med./Byrd Inst., Univ. of South Florida, Tampa, FL

Abstract: Background: Hyperhomocysteinemia (HHcy) is a risk factor for vascular cognitive impairment and dementia (VCID), as well as Alzheimer’s disease. Using the HHcy mouse model of VCID, we found the earliest detectable event in the brain is a robust neuroinflammatory response. This is followed by neurovascular astrocyte disruptions, cerebral hypoperfusion, microhemorrhages, white matter degeneration, and cognitive impairment.To gain mechanistic insights into the signaling pathways by which HHcy induces these events, we focused on heat shock protein 27 (Hsp27). Hsp27 binds protein-folding intermediates and prevents their aggregation without directly refolding them itself. Aberrant phosphorylation of Hsp27 has been reported in a variety of neurodegenerative diseases. Given that Hsp27 is shown to be involved in cerebrovascular dysfunction, and is known to signal through the p38 MAPK signaling pathway, we hypothesized Hsp27 is an early mediator of HHcy-induced neuroinflammation. **Methods:** C8-DIA astrocytes, BV2 microglia, and primary endothelial cells were independently cultured, after which they were treated with homocysteine and levels of HSP27 were assessed. Additionally, C8-DIA astrocytes and primary endothelial cells were co-cultured, treated with

varying concentrations of rHsp27 and subject to TEER measurements.Wildtype and Hsp27$^{-/-}$ mice were subject to a HHcy-inducing diet for 14 weeks. Mice were assessed behaviorally during week 12 using radial arm water maze. Tissue from the left hemisphere was histologically examined for microglial activation, the astrocytic end-foot integrity, and microhemorrhages. Tissue from the right hemisphere was used to evaluate the neuroinflammatory state using qRT-PCR. **Results:** Our wildtype-HHcy model displayed significant pro-inflammatory responses and astrocytic end-foot disruptions. Importantly, we found that that Hsp27$^{-/-}$mice subjected to the HHcy-inducing diet exhibited a markedly different pro-inflammatory response. **Conclusions:** Hsp27 appears to be an early essential mediator of HHcy-induced pathology. Deletion of Hsp27 provides protection from neuroinflammation, astrocytic end-feet disruption, and cerebrovascular events. This suggests that Hsp27 may be an attractive therapeutic target for the treatment of VCID.

Title: Time course of neuropathological events in hyperhomocysteinemic amyloid depositing mice

Authors: N. W. FIELDER[1], *E. M. WEEKMAN[2], T. L. SUDDUTH[2], B. R. PRICE[2], A. E. WOOLUMS[2], D. HAWTHORNE[2], C. E. SEAKS, IV[2], D. M. WILCOCK[2];
[1]Unversity of Kentucky, Lexington, KY; [2]Univ. of Kentucky, Lexington, KY

Abstract: Vascular contributions to cognitive impairment and dementia (VCID) are the second leading cause of dementia behind Alzheimer’s disease. In addition, VCID co-morbid with Alzheimer’s disease (AD) is estimated to occur in at least 60% of AD cases and is commonly found in the oldest old. This co-morbidity of vascular injury with AD pathologies is thought to act as an extra “hit” to the brain that increases the rate of cognitive decline. While the contribution of VCID to clinical dementia is increasingly recognized, the mechanistic underpinnings of VCID co-morbid with AD pathologies has been lacking.

We have previously shown that induction of hyperhomocysteinemia (HHcy) via a diet deficient in vitamins B6, B9, and B12 and enriched in methionine in APP/PS1 mice produces a co-morbidity model. While the pathological characteristics of HHcy have been identified, the time course for these changes is unclear. For this study, we examined neuropathological changes along a time course of 2, 6, 10, 14 and 18 weeks on diet in our co-morbidity model.
The first pathological changes that occur are an increase in microglial staining at 6 weeks along with a significant increase in the gene expression of several pro-inflammatory cytokines. Using the two-day radial arm water maze, we detected cognitive changes beginning at 10 weeks that persisted through the 18 weeks on diet. Prussian blue staining and T2* MRI revealed a significant increase in microhemorrhages starting at 14 weeks on the HHcy diet. Finally, induction of HHcy resulted in redistribution of amyloid from the parenchyma to the vasculature starting at 14 weeks on diet.
Overall, induction of HHcy in APP/PS1 mice initially leads to a pro-inflammatory response followed by cognitive decline. Interestingly, microhemorrhages and redistribution of amyloid to the vasculature occur after cognitive changes. However, taken together, this data suggests that neuroinflammation is an initiator in HHcy mediated VCID co-morbid with amyloid deposition and provides a possible target for therapeutics.

Title: Central adiponectin prevents olfactory dysfunction induced by amyloid β_{1-42}

Authors: *M. A. GUZMÁN-RUIZ[1], E. ORTA- SALAZAR[2], A. HERRERA-GONZÁLEZ, Jr.[1], A. CANDELAS-JUÁREZ, Jr.[1], C. BERNAL-MONDRAGÓN, Jr.[1], S. DÍAZ-MIRANDA[3], R. GUEVARA-GUZMÁN[1];
[1]Physiol., Facultad de Medicina, UNAM, Mexico City, Mexico; [2]Neurobio. Inst., MEXICO CITY, Mexico; [3]Neurobio. Inst., Mexico City, Mexico

Abstract: Metabolic dysfunctions predispose subjects to the development of Alzheimer disease (AD) and specifically, insulin resistance, which plays a central role in the pathogenesis of this neurodegenerative disease.
AD characterizes for the development of memory impairment and, eventually, dementia. These

effects are related to neurodegenerative processes in brain areas such as the hippocampus and associated cortexes. Furthermore, Amyloid-β (Aβ) accumulation induces olfactory dysfunction or anosmia, a condition considered an early marker of AD, which is related with damages in the olfactory bulb, the hippocampus and other odor related cortexes.
Adiponectin (APN) is a hormone with protective functions including insulin sensitizing, anti-inflammatory and anti-oxidative effects. In addition, studies have demonstrated that APN administration is able to decrease Amyloid-β (Aβ) neurotoxicity and hyperphosphorylation in the hippocampus, hence, reducing cognitive impairment and neurotoxic damage.
There are no studies regarding the neuroprotective effects of APN in the olfactory dysfunction observed in a $A\beta_{1-42}$ model.
The aim of this study is to determine whether the central administration of APN can prevent the olfactory dysfunction observed in an icv $A\beta_{1-42}$ model.
To assess if APN improves the olfactory function of Wistar rats (220-250g) injected with 5µl of $A\beta_{1-42}$ (1µg/µl), we administered 5µl of intracerebroventricular APN (16 µg/µl) prior to (30 min before) to $A\beta_{1-42}$injection. We determined the olfactory function of these animals 24h after the infusion and evaluated olfactory memory using the social recognition test. We observed that the rats administered with APN prior to $A\beta_{1-42}$ increased the exploration time of an unfamiliar juvenile as compared to the amount of time of $A\beta_{1-42}$ infused rats.
In addition, we assessed olfactory discrimination making use of the buried chocolate test observing a significant decrease in the time that the rats injected with APN prior to $A\beta_{1-42}$ took to find 5g of dark chocolate compared to that of animals that were only infused with $A\beta_{1-42}$.
Lastly, we evaluated the olfactory bulb of these subjects observing a decrease in IBA1 immunoreactivity in both the olfactory bulb and the hippocampus as well as a conservation in the amount of NeuN marked cells in spite of $A\beta_{1-42}$. These results suggest that the elevated central levels of APN are able to prevent the damage caused by $A\beta_{1-42}$.

Title: Stereological analysis of neurodegeneration and neuroinflammation in Tg4510 mice using manual and automatic stereology

Authors: *R. H. PATEL[1], S. S. ALAHMARI[1], D. B. GOLDGOF[1], H. A. PHOULADY[2], P. DAVE[1], L. O. HALL[1], P. R. MOUTON[3,1];

Abstract: A wide range of animal models are available for studying neurodegenerative and neurological diseases and evaluating novel strategies for the therapeutic management of patients. The Tg4510 mouse, a widely used model for studies of Alzheimer's disease (AD) and other tauopathies, has responder and activator transgenes that drive expression of a P301L tau mutation. The brains of Tg4510 mice express mutant tau that leads to neuron loss and activation of neuroglia cells in parallel with progressive cognitive decline. Here we use a series of six distinct manual, semi-automatic and fully-automatic applications of the unbiased optical fractionator method to quantify neurodegeneration and neuroinflammation in neocortex of Tg4510 mice. In contrast to conventional stereology based on user clicks without saving images, the present work involves automatic capturing and saving 3D stacks of images (disector stacks) labeled with the results of user counts, thereby allowing for comparison of the accuracy and identification of errors, i.e., false positives and negatives, in comparison to ground truth. Among the novel methods examined is a convolutional neural network (CNN) that has been previously trained from labeled images to allow self-counting (automatic) of immunostained cells using unbiased methods. This work uses n=12 Tg4510 mice aged 6-8 months and age- and sex-matched littermate controls. After brain removal and immersion fixation in 4% paraformaldehyde, 50-um frozen sections were cut through the entire neocortex and adjacent sets of sections were systematically sampled and immunostained for neurons (Neu-N) and microglia cells (Iba-1). Validation studies show the semi-automatic and fully automatic stereology approaches using unbiased methods are >5x and >10x faster, respectively, and the results show minimal variation (<3% error) compared to conventional manual stereology. We will also report on the effects of stain separation of immunostained sections processed with Nissl counterstain. The results from these ongoing blinded studies will establish baseline data for neurodegeneration and neuroinflammation in neocortex of Tg4510 mice, as well as identify the most accurate, precise and efficient methods for future studies in Tg4510 and other mouse models.

Title: Age-related changes in basal forebrain microglial activation

Authors: *B. L. SOMERA, J. R. FADEL;
PPN, USC Sch. of Med., Columbia, SC

Abstract: The basal forebrain is comprised of several nuclei including the substantia innominata, medial septum, nucleus basalis and diagonal band of broca. The basal forebrain is defined by the presence of cholinergic output neurons named the basal forebrain cholinergic system (BFCS) which provide the largest source of cholinergic neurons implicated in cognitive functions including attention, learning, and arousal. Moreover, evidence suggests basal forebrain neurons are particularly vulnerable to dysfunction and degeneration in aged humans and, more dramatically, in diseases such as Alzheimer's. Additionally, it is thought that age-related BFCS dysfunction may reflect alterations in afferent inputs and neuroinflammatory processes. In order to examine effects of aging on physiologically-relevant afferent stimulation of this area we deposited the retrograde neuronal tracer, cholera toxin B (CTb) in basal forebrain of aged (26-28 months) and young (2-3 months) F344/Brown Norway F1 hybrid rats and trained them for 7 days with repeated paired presentations of a conditioned stimulus consisting of palatable food and darkness. On the final test day, trained and control rats were either given the dark/food paired stimulus or a dark cue without food. Two hours later, animals were sacrificed, and their brains processed for immunohistochemical detection of the neuronal activity marker, c-Fos in

combination with several phenotypic markers of distinct neuronal populations. Additional tissue was process for microglial markers as a correlate of neuroinflammation. Aged rats showed altered activation of basal forebrain afferents located in the medial prelimbic cortex, infralimbic cortex, nucleus accumbens, and ventral tegmental area compared to young controls. Finally, in order to investigate the possible role of basal forebrain orexin signaling in these glial and neuronal alterations, we deposited an miRNA-expressing lentivirus designed to knock down orexin receptor 2 expression in the basal forebrain. Collectively, these studies suggest that early age-related alterations in afferent input to basal forebrain may contribute to BFCS dysfunction, and that orexin degeneration may contribute to these changes.

Title: Nrf2 induced shift in APP/AB processing and autophagy dysfunction in APP_{swe}/PS1ΔE9mice

Authors: *R. X. AVILES-REYES[1], D. JOHNSON[1], J. A. JOHNSON[2];
[1]Univ. of Wisconsin, Madison, WI; [2]Sch. of Pharm., Univ. of Wisconsin Madison, Madison, WI

Abstract: Alzheimer's disease (AD) is characterized by accumulation of extracellular amyloid beta (Aβ) peptides, intracellular hyperphosphorylated tau and dystrophic neurites. Failure in Aβ proteolytic clearance contributes to the neurodegenerative progression of AD. Additionally, axonal dystrophies interfere with the physiological intracellular proteolysis. These impairments could disrupt axonal transport, autophagic pathways and thus Aβ accumulation. Nrf2 (Nuclear Factor [erythroid derived 2] like 2) is a pivotal transcription factor regulating cellular homeostasis, particularly in response to oxidative stress and cellular injury. Previous studies in our laboratory using APP_{Swe}/PS1ΔE9 (APP-PS1) mice demonstrated that knockout of Nrf2 resulted in increased autophagic dysfunction leading to more Aß burden. Here, we analyze whether overexpression of astrocytic Nrf2 can modify and reverse autophagic dysfunction in APP-PS1 mice. Transgenic mice using the GFAP promoter to drive overexpression of Nrf2 in astroctyes have been generated (GFAP-Nrf2; Vargas et al. 2008) and were crossed with APP-PS1 mice. Hippocampus (HP) and cortex (CX) were fractionated into Triton-X-soluble, SDS-soluble and Urea-soluble fractions that were resolved on 10%Tris-tricine gels. Immuno-

histochemical and -fluorescence studies were also conducted. Our findings show decreased levels APP-FL, APP fragments, and Aβlevels in the SDS- and Urea-soluble fractions from CX and HP of APP-PS1/GFAP-Nrf2 double transgenic mice compared with APP-PS1 mice. The increase in phospho-APP(Thr668) observed in APP-PS1 mice was also reversed in the double transgenic. In accordance with the proteins results, 6E10 and phospho-APP histochemistry showed reduced staining intensity in plaques and neurons from CX and HP. Autophagy was evaluated by examining mTOR, AMPKα, p62, LC3B and numerous ATGs. The results indicate that autophagic dysfunction in the APP-PS1 mice is rescued by Nrf2 activation in astrocytes. Interestingly, the GFAP-Nrf2 mice alone had increased levels of phospho-AMPKαand ATG12, as well as reduced p62 in the Urea-soluble fraction suggesting an increased neuronal autophagic flux in these mice. In conclusion, the data strongly suggests that Nrf2 activation in astrocytes has significant modulatory effects on a neurons ability to produce and remove Aβin APP-PS1 mice.

Title: Expression of miRNA146 and regulation of neutrophil proinflammatory functions sheds new light on the pathogenesis of Alzheimer's disease

Authors: *S. KIM[1], S. KIM[2];
[1]Bundang Hosp. of Seoul Natl. Univ., Seongnam, Korea, Republic of; [2]Dept. of Neurol., Seoul Natl. Univ. Bundang Hosp. & Seoul Natl. Univ. Col. of Med., Seongnam, Korea, Republic of

Abstract: For more than two centuries now, Alzheimer disease (AD) is under research intending to develop various treatment and diagnosis. Despite decades of scientific advances, AD is still representing a challenge for contemporary medicine. Current drug therapies may provide a little relief about the quality of life of AD patients; however, they are still insufficient to reverse tissue injury and are often generating side-effects. The difficulty arises from the considerable fluctuation of the clinical course of AD among patients, making the predictive prognosis difficult. Resolution of inflammation needs effective and timely removal of dead cells and other toxic products of neutrophils, monocytes, and macrophages in AD mice model. In this study, we evaluated the role of monocytes in the clearance of neutrophil extracellular trap (NET) and apoptotic neutrophils in the inflammation site of early stage AD mice. For this study, immune cells were observed microscopically after exposing them with NETs and/or apoptotic bodies. A

subset of immune cells exposed to NETs ejected extracellular traps and this was shown to be mediated by proteins like elastase and citrullinated histones present in NET supernatant. More and more studies underline the profound influence of the neutrophil and immune cells multifaceted functions in the pathogenesis of AD. In this study, we aim to update the recent results on the multiple facets of neutrophils in AD, in particular their impact in promoting the inflammation-based AD through the release of the cytokine-like HMGB2 and S100A8/A9 protein complex, as well as the importance of NETosis in the disease progression and development. Furthermore, we delved into the complex question of neutrophil heterogeneity and plasticity and determine the emerging role of miRNA-146 and PTM (post-translational modification) markers influencing the inflammatory response of neutrophils in AD.

Title: Acute systemic LPS injections attenuate high-sucrose diet-induced neurodegenerative processes in estrous female wild-type mice

Authors: *A. G. PACHOLKO[1], L. K. BEKAR[2];
[1]Anatomy, Physiol. and Pharmacol., [2]Pharmacol., Univ. of Saskatchewan, Saskatoon, SK, Canada

Abstract: Alzheimer’s disease (AD) incidence is expected to double by 2038. This coincides with similar trends in obesity, diabetes, and chronic inflammation. It is known that diabetic and chronic inflammatory conditions can increase the risk of AD-like neurodegeneration, likely through mechanisms involving brain insulin resistance. Insulin resistant brain states are associated with increased GSK3β activity, whose constitutive functions are inhibited, in part, by the insulin pathway. Aberrant GSK3β signalling contributes to increased β-amyloid production (senile plaques) and Tau protein hyperphosphorylation (neurofibrillary tangles), hallmarks of AD-like neurodegeneration. In addition, nearly two-thirds of AD patients are female, which

strongly suggests a role for the post-menopausal loss of the female sex hormone, estrogen, in the pathogenic events associated with AD. Estrogen is known to diminish neurodegenerative processes in a variety of animal models. A reduction in estrogen levels following menopause has also been associated with increased risk of diabetes and inflammation, thus necessitating exploration of the neurodegenerative potential of these conditions in a female animal model. Using a combination of a high-sucrose diet (20% of the drinking water) with systemic intraperitoneal LPS injections (0.1 mg/kg; 1x/month over 3 months) over seven months in estrous female wild-type mice (C57Bl/6; n=10/group), we demonstrated a protective rather than deleterious effect of LPS on hS-induced pathology. Results from our hS group confirmed that a high-sucrose diet is a suitable model of neurodegeneration, as evidenced by exaggerated fecal glucocorticoid expression, spatial learning deficits (Barnes maze), irregularities within the insulin pathway, and increased β-amyloid production and Tau phosphorylation. Interestingly, while LPS had little to no effect in isolation, it exerted a protective influence when added to animals sustained on a high-sucrose diet. Corticosterone homeostasis, Aβ and pTau levels, and insulin pathway second messenger expression were all rescued following addition of LPS. This effect may have been due to the chosen dose, as low-doses of LPS have been shown to attenuate the inflammatory response mounted to subsequent inflammatory insults. In summation, the work presented supports a protective role for low-dose inflammation against high-sucrose diet-induced neurodegeneration in estrous female mice. Future work comparing reproductively normal males and females to ovariectomized females would contribute to our understanding of the role of estrogen in the interaction between inflammation and dietary stress.

Title: The role of IL-6 and glial response in neurotoxicity mediated by amyloid beta oligomers

Authors: *D. TORAL-RIOS[1], B. FLORAN-GARDUÑO[1], V. CAMPOS-PEÑA[2];
[1]CENTRO DE INVESTIGACIÓN Y DE ESTUDIOS AVANZADOS, MEXICO CITY, Mexico;
[2]INSTITUTO NACIONAL DE NEUROLOGIA Y NEUROCIRUGIA, MEXICO CITY, Mexico

Abstract: For years, Amyloid beta (Ab) aggregates have been related to neurotoxicity and neuroinflammation in Alzheimer’s disease. A critical point for neuronal survival to withstand Ab insult is to preserve the balance between proinflammatory and anti-inflammatory responses in

the microenvironment. Several molecules secreted by glial cells are involved in this balance; some of them are the IL6 cytokine and the kynurenine pathway metabolites. In this sense, Ab could alter the KP metabolites production, such as Kynurenic Acid (KYNA) and Quinolinic Acid; both of them have important roles in neurotoxicity and neuroinflammation. The principal aim of this study was to elucidate if Ab could impair KP metabolites production and impact directly in the inflammatory response favoring neurodegeneration. For this purpose, we performed an intrahippocampal injection of Ab oligomers in rats and evaluated cellular and molecular responses in acute and chronic stages after the stereotaxic surgery. First, we found a strong correlation between glial activation and neurodegeneration. Furthermore, we realized that this effect could be related to the IL6 signaling pathway activation in glial cells probably mediated by an increased expression of Indoleamine-2,3-dioxygenase (IDO) and the posterior increase of KYNA synthesis.

Title: Role of triggering receptor expressed in myeloid cells 2 (TREM2) in aging

Authors: *W. QU[1], A. GRAM[2], L. LI[2,1];
[1]Neurosci., [2]Exptl. and Clin. Pharmacol., Univ. of Minnesota, Minneapolis, MN

Abstract: Human genetic studies have shown that triggering receptor expressed in myeloid cells 2 (TREM2) loss of function leads to elevated risks of developing late-onset Alzheimer’s disease (AD). TREM2 is expressed by microglia in the brain and modulates microglial phagocytosis and inflammatory responses. To recapitulate TREM2 loss of function in a mouse model, *Trem2*-/- (KO) mice were generated and tested for cognitive function. It has been shown that at six months of age, *Trem2* deficiency does not alter cognitive performances or learning and memory function. At twelve months of age, TREM2 KO mice show a trend towards but not statistically significant deficits in learning and memory. These findings suggest that the effects of TREM2 deficiency on learning and memory may be age-dependent. We hypothesized that TREM2 deficiency and aging act synergistically to impair cognitive function. To test this hypothesis,

TREM2 KO and wild-type (WT) mice at the age of six and eighteen months, respectively, are assessed for cognitive function by a battery of neurobehavioral tests, including the open field, elevated plus maze, and Morris water maze tests. In addition, electrophysiological experiments for hippocampal long-term potentiation (LTP) were conducted to evaluate synaptic plasticity in these TREM2 KO and WT mice. In the present study, both male and female mice were included and the experiments were conducted blind with respect to the knowledge of genotype. Consistent with previous studies, our preliminary results showed that the six-month-old TREM2 KO mice only showed a trend of impairment in cognitive function and displayed normal hippocampal LTP. Experiments are underway with the eighteen-month-old group of TREM2 KO and WT mice. Results from this study are expected to shed lights on the roles of TREM2 in aging and shaping neuronal functions and provide novel insights into the pathogenesis of AD.

Title: Exploring adverse neuroinflammation for Alzheimer’s disease through prostaglandin D2 signaling

Authors: *C. H. WALLACE[1,4], G. OLIVEROS[1], R. SHRESTHA[1], P. ROCKWELL[1], L. XIE[2], P. SERRANO[3], M. FIGUEIREDO-PEREIRA[1];
[1]Biol. Sci., [2]Computer Sci., [3]Psychology, City Univ. of New York, Hunter Col., New York, NY; [4]Biochem. PhD Program, Grad. Ctr., New York, NY

Abstract: Non-resolving neuroinflammation plays a central role in Alzheimer’s disease (AD) and in accelerating AD pathology. Many studies link neuroinflammation to precede AD along with continuing during AD pathology. Our studies focus on a pathway of inflammation, the cyclooxygenase (COX) pathway, which has been explored for AD therapy, but requires further investigation. COX-2 is induced in AD and negatively impacts neuronal function. The COX pathway is required for the generation of prostaglandins (PGs), which are bioactive signaling lipids responsible for processes such as inflammation. Prostaglandin signaling is implicated in AD. Our goal is to elucidate the role of prostaglandin D2 (PGD2) signaling in AD. PGD2 is heavily studied in diseases with airway inflammation but is poorly understood in AD. Our hypothesis is that attenuating neuroinflammation in pre or early stages of AD by targeting PGD2

signaling, will slow down pathology. We focus on PGD2 signaling in conjunction with microgliosis known to occur in AD. PGD2 is the most abundant prostaglandin in the brain and is the one that increases most under pathological conditions. DP2 receptor activation by PGD2 leads to a decrease in cAMP and an increase in calcium mobilization, both of which can lead to neuronal damage. In fact, *in vitro* studies show adverse outcomes when treating cells with DP2 agonists. In our studies we analyzed the expression of PGD2 receptors and microgliosis in wild type rats, and TG-F344-AD (TG-AD) rats. TG-AD rats express human "Swedish" amyloid precursor protein (APPsw) and Δ exon 9 presenilin-1 (PS1ΔE9) driven by the prion promoter. TG-AD rats exhibit AD pathology including cerebral amyloidosis, tauopathy, gliosis, neuronal, and cognitive deficits are detected as early as 9 months of age. Our behavioral Active Place Avoidance data detected significant deficits in 9- and 11-month male TG-AD rats with outcome measures such as Maximum Avoidance Time and Latency, supporting hippocampal dysfunction. Changes in PGD2 receptor expression and gliosis were assessed by immunohistochemistry in the rat brains at pre-pathology (4 months of age) and when signs of neuroinflammation are significant (11 months of age). Our *in vivo* results demonstrate DP1 expression in microglia and DP2 expression in neurons. We also analyzed the levels of PGD2 in 4 month and 11 month WT and TG-AD rats. Our studies provide insights for the development of therapeutics that target PGD2 signaling to treat AD.

Title: Early life perturbation of the gut microbiome (short-term antibiotic) results in a sex-specific reduction of brain amyloidosis

Authors: H. B. DODIYA[1], ***J. XIA**[1], C. ZHANG[2], P. PATEL[3], X. ZHANG[1], M. J. SCHIPMA[3], R. E. TANZI[2], J. A. GILBERT[4], S. SISODIA[1];
[1]Neurobio., The Univ. of Chicago, Chicago, IL; [2]Massachusetts Gen Hosp, Harvard Med. Sch., Charlestown, MA; [3]Northwestern Univ., Chicago, IL; [4]Univ. of California San Diego, San Diego, CA

Abstract: Background: In continuation of our previous correlation studies (Minter M 2016, 2017), recently our group established a causal relation demonstrating long-term antibiotic (ABX)-mediated microbiome perturbations reducing cerebral Aβ amyloidosis and altered microglial phenotypes in the APPPS1-21 mouse model (Dodiya HB 2019). One limitation of this study is that (to prove causation) fecal microbiota transplantation (FMT) was performed simultaneously with diluted ABX in everyday drinking water. It is plausible that diluted ABX could impact the FMT efficiency that affects our measures of amyloidosis and microglia. To address this concern, we performed the present study evaluating short-term ABX microbiome perturbations and FMT transplantations in APPPS1-21 mice.
Method: Pups receiving ABX were gavaged with a cocktail of Kanamycin, Gentamicin, Colistin, Metronidazole, and Vancomycin in water from post-natal day (P)14 to P21. Control mice received water gavage. In addition, ABX+FMT (male mice only) group received fecal transplantation from control male mice. Mice were sacrificed at the age of 9 weeks and histopathology, microglia phenotype, brain transcriptome, peripheral cytokines and gut microbiota profiles were evaluated.
Results: Similar to our published results from $APP_{SWE}/PS1_{DE9}$ (Minter M 2017), histopathology and microscopic analysis showed significantly lower Aβ pathology in male APPPS1-21 mice with ABX treatment. Female APPPS1-21 mice showed no significant changes in amyloidosis. Importantly, ABX+FMT male mice showed complete restoration of brain amyloid pathology. These results were also confirmed using MSD analysis of insoluble Aβ40 and Aβ42 levels. RNA sequencing of total cortical RNA exhibited similar sex-specific effects. Specifically, DESeq analysis showed 942 altered genes in male mice while no changes in female mice with ABX treatment. As expected, FMT treatment in ABX-treated male mice restored this transcriptome profile similar to control mice showing only 76 altered genes. GO term enrichment analysis of biological process showed significantly different gliogenesis and microglia development pathways in ABX-treated male mice only. Further analysis is underway.
Conclusion: All together, early life microbiome perturbation using short-term ABX alters amyloidosis in a sex-specific manner. Data from the current study addresses concerns raised in our previous studies and strengthens the role of microbiota-microglia axis in AD pathogenesis.

Title: The effect of Alzheimer's disease associated mutations in APP on the progression of colorectal cancer induced by AOM/DSS in a mouse model

Authors: *M. SOHRABI, C. COMBS;
Biomed. Sci., Univ. of North Dakota, Grand Forks, ND

Abstract: Amyloid precursor protein (APP) is proteolyzed into specific fragments during its normal turnover in neurons. Although one product of APP metabolism is the Aβ peptide associated with Alzheimer's disease, there are several proteolytic products that are generated. In addition, APP is expressed by many cell types throughout the body. This suggests that the parent protein and/or its metabolites may regulate additional events beyond accumulation of extracellular Aβ peptide plaques in the brain. For example, we previously demonstrated in both mice and humans that APP is robustly expressed in intestinal epithelial cells which are capable of generating the Aβ peptide commonly associated with brain accumulation in Alzheimer's disease. Others have demonstrated that an additional fragment of APP, secreted APPα/β (sAPP α/β), is capable of regulating cell line proliferation *in vitro*. Based upon this data, we hypothesized that expression and proteolytic processing of APP may regulate colon cancer progression. To test this idea, we first verified robust expression of APP in human colorectal cancer (CRC) epithelial cells from various stage tumors. For further investigation, we utilized a common inflammation-associated colon cancer model in C57BL/6 wild type control, $APP^{-/-}$, and $App^{NL\text{-}G\text{-}F}$ mice to determine whether expression of APP or preferentially increased metabolism of APP into Aβ and sAPPβ fragments might influence the progression of disease. Both male and female mice at 5-8 months of age were treated with azoxymethane (AOM) and dextran sulfate sodium (DSS) to model human CRC. Mice were collected at the end of week 17 post-treatment and spleen weight, colon weight and length as well as tumor size and numbers were recorded. Interestingly, the male $App^{NL\text{-}G\text{-}F}$ mice demonstrated significantly larger spleen and colon weights compared to both wild type and $APP^{-/-}$ mice. This correlated with increased tumor number and size in these $App^{NL\text{-}G\text{-}F}$ mutant mice. On the other hand, female $App^{NL\text{-}G\text{-}F}$ mice had significantly smaller colon and spleen weights and developed fewer and smaller tumors than their wild type and $APP^{-/-}$ counterparts. These data demonstrated that mutations responsible for preferentially increasing metabolism of APP towards robust Aβ peptide production and accumulation in the brain during Alzheimer's disease also confer both protection against and increased risk of colon cancer progression in a sex dependent fashion. Further biochemical and histological analysis are needed to clarify the molecular mechanisms involved in these observations.

Title: CSF1-R directed inhibition suppresses inflammation and plaque burden, but enhances neuritic dystrophy in a mouse model of Alzheimer's disease

Authors: *B. CASALI[1,2], E. G. REED-GEAGHAN[2], G. E. LANDRETH[3];

[3]Stark Neurosci. Res. Institute, NB214C, Indiana Univ. Sch. of Med., Indianapolis, IN

Abstract: Alzheimer’s disease (AD) is a neurodegenerative disorder characterized by extensive amyloid plaque deposits, inflammation, and cognitive decline. Microglia act primarily to provide important immune defense and perform tissue maintenance, but these functions are frequently perturbed in neurodegenerative diseases. Since microglial dysfunction has been implicated in the pathogenesis of AD, pharmacological interventions that restore microglia function and ameliorate pathology are of clinical interest. Microglia are reliant upon colony-stimulating factor receptor-1 (CSF1-R) activation for survival. Small-molecule therapeutics that inhibit CSF1-R signaling resulted in microglia death in the brain, reduced microglial activation, and enhanced neuronal survival in AD mouse models. However, depletion of microglia in a disease state may elicit deleterious side effects and potentially limit the clinical appeal for long-term CSF1-R inhibitor use. Accordingly, we tested whether administration of the highly selective CSF1-R inhibitor PLX5662 altered pathology in the 5xFAD mouse model of AD at 4 months of age. Consistent with prior studies, PLX5662 diminished, but did not fully deplete, microglia from various brain regions after approximately one month of administration. Surprisingly, we observed striking suppression of markers of inflammation and plaque burden in PLX5662-treated animals, even with greatly diminished numbers of microglia compared to control-treated animals. We also observed trends toward reductions in thioflavin-positive, dense-core plaque coverage and plaque number in these animals. While other markers of pathology were reduced with inhibitor treatment, neuritic dystrophy was paradoxically enhanced. CSF1-R targeted inhibition also suppressed expression of genes associated with homeostatic microglia—genes which may impart enhanced neuroprotection in other mouse models of AD and neurodegeneration. We also saw reduced ApoE levels in insoluble fractions of the brain, which are associated with amyloid-laden plaques. Future studies are aimed at elucidating if CSF1-R inhibition perturbs the ability of microglia to maintain plaques in an inert, thioflavin-positive form and subsequent expansion to more diffuse, neurotoxic plaques. These findings imply that

while CSF1-R inhibition ameliorates amyloid pathology, neuroprotection is compromised—most likely due to repressed microglial homeostatic genes, abrogated microglial activation and numbers, and possible changes in plaque composition. Our findings have the potential to limit clinical appeal for CSF1-R targeted therapeutics in AD.

Abstract: Neuroinflammation is one of the hallmarks of Alzheimer’s disease pathogenesis. Inflammatory cytokines and chemokines released from glial cells and immune cells are implicated in neuroinflammation, neuronal toxicity and neurodegeneration in neurodegenerative diseases such as Alzheimer’s disease (AD), Parkinson’s disease (PD) and Multiple sclerosis (MS). Mast cells are multifunctional immune and inflammatory cells that are implicated in neuroinflammation by releasing prestored and newly synthesized cytokines, chemokines and neurotoxic mediators. However, the exact mechanisms involved in this process is not clearly understood. Here, we examined mast cell-associated neuroinflammation using cultured mouse bone marrow-derived mast cells (BMMCs), mast cell-deficient (MC-KO) mice and 5XFAD mouse model of AD. We first examined mast cells in the brains of 5XFAD and wild type mice using toluidine blue staining. We found increased mast cell numbers and its activation in the brains of 5XFAD mice as compared to wild type control mice. Protease activated receptor-2 (PAR-2), a receptor for mast cell derived and other proteases, and proinflammatory CD36 expressions are increased in the brains of 5XFAD mice as compared to wild type mice and mast cell deficient mice (MC-KO). Moreover, BMMCs incubated with AD pathogenesis-associated beta amyloid 1-42 (Aβ1-42) showed increased expression of CD36 as well as the release of

chemokine (C-C motif) ligand 2 (CCL2) *in vitro.* We conclude that mast cells augment neuroinflammation and neurodegeneration in neurodegenerative diseases including AD.

Title: Down regulation of GMF inactivates NLRP3-inflammasome and improves neurobehavioural functions in 5XFAD mice

Authors: *M. AHMED[1,2], R. THANGAVEL[1,2], G. SELVAKUMAR[1,2], D. KEMPURAJ[1,2], I. DUBOVA[1,2], S. RAIKWAR[1,2], S. ZAHEER[1], S. IYER[1,2], A. ZAHEER[1,2];

Abstract: Alzheimer’s disease (AD) is a progressive neurodegenerative disorder characterized by the presence of intracellular neurofibrillary tangles (NFTs) containing hyperphosphorylated tau, and the extracellular deposition of amyloid plaques (APs) with misfolded amyloid (Aβ) peptide. Glia maturation factor (GMF), a highly conserved pro-inflammatory protein was discovered in our laboratory, is a highly conserved protein predominantly localizes in glial cells and some neuronal cells has been shown to neuro inflammation and neurodegeneration in AD. Previously we have shown that inflammatory reaction promoted by the NLRP3-Caspase-1 inflammasome pathway triggers accumulation of Aβ which is amplified and regulated by GMF in human AD brain. We hypothesized that downregulation of GMF using GMF-specific shRNA could restrict the expression of NLRP3-inflammasome components. GMF-shRNA was injected bilaterally in 5XFAD mice brain to silence the GMF expression. Following 4 weeks of bilateral intracerebroventricular injection of GMF-shRNA, we observed improvement in cognition and reduction in the expression and co-localization of NLRP3 with Aβ, caspase-1 and product of inflammsosome activation IL-1β and IL-18 in the cortex of 9-month old 5XFAD mice brain. Furthermore, our data suggest that downregulation of GMF by using GMF-specific shRNA could be promising strategy to target neuro-inflammation and neurodegeneration in AD.

Title: Alterations in free fatty acids and phospholipids in an APP knock-in mouse model for Alzheimer's disease

Authors: C. EMRE[1], B. JUN[2], P. NILSSON[1], N. G. BAZAN[2], *M. SCHULTZBERG[1]; [1]Karolinska Institutet, Stockholm, Sweden; [2]Neurosci. Ctr., Louisiana State Univ. Hlth. Sci. Ctr., New Orleans, LA

Abstract: Alzheimer's disease (AD) is a neurodegenerative disorder and its clinical symptoms are reflections of neuropathological changes in the brain, including aggregates of hyper-phosphorylated tau protein (p-Tau) in neurofibrillary tangles (NFTs) and extracellular deposits of amyloid β (Aβ) peptide in amyloid plaques. Inflammation is part of the neuropathology in AD involving microglial activation, astrocyte proliferation and increased levels of pro-inflammatory factors. Presence of Aβ induces an inflammatory response as outcome of a protective host response and, conversely, activation of glia and secretion of pro-inflammatory cytokines stimulate the production of Aβ resulting in a vicious circle. Normally, inflammation is terminated by an active process called resolution to decrease pro-inflammatory factors, increase phagocytosis of cell debris, restore the tissue and regain homeostasis. These mechanisms are orchestrated by specialized pro-resolving mediators (SPMs) derived from omega-3 and -6 fatty acids (FAs) including docosahexaenoic acid (DHA) and arachidonic acid (AA). Neuroprotective effects of SPMs in *in vitro* studies resulted in downregulation of pro-inflammatory markers, upregulation of neuroprotective factors and stimulation of $A\beta_{42}$ phagocytosis. In order to further understand the role of dysfunction of resolution for AD development and to identify novel treatment target(s) we investigate the correlation between resolution of inflammation and AD neuropathology using an *App* knock-in AD mouse model. This model is free of APP overexpression and harbours high $A\beta_{42}$ levels due to the Swedish, the Beyreuther and the arctic mutations, and exhibits robust neuroinflammation including microglial activation and astrocytosis. This exploratory study involves characterization of bioactive lipid mediators (LMs) and related molecules, investigating their structure and stereochemistry in extracts of the hippocampus, cortex, cerebellum and liver from the *App* knock-in mouse model and wild-type

(WT) mice. Using liquid chromatography-tandem mass spectrometry (LC-MS/MS), SPMs (maresin 1, NPD1, RvD1 and RvE1), monohydroxy-derivatives of DHA and AA (*e.g.* 14-HDHA, 17-HDHA, and PGD2, PGE2), and elongated DHAs (very long-chain polyunsaturated FAs, VLC-FAs), were analysed at different ages (2, 4, 8 and 18 months) of the mice. The data show differential distribution of LMs within the brain of the *App* knock-in mice, and that the levels change with age and differ between these mice and WT mice. The results support a dysfunctional resolution pathway in AD, and the potential for pro-resolving LMs as treatment strategy.

Title: Effect of repeated exposure at low ozone doses on the expression of inflammatory cytosines in hippocampi of rats

Authors: *A. E. RODRÍGUEZ-MARTÍNEZ[1], M. VALDÉS-FUENTES[2], A. MIRANDA-MARTÍNEZ[1], M. CRUZ-REYES[1], A. LÓPEZ-VALDEZ[2], E. HERNÁNDEZ-OROZCO[1], S. RIVAS-ARANCIBIA[1];
[1]Dept. de Fisiología, Univ. Nacional Autonoma de México, Ciudad de México, Mexico; [2]Dept. de Investigación, Tecnológico de Estudios Superiores de Huixquilucan, Estado de México, Mexico

Abstract: Repeated exposure to environmental pollution caused by ozone induces a state of chronic oxidative stress in the body. Which causes loss of regulation of the inflammatory response. Both factors, the state of oxidative stress and the dysregulation of the inflammatory response contributing to the maintenance of the neurodegenerative process. The objective of this work was to evaluate the changes in cytokines and their correlation with the inducible synthase of nitric oxide (iNOS), as well as with the manganese superoxide dismutase (MnSOD) in a model of environmental pollution by ozone. For this purpose, 72 rats housed individually and with free access to water and food were used. Animal care and handling were in accordance with the Norma Official Mexicana NOM-062-ZOO-1999 and approved by the Institutional Committee for the Care and the Use of Laboratory Animals (CICUAL), of the Medicine School at the Universidad Nacional Autónoma de México. Each group received one of the following

treatments: group 1) exposed to ozone-free air. Group 2, 3, 4. 5 and 6 exposed to ozone for 7, 15, 30, 60 and 90 days respectively. The ozone dose used was 0.25 ppm for 4 hours daily. Once the treatment was finished, the groups were processed for RT-PCR techniques, Western Blot, and spectrophotometry for the following markers: IL-17, IL-1β, FoxP3 transcription factor, MnSOD, iNOS. The results obtained show a significant increase of mRNA for IL-17 at 60 and 90 days ($P < 0.05$), IL-1β at 7 ($P < 0.05$) and FoxP3 at 30 days ($P < 0.05$). Both IL-17, IL-1β, iNOS increased at 60 and 90 days ($P < 0.05$), FoxP3 showed an increase at 30 days of ozone exposure ($P < 0.05$). With the results obtained we can conclude that repeated exposure to low doses of ozone, similar to days of high contamination, causes alterations in both the inflammatory response and the antioxidant response similar to what occurs in chronic degenerative diseases, as in the Alzheimer's disease.

Title: Examining alterations of $GABA_B$ receptors in hyperglycemia and Alzheimer's disease related pathology

Authors: *A. A. ORTIZ, A. M. SALAZAR, A. M. LEISGANG, A. PLATT, M. PEREZ, C. GUESE, J. W. KINNEY;
Univ. of Nevada Las Vegas, Las Vegas, NV

Abstract: Alzheimer’s disease (AD) is a neurodegenerative disorder that is characterized by progressive learning and memory deficits, neuronal loss, and cognitive impairments. The two core pathological hallmarks of AD are 1) senile plaques, composed of accumulated amyloid beta (Aβ) proteins and 2) neurofibrillary tangles, composed of accumulated hyperphosphorylated tau (ptau). A third characteristic that has emerged is a chronic inflammatory response within the brain. Several studies have demonstrated that chronic neuroinflammation exacerbates Aβ and ptau pathology. The exact cause of AD remains unknown; however, several risk factors exist that greatly increase the likelihood of developing AD. Genetic risk factors such as ApoE and a mis-sense mutation in TREM2 have been linked to increasing the likelihood of developing AD. Non-genetic risk factors include age, cardiovascular disease, obesity, and diabetes mellitus (DM).

Individuals with DM express high levels of glucose in the vasculature (hyperglycemia). DM confers up to a 4-fold increase in risk that arises based on hyperglycemia, insulin receptor resistance, and changes in the vasculature. Furthermore, 80% of individuals with AD have (DM) or are insulin resistance. We have previously demonstrated that intermittent administration of streptozotocin (STZ), induces sustained hyperglycemia in an otherwise healthy animal (Murtishaw et al. poster 44.25/N12 SFN 2017). STZ mice exhibit learning and memory deficits, increased ptau, and neuroinflammation. In AD, there is a general loss of γ-aminobutyric acid (GABA), thus, in the present study we investigated these same measures in a novel $GABA_B$ knockout mouse model of male and female mice over a year old since. Our data indicate altered fasting blood glucose, and differences between males and females in response to the STZ administration.

Abstract: Alzheimer’s disease (AD) is the most common type of dementia. AD is a chronic neurodegenerative disorder with cognitive impairment among elderly people. Neuroinflammation and neurodegeneration play a key role in the pathogenesis of AD. The two major neuropathological features of AD are amyloid plaques (APs) made up of β-amyloid peptide and neurofibrillary tangles of hyperphosphorylated tau protein. We previously demonstrated the increased expression of glia maturation factor (GMF) in different regions of human AD brain. Triggering receptor expressed in myeloid cells 2 (TREM2) strongly increases the risk of developing AD pathology and confirming the role of microglia in AD. Here, we

studied the expression of TREM2 and GMF and their association with APs in 5XFAD mice brains. We used immunohistochemical, single and double immunofluorescence labeling to confirm the co-localization of TREM2 and GMF with APs. We found that TREM2 was strongly expressed in activated microglia, and was seen to be closely associated with APs. Results revealed an increased expression and co-association of GMF and TREM2 in 5XFAD mice brain compared to non-transgenic mice brain. TREM2 is upregulated and associated with GMF in the vicinity of APs. Additionally, an increased TREM2 immunoreactivity was found to correlate with strong immunolabeling of ionized calcium-binding adaptor molecule-1 (Iba-1), an activated microglial marker, along with anti-Aβ(6E10) labeled APs. Different brain regions with increased APs were associated with TREM2-immunoreactive microglia as well as GMF in 5XFAD mice brain. Furthermore, immunoblot analysis also revealed an upregulation of GMF and TREM2 proteins in 5XFAD transgenic compared with nontransgenic mice. These findings suggest that the increased expression and co-localization of GMF, TREM2 and Iba-1 within APs exacerbates neuroinflammation and neurodegeneration and together may be contributing to the pathogenesis of AD. In this study, we outlined our understanding of the involvement of GMF and TREM2 in AD development that may open new therapeutic strategies specifically targeting the microglia to control AD pathogenesis.

Title: Hyperactivity of hiPSC-glutamatergic neurons in response to $PM_{2.5}$ particles: A potential mechanism linking air pollution to increased incidence of Alzheimer's disease

Authors: *K. L. GORDON[1], C. HANDLEY[1], R. C. B. BASA[1], S. ANKAM[1], Y. HUANG[2], J. ZHENG[2], W. DING[3], J. H. PRICE[1,4], P. MCDONOUGH[1];
[1]Vala Sci. Inc., San Diego, CA; [2]Univ. of Nebraska Med. Ctr., Omaha, NE; [3]Chinese Acad. of Sci., Beijing, China; [4]The Scintillon Inst., San Diego, CA

Abstract: Recent epidemiology studies link air pollution, notably particulate matter of 2.5 μm or less in diameter ($PM_{2.5}$), to increased Alzheimer’s disease (AD) but the mechanisms responsible

for this have not yet been fully elucidated. Air pollution particles have been found within the brain and it is possible that they enter the brain along tracts of olfactory neurons from nasal cavities to the olfactory bulb. Consistent with this hypothesis, loss of olfactory function is a common prodromal symptom of AD, and AD-related pathology is commonly observed in the olfactory bulb, post-mortem. To investigate potential dysregulation of CNS neuron function by $PM_{2.5}$, we seeded excitatory glutamatergic neurons derived from human induced pluripotent stem cells (hiPSC-Gluts) into 384-well plates, and exposed the neurons to $PM_{2.5}$ (at doses of 0.625, 12.5, 25, 50, and 100 µg/ml) for 4 or 24 hrs. We then loaded the cells with Rhod-4 (an indicator of intracellular calcium) and monitored neuronal activity via kinetic image cytometry, a method featuring an automated digital microscope workstation, collection of video movies (20 seconds at 4 frames per second) from each well, and analysis of the videos on a cell-by-cell basis to quantify Rhod-4 fluorescence. Exposure to $PM_{2.5}$ increased calcium activity in a dose- and time-responsive manner (with a 2.4-fold increase in integrated activity above baseline at 100 µg/ml, at 24 hr). This suggests that $PM_{2.5}$ may increase calcium transients in the neurons, a stress that may correspond to hyperactivity and excitotoxicity, and ultimately, increased mortality of the neurons. Development of a high throughput assay system to test air pollution components for neurotoxic effects will enable research into the mechanisms that link air pollution to AD, and spur the search for agents that may protect against this neurodegenerative stimulus.

Title: Ablation of $p75^{NTR}$ signaling strengthens interaction of gamma and theta rhythms and counteracts amyloid beta induced degradation of neuronal dynamics in mouse hippocampus *in vitro*

Authors: *Y. ANDRADE-TALAVERA, H. BALLEZA-TAPIA, P. DOLZ-GAITÓN, A. FISAHN;
Karolinska Institutet, Stockholm, Sweden

Abstract: Gamma and theta oscillations have been associated with hippocampus-dependent cognitive tasks. These two brain rhythms are known to coexist and their interaction results in a cross-frequency coupling than can affect the features of gamma oscillations. The hippocampal theta rhythm depends, at least partially, on the cholinergic and GABAergic inputs from the

medial septum-diagonal band of Broca (MS/DB). MS/DB cholinergic neurons undergo a moderate degeneration during aging, likely due to an attenuation of the neurotrophic signalling. Among the receptors involved in the neurotrophic response, $p75^{NTR}$ is of special importance for the viability of these neurons. Also, they are among the few cell types in the brain that maintain high levels of expression of $p75^{NTR}$ throughout adulthood.
The role of the $p75^{NTR}$ receptor is still puzzling mediating both pro-apototic and survival signaling pathways. To test whether $p75^{NTR}$ plays a role for the MS/DB cholinergic projection onto hippocampus, particularly for the neuronal rhythms that are associated with its function, we performed local field recordings on $p75^{NTR}$ knockout ($p75^{-/-}$) mouse brain slices in presence of the muscarinic agonist carbachol. We found that gamma power and rhythmicity are increased in $p75^{-/-}$ mice. Furthermore, gamma activity is more phase-locked to the underlying theta phase compared to WT mice. We also found an increase in the amplitude-modulation of the gamma rhythm within the theta-frequency band. On the cellular level we found that fast-spiking interneurons (FSNs) fire more synchronized to a preferred gamma phase in the absence of $p75^{NTR}$ signalling. In addition, we found that the excitatory input onto FSN displayed an oscillatory pattern in the gamma range in accordance with the ongoing gamma oscillations in both mouse strains. However, the rhythmicity of the EPSCs input in the $p75^{-/-}$ strain was higher. Moreover, by analyzing the relationship between the field oscillations and the EPSCs we found a higher similarity in the $p75^{-/-}$ oscillatory patterns compared to $p75^{+/+}$. Notably, the ablation of $p75^{NTR}$ counteracted the Aβ-induced degradation of gamma oscillations and its relation with the underlying theta rhythm.
Our results show that the lack of $p75^{NTR}$signalling strengthens cholinergic modulation of hippocampal gamma rhythms pointing towards the involvement of this receptor in the downregulation of neuronal network dynamics during cognitive-relevant rhythmic activity in hippocampus. Functional data provided here suggest $p75^{NTR}$ as a suitable target in the search of efficacious treatments to counteract the loss of function observed in amyloid-driven pathologies such as Alzheimer´s Disease.

Title: Early network dysfunction in P301S tau transgenic neurons cultured on microelectrode arrays

Authors: *R. B. MEEKER, **A. DOMBROSKI**, T. DEMARSE, B. HARRIS;
Neurol., Univ. of North Carolina at Chapel Hill, Chapel Hill, NC

Abstract: Inflammation occurs early in the pathogenesis of Alzheimer's Disease (AD) in mouse models and is believed to contribute to disease progression. When in the presence of pathological entities such as oligomeric amyloid beta ($A\beta_o$), microglia and macrophages release factors that disrupt neuronal calcium homeostasis and induce cytoskeletal changes including modifications of the microtubule associated protein Tau. These changes are thought to increase the sensitivity of neurons to excitatory stimuli, leading to hyperactivity and further disease progression. However, the impact of this hyperactivity on neural communication within networks and the role of pathological modifications of Tau are not well understood. To better understand the functional impact of inflammation and early Tau modifications, we challenged primary wild type (WT) and P301S/PS19 Tau-transgenic mouse neurons with medium from microglia treated with Aβ oligomers (Aβ-MgCM) to mimic *in vivo* inflammation. The resulting electrophysiological and calcium changes under basal and inflammatory conditions were collected from microelectrode arrays (MEAs) to assess the effects of inflammation and aberrant Tau on neural network function. Under basal conditions, the PS19 neurons showed increased synchronous calcium signaling relative to WT neurons. Electrophysiologically, the PS19 neurons typically had a higher rate of action potentials within bursts, but exhibited shorter burst durations. We also found that PS19 networks exhibited lower node degrees and higher path lengths, indicating poor functional connectivity. Under inflammatory conditions, both the WT and PS19 cultures displayed network disruption in response to the conditioned medium. The PS19 neurons responded with a smaller increase in mean firing rate but an increased frequency within bursts suggesting a hyperactive phenotype within more limited networks. The aberrant development of neural network activity in the PS19 neurons and the altered responses to inflammation suggest that pre-tangle forms of Tau mediate neural dysfunction that may contribute to cognitive decline. This early dysfunction may provide opportunities for the development of new therapeutic strategies that slow the progression of AD and other neurodegenerative diseases.

Title: Exploring the impact of hyperphosphorylated tau on neuronal network connectivity

Authors: *L. RIS[1], P. VERSTRAELEN[2], G. GARCIA-DIAZ BARRIGA[2], A. VILLERS[1], B. LEROY[1], R. WATTIEZ[1], W. DE VOS[2], M. WAUTERS[1];

Abstract: In recent years, it has become clear that small species of Tau protein have the propensity to induce synaptic toxicity in neurons before larger aggregates appear. Moreover, it has been shown that Tau protein can be released in the extracellular space while its role and potential toxicity in this compartment is unknown. This may have important implications for the pathophysiology of tauopathies including Alzheimer's disease. To address the need for pathophysiologically relevant tau preparations, we have optimised a Multiple Reaction Monitoring (MRM)-based purification of tau proteins in mammalian cells. This approach was used to extract normal (Tau) and hyperphosphorylated (P-Tau) isoforms with sufficiently high concentration. While we are currently analysing the phosphorylation and O-glycosylation sites by mass spectrometry, we have already confirmed increased Serine 396 phosphorylation in P-Tau extracts compared to Tau using SDS PAGE with phospho-specific antibodies. Furthermore, native gel electrophoresis confirmed that the proteins remain in a soluble state. To study the toxicity of extracellular Tau and P-Tau, we incubated cortical cultures with the extracted tau proteins and immunolabelled the exogenously administered proteins by targeting their TEV-site. Next, we asked whether (one of) the proteins exerted a synaptotoxic effect. To this end, we quantified the synapse density after an acute exposure to one of two concentrations of tau protein (Tau or P-Tau) in immunostained cultures and we quantified functional connectivity in the neuronal networks using electrophysiology and a previously optimised live cell imaging approach based on a genetically encoded calcium reporter (GCAMP6, Verstraelen et al, Front Neurosci. 2018). We found that the application of physiologically relevant amount of P-Tau (60 ng) induced modifications in synaptic connections from 1h to 6h after the addition of the protein. This effect, absent when the protein is not hyperphosphorylated (Tau), disappeared after 24h when the protein is internalized and seems to be degraded in lysosomes. This result suggests that the release of P-Tau by neurons could impact synaptic function and neuronal processing.

Abstract: Phosphatidylinositol binding clathrin assembly protein (PICALM) is a cytosolic protein involved in clathrin-mediated endocytosis and a well-known risk gene for Alzheimer's Disease. PICALM gene has been identified with SNPs through multiple genome-wide association studies across various populations. PICALM has a central role in the regulation of clathrin-mediated endocytosis and has been well characterized along with LRP-1 in transcytosis of Aβ peptides across the blood-brain barrier. However, little is known about its function at synapses and how it regulates endocytosis of Amyloid Precursor Protein (APP). Differential subcellular localization of APP has the potential to affect the production of Aβ peptides. Through endocytosis, PICALM has the potential to compartmentalize APP from the plasma membrane to intracellular endocytic organelles. Dissecting out the molecular interaction between the two proteins is important to understand the localization of APP at presynapse, postsynapse, and perisynapse. We show data for APP-PICALM interaction which is consistent with the literature. Dynamics of wild-type APP and Swedish APP on cell membrane were studied in abundance of PICALM. Which elucidated a potential role of PICALM in regulating the mobility of APP and affecting subcellular localization by internalization. To study dynamics of internalization and interaction of APP with PICALM, we designed a strategy to alter the “YENPTY” sequence present at Carboxy-terminal tail of APP. To further characterize the role of APP-PICALM interaction and its implication on synapses, we performed a detailed analysis of compartmentalization of APP and PICALM in presynapse, postsynapse and perisynapse of rat hippocampal neurons using conventional and super-resolution microscopy.

Abstract: It is widely known that the toxic effects of the beta-amyloid soluble oligomers (SO-Aβ) are central elements on the pathogenesis of the Alzheimer Disease (AD). In our group, it has been demonstrated that SO-Aβ have the capacity to induce the pore formation in the plasma membrane, this produce an influx of calcium and leakage of big molecules, like ATP. Mainly, the cytosolic Ca^{2+} overload, induce mitochondrial dysfunction and synaptic failure, leading to cellular death. Several evidence suggests that common black garlic (*Allium sativum*) have a beneficial effects on the Aβ toxicity, and these effects are proposed could be mediated by S-allyl-cysteine (SAC), the main organosulfur metabolite present in the garlic. *Allium ampeloprasum* is an endemic species from the Chiloé Island, located in the Northwestern Patagonia of Chile, the study of the Elephant Black Garlic Extract (BG) has recently started in our lab, and the chemical composition and the neuromodulatory properties are the main objective of this research. BG (10 µg/mL) induce a neuroprotective effect evaluated by viability assays (MTT), recovery the cell viability about 52±5% on PC12 cell treated with Aβ during 24h. Additionally, the synaptic activity measured by Ca^{2+} oscillation on hippocampal neurons, show that BG recovered the frequency of Ca^{2+} oscillations of the neurons previously treated with Aβ during 24 h, about in a 54±6%. To corroborate these effects on more physiological model, we used hippocampal slices to tests the effects of BG on slices treated acutely (3h) with Aβ (2.5 µM). We observed that the slice viability was maintained near to control conditions when the BG was co-incubated with Aβ (Aβ: 53±5%; Aβ+BG: 113±6%). In parallel, the mitochondrial functionality was measured on hippocampal slices using JC-1 dye and fluorescence techniques. The presence of Aβ induced a strong fall in the mitochondrial potential near to 36±7%, while the co-incubation with BG maintain a potential with values near to control conditions. These last observations where correlated with changes on the key proteins related with mitochondrial dynamics in hippocampal slices [(Mfn1, Aβ: 48±7%; Aβ+BG: 79±9%) (DRP1, Aβ: 118±15%; Aβ+BG: 103±14%)]. Our result suggest that BG can induce a strong protection of the neuronal network against Aβ toxicity and could represent an interesting source of new compounds that can be useful to interfere with the physiopathology of amyloid beta peptide oligomers.

Title: Early sex differences in AMPA and NMDA receptor responses in 5xFAD

Authors: E. P. SACKINGER, T. VU, A. RADKE, F. NIGUSSIE, *K. R. MAGNUSSON; Oregon State Univ., Corvallis, OR

Abstract: Alzheimer's disease (AD), the most common form of dementia, affects 10% of the population over age 65. Mutations in presenillin or amyloid precursor protein (APP) in familial AD lead to overproduction of amyloid. Changes in amyloid occur early in AD, before the onset of behavioral signs. Based on this, and early changes seen in N-methyl-D-aspartate receptors (NMDARs) in presenillin models with single mutations, we aimed to study the difference in α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid receptors (AMPARs) and NMDAR between young mice that do not yet show behavioral signs of amyloid-related degeneration and older mice that do. In 5xFAD (two presenillin and 3 APP mutations) mice that were 15-days or 4 months old, the field excitatory post synaptic potentials (fEPSPs) of the CA3 Schaffer collateral to CA1 synapses in hippocampal slices were analyzed using a MED64 multielectrode array system. Antagonists of AMPAR, GluN2A and Glun2B NMDAR subunits, and full NMDAR were applied. The mice were euthanized via transcardial perfusion of ice-cold artificial cerebrospinal fluid (aCSF) and brain slices were prepared. Slices began in regular aCSF, followed by 30μM DNQX (AMPAR antagonist). Slices were changed into 0.5mM $MgSO_4$ aCSF, 30μM DNQX & 10μM picrotoxin (γ-aminobutyric acid (GABA) receptor antagonist) solution, followed by adding 4μM Ro-25-6981 (GluN2B antagonist), 500nM PEAQX (GluN2A antagonist), then 50μM AP5 (NMDAR antagonist). After drugs equilibrated, a stimulus response study was performed and the input (fiber volley amplitude) / output (fEPSP amplitude) was analyzed. The 15-day old hemizygous 5xFAD male mice showed increased fEPSP amplitudes for the AMPARs, NMDARs, GluN2A subunits and remaining NMDARs. By 4 months old, amplitudes were reduced in comparison to the wild type (WT) mice. Female hemizygous mice, however, showed no genotypic differences at 15-days old for AMPAR fEPSPs, but the hemizygotes had lower fEPSPs per given fiber volley amplitude than the WT mice by 4 months of age. Female hemizygotes were slightly hyporesponsive at 15- days old, but there was no genotype difference at 4 months for NMDARs. GluN2A fEPSPs for the female hemizygotes were reduced from WT at both 15-days and 4 months of age and for the remaining NMDARs

there were no differences between hemizygotes and WT at 15-days or 4 months of age. This data suggests that either the disease progresses differently in females then males, e.g., glutamate receptor changes may begin earlier than 15-days of age in female mice or the early enhancements in male glutamate receptors are not related to the later reductions seen in both sexes.

Abstract: Alzheimer’s disease (AD) is a chronically progressive disorder that causes synaptic and metabolic dysfunction before neuronal death, and AD begins in a ‘preclinical' stage before progressing to mild cognitive impairment and memory loss. Research on molecular events occurring during preclinical and clinical stages of AD has yielded insights into early pathogenic events, including the linked roles of amyloid β-protein (Aβ) and tau proteins. The Aβ peptide is produced in the early endosomal compartment and is released via exosomes. Exosomes from the central nervous system are under investigation, with a specific focus on their components or biochemical features. Their effect on the synaptic functions remains elusive. Field excitatory postsynaptic potentials (fEPSP) were recorded in stratum radiatum of CA1 in mouse hippocampal slices, with the stimulating electrode in the Schaffer collaterals. We found that exosomes from the media of induced pluripotent stem cell (iPSC)-differentiated neurons of AD patients impaired Hebbian synaptic plasticity (such as long-term potentiation, LTP). Similar studies also revealed that neurons exposed to low concentrations of Aβ (as in preclinical phases

of AD) lead to increased neuronal excitability, whereas higher doses of Aβ as in later phases of AD lead to decreased synaptic activity. These results suggest the homeostatic synaptic plasticity dysfunction closely links to Aβ and Aβ/tau-rich exosomes that promote AD pathogenesis.

Title: Effects of amyloid beta on excitatory synaptic transmission in layer II of the entorhinal cortex

Authors: ***M. E. SUVANTO**[1], J. SARAGOSA[1], O. J. OLAJIDE[2], C. A. CHAPMAN[1];
[1]Ctr. for Studies in Behavioural Neurobio., Concordia Univ., Montreal, QC, Canada; [2]Dept. of Anat. (Neuroscience Unit), Univ. of Ilorin, Ilorin, Nigeria

Abstract: Neuronal degeneration of the hippocampus and entorhinal cortex resulting from accumulation of amyloid-β protein (Aβ) are key factors in Alzheimer's disease (AD). Although the entorhinal cortex has a central role in the integration of sensory information and memory formation, and degenerates early in AD, synaptic effects of Aβ within the entorhinal cortex have not been studied extensively. Accumulation of Aβ in the hippocampus disrupts excitatory glutamatergic synaptic transmission. Previous studies in the hippocampus have shown that Aβ enhances activation of extrasynaptic NMDA glutamate receptors, which can result in calcium-dependent excitotoxicity that contributes to neuronal degeneration. We used electrophysiological measures to assess the effects of short-term application of Aβ on excitatory synaptic transmission in the rat entorhinal cortex in vitro. Evoked field EPSPs were recorded from layer II of the medial entorhinal cortex. Following stable baseline recordings in normal ACSF, the application of 10 nM Aβ for 20 min resulted in an increase in fEPSPs that persisted during the 30 min washout period (n=6). Effects of longer-term exposure to Aβ were also assessed in groups of slices incubated for 45 min to 3 h in either 10 nM Aβ or control ACSF (n=11). Field EPSPs were evoked in tests in which either the duration or intensity of stimulation pulses was varied. Results showed that fEPSP amplitude was increased in slices incubated in Aβ, and that longer-term incubation in Aβ resulted in a greater enhancement of fEPSPs in comparison to shorter-term acute exposure. The facilitation of synaptic responses induced by Aβ may result from activation of presynaptic NMDA receptors that enhance transmitter release, or may depend upon postsynaptic NMDA receptors that can enhance calcium influx. These effects of short-term

exposure to Aβ may contribute to mechanisms of excitotoxicity and neuronal degeneration that contribute to cognitive declines observed early during the progression of AD.

Title: Accumulation of oligomeric Aβ within neurons, and Tau phosphorylation, are part of a homeostatic mechanism aimed at restoring temporarily impeded axonal transport

Authors: *V. MURESAN, Z. LADESCU MURESAN;
Pharmacology, Physiol. and Neurosci., New Jersey Med. School, Rutgers Univ., Newark, NJ

Abstract: A primary challenge in Alzheimer's disease (AD) research is to identify the mechanisms that lead to the main pathological lesions (i.e., Aβ plaques, neurofibrillary tangles, granulovacuolar degeneration - GVD), and to provide a logical reason for why they develop. Here, we propose that these lesions are the result of persistent activation of a homeostatic mechanism that generates oligomeric Aβ (oAβ) and phosphorylated Tau (pTau) in an attempt to restore a temporarily halted axonal transport. We previously showed that, normally, a fraction of the Aβ precursor protein (APP) is transported into neurites by recruiting the microtubule motor, kinesin-1, via the adaptor protein, Fe65. Using CAD neuronal cells, we now show that, when axonal transport is experimentally impeded, an APP:Fe65:JNK complex accumulates in the soma, leading to phosphorylation of APP at Thr^{668}, while it resides at the endoplasmic reticulum (ER). This phosphorylation facilitates the amyloidogenic cleavage of APP, and leads to the accumulation of oAβ inside the ER. As a result of diminished affinity for phosphorylated APP, Fe65 is released, translocates into the nucleus, and upregulates GSK3β expression. Phosphorylation of Tau by GSK3β leads to its release from microtubules. We show that, in CAD cells cultured for extended time in conditions that block transport, pTau becomes localized to large spherical particles that accumulate in the soma, and show similarity to GVD bodies. The above-described events could be part of a "stress response" triggered by cargo accumulation in the soma, aimed at "decongesting" the impeded transport routes, and restoring the normal transport. We propose that the ER-accumulated oAβ binds to the nascent secretory proteins, preventing their exit from the ER and the clogging of the transport route, while the release of

pTau from microtubules allows for unhindered cargo translocation along microtubules. We also propose that the GVD bodies - likely autophagic in nature - appear as secondary response aimed at relieving the toxicity of overproduced pTau, when axonal transport is chronically impeded, and the homeostatic mechanism is persistently activated. Our results argue for physiological, beneficial, and independent roles of oAβ and pTau.

Title: Asymptotic long-term depression in aged Dp16 mice, a genetic model of 'Alzheimer's disease in Down syndrome'

Authors: A. V. BONDAR[1,2], M. Y. KHOTIMCHENKO[1], ***A. M. KLESCHEVNIKOV**[2];
[1]Sch. of Biomedicine, Far Eastern Federal Univ., Vladivostok, Russian Federation;
[2]Neurosciences, Univ. of California San Diego, La Jolla, CA

Abstract: Down syndrome (DS) can be considered as a model of Alzheimer disease (AD), since all people with DS have an AD-type pathology by the age of 40. Loss of memory in AD is best correlated with synaptic loss, and long-term depression (LTD) - like mechanisms can contribute to these changes. In this study, we assessed the asymptotic (extreme) LTD in hippocampal slices of aged (12-15 mo old) Dp16 mice, a genetic model of 'Alzheimer disease in Down syndrome' (AD/DS). The experiments were performed in ACSF containing 3 mM Ca^{+2} and 1 mM Mg^{+2}. LTD was induced in the CA1 slices by 2 series of low-frequency stimulation (LFS = 20 min x 2 Hz) with an interval of 2 h between the LFS series. In each series, 5 LFS were applied with an interval of 10 min. Presumably, such intense low-frequency stimulation would accelerate and exaggerate the synaptic changes, such as those that occur in AD/DS. We observed that LTD did not differ after the first series of LFS in Dp16 compared with the control littermate normosomic 2N mice (2N: 82.1 ± 7.5%, n = 6; Dp16: 73.5 ± 5.7%, n = 5; $p = 0.12$). In contrast, LTD was considerably greater in Dp16 than in 2N slices after the second LFS series (2N: 76.3 ± 15.4%, n = 6; Dp16: 45.5 ± 7.0%, n = 5; $p = 0.049$). Thus, total LTD evoked by both LFS series was significantly greater in Dp16 than in 2N slices (2N: 67.0 ± 17.9%, n = 6; Dp16: 31.4 ± 6.0%, n = 5; $p = 0.037$). Interestingly, the 'within genotype' comparison of LTD induced by the first and the second LFS series showed no difference in 2N slices (1^{st} LFS series: 82.1 ± 7.5%; 2^{nd} LFS series: 76.3 ± 15.4%; $p = 0.71$), but a significant increase of LTD induced by the second *vs.* first LFS series in Dp16 slices (1^{st} LFS series: 73.5 ± 5.7%; 2^{nd} LFS series: 45.5 ± 7.0%; $p = 0.01$). The results demonstrate that the hippocampus of aged Dp16 mice is prone to LTD, especially

during prolonged synaptic activity. *App* gene triplication in the DS model likely contributes to these changes.

Title: Increased functional excitatory/inhibitory synaptic ratio in the parietal cortex of Alzheimer's disease but not Down syndrome

Authors: J. C. LAUTERBORN[1], P. SCADUTO[2], C. M. GALL[3], C. D. KEENE[4], ***A. LIMON**[2]; [1]Julie Lauterborn, Irvine, CA; [2]UTMB, Galveston, TX; [3]Anat. and Neurobio., Univ. of California, Irvine, CA; [4]Univ. of Washington, Seattle, WA

Abstract: Disturbances in excitatory to inhibitory (E/I) balance in forebrain circuits may be a contributing factor to the progression of Alzheimer’s disease (AD) and dementia, although direct evidence for synaptic E/I imbalance in the human condition has not been shown. In the present study, fluorescent deconvolution tomography was used to assess the global synaptic E/I ratio in post-mortem parietal cortex samples from middle-aged individuals with AD, Down syndrome (DS), and controls. Although levels of both excitatory (PSD-95; DLG4) and inhibitory (gephyrin; GPHN) postsynaptic density proteins were reduced in AD and DS, the *anatomical E/I ratio* of PSD-95/gephyrin levels was markedly increased in AD only. Microtransplantation of synaptic membranes from each subject was then used to assess the *electrophysiological E/I ratio* for postsynaptic receptor responses. Peak responses to kainate (via AMPA receptors) and GABA revealed significantly elevated E/I ratios for the AD, but not DS, group vs controls. Surprisingly, phosphorylated Tau levels did not correlate with anatomical or electrophysical measures in the AD group but were negatively correlated with kainate current amplitudes and numbers of high intensity PSD-95-positive synapses in DS. Analyses using publicly available RNA-Seq transcriptional datasets for AD parietal cortex also demonstrated an increased transcriptional DLG4/GPHN ratio in AD vs controls. The collective findings provide the first evidence that despite a loss of both excitatory and inhibitory synaptic proteins, AD individuals exhibit a marked pro-excitatory perturbation of postsynaptic densities and electrophysiological synaptic E/I balance. As the parietal cortex is part of the default mode network that has been shown in AD

to be overly active and fails to deactivate during cognitive tasks, the present findings support the broader hypothesis that E/I imbalance in AD plays a role in the disruption of forebrain circuits that, in turn, contributes to the cognitive decline seen in this disorder.

Title: Impaired degradation dynamics of synaptic vesicle machinery in APP KI mice

Authors: T. HARK[1], ***N. R. RAO**[1], E. BOMBA[2], J. N. SAVAS[2];
[1]Neurol., [2]Northwestern Univ., Chicago, IL

Abstract: Alzheimer’s disease (AD) is a progressive neurodegenerative disorder that is characterized as the onset of dementia with the presence of tangles and amyloid-beta plaques. Synapses are an example of areas where AD pathology could spread via synaptic vesicle exocytosis and endocytosis. Along with the progressive spread of pathology, another hallmark of AD is impaired protein degradation dynamics. The inability for proper degradation to occur effectively leads to the build-up of proteins, such as APP fragments and toxic Aβ42 which forms into plaques. Aβ oligomers have also previously been shown to bind to synaptic vesicle machinery, specifically in the SNARE complex. (Yang et al., 2015) We hypothesize that in an APP KI AD mouse model, the increase of Aβ42 leads to selectively impaired degradation of synaptic vesicle (SV) machinery. To investigate this question, we used APP KI mice at 6 and 12 months and compared the abundance of synaptic vesicle machinery proteins in NL, NLF, and NLGF animals. Immunoprecipitation of APP was performed to identify interactions between APP and SV proteins. Cell culture treatments of primary rat hippocampal neurons with retrograde inhibitors or Aβ42 and SILAC labeling were utilized with LC-MS/MS. SILAC treatment allows for LC-MS/MS identification of which proteins are newly synthesized. An increased abundance in SV machinery could be attributed to impaired degradation. One explanation for this could be that degradation needs to occur in the soma and Aβ42 or APP fragments prevent retrograde transport to the soma for degradation. In order to investigate this hypothesis, we used CiliobrevinD to inhibit retrograde transport with SILAC media with treatment. Another explanation could be that Aβ42 binds to SNARE complexes preventing their ability to properly be degraded when necessary. Preliminary results indicate that blocking

retrograde transport does not affect the degradation of SV machinery. We used TMT labeling and SILAC LC-MS/MS analysis to investigate the protein degradation and turnover dynamics in response to these treatments. These preliminary results indicate that in APP KI mice, there is selective impairment of SV machinery degradation and that this degradation impairment does not seem to be attributed to the inability for proteins to travel to the soma for degradation. Preliminary results also indicate that addition of synthetic Aβ42 increases the abundance of synaptic proteins that were not degraded during the treatment. Developing an understanding of selectively impaired protein degradation dynamics in AD could prove important to uncovering the mechanism of pathogenic protein aggregation and impairment.

Title: Optogenetic activation of somatostatin interneurons selectively restores hippocampal spike timing-dependent long-term potentiation impaired by Aβ oligomers

Authors: *J. LEE[1], K. PARK[1], H. JANG[1], B. A. RICHARDS[2], M. M. KOHL[3], J. KWAG[1]; [1]Dept. of Brain and Cognitive Engin., Korea Univ., Seoul, Korea, Republic of; [2]Biol. Sci., Univ. of Toronto Scarborough, Scarborough, ON, Canada; [3]Dept. of Physiology, Anat. and Genet., Univ. of Oxford, Oxford, United Kingdom

Abstract: Abnormal accumulation of amyloid beta oligomer (AβO) in the hippocampus impairs long-term potentiation (LTP), which may underlie learning and memory deficits observed in Alzheimer’s disease (AD). Recent reports suggest that AβO causes structural dysfunctions in somatostatin-positive (SST^+) interneurons that are known to gate hippocampal LTP induction of CA1 pyramidal cells (PC) by providing disinhibition to CA1 PC proximal dendrites. However, the contribution of SST^+ interneurons to hippocampal LTP impairment in AD remains unclear. In order to address this question, we first induced spike timing-dependent long-term potentiation (tLTP) at CA3-CA1 synapse in DMSO and AβO (200 nM)-treated hippocampal slices by performing whole-cell current-clamp recordings in CA1 PC and pairing presynaptic excitatory postsynaptic potential evoked by Schaffer Collaterals (SC) stimulation with postsynaptic CA1 PC spike bursts (4 spikes at 100 Hz) with 10 ms time window, repeated 200 times at 5 Hz. Our

tLTP induction protocol induced robust NMDA receptor (NMDAR)-dependent tLTP at CA3-CA1 synapses in DMSO-treated slices, which was completely blocked in AβO-treated slices. Next, to test the role of SST^+ interneurons on AβO-impaired tLTP induction, we selectively expressed channelrhodopsin-2 (ChR2) to CA1 SST^+ interneurons using AAV virus (AAV-CaMKII-ChR2-mCherry) in SST-Cre mice and optogenetically activated them using blue light (470 nm) during tLTP induction. Surprisingly, optogenetic activation of SST^+ interneurons could fully restore NMDAR-dependent tLTP in AβO-treated slices. Since SST^+ interneuron-mediated disinhibition of proximal dendrites of CA1 PC has been shown to gate LTP induction, we next investigated whether AβO impaired SST^+ interneuron-mediated disinhibition, and thereby tLTP at the CA3-CA1 synapse. To analyze SST^+ interneurons-mediated disinhibition, we recorded SC stimulation-evoked inhibitory postsynaptic current (SC-IPSC) from CA1 PC through whole-cell voltage-clamp recordings and calculated the difference between SC-IPSCs before and during tLTP induction. We found that SST^+ interneuron-mediated disinhibition during tLTP induction significantly decreased in AβO-treated slices compared to that in DMSO-treated slices, which could be fully restored by optical stimulation of ChR2-expressing SST^+ interneurons to a level similar to that in DMSO-treated slices. These results show for the first time that reinstating SST^+ interneuron-mediated disinhibition during tLTP induction could restore tLTP impaired by AβO, indicating that SST^+ interneurons could be a potential therapeutic target for Alzheimer's disease.

Title: Optogenetic activation of parvalbumin-positive interneurons restores hippocampal theta-nested gamma oscillation impairment by Aβ oligomers

Authors: *K. PARK[1], J. LEE[1], M. M. KOHL[2], B. A. RICHARDS[3], J. KWAG[1];
[1]Dept. of Brain and Cognitive Engin., Korea Univ., Seoul, Korea, Republic of; [2]Dept. of Physiology, Anat. and Genet., Univ. of Oxford, Oxford, United Kingdom; [3]Biol. Sci., Univ. of Toronto Scarborough, Scarborough, ON, Canada

Abstract: Abnormal accumulation of amyloid beta oligomers (AβO) in the hippocampus is a hallmark of Alzheimer's disease (AD), which leads to learning and memory deficits. Hippocampal gamma (20 - 120 Hz) oscillations, generated by synchronized activation of reciprocally connected CA1 pyramidal cells (PCs) and parvalbumin-positive interneurons (PV^+ INs), contribute to memory function. This gamma oscillations have been shown to be impaired by AβO. However, the underlying synaptic mechanisms remain unclear due to experimental challenges in electrophysiological recordings of synaptic activity during gamma oscillations *in vivo*. Recent study showed that optical stimulation of channelrhodopsin-2 (ChR2)-expressing CA1 PCs at theta-frequency (5 Hz) could induce *in vivo*-like hippocampal theta-nested gamma oscillations *in vitro*. Using this experimental paradigm, we made targeted whole-cell current/voltage-clamp recordings from CA1 PC and PV^+ IN during theta-nested gamma oscillations in DMSO- and AβO-treated hippocampal slices. In DMSO-treated hippocampal slices, theta-nested gamma oscillations could be reliably induced with CA1 PC spike, CA1 PC-evoked excitatory postsynaptic currents (EPSCs) in PV^+ IN, PV^+ IN spike and PV^+ IN-evoked inhibitory postsynaptic currents (IPSCs) in CA1 PC each sequentially synchronized to a specific phase relative to the gamma oscillations. However, 20 min treatment with 200 nM AβO significantly reduced the peak power of gamma oscillations and also desynchronized spikes/synaptic currents of CA1 PC and PV^+ IN. In particular, AβO decreased the amplitudes of PV^+ IN-evoked IPSCs in CA1 PC and CA1 PC-evoked EPSCs in PV^+ IN during theta-nested gamma oscillations. Analysis of paired-pulse ratio and short-term plasticity of EPSCs in PV^+ IN and IPSCs in CA1 PC revealed that a presynaptic locus of dysfunction at reciprocal synapses between CA1 PC and PV^+ IN. Finally, to investigate whether optical activation of PV^+ IN could restore AβO-induced impairment of theta-nested gamma oscillations, we expressed C1V1 to PV^+ IN and ChR2 to CA1 PC in AβO-treated slices and optically stimulated them at 5 Hz with yellow and blue light, respectively, to find that activation of PV^+ IN restored the peak power of gamma oscillations to the level as observed in DMSO-treated slice by resynchronizing PV^+ IN and CA1 PC's spikes/synaptic currents relative to gamma oscillations. Our results show that presynaptic dysfunction of reciprocal CA1 PC and PV^+ IN synapses underlie AβO-induced impairment of theta-nested gamma oscillation, pointing towards PV^+ IN as a potential therapeutic target for AD.

Title: Interaction of Presenilin 1 with NMDA receptor: Effects of FAD mutants

Authors: *C. DIMOVASILI, M. A. RAHIM, A. GEORGAKOPOULOS, N. K. ROBAKIS; Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract: Mutations in presenilin 1 (PS1), account for the majority of familial Alzheimer's disease (FAD) cases. It has been reported that, besides its role as the catalytic component of γ-secretase complex, PS1 has also γ-secretase-independent functions such as neuroprotection and neurotransmitter trafficking. Importantly, PS1 has been reported to interact with transmembrane proteins including the NR1 subunit of the NMDA receptor. In addition to playing important roles in glutamate neurotransmission, NMDAR also modulates neurotrophin receptors and is critical to neuronal survival. Here we asked whether PS1 interacts with NR1 in brain, neurons and in an *in vitro* HEK293T cell system. To this end we coexpressed NR1 and WT PS1 holoprotein or its endo-proteolytic fragments NTF or CTF carried on PMX-IRES-GFP vectors, and tested the interaction by co-immunoprecipitation (co-IP) with anti-NR1 and anti-PS1 fragment-specific antibodies. Also, we coexpressed NR1 and WT PS1, M146V or I213T FAD mutants, constructed in our lab in the effective FCBAIGW vector and used co-IP experiments to test the interactions, as before. We found that both in neurons and in HEK293 cells overexpressing NR1 and PS1, the two proteins form complexes. Also, we obtained evidence that both full length PS1 as well as the PS1/NTF and PS1/CTF PS1 fragments associate with NR1. We also obtained preliminary evidence that the PS1-NR1 interaction is altered in cells expressing PS1 FAD mutants. Specifically, M146V and I213T tend to associate more potently with NR1 than WT PS1. The data that PS1 associates and possibly regulates the function of NMDAR reveals a possible connection of two major players of AD-related pathways. These data also provide a hopeful basis for attempts of therapeutic approaches, since targeting NMDAR function and/or its association with PS1 is a realistic goal for therapeutic interventions. Future studies will test this association on a functional level, focused on NMDAR regulation by PS1.

Title: Assessment of microglia influence in synaptic transmission and early amyloid-beta plaque deposition in knock-in mouse models of Alzheimer's disease

Authors: *D. P. BENITEZ[1], C. N. E. PEERBOOM[2], D. M. CUMMINGS[1], F. A. EDWARDS[1]; [1]Neurosci. Physiol. and Pharmacol., Univ. Col. London, London, United Kingdom; [2]Cell Biol., Utrecht Univ., Utrecht, Netherlands

Abstract: Genome-wide association studies have indicated that immune processes play an important role in Alzheimer's disease (AD). In transgenic mouse models, the expression of similar immune genes is altered in a tight correlation to amyloid-β (Aβ) pathology and are therefore potential targets for altering the progression of AD. Here we examine the role of microglia by blocking the microglial survival factor colony-stimulating factor 1 receptor (CSF1R) in APP knock-in mice (Saito et al, Nat Neurosci 2014;17:661) that harbour the Swedish and Beyreuther/Iberian mutations, with (NL-G-F) or without (NL-F) the Artic mutation. We then assess changes in CA1 hippocampal synaptic transmission and plasticity at an early stage of amyloidopathy.

NL-G-F mice were fed the selective CSF1R inhibitor PLX5622 (0, 300 and 1200 ppm of food) from 1.5-months-old for 7 weeks (i.e. prior to plaque deposition through to when the first plaques are detected). The low and high doses reduced IBA1+ microglial densities by ~50% and >95%, respectively but in control and 300 ppm PLX5622-fed animals, microglial counts were slightly higher in NL-G-F than wild type counterparts. The proportion of CD68+ microglia remained unchanged despite the changes in total microglial densities. The percentage coverage of the hippocampus by Aβ plaque was unaffected by treatment with PLX5622.

Assessment of CA3-CA1 hippocampal field excitatory postsynaptic potentials (fEPSPs) showed a larger input-output relationship in NL-G-F than in wild type animals. Paired-pulse ratios (PPRs) were identical between the genotypes (both fEPSPs and whole-cell excitatory postsynaptic currents -EPSCs). Treatment with PLX5622 had no further effect on either fEPSP slope or PPRs. Finally, the magnitude of long-term potentiation was similar, irrespective of genotype or drug treatment.

Long-term ablation of microglia was also studied in NL-F mice, which were fed PLX5622 from 7 to 10 months of age. Unlike the NL-G-F mice, when plaques were first detected at 9 months of age in the NL-F mice, PPRs were lower than in their wild type counterparts, indicating a higher probability of glutamate release. However, again, preliminary results show that the absence of microglia has no effect on PPRs.

These data indicate that, while NL-F and NL-G-F mice display different phenotypes regarding the probability of glutamate release at the stage when plaques are first detected, microglia have little effect on this. Similarly, ablation of microglia prior to the detection of plaques has no effect on plaque deposition, supporting the idea that the role of microglia in early AD is not removal of amyloid-β.

Title: Alterations in membrane excitability and synaptic properties of nucleus accumbens neurons in Alzheimer's disease mouse models

Authors: *S. S. GALLEGOS[1], E. J. FERNANDEZ[1], A. ARAYA[1], N. RIFFO[1], P. CISTERNAS[2], N. INESTROSA[2], B. MUÑOZ[3], B. K. ATWOOD[3], L. G. AGUAYO[1]; [1]Physiol., Univ. of Concepcion, Concepcion, Chile; [2]Dept. de Biología Celular y Molecular, Facultad de Ciencias Biológicas, Pontificia Univ. Católica de Chile, Santiago, Chile; [3]Dept. of Psychiatry, Indiana Univ. Sch. of Med., Indianapolis, IN

Abstract: Introduction
It is now recognized that clinical signs of Alzheimer´s disease (AD) involve impairment in brain functions including, but not limited to, language and memory. It is becoming clear that cognitive and executive functions predominantly mediated by limbic areas are also significantly affected in the disease. Recent studies investigating brain morphology and dementia showed alterations in the nucleus Accumbens (nAc). The nAc is a key component of the limbic reward system and is involved in cognition and emotional behaviors such as pleasure, fear, aggression and motivations; all affected in neurodegenerative diseases such as AD. Therefore, this study was initiated to examine if nAc was affected in AD animal models.

Results
Using Thioflavin-T (ThT), we detected the presence of amyloid plaques in the nAc of 2xTg (APP/PS1) mice, but not in the control WT aged mice (8-11 months). The presence of AD pathology was associated with alterations in membrane excitability and synaptic properties measured by recording dissociated medium spiny neurons (MSNs) from 2xTg (11 months) and J20 (14 months) mouse AD models. We found similar results in recordings of nAc MSNs in brain slices made from 5xFAD mice (6 months), another Alzheimer's disease mouse model strain. The whole cell recordings showed that several properties of action potentials, such as amplitude and firing, were affected in J20 and 5xFAD mice. On the other hand, most passive properties examined were unchanged, with the exception of input resistance. The J20 mice showed reduced amplitude of the AMPA-elicited current in dissociated neurons. In addition, inhibitory receptors appeared to be significantly affected in the three AD models. For example, the $GABA_A$-induced current desensitized to a larger extent with the second agonist application in J20 mice. The 2xTg mice exhibited a similar pattern to that observed in J20, but the magnitude

of the effects was less marked. In addition, the amplitude of inhibitory postsynaptic currents ($GABA_A$-mediated, IPSCs) elicited in the 5xFAD mice was also reduced.

Conclusions

Overall, these findings support the idea that increased Aβ production in the nAc can reduce inhibitory mechanisms affecting neuronal physiology, which might explain the higher excitability reported in AD models.

Title: Local synaptic PKR activation is involved in amiloyd-beta oligomer induced synapse degeneration

Authors: *N. W. MARTINEZ, S. MATUS, I. ALFARO;
Res. and Develop., Fundación Ciencia y Vida, Santiago de Chile, Chile

Abstract: Cognitive dysfunction during AD is strongly correlated with synaptic loss. Interestingly, local amyloid peptide beta (Aβ) accumulation has been related with nearby spine density reduction, changes in synaptic protein expression, synaptic morphology and neurotransmission. This suggests that synapse degeneration is mediated by a local synaptic response induced by Aβ. However, the molecular mechanism that mediates the Aβ induced synapse degeneration remains unknown. Recently, PKR activity has been related to Aβ induced significant LTP impairment at hippocampus and memory deficit. Furthermore, activation of PKR at CNS is a predictor of Alzheimer disease cognitive decline. Additionally, PKR co- localizes with histological features of Alzheimer pathology. However, the role of PKR in Aβ related synaptic morpho-functional changes remain unexplored. Considering this, we explore local synaptic PKR activation as a potential regulator of synapse degeneration induced by Aβ. To this goal, we explored the local activation of PKR at synapses by immunofluorescence analysis and

the role of PKR activation on synapse integrity in response to Aβ toxicity by 3D reconstruction of synaptic terminals. **Methods:** Local PKR activation was assayed by fluorescence intensity of phosphorylated PKR (Thr446) after colocalization with pre and post synaptic markers on 14DIV hippocampal neurons *in vitro*. Synapse integrity was analyzed by microscopy deconvolution and 3D reconstruction of EGFP transfected 14 DIV hippocampal neurons dendrites. Activation of PKR was induced by replacing neuronal culture media with Aβ oligomers containing conditioned media from CHO7PA2 cells. PKR activation was pharmacologically inhibited by addition of C16 (1 μM) to culture media. **Results:** PKR was found in discrete protein clusters in axonal and dendritic projections, partially colocalizing with pre- and post-synaptic compartments. We found that conditioned media containing Aβ oligomers induced a significant local activation of PKR at pre and post synaptic compartments on hippocampal neurons. Concomitantly, conditioned media containing Aβ oligomers induced morphological changes of post synaptic spines. Interestingly, synaptic integrity was preserved under pharmacological inhibition of PKR activation by C16 1μM. Discusions: These results suggest that PKR is a novel mediator of Aβ induced synaptic degeneration. However, whether induction of PKR activation by local Aβ oligomers leads to synapse degeneration as a local response remains unanswered. To address this, we are currently setting up live cell analysis of compartmentalized synapses in response to local treatment with Aβ oligomers.

Title: Modified mitochondrial function by histone deacetylase inhibitors in neuronal models of Alzheimer's disease

Authors: *I. L. FERREIRA[1], D. MARINHO[1], A. C. REGO[2];
[1]Univ. of Coimbra, Ctr. for Neurosci. and Cell Biol., Coimbra, Portugal; [2]Univ. of Coimbra, Ctr. for Neurosci. and Cell Biol. and Fac. of Med., Coimbra, Portugal

Abstract: Alzheimer’s disease (AD) is the most prevalent age-related neurodegenerative disorder associated with loss of neurons in the hippocampus, progressing to the cortex.

Extracellular senile plaques containing amyloid-beta peptide (Abeta) and intracellular neurofibrillary tangles constitute AD pathological hallmarks. Several molecular pathways have been described in AD, including repressed gene transcription, excitotoxicity and mitochondrial dysfunction; however, no effective therapeutics exist. In the present study we analysed the role of class I histone deacetylase inhibitors (HDACi), sodium butyrate (SB), suberoylanilide hydroxamic acid (SAHA) and tacedinaline (Tac), on mitochondrial function in AD hippocampal cells. Selective activation of *N*-methyl-D-aspartate (NMDA) receptor (NMDAR) containing GluN2B subunit leads to increased mitochondrial Ca^{2+} (mitoCa) retention along with mitochondrial hyperpolarization in 3xTg-AD, compared with WT hippocampal neurons. Both mouse hippocampal neurons and HT22 cells treated with nontoxic HDACi increased H3 histone acetylation. SB and Tac also prevented HT22 cytotoxic effects exerted by $Abeta_{1-42}$ oligomers (AbetaO). $Ca^{2+}{}_i$ levels evoked by NMDA/glycine decreased after SB, SAHA and Tac in 3xTg-AD, but not after immediate exposure to AbetaO in hippocampal neurons. However, enhanced mitoCa retention observed in NMDA/gly-stimulated 3xTg-AD neurons remained unchanged following HDACi treatment. Incubation with SB, SAHA and Tac significantly increased mmp after NMDAR activation in WT neurons, but only Tac showed this effect following immediate AbetaO exposure or in 3xTg-AD neurons. Data reveal the importance of defining the role of HDACs and their inhibitors in AD pathogenesis involving hippocampal glutamatergic synapses.

Title: Investigating the role of CD2AP, an Alzheimer's disease susceptibility gene, in mammalian synaptic structure and function

Authors: *M. PAVESKOVIC[1], S. A. OJELADE[2], B. T. PEKAREK[3], B. R. ARENKIEL[3], J. M. SHULMAN[2];
[1]Neurosci., [2]Neurol., [3]Mol. and Human Genet., Baylor Col. of Med., Houston, TX

Abstract: *CD2-Associated protein* (*CD2AP*) is an Alzheimer's disease (AD)-susceptibility gene that has a largely unknown role in the mammalian nervous system. In *Drosophila,* the *CD2AP* homolog, *cindr*, genetically interacts with tau neurotoxicity and modulates protein turnover and synaptic function. Based on studies using either an *in vivo* reporter (*Elav>GFP-CL1*) or direct biochemical assays, proteasome activity is compromised in *cindr* mutants. We also discovered

reduced expression of multiple regulatory subunits of the ubiquitin proteasome system (UPS) in *cindr* mutants, and genetic manipulation of the UPS phenocopies loss of *cindr*. Further supporting a defect in protein turnover, mutant flies have increased expression of the synaptic protein Synapsin as well as the Plasma Membrane Cytoplasmic ATPase (PMCA). Consistent with this, neurophysiologic studies at the *Drosophila* larval neuromuscular junction reveal impaired synaptic transmission and plasticity. Brain homogenates from *CD2AP*$^{-/-}$ mice show consistent changes in UPS activity and aberrantly increased levels of Synapsins1-3 and PMCA. Moreover, in mouse primary neuronal cultures *CD2AP* loss causes altered synapse structure, including decreased dendritic branching and increased PSD95 expression. In ongoing studies, we are also investigating potential electrophysiological changes in primary cultures. We are also generating a *CD2AP* conditional knockout strain (*CD2AP* cKO) to examine the *in vivo* consequences of neuron-specific loss for proteostasis and synaptic structure/function. Our results will inform both an understanding of requirements of *CD2AP* in the adult mammalian brain, as well as provide clues to its impact on AD pathogenesis.

Title: Alzheimer’s disease pathogenesis: The denied access model

Authors: *S. XU[1], W. DAUBERMAN[2];
[1]Florida Inst. of Technol., Melbourne, FL; [2]Biomed. Chem. Engin. and Sci., Florida institute of Technol., Melbourne, FL

Abstract: Amyloid plaques are hydrogels and their physical properties in Alzheimer’s disease pathogenesis are examined. In nature, hydrogels can be formed by fibers of aggregated proteins and polysaccharides. Examples of protein fibers like fibrin, gelatin and amyloid plaques, and polysaccharide gels like agarose gels, starch gels, and fruit jello. From a physics perspective, hydrogels are known to be capable of blocking fluid flow (Woodard et al. 2014). However, fluid movement is critical in circulating ions and molecules to and from cells including neurons to maintain cell homeostasis. When fibrin hydrogels are formed around nerve fibers, the propagation of action potential was reduced by 40% (Dauberman et al., 2017). Images of atomic force microscopy and transmission electron microscopy indicate that amyloid plaques have pore sizes much smaller than those in the fibrin gels, and the fiber bundles in the amyloid plaques would further reduce the pore size and then the transport of ions and molecules. Viscosity

analysis using a molecular rotor, 9-(2-carboxy-2-cyanovinyl)julolidine, for the change of the fluorescence intensity, shows a 42% increase in the viscosity of the media during hydrogel formation. Since Brownian motion and then diffusivity is dependent on viscosity, hydrogel formation, as occurred in amyloid plaque deposition, would also reduce the diffusion of molecules and ions in addition to the effect on fluid bulk flow. Indeed, diffusivity of amyloid plaques in AD brain is 47% lower than the surrounding normal tissue when analyzed using the method of fluorescence recovery after photobleaching. Buried inside each of the amyloid plaques in AD brain are thousands neurites. In theory, each plaque can then compromise the function of a large number of neurons. Such evidence led us to propose the denied access model in Alzheimer's disease pathogenesis, that amyloid fibers can further aggregate and form hydrogels, and the hydrogels are capable of eliminating bulk flow and reducing diffusion, which then attenuates the circulation of ions and molecules that are essential for neuronal function.

Title: The Alzheimer's disease risk gene BIN1 regulates neuronal hyperexcitability

Authors: *Y. VOSKOBIYNYK, J. ROTH, J. COCHRAN, T. RUSH, K. M. GREATHOUSE, N. CARULLO, L. L. MCMAHON, J. H. HERSKOWITZ, J. J. DAY, E. D. ROBERSON; Univ. of Alabama at Birmingham, Birmingham, AL

Abstract: Alzheimer's disease (AD) affects about five million Americans, who receive only a very modest benefit from current treatment options. Multiple clinical trials have failed in the past, raising interest in identifying new targets to treat AD. Genome wide association studies (GWAS) have identified bridging integrator 1 (*BIN1*) as one of the leading genetic risk factors in AD. Neurons express a unique BIN1 isoform, though the function of this isoform remains unclear and its contribution to AD is critical to investigate. A key question for the role of neuronal BIN1 in AD pathophysiology is whether it has a direct effect on the neuron's primary function - neuronal firing. To address this question, we developed a human neuronal isoform

BIN1 vector and evaluated the effects of BIN1 overexpression in primary hippocampal cultures. First, we determined that robust AAV-driven BIN1 overexpression increases spike and burst frequency on multielectrode arrays. Next, we determined that sparse transient transfection-driven BIN1 overexpression increases calcium influx of transfected neurons on calcium imaging of GCaMP6f calcium indicator. In addition, we determined that higher BIN1 levels induced changes in both excitatory and inhibitory synaptic transmission. To investigate the mechanism by which higher BIN1 induces network hyperexcitability, we evaluated the effect of higher BIN1 levels on intrinsic neuronal excitability using whole-cell patch clamp electrophysiology. In addition, we evaluated the effect of higher BIN1 level on both neuronal morphology by determining the complexity of dendritic arbors and spine morphometry. These data show BIN1's important role in regulating neuronal firing and network hyperexcitability and generate fundamental insights about the mechanistic role BIN1 plays in AD.

Title: Tau-SH3 interactions are critical mediators of amyloid-β toxicity in primary neurons

Authors: *J. R. ROTH, T. J. RUSH, S. J. THOMPSON, A. R. ALDAHER, J. S. MESINA, J. COCHRAN, E. D. ROBERSON;
Univ. of Alabama at Birmingham, Birmingham, AL

Abstract: The microtubule-associated protein Tau is strongly implicated in Alzheimer's disease (AD) and aggregates into neurofibrillary tangles in AD. Genetic reduction of Tau is protective in several animal models of AD and cell culture models of amyloid-β (Aβ) toxicity, making it an exciting therapeutic target for treating AD. A variety of evidence indicates that Tau's interactions

with Fyn kinase and other SH3 domain-containing proteins, which bind to PxxP motifs in Tau's proline-rich domain, may contribute to AD deficits and Aβ toxicity. Thus, we sought to determine if inhibiting Tau-SH3 interactions ameliorates Aβ toxicity. We developed a peptide inhibitor of Tau-SH3 interactions and a proximity ligation assay (PLA)-based target engagement assay. Then, we used membrane trafficking and neurite degeneration assays to determine if inhibiting Tau-SH3 interactions ameliorated Aβ oligomer (Aβo)-induced toxicity in primary hippocampal neurons from rats. We verified that Tau reduction ameliorated Aβo toxicity in neurons. Using PLA, we identified a peptide inhibitor that reduced Tau-SH3 interactions in HEK-293 cells and primary neurons. In primary neurons, endogenous Tau-Fyn interaction was present primarily in neurites and was reduced by the peptide inhibitor, demonstrating target engagement. Reducing Tau-SH3 interactions in neurons ameliorated Aβo toxicity by multiple outcome measures, namely Aβo-induced membrane trafficking dysfunction and neurite degeneration. Our results indicate that Tau-SH3 interactions are critical for Aβo toxicity and that inhibiting them is a promising therapeutic target for AD.

Title: Hyperexcitability in Alzheimer's disease hiPSC derived neurons and cerebral organoids is a result of both increased excitation and decreased inhibition

Authors: ***S. GHATAK**[1], N. DOLATABADI[1], R. GAO[3], D. TRUDLER[1], Y. WU[1], X. ZHANG[1], A. SULTAN[4], M. V. TALANTOVA[1], R. AMBASUDHAN[4], B. VOYTEK[3], S. A. LIPTON[2];

Abstract: Human Alzheimer's disease (AD) brains manifest hyperexcitability. This aberrant electrical activity is caused, at least in part, by neurite degeneration and ion channel dysfunction contributing to synaptic dysfunction (Siskova et al., Neuron 84, 1023-1033 (2014)) which represents the major pathophysiological correlate of cognitive decline. However, the underlying mechanism for this excessive excitability remains incompletely understood. To investigate the basis for the hyperactivity, we performed patch-clamp recordings, Ca2+-imaging, and immunofluorescence studies on hiPSC-derived cerebrocortical neuronal cultures and 3D cerebral organoids bearing AD-related mutations in presenilin 1 or amyloid precursor protein vs. controls. We found increased hypersynchronous electrical activity in AD hiPSC-derived neurons and in organoids compared to gene-corrected isogenic controls. Sodium currents in AD hiPSC-derived neurons showed increased amplitude and faster kinetics. AD hiPSC-derived neurons also displayed shorter neuritic processes. Additionally, AD hiPSC-derived neurons exhibited increased frequency and amplitude of miniature excitatory postsynaptic currents (mEPSCs) but decreased frequency of miniature inhibitory postsynaptic synaptic currents (mIPSCs). Along similar lines, we found that AD hiPSC-derived neurons manifested a smaller number of inhibitory neurons, lower VGAT levels/synapses, and diminished GABA-evoked whole-cell currents, while glutamate-evoked currents were larger in amplitude. Taken together, these results indicate that both active and passive mechanisms underlie the hypersynchronous excitatory burst activity of these neurons. Both pre- and postsynaptic changes are also involved that affect ion channel, vesicular release, and receptor properties. Importantly, the new dual allosteric-acting NMDAR antagonist NitroSynapsin, but not the FDA-approved drug memantine, robustly abrogated this hyperactivity in both hiPSC-derived cerebrocortical neuronal cultures and 3D cerebral organoids, while virtually sparing physiological synaptic activity. Our findings establish hiPSC-derived AD neurons as a relevant model of the aberrant hyperexcitability that is known to occur in human AD brain. Moreover, we suggest that hiPSC models of AD are suitable for initial drug screening aimed at decreasing excessive excitation and improving synaptic function.

Title: Membrane cholesterol homeostasis is regulated by amyloid precursor protein at axon terminals

Authors: *Q. Z. ZHANG[1], O. PELLETIER[2], S. ALAMGIR[2], H. HUANG[3], C. R. SANDERS[3]; [1]Biomed. Sci., Florida Atlantic Univ., Jupiter, FL; [2]The Brain Inst. at FAU, Jupiter, FL; [3]Vanderbilt Univ., Nashville, TN

Abstract: Cholesterol (Chol) is crucial for lipid membrane fusion and fission and thus greatly influences synaptic vesicle (SV) release and retrieval. SV membrane has the highest Chol content than any other neuronal membrane compartments, including the plasma membrane at the presynaptic active zone. Presynaptic terminals often undergo much more lipid exchange than any other parts of neurons. Moreover, long and thin axons lack Golgi and endoplasmic reticulum, in which cellular Chol sensor and regulator reside. Therefore, a local membrane Chol (mChol) sensor/regulator at presynaptic terminals is needed. Our previous studies have revealed that amyloid precursor protein (APP) at presynaptic surface membrane exhibits an inverse correlation to presynaptic mChol, which requires its Chol-binding motif (CBM). In the current study, we test if APP directly regulates mChol homeostasis at presynaptic terminals. First, we devise two ratiometric methods to monitor mChol fluctuation accompanied with SV exo-/endocytosis in live neurons. Second, we bidirectionally manipulate whole-cell Chol or plasma mChol and elucidate their impact on presynaptic mChol homeostasis during neuronal firing. Third, we implement a collection of APP point mutations associated with familial Alzheimer's disease (fAD), which are either outside or within its CBM and alters APP's trafficking or affinity to mChol. Our data illustrate how these APP mutants alters presynaptic mChol homeostasis, SV turnover and synaptic transmission. Fourth, we survey presynaptic Ca^{2+}-homeostasis, membrane integrity, SV organization and Tau hyperphosphorylation in mutant-expressing neurons. Our results not only reinforce the idea that APP is a presynaptic mChol sensor/regulator, but also indicate that the pathological contribution of those fAD mutations is likely through the disruption of presynaptic mChol homeostasis instead of the promotion of beta-amyloid aggregation.

Title: The damage of astrocytes induced by fatty acids may contribute to diabetic encephalopathy

Authors: *D. LI[1], F. MA[2], S. SHI[2], X. WANG[2];
[1]Pharmacol., Chinese Acad. of Med. Sci., Beijing, China; [2]Inst. Materia Med., Beijing, China

Abstract: Disturbance of glucose and lipid metabolism related with Diabetes could lead to diabetic encephalopathy (DE). The incidence of dementia was about twice as high as in the non-diabetic group of the same age. In our study with KK-A^y diabetic mice, it was found that in the early stage of diabetes, about 3-5-month-old mice, neuron damage was relatively mild, while glial cells showed obvious lesions. Further study found that increased levels of blood glucose and lipids could not significantly cause changes to neurons, but could cause damage to astrocytes, especially the fatty acids represented by palmitic acid (PA), which aggravate the apoptosis of astrocytes. The expression of fatty acid transporter, CD36 on astrocytes was about 3 times higher than that of neurons. Sulfo-N-succinimidyloleate (SSO), an inhibitor of CD36, could significantly reduce the uptake of PA and subsequently decrease the damage of PA to astrocytes. After entering astrocytes, PA significantly increased the release of Ca2+, the content of ceramide and oxidative stress injury, while SSO could reduce the above substances and cell apoptosis. In the co-culture experiments of neurons and astrocytes, it was further found that astrocytes could significantly protect neurons and reduce the damage to neurons induced by glutamate. When PA was added, the protective effect of astrocytes on neurons decreased. SSO could restore the protective effect of astrocytes. It is demonstrated that astrocytes could clear fatty acids in the brain. Therefore, at the early stage of DE, neurons do not damage seriously. However, neurons injury increased as the state of astrocytes become worse due to continuously damage of fatty acids. DE is different from AD because it is reversible by low-fat diet or medicine treatment.
Conclusion: the injury of astrocytes caused by fatty acids is an important cause of diabetic encephalopathy. CD36, an important fatty acid transporter in astrocytes, may be a potential therapeutic target for diabetic encephalopathy.

Title: *In vitro* modelling of progressive tauopathy in neuronal circuits using a novel high throughput assay platform

Authors: *S. ILLES, A. KARLSSON, P. KARILA, J. PIHL, M. KARLSSON;
Cellectricon AB, Mölndal, Sweden

Abstract: The appearance and spreading of misfolded tau protein within patient brain cells are common neuropathological hallmarks in several types of dementia (e.g. Alzheimer's disease, Pick´s disease and frontotemporal dementia). Deciphering the mechanisms behind uptake, spreading, aggregation, and propagation of tau is of high relevance for preclinical medical research programs.
Here, we combined our previously established optical electrophysiology system with a newly developed microfluidics platform to create a unique, high throughput *in vitro* assay platform. This platform allows for the assessment of spreading of neuropathological processes within spatially separated neuronal circuits. Furthermore, the screening plate design allows for local induction and intervention of neuropathology.
In detail, E18 mouse cortical neurons plated in wells of custom-developed microplates develop extensive processes and form functional synaptic connections within 14 days. Fluorescently labelled heparin-induced tau filaments were applied to cortical cultures to evaluate dose- and time-dependency of tau seed uptake and well-to-well spreading in cortical axons. By using sarkosyl-insoluble tau extracted from AD brain tissue, we describe concentration- and time-dependent AD tau-caused cell death and tau aggregation. Furthermore, we demonstrate that AD tau causes axonal retrograde spreading of tau aggregation.
The assay platform described here shows sufficient capacity and robustness to allow for screening and profiling of larger compound sets, in the search for molecules preventing progressive tauopathy processes spreading across synaptically coupled neurons.

Title: The neuroprotective actions of an active core sequence of amyloid beta on amyloid beta-induced neurotoxicity involves cellular prion protein

Authors: *R. M. TAKETA[1], R. A. NICHOLS[2];
[2]Cell and Mol. Biol., [1]Univ. of Hawaii, Honolulu, HI

Abstract: Alzheimer's disease (AD) is a devastating neurodegenerative disorder characterized by cognitive decline and memory loss. Currently, there is no cure and the exact cellular mechanism underlying the disease is still unknown. Pathological aggregation of soluble beta-amyloid (Aβ) into insoluble Aβ-plaques is one of two hallmarks of the disease, the other being hyperphosphorylated tau. The production of Aβ is through sequential enzymatic cleavage of the amyloid precursor protein (APP) resulting in a series of Aβ peptides. The most well-known, $A\beta_{1-42}$ ($A\beta_{42}$) is a primary component of Aβ-plaques and underlies synaptic dysfunction and neurotoxicity. Our laboratory has shown that in the presence of high affinity nicotinic acetylcholine receptors (nAChRs), low "physiological" levels of $A\beta_{42}$ (pM-nM) sensitize neurons to $A\beta_{42}$-induced toxicity, while high levels of $A\beta_{42}$ (μM) induce apoptosis independently of nAChRs, verifying the neuromodulator functions of $A\beta_{42}$. In contrast, we've shown an endogenously cleaved N-terminal Aβ Fragment (N- $A\beta_{1-15,16}$) and an essential core sequence, YEVHHQ (N- Aβcore) within it, is neuroprotective against $A\beta_{42}$-induced oxidative stress and apoptosis in *vitro* and ex *vivo* studies.
Here, we investigated the mechanism of the N- Aβcore in our neuroblastoma cell line and primary hippocampal cultures through high affinity targets for Aβ, such as nAChRs and cellular prion (PrP^c). We utilized a neuronal cell line null of functional nAChRs and methods such as monoclonal antibodies, to preferentially block, knockdown, and/or delete target receptors to assess the impact on neuroprotection. In primary hippocampal cultures, attenuation of elevated reactive oxygen species (ROS) via an anti-PrP^c antibody were similar to those mediated by the N-Aβcore at pathological concentrations of $A\beta_{42}$. In order to further understand the cellular mechanisms of the N- Aβcore, we examined markers for cellular stress, apoptosis, and synaptotoxicity. Differential receptor-linked protein levels downstream of nAChRs and PrP^c were compared via immunoblotting and immunohistochemistry.
Delineating the neuroprotective molecular mechanisms of the N- Aβcore will provide essential guidance for future use as a potential therapeutic. In addition, it will dissect the multiple and perhaps converging pathways involving nAChRs and PrP^c in $A\beta_{42}$-induced toxicity.

Title: Modulation of voltage-gated calcium channels via protofibrillar amyloid-β

Authors: *E. KAISIS, L. THEI, G. STEPHENS, M. DALLAS;
Sch. of Pharm., Univ. of Reading, Reading, United Kingdom

Abstract: The amyloid-cascade hypothesis proposes that one of the main protagonists in Alzheimer's disease is oligomeric amyloid-β (Aβ). Protofibrillar $A\beta_{1-42}$ induces cytotoxicity through various signalling cascades, including calcium dysregulation through neuronal voltage-gated calcium channels (VGCCs). SH-SY5Y cells express a host of VGCCs. Within undifferentiated cells, $Ca_v1.2$, $Ca_v1.3$, $Ca_v2.2$ and $Ca_v3.1$ were detected at gene level (PCR). Upon retinoic acid (RTA; 10μM; 3 days) differentiation, a reduction in $Ca_v3.1$ was observed. No expression of $Ca_v1.1$, $Ca_v1.4$, $Ca_v2.1$, $Ca_v2.3$, $Ca_v3.2$ and $Ca_v3.3$ at gene level was detected in SH-SY5Y of both differentiation states. Here, we examine the role of protofibrillar $A\beta_{1-42}$ on modulating VGCCs. Transmission electron microscopy, demonstrated time-dependent formation of $A\beta_{1-42}$ protofibrils (>100nm in length), prepared via pre-treatment in NH_4OH and further dilution in 2% SDS/PBS over a 48hr incubation period. XTT viability experiments revealed that exposure to protofibrillar $A\beta_{1-42}$ (24hr) induced neurotoxicity in undifferentiated SH-SY5Y, at a concentration-dependent manner, with 3μM (78.9±6.1%; n=11; $P<0.05$) and 10μM (76.1±6.8%; n=8; $P<0.01$) significantly reducing viability. In contrast, 100nM $A\beta_{1-42}$ (3.7±5.5%; n=16; NS) and 1μM (2.7±5.4%; n=17; NS) did not induce cytotoxicity. In parallel, PCR gene expression analysis revealed a reduction in $Ca_v1.3$ expression (19.0±4.3%; n=5; $P<0.05$) with 100nM $A\beta_{1-42}$ treatment (24hr) and an increase in $Ca_v1.2$ expression (78.7±14.9%; n=3; $P<0.05$) with 1μM $A\beta_{1-42}$ treatment (24hr), demonstrating differential $A\beta_{1-42}$ concentration-dependent modulation of VGCCs. Collectively, our work demonstrates that protofibrillar $A\beta_{1-42}$ can induce neurotoxicity, and can modulate VGCCs through changes in gene expression. Our work will aid the understanding of amyloid pathology, and highlight the potential to target VGCCs to suppress Aβ neurotoxicity. Ongoing work will investigate the effect of protofibrillar $A\beta_{1-42}$ on VGCCs at functional level (whole-cell patch clamp), and address novel VGCC modulators, which may go on to provide a novel therapeutic strategy to tackle dementia.

Title: Modulation of protein synthesis' regulators by amyloid beta oligomers

Authors: *F. CAMPOS RIBEIRO, D. COZACHENCO FERREIRA, F. GUARINO DE FELICE, S. TEIXEIRA FERREIRA;
Federal Univ. of Rio De Janeiro, Rio de Janeiro, Brazil

Abstract: Synapse loss is a key feature of Alzheimer's disease (AD) and the best correlate of cognitive decline in AD patients. Nevertheless, the specific mechanisms that mediate reduction of synaptic proteins and, ultimately, synapse elimination in AD remain to be fully understood. Reduced brain protein synthesis (translation) is an additional feature of AD that could explain the reduction in synaptic proteins. However, the interplay between the many regulators of translation during the course of the disease is not well established, with controversial literature reports on the levels of regulators of translation in AD and their roles in disease. Here, we have investigated levels of major regulators of protein synthesis using Western blotting in hippocampal extracts from mice that received an intracerebroventricular (i.c.v.) infusion of Aβ oligomers (AβOs),which are implicated as proximal synaptotoxins in AD. We found that AβOs trigger decreases in levels of p-eIF4E, p-4EBP1, p-S6K, p-S6, p-ERK, p-mTOR, and an increase in the levels of ATF4 in the hippocampi of mice 7 days, but not 24 h, after i.c.v. infusion of AβOs. Results thus, indicate that positive regulators of translation are reduced, while a translational repressor (ATF4) is enhanced in the hippocampi of AβO-infused mice. Future studies will attempt to correlate these findings with inhibition of translation in AD models and further investigate the specific role of each of these proteins in aberrant regulation of brain protein synthesis in AD.

Title: Synaptic failure and mitochondrial dysfunction are induced by direct interaction of soluble oligomers of beta amyloid with mitochondrial membranes

Authors: *J. PANES-FERNÁNDEZ, J. GAVILÁN, P. A. GODOY RIVERA, T. B. SILVA-GRECCHI, O. RAMÍREZ-MOLINA, N. MUNOZ-MOLINA, C. MUNOZ-MONTECINO, J. FUENTEALBA;
Univ. de Concepción, Concepción, Chile

Abstract: Alzheimer's disease (AD) is a neurodegenerative disorder characterized by impaired learning and memory loss. Amyloid beta peptide (Aβ) plays a key role in the pathogenesis of AD, especially soluble oligomers (SO-Aβ) because can reproduce the major aspects of the

disease.In vitro studies have associated mitochondrial dysfunction with an early role in the AD; however, the molecular events that underlie this effect are not understood with precision. In this work, we have studied the intracellular effects of acute and chronic SO-Aβ treatments, on key parameter of mitochondria functionality; morphology and mitochondrial potential. To develop this research, we use hippocampal primary cultures and hippocampal slices. First, using immunofluorescence techniques we performed colocalization analysis of fluorescent Aβ (Aβ-FAM) with an outer mitochondrial membrane marker (TOM20 antibody). We found that the degree of colocalization between Aβ and TOM20 was increasing, presenting a maximum of colocalization at 24 h of SO-Aβ treatments, with a Manders coefficient (0.640 ± 0.1). In parallel, we evaluated the mitochondrial membrane potential (ΔΨm) using the JC-1 probe, we observed that at chronic treatments (24h), SO-Aβ shown a decrease on ΔΨm near to 50% of the control conditions. Additionally, at the same times (SO-Aβ, 24h) strong changes were observed in the size of the mitochondrial network in primary cultures, displacing the equilibrium towards a more granular pattern in mitochondria that present a positive colocalization with Aβ. Secondly, the intracellular distribution of SO-Aβ (2.5uM) in a mouse hippocampal slices model was evaluated by immunohistochemistry (IHC) and electron transmission microscopy (TEM), Using the immunogold technique, we observed the presence Aβ targeted with gold nanoparticles in an intramitochondrial zone. On the other hand, it was observed that ΔΨm showed a progressive decrease in time manner on hippocampal slices under SO-Aβ treatments (JC-1590/520 C: 1.01 ± 0.01; SO-Aβ 40min: 0.94 ± 0.03; SO-Aβ 3h: 0.78 ± 0.04). This study suggest a new pathogenic mechanism in AD, where cytotoxic effects of SO-Aβ are related with their direct interaction with the mitochondria, and reveals a novel therapeutic strategies for neuroprotection.

Title: GAL-101 prevents beta-amyloid induced membrane depolarization in two different types of retinal cells

Authors: *C. G. PARSONS[1], M. MAZZANTI[2], S. V. GORNATI[3], E. PIZZI[4], G. RAMMES[5]; [1]Galimedix, Kensington, MD; [2]Univ. di Milano, Milano, Italy; [3]Erasmus MC, Rotterdam, Netherlands; [4]Univ. of Milan, Milano, Italy; [5]Clin. Rechts der Isar, Munich, Germany

Abstract: Glaucoma and age-related macular degeneration (AMD) are two of the major causes of progressive loss of vision and ultimate blindness worldwide. Retinopathies share several pathological features with Alzheimer´s disease (AD). Among other neurodegenerative events, in AD abnormalities in the retina such as visual function impairment, optic neuropathy, retinal ganglion cell (RGC) loss, decreased number of optic nerve fibres, astrocytosis and activation of immune competent microglia and Muller cells are evident. AD as well as glaucoma and AMD are characterized by the presence of elevated concentrations of amyloid beta (Aβ) peptide. Under such conditions $A\beta_{1-42}$has the tendency to aggregate forming toxic soluble oligomers that are now considered to be the most harmful amyloid species. One strategy adopted to prevent cell damage caused by these soluble toxic oligomers is to impair their aggregation. In the present work, using electrophysiological patch clamp measurements, we show that exposure of acutely isolated retinal cells to $A\beta_{1-42}$ caused a strong depolarization of the resting potential of the plasma membrane. The average resting membrane potential of cultured RGCs and retinal pigment epithelium (RPE) cells was -68.3 ± 1.9 mV and -40.2 ± 2.4 mV respectively. Acute application of $A\beta_{1-42}$ depolarized the membrane potential of RGCs with an $EC_{50}$of 44.1 ± 6.3 nM and a maximal effect at 100 nM to around -10 mV. Higher concentrations of $A\beta_{1-42}$ were required to cause depolarization of RPE cells (EC_{50}= 790 ± 80 nM). GAL-101 is a small D-amino acid dipeptide that modulates $A\beta_{1-42}$ aggregation by triggering a non-amyloidogenic aggregation pathway and thereby reduces the amount of intermediate toxic soluble oligomeric $A\beta_{1-42}$ species. Pre-incubation of RGCs for one hour with a 20:1 ratio was able to stabilize the cell resting potential to around -50 mV. Similar effects were seen with a 20:1 ratio of GAL-101 to $A\beta_{1-42}$ for RPE cells. Under therapeutic conditions, e.g. in the treatment of dry AMD or glaucoma, the pathological changes are more subtle in that there are much lower elevated concentrations of Aß but these persist chronically. Stoichiometric requirements for GAL-101 in relation to Aß would therefore no longer be an issue, but rather be superseded by the true affinity of GAL-101 for Aß of around 30 nM.

Abstract: Previous studies have shown that the administration of the $A\beta_{25-35}$ peptide in the hippocampus and the *medial septum* produces learning and spatial memory impairment and changes in cholinergic markers. I*n vitro* and *in vivo* studies show that $A\beta_{25-35}$ decreases the expresión of the nuclear factor erythroid 2-related factor 2 (Nrf2) in the hippocampuss. However there is no evidence about the efect of the administration of $A\beta_{25-35}$ into white matter like fornix. The aim of the study was to evaluate the effect of the administration of $A\beta_{25-35}$ into the precomisural fórnix on spatial memory, activity of acetylcholinesterase (AChE) and expression of Nrf2. Male Wistar rats were used and four experimental group were formed: control, SSI, $A\beta_{25-35}$ and KA. The rat were injected with 2 μL of SSI, KA (as positive control) or $A\beta_{25-35}$ [1mM] into the fornix.The learning assesment was made in eight-arm radial maze (Med Associates) at 21 days post injection and after 17 days of the test, the spatial memory was evaluated. The brain were obteined to asses the activity of a cholinergic marker like AChE in *medial septum* and hippocamppus by the Ellman assay and also a transcription factor like Nr2 in *medial septum* by immunofluorescence. Our findings shows that the injection of $A\beta_{25-35}$ into the fornix causes learning but not memory impairtment. Also, it causes a decrease of AChE´s activity in hippocamppus but not in *medial septum* and modifies the expresión of Nrf2 in *medial septum* fourty days after injection. These results suggest that $A\beta_{25-35}$ peptide can damage the axons which impairs the neural communication and causes learning impairment, decrease of the activity of the AChE in the hippocampus and the cytoplasmic localization of Nrf2 in the medial septum neurons that indicates a reduction in the antioxidant response.

Title: Association of aβ with astrocyte-derived and ceramide-enriched exosomes mediates aβ mitotoxicity in neurons which is prevented by novel ceramide analogs

Authors: *A. ELSHERBINI, H. QIN, Z. ZHU, S. KARKI, S. CRIVELLI, P. TRIPATHI, G. WANG, E. BIEBERICH;
Univ. of Kentucky, Lexington, KY

Abstract: The cause for neurotoxicity of Aβ in Alzheimer's disease (AD) is still not clear. Here, we show that serum from 5xFAD mice and AD patients, but not serum from wild type mice or healthy human controls contains a proportion of ceramide-enriched and astrocyte-derived (GFAP positive) exosomes termed astrosomes that are associated with Aβ. The novel ceramide analog N-oleoyl serinol (S18) prevented Aβ association with astrosomes suggesting that ceramide-mediated binding of Aβ to astrosomes. In contrast to Aβ alone, Aβ-associated astrosomes increased neurite fragmentation and neuronal cell death by 3-fold, suggesting that association with astrosomes enhanced Aβ neurotoxicity. Aβ-associated astrosomes from familial AD (5xFAD) mice and AD patient serum were taken up by mouse Neuro 2a cells and human iPS cell-derived neurons. They were transported to mitochondria and increased the concentration of Aβ and ceramide, induced mitochondrial clustering, and upregulated the fission protein Drp-1. We tested if Aβ-associated astrosomes mediated binding of Aβ to VDAC1, an ADP/ATP transporter known to form pro-apoptotic pores in mitochondria when bound to Aβ. Aβ-associated astrosomes induced complex formation between Aβ and VDAC1 concurrent with caspase activation. Complex formation and caspase activation were not observed with exosomes from wild type and human control serum or Aβ alone. Our data suggest that the association of Aβ with ceramide in astrosomes enhances Aβ interaction with VDAC1 and mediates Aβ neurotoxicity in AD, which can be prevented novel ceramide analogs.

Title: Comparison of salivary Aβ levels and oral microbiome in two different mouse models of AD

Authors: *A. M. FLODEN, M. SOHRABI, S. NOOKALA, G. D. MANOCHA, C. K. COMBS; Biomed. Sci., Univ. of North Dakota, Grand Forks, ND

Abstract: The amyloid precursor protein (APP) is robustly expressed by neurons. APP is proteolyzed into the peptide fragment, amyloid β (Aβ), which can aggregate to form extracellular plaques associated with Alzheimer's disease brains. However, APP is expressed by numerous cell types where its proteolysis and function remain less clear. For example, our prior work demonstrated robust expression of APP in intestinal epithelial cells which are also capable of producing and secreting Aβ. Based upon this finding, we hypothesized that salivary gland epithelium would also express APP and secrete Aβ peptide. To test this idea, we first verified immunoreactivity of APP and Aβ in ductal epithelium of control and AD salivary glands. We next assessed the consequences of APP expression and metabolism using male and female C57BL/6 wild type and $APP^{-/-}$ mice compared to two transgenic mouse models of AD, APP/PS1 and $App^{NL\text{-}G\text{-}F}$ mice. As observed in human samples, APP was robustly expressed in ductal epithelium of wild type, APP/PS1, and $App^{NL\text{-}G\text{-}F}$ mice. To quantify proteolysis of APP, we measured salivary Aβ levels. Only $App^{NL\text{-}G\text{-}F}$ saliva contained Aβ 1-42 with no detectable Aβ 1-40 in either APP/PS1 or $App^{NL\text{-}G\text{-}F}$ mice. No significant differences in total volume or flow rate were observed across genotypes. In order to examine consequences of attenuated or mutant APP expression on oral health, cavities and oral microbiome were assessed. There were no increases in cavity numbers in male or female APP/PS1 and $App^{NL\text{-}G\text{-}F}$ compared to wild type mice. However, male but not female $APP^{-/-}$ mice had increased cavities compared to wild type mice. Sequencing of oral microbiome from each line demonstrated that $App^{NL\text{-}G\text{-}F}$ mice had significantly higher abundance of the phyla Firmicutes and lower abundance of Proteobacteria compared to wild type mice. Consistent with the lack of detectable saliva Aβ 1-42 from APP/PS1 mice, this line demonstrated no differences in Firmicutes or Proteobacteria compared to wild type mice. These data indicate that APP expression outside of neurons may have specific effects on other organ systems that may or may not be relevant to AD. In addition, we have found that APP expression or its metabolites influences the oral microbiome in at least one transgenic mouse model of AD.

Title: Expression of P2X2 purinergic receptor in N2a differentiated cells, as a model to study amyloid beta related pathways

Authors: *P. A. GODOY[1], I. CUCHILLO-IBAÑEZ[2,3], D. MENNICKENT[1], O. RAMÍREZ-MOLINA[1], T. B. SILVA-GRECCHI[1], J. PANES-FERNÁNDEZ[1], J. GAVILÁN[1], J. SÁEZ-VALERO[2,3], J. FUENTEALBA[1];

Abstract: Purinergic receptors P2X (P2XR) are a family of trimeric receptors activated by ATP. Seven subunits have been described in mammals, from P2X1 to P2X7, with different affinities for the ligand, expression pattern and ion permeability. There are two main isoforms of P2X2 receptor, P2X2a and P2X2b. The longest isoform, P2X2a, is capable to interact with Fe65, an adaptor protein able to interact with the amyloid precursor protein (APP) and regulate its endocytosis and amyloidogenic processing. P2XR expression pattern is regulated in target tissues and cells during differentiation. N2a cells are a fast-growing neuroblastoma cell line that can be differentiated to a neuron-like phenotype in specific culture conditions, and therefore they can be used as a model to study neuronal signaling pathways. Undifferentiated N2a cells express mainly P2X1, P2X3, P2X4, P2X5 and P2X7, while it has been reported that P2X2 is barely expressed at mRNA and protein levels. After neuronal-like differentiation, it has been described that P2X7 levels are lower respect to those in undifferentiated cells, but to our knowledge possible changes in P2X2 expression have not been studied yet. In our hands, chronic exposure of soluble amyloid beta oligomers (SOAβ) in hippocampal neurons resulted in 30% increment of endogenous P2X2a isoform subunit protein levels, respect to that in non-treated neurons, which could be the predominant isoform in these primary cultures. Here, our aim is to study the expression and distribution of P2X2 subunit in neuronal-like differentiated N2a cells, and to analyze the effect of overexpressing both P2X2a and P2X2b isoforms on APP endocytosis, processing and amyloid beta production. Our preliminary results suggest that N2a cells cultured with 10% fetal bovine serum (FBS) express mainly the P2X2a isoform, while cells cultured with 5% FBS during 7 days express lower levels of P2X2a isoform (50% decrease respect to cells cultured in 5% FBS during 2 days) and P2X2b isoform become predominant (150% increase respect to cells cultured in 5% FBS during 2 days), in a time curse dependent manner (we examined 2 days, 5 days and 7 days cultures). These results show that N2a cells express P2X2 subunits and furthermore, along neuron-like differentiation, the isoforms expression is modulated. The possibility that Aβ, in turn, alters P2X2 expression pattern in N2a cells, and that P2X2 has a role modulating endogenous APP endocytosis and processing is assessed.

Title: Amyloid-beta dimers interfere with amyloid-beta plaque formation

Authors: E. VAN GERRESHEIM[1], A. HERRING[2], A. MÜLLER-SCHIFFMANN[1], K. KEYVANI[2], *C. KORTH[1];

Abstract: Background. Alzheimer’s disease (AD) is one of the most prevalent neurodegenerative disease in humans, with a growing burden on the human society. In AD, the presence of amyloid beta (Aβ) plaques in the brain is one of the pathological hallmarks. Soluble oligomers of the Aβ peptide are thought to be the primary neurotoxic species. Previously, our lab developed a mouse line producing exclusively covalently linked Aβ S8C dimers (tgDimer) to study the exclusive effect of Aβ dimers on the brain. The sole presence of Aβ S8C dimers in the brain of the tgDimer mouse did not result in Aβ plaques after 24 months, even though the animals showed cognitive deficits. After crossing the tgDimer mouse with the tgCRND8 mouse, which displays a robust plaque pathology, we observed incorporated Aβ S8C dimers in the plaques. Our objective here was to study the effect of Aβ S8C dimers on plaque formation in the brains. **Methods.** For this purpose, we performed immunohistological staining and microscopic imaging on brain sections derived from 3 and 5 months old tgCRND8/tgDimer animals. We measured the levels of Aβ40 and Aβ42 in the brain by performing a four-step ultracentrifugation biochemical fractionation followed by an Enzyme-Linked Immunosorbent Assay (ELISA). **Results and Conclusion.** We observed a significant lower number of Aβ plaques in the brain of tgCRND8/tgDimer animals compared to tgCRND8 animals, whereas the size of the plaques remained the same. The insoluble Aβ42/total Aβ ratio in the brain was significant lower in the tgCRND8/tgDimer animals compared to the tgCRND8 animals for both ages. These results confirm that Aβ S8C dimers can be incorporated into fibrils and indicate that they interfere with the initial seeding phase of plaque generation.

Title: Sensitivity of the aging brain to amyloid beta oligomers increases with age

Authors: *A. YEGANEH[1], S. LOGAN[2], H. PORTER[2], D. OWEN[2], J. FARLEY[2], W. M. FREEMAN[3], W. E. SONNTAG[4];

Abstract: Introduction: Age is, by far, the single most important risk factor for cognitive decline, neurodegeneration and Alzheimer's disease (AD). The etiology for the age-related increase in cognitive impairment and risk for neurodegenerative disease is unknown. The vast majority of animal models used in Alzheimer's research utilize a transgenic approach that has provided compelling information on the role of amyloid and tau in AD. Nevertheless, these models do not address the primary risk factor for AD, age. This series of studies were designed to assess the cellular changes associated with age that confer sensitivity to insults such as Aβ, thereby compromising cognitive function.
Methods: Male 4 and 24 month old C57Bl/6J mice were implanted with intracerebroventricular (ICV) osmotic mini-pumps into the lateral ventricle and 150µg of $A\beta^{1-42}$ oligomers or scrambled $A\beta^{1-42}$ (control) infused for 28 days. On day 21, mice were assessed for spatial learning and working memory using a discrimination task based on a food reward. The first two days (initial discrimination) mice learned to enter the feeding area through the left entrance and the correct entrance was reversed on days 3 and 4 (reversal). Data were recorded using Ethovision video tracking software and performance was assessed as a Cumulative Learning Index (Correct-Incorrect/Total entries). At the conclusion of behavior, were processed and utilized for RNAseq analysis to relate changes in gene expression to behavior.
Results: Preliminary studies indicated that oligomerized Aβ injected ICV rapidly crosses the

tanycyte barrier and enters the brain. Young and Aged mice with or without amyloid oligomers were equally able to learn the behavioral task during initial discrimination. However, cognitive plasticity (the ability of the animal to extinguish a memory and learn the reversal task) was impaired with age and the effect was exacerbated by Aβ in old but not young animals. RNAseq analysis revealed 68 transcripts that were differentially expressed in response to Aβ between groups. Additionally, there was a robust increase in TNF and other proinflammatory TNF associated transcripts as well as microglial transcripts in response to $A\beta^{1-42}$.
Conclusion: Our studies indicate that aged mice exhibit increased sensitive to oligomeric Aβ-induced cognitive deficits compared to young animals. Understanding the mechanisms contributing to the age-related component of the disease process and developing interventions may be a promising, novel and prudent approach to delay the onset and progression of Aβ related dementia.

Abstract: The dysfunctional accumulation of amyloid beta (Aβ) plaques in neuronal cells is widely regarded as a hallmark sign of Alzheimer’s disease (AD). However, despite extensive knowledge pertaining to the genesis of such plaques, the mechanisms by which Aβ causes the rampant apoptosis that leads to the characteristic memory loss and dementia observed in AD patients are much less understood. In this study, the regulatory relationship between $A\beta_{1-42}$, a

particularly toxic member of the Aβ peptide family, and polyamines (PA), a ubiquitous class of molecules associated with cell growth and proliferation, was investigated. Specifically, HT22 hippocampal cells were transfected with either empty IRES control or $A\beta_{1-42}$ expressing vectors to establish whether intracellular PA were upregulated by Aβ overexpression as well as determine if the inhibition of such upregulation had any effect on amyloidogenic aggregation and, by extension, neuronal cell death. Ultimately, it was found that $A\beta_{1-42}$ increases PA levels in a dose dependent fashion through enhanced expression of ornithine decarboxylase (ODC), the rate limiting enzyme of PA biosynthesis. Furthermore, treatment with the irreversible ODC inhibitor L--difluoromethylornithine (DFMO) was shown to decrease both $A\beta_{1-42}$ aggregation and cell death in transfected cells. Together, these data suggest that increased intracellular concentrations of PA are not only the result of aberrant amyloidogenic accumulation, but also that these molecules in turn contribute to $A\beta_{1-42}$ toxicity. Moreover, the protective benefits imparted on HT22 cells by DFMO offer a potentially novel therapeutic avenue to mitigating amyloid plaque aggregation in the treatment of AD.

Title: Role and regulation of E3 ubiquitin ligase itch in neuronal apoptosis

Authors: *M. CHAUHAN, P. K. MODI, P. SHARMA;
Natl. Inst. of Immunol., New Delhi, India

Abstract: Subsequent to differentiation, neurons exit the cell cycle and remain in terminally differentiated state. However, neurotoxic insults like Alzheimer's disease (AD) related amyloid beta peptide $A\beta_{42}$ compel neurons to re-enter the cell cycle, which results in their apoptosis. The mechanisms underlying cell cycle re-entry and apoptosis of neurons are poorly understood. We recently reported that p73 family member TAp73 is degraded in response to $A\beta_{42}$, which results in Cell Cycle Related Neuronal Apoptosis (CRNA). In this study, we report that E3 ubiquitin ligase Itch mediates proteasomal degradation of TAp73 and promotes CRNA. We observed enhanced interaction of Itch with TAp73 in cortical neurons treated with $A\beta_{42}$ or derived from AD transgenic mouse model (TgAD). Itch knockdown significantly reversed the process of CRNA indicating it to be a regulator of CRNA. Our studies indicate that post-translational

modifications like phosphorylation and self-ubiquitination of Itch, which is aberrantly regulated in response to $A\beta_{42,}$ facilitates TAp73 degradation. Furthermore, phosphorylation and auto-ubiquitnation site null mutants reverted TAp73 degradation and CRNA. Collectively, our study reveals a novel role for Itch in cell cycle related neuronal apoptosis in the process of neurodegeneration and shed light on its regulation during this process.

Title: Increased cell cycle reporter activity is not associated with amyloid β-induced death of neurons

Authors: *L. M. ITTNER[1], S. IPPATI[1,2], Y. DENG[1], J. VAN DER HOVEN[1], Y. LIN[1], A. ITTNER[1], N. HAASS[3], Y. D. KE[1];
[1]Dementia Res. Ctr., Macquarie Univ., Sydney, Australia; [2]San Raffaele Scientific Inst., Milan, Italy; [3]Translational Res. Inst., Univ. of Queensland Diamantina Inst., Brisbane, Australia

Abstract: Neurons are post-mitotic cells that do not undergo division after terminal differentiation. Re-activation of the cell cycle by neurons with multiplication of chromosomes, but pre-mitotic arrest has been reported in Alzheimer’s disease (AD) brains and models. This gave rise to the hypothesis that neurons that have re-entered the cell cycle become more vulnerable. However, the previous studies relied on staining of cell cycle proteins or DNA content allowing only snap-shot assessment. With the introduction of novel live reporter systems, such as the fluorescence ubiquitination cell cycle indicator (FUCCI) technology, it has become possible to visualize stages of the cell cycle in living cells; The two colour FUCCI system includes expression of FUCCI-red during the G1(G0) phase of the cell cycle, which is replaced by FUCCI-green expression during S/G2/M in dividing cells. Using the FUCCI reporter in primary neurons for live cell microscopy together with oligomeric amyloid-β (oAβ) challenging, we addressed the temporal connection between Aβ-induced re-activation of the cell cycle and death of neurons. Consistent with their post-mitotic state, all neurons expressed the FUCCI-red reporter. Interestingly, we found transient expression of FUCCI-green in the absence of cell division in a small subpopulation of naïve neurons in culture, possible suggesting physiological transient, self-terminating entry in early S/G2. Consistent with previous studies, challenging neurons with oAβ caused cell death, here visualized with the Draq7 dye. Furthermore, we

observed increased, persistent FUCCI-green expression upon oAβ treatment, indicative of cell cycle re-entry. Importantly, oAβ-induced death ($Draq7^+$) and persistent high FUCCI-green expression did virtually never occur in the same neurons. Consistent with our cell culture data, we found frequent and high expression of FUCCI-green in APP transgenic but not non-transgenic mice. Taken together, our data suggest that neurons with oAβ-induced cell cycle reporter activation have adopted a state that protected them from death, while cells that did not induce cell cycle reporter expression were vulnerable. This challenges the concept that molecular events associated with cell cycle re-entry renders neurons more vulnerable in AD.

Title: Concentration of pyroglutamate Abeta42 in the frontal cortex of high-pathology elderly controls, mild cognitive impairment, and Alzheimer’s disease

Authors: V. N. PIVTORAIKO[1], E. E. ABRAHAMSON[1], E. J. MUFSON[2], *M. D. IKONOMOVIC[1];
[1]Neurol., Univ. of Pittsburgh, Pittsburgh, PA; [2]Neurobio., Barrow Neurolog. Inst., Phoenix, AZ

Abstract: Background: Pyroglutamate amyloid-β (AβNpE) peptides are highly aggregation-prone truncated and modified Aβ forms present in amyloid deposits in Alzheimer’s disease (AD). Regional differences in concentrations of AβNpE relative to full-length Aβ as well as neuropathology burden and cognitive dysfunction in AD are unknown. We reported previously that AβNpE3-42 and Aβ1-42 concentrations are markedly higher in the posterior cingulate cortex of AD compared to both mild cognitive impairment (MCI) and controls (no cognitive impairment, NCI). The present study quantified AβNpE3-42 and Aβ1-42 concentrations in the frontal cortex (FC, BA10) and examined their relationship with [H-3]PiB binding, global cognition, and neuropathology ratings across the clinical-pathological spectrum of NCI, MCI, and AD. **Methods:** Samples of frozen FC were obtained postmortem from 52 participants in the Rush Religious Order Study with clinical diagnosis of NCI, MCI, or AD. The NCI subjects were divided into low pathology (LP-NCI) and high pathology (HP-NCI) groups. ELISA concentrations of formic acid-extracted AβNpE3-42 and Aβ1-42 as well as [H-3]PiB binding

were compared among the clinical groups and correlated with the last Mini Mental State Examination (MMSE) and neuropathology scores by CERAD and Braak staging. **Results:** FC concentration of AβNpE3-42 in AD was higher than in LP-NCI and MCI, but it did not differ from the HP-NCI group. FC Aβ1-42 concentration and [H-3]PiB binding were only higher in AD compared to the LP-NCI. Spearman rank correlation showed strong associations of FC AβNpE3-42 and Aβ1-42 concentrations with [H-3]PiB ($r=0.80$ and $r=0.76$, both $p<0.0001$), MMSE (r, -0.44, $p=0.001$ and r, -0.42, $p=0.003$), CERAD (r, -0.66, $p<0.0001$ and r, -0.57, $p<0.0001$), and Braak ($r=0.57$, $p<0.0001$ and $r=0.45$, $p=0.002$). **Conclusions:** This study demonstrates a relationship of AβNpE3-42 and full-length Aβ1-42 concentrations in FC with neuropathological and clinical progression of AD. While the observed associations are compelling, they do not prove a causality, thus changes in these molecules need to be investigated further in relation to other pathologies (e.g., tau, synaptic changes, inflammation) in key cortical associational areas across clinical stages of AD.

Abstract: Background: Frontal cortex (FC), a key component of the default mode network (DMN), undergoes marked amyloid deposition early in Alzheimer’s disease (AD). Previous studies report FC plasticity in prodromal AD, but the exact type of synaptic changes involved and their relation to regional increases in amyloid burden are not known. We studied changes in dendritic spines, dynamic postsynaptic structures associated with excitatory neurotransmission, and correlated their density with amyloid pathology in FC during the clinical-pathological course of AD. **Methods:** Dendritic spine densities were quantified using confocal microscopy and spinophilin/phalloidin fluorescence in postmortem tissue sections of FC (BA10) from 44 Rush

Religious Order Study (RROS) subjects with last antemortem clinical diagnosis of no cognitive impairment (NCI, n=19), mild cognitive impairment (MCI, n=10), and AD (n=15). NCI subjects were divided into low pathology (LP-NCI, n=9) and high pathology (HP-NCI, n=10) subgroups, and AD subjects were divided into mild-moderate AD (mAD, MMSE 11-19, n=8) and severe AD (MMSE less than 10, n=7). Dendritic spine density was compared among the clinical-pathological groups and correlated with amyloid burden marked with CN-PiB or X-34, CERAD and Braak neuropathology scores, and tests of global cognition and episodic, semantic, and working memory. **Results:** Densities of FC dendritic spines were higher in LP-NCI and MCI compared to severe AD (p=0.018 and p=0.003, respectively) but not the HP-NCI or mAD groups. Across all cases, lower densities of dendritic spines correlated with greater amyloid burden by CN-PiB (R, -0.41, p=0.007) and X-34 (R, -0.37, p=0.016), and CERAD (R=0.36, p=0.016), but not with Braak neuropathology scores or tests of cognition. **Conclusions:** Density of FC dendritic spines reaches significant loss only in frank AD dementia, which could explain lack of correlation with cognitive measures across the entire clinical AD continuum. While the process of synaptic loss appears to parallel advancement of amyloid pathology, overall stability of dendritic spines in HP-NCI, MCI, and mAD further indicates resilience of the FC to AD progression. How this compares to synaptic and amyloid changes in other regions of the DMN is currently under investigation.

Title: Real time imaging using quantum dot nanoprobes revealed cell membrane protrusion-dependent amyloid β_{42} aggregation at peripheral region of PC12 cells

Authors: Y. CHIKAI[1], R. YAMASHITA[1], ***M. KURAGANO**[1], M. TAKAHASHI[2], K. TOKURAKU[1];

Abstract: Alzheimer's disease (AD) is a progressive disorder of brain that gradually decreases thinking and memory skills. The amyloid cascade hypothesis is that the neurodegeneration in AD causes abnormal accumulation of amyloid β (Aβ) in the aged brain. Aβ consists of 39-43 amino acid residues and is derived from amyloid precursor protein that is cleaved by β- and γ-secretase. It is thought that the aggregation process of Aβ is a key step in the development of AD because aggregates of $A\beta_{42}$ showed neurocytotoxicity. However, the molecular mechanism of the cytotoxicity by $A\beta_{42}$ has not been clearly elucidated. Previously, we reported that a real time imaging method of $A\beta_{42}$ aggregation using quantum dot (QD) nanoprobes. To investigate the mechanism of $A\beta_{42}$ neurocytotoxicity, in this study, we tried to visualize the process of $A\beta_{42}$ aggregation around PC12 cells by applying QD imaging method. First, we examined whether $A\beta_{42}$ aggregation was observed in culture medium. PC12 cells were differentiated by 4.5 ng/ml neuronal growth factor, and then were incubated with 20 μM $A\beta_{42}$ and 30 nM QD$A\beta_{40}$ for 24 h. After incubation, we observed $A\beta_{42}$ aggregates by conventional fluorescence microscopy and confocal laser microscopy. The observation showed that $A\beta_{42}$ aggregates were particularly formed around cells. The 3D observation using confocal laser microscopy revealed that $A\beta_{42}$ aggregates did not localize at the top of cells. Next, we performed live cell imaging using QD to reveal $A\beta_{42}$ aggregation process at the cell peripheral region. Neuronal growth factor treated cells formed many protrusions. $A\beta_{42}$ preferentially started to aggregate at the region where membrane protrusions were frequently formed. Then, protrusions were suppressed at the cell membrane where excessive $A\beta_{42}$ aggregates had been accumulated. Finally, to investigate whether cell membrane motility promotes aggregation of $A\beta_{42}$, we inhibited actin polymerization using 20 μg/ml Cytochalasin D. The 3D observation revealed that Cytochalasin D treatment suppressed $A\beta_{42}$ aggregation around cells. These results indicate that actin-dependent cell motility is responsible for the promotion of $A\beta_{42}$ aggregation at peripheral region of PC12 cells. We hypothesize that the diffusion of $A\beta_{42}$ is transited from 3-dimensional in culture medium to 2-dimensional on the cell surface, and that the active cell membrane protrusions dramatically increase the frequency of collisions among $A\beta_{42}$ at the cell surface, which promotes additional $A\beta_{42}$ aggregation. Moreover, we have found the possibility that the reduction of cell membrane plasticity by $A\beta_{42}$ accumulation is involved in the expression of its neurocytotoxicity.

Title: Single walled carbon nanotube optical reporter for amyloid beta detection

Authors: *M. ANTMAN- PASSIG[1], A. S. AGUSTINUS[2], Z. CHEN[3], D. A. HELLER[1]; [1]Mem. Sloan Kettering Cancer CTR, New York, NY; [2]Pharmacol., [3]Weill Cornell Grad. Sch. of Med. Sci., New York, NY

Abstract: Amyloid beta (Aß) extracellular deposits are one of the pathohistological hallmarks of Alzheimer's disease (AD). In recent years intracellular accumulation of Aß has been linked with early pathogenic mechanisms and may serve as a marker for AD onset and progression. Aβ can be produced or uptaken into the early/late endosome system, where the acidic pH creates a favorable environment for generation and aggregation of Aβ. Numerous reports now associate intracellular Aβ accumulation, and lysosomal disfunction as an early event in the disease, preceding extracellular amyloid-deposits. Today methods to visualize intracellular Aβ accumulation rely on antibody staining or pre-labeled Aβ. Thus, a reporter that can probe intracellular Aß accumulation in live cells can greatly enhance the tool-kit for investigative research as well as potentially for drug screening applications. We have developed a carbon nanotube optical sensor that can monitor Aß in live cells dynamically and longitudinally. We based our design on previous reports indicating high affinity central hydrophobic core of Aß and single wall carbon nanotubes (SWCNTs). Notably, SWCNTs present advantages as optical sensors owing to their near-infrared emission, as well as photostability and high-sensitivity. SWCNT emission spectra (wavelength ranges of 1100-1150nm) is within the biological transparency window (1000-1700nm) allowing for optimal imaging in live samples. We bio-functionalized SWCNTs in aqueous solutions based on methods developed by ours and other reports. Our results indicate bio-functionalized nanotube sensors (BF-NS) produce a significant wavelength shift in response to biologically relevant concentrations of Aβ, as well as a dose-dependent response to increasing Aβ concentration. Additionally, in cell models, BF-NS accumulate intracellularly and specifically probe Aß (1-42) introduced to cells.

Abstract: Several lines of evidences suggest that apart from genetic factors, lifetime stressful events contribute to the pathophysiology of Alzheimer's disease (AD). Stressors induce breakdown of the blood-brain barrier (BBB) permeability leading to transport of amyloid beta peptide (ABP) and other toxicological elements from plasma to brain. This could cause biochemical, pathological and immunological challenges and phosphorylation of tau (p-tau). Generation of other free radicals ad oxidants such as nitric oxide (NO), carbon monoxide (CO) and other oxygen radical lead to further brain pathology. In this study we examined role of immobilization stress representing isolation and depressive state on the pathophysiology of ABP infused AD cases was examined in a rat model.
AD like brain pathology was induced by intracerebroventricular (i.c.v.) administration of soluble form of ABP 200 ng/30 µl per day into the left lateral ventricle for 4 weeks in a rat model. Identical ABP was also infused in chronic immobilized rats in a partial restraint tube 2 h daily for 4 weeks. Our observations showed that ABP infusion in immobilized rats resulted in 120 to 210 % increase in the BBB breakdown to serum proteins and Evans blue and 35 to 56 % greater accumulation of ABP in the brain and in CSF as compared to normal rats after identical ABP infusion. Immunoreactivity of heat shock protein (HSP 72) and neuronal nitric oxide synthase (nNOS) showed 43 to 68 & higher upregulation in stressed rats after ABP infusion in several brain regions associated with neuronal, glial and axonal injuries. CSF levels of ABP and p-tau were 95 to 134 % higher in stressed rats after ABP infusion that in normal rats. Immobilization

alone however did not show any brain pathology or accumulation of ABP, p-tau, HSP or nNOS in the brain. TiO2 nanowired delivery of cerebrolysin-a multimodal drug comprising several neurotrophic factors and active peptide fragments together with antibodies to ABP (1:20, 50 µl, i.c.v. daily for 2 weeks after ABP infusion) significantly attenuated brain pathology and BBB breakdown in both control and in stressed group. Deposition of of ABP, p-tau, HSP 72 and nNOS were much less evident in treated group in AD rats with or without stress. These observations are the first to show that stress could exacerbate AD brain pathology probably via generation of oxidative stress, free radicals and BBB breakdown. Neutralization of ABP by antibodies together with exogenous supplement of neurotrophic factors using nanowired delivery enhance neuroprotection in AD brain pathology, not reported earlier.

Abstract: Smoking induced nicotine exposure is a serious health hazard to human populations worldwide. Interestingly there are reports that smoking tendency is about 25 to 30 % higher in military personnel. Whether chronic nicotine exposure could accelerates brain pathology of neurodegenerative diseases is not well known. Thus, effect of nicotine on the development of neurodegenerative diseases requires further investigations.

Previous experiments from our laboratory have shown that nicotine (9 mg/kg, s.c.) for 1 week results in blood-brain barrier (BBB) breakdown and cell injuries. Since military personnel are also very probe to development of Alzheimer’s disease (AD), it would be possible that nicotine exposure could play some role in AD pathology. Few reports on nicotine induce amyloid beta peptide (ABP) is controversial. Thus, some suggests that nicotine exposure improves catabolism of ABP where several repots indicate worse deposition of ABP in nicotine exposed human cases or in preclinical studies.

In this investigation, we examine ABP infusion induced AD brain pathology and its modification with prior nicotine exposure. AD like symptoms was produced in normal rats or chronically nicotine exposed group by intraventricular (i.c.v.) administration of AβP (1-40) in the left lateral ventricle (250 ng/10 µl, once daily) for 4 weeks. After 30 days, the rats were examined for a degrading enzyme for ABP neprilysin (NPL) and AβP concentrations in the brain and related pathology. Our observations show that BBB to Evans blue is 124 to 153 % increased together with brain pathology in nicotine exposed AD rats as compared to naïve animals after ABP infusion. Interestingly, in nicotine-exposed rats ABP infusion resulted in 54 to 62 % decrease in NPL concentrations from the ABP alone group (NPL 65±8 pg/g nicotine+ABP, saline control 424±12 pg/g, ABP alone 122±5 pg/g). Whereas, ABP deposition significantly increased in nicotine exposed AD group (Nicotine+AD 98±6 pg/g; ABP alone 78±4 pg/g, control 38±9 pg/g). Treatment with cerebrolysin-a select combination of neurotrophic factors together with a chain breaking antioxidant H-290/51 significantly thwarted nicotine induced AD brain pathology. TiO2 nanodelivery of cerebrolysin (2 ml/kg, i.v.) with H-290/51 (50 mg/kg, i.p.) daily for 3 days after nicotine exposure resulted in significant reduction in ABP accumulation and marked enhancement of NPL activity together with decrease in BBB breakdown and cell injuries. These observations are the first to show that nicotine stimulates ABP deposition and decrease NPL activity thereby enhancing brain pathology in AD, not reported earlier.

Abstract: DL-3-n-butylphthalide (DL-NBP) is one of the constituents of Chinese celery extract that is used to treat stroke, dementia and ischemic diseases. However, its role in Alzheimer's disease (AD) is not yet well known. In this investigation, neuroprotective effects of DL-NBP in AD induced brain pathology were explored in a rat model. Since neprilysin (NPL) is an enzyme that degrades amyloid beta peptide (AbP) is downregulated, we explored the combination of NBP and NPL in AD model to achieve neuroprotection. We used TiO2 nanowired delivery of NBP and NPL on reduction in brain pathology in AD. AD like symptoms was produced by intraventricular (i.c.v.) administration of AβP (1-40) in the left lateral ventricle (250 ng/10 µl, once daily) for 4 weeks. After 30 days, the rats were examined for NPL and AβP concentrations in the brain and related pathology. Co-administration of TiO2 nanowired NPL (50 ng in 20 µl) once daily for 1 week after 2 weeks of AβP infusion together with nanowired NBP (40 mg/kg,

i.p.) for 1 week. Control group received saline instead of NPL and NBP in identical manner in AD model. Untreated AD group showed profound blood-brain barrier (BBB) disruption and brain edema together with neuronal injuries 4 weeks after AbP infusion as compared to intact control group. Nanowired treatment with NBP and NPL significantly attenuated AD induced BBB breakdown, brain edema and neuronal damages. Biochemical measurement of NPL showed a significant increase in hippocampus (360 pg/g) from untreated AD group (120 pg/g; Control 420±8 pg/g brain) along with significant decrease in the AβP deposition (55 pg/g from untreated AD control 75 pg/g; saline control 40±4 pg/g). Interestingly, these changes were also evident with moderate neuroprotection when normal NBP (60 mg/kg) or NPL (100 ng in 20 µl) were given in identical manner in AD group. Neuronal damages, gliosis and myelin vesiculation were also markedly reduced by the combined treatment of TiO2 NBP and NPL in AD. These observations are the first to show that co-administration of TiO2-nanowired NBP and NPL has superior neuroprotective effects in AD probably due to increasing the brain NPL level and decreasing AbP deposition effectively. Taken together our observations are the first to suggest that (i) DL-NBP is quite effective in reducing brain pathology and, (ii) nanodelivery of DL-NBP with NPL has far more superior effects in AD, not reported earlier.

Abstract: Sleep deprivation (SD) is a serious problem in military, emergency workers, intensive care unit professionals leading to judgmental error, intellectual disturbances and precipitation of neurological disorders. Military personnel often develop Alzheimer's disease (AD) that could be linked to post-traumatic stress disorder (PTSD) or traumatic brain injury (TBI). Thus, it would be interesting to explore contribution of SD in process.

Previous experiments from our laboratory show that SD for 12 to 72 h progressively induces blood-brain barrier (BBB) breakdown to proteins leading to edema formation and brain pathology. In this investigation we explored a link between SD and AD by examining brain and CSF levels of amyloid beta peptide (AbP) and phosphorylated tau (p-tau), the hallmarks of AD after SD in a rat model.

SD was induced in rats using the inverted flowerpot surrounded by water level 1 cm below the platform (6.5 cm in diameter). This set up allows free movement of rats but deep sleep is disturbed in animals when they fell down in water. AbP and p-tau was measured using commercial ELISA kit in the CSF obtained from cisterna magna and in the frontal, parietal, cingulate and temporal cortices as well as in hippocampus, thalamus and hypothalamus.

Our observations show that 12 to 72 h SD enhanced AbP deposition in the brain and in CSF in a progressive manner as compared to normal controls. p-tau levels followed closely with AbP in SD groups. SD increased brain AbP by 86 to 134 % (24 h) 150 to 185 % (48 h) and 205 to 265 % (72 h) from controls. In the CSF SD increased AbP levels by 35 % (24 h), 66 % (24 h) and 84 % (72 h) as compared to control group. The p-tau showed marked increase in SD by 92 to 134 % (24 h), 156 to 194 % (48 h) and 189 to 234 % (72 h) compared to controls. The CSF p-tau in SD enhanced by 67 % (24 h), 89 % (48 h) and 138 % (72 h) from respective controls. A close correspondence with neuronal damages with AbP and p-tau levels was seen in SD.

TiO2 nanowired delivery of cerebrolysin-a balanced composition of several neurotrophic factors and active peptide fragments (5 ml/kg, i.v.) significantly attenuates these enhancement of AbP and p-tau levels at 24 to 72 h following 6 and 12 h SD in 24 h; 6, 12, and 18 h in 48 h SD; and 6,12,18 and 24 h in 72 h SD groups. TiO2-naowired cerebrolysin also reduced cellular injuries in SD groups. These observations are the first to show that SD has the capability to induce AbP and p-tau accumulation in the brain and CSF that could be one of the key factors responsible for precipitating AD. Furthermore timely intervention with nanodelivery of cerebrolysin significantly induces neuroprotection and thwarted AbP and p-tau accumulation in SD, not reported earlier.

Abstract: Sleep deprivation (SD) is a serious problem in military personnel that affects mental functions. Moreover, neurodegenerative diseases like Alzheimer’s disease (AD) and Parkinson’s disease (PD) are also prevalent in veterans either due to post-traumatic stress disorders (PTSD) or following mild traumatic brain injury (TBI). Previous reports from our laboratory showed that TBI exacerbates PD induced brain pathology. However, it is still uncertain whether SD could also affect brain pathology in PD. In this investigation we explored effects of SD on PD induced brain pathology. Furthermore, we examined effects of nanowired delivery of ondansetron that was capable to induce neuroprotection in SD cases effectively. In addition, co-administration of cerebrolysin using nanodelivery was evaluated in PD that for superior neuroprotection. SD was

induced by inverted flowerpot methods surrounded by water (30±1°C) that disturbs continuous sleep.
PD like symptoms were induced in normal or SD mice by administration of 1-metyl-4-fenyl-1,2,3,6-tetrahydropyridin (MPTP, 20 mg/kg, i.p.) daily within 2-h intervals for 5 days induced PD like symptoms. This is confirmed by significant decreases in tyrosine hydroxylase (TH) positive cells in the substantia niagra pars Compacta (SNpc) and striatum (STr) together with dopamine (DA) and its metabolites 3,4-Dihydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVA) on the 8th day. At this time, alpha-synuclein (ASNC) and tau proetins increased profoundly in the CSF. We observed that 24 to 48 h SD mice when received MPTP loss of TH positive cells and reduction in DA, DOPAC an HVA were further potentiated. The levels of SNC and p-tau in the CSF were 80 to 109 % increased in PD cases with SD. Brain pathology in PD after SD was also 2- to 3-fold enhanced.
Treatment with TiO2-nanowired ondansetron (1 mg/kg, i.p. daily for 3 days) together with cerebrolysin (5 ml/kg, i.v. daily from day 5 to 8) resulted in significant reduction in brain pathology, and restored DA and DOPAC levels and TH immunoreactivity in the SNpc, STr by more than 78 to 90 % than the normal values. Interestingly, CSF levels of ASNC, and p-tau were also decreased by 70 to 85 % from the untreated PD mouse. When cerebrolysin or ondansetron were given alone in PD, the magnitude of biochemical or immunohistochemical changes together with brain pathology were much less evident in SD mice. Taken together our observations are the first to point a prominent role of SD in the pathophysiology of PD, not reported earlier.

Abstract: Previous reports from our laboratory shows that methamphetamine (METH) intoxication exacerbates traumatic brain injury induced brain pathology that is most marked at high altitude (HA). METH or substance abuse is quite common at high altitude leading to a variety of CNS disease and a well-known risk factor for Parkinson’s disease (PD). Thus, in this investigation we examined role of METH in PD induced brain pathology at HA as compared to sea level (SL).
Rats were exposed to chronic METH intoxication (3 mg/kg, s.c.) for 1 week at HA chamber mimicking 5000 M. In these rats PD like symptoms were induced 1-metyl-4-fenyl-1,2,3,6-tetrahydropyridin (MPTP, 20 mg/kg, i.p.) administration daily within 2-h intervals for 5 days. This treatment results in PD symptoms such as decrease in tyrosine hydroxylase (TH) positive cells in the substantia niagra pars Compacta (SNpc) and striatum (STr) together with dopamine (DA) and its metabolites 3,4-Dihydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVA) on the 8th day. At this time, alpha-synuclein (ASNC) and tau proetins increased profoundly in the CSF. The magnitude and intensity of these PD symptoms were 150 to 230 % higher in METH treated rats exposed to HA. At SL METH treated rats showed only 50 to 80 % greater changes in these symptoms as compared to MPTP alone treated animals at SL. In our hands MPTP induced PD also upregulated neuronal nitric oxide synthase (nNOS) immunoreactivity in the cerebral cortex that was also exacerbated by METH treatment both at HA and SL. MPTP indexed biochemical and immunochemical changes were significantly attenuated by nanowired delivery of cerebrolysin (NWCBL).
When NWCBL is administered (5 ml/kg, i.v.) with antibodies to nNOS (1:20, 50 µl into lateral cerebral ventricle) on 5th day for 3 consecutive days, brain pathology and breakdown of the blood-brain barrier (BBB) was considerably reduced in METH treated PD rats at HA. In these groups TH positive cells were significantly restored and the levels of DA, DOPAC and HVA is enhanced markedly. On the other hand nNOS antibodies or NWCBL alone were effective in METH treated PD rats at SL only. These observations for the first time show that METH can exacerbate PD symptoms that are further aggravated at HA. Combined treatment with nNOS

antibodies and NWCBL is needed to thwart brain pathology and PD symptoms in METH treated group at HA, not reported earlier.

Abstract: Several lines of evidences suggest that oxidative stress plays an important role in neuronal injuries after cardiac arrest. Oxidative stress is known to induce increased production of

carbon monoxide (CO) like nitric oxide (NO) and damage blood-brain barrier (BBB) inducing brain edema and cellular injuries.
Rats were anesthetized and an alternating transthoracic current induced 3 min cardiac arrest. Then, 8 min of cardiac pulmonary resuscitation (CPR) followed that often-resulted in return of spontaneous circulation (ROSC). After a monitoring period of 3 hours the rats were sacrificed and the brain was collected. Some rats were given nanowired methylene blue (MB) dye (3 ml/kg, i.v.) initially during CPR either alone or together with nanowired cerebrolysin (5 ml/kg, i.v.). ELISA analysis together with immunohistochemical studies was used to determine HO-1 and HO-2 enzymes content in the parietal cerebral cortex, hippocampus and cerebellum.
Our observations show that cerebral tissue from rats subjected to cardiac arrest (CA), CPR and surviving the monitoring period resulted in 150 to 230 % increase in HO-1 enzyme and 78 to 103% in HO-2 enzyme levels in the cerebral cortex, hippocampus and cerebellum together with BBB breakdown and cellular injuries. Interestingly hippocampus and cerebellum showed significantly higher increase in HO-1 and HO-2 as compared to cerebral cortical tissues. These biochemical changes were further confirmed by increased immunostaining of HO-1 and HO-2 in the parietal cortex especially in layer III as well as in the hippocampus CA1, CA3 and dentate gyrus. In cerebellum both Purkinje cells and granule cells showed increased immunostaining of HO-1 and HO-2 in untreated group. MB was able to slightly but markedly reduce HO-1 and HO-2 staining that was potentiated when combined with cerebrolysin. In general HO-1 expression was greater than HO-2 upregulation in all cases of cardiac arrest examined.
Our observations are the first to show that an experimental CA of long duration followed by successful CPR results in significant alteration of cerebral concentrations of HO-1 and HO-2 levels indicating role of CO in brain pathology after CA that was significantly reduced by nanowired methylene blue and cerebrolysin together with brain pathology.

CNS Injury & Repair (IECNSIR), Univ. Hospital, Anesthesiol. & Intensive Care Medici, Uppsala Univ. Hosp., Uppsala, Sweden

Abstract: Military personnel are prone to development of Alzheimer's disease (AD) largely due to either post-traumatic stress disorder (PTSD) or lifetime mild to moderate traumatic brain injury. Spinal cord injury (SCI) is also quite frequent in military due to motor vehicle accident, missile of gunpowder explosion or direct insult to the spinal cord. Although, AD is well known to induce brain pathology, damage or deposition of amyloid beta peptide (ABP) in the cord is still not well known. Recent clinical studies showed that patients with SCI lead to 37 % higher episodes of AD than non-SCI patients. This suggests that SCI and AD pathology are somehow inter-related.
We explored effects of SCI on AD induced spinal cord pathophysiology. Previous reports from our laboratory showed that topical application of cerebrolysin-a multimodal drug is able to reduce SCI induced cord pathology up to 24 and 48 h. Also topical application of monoclonal antibodies to tumor necrosis alpha over the injured cord 30 to 1 h after is able to reduce cord pathology. Thus, we investigated role of SCI in ABP infusion induced AD pathology in the cord and also evaluated effects of combined nanowired delivery of cerebrolysin and TNF-alpha on cord neuroprotection.
AD like symptoms were produced in rats by intraventricular (i.c.v.) administration of AβP (1-40) in the left lateral ventricle (250 ng/10 µl, once daily) for 4 weeks in normal or spinal cord traumatized animals. SCI was inflicted in anesthetized rats after laminectomy at T10-11

segments by making a longitudinal incision of 2 mm deep and 4 mm long of the right dorsal horn. In these ABP infused animals spinal cord pathology, ABP radioimmunoassay and blood-spinal cord barrier (BSCB) was examined.
Our observations showed that ABP deposits in AD rats after SCI was 85 to 98 % higher than normal intact AD group. BSCB breakdown to radioiodine or Evans blue was 250 and 340 % higher in AD rats with SCI as compared to normal AD group. Neuronal, glial and axonal injuries were 2- to 4-fold higher in the cord of ABP infused rats after SCI as compared to non-SCI rats. Topical application of nanowired cerebrolysin (50 µl/day) for 3 weeks resulted in significant reduction in the BSCB breakdown, cell injury and ABP deposition. These effects were further enhanced when TNF-alpha antibodies (1:20, 50 µl) was co-administered with cerebrolysin in identical manner. Significant reduction in nNOS activity was also seen in combined administration of TNF-alpha and cerebrolysin in AD cases within SCI. This suggests that co-administration of cerebrolysin with TNF-alpha antibodies potentiates neuroprotection in AD with SCI, probably via nitric oxide mediated mechanisms, not reported earlier.

Abstract: Traumatic brain injury (TBI) is one of the biggest challenges in military personnel during combat operations. TBI is also one of the predisposing factors for development of Alzheimer's disease (AD) and Parkinson' disease (PD). In addition, exposure to nanoparticles (NPs) from gun power explosion, environment and industrial hazards could further complicate TBI cases in military. Previous reports from our laboratory show that engineered NPs from metals e.g., Au, Cu, Al exposure to naïve rats exacerbates spinal cord injury (SCI) induced pathology and functional disabilities. In such cases of NPs exposure with SCI nanowired delivery of cerebrolysin (CBL)-a multimodal drug with balanced composition of several neurotrophic factors is able to thwart exacerbation of cord pathology and functional disturbances. However, NPs exposure and TBI is not well investigated. In this investigation, we examined Ag, Cu and Al NPs exposure (20-30 nm, 50 mg/kg, i.p.) on TBI induced brain pathology and functional disturbances in a rat model. Since SCI pathology was also attenuated by administration of dynorphin A (1-17) antibodies (Dyn Abs), we also evaluated effects of nanowired Dyn Abs together with nanowired CBL (NWCBL) in our TBI rat model.
TBI was performed in anesthetized rats by making an incision on the right parietal cerebral cortex (2 mm deep and 4 mm long) and animals were allowed to survive 24 and 48 after injury using standard procedures. In separate group TBI was inflicted in rats on the 8th day that were either exposed to Ag, Cu or Al daily (50 mg/kg, i.p.) for 1 week. Our observations show that NPs exposed rats exhibited 150 to 213 % higher blood-brain barrier (BBB) breakdown, 4 to 6 % greater edema formation and 120 to 230 % higher neuronal injuries than control TBI. These effects are most pronounced in Ag and Cu NPs treated injured rats as compared to Al exposed TBI group. Radioimmunoassay (RIA) of Dyn A showed 189 to 208 % increase after TBI in the cortex in NPs treated group from naïve rats after injury. The magnitude and intensity of these changes were significantly higher at 48 h after TBI as compared to 24 h injury. Intracerebroventricular (i.c.v.) administration of nanowired Dyn A abs (1:20, 50 µl) daily for 1 week followed by intravenous NWCBL (5 ml/kg) 4, 8 and 12 h after TBI significantly attenuated brain pathology, BBB breakdown and edema formation in NPs exposed TBI group at 48 h. Dyn a concentration was also reduced significantly in this group. These observations are the first to show that NPs exposure enhance brain pathology in TBI and NWCBL together with Dyn A abs could induce remarkable neuroprotection, not reported earlier.

Abstract: Brain blast injury (bBI) is quite frequent in military personnel often caused by several factors such as high blast pressure waves, penetrating injuries together with chemical explosives. Tissue losses, laceration, hemorrhage, destruction of neuronal networks, edema and neuronal, glial and axonal injury altogether lead to lifetime disability. There are reasons to believe that environmental temperature could affect the pathophysiology of bBI. In this investigation we explored the role of prior heat exposure on bBI and compared the results with normal

thermoneutral ambient temperature as controls.
Rats were heat exposed (HE) in a biological Oxygen Demand (BOD) incubator at 34°C for 1 h daily for 2 weeks without any brain pathology. Control rats were placed at 21±1°C. A shock tube blast devise in which compressed helium-driven membrane rupture induced pressure waves simulate bBI was used in a rat model. Equithesin anesthetized rat's head from HE and control group was subjected to overpressure blast (100, 150 or 200 kPa) in the shock-tube (shockwave velocity 400 to 450 m/sec). After 4 and 8 h bBI, breakdown of the blood-brain barrier (BBB) permeability to Evans Blue albumin (EBA) and Radioiodine ([^{131}-I]) was measured in 8 brain regions. Regional cerebral blood flow (rCBF) using radiolabelled microspheres was measured. Morphological examination for neuronal, glial, myelin changes and albumin leakage was examined. Profound progressive increase in the BBB permeability to EBA and radioiodine in the cerebral cortex, hippocampus, cerebellum, thalamus, hypothalamus and brain stem was seen that is progressive in time and blast overpressure strength. Severe reduction in the rCBF and brain edema also seen in these brain areas associated with neuronal, glial and myelin damages. Activation of astrocytes and albumin leakage were most pronounced in the areas associated with cellular injuries. These changes were 3- to 4-fold higher in HE rats after bBI. Cerebrolysin (a multimodal drug comprising neurotrophic factors and active peptide fragments) together with 5-HT receptor antagonist (SB-399885, 2 mg/kg, i.v.) given 30 min to 1 h after bBI (5 to 10 ml/kg, i.v.) significantly reduced brain pathology following 4 h trauma in normal and HE rats. However, TiO2 nanodelivery of cerebrolysin (5 ml/kg, i.v.) together with SB-399885 (1 mg/kg, i.v.) induce superior neuroprotection in HE rats after 8 h and 12 h after bBI. These results are the first to show that cerebrolysin together with 5-HT 6 receptor antagonist has the potential to enhance and prolong neuroprotection in rain pathology in HE group after bBI, not reported earlier.

Abstract: We reported that histamine H3 and H4 receptors are involved in modulating brain pathology of Alzheimer's disease (AD) and Parkinson's disease (PD). Also, involvement of histamine H1 and H2 receptors participate in traumatic brain injury (TBI) and spinal cord injury (SCI). Thus, potent H2 receptor antagonists cimetidine or ranitidine reduced brain or spinal cord pathology after trauma whereas, H1 receptor antagonist mepyramine aggravated cell injury in TBI or SCI. This suggests that histamine plays key roles in CNS injury and repair. Since SCI or TBI is associated with oxidative stress and cell injuries, we observed that pretreatment with a chain breaking antioxidant compound H-290/51 is highly neuroprotective. However, role of histamine H3 and H4 receptors in SCI is still not well known.
In this investigation, we used TiO2 nanodelivery of BF-2549 and clobenpropit administration together and also investigated combination of nanowired delivery of H-290/51 for superior neuroprotection in a rat model of SCI.
SCI was inflicted in Equithesin anesthetized rats by making a longitudinal lesion (2 mm deep and 4 mm long) of the right dorsal horn of the T10-11 segment after laminectomy. The animals were allowed to survive 15 days after the primary injury sealed wound and routine care. The animals develop hind leg disturbances but other autonomic functions were quite under control. Separate group of rats were treated with TiO2-nanowired BF 2649 (1 mg/kg, i.p.) and Clobenpropit (1 mg/kg, i.p.) once daily for 1 week after 12 h of SCI. Another group of SCI rats also received nanowired H-290/51 (50 mg/kg, i.p. /day for 7 days) besides histaminergic drugs. Control animals with SCI received saline instead of any drug. Our observations show that SCI at 30 days resulted in profound hind limb paralysis with significant edema formation extended to the C4 to L5 regions of the spinal cord. Cellular damage to motor neurons and sensory nerve cells were also present in remote areas as well as in the vicinity of the lesion. Treatment with histaminergic agents and H-290/51 together results in significant improvement in hind limb

function and the cell injuries were markedly reduced and confined to the injury side only at the T10-11 segments. Edema formation and leakage of plasma proetins were minimized to the inured segment only. However, treatment with either histaminergic agents or H-290/51 alone the neuroprotective effect was much less evident on after 2 weeks of SCI. These results are the first to point out that histamine H3 and H4 receptors are regulating SCI induced pathophysiology and a combination of antioxidant induces superior neuroprotection in chronic SCI, not reported earlier.

Abstract: Parkinson's disease (PD) induces large social burden in the society for which no suitable therapeutic agents are available so far to reduce miserly of patients across the Globe. Military personnel are often quite prone to develop PD in later phase of their life in association with post-traumatic stress disorder (PTSD). In PD alpha synuclein (ASNC) plays a major role in developing PD pathology. Antibodies to ASNC are able to neutralize some of PD induced brain pathology.
dl-3-n-butylphthalide (NBP) a synthetic drug (CSPC Pharma China) is an antioxidant and neuroprotective agents in stroke and traumatic brain injury. The drug is also capable to induce neuroprotection in Alzheimer's disease (AD). Since brain pathology of AD and PD are quite similar, we investigated the role of NBP and ASNC in brain pathology of PD in a mouse model. To enhance the efficacy of these agents we also used TiO2 nanowired delivery of these agents in our PD model.
PD like symptoms appeared on the 8^{th} day after 1-metyl-4-phenyl-1,2,3,6-tetrahydropyridin (MPTP, 20 mg/kg, i.p.) daily within 2-h intervals for 5 days in male mice. A significant decrease in dopamine (DA) and its metabolites 3,4-dihydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVA) along with a marked decrease in the number of tyrosine hydroxylase (TH) positive cells in the Substantia Nigra Pars Compacta (SNpc) and striatum (STr) confirms the validity of this model. Measurement of ASNC showed 150-220 % increase in CSF in PD mice as compares to saline administered control group. Neuronal, glial cell and myelin damages examined using Nissl stain, glial fibrillary acidic protein (GFAP) and myelin basic protein (MBP) immunoreactivities respectively using standard protocol. Our observations show that NBP (60 mg/kg, i.p.) either alone or together with antibodies to ASNC (1:20, 100 µg in 10 µl sterile saline) given after 2-days of MPTP daily for 5 days resulted in a marked increase in TH-positive cells in the SNpc and STr as compared to untreated PD mice. Also NBP and ASNC antiserum therapy significantly increased DA, DOPAC and HVA in SNpc and STr on the 8^{th} day. Behavioral function was also significantly improved in MPTP-treated animals that received NBP and ASNC antibodies therapy together. Interestingly, nanowired delivery of NBP (40 mg/kg) with antibodies to ASNC (1:20, 50 µg in 10 µl) significantly enhanced neuroprotection in PD. Neuronal, glial and axonal damages were also considerable reduced in nanowired delivery group of NBP and ASNC abs in PD. These observations are the first to demonstrate that NBP and ASNC abs together when given using nanowired delivery has superior neuroprotection in PD, not reported earlier.

Title: Hyperphosphorylated tau aggregation as a platform for Alzheimer's disease therapeutics and risk factors identification

Authors: *M.-H. KUO[1], M. LIU[2], S. HOVDE[1], D. SUI[1];

Abstract: Alzheimer’s disease (AD) is an irreversible neurodegenerative disease that has no cure or prevention to date. A defining feature of AD is neurofibrillary tangles (NFTs) composed of fibrils of hyperphosphorylated tau. Here we show a novel AD drug screening methodology based on the aggregation of hyperphosphorylated tau (p-tau). P-tau expressed by the PIMAX approach possesses clinically relevant sites of phosphorylation, fibrillizes autonomously, and causes cell death at sub-micromolar concentrations. This inducer-free p-tau aggregation assay was applied to a 1280-compound library screen, in which we identified two brain permeant prescription drugs as potent p-tau aggregation inhibitors that also counteract p-tau cytotoxicity. Conversely, selective benzodiazepines were found to enhance p-tau aggregation and cytotoxicity, lending molecular support to the epidemiological association of benzodiazepines and increased risks of dementia. These results pave the way for high-throughput screening for therapeutics candidates as well as for the identification of potential risk factors of AD and tauopathies.

Title: Alzheimer's disease-like tau toxicity is enhanced by its nuclear localization

Authors: R. CANDIA[1], *A. ALONSO[2];
[1]The Col. of Staten Island, Staten Island, NY; [2]Col. of Staten Island, CUNY, Staten Island NY, NY

Abstract: Abnormal hyperphosphorylation of the microtubule associated protein tau is a common feature that links several neurodegenerative disorders known as tauopathies. Hyperphosphorylated tau is known to bind to itself and form aggregates rather than associate with microtubules. This loss of cytoskeletal support interferes with neuronal signaling and is thought to underlie the neurodegenerative process. Mutations in tau have been causally linked with familial forms of certain tauopathies, most notably frontotemporal dementia. The mutated tau involved in familial frontotemporal dementia (R406W) has been shown to form aggregates at an accelerated rate. In order to better characterize tau-mediated toxicity, our group has developed PH-tau, which is full-length human tau that has been pseudophosphorylated by the mutations S199E, T212E, T231E, and S262E. When human embryonic kidney (HEK-293) cells are transfected with PH-tau, either with or without the R406W mutation, the protein is found localized to the nucleus. In both cases, there appear to be morphological changes associated with tau overexpression as cells expressing PH-tau are more rounded. In addition, there was an overall decrease in the number of surviving cells post-transfection with PH-Tau-R406W, and a lower number of cells expressing either type of pseudophosphorylated tau compared to cells transfected with wildtype tau. Cells expressing PH-Tau-R406W also exhibit markedly less mitochondrial staining than cells expressing other forms of tau, and this loss of staining extends to nearby un-transfected cells. Elimination of the importin binding site from these constructs prevents the expressed tau from entering the nucleus. The changes in cell morphology and survival also seem to be prevented. However, the loss of mitochondrial staining does not appear to be prevented by removal of PH-Tau-R406W from the nucleus. These initial results suggest that PH-tau is a toxic species, and this toxicity is enhanced by the presence of the R406W mutation. In addition, the toxicity of these pseudophosphorylated tau constructs appears to be at least partially linked to entry into the nucleus. Further investigation will examine how the structure of the actin cytoskeleton, mitochondrial health, and overall cell viability are affected by the presence of pseudophosphorylated tau.

Title: Key sequences within isoforms of human tau protein drive aggregation in Alzheimer's and related tauopathies

Authors: *S. S. MADHAVAN, S. P. LAD, D. T. DOUGHARTY, M. MARCUS, F. HENDERSON, L. WU, B. XU;
Virginia Tech., Blacksburg, VA

Abstract: Alzheimer's Disease (AD) is the sixth leading cause of death in the United States, and leaves characteristic trademarks in the brain, one being neurofibrillary tangles (NFTs). NFTs form as tau proteins are hyperphosphorylated and become insoluble, ultimately creating highly ordered aggregates that strangle and kill brain cells. Failures in clinical trials on other AD-related proteins make tau a major target for AD drug discovery. In the human brain, tau has six alternatively spliced isoforms, containing 0, 1, or 2 N-terminal inserts, and 3 or 4 C-terminal repeat regions, referred to as 0N3R, 1N3R, 2N3R, 0N4R, 1N4R, and 2N4R. Currently, how tau isoforms aggregate and induce neurotoxicity is largely unknown. Using the largest isoform, 2N4R, as a template, we expressed, purified, and systematically characterized three series of truncation mutants using molecular biology, biochemical, and biophysical techniques. These series included 8 N-terminal truncation mutants, 5 C-terminal truncation mutants, and 3 C-terminal truncation mutants with attached peptide sequences. Detailed aggregation analysis of the truncation mutants revealed the critical role of the second and third repeat regions (R2 and R3) in tau aggregation. Deletion of both R2 and R3 repeat regions prevented protein aggregation. Interestingly, truncation mutants regained aggregation competency when a hexapeptide sequence from the beginning of R2 (VQIINK) or R3 (VQIVYK) was added, but not if a shorter tripeptide sequence shared between R2 and R3 was added (VQI). Our work highlights the importance of R2 and R3 derived hexapeptide sequences (VQIINK and VQIVYK) for human tau isoform aggregation, and provides a possible target for pharmacological intervention.

Title: An Alzheimer's disease-related mutation in MARK4 promotes tau accumulation and exacerbates tau-induced neurodegeneration in a *drosophila* model of tau toxicity

Authors: *T. OBA[1], T. SAITO[1], A. ASADA[1], K. M. IIJIMA[2], K. ANDO[1];
[1]Biol. Sci., Tokyo Metropolitan Univ., Tokyo, Japan; [2]Dept. of Alzheimer's Dis. Research, Natl. Ctr. for Geriatrics and Gerontology, Obu, Japan

Abstract: Alzheimer's disease (AD) is the primary cause of age-dependent dementia. Accumulation of microtubule-associated protein tau is associated with AD and related neurodegenerative disorders. Tau in disease brains are abnormally phosphorylated at a number of sites, and phosphorylation at Ser262 and Ser356 is known to stabilize tau and trigger accumulation of hyperphosphorylated tau in disease brains. Microtubule Affinity Regulating Kinase (MARK) 4 is a kinase that phosphorylates tau at Ser262 and Ser356. Expression of MARK4 is increased in AD brains and colocalizes with tau lesions. A mutation in MARK4, $MARK4^{\Delta Gly316Glu317InsAsp}$, has been associated with an elevated risk of AD. However, it is not well understood how this mutation affects tau metabolism and tau-induced neurodegeneration. Here we report that the introduction of ΔGly316Glu317InsAsp mutation in MARK4 enhances its effects on tau accumulation and tau-induced neurodegeneration by using a *Drosophila* model. We established a transgenic *Drosophila* expressing human MARK4 ($MARK4^{WT}$) or a mutant version of MARK4 ($MARK4^{\Delta Gly316Glu317InsAsp}$). Co-expression of $MARK4^{WT}$ has been reported to increases total tau levels via its phosphorylation at Ser262 and Ser356 and enhances tau-induced neurodegeneration. Co-expression of $MARK4^{\Delta Gly316Glu317InsAsp}$ also increased total tau levels and enhanced tau-induced neurodegeneration, and these effects of $MARK4^{\Delta Gly316Glu317InsAsp}$ on tau were higher than those of $MARK4^{WT}$. The effects of $MARK4^{WT}$ on tau accumulation and toxicity is depending on Ser262 and Ser356, and blocking tau phosphorylation at those sites by substitution of Ser262/356 to unphosphorylatable alanines (S2A) protects tau from the effects of $MARK4^{WT}$. In contrast, we found that co-expression of $MARK4^{\Delta Gly316Glu317InsAsp}$ increased the levels of S2A tau, suggesting that $MARK4^{\Delta Gly316Glu317InsAsp}$ promotes tau accumulation and enhances its toxicity through additional mechanisms. Further studies would shed light on the mechanisms by which $MARK4^{\Delta Gly316Glu317InsAsp}$ increases the risk of AD as well as dysregulation of MARK4 in disease pathogenesis.

Title: Photooxygenation inhibits tau amyloid formation

Authors: *Y. HORI[1], T. SUZUKI[1], T. SAWAZAKI[2], Y. SHIMIZU[2], Y. NEMOTO[1], A. TANIGUCHI[3], S. OZAWA[1], Y. SOHMA[2], M. KANAI[2], T. TOMITA[1];

Abstract: Alzheimer Disease (AD) is the most common neurodegenerative disorder, which is characterized by two types of depositions of amyloidogenic proteins, amyloid β peptide (Aβ) and tau with cross-β-sheet structure. Several lines of evidence suggest that the aggregation and deposition of these amyloidogenic proteins are associated with the pathogenesis in AD. Therefore, it is important to suppress the formation and the spread of these amyloid depositions, especially via regulation of the seeding activity because it plays an important role in the spreading of pathology in the human brain. Previously, we have reported photooxygenation catalyst which could selectively oxygenate amyloids under light irradiation by binding to cross-β-sheet structure and photooxygenation could suppress the aggregation and the toxicity of Aβ *in vitro* and *in vivo* (Taniguchi et al., Nat Chem 2016; Ni et al., Chem 2018). However, the effect of photooxygenation on tau amyloid was unclear. To investigate this issue, we first developed the new catalyst that was able to oxygenate tau amyloid more effectively than previous catalysts. Oxygen adducts in recombinant tau amyloid by the photooxygenation reaction were detected using MALDI-TOF-MS. Next, to examine the effect of the photooxygenation on the tau aggregation, we performed the *in vitro* aggregation assay measured by Thioflavin-T, which is a selective probe for cross-β-sheet structure. We revealed that the photooxygenation markedly inhibited the seeding activity of tau, thereby suppressing its aggregation. Finally, we showed that the photooxygenation significantly reduced the induction of the tau aggregation in the cellular tauopathy model by seed transfection, indicating that the photooxygenated tau lost its seeding activity in the intracellular milieu. These results indicates that catalytic photooxygenation markedly suppresses the tau seeding activity and inhibits the tau amyloid formation, both *in vitro* and in cultured cells. Thus, photooxygenation for tau amyloid would have the potential for AD therapy by attenuating the seed activity.

Title: Tau propagation is dependent on the genetic background in multiple mouse strains

Authors: *S. DUJARDIN[1], M. B. DE LOS SANTOS[2], R. N. BANNON[2], C. COMMINS[2], T. V. KAMATH[2], B. T. HYMAN[3];

Abstract: The hyperphosphorylation and deposition of tau protein in insoluble aggregates inside neurons are hallmarks of around 20 pathologies called tauopathies including the well-known Alzheimer’s disease (AD). In AD and other tauopathies, histopathological studies have shown that tau lesions appear progressively and hierarchically in the brain along anatomical connections. The mechanisms underlying such evolution had remained unexplained for many years, but recent evidence support the idea that the spread across brain areas is the result of the active propagation of tau aggregation within the brain. We and others previously demonstrated in in vitro and in vivo models that tau assemblies are transferred from cell-to-cell and, by being taken up by a second cell, seed the aggregation of endogenous tau leading to the propagation of tau lesions in the brain. We hypothesized here that the genetic background of mice influences the propagation of tau across neural networks. We used a model of tau propagation that we previously described in which adeno-associated viral vectors (AAV) encoding the eGFP-2A-Tau construct are injected into the entorhinal cortex of mice. The 2A peptide is a self-cleaving peptide resulting in the equimolar independent expression of the eGFP and human tau. Using this model, we can therefore discriminate the neurons expressing the AAVs (GFP and tau positive) from the tau propagation recipient neurons (tau positive only). We injected mice from multiple strains (n = 5 males and 5 females per strain), with diverse genetic backgrounds with this construct and subsequently quantified the number of neurons positive for tau propagation in each condition. In a blinded analysis we found that the propagation of tau in vivo is highly dependent of the genetic background with strains (such as C57BL/6) that are mostly resilient to tau propagation whereas other strains (such as CD-1 or A/J) show a high degree of tau propagation.In conclusion, these results provide an important insight to the idea that tau

propagates from neuron-to-neuron in the human pathology. This could explain part of the human clinical heterogeneity and must be investigated further to understand the genetic factors responsible for such drastic differences.

Gemelli IRCCS, Rome, Italy; [5]San Raffaele Pisana, IRCCS, Telematic Univ., Rome, Italy

Abstract: Extracellular vesicles (EVs) are involved in cell-to-cell communication, spreading of intracellular proteins and miRNA, as well as used by viruses to pass from a cell to another one. Microvesicles shed from plasma membrane whereas exosomes are smaller vesicles, generated from multivesicular bodies and released by neurons and glial cells. A growing body of evidence supports the role of EVs in transferring neurotoxic proteins such as Aβ and Tau, key players in Alzheimer’s disease (AD). Recent studies reported that aggregated forms of Tau can be transmitted among neurons and that exogenous aggregates of Tau could enter inside cells acting as seeds for the aggregation of the endogenous protein, thus propagating Tau-dependent damages in the brain. Several data support the role of Herpes Simplex Virus-1 (HSV-1) infection in AD pathogenesis. We recently demonstrated the effect of multiple viral reactivations on the accumulation of Tau-related brain damages in an *in vivo* mouse model. Interestingly, brain slices from HSV-1 infected animals showed a higher number of phosphorylated Tau (pTau) positive cells with respect to virus positive ones. Here, we investigated whether HSV-1 infection in the

brain could promote Tau spreading among neurons via EVs, as well as virus spreading. To this aim, EVs were isolated from supernatants of human neuroblastoma and primary cultures of rat neurons following 24-48h of HSV-1- or Mock-infection, analysed in western blotting (WB) or incubated on uninfected neurons for 24h following UV-treatment. Cell lysates were then analysed in WB for pTau content and compared to untreated cells. Results showed that EVs derived from HSV-1-infected cells contained: a) viral proteins, suggesting that the virus exploits them for its spreading among cells; b) increased levels of pTau, indicating that the virus can promote pTau propagation among neurons via exosomes. Accordingly, cells incubated with EVs isolated from HSV-1-infected cells showed: a) the occurrence of HSV-1 productive infection, as visualized by the use of fluorescent recombinant HSV-1 virus; b) higher levels of pTau with respect to those detected in untreated cells, indicating that exosomes derived from infected cells can promote Tau phosphorylation and likely its aggregation. Overall, these data indicate that the virus can promote pTau propagation among neurons via EVs, as well as virus spreading, and support the hypothesis that repeated HSV-1 reactivations into the brain may concur to neurodegeneration.

Abstract: Alzheimer’s disease pathogenesis is associated with the conversion of monomeric tau protein into filamentous aggregates. Because toxicity and prion-like spread of tau pathology depend in part on aggregate size, the processes that underlie filament formation and size distribution are of special importance. Here we investigate human 2N4R tau fibrillation dynamics using a combination of biophysical and computational approaches. We find that tau filaments engage in a previously uncharacterized secondary process involving end-to-end annealing, and that rationalization of empirical aggregation data composed of total protomer

concentrations and fibril length distributions requires inclusion of this process along with fragmentation. Annealing of 2N4R tau filaments is robust, with an intrinsic association rate constant of similar magnitude to that mediating monomer addition, and consistent with diffusion-mediated protein-protein interactions in the absence of long-range attractive forces. In contrast, secondary nucleation on the surface of tau filaments makes no detectable contribution to tau aggregation dynamics. These data demonstrate that tau filament ends engage in a range of homotypic interactions involving monomers, oligomers and filaments. They further indicate that in the case of tau protein, annealing and fragmentation along with primary nucleation and elongation are the major processes controlling filament size distribution.

Title: Quantification of lysine methylation on tau protein in aging and Alzheimer's disease

Authors: *C. J. HUSEBY[1], C. N. HOFFMAN[2], J.-C. COCURON[4], A. P. ALONSO[4], J. KURET[3];

Abstract: Tau is a microtubule-associated protein that normally interacts in monomeric form with the neuronal cytoskeleton. In Alzheimer’s disease, however, it aggregates to form the key structural component of neurofibrillary lesions. The transformation is thought to be controlled in part by age and disease-associated post-translational modifications. Recently we showed that tau is modified on lysine residues by methylation, and that high-stoichiometry methylation can depress the aggregation propensity of recombinant tau *in vitro*. However, whether methylation site occupancy changes with aging and disease or reaches levels needed to influence aggregation is unknown. Here we address this problem using liquid chromatography-tandem mass spectrometry approaches. Results revealed that lysine methylation was present in soluble tau isolated from cognitively normal elderly cases at multiple sites that only partially overlapped with cognitively normal middle aged and AD cohorts. Furthermore, aging and disease also were accompanied by a shift from predominantly dimethyl-lysine to monomethyl-lysine forms.

However, the bulk mol methylation/mol tau stoichiometry did not exceed 1 mol methyl group/mol tau protein in any cohort. We conclude that lysine methylation is a physiological post-translational modification of tau protein that varies with aging and disease. Although basal modification stoichiometries are low, artificial elevation of tau methylation may provide a means for protecting against pathological tau aggregation in disease.

Title: Identifying unique sites of tau phosphorylation during hyperexcitation

Authors: *A. K. SCHNEEWEIS[1], J. MA[2], E. ANDRE[1], W. ZHU[3], D. PAK[1];
[1]Pharmacol., [2]Proteomics and Metabolomics, [3]Neurobio., Georgetown Univ., Washington, DC

Abstract: Alzheimer’s Disease (AD) is the sixth leading cause of death. Current therapies address the symptoms of AD, but not disease progression. There are two pathological hallmarks of AD, aggregation of amyloid beta and hyperphosphorylated tau, and amyloid beta is the major target of current therapeutic studies. However, it has been shown that tau hyperphosphorylation, resulting in synaptic simplification and neuronal death, correlate more closely with dementia. In fact, amelioration of tau pathology can rescue dementia, even with amyloid plaques present. Tau is a microtubule associated protein that has been well-characterized as an axonal protein but has also been reported in the dendrites and synapses. Although tau has over 80 phosphorylation sites, many studies rely heavily on a few sites of phosphorylation to broadly determine hyperphosphorylation of tau in a specific condition or disease. Unfortunately, this methodology tends to be biased due to the exclusion of many other phosphorylation sites in tau. Currently, there lacks a comprehensive atlas identifying phosphorylation sites that may be different during specific cellular conditions, including homeostatic synaptic plasticity. I hypothesize that specific pattern of phosphorylation occurs during hyperexcitation which leads to downregulation of AMPA receptors. To test this hypothesis, DIV21 primary hippocampal neurons were treated with 100μM picrotoxin to induce hyperexcitation. Using mass spectrometry, I observed sites with unique tau phosphorylation compared to control. Additionally, using recombinant tau and Polo-like kinase 2 (Plk2), a kinase upregulated during hyperexcitation and known to phosphorylate Amyloid Precursor Protein, two additional sites were identified to be directly phosphorylated by

Plk2. Using mass spectrometry, I have shown that I can characterize tau phosphorylation during homeostatic synaptic plasticity in a way that is unbiased. Creating an atlas of tau phosphorylation sites involved in homeostatic synaptic plasticity could be useful as a biomarker and could also aid in the development of therapies for Alzheimer's Disease and other tauopathies.

Title: Development of new ultra sensitive assays to quantify tau aggregation and pathological tau conformation using digital immunoassay technology

Authors: *A. FRANCOIS, G. DAS DORES, F. IOP, R. BILLIRAS, V. PASTEAU, F. PANAYI, R. JEGGO;
Neuropsychiatry Ctr. of Therapeut. Innovation, Servier Res. Inst., Croissy sur Seine, France

Abstract: As clinical trials aimed at clearing neurotoxic β-amyloid species have so far been largely unsuccessful, interest in tau-based treatments, including tau-aggregation inhibitors is increasing. Therefore, the validation of assays sensitive enough to measure onset/progression of tau pathology in preclinical rodent models, as well as biomarkers to measure therapeutic efficacy in patients is increasingly important. The recent introduction of digital ELISA has highly improved the sensitivity of immunoassays. In this context, we have developed digital ELISA assays using the SIngle MOlecular Array (SIMOA™) technology from Quanterix to quantify total tau aggregation and the pathological tau conformation, MC1. The detection of total tau aggregation is based on the principle that the same monoclonal antibody is used for both capture and detection to selectively quantify aggregated tau forms over monomeric form. The screening of commercially available monoclonal tau antibodies was performed with tau-5, tau-2, tau-12, tau-14, tau-46, HT7, SP70, D1M9X, DA9 (provided by Dr. Peter Davis) and using heparin aggregated tau as calibrator. HT7 was identified as having the lowest limit of quantification (7.86 pg/ml of equivalent monomeric tau) and the largest dynamic range (up to ~3 logs). In parallel, two SIMOA™ assays, one to detect MC1 (provided by Dr. Peter Davis) positive aggregates and another to evaluate the total level of tau MC1 conformation were developed. These three SIMOA™ assays were applied to characterize the tau pathology in postmortem samples of frontal cortex of Alzheimer's disease (AD) patients and healthy controls and the progression of tau pathology in a tau transgenic mouse model overexpressing the mutated P301S tau. As expected, levels of total tau aggregation, MC1 positive aggregates and total MC1 levels were

significantly higher in AD patients compared to healthy controls. Interestingly, MC1 positive aggregates in AD brain samples represent approximately 50% of the total tau aggregation. In the P301S mouse model the tau pathology time-course showed a significant increase of total tau aggregation and MC1 positive aggregates at 9 months compared to 3 and 6 months. MC1 positive aggregates represent approximately 12% of the total tau aggregation in this model and total MC1 levels increased progressively in a time-dependent manner.These three new ultra-sensitive assays provide new tools to investigate the progression of tauopathy in transgenic models, to evaluate the efficacy of different tau-targeting treatments and to determine the optimal treatment window with the best estimated translatability to the human situation.

Title: The dynamics of MAPT liquid-liquid phase separation are regulated by RNA binding proteins

Authors: P. E. ASH[1], S. LEI[1], S. BOUDEAU[1], L. JIANG[1], L. AL-MOHANNA[1], M. KNOBEL[1], N. M. KANAAN[3], *B. L. WOLOZIN[1,2];

Abstract: Microtubule-associated protein tau (tau), the hallmark aggregating protein of Alzheimer’s disease (AD), interacts with RNA binding proteins (RBPs) in the pathogenesis of

disease. Previously, we demonstrated that depletion of Tia1 (a core nucleating RBP of stress granules) in transgenic PS19 P301S tau mice results in behavioural recovery and increased life span. Recovery in PS19; Tia1+/- mice correlates with increased fibrillary tau pathology but reduced levels of oligomeric tau. Recombinant TIA1 interacts with tau, inhibits the elongation of fibrillary tau and stabilizes oligomeric tau, promoting its accumulation. Both RBPs and tau undergo liquid-liquid phase separation (LLPS).We hypothesized that the interaction of tau with RBPs would promote phase separation which would modulate production of pathogenic tau. LLPS of tau and RBPs, conjugated with DyLight fluorophores, was assayed by epifluorescent and super resolution microscopy. The dynamics and distribution of Tau LLPS were differentially affected by diverse RBPs. The rate of formation of tau droplets was strikingly increased in the presence of TIA1 in a dose dependent fashion. Initially, both tau and TIA1 were diffusely distributed in droplets, however over time, tau became concentrated into microdomains within the TIA1 droplets. Microdomains of tau show reduced diffusion suggesting conversion to gels. In contrast, Tau exhibits no phase separation with proteins, such as eIF4E. Tau microdomains are spherical, appear to exclude TIA1 and are sensitive hexandiol, suggesting LLPS within TIA1 droplets is governed by differential hydrophobicity. Introduction of pseudo phosphorylation into tau (E14) dramatically changes the dynamics of co-LLPS with TIA1. E14-tau forms amorphous microdomains within TIA1 droplets, suggesting that phosphorylation alters charge distribution in tau that changes the biophysical properties by which tau undergoes LLPS in the presence of TIA1. Progression of AD is characterized by increasing accumulation of phosphorylated-tau. Our results suggest that tauopathy results from the interaction of hyper-phosphorylated tau with RBPs as part of the protein translation stress response. This interaction is mediated by phase separation of tau with RBPs. The concentration of tau in the RNA granules accelerates oligomerization and then fibrillization, resulting in formation of pathological aggregates. As such, phase separation of phospho-tau with RBPs may be the focal point for generation of tau pathology.

Title: Neuroprotective effects of cannabinoid ligands in a model of early Alzheimer pathogenesis

Authors: *E. BOESCH[1], T. B. DEMARSE[2], B. HARRIS[3], A. DOMBROSKI[3], A. SUCHY[3], A. AMIN[3], R. B. MEEKER[3];

Abstract: Alzheimer disease (AD) is a devastating neurodegenerative disorder with no disease-modifying therapies currently available. Since AD pathology is preceded by inflammation and neural dysfunction, control of these early manifestations has the potential to modify the course of the disease. Cannabidiol (CBD) has both anti-inflammatory and network stabilizing effects that could offer early protection. To determine if CBD has neuroprotective properties in the context of early AD pathogenesis, we evaluated its effects on regulation of intracellular calcium in primary neurons challenged with conditioned medium from microglia treated with amyloid beta oligomers ($A\beta_o$). Since microglia are potential targets, we also investigated the "anti-inflammatory" properties of CBD by pretreating microglia with CBD before exposure to $A\beta_o$. Network stabilizing properties were measured through electrophysiological recordings of neurons cultured on microelectrode arrays. In neurons, CBD partially decreased the aberrant neuronal calcium accumulation in response to microglial conditioned medium while also increasing the intensity of individual calcium signaling events. CBD also stabilized neuronal network activity and facilitated synchronous activity while decreasing the frequency of synchronous firing events. CBD treatment of microglia robustly decreased secretion of neurotoxic factors suggesting a strong effect on microglial secretory phenotype. Since the pharmacology underlying the potential benefits of CBD is still poorly understood, we examined potential signaling through CB_2 and GPR55. The GPR55 antagonist, ML193, and the CB_2 agonist, JW133, but not CBD, decreased the frequency of intrinsic neuronal calcium signaling in neurons. The GPR55 agonist, LPI, induced a prominent facilitation of mononuclear phagocyte calcium signaling but had a marginal effect on neurons indicating that microglia and macrophages may be prominent targets. Different effects of CBD versus CB_2 and GPR55 ligands indicated a complex pharmacology that needs to be explored in greater depth. The suppression of neural calcium dysregulation, "anti-inflammatory" effects on the microglial secretome and stabilization of neural network activity support the hypothesis that CBD has disease modifying potential for AD.

Title: Regulatory effect of resveratrol on neuronal apoptosis in Alzheimer's disease

Authors: *X. WANG[1], F. JIAO[1], Q. ZHAO[2], S. ZHANG[3], Y. ZHANG[3], Y. ZAI[3], Y. WU[1]; [1]Shandong Key Lab. of Behavioral Medicine, Inst. of Mental Health,Jining Med. Univ., [2]shool of Mental Health,Jining Med. Univ., [3]Jining Med. Univ., Jining, China

Abstract: Alzheimer's disease is achronic neurodegenerative disorder. It's one of observably characters is progressive loss of cognitive and behavioral abilities. AD shares the same pathological hallmarks in the brain, including extraneuronal neuritic plaques,intraneuronal neurofibrillary tangles and synaptic/neuronal loss leading to brain atrophy. In the past few years, many studies have reported interesting in sights about the neuroprotective properties of the poly phenolic compound resveratrol when used with in vitro and in vivo models of AD.Resveratrol(3,5,4_-trihydroxy-*trans*-stilbene)is widely found in skin and seeds of more than 70 different plant species, including hellebore, grapes, berries, grains, tea, peanuts. Resveratrol as a natural herbal extracts in many Chinese herbal medicine has been reported that Resveratrol play an important biological role in protective against oxidative stress, inflammation, and the development of cardiovascular diseases, diabetes, neurodegenerative diseases and cancer. Recent studies reported that resveratrol protects neurons against peroxide (H_2O_2), 1-methyl-4-phenylpyridine ion (MPP) and Aβ injury. A rat model of AD suggests that resveratrol can prevent the cognitive impairment. However, the neuroprotection of resveratrol against Aβ cytotoxicity, oxidative stress or endoplasmic reticulum stress,especially the underlying mechanism, remains largely unknown due to its widely pharmacological actions. Therefore, our study devoted ourselves to the protective effect of resveratrol against oxidative stress or endoplasmic reticulum stress and explored the possible underlying mechanisms.***Results:***1) Resveratrol can increase SH-SY5Y cell viability in oxidative stress/ Ca^{2+} overexpress.2) Resveratrol reduces the oxidative stress/ Ca^{2+} overexpress which induced Ca^{2+}level in SH-SY5Y cell. 3) Resveratrol downregulates the RCAN1 ,BACE1,PSN1,GRP78,CHOP expression in oxidative stress/ Ca^{2+} overexpress cells.

Title: The interaction between fructose and DHA consumption on Alzheimer's disease (AD) pathogenesis

Authors: *V. PALAFOX-SANCHEZ[1], Z. YING[1], X. YANG[1], F. GOMEZ-PINILLA[1,2]; [1]Integrative Biol. and Physiol., UCLA, Los Angeles, CA; [2]Dept. of Neurosurg., UCLA Brain Injury Res. Ctr., Los Angeles, CA

Abstract: It is becoming an alarming public health issue that a large portion of the American population is affected by some degree of metabolic disorder such as diabetes and obesity with subsequent risk for the pathogenesis of AD. Although AD is getting recognition as a metabolic disorder, how dysfunctional metabolism exacerbates the pathogenesis of AD is poorly understood. Fructose is the most consumed sugar in our society in soft drinks and processed foods and is a major contributor to the epidemic of metabolic disorders. Fructose explains a remarkable 20% increase in diabetes, and the connection between diabetes and dementia is increasingly recognized. We are embarked in studies to examine the effects of the metabolic perturbation posed by fructose and the potential of the omega-3 fatty acid DHA to counteract these effects on the AD pathogenesis using the 5xFAD mice. We started treatment when the 5xFAD mice were 2 month-old and found that the mice developed peripheral insulin resistance by 3 months old. The capacity to manage glucose was further altered in the 5xFAD mice treated with fructose. The insulin resistance has been related with alteration in the progression of DA and is becoming an important hallmark in the AD pathogenesis. Fructose ingestion disrupts cognitive performance in the Barnes Maze and open field center time starting by 8 weeks after treatment and continued progression by 12 weeks after fructose ingestion, compared to the 5xFAD+water consumption group. Most of the effects elicited by fructose were counteracted by DHA. Most of these alterations were counteracted by DHA supplemented in the diet. Fructose is metabolized differently to glucose favoring pathogenic pathways and posing additional toll to AD pathogenesis. Our results indicate that metabolic dysfunction carried by fructose increased predisposition to AD pathology. These results are important for the design of public health programs to counteract the effects of AD pathology.

Abstract: Alzheimer’s disease (AD) is a progressive neurodegenerative disorder that accounts for 60-70% of dementia cases. In AD, the Aβ42 fragment of the amyloid precursor protein (APP) and hyperphosphorylation of the microtubule associated protein Tau, play important roles in disease pathology. Moreover, familial AD is associated with higher levels of Aβ42. Drug discovery for AD has had limited success. Repurposing of FDA-approved drugs could streamline the identification of AD therapeutics. Our *in silico* studies predicted the following: (1) Diazoxide (DZ), which is FDA-approved for hypertension, is a potassium channel activator that could activate multiple AD-relevant kinases. (2) The anti-inflammatory Ibudilast (IBU) and the antidepressant Rolipram (ROL) could inhibit AD-relevant phosphodiesterases. (3) The cancer-preventing Dibenzoylmethane (DIB) could induce the expression of antioxidant enzymes. We investigated the therapeutic potential of these four drugs against Aβ42 and Aβ40 production in skin fibroblasts from a familial AD patient carrying the A246E mutation in the presenilin 1 gene, and human neuroblastoma SY5Y cells overexpressing APP695 (APP695-SY5Y). Cell viability (MTT) assays established that DZ, DIB and ROL are not toxic, but DIB is in both fibroblast and neuroblastoma. Assessing Aβ42 and Aβ40 secretion with ELISAs demonstrated that DZ and IBU decrease Aβ42 production, suggesting that these drugs may reduce AD pathology. The effect of these drugs on tau hyperphosphorylation is also being determined. Moreover, we are testing whether the *in vitro* anti-AD effects of IBU will be reproduced in a transgenic rat model of AD, thus offering a new treatment strategy for this disease.

Title: Disease model for progranulin-linked frontotemporal dementia using patient and engineered stem cells

Authors: ***J. TERRYN**[1], F. NAMI[1], M. GAJJAR[1], W. DECRAENE[1], L. ORDOVAS VIDAL[1], S. RAITANO[1], P. VAN DAMME[2], C. VERFAILLIE[1];
[1]KU Leuven, Leuven, Belgium; [2]Neurol. Department, UZ Leuven, Leuven, Belgium

Abstract: INTRODUCTION: Frontotemporal lobar degeneration (FTLD) is a progressive neurodegenerative disease, characterized by behavior and language problems. FTLD is related to the progressive motor neuron disease Amyotrophic Lateral Sclerosis on a clinical, genetic and pathophysiological level. We focus on FTLD linked to mutations in the progranulin gene (*GRN*) and use stem cell technology to model the disease. Provoked by the great clinical heterogeneity seen in these patients, we sought to study the specific contribution of the progranulin (*GRN*) mutation versus its genetic background and disease modifiers.
METHODS: We seamlessly inserted the *GRN* gene mutation (*IVS1 +5G>C*) into an iPSC line and an embryonic stem cell line. In addition, we created patient iPSC lines that conditionally overexpress a copy of the *GRN* gene with the aim to create a flexible inducible correction of the PGRN haploinsufficiency. Genome engineering to introduce the $GRN^{IVS1\ +5G>C}$ gene mutation was performed using TALE nucleases and the Piggybac transposon system. To create the flexible PGRN overexpression system, two patient iPSC lines first underwent site specific targeting of the *AAVS1* locus, using zinc-finger mediated integration of a donor cassette, to create master cell lines suitable for Flippase (FLPE) mediated recombinase mediated cassette exchange (RMCE). We next performed RMCE to create doxycycline inducible progranulin $GRN^{IVS1+5G>C}$ iPSC lines. Patient- and engineered stem cells were characterized, differentiated into cortical neurons using published methods (Shi et al. Nature protocols 2012; 7 1836-1846) and subjected to RNA-sequencing.
RESULTS: We successfully introduced the $GRN^{IVS\ +5G>C}$ gene mutation in an iPSC and ESC line. Sequencing confirmed the introduction of the $GRN^{IVS1+5G>C}$ mutation and *GRN* expression

levels, assessed by RT-qPCR, confirm *GRN* haploinsufficiency throughout cortical neuron differentiation. Conditional overexpression of PGRN to correct PGRN haploinsufficiency in patient derived iPSC lines was confirmed by qRT-PCR and Western blot. Functional characterization of the PGRN haploinsufficient stem cells revealed possible cytoskeletal dysfunction. Transcriptome analysis of the patient derived and engineered lines supported this possibility and revealed the presence of a disease-related transcriptional signature in the pluripotent stem cells that persisted throughout neuronal differentiation. In conclusion, by investigating patient derived and genome engineered $GRN^{IVS\ +5G>C}$ PSC and cortical neurons, we could unequivocally link disease related phenotypes to progranulin haploinsufficiency.

Title: Novel NAMPT activators attenuate neurotoxicity and neuroinflammation associated with neurodegeneration

Authors: *J. GORDON-BLAKE, K. RATIA, B. KARUMUDI, K. DYE, R. C. KNOPP, M. BEN AISSA, K. TAM, G. THATCHER;
Medicinal Chem. and Pharmacognosy, Univ. of Illinois at Chicago, Chicago, IL

Abstract: Background: Therapies directly targeting amyloidβ (Aβ) and hyperphosphorylated tau in Alzheimer’s disease (AD) have been unsuccessful, so an alternative drug target is desperately needed. One potential strategy to prevent or reverse the course of the disease is to target the NAD/NAMPT pathway, proposed largely with reference to dietary supplements. Increasing catabolism of NAD with age, leading to NAD depletion, impacts cellular energy pathways crucial to neuronal function. In combination with protein misfolding associated AD pathophysiology, NAD depletion can drive disease progression. An efficient way to increase NAD is to activate nicotinamide phosphoribosyltransferase (NAMPT), which catalyzes the rate limiting step in NAD biosynthesis. We hypothesize that by activating NAMPT, increased NAD levels will support neuroprotective pathways that will prevent neurodegenerative progression. **Method:** To test our NAMPT activation hypothesis, we employed a high throughput screen (HTS) of 10,000 compounds measuring NMN production and ATP depletion. Structural analogs of hits were synthesized to generate cocrystal structures with NAMPT. Neuroprotection by the hit and analogs against oxygen-glucose deprivation (OGD) was measured, in addition to effects

on neuroinflammation. Cellular NAD was also measured.
Result: Our HTS campaign produced several hits that increased NAMPT activity. Novel NAMPT activators were shown to activate NAMPT with nanomolar potency and binding was validated by surface plasmon resonance (SPR) and X-ray crystal structure diffraction. In contrast, the reported NAMPT activator, P7C3, showed no activity in NAMPT assays. Several analogs showed concentration-dependent neuroprotection and reduced neuroinflammation. Cellular NAD was partially restored in models of oxidative stress, and ATP consumption was greatly attenuated by activators in enzyme assays.
Conclusion: These results provide a proof-of-concept for the first small molecule activators of NAMPT, with a detailed mechanism of action supported by enzymology and structural biology. The use of NAMPT activators in treatment of ADRD, possibly in combination with NAD supplements, is proposed.

Abstract: Alzheimer’s disease (AD) is a progressive neurodegenerative disorder that causes an irreversible cognitive decline in elderly people. Towards fulfillment of the unmet need for an effective AD therapy, our ultimate goal is to develop a robust AD patient-specific personalized precision-guided targeted gene knockdown and gene editing therapy. Glia maturation factor (GMF), a brain specific pro-inflammatory molecule discovered in our laboratory plays a crucial role in neuroinflammation and AD pathogenesis. We hypothesized that GMF knockdown by short-hairpin RNA (shRNA) and CRISPR/Cas9-mediated GMF gene editing in microglia is a novel approach to reduce neuroinflammation. To achieve GMF knockdown and gene editing, we

developed and tested recombinant lentiviral vectors (LVs) expressing either GMF-specific shRNAs or recombinant adeno-associated viral (AAV) vectors and LVs expressing CRISPR/Cas9 and GMF-specific sgRNAs. LV-mediated GMF knockdown by GMF-specific shRNAs in BV2 microglial cell line was confirmed by western blot analysis. Confocal microscopy of BV2 cells transduced with an AAV simultaneously co-expressing SaCas9 and a GMF specific sgRNA revealed a small subset of BV2 cells expressing SaCas9 while completely lacking GMF expression, thereby confirming successful biallelic GMF gene editing. Further, sequential transduction of BV2 cells with LV-SpCas9 and LV-GMF-sgRNAs was used to generate stable GMF-edited clones. Confocal microscopy revealed reduced GMF expression in GMF-edited BV2 cells as compared to non-edited BV2 cells. DNA sequencing of GMF-edited clones revealed indels in the exons 2 and 3 of GMF coding sequence thereby conclusively proving SpCas9-mediated GMF gene editing in BV2 cells. Treatment of wild type non-edited and GMF-edited BV2 cells with LPS revealed differences in basal p38 MAPK as well as LPS-induced phosphorylation of p38 MAPK. In wild type non-edited BV2 cells, LPS treatment induced significant upregulation of pp38 MAPK; however, in GMF-edited BV2 cells the pp38 MAPK levels were significantly lower, thereby indicating that GMF gene editing leads to attenuation of microglial activation. Overall, our data suggest that GMF knockdown and GMF gene editing represent novel approaches to develop precision-targeted AD patient-specific therapy.

Abstract: Pharmaceutical companies are currently revisiting palliative therapies for Alzheimer’s disease (AD) because of the setbacks observed in the development of a disease-modifying therapy. The current greatest interest is to exploit the therapeutic potential of 5-HT_6 receptor. SUVN-502, a 5-HT_6 receptor antagonist, was evaluated using a novel approach for the

symptomatic treatment of AD dementia. SUVN-502 was added to background dual combination treatment of donepezil and memantine (triple therapy). The trial was a phase-2a proof-of-concept, randomized, double-blind, placebo-controlled, multicenter, parallel groups study conducted in the United States (NCT02580305). Total trial duration was 30- weeks i.e., 26-weeks double-blind treatment period followed by a 4- weeks placebo washout. A total of 558 subjects aged between 50-85 years, received double-blind oral treatment of SUVN-502 (50 or 100 mg) or placebo once daily in a ratio of 1:1:1. The primary efficacy endpoint was evaluated using Alzheimer's Disease Assessment Scale for Cognition (ADAS-Cog 11). Secondary endpoints include change in the Clinical Dementia Rating Scale - Sum of Boxes Score (CDR-SB), the Alzheimer's Disease Co-operative Study - Activities of Daily Living Scale (ADCS-ADL), the Neuropsychiatric Inventory (NPI), the Cornell Scale for Depression & Dementia (C-SDD) and Mini-Mental State Examination (MMSE). For primary and secondary analyses, SUVN-502 (50 or 100 mg) was compared with the placebo. Treatment groups were compared in terms of mean change from baseline for all the endpoints. Between-group comparisons were based on the intent-to-treat population using a mixed effects model for repeated measures using the z-score last observation carried forward approach prior to analysis. No adjustments for multiple comparisons were made. Topline efficacy results will be presented in the meeting.

Abstract: A novel symptomatic therapy that addresses the limitations of current standard of care is needed for the treatment of Alzheimer's disease (AD). Central antagonism of the 5-HT_6 receptor may provide a mechanistically distinct palliative treatment for AD that works through cholinergic and glutamatergic neuronal systems. SUVN-502, a promising 5-HT_6 receptor antagonist, is evaluated as a novel approach for the management of AD dementia: triple therapy with SUVN-502 added to background treatment with donepezil and memantine. This study is a phase-2a proof-of-concept, 26-weeks, randomized, double-blind, placebo-controlled, multicenter, parallel groups study conducted in the United States (NCT02580305). The study involves a 2 to 4- weeks screening period followed by a 26- weeks double-blind treatment which is followed by a 4-weeks placebo washout period. Total of 558 subjects, aged 50-85 years, received double-blind oral administration of one of three treatments once daily; SUVN-502 (50 mg), SUVN-502 (100 mg), or placebo in a 1:1:1 ratio. The primary efficacy endpoint was evaluated using Alzheimer's Disease Assessment Scale for Cognition (ADAS-Cog 11). Secondary endpoints were change in the Clinical Dementia Rating Scale - Sum of Boxes Score (CDR-SB), the Alzheimer's Disease Co-operative Study - Activities of Daily Living Scale (ADCS-ADL), the Neuropsychiatric Inventory (NPI), the Cornell Scale for Depression & Dementia (C-SDD) and Mini-Mental State Examination (MMSE). The baseline patient characteristics of the enrolled population were analyzed using customary summary statistics and comparisons. Subject characteristics are highly consistent with moderate AD clinical trial populations in the U.S.

Title: The effect of clinical vestibular repeating stimulation on Alzheimer's disease by air caloric device

Authors: *K. NAKAMAGOE[1], S. YAMADA[1], R. KAWAKAMI[1], T. KOGANEZAWA[2], A. TAMAOKA[1];
[1]Dept. of Neurology, Div. of Clin. Medicine, Fac. of Medicine, Univ. of Tsukuba, Tsukuba, Japan; [2]Dept. of Physiology, Div. of Biomed. Science, Fac. of Medicine, Univ. of Tsukuba, Tsukuba, Ibaraki, Japan

Abstract: Objective and rationale: We have previously demonstrated that cortical vestibular dysfunction with Alzheimer's disease (AD) is one cause of balance disorders with dementia (Nakamagoe et al. *J Alzheimers Dis* **47**:185-196, 2015). The present clinical study is the first to explore the prevention of balance disorder progression in patients with AD through vestibular stimulation with an air caloric device. The purpose of this study was to delay the progression of balance disorders by inducing vestibular compensation by utilizing the effects of vestibular stimulation on cerebral activation. **Methods:** Eight AD patients underwent vestibular stimulation every two weeks for six months as a "stimulation group." As a control group, 7 AD patients participated as the "non-stimulation group." Both groups were subsequently evaluated with a higher function test, stepping test, a caloric test, and a smooth-pursuit eye movement test just before and 6 months after starting the study. The rate of decline of these test parameter values of both groups were compared. **Results:** Vestibular stimulation was performed on all patients without dropouts. The stimulation group's rate of decline in their Mini-Mental State Examination (MMSE) scores decreased more than in the non-stimulation group (P=0.02). Those tests, except for MMSE scores, did not show any significant differences. **Conclusion:** From the MMSE results, repeating vestibular stimulation is suggested to delay the progression of functional impairment of the cerebrum. On the other hand, we were unable to prove the effect for vestibular and eye movement control. Future clinical application will require an increased number of cases. *Research projection*: Dr. Nakamagoe, Conception. Dr. Nakamagoe and Dr. Tamaoka, Organization. Title: Repetitive transcranial magnetic stimulation as an emerging treatment of cognitive dysfunction in Alzheimer’s disease

Authors: ***M. W. MCNERNEY**[1,2], J. CHENG[1], A. NODA[1], B. HERNANDEZ[1], L. SHERE[1], J. YESAVAGE[1,2];

Abstract: Alzheimer’s disease (AD) and mild cognitive impairment are debilitating neurodegenerative conditions characterized primarily by loss of memory. Although medications can be used to help alleviate symptoms, current treatments are insufficient. We therefore aimed to determine if an emerging therapy, repetitive transcranial magnetic stimulation (rTMS), can be utilized to help individuals suffering from Alzheimer’s symptoms. rTMS is a noninvasive brain

stimulation technique which can be used to target magnetic fields into the brain, thereby inducing changes in cell singling and plasticity. In the current study, 13 patients received sham stimulation and 10 received magnetic stimulation directed at the dorsolateral prefrontal cortex. The treatment consisted of 20 sessions of 10Hz stimulation. Prior to and following treatment, patients were given a battery of cognitive tests and a blood draw to test for changes in circulating brain-derived neurotrophic factor (BDNF), a protein which underlies plasticity and is decreased in AD. The treatment group showed a modest improvement in both the Trails B test and the California Verbal Learning test while no difference was found for the sham controls. There was a small increase in circulating BDNF levels compared to sham controls, but the was also high variability between samples in both conditions. These results show preliminary evidence that rTMS can help the cognitive deficits seen in AD, but more research needs to be done to determine if BDNF is reliably responding to treatment. Another future step will be to incorporate brain imaging results.

Title: A possible role of Palmitoylethanolamide combined with Luteoline in Frontotemporal Dementia treatment: A clinical and neurophysiological study

Authors: *M. ASSOGNA[1], E. CASULA[2], C. MOTTA[1], S. BONNÌ[2], I. BORGHI[2], F. DI LORENZO[2], M. MINEI[2], A. MARTORANA[1], G. KOCH[2];

Abstract: Frontotemporal dementia (FTD) is a frequent cause of presenile neurodegenerative dementia and there is no effective pharmacological treatment to slow its progression. A link has been proposed between neuroinflammation and specific forms of FTD, suggesting that neuroinflammation is an important component of the disease since the early phases. We aim to investigate efficacy and safety of Palmitoylethanolamide combined with Luteoline (PEA-LUT) in a sample of FTD patients to reduce behavioral disturbances. We enrolled ten patients with a diagnosis of probable FTD. We performed cognitive and neurophysiological evaluations at baseline (T0) and after 4 weeks (T1) treatment with PEA-LUT 700 mgx2/day. To evaluate the cognitive effects of PEA-LUT administration we used a battery of tests including the MMSE, the Frontal Assessment Battery (FAB), the Neuropsychiatric Inventory (NPI), the screening for

aphasia in Neurodegeneration (SAND), the Activity of daily living inventory (ADCS/IADL) and the FTD modified Clinical Dementia Rating (FTD-CDR). We measured change on synaptic transmission using SICI-ICF, LICI and SAI paired-pulse TMS protocols over the primary motor cortex. We used iTBS protocol to measure changes in cortical plasticity. We used combined TMS/EEG methods to evaluate changes in DLPFC cortical oscillatory activity. We observed an improvement in NPI mean score (p=0.018) and FAB score (p=0.038). Neurophysiological evaluation showed a restoration of LICI (p=0.040), in particular at ISI 100ms (post-hoc p=0.035), suggesting a modulation of GABA(B) activity. We observed an increase of LTP-like cortical plasticity (p=0.079) and of DLPFC oscillatory activity in beta/gamma range. PEA-LUT could reduce behavioural disturbances and improve executive function in FTD patients through the modulation of cortical excitability and GABAergic transmission.

Title: Role of Akt2 in activity dependent protein translation in Alzheimer's disease pathology

Authors: *V. RAVINDRANATH[1], **R. D. GOWAIKAR**[2];
[2]Ctr. for Neurosci., [1]Indian Inst. of Sci., Bangalore, India

Abstract: The clinical stage of Alzheimer’s disease is characterized by memory and cognitive impairments leading to severe dementia. This however is the culmination of a long series of physiological events, that may have their origins decades prior to the manifestation of the symptoms. One such physiological process to be affected in early stage of AD is activity dependent translation at the synapse. Work in our lab has shown that this process of activity dependent translation which is responsible for maintenance of normal synaptic function and consolidation of long-term changes at the synapse is affected in young AD mice. This process is regulated by intracellular signaling cascades like Akt-mTOR signaling cascade. Akt also known as Protein Kinase B which plays a central role in this signaling cascade is a Serine-Threonine kinase.There are 3 known forms of Akt kinase: Akt1,Akt2,Akt3. Akt1 is implicated in cell growth and survival. Akt2 is expressed in muscles and adipocytes and has a role in glucose homeostasis. Akt3 is expressed in the brain and testes. Despite sharing a high degree of amino acid identity, phenotypes observed in knockout mice suggest that Akt kinases are not functionally redundant. However, the functional roles of the individual kinases are not completely understood and require further investigation, especially in the brain in general and at

the synapse, in particular. Our study first focused on characterization of Akt isoforms in the brain, and the study of their individual contribution to activity dependent synaptic translation. To this effect we measured the RNA and protein levels of Akt isoforms in C57 mice of different age groups. We observed that Akt2 is the most abundant protein in the brain. Next, we measured the activity of Akt isoforms in a transgenic mouse model of AD, APPswe/PS1ΔE9(APP/PS1). We did this by measuring phosphorylated levels of Akt isoforms and by performing kinase assays. We observed that Akt1 & Akt2 show a decrease in activity in 1 month old APP/PS1 mice. The decrease in activity of Akt2 is the most while Akt3 isn't affected at all. We therefore, downregulated each isoform in primary cultures using shRNA. A protein translation assay based on puromycin uptake was performed on these cells. Our results indicate that downregulation of Akt2 has the most substantial negative effect on activity dependent protein translation in cultured hippocampal cells. In conclusion, our study has revealed the differential distribution of Akt isoforms in the brain and also differential regulation by them of activity dependent protein translation.We also observed Akt2 activity to be reduced in young AD mice thus indicating a role of Akt2 in AD disease progression.

Title: Sex specific differences in synaptic dysfunction and behavioral deficit in Alzheimer's disease mouse model

Authors: *R. KOMMADDI[1], K. CHITHANATHAN[1], R. D. GOWAIKAR[1], S. KARUNAKARAN[2], V. RAVINDRANATH[1,2];
[1]Ctr. for Neurosci., [2]Ctr. for Brain Res., Indian Inst. of Sci., Bangalore, India

Abstract: The occurrence of Alzheimer's disease (AD) is greater in women than in men. Several processes such as brain development, adult brain structure and function, molecular and biochemical signatures differ by sex. Sex differences in the brain are initiated through sex-determining genes and hormonal factors and these differences have important clinical implications for AD risk. However, the molecular mechanisms underlying the higher burden of AD in women remain unknown. Thus, we are interested in looking at sex-specific differences in

terms of the progression of the disease and that we studied younger ages because the disease starts early. Associative learning and memory test was assessed by contextual fear conditioning (cFC). Male APP/PS1 mice, but not female mice showed deficient recall upon contextual fear conditioning at 2, 4 and 6 months of age. Female APP/PS1 mice started showing deficient recall upon contextual fear conditioning only after the age of 8 months after onset of menopause and this was sustained as the mice aged. Further, we found significant decrease in synaptosomal F-actin levels in male (indicative of dendritic spine dysfunction), but not in female, APP/PS1 mice at 4 months of age. Intriguingly, synaptosomal F-actin levels also started decreasing in female APP/PS1 mice at the age of 8 months. Activity dependent synaptic protein translation (^{35}S-methionine incorporation) was affected only at 8 months of age and no deficits were seen in 3-4 months old APP/PS1 female mice. Synaptosomal Akt1-mTOR signaling pathway , which is significantly down-regulated in male APP/PS1 mice was actually upregulated in female mice at 4 months and declined as they aged and entered menopause. We conclude that the appearance of cognitive deficits, loss of synaptosomal F-actin and perturbation of Akt1-mTOR pathway occurred in females only as they aged, specifically as they entered menopause. These findings indicate that the neuroprotective effects of estrogen may play an important role in protecting from β-amyloid induced toxicity at the synapse and estrogen plays a critical protective role in preventing synaptic dysfunction during early stages of AD progression.

Title: Cortical synaptic transcriptomic profile of a mouse model of Alzheimer’s disease

Authors: *R. D. GOWAIKAR[1], A. VERMA[2], V. RAVINDRANATH[3];
[2]Ctr. for Neurosci., [1]Indian Inst. of Sci., Bangalore, India; [3]Ctr. for Neurosci., Indian Inst. of Sci., Bangalore North, India

Abstract: One of the most debilitating aspect of Alzheimer’s disease (AD) at the pathophysiological level is the degeneration of neurons. But increasing evidence points to synaptic dysfunction as one of the earliest events in the cascade of events of this progressive disease. Synaptic dysfunction observed at early stages of AD can be both structural and functional in nature; for example, dysfunction in actin cytoskeleton, and activity dependent synaptic protein translation respectively. Substantial evidence of presence of functional protein translation machinery at the synapse has accumulated over the past decade. We characterized the

synaptic transcriptome of a widely used AD mouse model, APPswe/PS1ΔE9 (APP/PS1). To this effect we prepared synaptosomes using sucrose density gradient method from cortex of 3-month-old wild type and AD mice. We then isolated RNA from the synaptospmes, after ribo-depletion we proceeded to library preparation. We performed paired -end (100X2 bp, 45 million reads) RNA sequencing on the Illumina HiSeq2500 platform. Raw RNA seq reads were quality controlled and adapter trimmed and then aligned to reference mouse genome using TopHat2. Differential gene expression analysis was performed using DESeq2 normalization followed by pathway analysis. Cell type enrichment analyses of the total 4509 differentially expressed genes revealed that 209 were unique to astrocytes, 243 to microglia, 129 to oligo-dendrocytes, while 3928 genes were unique to synaptic compartment. Of the differentially expressed genes, 2630 genes were up regulated, and 1879 genes were down- regulated in the APP/PS1 mice. Pathway analysis of the differentially expressed genes revealed that genes involved with proteasome machinery, protein translation, glycolysis, oxidative phosphorylation, and glutathione metabolism were upregulated. Our analysis suggeststhat in early stages of AD in a transgenic mouse model various cellular processes are perturbed at the synapse and that is reflected in the local transcriptome.

Title: Transcriptomic profiling in young AD transgenic (APPswe/PS1ΔE9) mice reveals a novel candidate gene

Authors: A. VERMA[1], :. V. RUPANAGUDI[4], *A. RAMACHANDRAN[2], V. RAVINDRANATH[3];
[1]Ctr. for Neurosci., Indian Inst. of Sci., Bangalore, India; [2]Ctr. for Neurosci., Indian Inst. of Sci., Bengaluru, India; [3]Ctr. for Neurosci., Indian Inst. of Sci., Bangalore North, India; [4]Ctr. for Brain Res., Bengaluru, India

Abstract: Alzheimer’s disease (AD) is a progressive neurodegenerative disorder characterized by deposition of amyloid β (Aβ) and hyperphosphorylated tau, loss of neurons and cognitive deficit. While cognitive deficit characteristic to AD is most often manifested in late stages of life, studies from our lab have shown that synaptic dysfunction and associated molecular changes

occur at early, pre-symptomatic stage in APPswe/PS1ΔE9 (APP/PS1) mouse model of AD indicating that the disease pathogenesis starts early in AD. Understanding early mechanisms in the disease course can help in timely intervention through design of strategies that may impede disease progression. We, therefore aimed to investigate changes in transcriptomic profiles in the entorhinal cortex (EC) and hippocampus (HP) in adolescent (1-month old) and young adult (3-months old) APP/PS1 mice using RNA sequencing. Total RNA was isolated from EC and HP from male APP/PS1 transgenic (Tg) and wild type (WT) control mice at 1 month and 3 months of age. Total RNA was processed for depletion of ribosomal RNA, cDNA library preparation followed by Illumina paired end sequencing. The raw reads were quality controlled to remove reads with low quality and adapters. The reads were aligned to mouse genome and read counts were generated and normalized using DESeq2 to obtain information on differential gene expression. In both EC and HP at 1 month and 3 months of age in APP/PS1 mice, APP was found to be upregulated, which served as a positive control. A single gene was consistently down-regulated in EC and HP at both 1 and 3 months of age. The gene is a regulator of calmodulin (CaM) signalling. Further, splice variant analysis of RNA sequencing data revealed specific down-regulation of a specific isoform of this gene. We further validated the down-regulation of this gene in entorhinal cortex and hippocampus from transgenic mice using qRT-PCR. We also observed down-regulation of this gene in fronto-polar prefrontal cortex from AD human autopsy samples. In conclusion, our results indicate the identification of this gene as a novel gene candidate that may be involved in AD pathogenesis early in the disease.

Title: Aging is associated with risk-averse decision making in fischer 344 x Brown Norway F1 hybrid rats

Authors: *R. J. DRAGONE[1], C. A. ORSINI[2], M. POMPILUS[2], A.-R. WHEELER[2], M. FEBO[2], B. SETLOW[2], J. L. BIZON[3];
[1]Psychiatry, Univ. of Florida, Gainvesville, FL; [2]Psychiatry, Univ. of Florida, Gainesville, FL; [3]Neurosci., Univ. of Florida McKnight Brain Inst., Gainesville, FL

Abstract: The ability to make adaptive decisions among options that vary in both risks and rewards is critical for managing finances, health care, and other activities of daily living necessary to maintain personal independence. Such risky decision making can be compromised at advanced ages, however, which can lead to maladaptive choices and reduced quality of life. Optimizing decision making could broadly benefit functional outcomes and promote independent living among older adults; however, development of interventions is currently hindered by limited understanding of the neural mechanisms underlying maladaptive decision making in aging. To begin to address this issue, we used a rat model to determine how performance on a risk-based decision-making task changes as a function of age, and to investigate the neurobiological mechanisms that may underlie these changes. Young adult (6 mo, n=12) and aged (24 mo., n=15) Fischer 344 x Brown Norway F1 hybrid rats were trained in a risky decision-making task in which they made discrete trial choices between a small (1 food pellet) "safe" reward and a large (2 food pellets) "risky" food reward accompanied by varying probabilities of mild footshock punishment. Aged rats exhibited an attenuated preference for the large, risky reward in comparison to young adult rats. This age difference in choice behavior was not due to compromised behavioral flexibility, nor was it readily attributable to altered shock reactivity, as young and aged rats had similar shock sensitivity thresholds. Importantly, this risk averse pattern of behavior in aged rats is consistent with findings of elevated risk aversion in older humans. To begin to investigate the neural mechanisms mediating age changes in risky decision making, a subset of the rats (young n=10, aged n=5) underwent resting state functional magnetic resonance imaging to assess functional connectivity among brain regions implicated in decision making including basolateral amygdala, nucleus accumbens, prefrontal cortex, and ventral hippocampus.

Title: Age-related decreases in CA3-CA1 ripple coordination

Authors: *N. M. DICOLA[1], A. L. LACY[2], O. J. BISHR[2], K. M. KIMSEY[3], K. DIBA[4], S. N. BURKE[1], A. P. MAURER[1];

Abstract: Local field potential oscillations are mainly generated by the superposition of synaptic activity (G. Buzsáki, *et al.*, 2012). Therefore, changes in hippocampal oscillations are capable of providing insights into the synaptic alterations that occur during aging and neurodegenerative diseases such as Alzheimer's disease. In the hippocampus, high-frequency oscillations known as ripples can be detected in the pyramidal layer and are observed most frequently during rest and 'offline' periods. Ripples are thought to support several cognitive functions including reactivation and memory consolidation (GM. van de Ven, *et al.*, 2016; G. Girardeu, *et al.*, 2009); however, most of these studies have focused on ripples in CA1. Ripples can also be detected in the CA3 pyramidal cell layer and these events, along with their associated sharpwave, are thought to initiate ripple events in CA1 through a large, transient, excitatory drive to the stratum radiatum of CA1 (G. Buzsáki, 1986; D. Sullivan, *et al.*, 2011). During aging, the hippocampus exhibits several synaptic alterations including CA3 hyperexcitability (MA. Yassa, ML. Tugan, CE. Stark, 1986; IA. Wilson, *et al.*, 2005), loss of Schaffer collateral synaptic efficacy (CA. Barnes, G. Rao, J. Shen, 1997), and hilar interneuron functional loss (AM. Spiegel, *et al.*, 2013). Moreover, the frequency of CA1 ripples has been shown to be reduced in aged compared to young rats (SL. Cowen, *et al.*, 2018). Each of these age-associated changes could impact ripple dynamics across the hippocampus, but CA3-CA1 ripple co-occurrence has not been interrogated in the context of age-related cognitive decline. The current study recorded from the right CA1 and CA3 hippocampal subregions of young (4 month) and aged (24 month) rats using two different 64 channel silicon probes. We recorded extracellular local field potentials and examined ripples during rest periods that flanked an epoch of behavior on a hippocampal-dependent task. CA1-CA3 ripple co-occurrence probability was measured as the portion of the time CA1 ripples occurred within a 100 ms time window of CA3 ripples. Preliminary data showed that the probability of CA3-CA1 ripple co-occurrence is decreased in aged animals, suggesting that the aged CA3 has less influence over CA1 than the young CA3. Further studies are required to determine if the aged CA1 receives a greater proportion of influence from cortical input or if the overall activity level is decreased.

Title: Neuropathological outcomes in a mouse model of amyloid beta and tau

Authors: *E. J. KOLLER, K. R. IBANEZ, E. GONZALEZ DE LA CRUZ, T. A. MACHULA, D. RYU, C. JANUS, B. I. GIASSON, D. R. BORCHELT, P. CHAKRABARTY;
Neurosci., Univ. of Florida, Gainesville, FL

Abstract: Amyloid β (Aβ) and tau neurofibrillary tangles (NFTs) are the two hallmark pathologies of Alzheimer's disease (AD), but how these two pathological components of AD influence each other is unclear. It has been hypothesized that tau and Aβ synergize to produce the AD pathological cascade which results in neurodegeneration and cognitive impairment, but it remains unknown whether insoluble NFT tau or soluble form(s) of tau synergize with Aβ to produce the pathological effects. To examine the consequences of tau and Aβ in mouse brains, we used adeno-associated virus (AAV)-mediated delivery of human tau variants in the TgCRND8 mouse model of Aβ plaques. These tau variants were delivered via intracerebral injection of AAV in neonatal TgCRND8 litters. Expression of these different tau variants results either in accumulation of abundant soluble hyperphosphorylated tau (WT tau or P301L tau variants) or primarily NFT-type tau (P301L/S320F tau variant) in nontransgenic mice.
At 3 months of age, AAV-tau expression in TgCRND8 mice led to the accumulation of phosphorylated tau in all the experimental groups, with NFT-type tau and robust widespread astrogliosis observed exclusively in the P301L/S320F tau expressing mice. While expression of WT tau or P301L tau expression did not alter Aβ plaques, surprisingly, expression of AAV-P301L/S320F tau lowered Aβ plaque burden. We also observed modest levels of tau in the sarkosyl-insoluble cellular fraction of P301L tau expressing TgCRND8 mice (not observed in nontransgenic mice), indicating that presence of Aβ plaques can modify solubility of P301L tau protein. When investigating synaptic protein profiles, we found that expression of both P301L tau and P301L/S320F tau resulted in increased amounts of GluR1, vGlut1, and spinophilin. Overall, we conclude that tau variants affect neuroinflammation, Aβ burden, self-aggregation and synaptic alterations to differential degrees in the presence of Aβ plaques, leading to the concept that these variants might represent different tau conformers.

Title: Progranulin deficiency causes structural abnormalities in the periphery of knockout mice

Authors: *A. WALKER[1], S. RAYAPROLU[4], J. GASS[5], J. HOWARD[2], L. JAMES[2], C. DUFFY[2], J. M. LEWIS[3];
[1]Neurosci., [3]Dept Neurosci., [2]Univ. of Florida, Gainesville, FL; [4]Neurosci., UF Col. of Med., Gainesville, FL; [5]Mayo Clin., Jacksonville, FL

Abstract: Progranulin (PGRN) is a secreted glycoprotein that can be cleaved into granulin motifs depending on the biological needs of the body, with full-length PGRN acting as an anti-inflammatory molecule. Mutations within the granulin gene (*GRN*) exert pleiotropic effects as heterozygous loss-of-function mutations cause frontotemporal lobar dementia with TDP-43 pathology (FTLD-TDP43) and homozygous loss-of-function mutations cause a rare form of neuronal ceroid lipofuscinosis (NCL). Mice deficient of *Grn*, develop excessive intraneuronal accumulations of lipofuscin throughout the brain, a pathological hallmark of NCL. Current studies of NCL pathology have been mainly focused in the brain, but PGRN is also expressed throughout the periphery; therefore, we sought to determine whether *Grn*-deficient mice develop NCL relevant pathology in organs peripheral to the brain. We assessed the liver, kidney, lung, and heart from 7 and 12-month-old *Grn*-knockout (KO) (N=4) and wild-type (WT) (N=4) mice per age using immunohistochemical stains and immunoblotting. The livers of the KO mice show abnormal hepatocyte structure, glycogen deposits, and enlarged lysosomes and macrophages at 7 and 12 months compared to the WTs. Cathepsin Z and TFEB are both elevated in 7-month-old KO kidneys compared to 7-month-old WT kidneys. Lastly, the lungs and hearts of the KO mice do not have any overt differences in pathology compared to the WTs at 7 and 12-months of age. These data highlight the presence of peripheral pathologies due to PGRN loss and raise the potential that peripheral symptoms may be overlooked in patients with PGRN deficiency. Although obtaining brain tissue is rare from individuals carrying homozygous *GRN* mutations, peripheral tissue biopsies, such as liver or kidney, can be taken in relatively non-invasive procedures and peripheral pathology could then serve as a peripheral marker for disease progression and treatment.

Title: Mediation of periventricular white matter hyperintensity burden, cognition, depression, and quality of life in older adults with amnestic mild cognitive impairment

Authors: *B. DEFEIS[1], J. TANNER[1], D. O'SHEA[1], L. DE WIT[1], A. MEJIA[1], P. AMOFA[1], S. MAYEWKSI[2], M. CHANDLER[3], G. SMITH[1];
[1]Univ. of Florida, Gainesville, FL; [2]Tallahassee Mem. HealthCare, Tallahassee, FL; [3]Mayo Clin., Jacksonville, FL

Abstract: Introduction: Periventricular white matter hyperintensities (PVWMH) have been previously associated with the development of depression in older adults, contributing to a vascular theory of late-life depression. Progression of these hyperintensities through development of new clusters or increasing volume has been also associated with cognitive decline and poor depression outcomes, which may impact overall quality of life. Previous studies have suggested that varying numbers and sizes of clusters may indicate specific etiologies and clinical symptoms. The aim of this study is to examine the relationship of the number and sizes of PVWMH clusters on general cognition, depression, and quality of life in older adults with amnestic Mild Cognitive Impairment (aMCI).
Methods: Data for the present study were obtained from 35 older adults with aMCI who completed the baseline assessment as part of a larger ongoing intervention study. PVWMH were extracted using UBO Detector, a cluster-based, automated pipeline which extracts white matter hyperintensities from FLAIR and T1-weighted scans using SPM12 and FSL functions. In this analysis, PVWMH were qualified as total number of clusters (NoC) of various sizes (punctuate [$<10.125mm^3$], focal [$<30.375mm^3$], medium [$<50.625mm^3$], and confluent [$>50.625mm^3$]), and total volume. Mediation analyses were performed predicting whether the impact of PVWMH on quality of life was mediated by cognition and depression when controlling for age, gender, and education.
Results: Participants were, on average, 75.05(.50) years old, 58% women, and had 16.82 (2.8) years of education. Average cognitive performance on the DRS was 130.49 (8.64), and the average depression score was 10.28 (6.89). Quality of life scores ranged from 33 to 50 (M=40.62; SD=4.66). The number of focal white matter hyperintensity clusters was significantly associated with lower quality of life and higher depressive symptoms. Mediation analyses

revealed that the indirect effect of white matter on quality of life as mediated by depression was statistically significant (Effect= -.321; Boot CI= -.684 to -.092). No association between PVWMH and general cognition was detected.
Discussion: Depression fully mediated the relationship between PVWMH and quality of life. There was no relationship found between PVWMH and general cognition, which can be expected given conflicting findings in the literature. The association between the number of PVWMH clusters, rather than total volume, and depression may warrant consideration of etiological differences, and represent more evidence towards the vascular hypothesis for late-life depression.

Title: Investigating the neuroprotective mechanisms of the presubiculum in a knock-in App mouse model of Alzheimer’s disease

Authors: *J. SHI, *A. B. ALI;
Sch. of Pharm., Univ. Col. London, London, United Kingdom

Abstract: Alzheimer’s disease (AD) pathogenesis is correlate with dramatic changes of network homeostasis attributed to the altered astrocyte-neuron interactions. During the progression of the disease, astrocytes adopt a hyperactive phenotype, leading to up-regulated glial fibrillary acidic protein (GFAP) and purinoreceptors, P2Y1 receptors. These cellular changes are evidenced in various cortical regions, but interestingly, it has been shown that the presubiculum is preserved from these pathological changes in AD.
To investigate the neuroprotective mechanisms of presubiculum, we employed a knock-in mouse model of AD that harbors mutant form of amyloid precursor protein (App), (App^{NL_F/NL_F}) (Saito et al., 2014), and the wild-type (C57BL/6) mice were used as control. The presubiculum and CA1 tissue was also obtained from post-mortem AD patients and age-matched healthy controls. Previously, we have shown that there is a preservation of calretinin (CR)-expressing interneurons in CA1 in the presence of the age-dependent cellular phenotypical changes of AD, including amyloid beta accumulation, pyramidal neuron loss and neuroinflammatory markers such as

astrocytes and microglia. In the present study, analysis from z-stack images obtained with confocal microscopy reveals that the expression of P2Y1 receptors was apparent in astrocytes (GFAP), CR-expressing interneurons and pyramidal cells, and the CR-expressing interneurons showed the highest level of P2Y1 receptors, followed by GFAP, while pyramidal cells expressed the lowest level in both control and in AD human and mice tissue. Interestingly, in CA1 of App^{NL_F/NL_F} mice and AD patients, CR-expressing interneurons and astrocytes expressed significantly higher levels of P2Y1 receptors, which is not present in the presubiculum of control or AD tissue. In vitro whole-cell electrophysiological recordings were performed in the App^{NL_F/NL_F} mice age matched to wild-type mice (9-12 months) to investigate whether there was any aberrant excitatory-inhibitory imbalance in the presubiculum reported in CA1 (Petrache et al., 2019). The pyramidal cells in the presubiculum seems to display “normal” biophysical and synaptic properties consistent with control wild-type mice.
In summary, our data suggests that astrocytes and CR-expressing interneurons preserved in CA1 region of App^{NL_F/NL_F} mice and AD patients up-regulate P2Y1 receptors, which may contribyte to the enhanced purinergic signaling. The absence of these cellular changes in the presubiculum may underlie the neuroprotective mechanisms of the presubiculum.

Title: Alpha5 subunit-containing $GABA_A$ receptors are preserved on resilient calretinin interneurons in the AppNL-F/NL-F mouse model of Alzheimer’s disease

Authors: *A. L. PETRACHE, A. B. ALI;
Sch. of Pharm., Univ. Col. London, London, United Kingdom

Abstract: The hippocampus, important in memory formation and consolidation, is significantly affected in Alzheimer’s disease (AD). The cells of the hippocampus consist of excitatory neurons and diverse inhibitory interneurons that release gamma-aminobutyric acid (GABA) neurotransmitter to control these excitatory networks.
Evidence suggests a preservation of the α5-containing $GABA_A$ receptors, which play a crucial role in memory in human brain areas most affected by AD (Howell *et al.*, 2000). This is despite

the early stage synaptic hyperexcitability observed in mouse models of AD (Petrache et al., 2019) prior to the manifestation of the cellular symptoms of AD such as amyloid beta (Aβ) accumulation and neuroinflammation.
To investigate the underlying mechanisms that causes the synaptic imbalances preceding the symptoms of AD, we investigated whether the α5 subunit-containing $GABA_A$ receptors were restricted to specific cell-types and whether they were performing their intended functions using the $App^{NL-F/NL-F}$ knock-in mouse model of AD age-matched to wild-type control mice.
Using immunohistochemistry and confocal microscopy we investigated 3 sub-types of modulatory inhibitory interneurons co-expressed with GAD67 (enzyme that indicates GABA synthesis), $Aβ_{42/40}$, or α5 $GABA_A$ receptors in the CA1 region of the hippocampus. We show that α5 $GABA_A$ receptors are selectively expressed at a the highest levels on calretinin- (CR) expressing interneurons compared to the other two interneuron subtypes, and on pyramidal cells, in both age-matched wild-type and $App^{NL-F/NL-F}$ mice. Interestingly, this pattern of expression correlated with the selective penetration of Aβ in somatostatin- (SST) and cholecystokinin- (CCK) expressing cells, which reduced significantly in cell density in the later stages of AD. In contrast, there was a lack of Aβ presence in CR interneurons consistent with their anatomical preservation. Furthermore, using whole-cell recordings we find that CR cells were synaptically hyperinhibited correlated with the excess GAD67 expressed in these cells in the $App^{NL-F/NL-F}$ mice compared to the age-matched wild-type mice (Shi et al., 2019).
In summary, our data suggests that α5 subunit-preservation is correlated with interneuron resilience in AD. Therefore, we propose that pharmacological modulation of α5 subunit-containing $GABA_A$ receptor networks is a potential therapeutic target, which we are investigating using behavioural learning memory paradigms for cognitive impairment.

Title: Maternal choline supplementation ameliorates Alzheimer’s disease pathology by reducing brain homocysteine levels across multiple generations

Authors: *R. VELAZQUEZ, Jr[1], E. FERREIRA[1], W. WINSLOW[1], I. S. PIRAS[2], N. DAVE[1], M. NAYMIK[2], M. J. HUENTELMAN[2], A. TRAN[1], S. ODDO[1,3];

[1]Arizona State Univ. - Banner Neurodegenerative Dis. Res. Ctr., Biodesign Inst. At Arizona State Univ., Tempe, AZ; [2]Translational Genomics Res. Inst., Phoenix, AZ; [3]Sch. of Life Sci., Arizona State Univ., Tempe, AZ

Abstract: The lack of effective treatments for Alzheimer's disease (AD) is alarming, considering the number of people currently affected by this disorder and the projected increase over the next few decades. Elevated homocysteine (Hcy) levels double the risk of developing AD. Choline, a primary dietary source of methyl groups, converts Hcy to methionine and reduces age-dependent cognitive decline. Here, we tested the transgenerational benefits of maternal choline supplementation (ChS; 5.0 g/kg choline chloride) in two generations of APP/PS1 mice. We first exposed 2.5-month-old mice to the ChS diet and allowed them to breed with each other to generate generation-1 mice. Generation-1 mice were exposed to the ChS diet only during gestation and lactation; once weaned at postnatal day 21, generation-1 mice were then kept on the control diet for the remainder of their life. We also bred a subset of generation-1 mice to each other and obtained generation-2 mice; these mice were never exposed to ChS. We found that ChS reduced Aβ load and microglia activation, and improved cognitive deficits in old generation-1 and generation-2 APP/PS1 mice. Mechanistically, these changes were linked to a reduction in brain Hcy levels in both generations. Further, RNA-Seq data from APP/PS1 hippocampal tissue revealed that ChS significantly changed the expression of 27 genes. These genes were enriched for inflammation, histone modifications, and neuronal death functional classes. Our results are the first to demonstrate a transgenerational benefit of ChS and suggest that modifying the maternal diet with additional choline reduces AD pathology across multiple generations.

Abstract: Alzheimer's disease (AD) is the most prominent neurodegenerative disease in aging societies with no effective treatment at this time. The major pathogenic hallmarks of AD include extracellular amyloid plaques and intracellular neurofibrillary tangles. Adenosine is a nucleoside that modulates many pathophysiological functions and the bioenergetic network in the brain. We have previously demonstrated that augmentation of adenosine tone in the brain using an orally active inhibitor (J4) of the equilibrative nucleoside transporter 1 (ENT1) improved the impairment of cognitive functions and neuronal plasticity in a mouse model of AD (APP/PS1). In the present study, we reported that chronic treatment of a mouse model of tauopathy (THY-Tau22) also provided significant beneficial effects. Briefly, J4 treatment ameliorated spatial memory deficiency, synaptic plasticity impairment, and the level of hyperphosphorylated Tau in THY-Tau22 mice. Phosphoproteomic analysis of the hippocampus of THY-Tau22 mice further demonstrated that chronic J4 treatment normalized 24% of the total 170 proteins (including kinases, transcription regulators, phosphatases and ion channels) with altered phosphorylation levels in THY-Tau22 mice. Collectively, our findings suggested that adenosine augmentation induced by an ENT1 inhibitor (J4) provides a new therapeutic strategy for Tauopathy, and may contribute to the development of therapeutic treatment for AD.

Title: Utilization of γ-secretase trimming activity for proper evaluation of Aβ targeting compounds

Authors: *S. TAGAMI[1], K. YANAGIDA[1], M. IKEDA[1], T. KUDO[2], M. OKOCHI[1];
[1]Osaka Univ. Grad. Sch. of Med., Suita, Japan; [2]Dept Mental Hlth. Promoion, Osaka Univ. Grad. Sch. of Med., Toyonaka-Shi, Japan

Abstract: Introduction: Beta-amyloid (Aβ), which accumulates in the brain of Alzheimer's disease, is generated from its precursor protein, βAPP. βAPP is first shed by BACE followed by sequential intramembrane cleavages of the transmembrane remnant by presenilin/γ-secretase. Following an initial ε-cleavage at the border between cytosol and transmembrane domain, γ-secretase cleaves the remaining membrane-bound long Aβ with stepwise trimming by every 3 to 4 amino-acids. These small peptides such as ITL, VIV, and IAT termed γ-byproducts were identified not only in *in vitro* γ-secretase cleavage assay but also inside cultured cells and in brain of βAPP transgenic mice. Unlike Aβ, γ-byproducts are not secreted and thus could serve as a more direct indicator of γ-secretase activity than secreted Aβ.
Objective: By quantification of γ-byproducts generated during sequential cleavages upon Aβ production, we aimed to properly evaluate effects of Aβ targeting compounds such as γ-secretase modulators and BACE inhibitors.
Methods: The γ-byproducts extracted from cells treated with each compound were measured using LC/MS/MS (Quattro Premier XE tandem quadrupole mass spectrometer equipped with UPLC, Waters).
Results: Previously, we reported that non-transition state analogue γ-secretase inhibitors did not decrease but rather increased the levels of γ-byproducts. In addition to the increased level of γ-byproducts, we found accumulation of Aβ inside neurons derived from human iPS cells, although non-transition state analogue γ-secretase inhibitors decreased secreted Aβ as reported. In this study, we investigated whether other Aβ targeting compounds might cause unexpected increase in the levels of γ-byproducts.
Conclusions: We propose that γ-secretase activity should also be evaluated in terms of the levels of γ-byproducts in development of Aβ targeting compounds.

Title: Lim kinase inhibition provides dendritic spine resilience against amyloid-β

Authors: *J. H. HERSKOWITZ, B. HENDERSON, K. M. GREATHOUSE, R. RAMDAS, T. RAO, S. BACH, C. WALKER, K. CURTIS, J. DAY, A. MATTHEYSES;
The Univ. of Alabama At Birmingham, Birmingham, AL

Abstract: Alzheimer's disease (AD) therapies predominantly focus on amyloid-β (Aβ), but Aβ effects may be maximal before clinical symptoms. Downstream of Aβ, dendritic spine loss correlates most strongly with cognitive decline in AD. Rho-associated kinases (ROCK1 and ROCK2) regulate the actin cytoskeleton and ROCK1 and ROCK2 protein levels are increased in early AD. We show that expression of ROCK1 in hippocampal neurons reduces dendritic spine length through a myosin-based pathway, while expression of ROCK2 induces spine loss through LIMK1. Aβ42 oligomers can activate ROCKs, and using static imaging studies combined with multi electrode array analyses we show that the ROCK2-LIMK1 pathway mediates Aβ42-induced spine degeneration and neuronal hyperexcitability. Living cell microscopy revealed that pharmacologic inhibition of LIMK1 renders dendritic spines resilient to Aβ42 oligomers. Treatment of hAPP mice with a LIMK1 inhibitor rescued Aβ-induced hippocampal spine loss and morphologic aberrations. Our work suggests that therapeutic targeting of LIMK1 may provide dendritic spine resilience to Aβ, benefitting cognitively normal patients at high risk for dementia.

Title: Synergistic analysis of dendritic spine morphology and the synaptic proteome in human entorhinal cortex uncovers mechanisms of synapse loss in Alzheimer's disease

Authors: *C. K. WALKER[1], B. D. BOROS[1], K. M. GREATHOUSE[1], E. B. DAMMER[2], K. A. CURTIS[1], H. M. MUHAMMAD[1], R. RAMDAS[1], I. CHAUDHARY[1], D. M. DUONG[2], N. T. SEYFRIED[3], J. H. HERSKOWITZ[1];

Abstract: Amyloid-β (Aβ) plaques and neurofibrillary tangles (NFTs) of the microtubule-associated protein tau are the pathological hallmarks of AD; however, synapse or dendritic spine loss correlates more strongly with cognitive impairment than plaques or NFTs. Approximately one-third of individuals that come to autopsy in their eighties have Aβ plaques and tau NFTs, yet did not have dementia in life. These cognitively normal individuals with AD pathology (CAD) were likely in preclinical stages of AD. Unlike individuals with AD dementia, CAD cases do not exhibit dendritic spine loss in the prefrontal cortex. NFT burden negatively correlates with dendritic spine loss, suggesting that tau contributes to synapse loss in AD. In this study, we asked whether the entorhinal cortex (EC), one of the earliest regions to exhibit tau pathology, shows alterations in dendritic spine density and morphology in AD. Dendrites in postmortem human EC samples from 20 normal controls, 6 CAD cases, and 24 AD cases were visualized using the Golgi–Cox technique and spines were imaged using high-resolution brightfield microscopy. Neurolucida 360 was employed for three-dimensional dendrite reconstruction and dendritic spine morphometry analysis. CAD cases maintained spine density at levels similar to healthy controls, while spine density was reduced in AD patients. To begin to understand the mechanisms of EC synapse loss in AD, we undertook a systems approach to identify synaptic proteins that are differentially expressed in AD and associated with dendritic spine density and morphology. EC synaptosomal fractions were isolated from 20 normal controls, 7 CAD cases, and 31 AD cases. Liquid chromatography coupled with tandem mass spectrometry-based proteomics was performed on synaptosomes, followed by weighted protein co-expression network analysis. Resulting modules were correlated with numerous traits, including clinical data, spine density and morphology, and neuropathology to reveal protein targets that associate with EC synapse loss in AD.

Title: My active and healthy ageing (My-AHA), an ICT-based project for risk detection and prevention

Authors: *A. E. VERCELLI[1,2], I. RAINERO[2], G. AUMAYR[3], M. SUMMERS[4];
[1]Neurosci. Inst. Cavalieri Ottolenghi, Orbassano (TO), Italy; [2]Neurosci. R.L.Montalcini, Univ. of Torino, Torino, Italy; [3]Johanniter Austria, Vienna, Austria; [4]Sunshine Coast Mind & Neurosci. – Thompson Inst., Univ. of the Sunshine Coast, Birtinya, Australia

Abstract: Stemming from a holistic view of interrelated frailties, cognitive decline, physical frailty, depression and anxiety, social isolation and poor sleep quality, My-AHA proposes an ICT platform for early detection of pre-frailty and intervention to sustain active and healthy ageing and slowing or reversing further decline. The main aim of My-AHA is to reduce frailty risk by improving physical activity and cognitive function, psychological state, social resources, nutrition, sleep and overall well-being in older adults with pre-frailty symptoms. It empowers older citizens to better manage their own health, providing new ways of health monitoring and disease prevention through individualized profiling and personalized recommendations, feedback and support. An ICT-based platform detects defined risks in the frailty domains early and accurately via non-stigmatising embedded sensors and data readily available in the daily living environment of older adults. When risk is detected (pre-frail), My-AHA provides targeted ICT-based interventions. These interventions follow an integrated approach to motivate users to participate in physical exercise, cognitively stimulating games and social networking to achieve long-term behavioural change, sustained by continued end user engagement with My-AHA. A randomized controlled study (RCT), involving 150 subjects receiving intervention, and 150 controls from many EU and non EU countries, to evaluate intercultural aspects, is ongoing in order to evaluate efficacy of the my-AHA platform. The ultimate aim is to deliver significant innovation in the area of active and healthy ageing through cooperation between European health care organizations, SMEs, and NGOs.On behalf of the My-AHA ConsortiumMy Active and Healthy Ageing is supported by the European Union with a Horizon 2020 (PHC-21-2015) grant, Contract # 689592.

Title: Neuroprotective effects of a novel lipoic acid-dl-3-n-butylphthalide hybrid

Authors: *K. UPPAKARA[1], S. B. WAN[3], W. SAENGSAWANG[2];
[1]Toxicology Grad. Program, [2]Physiol., Fac. of Sci. Mahidol Univ., Bangkok, Thailand; [3]Sch. of Med. and Pharm., Ocean Univ. of China, Qingdao, China

Abstract: Neurodegenerative diseases such as Alzheimer's disease (AD) and Parkinson's disease (PD) are progressive and irreversible damage of the nervous system. The pathogenesis of these diseases is still unclear but several evidences suggest that oxidative stress is one of major causes of the degeneration. In this study, series of new alpha lipoic acid hybridized dl-3-n-butylphthalide were synthesized and tested for their antioxidant activity and protective effects against oxidative damages to neuronal cells. An analogue combination, dlx-23, showed strong antioxidant activity in *in vitro* DPPH scavenging assay. To determine the protective effect of dlx-23 in neuronal cells we used Cath. a differentiated (CAD) cells as a model. Dlx-23 effectively prevented H_2O_2-induced neuronal cells death. Using antioxidant assay, we found that intracellular ROS level after exposure to H_2O_2 was significantly reduced when the cells were pretreated with dlx-23. Dlx-23 also increased the level of glutathione in the cells. These activities are more potent than the parent compounds alone. In addition, Live imaging of the neuronal growth cone demonstrated that dlx-23 protected the growth cone of primary cortical neurons from damages induced by H_2O_2. Taken together these results suggest the potential of dlx-23 to be further developed into a novel neuroprotective agent.

Title: Therapeutic effects of human LDLR overexpression on ApoE-related tau pathology and brain dysfunction

Authors: *C. WANG[1], A. LI[1], S. NATHAN[1], R. SPELLMAN[1], M. MANIS[1], M. FINN[1], Y. SHI[1], M. XIONG[1], J. REMOLINA SERRANO[1], P. SULLIVAN[2], D. HOLTZMAN[1];
[1]Washington Univ. In St. Louis, St. Louis, MO; [2]Dept. of Med., Duke Univ., Durham, NC

Abstract: Apolipoprotein E gene (*APOE*) is the strongest genetic risk factor for late-onset Alzheimer's disease (AD) with the ε4 allele increasing risk in a dose-dependent fashion and the ε2 allele decreasing risk relative to the ε3 allele. Although the mechanisms are not fully

elucidated, apoE appears to influence AD at least in part via influencing amyloid β (Aβ) aggregation and clearance. In addition, our lab has recently reported that apoE isoforms also directly affect tauopathy and tau-mediated neurodegeneration in P301S tau transgenic mice expressing different human apoE isoforms. Specifically, apoE4 results in significant loss of brain volume and increase in glial inflammatory response compared to other apoE isoforms. The absence of apoE alleviated both neurodegeneration and the inflammatory response. Low-density lipoprotein receptor (LDLR) is a cell surface glycoprotein that plays a pivotal role in maintaining plasma cholesterol homeostasis. In the brain, abundant evidence reveals that LDLR is one of the main apoE receptors that regulate apoE levels, but LDLR has very few identified ligands compared to other apoE receptors. LDLR overexpression in the brain can dramatically lower apoE and Aβ levels, as well as decrease Aβ accumulation and deposition. Therefore, we propose to evaluate whether AAV-mediated overexpression of human LDLR (hLDLR) is an efficient way to reduce apoE levels, tau pathology, and neurodegeneration. To study the effect of LDLR overexpression on apoE4-related tau pathology and neurodegeneration, P301S Tau/ApoE4 (TE4) male mice received a bilateral intracerebroventricular injection with AAV expressing hLDLR or GFP-control, starting before the onset of tau pathology development. Brains were isolated after 9 months, divided into hemispheres, and analyzed by histological and biochemical techniques. Widespread expression of hLDLR throughout the brain was observed and apoE levels were significantly decreased. Furthermore, mouse nest-building impairment was rescued after hLDLR overexpression. Strikingly, there is a significant decrease in brain atrophy, phosphorylated tau deposition in TE4 mice overexpressing hLDLR. In summary, these data suggest that LDLR may be a promising target to lower apoE levels and decrease neurodegeneration.

Title: Synaptic tau targeted immunotherapy for Alzheimer's disease

Authors: *C.-Y. TAI, H.-T. MA, S.-C. HUANG, C.-L. LI, M.-F. WU, C.-L. WU, S.-H. LIN, M.-K. JANG;

Abstract: Alzheimer’s disease (AD) is the most common form of dementia in aging population. Propagation of tau aggregates along the synaptically connected brain regions tightly correlates with pathophysiological changes such as neuronal loss and cognitive impairment of the disease. We propose here an immunotherapeutic approach to block the tau pathology in AD by an anti-tau antibody specifically targeting synaptic tau species. We ranked order the synaptic tau specificity of our anti-tau antibodies using dot-blot assay, and synaptic preferred antibodies were highly specific to sarkosyl-insoluble tau aggregates extracted from AD brains. Immunohistochemistry study with brain slices obtained from 3-mo-old rTg4510 mice showed distinct patterns of localization in either somatic or axodendritic space, indicating diverse tau species identified by our tau antibodies. Some of the tau species seem to be actively transported/segregated in specific sub-cellular compartments. Moreover, a few synaptic preferred antibodies labeled tau aggregates in the entorhinal cortex of early Braak stage I-II subjects before clinical symptoms onset, and removal of tau aggregates by the antibody drastically blocked the seeding ability of rTg4510 brain lysate in a HEK cell-based assay. Membrane depolarization of rTg4510 synaptoneurosomes enhanced the release of several tau species that were recognized by our antibodies, suggesting a therapeutic utility of our antibodies by blocking the releasable tau in the extracellular space. These results imply a role for synaptically localized AD tau species in disease causing mechanism. They also profile the molecular and cellular properties of these tau species and suggest an immunotherapy by blocking the releasable tau at the synapse.

Title: Neuroprotective effects of peripherally-administered irisin in a tauopathy model of Alzheimer's

Authors: *K. A. BRETLAND[1], L. LIN[1], K. M. BRETLAND[2], C. M. DENGLER-CRISH[1]; [1]Pharmaceut. Sci., Northeast Ohio Med. Univ., Rootstown, OH; [2]Kent State Univ., Kent, OH

Abstract: As clinical trials for single-target therapies continue to fail, there is a critical call for developing complete treatments that address the multifactorial nature of Alzheimer's disease (AD) pathology. One emerging candidate is the recently discovered hormone irisin, which is cleaved from the fibronectin type III domain-containing protein 5 (FNDC5) transmembrane protein. A small but increasing number of studies show that irisin may protect against AD by a) ameliorating peripheral inflammation associated with metabolic disease, b) inhibiting neuroinflammatory responses, and c) reducing production of amyloid beta. However, the mechanisms by which irisin provides direct neuroprotective effects are not well-understood, and nothing is known about how it interacts with AD-related tauopathy. Studies have shown that peripheral enhancement of irisin (either exercise-induced or by exogenous administration of recombinant irisin protein) can elevate central levels of this hormone. Therefore, we sought to determine whether exogenous administration of irisin would reduce brain levels of hyperphosphorylated tau (ptau) in htau mice, a transgenic model that develops age-related tauopathy and cognitive deficits akin to the clinical presentation of AD. We treated female and male htau mice with weekly injections of 100 ug/kg (i.p.) recombinant human irisin or saline vehicle for 4 weeks and then sacrificed animals for fresh or fixed tissue collection. Using capillary-based western blotting (Wes; ProteinSimple) and fluorescent immunohistochemistry, we measured ptau, FNDC5/irisin, neuroinflammation, and additional pathological indicators within the hippocampus, cortex, and brainstem. We found that irisin treatment significantly reduced hippocampal ptau in female htau mice, whereas male htau mice only trended towards a similar reduction. These results indicate that irisin may be neuroprotective against tauopathy, increasing its potential as a multi-target therapeutic in AD.

Rio de Janeiro, Rio de Janeiro, Brazil; [4]Inst. of Med. Biochem. Leopoldo de Meis, Fed Univ. Rio De Janeiro, Rio de Janeiro, Brazil

Abstract: Alzheimer’s disease (AD) is a disorder characterized by synapse and memory failure, which has been closed linked to impaired hormonal action in the brain. Irisin is an exercise-induced myokine released on cleavage of the precursor protein fibronectin type III domain-containing protein 5 (FNDC5), which is also expressed in the hippocampus. We examined whether FNDC5/irisin would display neuroprotective properties in animal models of AD and whether it mediates the beneficial actions of exercise in the degenerating brain. We found that brain or peripheral overexpression of FNDC5/irisin rescued synapse and memory defects in AD mice. Recombinant irisin stimulated cAMP/PKA-mediated signaling and prevented translational repression induced by soluble amyloid-beta in primary neurons. In mice, blockade of either peripheral or brain FNDC5/irisin attenuated the neuroprotective actions of physical exercise on AD-linked synaptic plasticity and memory failure. Our results provide a novel mechanism of neuroprotection by physical exercise and suggest a novel potential target for effective therapeutics in AD.

Title: Dose-dependent neurochemical, molecular, and behavioral effects of intranasal insulin

Authors: *J. M. ERICHSEN[1], J. L. WOODRUFF[1], H. E. BURZYNSKI[1], C. A. GRILLO[1,2], L. P. REAGAN[1,2], J. R. FADEL[1];
[1]Pharmacology, Physiology, and Neurosci., Univ. of South Carolina Sch. of Med., Columbia, SC; [2]WJB Dorn VA Med. Ctr., Columbia, SC

Abstract: Cognitive dysfunction with aging is a dreaded and costly (both economically and personally) aspect of growing old. Unfortunately, there is no therapeutic strategy to date that effectively treats age-related cognitive decline (ARCD). It is plausible that intranasal insulin (INI) could fill this gap, as a number of studies have demonstrated that INI improves memory. However, the mechanistic basis for these pro-cognitive changes has yet to be elucidated. Behavioral, neurochemical, and molecular techniques were employed in adult Sprague-Dawley and Fischer 344/Brown Norway F1 hybrid rats following INI with the goal of beginning to understand this mechanism. In order to determine the optimal dose for the molecular and behavioral effects of INI, several doses of insulin were explored in these experiments. First, feeding behavior was assessed for 18 hours following INI or IN vehicle to examine if the insulin elicited a behavioral effect. INI produced dose-dependent effects on food intake post-administration. Next, cholinergic transmission and insulin receptor signaling in the brain were assessed. Probes were inserted into the medial prefrontal cortex and hippocampus of the rats for *in vivo* microdialysis. Levels of acetylcholine, glutamate, and GABA varied in the three hours after IN vehicle compared to different doses of insulin. On a separate day, the rats were euthanized 30 minutes post-INI. Olfactory bulb and hippocampal extracts were processed for immunoblot analysis to determine if changes in central insulin signaling in response to IN vehicle vs. different doses of insulin could be seen. The results of these experiments provide a potential molecular/neurochemical basis for the pro-cognitive effects of INI. It is important to understand the mechanism of action, as INI could eventually be used in the broader clinical setting to treat ARCD. Further, this could initiate the development of other treatments for ARCD that exploit the same mechanism of action. More studies are needed to fully understand the neurochemical, molecular, and behavioral changes following INI and to determine the most effective clinical dose, but these results demonstrate the ability of INI to rapidly target the brain and influence neurotransmission, central insulin signaling, and feeding behavior.

Title: Insulin sensitizers and the risk of incident dementia: A meta-analysis using real-world evidence

Authors: *M. HUSSAIN[1], A. HABIB[2], A. NAJMI[3];
[1]Dept. of Pharmaceut. Med., [2]Dept. of Med., [3]Dept. of Pharmacol., Jamia Hamdard, New Delhi, India

Abstract: Several epidemiological studies considered diabetes as a risk factor for developing dementia. Published clinical studies found insulin resistance as a culprit for developing dementia. So, this study is aimed to explore the effects of insulin sensitizers (biguanides, thiazolidinediones and DPP-4 inhibitors) on the incidence of dementia. An electronic search was performed in PubMed and Cochrane central to identify the suitable articles using Mesh term related to "insulin sensitizers" and "dementia." The search period was from inception to December 2018. Risk of bias was assessed using an appropriate tool based on the study design of articles qualified for inclusion. The primary outcome was to quantify the effects of insulin sensitizers on the incidence of dementia. The secondary outcome was to assess the dementia risk based on subgroups like drug class, dementia types. All the analysis was performed using Review Manager v5.3. This meta-analysis comprised of total 102,580 patients of which 95,968 belongs to biguanide (metformin) and 6,612 belongs to thiazolidinediones (TZD) group. Majority of the studies were of high quality as reflected on the score attainment in Newcastle-Ottawa Scale. Insulin sensitizers (pooled effect of each drug class) has no effect on the incidence of dementia with a relative risk (RR) of 1.02 (95% CI: 0.87 to 1.20, p = 0.78). Only drugs belong to TZD group was found to have statistically significant protective effects for the dementia incidence with RR of 0.74 (95% CI: 0.56 to 1.0, p = 0.05). None of the subgroups has statistically significant effects on dementia incidence. This meta-analysis concludes that only the use of thiazolidinediones was associated with a significant reduction in the risk of developing dementia. However, well-designed randomized controlled trials are warranted to generalize the evidence.

Title: A novel Cdk5 inhibitory peptide attenuates pathological features in human and mouse models of Alzheimer's disease

Authors: *O. KRITSKIY[1], J. SEO[2], L.-H. TSAI[3];
[1]Picower Inst. for Learning and Memory, [2]Picower Inst. for Learning and Memory, Brain and Cognitive Sci., MIT, Cambridge, MA; [3]The Picower Inst. for Learning and Memory, MIT, Cambridge, MA

Abstract: Cyclin-dependent kinase 5 (Cdk5), a serine/threonine kinase, plays a critical role in many aspects of neuronal function such as neuronal migration and positioning, cytoskeletal regulation, presynaptic neurotransmitter release, and synaptic plasticity and learning. However, it has also been reported that Cdk5 becomes hyperactive in neurodegenerative diseases such as Alzheimer’s due to increased levels of p25, a proteolytic fragment of the regulatory subunit p35. We previously showed that inhibition of p25 generation by replacing endogenous p35 with a non-cleavable mutant p35 (Δp35) ameliorated amyloid and tauopathic phenotypes in familial Alzheimer’s disease and frontotemporal mouse models, respectively. Here we show that a modified, truncated peptide (Cdk5 inhibitory peptide- Cdk5i), derived from Cdk5, effectively and specifically inhibits aberrant Cdk5 hyperactivity in vitro. In addition, Cdk5i-TAT peptide penetrates blood-brain barrier in mice after an intraperitoneal injection, rendering it a potentially small and readily diffusible therapeutic agent to combat pathological features of neurodegeneration.

Title: The HDL mimetic peptide 4F mitigates cerebral amyloid angiopathy in transgenic APPswDI mice

Authors: *R. ZHONG[1], D. S. CHERNICK[2], D. A. HOTTMAN[1], L. LI[1];
[1]Dept. of Exptl. and Clin. Pharmacol., [2]Dept. of Pharmacol., Univ. of Minnesota, Minneapolis, MN

Abstract: Cerebral amyloid angiopathy (CAA) features amyloid-β (Aβ) deposition in small arteries and capillaries of the cerebral cortex and the leptomeninges, and constitutes one of the pathological hallmarks of Alzheimer's disease (AD) along with senile plaques and neurofibrillary tangles. CAA is associated with intracerebral hemorrhage, cerebrovascular dysfunction and cognitive impairment. There is currently no effective clinical therapy for CAA or AD. Substantial evidence has shown that high levels of high-density lipoprotein (HDL), and its main protein component, apoA-I, are associated with superior cognitive function in the elderly; in animal models, our previous studies have shown that overexpression of human apoA-I rescues cognitive function in AD mice by attenuating CAA and neuroinflammation. 4F is an 18 amino acid HDL mimetic peptide that has advanced into clinical trials for cardiovascular disease. Our preliminary data have shown that 4F inhibits Aβ aggregation and enhances Aβ efflux across the blood-brain barrier. The present study was undertaken to investigate whether acute or chronic treatment with the HDL mimetic peptide 4F mitigates CAA and associated cognitive deficits and neuropathologies in the transgenic APPswDI mouse model of CAA/AD. APPswDI mice were treated with i.p. injections of D-4F, the D-isomer of 4F that exhibits higher bioavailability and longer half-life. Two cohorts of age- and sex-matched APPswDI mice received either a 1 week (acute) or 12 week (chronic) daily treatments of D-4F or vehicle (PBS), respectively. In the acute treatment study, soluble Aβ levels were significantly reduced in the brain of D-4F treated APPwDI mice; consistently, D-4F treatment trends toward decreased amyloid deposition and microglia recruitment in cortical and hippocampal regions. In the chronic study, D-4F administration was shown to rescue CAA-associated memory deficits in male APPswDI mice, suggesting a sex-dependent effect in this mouse model of CAA/AD. Additional analyses are underway to unravel the molecular mechanisms underlying the effects of D-4F treatment in these mice. These findings suggest that HDL memetic peptides could be a potential therapeutic agent to mitigate CAA/AD.

Title: LC1405 prevents beta-amyloid peptide-induced toxicity by regulating histamine H3 receptor signaling pathway

Authors: *R. LIU[1], L. WANG[2], H. JIANG[2], Q. WANG[1];
[1]Inst. of Medicinal Biotech., Beijing, China; [2]Inst. of Medicinal Biotech. Chinese Acade, Beijing City, China

Abstract: In studies on the treatment of Alzheimer’s disease (AD), in which cognition is enhanced even modestly or selectively, it has been considered that the histamine H3 receptor (H3R) may be a potential target. In this study, we aimed at evaluating the ability of 7-pyrrolidinethoxy-4'-methoxyisoflavone (indicated as LC1405), a novel potential H3R antagonist identified from our H3R antagonist screening system, to ameliorate amyloid β (Aβ)-induced cognitive deficits, and to explore the underlying mechanisms that are related to H3R-modulated signaling. Our results demonstrated that LC1405 effectively reduced the progression of Aβ-associated disorders, such as improved learning and memory capabilities, preserved tissues from suffering neurodegeneration and ultrastructural abnormalities, and ameliorated cholinergic dysfunction in an APP/PS1 double transgenic mouse model of AD. In an *in vitro* model, LC1405 protected neuronal cells against copper-induced Aβ toxicity, as demonstrated by the improvement in cell viability and decrease in neuronal apoptotic ratio. In addition, treatment with LC1405 resulted in the up-regulation of acetylcholine (ACh) or histamine release and provided neuroprotection through cellular signaling cascades involving H3R-mediated cAMP/CREB and AKT/GSK3β pathways. Furthermore, the beneficial effects of LC1405 on Aβ-mediated toxicity and H3R-mediated cAMP/CREB and AKT/GSK3β axes were reversed after pharmacological activation of H3R. In conclusion, our results demonstrated that LC1405 blocked Aβ-induced toxicity through H3R-modulated signaling transduction both *in vitro* and *in vivo*. The results also suggested that LC1405 might have translational potential as a complementary therapy to control disease progression in AD patients who developed cognitive deficits with H3R-related ACh neurotransmission abnormality.

Title: Soluble TNF mediates obesogenic diet-induced alterations in peripheral and brain immunophenotype in a mouse model of Alzheimer's disease

Authors: *M. G. T. TANSEY[1], K. P. MACPHERSON[2], L. N. EIDSON[3], M. K. HERRICK[3], M. DE SOUSA RODRIGUES[4], L. SNIFFEN[4], S. D. KELLY[3], A. M. HAMILTON[3], D. L. OLIVER[3], Y. YANG[3], J. CHANG[3];

Abstract: Increasing evidence indicates that neurodegenerative disease, such as Alzheimer's disease (AD), is the product of an individual's genetic risk in the context of their environmental exposures. A major contributor in mediating the gene-environment effect in AD is the immune system. Peripheral immune cell signaling plays an important role in AD through regulating immune cell interactions within the microvasculature and meninges of the CNS, as well as mediating effects at the Blood-Brain Barrier (BBB) and Gut. A diet high in fat and sugar dysregulates several signaling pathways that trigger immune and metabolic responses that can result in metabolic syndrome and is linked to increased risk for AD. Among these, cytokine and chemokine mechanisms regulate peripheral immune cell trafficking to inflamed tissues, including the gut and brain. The cytokine, tumor necrosis factor (TNF), is elevated in AD patients, regulates brain and gut barrier permeability, and is produced by central and peripheral immune cells. Further, TNF mediates conditions involved in metabolic syndrome. We hypothesize that soluble TNF (sTNF) is a key mediator of peripheral immune cell contributions to AD-like pathology and metabolic dysfunction. Here we aim to determine the effect of chronic high-fat-high-carbohydrate (HFHC) diet-induced peripheral inflammation on neuroinflammation and neuronal health in a model of AD. Two-month old female 5xFAD mice were fed a HFHC or a control diet (CD) for 8 weeks. After 4 weeks of diet, XPro1595, a BBB-permeant peptide, was used to selectively inhibit sTNF signaling. XPro1595 ameliorated HFHC diet-induced increased hippocampal Abeta and Iba1 protein levels as well as TNF and ZO-1 mRNA. 5xFAD mice had increased T cell populations in the brain when fed HFHC, and in HFHC diet-fed Tg mice as compared with HFHC non-Tg mice. An increase in Ly6C+ T cells was observed in HFHC diet-

fed Tg mice versus CD fed mice. Tg mice fed a HFHC diet had decreased PBMC T cell expression. Experiments are ongoing to assess additional effects of sTNF in AD pathogenesis gut permeability and inflammation, and alterations in the gut microbiome. Together, these data suggest that diet -induced obesity alters immune cell populations in 5xFAD mice and promotes BBB associated alterations that may enhance neuroinflammation, amyloid burden, and neurodegeneration.

Title: Suppression of ATAD3A aberrant activation attenuates neuropathology and cognitive deficits in experimental models of Alzheimer's disease

Authors: *Y. ZHAO, X. SUN, X. QI;
Dept. of Physiol. and Biophysics, Case Western Reserve Univ. Sch. of Med., Cleveland, OH

Abstract: Alzheimer’s disease is the most common age-dependent neurodegenerative disease, which is featured by accumulation of amyloid deposition, neurofibrillary tangles, loss of synapses and progressive loss of memory and other cognitive functions. So far, there is no effective treatment available for AD. ATAD3A (ATPase family AAA-domain containing protein 3A) is a nuclear-encoded mitochondrial protein that regulates mitochondrial morphology and controls cholesterol trafficking at mitochondrial contact sites. Our recent study demonstrates that ATAD3A oligomerization elicits mitochondrial bioenergetics failure and neuronal dysfunction under stress and pathological condition. In AD cell culture, animal brains and patient postmortem brains, we observe an increase in ATAD3A oligomerization, suggestive of ATAD3A aberrant activation. We developed a peptide blocker, DA1, that binds to ATAD3A to block its oligomerization. Treatment with DA1 reduces the production of mitochondrial reactive oxygen species, improves the cholesterol metabolism and decreases the expression of APP level

in both mouse hippocampus neuronal HT-22 cells exposed to oligomeric $A\beta_{1-42}$ and neuro2a cells stably expressing APP. Notably, sustained treatment with DA1 peptide inhibitor attenuates the cognitive deficits and memory loss, and reduces Aβ accumulation and neuro-inflammation in the brains of 5xFAD AD transgenic mice. Our findings suggest that ATAD3A oligomerization may contribute to the pathogenesis and cognitive decline in AD and that DA1-like reagent might be useful for therapeutic development of AD and aging-related dementia.

Title: A rationally designed peptide based on the ɣ-secretase cleavage product of ephrinB2 promotes angiogenesis *in vitro*

Authors: *S. Z. VANCE[1], Y. YOON[2], N. WARREN[3], N. K. ROBAKIS[3], A. GEORGAKOPOULOS[4];
[1]Psychiatry, Icahn Sch. of Med. At Mount Sinai, New York, NY; [2]Psychiatry and Neurosci., [3]Icahn Sch. of Med., New York, NY; [4]Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract: Presenilin1 (PS1) is part of the γ-secretase complex which cleaves type I transmembrane proteins. Previous studies have shown its role in regulation of vascular function in addition to linking it to familial Alzheimer's disease (fAD). Vascular impairment is commonly observed in Alzheimer's disease. Our lab has previously shown PS1 participates in ephrinB2 (efnB2) signaling by creating a cytoplasmic peptide (efnB2/CTF2) that promotes angiogenic activity *in vitro* through a PDZ-domain. In order to develop therapeutics to treat vascular dysfunction in both AD and related conditions such as ischemic stroke, we aim to develop a deliverable angiogenic peptide *in vivo* based on the PDZ-binding domain from the efnB2/CTF2 sequence. A small peptide (NCB2) was designed based on the PDZ-binding domain of efnB2/CTF2 and fused with the HIV TAT sequence to enhance delivery. Peptides lacking either TAT or PDZ sequence or a scrambled sequence served as controls. Bovine adrenal microvascular endothelial cells (BAMEC) were used to test angiogenic function. NCB2 delivery was confirmed via fluorescent microscopy. To assess the ability of NCB2 to promote sprouting, cells were grown on microcarrier beads in fibrin gels containing peptides. After 48 h, sprouts

were quantified. The ability of NCB2 to promote cell migration was also determined using an *in vitro* scratch assay. Cells were treated and imaged for 5 h. The number of cells invading the scratched area was reported. Results were confirmed in primary mouse brain microvascular endothelial cells (BMEC). NCB2 promotes sprout formation in both BAMEC and BMEC comparable to that of efnB2/CTF2; both enhance sprouting 6-fold larger than untreated cells. Additionally, NCB2 promotes a wound healing phenotype *in vitro* in BAMEC. PDZ-null, scrambled and peptides lacking TAT sequence created neither angiogenic property. NCB2 is a bioactive peptide that possesses the angiogenic properties of efnB2/CTF2. By integrating the TAT sequence, we have created a peptide that can penetrate a variety of cell lines and cause the formation of angiogenic phenotypes. Future studies will explore other angiogenic potential of this peptide such as tube formation and its ability to act *in vivo*.

Title: A new unbeneficial myokine secreted from atrophied skeletal muscle accelerates the onset of Alzheimer's disease

Authors: T. NAGASE, C. TOHDA;
Inst. of Natural Medicine, Univ. of Toyama, Toyama, Japan

Abstract: Several epidemiological and clinical studies show that exercise is positively associated with cognitive function and preventing Alzheimer’s disease (AD). On the contrary, physical inactivity is known as one of risk factors for AD onset. Several myokines are reported to be secreted by exercise, so the positive contribution of those beneficial myokines to cognitive improvement is supposed. In contrast, unbeneficial myokines directly deteriorating cognitive function have not been identified. We hypothesized that unbeneficial myokines exist and accelerate AD onset, and those might be secreted from skeletal muscles at the physically inactivated state. Therefore, this study aimed to investigate the relationship between skeletal muscle atrophy and AD onset, and to identify new myokines involved in the phenomenon. To prepare a disuse muscle atrophy model, bilateral hindlimbs were immobilized by putting into casts for 14 days. Young age of 5XFAD mice (3 months old, male) were used. 5XFAD mice

usually reveal cognitive impairment after 4 - 5 months of age. Object recognition memory and object location memory in casted 5XFAD mice was impaired after the 14-day casting although age matched wild-type mice and non-cast 5XFAD mice showed normal memory function. Numbers of amyloidβ plaques in the brain were not different between casted and non-casted 5XFAD groups. After the memory test, hindlimbs were isolated for organ culture. Conditioned medium of each muscle culture was separated on SDS-PAGE and silver stained. Increased proteins in the conditioned medium of casted 5XFAD were identified by nanoLC-MS/MS analysis. Transferrin was significantly increased in conditioned medium both of gastrocnemius and tibialis anterior muscles of casted 5XFAD mice. Source of increased transferrin was skeletal muscle, but not blood. These results suggest that atrophied skeletal muscles secrete transferrin. Transferrin has never been recognized as a myokine. We suppose that secreted transferrin from skeletal muscles reach to and affect the brain, specific function of transferrin against neurons was investigated. This study found a new myokine, transferrin that might be first identified as unbeneficial myokine for AD onset. Regulating secretion and/or signaling of the transferrin possibly leads to deceleration and inhibition of AD progress.

Title: Clathrin nanoparticles efficiently deliver brain-derived neurotrophic factor to the hippocampus, reverse oxidative stress and enhance synaptogenesis and memory in Alzheimer’s mouse model

Authors: *G. VITALIANO[1], C. ADAM[1], G. ZEBALLOS[1], X. CHEN[1], F. DU[1], F. VITALIANO[2];
[1]McLean Hosp., Belmont, MA; [2]ExQor Technologies, Boston, MA

Abstract: Background: Advances in treatment of neurodegenerative disorders have been made by administering brain derived neurotrophic factor (BDNF) directly to the brain, or by using drugs that increase BDNF indirectly. BDNF promotes neuroregeneration and restores brain functions but cannot easily cross a blood brain barrier (BBB). Our goal was to develop BDNF-clathrin nanoparticles (CNPs) that can efficiently target brain TrkB receptors and reverse deficits in 3xTg-AD mouse model of Alzheimer’s disease. **Methods:** 3xTg-AD female mice (n=16) were

treated intranasally 2 times weekly from 3-7 months of age with saline (40µl) or CNPs (0.3mg/kg of BDNF with 2.4mg/kg of clathrin). During week 11 of treatment, mice were tested with Barnes maze and Novel Object Recognition tests. During week 12, proton MRS was acquired in the mouse hippocampus (n=8) at a 9.4 T (Varian Inc.) using LASER sequence (Repetition Time/Echo Time, TR/TE = 3000/19 ms). Mice were then sacrificed, and brains were processed using immunohistochemistry. Synaptogenesis and dendritic integrity were determined in the hippocampal regions with Synaptophysin (SYP) and Map2 antibodies respectively. For CNS distribution studies, mice (n=8) received CNP radiolabeled with tritium (4.8 µCi). Brain regions were removed at 4 or 24 hours after CNP administration and concentrations (% injected dose ID/g tissue) were analyzed. **Results:** CNPs delivered BDNF to the mouse hippocampus (0.7 %ID/g) and reversed glial hyperactivity and oxidative/ metabolic stress by significantly decreasing hippocampal levels of myoinositol (mIns/tCr, P=0.0241), glutathione (GSH/H2O, P=0.0231) and lactate (Lac/tCr, P=0.0442) in CNP vs. saline treated 3xTg-AD mice. CNPs significantly improved hippocampal synaptogenesis and dendritic integrity. The SYP immunoreactivity was significantly higher in the CA1 (P=0.0141), CA3 (P=0.0152) and dentate gyrus (DG) (P=0.0073) in CNP vs. saline treated mice. The Map2 immunoreactivity was increased in DG (P=0.0312) of CNP vs. saline treated mice. Hippocampal-based memory acquisition (P=0.029) and novel object recognition (P=0.0073) significantly improved in CNP vs. saline treated 3xTg-AD mice. **Conclusions:** CNPs delivered BDNF to the hippocampus, reversed glial hyperactivity and oxidative stress, enhanced synaptogenesis and dendritic integrity and improved memory in 3xTg-AD mice. Hence, clathrin provides a highly efficient nanoplatform for delivery of BDNF to the brain. This noninvasive nanotechnology may be able to enhance neuronal regeneration and plasticity and restore brain functions better than existing treatments for neurodegenerative disorders.

Title: *In vivo* methods for characterizing visual system pathology in Alzheimer's mouse models

Authors: *G. FRAME[1], E. S. PLYLER[1], C. M. DENGLER-CRISH[2];
[1]Northeast Ohio Med. Univ., Rootstown, OH; [2]Northeast Ohio Med. Univ. (NEOMED), Rootstown, OH

Abstract: Alzheimer's disease (AD) is one of the top ten causes of death in the U.S., yet disease-modifying therapies remain elusive. Given this, early disease detection is a crucial aspect of symptom management and monitoring of disease progression. Of the new techniques being investigated for early detection of AD, retinal imaging and disease-related changes to the visual system remain promising approaches. As such, our lab has data showing that pattern electroretinogram (PERG) and high-resolution ophthalmic imaging can be used *in vivo* to track progression of visual system pathology and functional deficits in 3xtg and APP/PS1 mice. Using a Celeris system (Diagnosys) to measure PERG, we characterized age-related signaling deficits in retina of AD model mice that were contrasted with the same measurements from age-matched healthy control mice. Additionally, we used a Micron-IV Ophthalmoscope (Phoenix Research Labs) to perform *in vivo* imaging of retinal pathology in anesthetized AD-model mice. Following intravitreal injection of fluorescence-tagged amyloid beta antibodies, we were able to visualize retinal amyloid pathology, providing a method for tracking progression of this pathology over time. We also validated these detection methods using post-mortem immunohistochemical approaches. Our results support using these minimally invasive methods to detect early disease pathology in the visual system of experimental AD models and track its progression over time. These techniques provide a means for researchers to investigate the interface between retinal and neural pathology in AD, which will inform our understanding on the utility of clinical retinal imaging in determining disease onset or progression.

Title: A novel MSD ELISA-based assay for the selective detection and quantitation of rodent HTT protein

Authors: *S. DIJKSTRA[1], A. C. P. CORREIA[1], J. SUIJKER[1], N. A. NGAI[2], P. NAUD[2], M. POIRIER[2], D. F. FISCHER[3], D. MACDONALD[4];

[1]Charles River, Leiden, Netherlands; [2]Charles River, Shrewsbury, MA; [3]Discovery, Charles River, Saffron Walden, United Kingdom; [4]CHDI Management, Inc., Los Angeles, CA

Abstract: ELISA-type assays are widely used for the detection and quantification of disease related biomarkers, and their robustness and reliability depend mainly on the capture/detection antibody combination used. We previously described a panel of ELISA-based assays for the detection and quantification of various huntingtin (HTT) proteins on the Meso Scale Discovery (MSD) platform, including an assay specific for rodent huntingtin (mouse and rat). This assay employs a rabbit polyclonal antibody directed at the mouse proline-rich domain (PRD)(CHDI-90000147) for capture and a monoclonal anti-HTT antibody (MAB2166) for detection. Long term use of polyclonal antibodies is problematic, therefore we sought to replace CHDI-90000147 with a monoclonal antibody equivalent version to develop a novel rodent HTT assay. The ABfinity platform (Thermo Fisher) was used to generate a set of novel rabbit monoclonal antibodies selective for mouse HTT by targeting the mouse HTT PRD, which is distinct from the human HTT PRD. Antibody characterization was initially performed by Western blot analysis of mouse and human recombinant HTT proteins as well as brain lysates of wild type and homozygous Q175 knock-in mice (which have no endogenous mouse HTT exon 1). Our mAb CHDI-90002133 displayed the most optimal performance in regards to selectivity and specificity, therefore we used it to develop a novel fully monoclonal antibody immunoassay selective for mouse HTT detection on the MSD platform. Here, we describe the use of CHDI-90002133 as capture antibody in combination with either MAB2166 or D7F7 as a detection antibody. Both antibody combinations were able to quantify mouse HTT protein with sensitivity and accuracy. However, only assay CHDI-90002133/D7F7 showed similar or better sensitivity for mouse HTT when compared to the reference original assay CHDI-90000147/MAB2166. Furthermore, we confirmed that this assay is able to detect endogenous rat HTT protein. Assay CHDI-90002133/D7F7 was then validated by demonstrating the expected gene dosage effects in brain lysates from a cohort of Q175 knock-in homozygous, heterozygous and wild type mice. Importantly, this assay is one of a set of HTT quantitation assays transferred from a location in Europe to one in the US for enhanced access. In conclusion, the CHDI-90002133/D7F7 combination of monoclonal antibodies demonstrated to be a promising replacement for our current, polyclonal MSD assay for rodent HTT detection, showing similar performance while mitigating the risk of antibodies being depleted.

Title: Hippocampal ultrastructural alterations accompany cognitive and affective deficits in the YAC128 mouse model of Huntington's disease

Authors: *P. S. BROCARDO[1,2], C. DE PAULA NASCIMENTO-CASTRO[2], E. PLÁCIDO[2], E. C. WINKELMANN- DUARTE[1], A. L. S. RODRIGUES[3], J. GIL-MOHAPEL[4];
[1]Morphological Sci., [2]Neurosci. Grad. Program, [3]Biochem., Federal Univ. of Santa Catarina, Florianópolis, Brazil; [4]Med. Sci., Univ. of Victoria, Victoria, BC, Canada

Abstract: Introduction: Huntington's disease (HD) is a neurodegenerative disorder characterized by motor, cognitive and psychiatric symptoms. Psychiatric and cognitive disturbances often precede motor symptoms. The main neuropathological characteristic is the selective degeneration of the striatum. However, the involvement of other non-striatal structures such as the hippocampus may contribute to non-motor alterations. Objectives: To characterize behavioral and mitochondrial alterations, as well as to evaluate morphological and ultrastructural changes in the hippocampus of the YAC128 transgenic mouse model of HD. Methods: Experiments to analyze depressive-like behavior (tail suspension test and splash test), and mitochondrial function (respiratory activity) were carried out on 4 and 12-month old YAC128 mice and wild-type (WT) littermate controls. In addition, cognitive deficits (T-maze and rotarod) were evaluated in late symptomatic 12-month old animals. A separate cohort of late symptomatic animals (13 months) was used to evaluate hippocampal morphological alterations. Ultrathin brain sections were obtained stained with 2% lead citrate and 1% uranyl acetate and examined by transmission electron microscopy. Results: YAC128 mice presented depressive-like behaviors at both 4 and 12 months of age, as assessed by the tail suspension test. YAC128 mice also demonstrated a deficit in motor skills acquisition in the rotarod and a deficit in strategy response in the T-maze aquatic test when compared to WT animals. Evaluation of mitochondrial respiration in hippocampal homogenates in the initial (3-4 months) and late (11-14 months) symptomatic phases did not reveal functional deficits. Similarly, YAC128 mice did not present robust alterations in hippocampal mitochondrial ultrastructural morphology. In contrast, the Rough Endoplasmic Reticulum (ER) and Golgi apparatus showed intense dilatation. Analysis of semithin hippocampal sections revealed the presence of degenerate, hyperchromic neurons with irregular morphology as well as nuclear and cytoplasmic condensation in the hippocampal dentate gyrus (DG) of YAC128 mice. Conclusion: Abnormalities in mitochondrial respiratory chain and morphology were not observed in symptomatic YAC128 mice. Therefore, the behavioral alterations present in the early and late stages of HD do not seem to correlate with changes in mitochondrial function. However, a neuronal degenerative process was found in the hippocampal DG granule cells. These results reinforce the progressive nature of HD and the potential role of hippocampal dysfunction in the etiology of the behavioral deficits associated with HD.

Title: Abnormal basal ganglia activity in the Q175 knock-in mouse model of Huntington's disease

Authors: *J. W. CALLAHAN, M. D. BEVAN;
Northwestern Univ., Chicago, IL

Abstract: Huntington's disease (HD) is a neurodegenerative, hereditary, trinucleotide repeat disorder, initially characterized by excessive movement and impulsive behavior. The GABAergic external globus pallidus (GPe) and reciprocally connected glutamatergic subthalamic nucleus (STN) are key components of the indirect and hyperdirect pathways of the basal ganglia that suppress involuntary action. Therefore, abnormal GPe and STN activity could be critical for the symptomatic expression of HD. Using *in vivo* and *ex vivo* cell class-specific recording and optogenetic interrogation approaches, we investigated alterations in the operation of the GPe-STN network in Q175 knock-in (KI) HD mice. We found that in urethane-anesthetized Q175 KI mice 1) GABAergic D2-receptor expressing striatopallidal projection neurons (D2-SPNs) were hypoactive, consistent with their abnormally reduced dendritic excitability; 2) prototypic GPe neuron activity was elevated, consistent with D2-SPN hypoactivity, and the elevation of autonomous GPe neuron activity *ex vivo*; 3) STN neuronal activity was reduced in both anesthetized and awake, behaving Q175 KI mice, consistent with prototypic GPe neuron hyperactivity; 4) STN activity could not be fully restored by optogenetic silencing of prototypic GPe neurons, consistent with the impaired autonomous activity of STN neurons *ex vivo*. Together these data demonstrate that before the loss of neurons, indirect and hyperdirect pathway function is profoundly impaired in HD mice. We are currently investigating whether lowering mutant huntingtin protein in the STN through viral expression of inhibitory zinc finger proteins is sufficient to rescue neuronal activity.

Title: Progressive basal ganglia pathology in male heterozygous q175 knock-in Huntington's disease mice

Authors: Y. DENG, H. WANG, M. JONI, ***A. REINER**;
Anat. & Neurobio., Univ. of Tennessee Hlth. Sci. Ctr., Memphis, TN

Abstract: We have characterized the progression of basal ganglia pathology from 2 to 18 months of age in heterozygous male Q175 Huntington's disease (HD) mice compared to age-matched littermate WT mice. We found that striatal projection neurons (SPNs) immunolabeled for DARPP32 were normal in abundance at 2 months but were significantly reduced in abundance by about 20% at 6 months, with reduction of about 40% by 18 months. As the abundance of enkephalinergic (ENK+) indirect pathway SPNs (iSPNs) was similarly decreased, but the abundance of substance P-containing (SP+) direct pathway SPNs (dSPNs) unchanged, the DARPP32 perikaryal reduction appears preferential for ENK iSPNs. Consistent with this, we found reduction in DARPP32 in striatal terminals in globus pallidus externus (GPe) but not in striatal terminals in globus pallidus internus (GPi) or substantia nigra pars reticulata (SNr) by 12 months of age in Q175 mice. Stereological analysis of NeuN+ striatal neurons, however, showed no loss out to 18 months of age, indicating the reductions in DARPP32+ SPNs and ENK+ iSPNs reflect reduced expression rather than neuronal loss. Despite reduced ENK+ iSPNs and unaltered SP+ dSPNs, the abundance of ENK+ terminals in GPe and SP+ terminals in GPi and SNr were increased by 6 months of age, and remained so out to 18 months. Of note, the DARPP32 reductions in SPNs and striato-GPe fibers, and the increased ENK+ and SP+ terminals in striatal target areas were correlated with motor abnormalities such as reduced time on rotarod, and/or shorter distance traveled, slowed speed, and increased turning (a hyperkinetic sign) in open field. Analysis of striatal cholinergic, parvalbuminergic, and NOS+ interneurons revealed they were normal in abundance out to 18 months of age, although cholinergic interneurons showed dendritic attenuation by 6 months. GABAergic neuron abundance was normal in GPe, GPi and SNr out to 18 months, as was nigral dopaminergic neuron abundance, but by 18 months arkypallidal GPe neurons and STN neurons were reduced by about 25%. Our results indicate that progressive SPN neurochemical pathologies have an onset after 2 months of age in heterozygous

male Q175 mice, and arkypallidal GPe and STN neuron loss is seen by 18 months. Heterozygous male Q175 mice may thus model a very early stage of human HD, before there is overt SPN loss.

Abstract: Using a ZFN-mediated gene editing approach, a knock-in Long-Evans rat model of Huntington's disease (Htt-Q130-LEH) was developed. The model carries a pure ~130 CAG repeat followed by CAACAGCAGCAGCAACAG in Exon 1 of the endogenous rat Htt gene. The mHTT protein is expressed at ~65% of the WT HTT protein throughout the CNS. Heterozygote (HET) and wild type (WT) littermates were subjected to a battery of motor tests every 3 months (m) starting at 3 m of age, including fine motor kinematic analysis, open field, tapered beam balance, grip strength, and weekly bodyweight monitoring. In addition, in vivo tetrode recordings of cortico-striatal and cortico-subthalamic nucleus (STN) transmission were assessed at 12 m for evidence of altered cortico-basal ganglia function. Ex vivo analysis included MesoScaleDiscovery (MSD) quantitation of mHTT, immunohistochemical (IHC) assessment of mHTT aggregation, RNA sequencing, and analysis of striatal medium spiny neuron (MSN) membrane properties and synaptic activity between 3 - 12 m of age.
Until 6 months of age, HET Htt-Q130-LEH rats appear to be largely equivalent to their WT counterparts on all investigated parameters. However, with advancing age, HET rats start to display motor deficits, most notably as altered gait, decreased rearing and velocity in the open field. Bodyweight in male HET and WT rats is similar, whereas female HET rats are slightly heavier from 50 weeks onwards. At 12 m, in vivo electrophysiology showed that both cortico-

striatal and cortico-STN transmission are significantly impaired in HET rats and striatal and cortical aggregates are detectable by MW8/4C9 MSD and S830 IHC analysis. Moreover, RNA sequencing revealed alterations in genes predominantly involved in GPCR / cAMP-mediated and calcium signaling, as well as neuro-inflammation.
In summary, the Htt-Q130-LEH rat exhibits a relatively delayed onset of phenotype that will continue to be monitored at more advanced ages. This model may prove useful for further investigation of mHTT-induced neuropathophysiology.

Title: Working memory and cortico-basal ganglia circuitry in a novel AAV2.retro-mediated non-human primate (NHP) model of Huntington’s disease (HD)

Authors: *A. R. WEISS[1], Z. LIU[1,2], X. WANG[1,2], J. DOMIRE[1], W. LIGUORE[1], K. BRANDON[1], C. D. KROENKE[1,2,3], J. L. MCBRIDE[1,3];
[1]Div. of Neurosci., Oregon Natl. Primate Res. Ctr., Beaverton, OR; [2]Advanced Imaging Res. Ctr., [3]Dept. of Behavioral Neurosci., Oregon Hlth. & Sci. Univ., Portland, OR

Abstract: Our laboratory has previously shown that AAV1-mediated expression of mutant HTT (mHTT) in the striatum of rhesus macaques induces motor impairments, disease-related striatal pathology, and reduced working memory capabilities. We recently expanded this NHP model using AAV2.retro, a new capsid with enhanced retrograde transport, to deliver a pathogenic fragment of mHTT with 85 CAG repeats into the striatum, as well as to the cortex, thalamus,

amygdala and other regions in the basal ganglia. Using this approach, we have recently generated a large cohort of NHPs and are querying the disruption of cortico-basal ganglia circuitry for 12-months following intracranial delivery of this mHTT construct (85Q, n=6), a control HTT construct (10Q, n=6), or buffer (n=6). We are collecting repeated MRI scans from these animals to measure volume alterations of cortical and basal ganglia structures (T1-weighted and T2-weighted), to detect changes in white and grey matter microstructure (diffusion tensor imaging, DTI), and to identify areas of decreased cortico-basal ganglia functional connectivity (resting state functional connectivity MRI, RSfcMRI). We are also administering a touchscreen task to assess working memory changes (Delayed Non-match to Sample, DNMS). Here, we will describe our MRI data processing pipelines, and report correlations of behavior and MRI measurements during task acquisition pre-surgery, as well as potential correlations of cognitive and motor decline and imaging as the disease progresses. Using a customized brain atlas, cortico-basal ganglia circuitry was labeled with 22 gray matter regions and 10 white matter tracts. We observed that MRI measures of structural connectivity among these regions correlate with working memory measures collected pre-surgery. Our analyses revealed a significant negative correlation ($p<0.05$) between acquisition of the DNMS task and fractional anisotropy (FA) in dorsolateral prefrontal white matter tracts, indicating that monkeys who made relatively more errors learning the DNMS rule also had lower FA within a subset of prefrontal WM tracts. Serial MRI and DNMS task performance data are currently being collected. We hope that our new model will better replicate the more widespread neuropathology seen throughout the brains of HD patients, enhance our understanding of the mechanisms impacted by mHTT, validate neuroimaging measurements used to stage HD pathology in human subjects, generate new therapeutic biomarkers of disease progression, and provide a second generation viral-vector based monkey model of HD available to the research community for evaluation of promising therapeutics.

Title: The difference of mutant Huntingtin expression between HD KI pig and KI mouse tissues

Authors: *X. ZHANG[1], S. YAN[2], X.-J. LI[3];
[1]Guangdong-Hong Kong-Macau Inst. of CNS Regener, Guangzhou, China; [2]Guangdong-

Hongkong-Macau Inst. of CNS Regeneration, Jinan Univ., Guangdong, China; [3]Guangdong-Hong Kong-Macau Inst. of CNS Regeneration, Guangzhou, China

Abstract: Huntington's disease (HD) is a typical monogenic neurodegenerative genetic disease that is caused by CAG triplet repeats expansion in the Huntingtin gene (*HTT*). The CAG repeat expansion (>36 CAGs) in the *HTT* gene leads to a polyglutamine (polyQ) expansion that causes HTT to misfold and aggregate in the brain. It is characterized by the accumulation of mutant proteins and neuronal death in the HD patient brains and abnormal behavioral, cognitive, and mental function. HD disease is an ideal model for investigating the pathogenesis of misfolded proteins in neurodegenerative diseases. Recently, we have established HD knock-in (KI) pig model that expresses full-length mutant HTT at the endogenous level. Here we report the expression of mutant HTT in HD KI pig and mouse tissues. We found that mutant HTT expression is not identical between HD KI pig and mouse tissues. Pathological analysis showed that HD KI pig brains display more severe and obvious degeneration than HD KI mouse brains. The differences in HTT expression between HD KI pig and mouse brain tissues may contribute to the differential pathology of HD in different species.

Title: Characterision of kynurenine 3-monooxygenase as a therapeutic target for Huntington's disease

Authors: *M. K. BONDULICH[1], A. PAPADOPOULOU[1], G. P. BATES[1], F. GIORGINI[2], Y. SONG[1];
[1]Neurodegenerative Dis., UCL, London, United Kingdom; [2]Dept. of Genet. and Genome Biol., Univ. of Leicester, Leicester, United Kingdom

Abstract: Huntington's disease (HD) is a fatal neurodegenerative disorder characterized by involuntary movements and cognitive decline. HD is caused by a trinucleotide CAG expansion producing an extended polyglutamine stretch in the huntingtin protein (HTT), leading to HTT aggregation and death of vulnerable neurons. The kynurenine pathway (KP) of tryptophan degradation has been closely linked to the pathogenesis of HD, containing several neuroactive metabolites. The enzyme kynurenine 3-monooxygenase (KMO) lies at a pivotal branch of the KP

between the formation of neuro-toxic/protective metabolites. Notably, KMO inhibition ameliorates disease-relevant phenotypes in yeast and fly models of HD. To investigate the role KMO plays in HD pathogenesis, we crossed R6/2 HD model mice to KMO knockout (KO) mice to characterise KP gene expression and metabolite profiles in R6/2 vs R6/2 KMO KO mice, and to test potential therapeutic benefits of ablating KMO.
R6/2 mice were crossed to KMO KO mice to generate six genotypes: wild type (WT), KMO KO heterozygotes (het) and homozygotes (hom), and R6/2 on het and hom KMO KO backgrounds. Body weight was measured from 4-12 weeks of age. Mice were sacrificed at 12 weeks (R6/2 symptomatic stage), with plasma and peripheral/brain tissues analysed. KP gene expression was quantified using QuantiGene Assays. KP metabolites were analysed using HPLC with tandem mass spectrometry. We visualised KP gene expression in cells via RNA in situ hydridization (ISH) using RNAScope Technology. Plasma cytokine levels were measured using the Mesoscale detection system.
R6/2 mice show increase in KMO gene expression at 12 weeks of age in peripheral and brain tissues analysed, as well as alterations in both KP enzyme expression and metabolites as compared to WT controls. The failure to gain weight was less pronounced in R6/2 mice het for KMO KO. Ablation of KMO led to an increase in KYNA and KYN and a decrease in QUIN metabolites in both the periphery and brain tissue in WT and R6/2 mice. Both KP enzyme gene expression and plasma cytokine levels were altered in R6/2 vs WT mice with several significant changes observed upon KMO knockout.
KP metabolites, enzyme gene expression and plasma cytokine levels are dysregulated in R6/2 mice. Knockout of KMO in R6/2 mice restored some of the differences observed. Further analysis is essential to establish a more detailed profile of altered KP function in R6/2 KMO KO mice as well as to evaluate the potential therapeutic effects of KMO knockdown on HD-related phenotypes.

Abstract: Huntington's disease (HD) is an inherited neurodegenerative disorder that is caused by a CAG abnormal repeat expansion in the huntingtin gene coding for a protein with the same name. HD patients present choreiform movements, which are caused by the loss of neurons in the striatum and cerebral cortex. One of the mechanisms proposed to explain neuronal loss is a decrease in brain-derived neurotrophic factor (BDNF). BDNF is involved in different processes in the central nervous system and is regulated by normal huntingtin. Previous works have shown that knocking down the aryl hydrocarbon receptor (Ahr) in cortical neurons results in the increase of BDNF levels. Based on this data, our objective was to evaluate a double transgenic mouse, expressing human mutated huntingtin and knockout for Ahr. Our results show that 30 week-old double transgenic mice have a body weight similar to R6/1 mice, however, feet-clasping, an indicative of neuronal damage in the R6/1 animals, was not observed. In addition, motor coordination and ambulatory behavior did not deteriorate over time unlike the R6/1 mice, but exploratory behavior decreased. Finally, the anxiety behavior of double transgenic mice was similar to wild type mice. This work provides evidence supporting that the absence of Ahr partially prevents the motor and behavioral deterioration observed in a transgenic model of HD.

Title: Signaling pathways associated to plasticity recover induced by NT-3 in striatal degeneration

Authors: V. G. GÓMEZ-PINEDA[1], ***E. HERNANDEZ-ECHEAGARAY**[2];
[1]Univ. Nacional Autónoma de México, Mexico City, Mexico; [2]Univ. Nacional Autónoma De México, Mexico City, Mexico

Abstract: Neurotrophins are associated to development and plasticity of nervous system. Our group has shown that Neurotrophin-3 (NT-3) plays an important role in regulating corticostriatal synaptic transmission and plasticity. Interestingly, NT-3 recovers striatal long term plasticity which is altered in slices from cerebral tissue of mice treated *in vivo* with the mitochondrial toxin 3-nitropropionic acid (3-NP), used to mimic the histopathology of Huntington's disease (HD). In general, high frequency stimulation (HFS) of the corticostriatal pathway in slices recorded *in vitro* produces long term depression (LTD); however, striatal synaptic plasticity is modified by the 3-NP treatment, where HFS produces long term potentiation (LTP) instead of LTD. Also, we know that NT-3 modulates corticostriatal synaptic transmission by stimulating TrkB receptors, while corticostriatal plasticity is modulated by NT-3 through the activation of TrkC receptors. In this study, we evaluated which signaling pathway is triggered by NT-3 to reestablish LTD in brain slices recorded *in vitro* and obtained from male C57/BL6 mice treated *in vivo* to produce striatal damage. Population spikes were recorded at the striatum in the presence of NT-3 and the inhibitors for PLC, MAPK, PI3K or PTPσ. All the evaluated signaling pathways inhibitors prevented the amplitude increase of the synaptic spike induced by NT-3. HFS (100Hz) protocol was used to generate long term plasticity, and it was given in the presence of NT-3 and the signaling pathways inhibitors. The restoration of LTD induced by NT-3 was only impeded by the PLC inhibitor, demonstrating that NT-3 restores LTD in damaged striatum through the stimulation of PLC signaling.

Title: Targeted delivery of Huntington's disease gene therapeutics

Authors: N. TODD[1], B. ELMER[2], K. B. KEGEL[3], L. S. SHIHABUDDIN[2], L. M. STANEK[2], *J. UPADHYAY[4];
[1]Radiology, Brigham and Women's Hosp., Boston, MA; [2]Rare and Neurologic Dis. Therapeut. Area, Sanofi, Framingham, MA; [3]Neurol., Mass Gen. Hosp., Charlestown, MA; [4]Dept. of Anesthesiology, Critical Care and Pain Med., Boston Children's Hospital, Harvard Med. Sch., Boston, MA

Abstract: The goal of this study is to use the novel technology of focused ultrasound (FUS) to improve the delivery of gene therapies to specific brain structures for the treatment of Huntington's disease. FUS can achieve non-invasive, transient and spatially targeted opening of the blood-brain barrier (BBB) to facilitate delivery of normally non-penetrant agents into the brain at the targeted site. FUS is applied through the intact skull, can be focused to a region of only several millimeters, and can reach both cortical areas and sub-cortical structures.

Gene therapies that knock down expression of the mutant Huntingtin protein are a promising approach to the treatment of Huntington's disease. However, all gene therapies face the interrelated challenges of delivering the therapy across the BBB, targeting a specific brain region, and achieving an adequate therapeutic exposure at the targeted site while minimizing toxicity in healthy brain tissue and other organs. FUS-BBB opening may be an approach to improving the delivery of gene therapies over more invasive existing methods of intrathecal injection or direct neurosurgical injection.

We demonstrated the feasibility of this approach in a pilot study of n=3 wild type mice. FUS-BBB opening was targeted to the right striatum. Microbubbles were given by tail vein injection and FUS sonications were applied at 10 ms bursts and 2 Hz repetition frequency over 120 seconds. An AAV1 capsid label with green fluorescent protein (AAV1-GFP) was given by tail vein injection at a dose of 5.5 vg/mouse. BBB opening was confirmed with contrast MRI. The three mice were sacrificed after three weeks, brains were extracted and prepared for fluorescence microscopy. Figure 1 shows the FUS system, striatum targeting, MRI results, and fluorescence microscopy results.

FUS-BBB opening succeeded in delivering the normally non-penetrant AAV1 capsid into the brain parenchyma in a non-invasive and targeted manner. Future studies will optimize the FUS parameters for improved delivery in wild type mice and YAC128 Huntington's disease model mice.

Title: The toll-like receptor 4 in the process of brain damage associated with Huntington's disease

Authors: *P. E. MARTINEZ-GOPAR[1], F. PEREZ-SEVERIANO[2], C. GONZALEZ-ESPINOSA[3];
[1]Natl. Inst. of Neurol. and Neurosurg., Mexico, Mexico; [2]Neurofarmacología Mol. y Nanotecnología, Inst. Nacional De Neurología Y Neurocirugía, Mexico, Mexico; [3]Ctr. for Res. and Advanced Studies of the Natl. Polytechnic Inst., Mexico, Mexico

Abstract: Toll-like receptors (TLRs) have a broad tissue distribution. TLRs can recognize molecules derived from injured tissues and trigger immune and metabolic responses typical of pathologic states. TLR-4 recognizes molecules of tissue damage, as well as proteins associated with neurodegenerative diseases. Recently, its participation in models of neurodegeneration has been documented. Huntington's disease (HD) is a hereditary neurodegenerative disorder caused by a mutation in the huntingtin protein gene. HD courses with loss of GABAergic neurons in basal ganglia, oxidative damage and neuroinflammatory processes. Intrastriatal (i.s.) administration of quinolinic acid (QA; NMDA agonist) in rodents mimics the neurochemical characteristics of HD (loss of GABAergics neurons and oxidative damage). The objective of this work was to study the participation of TLR-4, in the processes of neurological and oxidant damage observed in a neurochemical model of HD. For this purpose, C57 BL5/J mice (WT) and B6.B10scN-TLR4*lps-del* mice (TLR4-KO) were administered with QA (30 nmol / 1μL, i.s.) and distinct parameters of damage were evaluated, i.e. ipsilateral rotation induced by apomorphine , lipid peroxidation (LP) and the formation of reactive oxygen species (ROS). Results showed that TLR4-KO mice presented a lower number of turns, as well as less oxidative damage (LP and ROS) with respect to the WT animals administered with QA. It is known that the TLR-4 participates in the responses of innate immunity and inflammation caused by molecular patterns associated with pathogens (PAMPs) and tissue damage (DAMPs). Although its influence on the onset of inflammatory reactions that can trigger chronic diseases has been described, its

participation in the damage process observed in HD has not been fully addressed. This work presents, for the first time, evidence that this receptor participates in oxidative damage observed in a neurochemical model of HD. Our work strongly suggests that the TLR-4 receptor could be considered as a therapeutic target for the pharmacological treatment of some deleterious reactions observed in HD.

Title: Flexible and inflexible T-maze decision-making and neural coding of cost and benefit in wild-type and Huntington’s disease model mice

Authors: *L. G. GIBB, D. HU, A. FRIEDMAN, B. BLOEM, A. GARDNER, K. O'NELL, J. K. XIONG, A. M. GRAYBIEL;
MIT, Cambridge, MA

Abstract: Huntington’s disease (HD) is a devastating, fatal neurodegenerative disease characterized by altered neural function and cell loss in the striatum, cortex and other brain areas, and by emotional, cognitive and motor dysfunction. Reported symptoms include perseveration, aberrant decision-making, abnormal risk evaluation and low motivation. Previous work suggests that HD patients whose early symptoms are predominantly emotional rather than motor tend to show cell loss preferentially in the striosome compartment of the striatum in contrast to the surrounding matrix. Based on this result and on other evidence linking striosomes to evaluation, repetitive behavior and cost-benefit conflict decision-making, we hypothesized that Q175 HD model mice would show altered behavior in T-maze decision-making tasks, including tasks with various combinations of cost and benefit, and that these changes would be related to changes in the patterns of striosomal and matrix activity.
Therefore, we trained 7 Q175 (‘HD’) model and 5 wild-type (WT) mice (11-27 months old) on T-maze tasks similar to ones we have published previously, including benefit-benefit (BB) tasks with equal and unequal rewards, a cost-benefit conflict (CBC) task and, in some mice, a cost-cost (CC) task. Consistent with the perseveration observed in HD patients, we observed a tendency of

HD mice to perseverate in their choice behavior. In the BB task with unequal rewards, HD mice were more likely to choose the high reward again if they had chosen it in the previous trial, whereas WT mice were not.
We made use of the fact that striosomal neurons tend to be born earlier than matrix neurons during embryonic development to express GCaMP6m predominantly in either striosomal or matrix neurons of mice carrying an inducible CreERT2 construct. We implanted GRIN lenses with attached prisms and performed calcium imaging on 5 striosome-labeled and 3 matrix-labeled WT mice performing the BB, CBC, and CC tasks, using the Inscopix nVista 2.0 miniature microscope. Analysis of a subset of our imaging data using linear classifiers suggested that striosomal neurons may be particularly predictive of choice in the cost-cost task. Based on these promising preliminary results, we performed calcium imaging in another group of 2 HD mice and 3 WT mice (7-12 months old). As in our first group of mice with behavioral testing, HD mice tended to perseverate in their choices during the maze imaging sessions. We will discuss the neural underpinnings of this perseverative behavior, a deep understanding of which may contribute to the development of therapies for behavioral changes in HD patients.

Title: Mu opioid receptors are strongly upregulated in the Q175 mouse model of Huntington's disease

Authors: *R. MORIGAKI[1,2], J. H. LEE[1,3], T. YOSHIDA[1], C. WÜTHRICH[1], A. M. GRAYBIEL[1];
[1]McGovern Inst. for Brain Res. and Dept. of Brain and Cognitive Sci., MIT, Cambridge, MA; [2]Dept. of Neurosurg., Grad. Sch. of Biomed. Sciences, Tokushima Univ., Tokushima, Japan; [3]Neurosci. Grad. Program, Mayo Clin. Grad. Sch. of Biomed. Sci., Jacksonville, FL

Abstract: The mu-opioid receptor (MOR1) is highly expressed in the dorsal striatum and exhibit, in particular, enhanced expression in striosomes. This expression pattern, in fact, has been used as a key marker for the striosomal system (Gerfen, 1984; Graybiel et al, 1981).

However, it is known that the expression of MOR1 is not strong in the lateral caudoputamen of rodents, or in the caudal striatum. This distribution pattern places MOR1-expressing neurons and fibers in a position to modulate associative and limbic-related districts of the striatum. Here we examined the distribution of the MOR1 in the caudoputamen of the Q175 mouse model of Huntington's disease, with the goal of determining whether this important receptor in the striatum was regulated in Q175 mice at successively advanced ages, beginning with mice at post-natal ages of 3 months to 12 months, equivalent to aged mice. We observed striking up-regulation of MOR1 immunostaining (rabbit monoclonal anti-mu opioid receptor antibody ab134054, Abcam, MA) beginning at early ages and becoming more prominent with advancing age. Remarkably, this rendered MOR1 expression, as seen by immunohistochemistry, is highly expressed in the lateral and caudal striatum, where, especially in the caudoputamen, it is scarcely expressed at detectible levels in control littermates of the Q175 mice. It is our hope that these findings could be important in understanding, at the level of rodent models, the distinctions between the motoric and cognitive-emotional symptoms expressed in humans suffering from this debilitating disorder.

Title: Developmental organization of striosomes and striosome-related circuits

Authors: *A. MATSUSHIMA, A. M. GRAYBIEL;
McGovern Inst. for Brain Res. and Dept. of Brain and Cognitive Sci., MIT, Cambridge, MA

Abstract: Striosomal neurons are generated over a protracted time-period during development (from embryonic day (E) 10 until ~E15 in mice), followed by matrix neurons invading the striatal mantle. Within the time window of striosomal neurogenesis, however, there exists a birthdate-dependent difference in ultimate cellular distribution in the mature striatum (Kelly et al., 2017), and in vulnerability to prenatal intervention (Kuo et al., 2017). Here, we aimed to dissect developmental sub-lineages of striosomes by administering fast-kinetic version of tamoxifen to *Dlx1*::CreER/floxed tdTomato or floxed Flp mouse embryos.

First, we found a gradient-pattern of distribution of cell bodies across the striatum, and of axonal projections to the substantia nigra. In combination, only one group of cells, born at a specific developmental timepoint and also located in a specific sector in the striatum, were destined to project to the striosome-dendron bouquets (Crittenden et al., 2016), the highly characteristic feature of the dopamine-containing substantia nigra.
Second, we examined the sub-compartmental distribution of future striosomal cells, and observed stereotypical patterns suggesting rules of development observed by the earliest-born to later-born cells. In addition, the exact birthdates of future striosomal neurons differed across the anterior to posterior striatum, so that they follow the gradient patterns described previously. Thus at least two time-sensitive developmental influences are active in the eventual organization of the striosomal system. Likely there are others.
These results imply that the developmental timepoint of neurogenesis dictates the positions of cells at a sub-compartmental scale, and organizes compartments that form specialized circuits to exert specialized functions. Some of these circuits might be particularly vulnerable to genetic perturbation as in Huntington disease, now under study in the Q175 mouse model of this disorder.

Title: Huntington's disease model Q175 mice exhibit deficits in adaptation of reward licking response in a visual cue-reward learning task

Authors: *M. J. KIM, A. M. GRAYBIEL;
McGovern Inst. for Brain Res. and Dept. of Brain and Cognitive Sci., MIT, Cambridge, MA

Abstract: Animals can acquire responses to sensory stimuli that precede a reward. For example, normal animals typically develop the anticipatory licks to reward-predictive cues as cue-reward association gets strengthened through many repeated trials. The cue-reward association and its correspondent motor (anticipatory licking) adaptation are key features of learning based on the striatum. We hypothesized that Huntington’s disease (HD) model mice would show impairment

in this learning process due to their altered corticostriatal function. To test this hypothesis, Q175 heterozygous (HD) and wild-type (WT) littermate mice (6-8 months old) were trained on a Pavlovian conditioning task using visual cue and reward in a head-fixed apparatus, and their licking responses were monitored throughout training. A drop of sucrose solution was always delivered after an LED light was presented at the left side, but not after the LED illumination on the right side. In WT mice, it was commonly observed that licking responses were gradually shaped over the course of learning. That is, with training, their consummatory licks gradually occurred close to reward delivery, the number of licks increased during the cue period, and the mice exhibited regular lick-bouts initiated by the onset of the reward-predicting cue. At the same time, unnecessary licks (spontaneous licks during unrewarded trials, including unrewarded cue responses) were gradually suppressed. Therefore, the licking response became efficient and occurred selectively in response to the rewarding cue. By contrast, HD mice were not able to adapt their licks to the cue predicting upcoming reward. Rather, they kept relying on their spontaneous licking to check reward availability and obtained the reward. The transition from spontaneous licking to cue-elicited response did not occur even after prolong training. This deficit cannot be accounted for by their motivational drive, as all HD mice failed to develop lick adaptation to the rewarding cue regardless of their total average lick rates. However, when the cue presentation was extended up to their first lick for reward, some of HD mice started to form lick-bouts similar to those commonly observed in WT mice. Therefore, this behavioral phenotype indicates that HD in the early phase disrupts the function of corticostriatal circuitry that might serve important roles in regulating the timing and execution of motoric activity to enable cue-reward association during learning.

Title: Pharmacological reduction of elevated calcium levels in cortical pyramidal neurons for the treatment of Huntington’s disease

Authors: *K. D. OIKONOMOU[1], X. YU[2], B. S. KHAKH[2], M. S. LEVINE[1], C. CEPEDA[1]; [1]IDDRC, Semel Inst. for Neurosci. and Human Behavior, BRI., [2]Dept. of Physiol., UCLA, Los Angeles, CA

Abstract: Huntington's disease (HD) is a hereditary neurodegenerative disorder that predominantly affects striatal medium-sized spiny neurons (MSNs) and cortical pyramidal neurons (CPNs). Functional studies revealed that somatosensory, attention, and cognitive deficits precede motor abnormalities. As such, examining cortical alterations before the onset of striatal dysfunction is of utmost importance. Ca^{2+} dyshomeostasis plays a significant role in the degeneration of MSNs in HD mouse models, as drugs that target the store-operated Ca^{2+} channel (SOC) pathway rescue spine loss and long-term administration of a ryanodine receptor blocker, dantrolene, significantly improves the HD phenotype. Previous studies in our laboratory demonstrated early increases in voltage-gated Ba^{2+} currents in CPNs from symptomatic R6/2 mice. However, there have been no studies assessing modifications of Ca^{2+} signaling in somata and dendrites of CPNs of primary motor cortex throughout HD progression. To test the hypothesis that CPN Ca^{2+} homeostasis is significantly disturbed before the emergence of overt behavioral symptoms, we used the R6/2 mouse model of juvenile HD. Three age groups were studied: postnatal day (P)21-31 before overt symptoms start, P35-42 when overt symptoms begin, and >P60 when the mice are fully symptomatic. We combined whole-cell patch clamp electrophysiology and two-photon microscopy to image layer 2/3 CPNs filled with Oregon Green BAPTA-1. Single or multiple action potentials (APs) were evoked by a series of 50 ms depolarizing current pulses from the resting membrane potential. Accompanying somatic as well as dendritic Ca^{2+} transients were compared between different age groups of mutant mice and their wildtype (WT) age-matched littermates. We found that the amplitude and kinetics of AP-induced Ca^{2+} signals recorded at the somata of CPNs were altered in R6/2 mice from all age groups compared with age-matched WTs. Specifically, in the two older groups, significant differences were observed including increased amplitude and slower kinetics of Ca^{2+} transients associated with either one, two or three APs. In all age groups, Ca^{2+} levels in proximal and distal dendrites of CPNs were greater in R6/2 than WT mice but differences did not reach statistical significance. Importantly, treatment with EVP4593 (3 μM) or dantrolene (20 μM), significantly restored elevated Ca^{2+} responses at the somata of CPNs from symptomatic R6/2 mice. Our findings demonstrate that perturbations of Ca^{2+} homeostasis occur before the onset of overt symptoms, and that they can be rescued by introducing agents that inhibit intracellular Ca^{2+} release.

Title: Thalamocortical projections are significantly impaired in the R6/2 mouse model of Huntington's disease

Authors: *S. M. HOLLEY, K. OIKONOMOU, G. MKRTCHYAN, C. M. SWIFT, L. MOHAN, C. CEPEDA, M. S. LEVINE;
IDDRC, Semel Inst. for Neurosci. and Human Behavior, BRI, UCLA, Los Angeles, CA

Abstract: Huntington's disease (HD) is a heritable neurodegenerative disorder characterized by impaired motor control in addition to cognitive and psychiatric disturbances. As the disease progresses, there is a massive degeneration of striatal medium-sized spiny neurons (MSNs) and cortical pyramidal neurons (CPNs). Previously, we showed that cells in both motor and sensory thalamic nuclei of R6/2 mice are hyperexcitable and exhibit signs of degeneration. In humans, early reports have observed decreases in the volume of certain thalamic nuclei at later stages of the disease; however, electrophysiological studies designed to assess whether thalamocortical circuits are affected in HD are lacking. Using whole-cell patch clamp electrophysiology in ex vivo brain slices, we recorded membrane properties and synaptic inputs onto cortical pyramidal neurons (CPNs) in the barrel (somatosensory) cortex of ~75 day-old wildtype (WT) and symptomatic R6/2 mice. Similar to previous reports on motor cortex CPNs, we also observed alterations in cell membrane properties in barrel cortex CPNs from R6/2 mice. The CPNs had significantly smaller membrane capacitance, higher input resistance and faster time constant. We also observed the frequencies of both spontaneous inhibitory and excitatory postsynaptic currents (IPSCs and EPSCs, respectively) were reduced in R6/2 CPNs. In order to investigate the contribution of excitatory inputs onto CPNs originating from the thalamus, we expressed channelrhodopsin, driven by the CaMKII promoter, in ventral posteromedial nucleus (VPM) thalamic neurons. Optical activation of VPM terminals elicited large-amplitude IPSCs in both WT and R6/2 CPNs when recorded at a holding potential of +10 mV. This inhibitory response was the result of polysynaptic transmission since optically-evoked IPSCs were completely abolished with the addition of the sodium channel blocker, tetrodotoxin (TTX). Notably, we observed smaller amplitude IPSCs in barrel cortex CPNs from R6/2 mice compared to WTs. The amplitude of optically-evoked EPSCs also was reduced in R6/2 CPNs. Furthermore, we observed a decrease in the frequency of excitatory quantal events in R6/2 CPNs in recordings where extracellular calcium was replaced by strontium. Taken together, these results suggest symptomatic R6/2 mice exhibit reduced connectivity between the thalamus and somatosensory cortex which ultimately may result in faulty integration and processing of somatosensory information.

Title: Characterization of the equilibrium mutant mice induced by the N-ethyl-N-nitrosourea agent: Behavioral, astrocytes and neurochemical aspects

Authors: *K. E. KIATAQUI, B. C. G. ORLANDO, P. S. RODRIGUES, E. P. SILVA, A. S. SAMPAIO, N. MOREIRA, L. S. MEDEIROS, M. C. GALVAO, T. M. REIS-SILVA, M. M. BERNARDI;
Paulista Univ., São Paulo, Brazil

Abstract: The equilibrium (eqlb) mutant mouse presents a deficiency and motor incoordination induced by a recessive mutation due the exposure of the N-ethyl-N-nitrosourea agent. This mutation causes vestibular defects in the formation of the otoconia, allowing the study of different human pathogenesis. In order to characterize the possible differences of the eqlb mouse, we evaluated 18 eqlb BALB/c mice in the essays of social and aggressive behavior in stable colonies and after isolation, olfactory memory and spatial perception in the hidden cookie protocol and tail suspension test (TST), respectively. Thus, the levels of serotonin and metabolite in the prefrontal cortex (PFC) and astrocytes expression in the superior colliculus were also evaluated. Significant differences were determined by a student t test when pertinent. For the results with more than one variable a two-way ANOVA was conducted. Our results demonstrated lower social interaction of eqlb mice compared to balb/c mice of control group (p=0,002) in stable colonies and an increased social interaction with the intruder (p<0,0001). Regarding the olfactory test, eqlb mice displayed an increased latency to find the cookie [F (1,76) = 18.91, p<0.0001). In the spatial perception test, eqlb presented a decreased immobility compared to control group (p=0,007). Despite the TST has been commonly used for evaluation of depressive-like behavior, it also provides insights of area perception (Manes M., et al 2019). Finally, we observed an increased serotoninergic turnover activity in the PFC (p=0,01) and reduction in the index area of astrocytes in the superior colliculus (p=0,0006). We propose that the lower social interaction in the stable colony and the greater social interaction with the foreign mouse as well as the absence of aggression may be a consequence of deficits in olfactory memory, spatial perception, increased serotonergic activity in the PFC and reduction of the index by astrocyte area of the superior colliculus. This study was financed in part by the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior - Brasil (CAPES) - Finance Code 001.

Title: The role of mitochondrial complex I dysfunction in synaptic plasticity and maintenance

Authors: *C. FRANK, B. MALLIK;
Univ. of Iowa, Iowa City, IA

Abstract: Neurons are highly polarized cells with immense energy demands. Those energy demands are mainly fulfilled by mitochondria. In response to altered energy states of the neuron, mitochondria can adapt to maintain energy homeostasis and nervous system function. This adaptation, also called mitochondrial plasticity, can be observed as changes in morphology, function or localization of mitochondria at the synapses. Through an RNAi-mediated genetic screen in *Drosophila melanogaster* (about 300 *UAS-RNAi* lines) that covered homologs of genes associated with human neurodegenerative diseases, we have identified mitochondrial complex I subunits as essential for maintaining mitochondrial morphology and synapse function. Mutations affecting mitochondrial complex I subunits have been reported to be involved in severe mitochondrial diseases. The mechanisms by which complex I dysfunction results in disease remain elusive. Here, we report a *Drosophila* model of complex I deficiency caused by a nuclear DNA-encoded *NADH dehydrogenase subunit 20* (*ND-20L*) gene. We show that *ND-20L* RNAi depleted larvae exhibit phenotypes that resemble symptoms of mitochondrial disease, including progressive degeneration of muscle and presynaptic cytoskeleton, enhanced reactive oxygen species (ROS) formation and alteration in mitochondrial morphology. Our genetic and electrophysiological analyses reveal that ND-20L in muscle regulates Dlg-Spectrin scaffold for maintaining Brp-GluR clusters (active zone-receptor apposition) which are crucial for evoked release at the synapses. We also find the ND-20L subunit participates in evoked release at the NMJ terminals. Together, our findings support a model in which diminished complex I activity, and consequent energy deficiency, is responsible for specific synaptic defects. In the context of human complex I dysfunction, similar defects could contribute to pathogenesis.

Title: SMN regulates neuromuscular junction integrity through U7 snRNP

Authors: S. TISDALE, M. VAN ALSTYNE, C. M. SIMON, G. Z. MENTIS, ***L. PELLIZZONI**;
Pathology and Cell Biol., Columbia Univ., New York, NY

Abstract: Spinal muscular atrophy (SMA) is an inherited motor neuron disease caused by reduced levels of the ubiquitously expressed SMN protein. SMN is required for the assembly of small nuclear ribonucleoproteins (snRNPs) that carry out pre-mRNA splicing as well as U7 snRNP, which is essential for the 3'-end processing of histone mRNAs. While SMN is well-established to control key aspects of gene expression through its multiple functions in RNP biogenesis, the contribution of individual SMN-dependent RNA pathways to motor circuit pathology in SMA remains poorly defined. We previously demonstrated that SMN deficiency disrupts U7 snRNP biogenesis and histone mRNA 3'-end processing in SMA mice and human patients. Here, we investigated whether impairment of this RNA pathway contributes to SMA pathology in a mouse model of the disease. To do so, we first established a means to selectively enhance U7 snRNP biogenesis and function by overexpression of Lsm10 and Lsm11—two U7 snRNP-specific proteins normally expressed at limiting amounts—leading to increased U7 snRNP levels and histone mRNA 3'-end processing in both normal and SMN-deficient cells. We then applied this approach *in vivo* using AAV9-mediated postnatal delivery of Lsm10 and Lsm11 into the central nervous system of SMA mice. Overexpression of Lsm10 and Lsm11 in SMA mice specifically corrects U7-dependent histone mRNA 3'-end processing defects, but not RNA processing events linked to other functions of SMN (i.e. splicing). Remarkably, comprehensive analysis of morphological and functional parameters of motor circuit connectivity that are affected in SMA revealed strong and specific improvement of neuromuscular junction (NMJ) innervation of vulnerable muscles following restoration of U7 snRNP function in SMA mice. Improved innervation was further associated with enhanced NMJ neurotransmission, reduced skeletal muscle atrophy, and improved motor function. Importantly, we found that SMN deficiency decreases Agrin mRNA expression and the levels of this critical synaptic organizing protein at NMJs of vulnerable but not resistant SMA motor neurons, a defect specifically rescued by LSm10/11 co-expression. Thus, through selective restoration of U7

snRNP biogenesis in SMA mice, our findings demonstrate a key role for U7 snRNP function and histone mRNA 3'-end processing in preserving the functional integrity of the NMJ, uncovering an RNA-mediated mechanism of NMJ loss in SMA. They also highlight an unanticipated functional requirement in post-mitotic motor neurons for an RNA processing pathway that controls histone synthesis and is thought to be biologically relevant only in dividing cells.

Title: Reduction of serotonergic synapses and its effects in sensory-motor function in spinal muscular atrophy

Authors: *N. DELESTRÉE, E. SEMIZOGLOU, J. G. PAGIAZITIS, A. VUKOJICIC, V. PAUSHKIN, G. Z. MENTIS;
Depts. Pathology and Cell Biol. and Neurol., Columbia University, Ctr. for Motor Neuron Biol. and Dis., New York, NY

Abstract: Spinal muscular atrophy (SMA) is a neurodegenerative disease characterized by motor neuron loss, muscle atrophy and impairment of motor reflexes. One of the earliest hallmark of the disease is the dysfunction and loss of proprioceptive synapses leading to muscle paralysis. Furthermore, gait and posture, which are controlled largely by the neuromodulatory synapses, are dramatically altered in SMA patients. The serotonergic (5-HT) inputs originating in the brainstem Raphe nuclei exert a major neuromodulatory influence on motor neurons. However, whether serotonergic synapses are affected in the course of SMA is not known.
To address this, we utilized the SMN-Δ7 mouse model and investigated the morphological and functional characteristics of 5-HT synapses on motor neurons at different ages. We found that the 5-HT synaptic coverage is reduced by ~40% as early as P4 in vulnerable (L1 and L5-MMC) but not resistant (L5-LMC) motor neurons in SMA mice. Functionally, 5-HT is also known to modulate the monosynaptic sensory-motor arc reflex mediated by proprioceptive synapses on motor neurons. We confirmed that optical stimulation of 5-HT neurons expressing ChannelRhodopsin2 (ChR2) under the Pet1 promoter modulated the spinal reflexes using the *ex vivo* brainstem-spinal cord preparation.

Selective restoration of SMN in serotonergic neurons was investigated using a conditional inversion SMA mouse line, in which Cre is expressed under the selective serotonergic promoter Pet1. We found that this approach rescued 5-HT synapses, indicating the non-cell autonomous effects of SMN deficiency in 5-HT neurons, similar to what we have previously shown in proprioceptive neurons. Surprisingly, SMN restoration in 5-HT neurons also resulted in a partial rescue of proprioceptive synapses on motor neurons, suggesting that 5-HT influences the number and function of proprioceptive synapses during early development and may be involved in the pathological mechanisms of sensory-motor circuit dysfunction in SMA.

Title: Machine learning enhanced dynamic meta-analysis for preclinical ALS combination therapy optimization

Authors: ***A. J. LEE**[1], B. M. LEE[1], E. J. RIDGEWAY[1], C. S. MITCHELL[2];
[2]Biomed. Engin., [1]Georgia Inst. of Technol., Atlanta, GA

Abstract: Attempts to therapeutically target a single Amyotrophic Lateral Sclerosis (ALS) etiological factor have largely failed. Our previous research has showed ALS is a multi-factorial disease with pathophysiology that is dynamically changing and inherently unstable. This project contends carefully timed combination therapy will be ultimately required for therapeutic success. However, predictive medicine is needed to prioritize hundreds of thousands of potential combination therapies and corresponding protocol parameters. This study builds upon and optimizes a relatively new mathematical modeling method called dynamic meta-analysis (DMA), which enables simultaneous examination of interrelationships and regulatory system dynamics not accessible to traditional experimentation or meta-analysis. Both homeostatic wild-type (WT) mouse model and disease-state SOD1 G93A ALS transgenic mouse models are constructed *in silico* and compared to find the best treatment targets as a function of ALS progression. Presently, 2148 data points from 119 peer-reviewed articles (and counting) are included to construct the models. Data is categorized into seven pathophysiological ontologies: apoptosis, bioenergetics, chemistry, excitotoxicity, inflammation, oxidative stress and proteomics based on physiology definition. Each of these factors have two aggregation schemes:

inducing factors and inhibiting factors. The base DMA model is constructed of ordinary differential equation systems that describe each aggregation schemes' dynamics over time. However, this study also applies machine learning global optimization methods to identify and optimize missing parameters due to lack of published data in some categories. Unsupervised learning is used to select the overall pathophysiological solution matrix that best approximates actual mice functional behaviors (rotarod performance, body weight, survival, etc.). The models are validated with external experimental mouse data not included in model construction or training. Results are presented for full, quantitative *in silico* solutions for the "best" WT and ALS mouse models. These models can be applied to better elucidate the dynamic systems etiology of ALS and to prioritize preclinical testing of promising ALS combination therapies. Moreover, this updated technology of employing machine learning to optimize dynamic meta-analysis opens the door to using the same optimized technique for literature mined pathology and therapy assessment models for other multi-factorial neurological diseases.

Title: The effects of chemogenetic inhibition of L5-M1 pyramidal neurons in the SOD1-G93A mouse model of amyotrophic lateral sclerosis on the onset and severity of motor symptoms and neurodegeneration

Authors: *S. A. BEDARD[1], K. CHEN[1], J. C. PRESSEY[1], A. LAU[2], J. ROBERTSON[2], M. A. WOODIN[1];
[1]Cell and Systems Biol., [2]Lab. Med. and Pathobiology, Univ. of Toronto, Toronto, ON, Canada

Abstract: Amyotrophic lateral sclerosis (ALS), also commonly known as Lou Gehrig's disease, is a neurodegenerative disease characterized by loss of neurons responsible for voluntary muscle movement and as there are no effective treatments ~80% of those diagnosed will die within 2-5 years. An early characteristic of ALS is hyperactivity of the primary motor cortex (M1), the region of the brain controlling voluntary movements. Cortical hyperexcitability promotes the degeneration of layer 5 excitatory pyramidal neurons in the primary motor cortex (L5-M1 PN) that connect through the spinal cord to control muscles and are therefore a therapeutic target. We recently discovered that by reversing the hyperactivity in the motor cortex we could delay the

onset of motor symptoms and L5-M1 PN neurodegeneration in the SOD1-G93A mouse model of ALS. We accomplished this reversal of hyperactivity by using Cre-dependant excitatory chemogenetics to specifically increase the activity of inhibitory interneurons in the cortex that synapse onto L5-M1 PNs. While our chemogenetic-mediated functional regeneration holds significant therapeutic potential for ALS patients, the clinical translation of this discovery is limited by the Cre-dependant delivery method of the chemogenetic tools used. In the current work we overcome this limitation by delivering an inhibitory chemogenetic construct directly to L5-M1 PNs using a non-Cre-dependant viral vector strategy. We then assess the effects this intervention on functional and cellular outcomes in the SOD1-G93A mouse model of ALS by subjecting animals to a battery of behavioural motor tasks as well as immunohistochemical, electrophysiological, and biochemical assays in both the pre-symptomatic and symptomatic phases of the disease. This approach holds significant clinical potential because viral vectors are in multiple phase I-III clinical trials, and the chemogenetic activator used in this study (clozapine) is also widely used clinically. To our knowledge this research is the first worldwide to use AAV-directed chemogenetics to promote regeneration in a neurodegenerative disease.

Title: Profiling neuronal stress responses regulated by dual leucine zipper kinase (DLK)

Authors: *E. ASGHARI ADIB[1], J. SHADRACH[2], X. CHEN[4], D. DICKMAN[5], B. A. PIERCHALA[3], C. A. COLLINS[1];
[1]Mol. Cell. and Developmental Biol., [3]Biologic & Materials Sci., [2]Univ. of Michigan, Ann Arbor, MI; [4]Dept. of Neurobio., [5]USC, Los Angeles, CA

Abstract: One of the prominent aspects of neuronal communication is the maintenance of proteins and molecules that are building blocks of functional synapses. Neurons appear to lose this ability in conditions of neurodegenerative diseases (including Alzheimer's disease, Parkinson's Disease and ALS). Recent work has found that the evolutionarily conserved dual leucine zipper kinase DLK mediates pathology in multiple models of ALS and Alzheimer's disease (Le Pichon et al. 2017). DLK is previously known for its role in regulating responses to axonal injury, and recent studies have noted that DLK also becomes activated in scenarios that

disrupt axonal cytoskeleton and axonal transport (reviewed in (Asghari Adib et al. 2018)). Our lab has noted that a consequence of DLK activation in *Drosophila* motoneuron larvae is the down-regulation of multiple synaptic proteins (Li et al. 2017). Collectively these observations raise the hypothesis that DLK may become activated in conditions of stress that impair axonal transport, and that downstream consequences of DLK can lead to synapse loss. This points to DLK as an attractive potential mediator of synapse loss in paradigms of neurodegenerative disease. However, a mechanistic role for DLK in promoting synapse loss is not currently known. With a goal to understand the downstream mechanisms of DLK we are undertaking a RiboTag approach to profile ribosome associated transcripts in motoneurons using both fly and mouse models. In mice we are using ChAT-Cre to conditionally tag ribosomal protein RPL22 in motoneurons that are also conditionally deleted for DLK. In this model we are using sciatic nerve crush as our initial paradigm for activating DLK, however we are interested in additional models including ALS. In flies we are currently determining a deeper phenotypic understanding of the consequences of DLK activation in adult neurons. Using the GeneSwitch system to acutely induce DLK expression in the adult nervous system we observed a rapid decline in locomotor activity and early lethality after shifting 5-day old flies to conditions that induce DLK expression. The brains of these flies show evidence of neuronal remodeling and degeneration: the axon tracts in the mushroom body - a center for learning and memory in the fly - were degenerated and nearly absent 12 days after DLK induction. From these observations we hope to develop a new paradigm for studying the mechanism by which DLK activation in a mature adult nervous system can lead to axon and synapse loss.

Title: Behavioral and neurochemical abnormalities in a pharmacologically-induced mouse model of Gaucher disease

Authors: *M. MONBUREAU, N. MORISOT, A. MALIK, G. CARROT, J. ROESER, H. JANSSENS, A. RASSOULPOUR;
Discovery, Charles River Labs, South San Francisco, CA

Abstract: A growing body of evidence has linked Parkinson's disease (PD) to the neurological form of Gaucher disease (GD). GD is caused by a hereditary deficiency in activity of the lysosomal hydrolase, acid beta-glucosidase (Gba). As a result, the glycosphingolipid

glucosylceramide (GlcCer) accumulates within the lysosomes of cells, including neurons, leading to motor abnormalities. Animal models that exhibit GD hallmarks are needed to help develop new therapies that could benefit GD- and PD-affected patients. Here, we established a pharmacological GD mouse model using subchronic exposure to conduritol-ß-epoxide (CBE). CBE (100 mg/kg, i.p.) was injected daily for 10 days in C57/Bl6 mice starting on post-natal day 15. Immediately after the last CBE administration, mice were tested for hindlimb splay and rotarod performance. We found that CBE-treated mice had a higher hindlimb score compared to control mice, revealing neuromuscular abnormality. In addition, CBE treatment resulted in a shorter latency to fall from the rotarod, indicating motor deficits. Growth in CBE-treated mice was also affected as body weight gain was reduced compared to controls. Following behavioral evaluation, liver, hippocampus, striatum and prefrontal cortex were collected from control and CBE-treated mice. Ongoing experiments are testing the GlcCer levels in the collected tissue. In addition, a future line of research will compare the behavioral and GlcCer profile of the CBE-induced GD model to transgenic mouse models of Gba deficiency. Our data show that CBE-induced GD model recapitulates neuropathologic and behavioral manifestations associated with the disease. The combined use of pharmacological and transgenic mouse models of GD will help evaluate the efficacy of new drug candidates.

Title: Hypoxia induced brain injury and cellular recovery in adult zebrafish

Authors: *N. KAYA, J. D. LAUDERDALE, S. T. DOUGAN;
Dept. of Cell. Biol., Univ. of Georgia, Athens, GA

Abstract: There are many effects of hypoxia brain injury in human brain such as memory deficit, motor coordination, and visual impairment. Remarkably, many of these symptoms improve over time, albeit to different extents in different individuals, indicating existence of mechanisms in the human brain to repair and/or compensate for hypoxic/anoxic injuries (HAI); however, the mechanisms involved in hypoxic injury and repair are not well understood. We are developing adult zebrafish as a model for studying hypoxic brain injury. The zebrafish offers several advantages for use in this research, including the ability to visualize and manipulate specific neuronal populations in the brain, use as a drug screening platform to identify compounds for the treatment of HAI, and the potential to identify regenerative mechanism that

could be harnessed in the treatment of people with HAI. In our preliminary experiments, adult zebrafish exposed to hypoxic conditions via an air-proof water chamber exhibited abnormal swimming behavior after hypoxic treatment. Histological analyses revealed a correlation between the extent of hypoxic treatment and damage. Current experiments are focused on determining if there are specific brain regions that are preferentially affected by hypoxic insult and in examining cellular and molecular changes associated with hypoxic insult. Our data suggest that zebrafish can be used as a model to investigate the cellular and molecular events associated with hypoxia-induced brain injury and repair.

Title: Enhanced oligodendrocytes regeneration reduces the early decline in motor coordination and extends the survival of SOD1 (G93A) mice

Authors: *E. GONZALEZ FERNANDEZ, B. PARKER, S. H. KANG;
Ctr. for Neuronal Repair and Rehabil., Shriners Hosp. Pediatric Res. Ctr., Philadelphia, PA

Abstract: Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disease characterized by progressive motor neuron (MN) degeneration. Non-neuronal cells near the MNs appear to also play critical roles in the progression of ALS. Oligodendrocytes (OLs), the CNS glia forming myelin sheaths, provide metabolic support to neurons, as well as allowing rapid axonal propagation. In a previous study, the genetic deletion of *hSod1 (G37R),* specifically in OLs and OL progenitor cells (OPCs) at a young age, delayed onset of the disease, and prolonged animal survival, implicating OLs in the pathophysiology of MN in ALS. In hSOD1 (G93A) mice, OLs also undergo massive degeneration near MNs, but at the same time, OPCs markedly proliferate and generate new OLs, although it appears that the newly born OLs fail to form compact myelin. However, it is unclear whether OL regeneration in the diseased spinal cord is a natural attempt to mitigate MN dysfunctions, or contributes to disease progression by wasting cellular and nutritional resources in the degenerating spinal cord. To better understand the role oligodendroglia in ALS pathogenesis and the significance of oligodendroglial responses in the disease, we further promoted OL regeneration in *hSOD1 (G93A)* mice. Using *Pdgfra-CreER*

mice, an OPC-specific tamoxifen-inducible Cre driver, we deleted PTEN from OPCs, a negative regulator of OL development, starting at P55. When observed at P100 (P55+45), $CC1^{+}Olig2^{+}$ OLs significantly increased in *Pten* cKO-hSOD1 (G93A) mice compared with littermate mutant SOD1 mice, but the number OPCs did not differ. Whereas there was a sharp decline in rotarod performance in hSOD1 (G93A) mice through an age window (10 - 14 weeks) near disease onset, the *Pten* cKO-hSOD1 (G93A) mice maintained motor skills in this period. The *Pten* cKO also slightly delayed the development of disease-related changes in splay reflex, although the differences in motor performance did not last at later stages. Most strikingly, the *Pten* cKO significantly extended survival of hSOD1 (G93A) mice (median survival: 141 vs. 153 days, n = 19 (control) and 15 (Pten cKO) mice; $P = 0.0051$). Currently, we are further investigating the cellular basis of the positive impacts given by increased oligodendroglial size. Our results reveal that the experimentally enhanced adult-born OL regeneration benefits MN functioning and animal survival in hSOD1 (G93A) mice. Similarly, endogenous OL regeneration may be a natural cellular reaction to compensate for motor deficits caused by MN loss. We conclude that improved survival or facilitated regeneration of OL could be a potential therapeutic strategy for slowing or arresting disease progression in ALS.

Title: Tdp-43 q331k overexpression leads to adult-onset motor and cognitive impairment in a mouse model

Authors: *E. H. JENSEN, E. MCGUIRK, A. BIALAS, J. YU, L. SHIHABUDDIN, J. DODGE;
CNS Genet. Dis., Sanofi Genzyme, Framingham, MA

Abstract: TDP-43 protein inclusions are major hallmarks of the neurodegenerative diseases, amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD). The familial ALS TDP-43 mutation, Q331K, has been shown to lead to motor deficits in a Prp-TDP-43-Q331K mouse model. However, the effect of this mutation on cognitive and social function has not been fully explored. Starting at 3 months of age, we observed motor dysfunction with significant rotarod impairment, consistent with previous reports. In a sociability assay at 5 months of age, the Q331K TDP-43 mice displayed significantly reduced velocity, fewer movements, but no sociability impairment. Finally, the 6-month old Q331K TDP-43 mice demonstrated mild associative learning and cognitive impairments in fear conditioning and marble burying tests

respectively. Altogether, these results demonstrate that Q331K TDP-43 overexpression leads to adult-onset motor and cognitive deficits that mirror those observed in ALS and FTD disease progression.

Title: Changed expression of potassium rectifying channel in glial cells in spinal cord of the ALS rat model

Authors: M. PERIC, D. BATAVELJIC, *P. R. ANDJUS;
Univ. of Belgrade Fac. of Biol., Belgrade, Serbia

Abstract: Amyotrophic lateral sclerosis (ALS) is a progressive and fatal neurodegenerative disease. Although it mainly affects lower and upper motor neurons, studies demonstrate that glia has significant role in neuronal death and disease progression. Glial cells maintain equilibrium ion concentration and provide support for neuronal functioning. Important role of glial cells is the potassium uptake and maintenance of ion homeostasis in the extracellular environment. Potassium inwardly rectifying channel 4.1 (Kir4.1) has significant role in keeping potassium ion equilibrium in the central nervous system. Kir4.1 is well studied in astrocytes although its role in other glial cells in ALS is not fully understood. Using markers for oligodendrocytes and microglia, CNPase and Iba1, OX-42, respectively, we examined Kir4.1 expression in cervical and lumbar spinal cord of the end phase $hSOD^{G93A}$ ALS rat model. Colocalization of signal intensity of oligodendroglial and microglial markers and Kir4.1 was quantified by Pearson and Manders coefficients. *In vitro* studies were done on microglia isolated from spinal cords of 2 days old transgenic $hSOD^{G93A}$ rats and their non-transgenic littermates. Presence of Kir4.1 protein was investigated using Western blot while the presence of Kir4.1 mRNA was examined using qPCR. Oligodendrocytes in ALS showed changed organization, morphology and signs of degeneration. In addition, Pearson and Manders colocalization coefficients showed a decrease in Kir4.1 and CNPase signal colocalization in the ventral horn of cervical and lumbar spinal cord of

the end stage ALS animals. Despite global reduction of Kir4.1 in gray matter of spinal cord, islets of Kir4.1 reactivity were observed in ventral gray matter and assigned white matter in ALS model tissue. These islets were also immunopositive for microglial markers showing that microglia forms Kir4.1 positive cell clusters in the end phase of the disease. Further studies on primary microglia demonstrated increased expression of Kir4.1 as well as increase of mRNA for this channel in ALS microglia compared to control. Changes in Kir4.1 in oligodendrocytes and microglia in ALS emphasize the importance of this channel in pathological processes. Reduced Kir4.1 expression in oligodendrocytes and increase of expression in microglia suggest potentially significant role of inwardly rectifiers in physiology of glial cells in neurodegeneration.

Abstract: Mutations in coiled-coil-helix-coiled-coil-helix domain containing 10 (CHCHD10), a mitochondrial protein of unknown function, cause a disease spectrum with clinical features of motor neuron disease, dementia, myopathy and cardiomyopathy. To investigate the pathogenic mechanisms of CHCHD10, we generated mutant knock-in mice harboring the mouse-equivalent of a disease associated human S59L mutation, S55L in the endogenous mouse gene. CHCHD10^{S55L}mice develop progressive motor deficits, myopathy, cardiomyopathy and accelerated mortality. Critically, CHCHD10 accumulates in aggregates with its paralog CHCHD2 specifically in affected tissues of CHCHD10^{S55L}mice, leading to aberrant organelle morphology and function. Aggregates induce a potent mitochondrial integrated stress response (mtISR) through mTORC1 activation, with elevation of stress-induced transcription factors, secretion of myokines, upregulated serine and one-carbon metabolism, and downregulation of

respiratory chain enzymes. Conversely, CHCHD10 ablation does not induce disease pathology or activate the mtISR, indicating that CHCHD10S55L-dependent disease pathology is not caused by loss-of-function. Overall, CHCHD10^{S55L}mice recapitulate crucial aspects of human disease and reveal a novel toxic gain-of-function mechanism through maladaptive mtISR and metabolic dysregulation

Title: Retromer complex deficiency in amyotrophic lateral sclerosis

Authors: *E. J. PÉREZ-TORRES[1], V. MISHRA[2], F. LOTTI[1], S. E. PRZEDBORSKI[3]; [2]Motor Neuron Ctr., [3]Neurolog Inst., [1]Columbia Univ., New York, NY

Abstract: Amyotrophic lateral sclerosis (ALS) is a rapidly progressive and fatal neurodegenerative disease that results in the death of motor neurons (MNs) in the spinal cord and brain. The retromer complex's function is to traffic proteins away from the endosome to the trans-Golgi network and to the plasma membrane. Defects in the retromer complex—which traffics proteins away from the endosome to the trans-Golgi network and to the plasma membrane—have been linked to multiple neurodegenerative diseases, including Parkinson's disease and Alzheimer's disease. Here, we study the possible contribution of defects in retromer trafficking to ALS pathology. We started by looking at the expression of retromer complex proteins in post-mortem tissue from ALS patients. We found no significant change in retromer expression in these samples, but noticed high variability among samples and a non-significant average decrease in VPS35 and VPS26A in the spinal cord. Thus, we performed similar experiments in a mouse model of ALS that expresses a G93A mutation in SOD1 (SOD1^{G93A}). In the spinal cord extracts of these models, we saw less variability than we did in the patient extracts and a marked significant decrease in retromer complex proteins. To explore the effects of this deficiency on ALS pathology, we designed two experiments in the SOD1^{G93A}-Tg mouse. We (1) overexpressed Vps35 via an AAV9—which increases the levels of the other retromer components as well—, or (2) knocked out one allele of Vps35—which disrupts the complex—and investigated the effects of these interventions on the ALS-like phenotype of these animals.

Title: Investigating recurrent inhibition in pre-symptomatic adult SOD1-G93A mice

Authors: N. CORNU[1], M. BACZYK[2], D. ZYTNICKI[1], ***M. MANUEL**[1];
[1]Univ. de Paris, SPPIN - Saints-Pères Paris Inst. for the Neurosciences, CNRS, Paris, France;
[2]Dept. of Neurobio., Poznań Univ. of Physical Educ., Poznan, Poland

Abstract: Excitotoxicity has long been hypothesized to play a key role in motoneuron degeneration in Amyotrophic Lateral Sclerosis (ALS). This excitotoxicity could arise either from an intrinsic hyperexcitability (which would increase the discharge probability and thereby the calcium inflow), or from alterations in the pre-motor networks leading to excessive glutamatergic excitation of MN and/or decreased inhibition. We have previously provided critical evidence demonstrating that intrinsic hyperexcitability cannot contribute to MN degeneration in ALS (Leroy et al, eLife 2014; Delestrée et al, J Physiol 2014; Martínez-Silva et al, eLife 2018). Furthermore, we have shown that excitatory synapses to motoneurons are depressed in SOD1-G93A mice before degeneration onset (Baczyk et al, SfN 2016). The goal of the present work is to test whether there are alterations in inhibitory circuits that could lead to an excitotoxic stress.
We studied the recurrent inhibition elicited by Renshaw cells. We performed *in vivo* intracellular recordings in adult SOD1-G93A and SOD1-WT transgenic mice at a presymptomatic age (P45-P55). Recurrent inhibition was elicited in Triceps Surae motoneurons by stimulating either the medial gastrocnemius or lateral gastrocnemius nerve after dorsal rhizotomy, to remove any sources of sensory-mediated excitation. The effective synaptic conductance at the soma was measured by injecting small (±0.5 nA) pulses of current immediately before, and during a steady-state IPSP elicited by a 200 Hz stimulation of the nerve, and calculating the difference in the slopes of the I-V plots obtained from each series of pulses.
Our preliminary results from 23 SOD1-G93A MNs (10 mice) and 34 SOD1-WT MNs (7 mice) show that the increase in input conductance elicited by recurrent inhibition was not different between mutant and WT animals (SOD1-G93A: 32 ± 22 nS [0-101 nS]; N=23 vs. SOD1-WT: 29 ± 29 nS [1-146 nS]; N=34). Furthermore, the reversal potential of the synapse, extrapolated from the I-V curves, was also not different between mutant and WT animals (SOD1-G93A: -67 ± 9

mV; [-82--49 mV]; N=23 vs. SOD1-WT: -65 ± 13 mV; [-95--45 mV]; N=34).
Conclusion: MN death in ALS is unlikely to be caused by a decrease in inhibitory inputs to MNs just before the onset of denervation.

Title: A Charcot-Marie-tooth disease type 2E point mutation in neurofilament protein L causes protein instability, atrophied axons, and proximal neurofilament accumulations

Authors: *E. J. STONE, A. UCHIDA, P. C. MONSMA, A. BROWN;
Neurosci., The Ohio State Univ., Columbus, OH

Abstract: Charcot-Marie-Tooth disease type 2E (CMT2E) is a slowly progressive peripheral neuropathy of unknown mechanism caused by mutations in the gene that encodes neurofilament protein L (NFL). NFL is one of five subunits that comprise neurofilaments, which are neuron-specific cytoskeletal polymers that contribute to axon expansion during development. The $NFL^{N98S/+}$ CMT2E mouse model, which is heterozygous for the N98S mutation in the endogenous mouse *Nefl* locus, presents with a disease phenotype and offers an opportunity to study the effects of a CMT2E mutation on neurofilaments *in vivo*. We are using this mouse to ask several questions: 1) Is the mutant protein stably expressed? 2) Does the mutant NFL protein affect the expression levels and assembly of the other neurofilament subunits? 3) Is the mutant protein incorporated into filaments? 4) Does the mutant protein impair neurofilament transport and/or interactions? By Western blotting, we observe a reduction in neurofilament proteins in the mutant sciatic nerve and spinal cord when compared to wild type. Using tandem mass spectrometry of tryptic digests, we find that 41% of the NFL protein in the spinal cord is N98S mutant. To determine the assembly state of the neurofilament subunit proteins, we homogenized spinal cord tissue in Triton X-100 and performed centrifugation to separate soluble (unassembled) and insoluble (assembled) fractions. In the mutant, we observe an elevation of neurofilament triplet proteins in the Triton-soluble fraction and a reduction in the Triton-insoluble fraction. On average, 41% of the NFL protein in the insoluble fraction was mutant compared to 30% in the insoluble fraction. Electron microscopy of spinal cord, dorsal root ganglia, and sciatic nerve confirmed the presence of atrophied axons lacking neurofilaments,

with some axons containing neurofilament accumulations proximally. Strikingly, the neurofilament accumulations exhibited widespread segregation of neurofilaments from their microtubule tracks, which implies an impairment of neurofilament transport. We conclude that the mutant NFL is capable of assembly, but assembles less efficiently than wild type, thereby altering the subunit stoichiometry of the assembled neurofilaments and increasing the soluble pool of all neurofilament subunit proteins. Our data suggest that disease arises from a loss of neurofilaments in axons due to sequestration in cell bodies and proximal axons caused by either (1) alterations in the structure or subunit stoichiometry of the filaments, or (2) toxicity of elevated soluble neurofilament protein. We are currently working to test these hypotheses.

Title: Electroceutical treatment of dysphagia in a mouse model of ALS

Authors: *B. BALLENGER[1], C. HAXTON[2], K. L. OSMAN[2], J. ARNOLD[1], T. E. LEVER[2]; [1]Sch. of Med., [2]Dept. of Otolaryngology - Head & Neck Surgery, Univ. of Missouri, Columbia, MO

Abstract: Objectives: Dysphagia (swallow impairment) is a debilitating condition that eventually affects every individual diagnosed with ALS, often resulting in malnutrition, dehydration, and fatal aspiration pneumonia. Current treatments are largely palliative and do little to address the underlying neurophysiology. Here, we explore an electroceutical approach targeting the brainstem central pattern generator for swallowing in a mouse model of ALS. **Methods:** We established a surgical protocol for acute delivery of electrical stimulation (ES) to the superior laryngeal nerve (SLN) in the low copy number (LCN) *SOD1-G93A* transgenic mouse model of ALS (i.e., LCN-SOD1). The procedure is performed once as a survival surgery at 6 months of age, corresponding to clinical disease onset in this model. The right SLN is draped over bipolar electrodes for 1 hour of continuous ES using parameters established by our pilot work. Twenty LCN-SOD1 mice (either sex) underwent the surgical protocol, equally divided into 2 groups (SLN stimulation versus sham treatment) for comparison with 2 non-surgical control groups: LCN-SOD1 mice (n=20) and non-transgenic littermates (n=20); age-matched, either sex. To evaluate swallowing function, all mice underwent our established videofluoroscopic swallow study (VFSS) assay that entails monthly testing of awake, freely-behaving animals using low-dose x-ray, starting at 4 months until disease end-stage (20% reduction from maximum body weight).

Results: Preliminary VFSS findings from 3 ES-treated mice demonstrated preserved lick rate during drinking, compared to non-transgenic controls. In contrast, the lick rate of sham-treated and non-surgical LCN-SOD1 controls was significantly slower than ES-treated mice and non-transgenic controls. Analysis of the remaining mice and additional VFSS outcome measures is in progress.
Discussion: Our preliminary results of preserved lick rate in end-stage LCN-SOD1 mice after a single, 1-hour ES treatment to the SLN nerve are quite promising. If additional beneficial outcomes (i.e., preserved swallowing function and extended survival) emerge following completion of data analysis, this pioneering work will provide the scientific premise for exploring electrical stimulation in the treatment of dysphagia in ALS patients.

Title: Distinct populations of layer 5b pyramidal neurons in the primary motor cortex

Authors: M. V. MOYA[1], M. N. RAO[1], R. KIM[2], C. E. SFERRAZZA[2], N. HEINTZ[1,3], *E. F. SCHMIDT[2];
[1]Lab. of Molec Biol, The Rockefeller Univ., New York, NY; [2]Lab. of Molec Biol, Rockefeller Univ., New York, NY; [3]HHMI, New York, NY

Abstract: Many neurodegenerative diseases lead to the selective degeneration of discrete cell types in the CNS even though many disease-causing mutations occur in genes that are ubiquitously expressed. This is true for amyotrophic lateral sclerosis (ALS), an aggressively fatal disease characterized by the progressive degeneration of the alpha-motoneurons in the spinal cord and the spinal cord projecting “upper” motor neurons in the cerebral cortex. To fully understand the causes of disease onset and to develop more effective therapeutic strategies it is imperative to understand the molecular properties of afflicted cells and identify cellular pathways that may underlie pathological processes. Much of the work over the last three decades has focused on the spinal cord, while relatively little is known about the mechanisms leading to cortical phenotypes. This likely reflects the complexity and heterogenous organization of the cortex and the lack of reliable markers to distinguish the upper motor neurons from other

pyramidal cells. We therefore employed a combination of anatomical and molecular strategies to determine the characteristics that differentiate vulnerable cells from nearby resistant cell types. We show that there are two distinct, but closely related, pyramidal cell subtypes in layer 5b of mouse primary motor cortex with overlapping and distinct axonal projections. Only one of these subtypes is lost in the SOD1-G93A mouse model of familial ALS, establishing vulnerable and an analogous resistant layer 5b populations. Molecular profiling using the translating ribosome affinity purification (TRAP) approach revealed important differences in baseline gene expression in healthy mice, and differential changes in gene expression during disease progression in SOD1-G93A mice. These studies also elucidated novel immunohistological markers to visualize these populations across species. Together, our results provide a foundation to elucidate how molecular properties of distinct cell populations reflect their distinct anatomy and establish selective vulnerability in neurodegenerative disorders.

Abstract: Amyotrophic lateral sclerosis (ALS) is a fatal, progressive neurodegenerative disease without effective treatment, characterized by the impairment of the upper and lower motoneurons. Although the pathogenic mechanisms of ALS are not very well understood, it is known that this is a multifactorial disease in which mutations in different genes and/or different pathways are affected leading to neuronal death. In this sense, cell therapy has emerged as a promising alternative and several studies have been carried out to verify its effects and benefits. In the present work, we used different functional tests to evaluate disease progression in

SOD1(G93A) mice and analyzed the effect of cell therapy with human Whaton's jelly mesenchymal stem cells (MSC). Three functional tests were used to evaluate the motor performance of the animals: rotarod, motor score and CatWalk. According to our functional tests, the disease manifests itself between the 12th and 15th weeks. After establishing the functional profile of the mice, we injected MSC intravenously. In this protocol, treated animals showed a delay in disease progression and an increase in lifespan. In addition, preliminary analysis of the anterior horn of the lumbar spinal cord has shown that the number of microglial cells is reduced in the animals receiving MSC. When analyzing the number of motoneurons in the same region of the spinal cord, we did not observe any difference between the groups. Therefore, this work shows that intravenous therapy with MSC is a promising therapy in the treatment of ALS.

Title: SMA-specific differences in the translatome of spinal motor neurons *in vivo*

Authors: *P. L. PRICE[1], K. ENGEL[2], C.-W. TSAI[3], M. TALIAFERRO[2], C. DIDONATO[4], G. J. BASSELL[1], W. ROSSOLL[3];

Abstract: Spinal Muscular Atrophy (SMA) is a neuromuscular disease characterized by a progressive loss of spinal motor neurons and consequently, a loss of locomotor abilities. SMA is directly caused by insufficient levels of the Survival of Motor Neuron (SMN) protein, yet the molecular mechanisms by which reduced levels of SMN influence motor neuron development and susceptibility remain elusive. Several studies have identified differences in global and compartmentalized mRNA expression *in vitro*, yet evidence for mRNA processing and localization defects *in vivo* remains scarce. By combining motor neuron–specific transgene expression with affinity purification of translating ribosomes, we have performed a

comprehensive RNA-seq study to establish the profile of ribosome-bound mRNAs, or "translatome", in spinal motor neuron cell bodies at pivotal time points in a mouse model of SMA. We observed an early and persistent upregulation of transcripts involved in p53-mediated signaling pathway, as well as a down-regulation of several motor neuron-enriched markers that may contribute to sub-type specification axon growth such as matrix metalloproteinase 9 (MMP9) and chondrolectin (Chodl). Functional studies conducted with novel dysregulated transcripts link SMN-deficiency to cell-type specific changes that directly influence the development of SMA pathology in cell models. Taken together, data from these studies reveal novel targets that contribute to motor neuron pathogenesis in SMA and may serve as valuable candidates for the preservation of motor neurons in neurodegenerative diseases.

Title: Post-paralysis treatment with the electrophilic compound EOLO42016 abrogates neuroinflammation and slows disease progression in inherited ALS

Authors: *S. IBARBURU[1], E. TRÍAS[2], J. RODRIGUEZ-DUARTE[2], G. GALLIUSSI[2], V. LÓPEZ[3], M. KOVACS[2], V. VARELA[2], M. INGOLD[2], C. BATTHYANY[2], L. BARBEITO[2]; [1]Inst. Abstract: Neuroinflammation is a pathological hallmark in Amyotrophic Lateral Sclerosis (ALS), causally associated to the progressive degeneration of upper and lower motor neurons. Drugs targeting neuroinflammation have the potential to slow paralysis progression. We have recently developed new electrophilic drugs capable of inhibiting neuroinflammation by targeting Nrf2/Keap1, NFκB and NLRP3 inflammasome. Here, we have analyzed the protective effects of the compound EOLO42016 on the post-paralysis survival of ALS transgenic rats carrying the $SOD1^{G93A}$ mutation. The drug was orally administered at 100 mg/kg/day starting after paralysis onset. Also, adult microglia isolated from the symptomatic spinal cord of $SOD1^{G93A}$ rats were used to determine the the effect of the drug on inflammatory pathways. We found that EOLO42016 inhibits p65 NF-κB nuclear translocation and the release of interleukin-1β in cultured adult $SOD1^{G93A}$ microglia stimulated with LPS. Furthermore, administration of

EOLO42016 to SOD1^{G93A} rats starting after paralysis onset, significantly prolonged survival by 30% when compared with vehicle. Extend survival was associated to a potent histopathological protective effect denoted by decreased microgliosis and preservation of spinal cord motor neurons and NMJ in the EDL muscle. Therefore, compound EOLO42016 appears unique among other ALS-developmental drugs, being capable of exerting a multi-faceted neuroprotection in both central and peripheral nervous systems via modulation of different mechanisms implicated in ALS pathogenesis.

Title: Targeting Nox2 to reduce autoimmune elicited neural damage in the central nervous system

Authors: *C.-F. HU[1], S.-P. WU[4], C.-S. HSU[2], J.-S. HONG[5], S.-J. CHEN[3], C.-C. SHIEH[6]; [2]Ctr. for Precision Med. and Genomics, [3]Pediatrics, [1]Tri-Service Gen. Hosp., Taipei City, Taiwan; [4]Reproductive and Developemental Biol. Lab., Natl. Inst. of Envrn. Hlth. Sci., Durham, NC; [5]NIEHS, Rtp, NC; [6]Lab. of Human Immunological Dis., Natl. Cheng Kung Univ., Tainan city, Taiwan

Abstract: The roles of reactive oxygen species (ROS) contributing to the pathogenesis of experimental autoimmune encephalomyelitis (EAE) is not yet totally understood. Recent strategies of multiple sclerosis treatment centered on T cell-based interventions work successfully on a subset of patients. In this study, we focus roles of innate immunity in the pathogenesis of EAE. We hypothesize that dysregulated ROS production by both macrophage and microglia NADPH oxidase (Nox2) contributes to neural inflammation, damage and demyelination after EAE induction.
We found that Nox2 deficient mice are more resistant to EAE induced neural damage compared

with control mice (C57). Nox2 deficiency results in reduced disease severity scores, less body weight loss, less leukocytes infiltration, lower grades of demyelination, decreased oxidative stress markers 3-nitrotyrosine (3-NT) and Myeloperoxidase (MPO), and lower levels of genes encoded for Nox2, CD11b, proinflammatory cytokines (IL-4, IL-17α, IFNɣ) and chemokine (CCL2, CCL5, CCL6, CCL20, CXCL10) in the spinal cords in comparison with control. Our findings suggest that Nox2-mediated ROS production in macrophage and microglia plays an important role in EAE-induced neuronal damage. Roles of Nox2 in macrophage and microglia in the pathogenesis of EAE are being investigated by using a variety of Nox2 inhibitors. Further studies on the functional assessment of dendritic cells, macrophages and microglia in Nox2 deficient mice after EAE induction.

Title: Cellular source of hypothalamic macrophage accumulation in diet-induced obesity

Authors: *C. LEE;
Asan Med. Ctr., Seoul, Korea, Republic of

Abstract: Obese mice on a high fat diet (HFD) display signs of inflammation in the hypothalamic arcuate nucleus (ARC), a critical area for controlling systemic energy metabolism. This has been suggested as a key mechanism of obesity-associated hypothalamic dysfunction. We reported earlier that bone marrow-derived macrophages accumulate in the ARC to sustain hypothalamic inflammation upon chronic exposure to an HFD. However, the mechanism of hypothalamic macrophage accumulation remained unclear.We investigated whether circulating monocytes or myeloid precursors contribute to hypothalamic macrophage expansion during chronic HFD feeding. To trace circulating myeloid cells, we generated mice expressing green fluorescent protein (GFP) in the lysozyme M-expressing myeloid cells ($LysM^{GFP}$ mice) and then conducted parabiosis and bone marrow transplantation experiments using these mice. Mice were fed HFD for 12 or 30 weeks before sacrificed to evaluate the presence of $LysM^{GFP}$ cells in the hypothalamus. Hypothalamic vascular permeability in HFD-fed obese mice was also tested by examining extravascular leakage of Evans blue and fluorescence-labelled albumin. Finally, we studied when $LysM^{GFP}$ cells entered the hypothalamus during the development.Our parabiosis

and bone marrow transplantation experiments revealed a significant infiltration of circulating $LysM^{GFP}$ cells in the liver, skeletal muscle, choroid plexus and leptomeninges but not in the hypothalamic ARC during chronic HFD feeding, despite increased hypothalamic vascular permeability. These results suggested that the recruitment of circulating monocytes is not a major mechanism for maintaining and expanding the hypothalamic macrophage population in diet-induced obesity. Instead, we demonstrated that $LysM^{GFP}$ cells infiltrated the hypothalamus during its development. $LysM^{GFP}$ cells appeared in the hypothalamic area from the late embryonic period. This cellular pool suddenly increased immediately after birth, peaked at the postnatal second week, and adopted an adult-pattern of distribution after weaning.These findings suggest that bone marrow-derived macrophages mostly populate the hypothalamus in early postnatal life and may maintain their pool without significant recruitments of circulating monocytes throughout life, even under conditions of chronic HFD-feeding.

Title: Functional interplay between neurons and glia in mice models of familial epilepsy

Authors: *P. SINHA, B. VERMA, S. GANESH;
Biol. Sci. and Bioengineering, Indian Inst. of Technol. Kanpur, Kanpur, India

Abstract: Epilepsy is a chronic neurological condition characterized by recurrent and unprovoked seizures, affecting up to 1% of the global population. The serendipitous discovery of various channel blockers as anti-epileptic drugs (AEDs) substantiated the age-old concept of epilepsy being a channelopathy. Almost all AEDs currently being used are channel blockers. However, a critical look at the genetic basis of epilepsy reveals genetic defects in channel proteins are limited to a few affected families. Genetic defects resulting in epilepsy in a large number of independent families are associated with genes coding for non-channel proteins. For example, genes coding for cysteine protease inhibitors, protein phosphatases, and ubiquitin ligases are mutated in familial forms of epilepsies. The use of channel blocker AEDs is effective in controlling the seizures even in such cases. Their continued usage, however, results in refractive forms (drug-resistant) in over 40 % of the cases, highlighting the need to understand the molecular basis of epileptogenesis better and to develop new drugs.

Far more active than once thought glia plays a significant role in the incidence of epilepsy. We wanted to understand the role of microglia and astrocytes in causing epilepsy in mice models of an autosomal recessive familial epilepsy. Microglia and astrocytes are the major players in regulating neuroinflammation. In our previous studies, we could show that reactive glia causes neuroinflammation with advancing age which in turn renders the aged brain more susceptible to seizure episodes. In our mice models of epilepsy, we see increased gliosis and incidence of seizures. We hypothesized that rescuing neuroinflammation could ameliorate the seizure phenotype in our mice models.
6-month-old mice (C57BL/6J strain) (n=12) were administered with NSAIDs mixed in drinking water ad libitum for two months. Age-matched controls fed with regular water served as control (n=12). We injected pentylenetetrazole (a seizure-inducing drug) intraperitoneally to the NSAIDs administered and control mice to induce seizures and videotaped them for 30 minutes to score seizures. We have looked into the extent of neuroinflammation and oxidative stress by immunohistochemical staining, quantitative RT-PCR, western blotting and enzymatic assays. We found a significant reduction in seizure susceptibility along with downregulated neuroinflammation and decreased oxidative stress markers in treated mice. We conclude that glia plays an important role in maintaining the balance between excitation and inhibition in neurons by regulating inflammation and oxidative stress in the brain.

Title: GLP1 receptor agonist prevents development of Wolfram syndrome symptoms in the Wfs1 deficient rat

Authors: *K. SEPPA[1], M. TOOTS[1], R. REIMETS[1], T. JAGOMÄE[1], J. R. NYENGAARD[2], E. VASAR[1], A. TERASMAA[1], M. PLAAS[1];

[1]Inst. of Biomedicine and Translational Med., Univ. of Tartu, Tartu, Estonia; [2]Stereology and Electron Microscopy Lab., Aarhus Univ. Hosp., Aarhus, Denmark

Abstract: Background: Wolfram syndrome (WS) is a rare neurodegenerative disorder that is mainly characterized by diabetes mellitus, optic nerve atrophy and progressive brainstem degeneration. Currently, there is no cure for WS and death usually occurs due to brainstem atrophy. Therefore, it is important to find therapies that could protect against the progression of the disease. We have developed and characterized the WS rat model, where exon 5 deletion of the *Wfs1* gene resulted in development of the main symptoms of WS: diabetes mellitus, optic nerve atrophy and medullary degeneration. GLP-1 (glucagon-like peptide-1) receptor agonists (RA) have been accepted as a promising class of anti-diabetic drugs, having the potential to delay or even reverse disease progression. Chronic GLP-1 RA liraglutide treatment reduced ER stress and inflammation in Wfs1 KO rats Langerhans islets and thereby prevented the development of diabetic phenotype. Therefore, potential neuroprotective effects of GLP1 RA were evaluated in Wfs KO rats.
Methods: Wfs1-deficient and wild-type (WT) littermate control rats were used. The rats were 8 months old at the beginning of the experiment and were randomly allocated into the liraglutide or control group (n=6-10) and were treated for 6 months. To evaluate liraglutide therapeutic effect, in vivo MRI was performed and cellular stress markers were measured using histological and stereological methods.
Results: In addition to antidiabetic effect, our recent data suggest that long-term liraglutide treatment has also neuroprotective effects on WS.
Conclusions: Wfs1-KO rat is the only WS animal model with well characterized progression of disease symptoms, including diabetes and neurodegeneration. Therefore, Wfs1-KO rat is valuable pre-clinical tool to evaluate treatment strategies.

Title: Osteoporosis in a clinically relevant mouse model of multiple sclerosis

Authors: *B. LIN, D. LAUNDER, **O. A. MILLER**, D. Y. BAILEY, F. K. ASSIFUAH, H. R. CONTI, B. M. KOFFMAN, J. DU;
The Univ. of Toledo, Toledo, OH

Abstract: Multiple sclerosis (MS) is a CNS disease in which the myelin sheath in the brain and spinal cord are damaged, leading to disruption of neural communication. In addition to inciting autoimmunity to neurons, activated T cells causing peripheral inflammation also impacts bone metabolism. The imbalance of bone breakdown and formation is the underlying mechanism of diseases such as osteoporosis. Studies suggest that MS patients are at increased-risk of having osteoporosis. To demonstrate if experimental autoimmune encephalomyelitis (EAE), a widely accepted model of MS, predisposes mice to this bone disorder, C57BL/6 mice were immunized with myelin oligodendrocyte glycoprotein (MOG) to induce EAE, and changes in bone structure/quality were assessed by using μCT. Three-dimensional reconstruction of the mouse tibia showed significant bone loss in EAE mice, compared to healthy mice (control) (Fig 1). Osteoporotic bone in EAE mice was also characterized by decreases in the ratio of bone volume over total volume (BV/TV) and connectivity density (Conn. D) as well as a shift in bone shape from more planar (structure model index (SMI)=0) to more cylindrical (SMI=3) (Fig 2). Activation of osteoclasts, the major cell type mediating bone resorption, was found induced in EAE mouse bone by qRT PCR analysis of osteoclast marker TRAP, Cathepsin K, MMP9 and RANK. Together, our data suggested that EAE can cause osteoporosis in mice, and that this model may be useful to investigate metabolic bone diseases associated with MS.

Title: Goshajinkigan, a Japanese traditional herbal medicine, prevents age-related allodynia in senescence-accelerated mice

Authors: ***M. NAKANISHI**[1], N. KOYAMA[2], S. FUKUI[3], H. KITAGAWA[1];
[1]Dept. of Anesthesiol., [2]Dept. of Physiol., Shiga Univ. of Med. Sci., Otsu, Japan; [3]Dept. of Anesthesiology, , Pain Mgmt. Clinic, Interdisciplinary Pain Mgmt. Ctr., Shiga Univ. of Med. Sci. Hosp., Otsu, Japan

Abstract: The elderly population is increasing, and they generally exhibit a higher incidence of chronic neuropathic pain and frailty. However, as the incidence of side effects is higher in elderly patients, treatment methods are limited. Goshajinkigan (GJG), a traditional Japanese herbal medicine, is often used to treat symptoms of aging, such as leg pain, low back pain, numbness, itching, and swelling. GJG has few side effects and can be safely administered to elderly. The aim of this study was to investigate the effect of GJG on age-related allodynia using chronic constriction injury(CCI) mice and senescence-accelerated mice (SAMP8). First, C57BL/6J male mice aged 6 weeks were randomly divided into four groups (n = 5): sham, GJG-treated sham, CCI, and GJG-treated CCI groups. CCI mice were prepared using a modification of the procedure of Bennett and Xie. Briefly, three ligatures of 6-0 silk suture were tied loosely around the sciatic nerve at intervals of 1 mm. Sham controls were subjected to the same surgical procedure, except that the sciatic nerve was undisturbed. The mice were fed a normal diet with or without 4% (w/w) GJG. The analgesic effect was evaluated by behavioral tests, the Von Frey test, and cold plate test at 1 day before surgery,and 3, 7, 14, 21, and 28 days after surgery. GJG

significantly reduced allodynia and hyperalgesia from the early phase (von Frey test, $p<0.0001$; cold-plate test, $p<0.0001$; two-way repeated measures ANOVA). Immunohistochemistry and Western blot analysis revealed that GJG decreased the expression of Iba1 and tumor necrosis factor-a(TNF-a) in the spinal cord. Double staining immunohistochemistry showed that most of the tumor necrosis factor-a was co-expressed in Iba1-positive cells at day 3 post-operation. Additionally, senescence-accelerated mice, aged 7 weeks, were randomly divided into four groups ($n = 5$): SAMR1(control), GJG-treated SAMR1, SAMP8, and GJG-treated SAMP8 groups and fed a normal diet with or without GJG. We performed behavioral tests at the age of 12, 24, and 36 weeks. Among senescence-accelerated mice, the SAMP8 group mice showed apparent allodynia compared with SAMR1 (von Frey test, $p<0.05$; cold-plate test, $p<0.05$; two-way repeated measures ANOVA). GJG significantly reduced mechanical and cold allodynia in SAMP8 mice (von Frey test, $p<0.05$; cold-plate test, $p<0.001$; two-way repeated measures ANOVA). GJG ameliorates allodynia in CCI model mice via suppression of TNF-a expression derived from activated microglia. and GJG also prevented allodynia in senescence-accelerated mice. GJG may be a promising drug for the treatment of allodynia induced by neuro-inflammation and aging.

Race to Erase MS

Title: Ultra-high field MRI to monitor leptomeningeal inflammation in an animal model of multiple sclerosis

Authors: *S. KIM, M. D. SMITH, P. BHARGAVA, P. CALABRESI;
Neurol., Johns Hopkins SOM, Baltimore, MD

Abstract: Leptomeningeal inflammation has been noted to occur in both multiple sclerosis (MS) patients and animal models of MS. Studies have demonstrated that areas of meningeal inflammation consist of B-cells, T-cells, follicular dendritic cells (FDC) and macrophages, with some of these areas demonstrating features of ectopic lymphoid tissue. Meningeal inflammation is associated with increased gray matter demyelination and neuronal damage in adjacent cortical areas in MS patients and a more severe disease course. In recent studies, sites of leptomeningeal

enhancement were detected utilizing contrast-enhanced magnetic resonance imaging (MRI) and these lesions corresponded to areas of meningeal inflammation on autopsy. Thus, meningeal inflammation appears to play an important role in MS disease progression and is detectable at both radiological and pathological level.
Here, we utilized high-field (11.7 Tesla) gadolinium-enhanced FLAIR MRI to identify areas of meningeal inflammation in the relapsing-remitting model of experimental autoimmune encephalomyelitis (rr-EAE) in female SJL/J mice and to test a potential therapy targeting B-cells (anti-CD20). We first identified areas of leptomeningeal enhancement predominantly over the cerebral cortex or in the hippocampal fissure. These areas corresponded to dense inflammatory infiltrates in the meninges, which included B-cells, T-cells, FDC, and macrophages. In longitudinal experiments we noted an increase in the number of these lesions from early (2 weeks) to late stages (> 8 weeks) of EAE and pathologically, we noted increased abundance of B-cells (B220+) within the areas of meningeal inflammation over time. Evaluation of the adjacent cerebral cortex in rr-EAE animals revealed an increase in microglia/ macrophages (Iba-1+ cells) and astrocytes (GFAP+). We also noted increased axonal damage (SMI-32+ spheroids) and demyelination (vacuolar degeneration in luxol fast blue staining), suggesting meningeal inflammation could lead to axonal damage and demyelination in the underlying cortex.
We then used this model to evaluate the effect of anti-CD20, a treatment used to deplete peripheral B-cells, on meningeal inflammation. Despite a reduction in the proportion of B- and T-cells within lesions, there was no significant difference in number of leptomeningeal enhancing lesions between anti-CD20 and isotype control groups suggesting that targeting of B-cells alone may be insufficient to eliminate meningeal inflammation in MS. This model will help evaluate putative treatment strategies that may impact meningeal inflammation and may help identify those that hold promise in human trials.

Title: Characterization of cytokine levels in LPS-treated mice: Multiplex assay of key inflammatory mediators in neurodegenerative disorders

Authors: *K. M. PALDANIUS, L. RAUHALA, T.-K. STENIUS, F. KHAN, T. BOLKVADZE, R. O. PUSSINEN, T. HUHTALA, D. MISZCZUK;
Charles River Discovery, Kuopio, Finland

Abstract: Inflammation is a key feature in several neurodegenerative disorders. Multiplex assays, such as Luminex platform, offer a possibility to simultaneous detection of multiple inflammatory mediators from single sample for better evaluation of complexity of immune response. However, detecting minute concentrations of secreted cytokines particularly in solid tissues can be challenging. The objective of this study is to optimize a multiplex assay platform for assessment of a time course of inflammatory response in the brain, peripheral tissues and body fluids in C57BL/6J mice after systemic lipopolysaccharide (LPS) challenge.
A single intraperitoneal LPS injection (5-20 mg/kg of serotype 055:B5) was used to activate the immune system of the test animals, and to induce measurable local and systemic levels of inflammation regulating cytokines and chemokines. At 6h, 24h, and 7d after LPS administration CSF, plasma, hypothalamus, hippocampus, striatum, and cortical pieces were collected. Liver and spleen were used as systemic control tissues. All samples were fresh-frozen for the measurement of IFN-γ, IL-10, IL-1β, IL-6, MCP-1/CCL2, and TNF-α using Luminex platform. The results of this work will help to characterize the effect of systemic LPS in mice, as well as give valuable insight into the relationship between brain and peripheral tissue and body fluids in levels of key mediators of inflammation using validated measurement protocols. Overall, the data helps in validating biomarkers, which are relevant to neuroinflammatory models.

Epidemiology, Hannover, Germany; [6]Helmholtz Ctr. for Infection Res., Braunschweig, Germany

Abstract: *Introduction:* Cerebral malaria (CM) is a complex neurological syndrome of human malaria caused by the parasite *Plasmodium falciparum*. Experimental cerebral malaria (ECM),

induced by *Plasmodium berghei* ANKA (*Pb*A), is the widely used rodent disease model to study CM. Early detection of the disease before the rapid onset of clinical symptoms would aid in development of better anti-malarial treatment regimes.
Objective: To detect the disease before the onset of clinical symptoms and to study the brain pathology associated with the disease progression.
Materials and methods: C57BL/6 mice were injected with *Pb*A-infected red blood cells. One group of mice was treated with pyrimethamine (anti-malarial drug) starting at day 5 post infection (p.i.) (asymptomatic stage) while the control group received PBS. Single-photon emission computed tomography (SPECT) was performed to visualize the changes in regional blood flow. Blood brain barrier (BBB) integrity was monitored by Evans blue staining. Cerebral chemokine and cytokine expression were measured by qRT-PCR. Brain pathology was studied by immunohistochemistry.
Results: Parasite DNA was detectable in the brain at day 5 p.i. suggesting an early accumulation of infected RBCs in the brain. SPECT imaging of untreated mice showed heterogeneous and diffused hypo-perfusion in the cortical region beginning at day 5 p.i, before the onset of clinical symptoms and progressed until day 7 where the mice succumb to the infection. The disturbance of the rostral migratory stream (RMS) could also be detected at day 5 p.i which progressed until day 7 where the RMS was completely disrupted. Further immunohistochemistry analysis showed widespread brain pathology particularly in the olfactory bulb and the brain stem regions. Concomitantly, the chemokine and cytokine responses in these areas were also enhanced. The above mentioned changes were detectable at day 5 p.i, when the BBB was still intact and progressed till day 7 when the integrity of the BBB was disrupted and the mice succumbed to ECM. Treatment of the mice with pyrimethamine from day 5p.i prevented the progression of the brain pathology and protected mice from ECM.
Conclusion: Brain pathology begins in the asymptomatic stage of the disease. Disruption of the RMS and consequently, neurogenesis could explain the loss of neurocognitive functions in human cerebral malaria. Olfactory bulb and brain stem are the worst effected regions of the brain during disease progression. Early detection and treatment would prevent the progression of brain pathology and protect from ECM.

Title: Hippocampal inflammation in a mouse model of perioperative neurocognitive disorders

Authors: *X. XIANG[1], G. YANG[2], S. ZHU[1];
[1]Zhejiang Univ., Hangzhou, China; [2]Anesthesiol., Columbia Univ., New York, NY

Abstract: Perioperative neurocognitive disorders include acute delirium and longer-lasting postoperative cognitive dysfunction. Despite the prevalence of these conditions in older adults, the pathophysiology of perioperative neurocognitive disorders remains unknown. Many lines of evidence indicate that systemic inflammation has a profound impact on neurocognitive function. Using ELISA, we found that peripheral surgery caused a transient elevation of proinflammatory cytokine IL-6 in both plasma and the central nervous system, which peaked 6 hours after surgery and returned to baseline thereafter. We then performed transcriptome analysis to further investigate surgery-induced neuroinflammatory responses. Mouse hippocampus was collected 6 hours post-surgery and processed for RNA-Seq. We found a total of 268 genes that showed altered expression levels following surgery, among which 170 genes were up-regulated and 98 were down-regulated. Subsequent functional enrichment analysis identified several KEGG pathways involved in inflammatory mediator regulation of TRP channels, neuroactive ligand-receptor interaction and cholinergic synapses. Quantitative real-time PCR confirmed 15 genes of interest associated with dysregulation of the immune responses. The results of this ongoing study suggest a potential role of hippocampal inflammation in the development of perioperative neurocognitive disorders.

Title: Holothuria scabra extract reduces cytosolic phospholipase A2 expression induced by Plasmodium yoelii infection

Authors: *S. CHOMPOOPONG[1], L. KWATHAI[1], P. SANGUANWONG[1], P. UAWITHYA[1], I.-C. LIU[2];
[1]Dept. of Anatomy, Fac. of Med. Siriraj, Bangkoknoi, Thailand; [2]Inst. of Med. Sci., Tzu Chi Univ., Hualien, Taiwan

Abstract: Cytosolic phospholipase A2 (cPLA2), the lipolytic enzyme, plays a key role in mediating agonist-induced arachidonic acid (AA) release from membrane phospholipids for eicosanoid production in various cell types. AA is further converted to prostaglandin (PG) by

constitutive cyclooxygenases (COX)-1 or inducible COX-2 during inflammation triggered by tumor necrosis factor-alpha (TNF- α). To confirm the anti-inflammatory effect, whether the ethanol extract of sea cucumber, *Holothuria scabra (*HsE) can reduce cPLA2 in *Plasmodium yoelii* infected mice (Py). At day 5 after infection, Py mice were daily treated for 3 days with HsE,10 mg/kg. Artesunate (As), 32 mg/kg was used as standard anti-malarial drug. HsE has not directly suppressed the parasitic infection of red blood cells. However, co-treatment with anti-malarial drug, HsE+As showed the increase in survival rate of Py mice. The rapid murine coma and behavior score (RMCBS) demonstrated the more improved neurological score in HsE+As group. Western blot analysis resulted on the decrease in cPLA2 at day 8, together with the significant decreased TNF-α and COX-2 expression of brains in Py-HsE mice that showed prolong survival rate ($P<0.05$). In acute plasmodium infection, parasites can bind to Toll-like receptors (TLR) on macrophages and triggering the production of cytokines, reactive oxygen species, and lipid mediators. Therefore, high systemic levels of TNF-α that is both protective (by restricting parasitemia) and pathogenic (by promoting anemia) can promote acute inflammatory responses such as increased vascular permeability, by recruiting leukocytes to the site of infection. The bioactive components of HsE, saponins or triterpene glycosides have also shown the anti-inflammatory effects by regulating the enzymatic activity of cPLA2 and COX-2 in metabolism of AA to PG.

Title: Behavioural and histological changes in cuprizone-fed mice

Authors: *P. J. SHORTLAND[1], M. K. SEN[1], M. S. ALMUSLEHI[1], J. R. COORSSEN[2], D. A. MAHNS[1];
[1]Western Sydney Univ., Penrith, Australia; [2]Brock Univ., St. Catharines, ON, Canada

Abstract: Feeding cuprizone (CPZ) to rodents causes demyelination and reactive gliosis in the CNS; these are hallmarks of some neurodegenerative diseases like multiple sclerosis. Clinically, these conditions cause changes in sensory and motor symptoms, such as pain and loss of motor function. However, relatively little is known regarding the behavioural deficits associated with CPZ treatment and much of what is known is contradictory. This study investigated whether 5

weeks oral feeding of 0.2% CPZ to young adult mice triggers sensorimotor behavioural changes. Behavioural tests included measurement of nociceptive withdrawal reflex responses (Hargreaves and dynamic plantar aesthesiometer) and exploratory behaviour (cylinder) and locomotion (ladder crossing and walking beam) tests and this was compared to histological analysis of the relevant CNS regions by analysis of neuronal and glial cell components. Within 2-3 weeks of CPZ feeding, mice showed hyperactivity using the grooming and rearing tests and crossed ladder more quickly compared to control mice. On both the ladder and beam tests, CPZ mice exhibited more foot slips compared to controls. In contrast, no changes in nociceptive thresholds to thermal or mechanical stimuli were seen between groups. Histological analysis showed demyelination throughout the CNS, which was most prominent in white matter tracts in the cerebrum but also elevated in areas such as the hippocampus and diencephalon. Profound demyelination and gliosis was seen in the cerebellar peduncles, deep cerebellar nuclei and brainstem regions associated with the vestibular system. However, in the spinal cord changes were minimal. No loss of neurons (assessed by neuronal nuclei protein, NeuN) or motoneurons (assessed by choline acetyl transferase, ChAT) staining was found but a significant increase in astrocyte staining (seen with glial fibrillary acid protein, GFAP) was seen throughout the white matter tracts of all levels of the spinal cord. The results suggest that CPZ induces subtle motor changes such as ataxia and that this is associated with deficits in CNS regions associated with motor and balance functions such as the cerebellum and brainstem. This study also provides the first comprehensive histological analysis of demyelination and gliosis in the CNS of CPZ-treated mice.

Title: Overexpression of catalase in mitochondria mitigates changes in inflammatory cytokine levels in the mouse hippocampus due to simulated microgravity and social isolation

Authors: *L. RUBINSTEIN[1], A.-S. SCHREURS[2], C. TAHIMIC[2], S. STEZINA[2], S. THORES[2], M. LOWE[2], A. RONCA[2], R. GLOBUS[2];
[1]NASA Ames Res. Ctr., Mountain View, CA; [2]NASA, Mountain View, CA

Abstract: Spaceflight missions are becoming longer and the physiological toll these missions have on human health is high. Aging, sedentary lifestyle, and spaceflight have degenerative effects on multiple systems, including CNS deficits, and immune dysfunction. We hypothesize that prolonged exposure to the spaceflight environment leads to accumulation of oxidative damage which may lead to neurodegeneration. We used the hindlimb unloading (HU) model to simulate weightlessness in wildtype or transgenic mCAT mice, overexpression human catalase in the mitochondria. HU model is typically conducted in single housing conditions. Since mice are social animals, a social HU model was developed in our lab, enabling us to determine the effects of both social isolation and simulated microgravity. Responses to 30 day of HU were assessed: abundance of 4-Hydroxynonenal (4HNE),Park7,cytokine Luminex array in the hippocampus and in plasma and behavioral data was collected. The analysis of behavior patterns showed that mCAT HU mice were more active and conducted more exploratory activities compared to normally loaded mice. Simulated microgravity and/or social isolation both caused changes in patterns of cytokine protein expression in the hippocampus and in plasma. Two-way ANOVA revealed significant interaction effects of HU and genotype in expression levels of five cytokines (out of 35) amongst socially-housed animals in the hippocampus. Interestingly, elevation of these generally pro-inflammatory cytokines by HU in WT mice was mitigated in MCAT mice, suggesting a role for mitochondrial ROS signaling in inflammatory CNS responses to microgravity. Socially housed mice had lower level of 4HNE in the hippocampus compared to singly housed animals. Substantive cytokine hippocampal changes were observed in the socially isolated mice; protein abundance of 15 cytokines, was significantly higher in single vs social housed animals. This effect was mitigated in MCAT mice, implicating the importance of mitochondrial ROS in social isolation. The cytokine responses to social isolation were more extensive in brain vs plasma. Interestingly, there was no overlap in cytokine responses to microgravity and isolation suggesting two separate mechanisms were involved in response to these stressors. Taken together, our results showed that both simulated microgravity and social isolation affected cytokine levels in the hippocampus and plasma and MCAT mice were at least partially protected from these changes. These findings implicate a potentially important role for mitochondrial ROS in CNS responses to the challenges posed both by prolonged missions in space and bedrest on Earth.

Title: TNF-alpha, IL-1 beta and myeloperoxidase inhibition contribute to the analgesic and anti-inflammatory curative effects of the aqueous and methanol extracts of paullinia pinnata (sapindaceae) in septic mono-arthritis in rats

Authors: *P. T. TSEUGUEM PUM[1], A. NGANGOUM MOUGA[1], M. KENFACK TSAGUE[1], B. KOLBER[2], K. TIDGEWELL[2], T. NGUELEFACK[1];
[1]Univ. of Dschang, Dschang, Cameroon; [2]Duquesne Univ., Pittsburgh, PA

Abstract: Our previous study showed that the aqueous (AEPP) and methanol (MEPP) extracts from the leaves of *Paullinia pinnata* possess preventive anti-arthritic effects but whether it could treat well established arthritis was still unknown. This work was undertaken to evaluate the curative effect of AEPP and MEPP on Complete Freud's Adjuvant (CFA) induced septic mono-arthritis (SM-A).
SM-A was induced by injecting 50 µl of CFA in the left hind ankle of each rats and *P. pinnata* extracts were administered orally at the doses of 100 and 200 mg/kg for 16th days, starting on the 7th day after CFA injection. Methotrexate (250 µg/kg) was used as reference drug. Hyperalgesia and inflammation were monitored for 24 hours after the first treatment (acute) or for 16 days from the beginning of the treatment (chronic). At the end of the experiment, plasma samples were collected for TNF-α and IL-1β assays. The synovial liquid was collected for MPO quantification and the histo-morphology of the injected ankle was also assessed.
Treatment with the AEPP and MEPP significantly ($p<0.001$) and dose-dependently reduced CFA-induced hyperalgesia by up to 65.6%. *P. pinnata* extracts significantly reduced the ankle/paw oedema with a maximal effect observed at the 4th hour after administration. In the chronic treatment, both extracts induced significant and time-dependent antihyperalgesic and anti-inflammatory effect with up to 97.8% inhibition of pain and complete resorption of inflammation. AEPP and MPP significantly ($p<0.01$) inhibited plasma TNF-α by 51.5%. At all the doses used, both extracts significantly ($p<0.001$) reduced IL-1β by up to 88% and MPO by 90%. *P. pinnata* extracts improved tissue reorganization in treated SM-A rats.
These results shows that *P. pinnata's* leaves extracts possess curative effects against CFA-induced SM-A. The inhibition of TNF-α, IL-1β and the reduction of inflammatory cells infiltration may contribute to these activities.

Title: Neuroimmunological characterization of a mouse model of primary progressive multiple sclerosis and effects of immunosuppressive or neuroprotective strategies on disease evolution

Authors: *G. RANIERI, D. BUONVICINO, S. PRATESI, D. GUASTI, A. CHIARUGI; Univ. of Florence, Florence, Italy

Abstract: Progressive multiple sclerosis (PMS) is a devastating disorder sustained by unknown neuroimmune interactions. Recently, immune-independent, neural bioenergetic derangements have been hypothesized as causative of neurodegeneration in PMS patients. To gather information on the immune and neurodegenerative components during PMS, in the present study we investigated the molecular and cellular events occurring in the NOD mouse model of experimental autoimmune encephalomyelitis (EAE). In these mice, we also evaluated the effects of clinically-relevant immunosuppressive (dexamethasone) or bioenergetic (bezafibrate and biotin) drugs on functional, immune and neuropathological parameters. We found that disease evolution in NOD mice is similar to that of the clinical form of primary PMS, and is characterized by severe neurodegeneration in the spinal cord. Unexpectedly, although CD4 and CD8 lymphocytes but not B or NK cells infiltrate the spinal cord linearly with time, their suppression by different dexamethasone treatment schedules does not affect disease progression. Even the spreading of the autoimmune response towards new immunogenic myelin antigens occurs neither in the periphery nor in the CNS of EAE mice. Conversely, we found that mitochondrial dysfunctions evidenced by altered morphology, reduced contents of mtDNA and decreased transcript levels for respiratory complex subunits occur at early disease stages and precede axonal degeneration within spinal cord columns. However, the mitochondria boosting drugs bezafibrate and biotin are unable to reduce disability progression. Overall, for the first time we show that EAE in NOD mice is featured by early CNS mitochondrial dysfunctions and neuroimmune infiltrates at least in part secondary to neurodegeneration. Data suggest that the EAE NOD mouse model recapitulates primary PMS, and can be harnessed to identify innovative therapies to counteract disease progression.

Title: Dimethylfumarate plays a protective role against migraine in nitroglycerin-treated mice

Authors: *E. ESPOSITO, G. CASILI, M. LANZA, A. FILIPPONE, I. PATERNITI, M. CAMPOLO, S. CUZZOCREA;
Univ. of Messina, Messina, Italy

Abstract: Migraine is a primary headache disorder characterized by recurring, episodic, and unilateral throbbing pain in the head. Cutaneous hyperalgesia occurs during migraine attacks, and is a risk factor for the recurrent attack and chronification of migraine. Exploring the potential mechanisms of this feature may warrant preventive treatment strategies. Systemic administration of NTG causes a delayed spontaneous headache attack. It has been found that the nuclear factor E2-related factor 2/antioxidant response element (Nrf2/ARE) pathway is the most important endogenous antioxidant defense system. However, the role of Nrf2/ARE pathway in hyperalgesia in migraine remains unclear. Thus, the aim of this study was to investigate the involvement of Nrf2/ARE pathway in NTG-induced hyperalgesia.Mice were orally administered dimethylfumarate (DMF) at the doses of 10-100 mg/kg, 5 minutes after NTG intraperitoneal injections. The expression levels of NF-B p65, IκBα, iNOS, COX-2, Nrf-2, Mn-SOD, HO-1 HO, and NQO1 in the trigeminal nucleus caudalis (TNC), were detected by Western blot. Tail flick, hot plate, formalin and photophobia tests were used to evaluate neuropathic pain and migraine-related light sensitivity.DMF upregulated downstream HO1 and NQO1, suppressed TGVS activation, and ameliorated the decrease of tactile thresholds in NTG-induced mice. Our findings indicated that DMF was involved in anti-hyperalgesia through Nrf2/ARE pathway. In addition, the anti-inflammatory effect of DMF, reducing the production of proinflammatory cytokines and microglia activation, may contribute to its role in migraine treatment.Our data provides a novel insight into the potential application of antioxidants as novel candidates in drug development for migraine.

Title: miRNA regulation in early inflammatory signals induced by hypoxic ischemia encephalopathy in neonates

Authors: *T. C. HILLMAN, L. SIEBOLD, J. A. ABDALA, C. G. WILSON;
Dept. of Perinatal Biol., Loma Linda Univ., Loma Linda, CA

Abstract: Hypoxic ischemic encephalopathy (HIE) is a devastating perinatal injury which claims the lives of millions and leaves thousands more with long-term morbidities. Post-HIE insult, an inflammatory response occurs resulting in a cascade of additional damage to the neural circuits surrounding the primary location of insult. Three stages characterize this response: latent (0 to ~12 hours), secondary (12 hours to 3 days) and tertiary (3 days to months). While current therapies work to slow down inflammation (i.e., hypothermia), little is known about the expression and regulation of cytokines during the early inflammatory response (0 - 12 hours). Understanding the early inflammatory response provides a target for treatment of high-risk neonates. Using *Cytoscape* and *Targetscan*, we found that four miRNA targets (miR-155, 146a, 124 and 210) play a key role in neuroinflammation in stroke. We hypothesize that the decreased levels of miR-155, 146a and 124 in HIE increase early pro-inflammatory signaling and promote inflammation immediately following HIE insult. To test this hypothesis, we will analyze cytokine profiles using Western blot and *LEGENDplex* at 1, 2, 6, 9 and 12 hours in Rice-Vannucci (RV) and intrauterine occlusion hypoxia (IUO-H) models. Total tissue samples, isolated from cerebral cortex and hippocampus will be processed using *Qiagen* kits for both miRNA and protein isolation. Expression profiles of both pro-inflammatory and anti-inflammatory cytokines will show a peak in early inflammatory cytokines and allow us to identify key cytokines involved in the early inflammatory response. Additionally, we will determine the role of maternal factors in IUO-H surgery on the expression of cytokine profiles post-HIE insult. Cytokine profiles will provide key expression peaks for pro-inflammatory and anti-inflammatory cytokines post insult. These studies hold the promise of interventional therapy to alleviate the impact of HIE in neonates.

Title: The use of curcumin encapsulated dendrimer nanoparticles as anti-inflammatory agents for glioblastoma therapy in C57BL/6J mice

Authors: *N. MUNRO;
Central Michigan Univ., Mount Pleasant, MI

Abstract: Glioblastoma (GB) is an aggressive form of brain tumor. Currently there are no viable treatment options outside of radiation and chemotherapy for this disease. Less than 30% of patients with GB live two years post-diagnosis. GB is known to cause significant inflammation leading to increase in tumor size and metastasis. Therefore, reducing inflammation in GB could be a potential therapy for the cancer. We are utilizing dendrimer nanoparticles (D) with curcumin (a known phytochemical having anti-inflammatory property) encapsulated within the dendrimers. Dendrimers are multi-branched, star-shaped macromolecules with nanometer-scale dimensions. Dendrimers can be defined by three components. The first being a central core, the second being an interior dendritic structure (the branches), and finally an exterior surface with functional surface groups. What makes dendrimers potentially very useful for the treatment of many diseases is that fact that the shielded interior cores can carry cargo within them. For this study, we used Cystamine core (S=S) dendrimer, which has the ability to split in two to dendrons (halves) in the presence of glutathione, which is present at high concentrations in the GB cells. This will enable the curcumin cargo to be delivered within the GB cells thereby rendering their anti-inflammatory properties. WIn addition to Curcumin, when the dendrimer splits, it is converted into its reduced form and forms thiol groups (-SH), having the anti-inflammatory effect. Our *in vitro* study showed that curcumin causes GB cell death while specifically sparing other types of cell such as stem cells and neurons at certain concentrations. In addition, we have showed that Curcumin as well as the cystamine dendrimers show anti-inflammatory effects in cells. OFollowing this, our *in vivo* study involved use of mice having tumor induced by Gl261 cells. Following treatment with dendrimers and dendrimer encapsulated curcumin showed a decrease in astrocytes within the brain suggesting a decrease in inflammation around the tumor site; a decrease in the amount of activated microglia within the brain, also suggesting a decrease in inflammation; and a significant increase in lifespan of mice with GB. Overall our study shows that the use of curcumin encapsulated dendrimer nanoparticles is a viable treatment for GB due to the anti-inflammatory effect and longer lifespan that has been observed.

Title: Study of a new analogue of paroxetine 3HPSS in a model of depression induced by lipopolysaccharide

Authors: P. HERNÁNDEZ-ARRAMBIDE, D. CHAMORRO-ARENAS, I. PARRA, I. MARTÍNEZ, F. LUNA, I. D. LIMÓN, V. ALATRISTE, L. QUINTERO, S. CRUZ-GREGORIO, R. MEZA-LEÓN, F. SARTILLO-PISCIL, *L. MARTINEZ MENDIETA; Benemérita Univ. Autónoma de Puebla, Puebla, Mexico

Abstract: Depression is a common psychiatric disorder with a complex and multifactorial etiology, according to WHO, 2018 around 300 million people around the world suffer from it. The study of diseases such as depression in animal models is of great interest to clarify the processes that underlie it, in the same way, the use of drugs in these models helps the development of new therapeutic targets. As a treatment in depression, paroxetine, a selective inhibitor of serotonin reuptake, has shown better results in comparison with other antidepressants. Due to the importance of the development of new drugs, we designed and synthesized a new analog of paroxetine, which is named 3HPSS. Our objective was to evaluate the possible antidepressant and neuroprotective effects of the paroxetine analog in an animal model of depressive behavior. Adult male Wistar rats 280-330g received an injection of LPS [32µg / 2µl] into the dorsolateral striatum by stereotaxic surgery. Animals with LPS received saline, paroxetine or 3HPSS (10 mg/kg i.p. x14 days) the depressive behaviors were evaluated in sucrose preference test, cylinder model, open field and forced swimming, as well as the expression of TH and Caspase-3 in the nigrostriatal pathway. Rats injured with LPS and treated with the paroxetine analog, showed a decrease in depressive behaviors, as well as motor asymmetry. Also, animals treated with LPS had a lower TH-ir and major expression of Caspase-3 in nigrostriatal pathway. The treatment with 3HPSS reduces depressive behavior and motor asymmetry. Moreover, the immunoreactivity to TH and Nurr-1 was improved by 3HPSS treatment. In summary, the new analog of paroxetine, 3HPSS has a high-potential as anti-depressive in the LPS - model.

Title: Characterization of the immune response to sciatic nerve injury: Implications for sensory axon growth and regeneration

Authors: *A. L. KALINSKI[1], C. YOON[2], P. DUNCKER[2], L. HUFFMAN[2], J. ATKINSON[2], B. SEGAL[2], R. GIGER[2];
[1]Univ. of Michigan, Ann Arbor, MI; [2]Univ. of Michigan Med. Sch., Ann Arbor, MI

Abstract: To investigate the immune response to sciatic nerve injury (SNI), adult C57BL/6 mice were subjected to a mid-thigh crush injury. To assess the presence, abundance and phenotypes of immune cells that respond to SNI, we used immunofluorescence staining of tissue sections combined with flow cytometry of *(i)* lumbar DRGs, *(ii)* the proximal nerve stump, *(iii)* the distal nerve stump, and *(iv)* the spinal cord. Changes in SNI-induced gene expression were assessed by RNA-sequencing of DRGs and NanoString analysis of FACS isolated immune cells from injured nerve tissue. As an orthogonal method we measured cytokine and chemokine levels in the nerve and DRGs by luminex. The principal findings are as follows: Neutrophils are the first responders to SNI, they rapidly swarm into the injury site and distal nerve stump, peak around 24 hours, and disappear by 3 days following SNI. Monocytes/macrophages arrive later, peak around day 3 and show a significant decline 7 days post-SNI. Dendritic cells and lymphocytes responded more slowly and gradually increase in the distal nerve. Inflammation in the proximal nerve and DRGs is comparatively mild; with a modest increase in monocytes/macrophages. Experiments with wildtype/TdTomato parabiotic mice revealed that blood-derived immune cells infiltrate the crush site and distal nerve stump, but are largely absent from the proximal nerve, DRGs and lumbar spinal cord. Consistent with flow cytometry, RNA-seq revealed a modest increase in immune cell specific transcripts in de-afferented DRGs. In a similar vein, few cytokines and chemokines show a significant increase in de-afferented DRGs, but they are strongly upregulated in the injured nerve. The monocyte/macrophage population in the injured nerve is highly heterogeneous: cells show a pro-inflammatory $Ly6C^{high}$ phenotype on day 1 that gradually changes to a $Ly6C^{low}$ phenotype on day 3 and day 7 post injury. Ingenuity pathway analysis of RNA-seq data identified GM-CSF (Csf2) as a top regulator of SNI triggered inflammation. In Csf2 knock-out mice, maturation of $Ly6C^{high}$ to $Ly6C^{low}$ monocytes/macrophages is attenuated and conditioning injury induced regeneration of ascending sensory axons in the dorsal columns is significantly compromised when compared to wildtype mice. Collectively, our studies show that SNI triggers a sterile immune response reminiscent of the immune response to injured non-neural tissues, and when perturbed, as in Csf2 KO mice, leads to defects in axon regeneration. Our studies underscore the importance of a carefully orchestrated immune response to successful nervous tissue regeneration.

Title: Neuroprotective effect of dimethylfumarate on oxaliplatin-induced neuropathic pain

Authors: *M. CAMPOLO[1], G. CASILI[1], I. PATERNITI[1], A. FILIPPONE[1], M. LANZA[1], S. CUZZOCREA[1], E. ESPOSITO[2];

Abstract: Introduction: Chemotherapy-induced neuropathy is a common, dose-dependent adverse effect of several antineoplastics, like oxaliplatin. It can lead to detrimental dose reductions and discontinuation of treatment, and severely affects the quality of life of cancer survivors.Fumaric acid esters (FAEs) showed beneficial effects in pre-clinical models of neuroinflammation and toxic oxidative stress, so the aim of the present work was to evaluate the potential beneficial effects of dimethyl fumarate (DMF), the most pharmacologically effective molecules among the FAEs,in a model of oxaliplatin-induced peripheral neuropathy.**Materials and methods:**Chemotherapic pain was induced by an intraperitoneally injection of oxaliplatin (oxa) in rats on 5 consecutive days (D0-4) at an injection volume of 0.2 ml for a final cumulative dose of 10 mg/kg. In prophylactic paradigms, DMF was given orally 15-20 min prior oxa. Sacrifice was made on day 25.**Results:**Our results demonstrated that oxaliplatin developed mechano-hypersensitivity (allodynia and hyperalgesia) in rats; this was associated with the hyperactivation of astrocytes and an increased production of pro-inflammatory cytokines (IL-1β and TNF) in the dorsal horn of the spinal cord. Moreover, we showed that oxaliplatin activated NFkB pathway and modulated Nrf-2 ones. The oral injection of DMF attenuated inflammatory and oxidative process, decreasing neuropathic pain.**Discussion and conclusion:**Our findings identify DMF as a therapeutic target in chemotherapy-induced painful neuropathy, throughout the biomolecular signaling NF-κB/Nrf-2 axis. Therefore, we can consider DMF as a promising adjunct to chemoterapy to reduce chronic pain in patients.

Title: Aluminum exposure linked to neurodegeneration in honey bees (Apis mellifera spp.)

Authors: *A. CHICAS-MOSIER[1], T. E. BLACK[2], K. P. HESTER[3], L. BELZUNCES[4], J. L. AGOSTO-RIVERA[5], C. I. ABRAMSON[2];
[1]Integrative Biol., [2]Psychology, [3]Physiol., Oklahoma State Univ., Stillwater, OK; [4]Envrn. Toxicology, Inst. Natl. de la Recherche Agronomique, Avignon, France; [5]Biol., Univ. of Puerto Rico-Rio Piedras, San Juan, PR

Abstract: Poor mining practices and soil acidification increase bioavailability and uptake of aluminum by flora. Contaminated plant tissues are then ingested by other organisms and can cause neurodegeneration by degrading acetylcholinesterase. Aluminum exposure has been implicated in the development of human brain disorders such as Alzheimer's and Parkinson's Diseases. The cholinergic system is conserved across taxa and therefore model species can be used to understand toxicant induced change. This presentation discusses captive survival, individual motility, acetylcholinesterase (AChE) enzyme activity, and brain accumulation experiments in honey bees exposed to aluminum. Captive experiments in *Apis mellifera mellifera* have shown that exposure destabilizes circadian rhythmicity, causes hyperactivity, and decreases lifespan ($p<0.0001$). These data have been corroborated by bee-head AChE enzyme activity and suggest a hormetic response in *Apis mellifera mellifera* ($p<0.0001$). However the AChE response is dependent on subspecies and some tolerance is demonstrated in *Apis mellifera ligustica*. Brain accumulation studies are not yet complete but literature suggests that bioaccumulation of aluminum occurs in bumble bee larvae. The aim of the accumulation studies is to determine if and where aluminum is stored in the bodies of honey bees. The severity of the response to aluminum exposure in completed datasets has been tied to subspecies but effects of aluminum exposure have occurred across *Apis mellifera spp.* We conclude that neurodegeneration from ingesting aluminum is likely a limiting factor to pollinator health and may contribute to population decline in insects, however further understanding of subspecies tolerance is needed. Additionally, given the cholinergic conservation across taxa; these results

indicate that neurodegeneration could occur in other species but subpopulation tolerance requires further study.

Hosp. and Harvard Univ., Charlestown, MA

Abstract: Brain aging and Alzheimer's disease demonstrate the accumulation of beta-amyloid protein plaques, tau protein tangles, and neuroinflammation. Plaques, Tangles and Inflammation (“PTI") is the trilogy that contributes directly to accelerated memory loss and cognitive decline. Over 10 years of research studies are presented that identified a specific plant extract and its constituents as a potential alternative natural solution for preventing and reducing brain plaques, tangles and inflammation. PTI-00703 cat's claw (*Uncaria tomentosa* from a specific source) is a natural plant extract from the Amazon rain forest woody vine identified as a potent inhibitor and reducer of beta-amyloid plaque fibrils, tau protein filaments/fibrils, and neuroinflammation. *In vitro* testing (Thioflavin T fluorometry, Congo red and Thioflavin S staining, electron

microscopy) showed remarkable inhibition of beta-amyloid fibril formation and tau protein filament formation, and near-instant dissolution of pre-formed plaque fibrils and tau tangles. Circular dichroism spectroscopy demonstrated a marked reduction in beta-sheet secondary folding of both beta-amyloid fibrils and tau protein paired helical filaments. Sophisticated structural elucidation studies identified the main constituents in PTI-00703 cat's claw responsible for the observed effects to be specific proanthocyanidins (i.e. epicatechin dimers and variants thereof) as newly identified polyphenolic components within *Uncaria tomentosa* that possess both plaque and tangle reducing and inhibitory activity. One major identified specific polyphenol within PTI-00703 cat's claw was epicatechin-4β-epicatechin (proanthocyanidin B2) that markedly reduced brain plaque load and improved short-term memory in younger and older APP plaque-producing TASD-41 transgenic mice (over 55% in a 3-month period). Proanthocyanidin B2 was also a potent inhibitor of brain inflammation as shown by a marked reduction in astrocytosis and microgliosis in TASD-41 transgenic mice. Cat's claw is previously known to be a potent reducer of both interleukin-1 and TNF-alpha. Blood-brain-barrier studies in Sprague-Dawley rats and CD-1 mice indicated that the major components of PTI-00703 cat's claw crossed the blood-brain-barrier and entered the brain parenchyma and cortex within 2 minutes of being in the blood (following capillary depletion methods). The discovery of a plant extract from the Amazon rain forest as a natural potent inhibitor and reducer of plaques, tangles and inflammation is postulated to represent a potential breakthrough for the non-pharmaceutical approach for brain aging and Alzheimer's disease.

Title: C1q knockout mice have elevated sensitivity to glycolipid elevations and show aberrant forms of lipidated alpha-synuclein

Authors: *O. R. BREKK, J. KORECKA, A. MOSKITES, O. ISACSON, P. J. HALLETT; McLean Hosp., Belmont, MA

Abstract: Aging is the most significant risk factor for developing genetic and sporadic neurodegenerative disorders, including Parkinson's disease (PD) and Alzheimer's disease (AD). At the level of genetics, mutations in *gba1* - encoding the lysosomal hydrolase glucocerebrosidase (GCase) - is the strongest predictor of PD risk. We have previously observed age-dependent reductions in GCase activity in PD, and normal aging of both human (Rocha et al., 2015, Ann. Clin. Trans. Neurol.) and mouse brain (Hallett & Huebecker et al., 2018, Neurobiol. Aging), with concurrent accumulation of a variety of glycosphingolipid species (GSLs), including glucosylceramide and glucosylsphingosine. Pharmacological inhibition of GCase by systemic conduritol-b-epoxide (CBE) application as a mouse model of complete GBA loss (Gaucher's-like) induces aggregation of the PD-associated protein alpha-synuclein (aSYN) with concurrent neuroinflammation and induction of the classical complement (CC) innate immunity pathway, as evident by C1q accumulation in the brain (Rocha et al., 2015, Antioxid. Redox Signal.). To assess whether lipid perturbations induced by systemic CBE application could be attenuated by inhibition of canonical CC initiation, we challenged C1q-deficient transgenic mice (C1qKO) with a 28-day chronic CBE paradigm. C1q-deficient mice showed much greater sensitization to CBE compared to WT. Western blot analysis revealed a ~4 times elevation in cleaved C5a compared to WT brains at baseline with further induction upon CBE treatment. Remarkably, at baseline and after CBE treatment, the typical monomeric, soluble aSYN was absent in both C1qKO mouse brain and red blood cells (RBCs). Instead, the C1qKO mice had the insoluble aSYN lipidated species of ~24kDa, which we have previously identified to coincide with normal aging of the mouse brain (Brekk et al., 2019). We interpret the C5a elevation as a compensation in the C1qKO mice to initiate and accelerate the complement cascade. Furthermore, the C1qKO mice have evidence at baseline for lipidation changes of aSYN that is consistent with greater sensitivity to glycosphingolipid challenges.

Title: Huntingtin mediates internalization of the TLR-4 and intracellular signaling in mast cells

Authors: *M. J. PEREZ-RODRIGUEZ[1,2], A. IBARRA-SANCHEZ[1], C. GONZALEZ-ESPINOSA[1], F. PEREZ-SEVERIANO[2];
[1]Farmacobiologia, Cinvestav, Sede Sur, Ciudad de México, Mexico; [2]Neurofarmacología Mol. y Nanotecnología, Inst. Nacional de Neurología Y Neurocirugía, Mexico, Mexico

Abstract: Mast cells (MCs) are tissue-resident immune cells that modulate local inflammatory reactions related to allergies and tissue damage. MCs are also important on immune responses against Gram-negative bacteria since, after activation of Toll-like receptor 4 (TLR-4) with bacterial lipopolysaccharide (LPS), produce Tumor Necrosis Factor (TNF) and a number of pro-inflammatory and regulatory cytokines. Despite the existing information on the molecular events that lead to the production of pro-inflammatory mediators in MCs, a detailed description of all the molecular elements involved in the phenomenon is far from being complete. Recent evidence in patients with Huntington's disease (HD) suggests that the mutated huntingtin (mHtt) modifies vesicular transport, protein trafficking, and gene expression on distinct cell types that could contribute to the pathology. However, the role of Htt in the process of cytokine secretion in MCs has not been elucidated. In this work, characterization of bone marrow-derived mast cells (BMMCs) from transgenic mice expressing mHtt (line R6/1) was performed by transmission and scanning electron microscopy. Expression of the high affinity IgE receptor (FcεRI) and TLR-4 was evaluated by flow cytometry. Secretion of inflammatory mediators by anaphylactic degranulation or the constitutive pathway was evaluated measuring the release of β-hexosaminidase after FcεRI triggering, or TNFα, IL-6 and CCL-2 production after TLR-4 activation using LPS. The results show that similar shape, size and receptor expression were found in both types of BMMCs, mHtt did not modify the anaphylactic secretion pathway but mHtt-expressing BMMCs secreted significantly less *de novo* synthesized cytokines after TLR-4 triggering. The defect on TNF production was related to the lack of intracellular trafficking of TLR4, absence of ERK1/2 phosphorylation, and TNF mRNA accumulation. The defect was proven to be relevant *in vivo*, in a MCs-dependent model of endotoxemia. Our data show, for the first time, that Huntingtin has a differential participation in the secretion of inflammatory mediators in MCs, which can be potentially relevant for inflammatory reactions in humans.

Title: The effects of a non-steroidal anti-inflammatory agent on cyclophosphamide induced changes in behavior, hippocampal neurogenesis, and neuroinflammation

Authors: *S. M. PAVLOCK[1], A. KESARWANI[1], D. M. MC CARTHY[2], P. JEAN-PIERRE[3], P. G. BHIDE[1];
[1]Biomed. Sci., [3]Behavioral Sci. and Social Med., [2]Florida State Univ. Col. of Med., Tallahassee, FL

Abstract: Breast cancer is one of the most commonly diagnosed cancers among U.S. women. Breast cancer patients undergoing chemotherapy report behavioral deficits including depression, anxiety, and memory loss, collectively referred to as “chemo brain.” In addition, inflammatory biomarkers are upregulated in breast cancer patients undergoing chemotherapy suggesting that neuroinflammation contributes to “chemo brain”. We hypothesized that anti-inflammatory drugs alleviate chemotherapy-induced behavioral deficits by mitigating neuroinflammation. Intact and ovariectomized female C57Bl/6 mice were placed on a diet containing naproxen (375 ppm), a non-steroidal anti-inflammatory drug, or on a control diet. One-week later cyclophosphamide (CP), a chemotherapy drug that crosses the blood brain barrier was administered (100 mg/kg; i.p.) every 3 days for 2 weeks. Mice were tested in the elevated zero maze (anxiety-like behavior), the Y-maze (spatial working memory), tail suspension test (depression), and a photobeam home-cage activity monitoring system (exploratory behavior and locomotor activity). Following the behavioral testing, the mice were administered bromodeoxyuridine (BrdU; 50 mg/kg, i.p) every 12 hours for 2.5 days. Upon sacrifice, trunk blood and hippocampi were collected to analyze cytokines and hippocampal neurogenesis. All groups of mice displayed significant anxiety-like phenotype. CP decreased exploratory behavior and spontaneous locomotor activity, and naproxen restored both these behaviors to baseline. CP, ovariectomy or naproxen did not produce significant effects on any other behavioral phenotypes. There was a significant CP x ovariectomy interaction on depression-like behavior, with CP producing opposite effects on intact versus ovariectomized mice. Ovariectomy reduced multiple cytokines in the hippocampus and the effect was independent of CP. Hippocampal IL-10 level was significantly influenced by CP. There was a significant CP X naproxen interaction for IL-1α, IL-12p70, IL-2, IL-3 and IL-10. CP decreased BrdU+ cells in the dentate gyrus and decreased

hippocampal volume. Unexpectedly, cytokine levels were increased by naproxen in CP-exposed mice suggesting that neuroinflammation induced by CP was heightened by naproxen. Thus, our data show that CP contributes to chemo brain by producing significant changes in behavior, neuroinflammation and hippocampal neurogenesis. These changes occur in the absence of cancer, and they may be influenced by hormonal factors.

Title: Studying the role of toxoplasma effector protein GRA15 in the CNS

Authors: *S. KUMAR, A. A. KOSHY, J. A. KOCHANOWSKY;
Univ. of Arizona, Tucson, AZ

Abstract: *Toxoplasma gondii* is an intracellular parasite that causes a chronic, asymptomatic infection of the central nervous system (CNS) in up to 1/3 of the human population. In the immunocompromised, this CNS infection can be fatal. Like most intracellular pathogens, *T. gondii* highly manipulates host cells through the secretion of effector proteins that target host signaling pathways. Some of these effector proteins are polymorphic between different *T. gondii* strains leading to *T. gondii* strain-specific manipulations of host cells. For example, dense granule protein 15 from a type II *T. gondii* strain ($GRA15_{II}$), but not from a type I or type III strain, activates the NFκB pathway in macrophages, leading to strain-specific differences in macrophage polarization. Though the impact of GRA15 has been studied *in vivo* in acute infection, no studies have addressed how $GRA15_{II}$ might affect CNS host cells or the CNS immune microenvironment.
To determine the role of GRA15 in persistent infection, we used CRISPR/Cas9 to generate a type II GRA15 knockout (IIΔ*gra15*) that also secretes Cre recombinase fusion protein (IIΔ*gra15:TCre*) into host cells early in invasion. The IIΔ*gra15:TCre* strain was validated to no longer activate NFκB and be capable of causing Cre-mediated recombination. We then used this strain and a wild-type type II:*TCre* strain to infect mice that express a green fluorescent protein (GFP) only after Cre-mediated recombination, allowing us to track CNS cells injected with the *T. gondii* protein *in vivo*. At three weeks post infection, the brains were harvested and analyzed for several parameters including: the number of GFP^+ neurons, the number of infiltrating T cells and macrophages, and the brain parasite burden. To date, our preliminary data has revealed that compared to the infection with the II:*TCre* strain, the IIΔ*gra15:TCre* strain: i) fails to activate

NFκB, ii) has less dissemination to the CNS, and iii) has a lower CNS parasite burden. Current studies we will perform include a cyst count that will quantify the number of live parasites as the qPCR for B1 picks up all, whether the parasite is alive or dead. We are also generating the complement strain to determine if the original effects of the *gra15* locus are shown. Lastly, we will infect neurons with the II:*TCre* strain and stain for NFκB to determine if the same effects occur in this cell type. Performing these studies will continue to allow us to determine the role of GRA15 on *T. gondii's* ability to disseminate to the brain, establish a chronic infection in the brain, and provoke a CNS immune response.

Title: Aging modulates inflammatory and behavioral responses to a tumor

Authors: *L. D. STREHLE, A. A. LAHOUD, J. KAUR, J. J. KRUEPKE, J. M. JOHNSON, R. M. BARRIENTOS, L. M. PYTER;
Inst. for Behavioral Med. Res., The Ohio State Univ., Columbus, OH

Abstract: Breast cancer is the most common cancer among women, with the median age of diagnosis being 62. These patients report persistent behavioral issues (mood disorders, cognitive decline), as well as elevations in circulating inflammatory markers. Despite the clinical population consisting primarily of women who have already gone through menopause, few rodent cancer models by which to study underlying mechanisms incorporate aging into their models. Aging and tumors independently increase inflammation and induce anxiety-like behavior and cognitive deficits in rodent models; therefore, we predicted that aging would further exacerbate tumor effects on these endpoints. Aged female balb/c mice (16-17 months old) were ovariectomized (to simulate hormonal menopause); young adult female mice (3-4 months old) with intact ovaries served as controls. Half of the aged mice and half of the young adult mice were orthotopically inoculated with non-metastatic mammary tumor cells; controls underwent a sham surgery. Mice were tested 2.5 weeks following surgery, using a battery of standardized behavioral tests to assess cognitive performance and affective-like behavior (tail suspension test). Blood, tumors, and brain tissue were then collected. Tumors in young mice grow more quickly than in aged mice. Using PCR arrays of hippocampal tissue, tumors in aged

mice increased inflammatory gene expression (*Il-1B, Il-6*), whereas protein concentrations of the same markers decreased. In parallel, tumors decreased immobility in the aged mice only during the tail suspension test. Regardless of age, tumors increased circulating levels of cytokines and chemokines in the blood (Il-2, Il-10, Cxcl1). These results suggest that cancer modulates inflammatory pathways and hippocampal translational mechanisms in an age-dependent manner, indicating the importance of utilizing aged models in understanding breast cancer and its effects.

Title: Small molecule ONC201 inhibits HIV-1 replication in brain macrophages via FOXO3a and TRAIL

Authors: *Y. HUANG[1], R. ZHAO[1], Y. LI[1,2], J. ZHENG[2];
[1]Univ. Nebraska Med. Ctr., Omaha, NE; [2]Ctr. for Translational Neurodegeneration and Regenerative Therapy, Shanghai Tenth People's Hosp. Affiliated to Tongji Univ. Sch. of Med., Shanghai, China

Abstract: Despite the success of antiretroviral therapy (ART), eradication of HIV-1 from brain reservoirs remains elusive. HIV-1 brain reservoirs include perivascular macrophages that are behind the blood-brain barrier and difficult to access by ART. Macrophages express transcription factor FOXO3a and the TNF superfamily cytokine TRAIL, which are known to target HIV-1-infected macrophages for viral suppression. ONC201 is a novel and potent FOXO3a activator capable of inducing TRAIL. It can cross the blood-brain barrier, and has shown an antitumor effect in clinical trials. We hypothesized that activation of FOXO3a/TRAIL by ONC201 will reduce the size of HIV-1 brain reservoirs. Using primary human monocyte-derived macrophages, we demonstrated that ONC201 dose-dependently decreased HIV-1 replication levels as determined by HIV-1 reverse transcriptase activity assay and Western blots for p24. Consistent with data on HIV-1 replication, ONC201 also reduced integrated HIV-1 DNA in infected macrophages in two-step Alu-based nested PCR. Blocking TRAIL or knockdown of FOXO3a with siRNA reversed ONC201-mediated HIV-1 suppression, suggesting that ONC201 inhibits

HIV-1 through FOXO3a and TRAIL. The anti-HIV-1 effect of ONC201 was further validated *in vivo* in NOD/scid-IL-2Rgcnull mice. After intracranial injection of HIV-1-infected macrophages into the basal ganglia, we treated the mice daily with ONC201 through intraperitoneal injection for 6 days. ONC201 significantly decreased p24 levels in both the macrophages and the brain tissues, suggesting that ONC201 suppresses HIV-1 *in vivo*. Therefore, ONC201 can be a promising drug candidate to combat persistent HIV-1 infection in the brain reservoirs.

Title: Differential effects of piroxicam versus minocycline on acute lipopolysaccharide-induced sickness behavior and slow wave EEG activity in young c57bl6 mice

Authors: *Z. W. SULTAN, B. M. KRAUSE, S. M. GRADY, C. A. MURPHY, R. D. SANDERS, M. I. BANKS;
Sch. of Med. and Publ. Hlth. - Dept. of Anesthesiol., Univ. of Wisconsin-Madison, Madison, WI

Abstract: Targeting inflammatory pathways may underlie successful therapies for postoperative delirium. Previously, we have shown bacterial lipopolysaccharide (LPS) given intraperitoneally increases cortical slow wave activity (SWA) during wakefulness in normal C57BL/6 mice, recapitulating electrophysiological signs of delirium. Here we demonstrate that piroxicam, a COX inhibitor, attenuates this LPS response in mice while minocycline, a tetracycline, does not. We evaluated the effects of piroxicam (10 mg/kg) or minocycline (50 mg/kg) treatment on the response to LPS (25 μg/kg) in 4-month old adult C57BL/6 mice. All experiments lasted 6 hours, with IP injections of treatment or vehicle administered after hour 1 and LPS after hour 2. Minocycline/vehicle or piroxicam/vehicle pre-treatment began 2 days and 1 day prior to LPS administration, respectively. Behavioral effects of LPS +/- treatment were assayed by monitoring activity levels, derived from luminance changes in the video signal. Two sets of experiments were performed: 1) behavior-only (n = 16) and 2) simultaneous EEG and behavior (n = 7). In behavioral experiments, mice received minocycline/vehicle or piroxicam/vehicle (n=4 each). In EEG experiments, animals were chronically implanted with skull screws to record cortical activity during behavior (n=3 minocycline, n=4 piroxicam). We compared changes in animal activity and slope of the least-squares fit between 4-second windows of movement and 1-4 Hz power spectral density over hours 4 & 5 relative to hour 1 (baseline).

Animal movement decreased in hours 2 & 3 after LPS injection (95, 96, and 81% decreases from baseline for vehicle, minocycline, and piroxicam, respectively). Piroxicam rescued activity in hour 4 after LPS (7% decrease from baseline compared to 93 and 94% for vehicle and minocycline). Following LPS treatment, the piroxicam group showed smaller increases in slope [mean (SD) frontal channels: 0.26 (0.12); parietal: -0.02 (0.11)] compared to minocycline [0.98 (0.33); 0.53 (0.22)].
These results suggest piroxicam, but not minocycline, attenuates the LPS-driven decrease in activity and increase in SWA during movement in mice. In the future we will seek to understand the neural mediators underlying the relationship between wakeful SWA and systemic inflammation.

Title: Impact of prenatal ZIKV infection on the development of hippocampal and cortical structures

Authors: *R. T. PATEL[1], M. L. SHERER[2], N. A. HAAS[1], M. PARCELLS[3], J. M. SCHWARZ[4];
[2]Psychology, [3]Animal and Food Sci., [4]Psychological and Brain Sci., [1]Univ. of Delaware, Newark, DE

Abstract: The widespread epidemic of Zika infection (ZIKV) first reported in the Americas, has uncovered the devastating impact of ZIKV infection especially in pregnant women. ZIKV has emerged as a major challenge for global health agencies due to its ability to cause congenital Zika syndrome which is characterized by brain abnormalities and microcephaly in neonates as well as cognitive developmental challenges in young children. Although, the causal link between ZIKV prenatal infection and serious brain abnormalities seems unquestionable, present findings only offer a limited scope of ZIKV pathogenicity. Pediatricians are now reporting an increased risk of seizures, irritability, and cognitive developmental delays in ZIKV affected children, some of whom appeared asymptomatic at birth Currently, our lab has developed a rat model of prenatal ZIKV infection which results in vertical transmission of the virus to the fetus, produces a significant febrile response in the dams, and a significant increase in cell death in the cortex and hippocampus of surviving affected offspring. Using our model in conjunction with functional magnetic resonance imaging, a non-invasive technique of MRI, we hope to identify

early on which offspring are at later risk for developmental delays in learning so that we can target these individuals for therapeutic interventions. In this study, we find that fMRI shows subtle but significant maturational changes in specific brain regions. This model will allow us to better understand 1) how structural changes in the brain correlate with active infection, 2) when these changes begin to emerge during development, and 3) how they may correlate with or predict the onset of deficits in learning and memory. We demonstrate that prenatal ZIKV infection significantly affects neurodevelopment, suggesting that long-term clinical monitoring of pediatric cases is warranted.

Title: [^{11}C]PIB PET imaging can detect white and grey matter demyelination in a non-human primate model of progressive multiple sclerosis

Authors: *C. C. REAL[1], R. H. CARVALHO[1], S. CININI[2], A. T. GARCEZ[1], F. L. S. DURAN[1], F. L. N. MARQUES[1], L. E. MELLO[2], G. BUSATTO FILHO[1], E. F. J. DE VRIES[3], L. R. G. BRITTO[4], C. A. BUCHPIGUEL[1], D. DE PAULA FARIA[1];
[1]Faculdade de Medicina da Univ. de Sao Paulo, Sao Paulo, Brazil; [2]Escola Paulista de Medicina, Univ. Federal de Sao Paulo, Sao Paulo, Brazil; [3]Univ. Med. Ctr. Groningen, Gronigen, Netherlands; [4]Univ. de Sao Paulo, Sao Paulo, Brazil

Abstract: Multiple sclerosis (MS) is a demyelinating and inflammatory disease of the central nervous system. Its diagnosis is clinical, and confirmed by magnetic resonance imaging that is not ideal for discrimination of white or grey demyelination from inflammatory lesions. Positron Emission Tomography (PET), using specific radiopharmaceuticals, can be a tool to differentiate between these processes. [^{11}C]PIB PET is widely used for detection of β-amyloid plaques, but has also been suggested for the analysis of myelin content due to white matter uptake. The aim of this study was to evaluate [^{11}C]PIB PET imaging as a tool for detecting demyelinated regions in white and grey matter of non-human primate model of progressive MS. Experimental autoimmune encephalomyelitis (EAE) was induced in marmosets by injection of recombinant

human myelin oligodendrocyte glycoprotein (rhMOG) emulsified in either Incomplete Freund's Adjuvant (IFA) or Complete Freund's Adjuvant (CFA). The animals were evaluated for neurological signs. [^{11}C]PIB PET images were acquired prior to immunization (baseline) and after the appearance of signs of the disease (end of experiment). Brain tissue was isolated for histological analysis by luxol fast blue and *in vitro* autoradiography with [^{11}C]PIB. PET image analysis was performed with PMOD© 3.4 software. The scans were manually co-registered to a T2 weighted magnetic resonance imaging (MRI) template for marmoset. Volumes of interest for 39 brain regions were drawn on the MRI based on the marmoset brain atlas. All experiments were approved by the Ethical Committee (FMUSP 056/15). All rhMOG/IFA-treated and rhMOG/CFA-treated animals showed clinical signs of EAE, with different aggressiveness. In general, immunization with rhMOG/IFA resulted in a less aggressive EAE model. The body weight loss was significantly higher after immunization with rhMOG/CFA (8.2%, P=0.03). The rhMOG/CFA group presented a significant [^{11}C]PIB uptake reduction only in the left motor cortex (-9.5 %, P=0.008). For the rhMOG/IFA group, significant regional unilateral decreases in [^{11}C]PIB uptake in the right hemisphere of the brain were observed in the splenium of corpus callosum (-38.4 %, P = 0.04), globus pallidus (-22.9%, P=0.04) and tail of the caudate nucleus (-28.9 %, P=0.03). [^{11}C]PIB uptake significantly correlated with luxol fast blue histology (myelin marker), both in the rhMOG/IFA (r^2= 0.32, P < 0.0001) and the rhMOG/CFA group (r^2= 0.46, P < 0.0001). In addition, *in vitro* autoradiography corroborated PET image analyses. [^{11}C]PIB PET imaging is an efficient tool for detecting demyelination in grey and white matter, in a non-human primate model of progressive MS.

Title: Transcriptional changes in mouse amygdala and hippocampus after exposure to firefighting overhaul environment

Authors: *S. A. KRAUKLIS[1], S. J. GAINEY[2], J. DRNEVICH[3], A. E. TOWERS[4], S. KERBER[6], D. L. SMITH[7], K. W. FENT[8], G. P. HORN[5], G. G. FREUND[4];
[1]Div. of Nutritional Sci., [2]Dept. of Animal Sci., [3]Roy J. Carver Biotech. Ctr., [4]Dept. of

Pathology, [5]Illinois Fire Service Inst., Univ. of Illinois At Urbana-Champaign, Urbana, IL; [6]Firefighter Safety Res. Inst., Univ. of Loyola-Maryland, Colombia, MD; [7]Dept. of Hlth. and Human Physiological Sci., Skidmore Col., Saratoga Springs, NY; [8]CDC/NIOSH/DSHEFS, Cincinnati, OH

Abstract: In addition to increased respiratory health risks, fire service workers also display an increased incidence of mental illnesses including anxiety, depression, and post-traumatic stress symptoms. Self-contained breathing apparatuses (SCBA) are used by fire service workers to diminish exposure to products of combustion. The use of personal protective equipment, including SCBA is often absent in the overhaul environment, where the building is inspected following the extinction of the active blaze. In examining the effect of exposure to the overhaul environment in lung tissue, we found evidence of overrepresentation of gene expression changes in pathways involved with cancer and immune regulation. The overhaul group (OH) was compared to the fireground group (FG), which was transported to the site of the exercise and placed in the portion of the structure where fire and overhaul did not occur. Due to the implications of neuroimmune pathways on mental illness, we examine the effects of unprotected exposure to overhaul on transcript expression in the amygdala and hippocampus. Amygdalae and hippocampi were harvested 2 hours after removal from the overhaul environment. Total RNA was extracted and submitted for sequencing with 100nt single-end reads. Surrogate variable analysis identified 5 surrogate variables to remove sources of variation, such as day effect. Compared to FG, OH amygdala displayed transcription changes in 1269 genes (FDR $p<0.05$) and the hippocampus showed changes in 1412 genes (FDR $p<0.05$). In the amygdala, 20 of the affected genes are annotated by Gene Ontology for involvement in inflammatory response and 14 of the affected genes are implicated in the activation of the MAPK cascade, which is associated with neuroinflammation, depressive behavior, and cognitive impairment in mice. The apoptotic process is annotated in 43 of the impacted amygdala transcripts and in 53 in the hippocampus. Of the affected hippocampus genes, 15 are identified as playing a role in potassium ion transport by Gene Ontology annotation. Potassium ion flux plays a key role in neuronal hyperpolarization and brain-based inflammasome activation. Thus, our findings suggest unprotected overhaul exposure may impact mental health through the modulation of pathways tied to neuroinflammation and excitotoxicity.

Title: Immunohistochemical characterization of ACTA2 knockout mice reveals significant vascular, white matter and glial cell abnormalities

Authors: *S. MCCARTHY[1], F. E. HERISSON[2], J. WRIGHT[3], D. MILEWICZ[4], P. L. MUSOLINO[5];
[1]Massachusetts Gen. Hosp., Boston, MA; [2]Systems biology, Massachusetts Gen. Hosp. / Harvard Med. S, Cambridge, MA; [3]Univ. of Texas Hlth. Sci. Med. Ctr. at Houston, Houston, TX; [4]Univ. of Texas Hlth. Sci. Ctr. at Houston, Houston, TX; [5]Neurol., MGH/Harvard, Boston, MA

Abstract: The ACTA2 gene encodes for alpha smooth muscle actin isotope 2 (SMA), a critical component of vascular smooth muscle cells and pericytes. Mutations in this gene can cause smooth muscle cell dysfunction and a severe form of cerebrovascular disease that leads to white matter injury and stroke in childhood. Mechanisms by which the mutant protein causes the disease are still unknown; however, preliminary data indicates mice with mutant heterozygous ACTA2 share aspects of the systemic vascular phenotype with ACTA2 knockout (KO) mice. In this study, our goal is to characterize differences in cellular characteristics of vasculature, white matter, cortical and subcoritical structures in ACTA2 KO mice. We hypothesize that loss of SMA causes abnormalities in the vessels and leads to white matter disease by increased astrocyte and microglial activation. To characterize brain elements, wild type (N=4), ACTA2 KO (N=6), and heterozygous (N=2) mouse strains were sacrificed at 3 months and brains were sectioned for immunohistological analysis. 10x, 20x, and 40x (where necessary) imaging comprehensively visualized the entire brain and provided high resolution images of smaller molecules. ImageJ and Prism Graph Pad were used to quantify differences between strains. Immunohistochemistry of calponin staining in wild type and KO mice revealed large and medium vessel dilation and increased tortuosity of perforating arterioles in KO mouse models throughout cortex and white matter regions. Immunofluorescence of MBP revealed less compacted myelin in the body and forceps of the corpus callosum with decreased thickness in the KO mouse compared to wild type ($p=0.0165$). IBA-1 staining showed depletion of overall microglial count and globular morphology consistent with activated microglia/monocyte phenotype in the cortex and white matter of the KO mice ($p=0.029$). Increased intensity and more prominent arborization of astrocytes was observed by GFAP stain in the KO mice. Endothelial staining with CD31 showed thinner capillaries with increased cells per vessel (quantified by DAPI nuclear stain) and branching patterns ($p<0.001$) distributed in the cortex of both heterozygote and KO mice. In summary, ACTA2 KO mice demonstrate significant diffuse micro and macro vascular abnormalities. White matter injury was observed, as is seen in patients with ACTA2 mutations. Decreased microglial cells, and activation of astrocytes and microglia suggests SMA loss impacts the brain's innate inflammatory system. Further research is necessary to determine functional consequences of these observation as well as developmental and longitudinal aspects of the ACTA2 cerebrovascular phenotype.

Title: S-nitrosylation of cathepsin B inhibits autophagic flux, contributing to neurodegenerative disease

Authors: *K. KIM[1], T. NAKAMURA[2], J.-Y. KOH[3], C.-K. OH[4], S. A. LIPTON[5], Y.-H. KIM[1]; [1]Sejong Univ., Seoul, Korea, Republic of; [2]Mol. Med., The Scripps Res. Inst., La Jolla, CA; [3]Univ. Ulsan Col. Med., Seoul-City, Korea, Republic of; [4]Scintillon Inst., San Diego, CA; [5]Ctr. for Translational Neurosci., Scripps Res. Inst. and UC San Diego, La Jolla, CA

Abstract: It is well known that inhibition of autophagic flux or the ubiquitin-proteasome system (UPS) is critical in neurodegenerative diseases because these diseases manifest protein aggregates, including amyloid β, tau, α-synuclein, and mutant huntingtin in brains. In addition, nitric oxide (NO) is known to contribute to neurodegenerative diseases. Therefore, in the present study we examined the possible relationship between NO and autophagic flux. First, we found that addition of exogenous NO donors blocked autophagic flux at both the initiation and final degradation stages. Demonstrating inhibition of initiation of autophagy by NO, we found GFP-LC3 puncta and LC3 II conversion were significantly decreased 2 hr after addition of the NO donor S-nitrosocysteine (SNOC) to GFP-LC3-expressing H4 glioma cells (GL-H4). In contrast, at later time points up to 8 hr after NO addition, we observed accumulation of GFP-LC3 puncta, LC3 II, and p62 protein levels. In addition, using mCherry-GFP-LC3 for monitoring autophagy flux, we found that mCherry red fluorescence was increased by NO, consistent with the notion that autophagic flux was blocked at a step after fusion of autophagosomes and lysosomes. As further evidence, we also observed that protein aggregates of mutant Huntingtin and α-synuclein were increased after exposure to NO. Next, since autophagic flux appeared to be blocked after fusion of autophagosomes and lysosomes, we focused on lysosomal dysfunction and examined whether protease activity of the major cathepsins, cathepsin B (CTSB), cathepsin L or cathepsin D, was inhibited by protein S-nitrosylation. We found that only CTSB was S-nitrosylated, resulting in inhibition of its enzymatic activity. Additionally, the specific CTSB chemical

inhibitor, CA074, also blocked autophagic flux, mimicking exposure to NO. To identify the cysteine residue(s) that is S-nitrosylated in CTSB, we mutated each cysteine residue to alanine; Cys43 in the pro-form of CTSB as well as Cys29 and Cys240 in mature CTSB appeared to be sites of S-nitrosylation because S-nitrosylation was completely abrogated only in the triple mutant. Finally, we also found increases in S-nitrosylation of CTSB and reduction of CTSB activity *in vivo* in the 5XFAD transgenic mouse model of Alzheimer's disease (AD). Our results suggest that S-nitrosylation of CTSB may affect autophagic flux, contribute to the pathogenesis of AD, and represent a novel target for therapeutic intervention.

Title: Zinc protects against A2E-induced toxicity in ARPE19 cells

Authors: *J. CHOI[1], B.-R. SEO[1], J.-Y. KOH[2], Y. YOON[3];
[1]Neural Injury Res. Ctr., Asan Inst. For Life Sci., Seoul, Korea, Republic of; [2]Neurol., [3]Ophthalmology, Asan Med. Ctr., Seoul, Korea, Republic of

Abstract: Accumulation of extracellular aggregates called drusen and degeneration of photoreceptor and retinal pigment epithelial (RPE) cells are hallmark features of dry age-related macular degeneration (AMD). A growing body of evidence indicates that lysosomal dysfunction in RPE cells may contribute to dry AMD pathology. We have previously shown that raising intracellular zinc levels can restore lysosomal acidity and its degradative function (Yoon et al. IOVS, 2010; Seo et al Neurobiol Aging, 2015). In the present study, we examined the effects of raising intracellular zinc on lysosomal alkalization/dysfunction and cell death induced by retinal lipofuscin, A2E.
To induce lysosomal dysfunction in a human RPE cell line (ARPE19), we used A2E. To examine the effect of raising intracellular zinc against A2E-induced changes, we used zinc ionophores (clioquinol and 1H10). A2E accumulation in ARPE19 cells was evaluated by measuring its autofluorescence. Lysosomal pH was measured by using pHrodo™ Red-AM. A2E-induced cell death was quantitatively assessed by measuring lactate dehydrogenase (LDH) activity released into the culture medium.
Twenty-four hours after A2E treatment, ARPE19 cells exhibited A2E accumulation and

decreases in pHrodo™ Red fluorescence (i.e. increases in lysosomal pH), and subsequently underwent cell death. Zinc ionophores reduced A2E accumulation and restored lysosomal pH back to the acidic range. In addition, zinc ionophores substantially reduced cell death induced by A2E. All the effects of zinc ionophores on A2E-induced changes were blocked by the addition of TPEN, a membrane-permeant zinc chelator.
Our results support the possibility that adequate levels of zinc, especially in lysosomes, may help overcome A2E-induced cytotoxic changes in ARPE19 cells, which may contribute to the pathogenesis of AMD.

Title: Improved biopharmaceutic properties of asparagus racemosus root ethanolic extract to confer neuroprotection in cerebral stroke via phytosomal delivery

Authors: *H. AHMAD[1], D. MISHRA[2], R. SAXENA[2], D. MISHRA[2], C. V. RAO[1], A. K. DWIVEDI[2];
[1]CSIR-NBRI, Lucknow, India; [2]CSIR-CDRI, Lucknow, India

Abstract: *Asparagus racemosus* (AR; also known as Shatavari) roots have been extensively used in traditional systems of medicine. It has been found to possess several neuropharmacological effects like nootropic, antiamnesic, antidepressant and antiepileptic properties. However; like most botanicals its efficient oral use is limited due to issues in solubility and bioavailability. Phytosomes are amphiphilic moieties where the bioactive is anchored through the chemical bond to the polar head of phospholipids. These lipid compatible molecular complexes have been known to be effective carriers of plant based polar bioactives and other botanicals. The authors here have reported preparation of AR loaded phytosomal systems (ARP) aimed at improved biopharmaceutic properties based on assessment of aqueous solubility, surface morphology, zeta potential, physical stability, FT-IR, in vitro dissolution, pharmacokinetic parameters. The neuro-protective effects of ARP were investigated in an experimental ischemia model in rats 1 hour prior to ischemia and 3 hours post reperfusion at 50 mg/kg per oral equivalent dose. It was found that ARP could successfully reduce neurological deficit scoring as well as the infarct size. Findings revealed that 1 hour pre treatment with ARP significantly reduced infarction to about 17.56% compared to a reduction of 41.58% brought

about by AR and likewise a at 3 hours post treatment ARP reduced infarct volume by about 27.22% compared to a 40.28% reduction afforded by AR alone. This study demonstrates that AR can elicit improvement in biopharmaceutic and neuro-protective properties when administered as phytosomes (ARP) and shows promise for carrying on further investigations in its role in alleviating I/R injury in stroke.

Title: DNA methylation in neuronal cell death at the early stage of ischemic status

Authors: *M. ASADA[1], H. HAYASHI[1], K. KIKUIRI[1], K. MURAKAMI[1], B. YUAN[2], N. TAKAGI[1];
[1]Applied Biochem., Tokyo Univ. of Pharm. and Life Sci., Hachioji, Japan; [2]Lab. of Pharmacol., Josai Univ., Sakado, Japan

Abstract: DNA methylation observed in mammals occurs in cytosine of CpG dinucleotide. Cytosine methylation is mediated by DNA methyltransferases (DNMTs) that transfer methyl groups to carbon C-5 of cytosine and then produce 5-methylcytosine (5mC). Especially, DNA methylation of promoter region is thought to be one of the gene repression mechanisms. Thus, it is an essential epigenetic mark for the gene expression in mammals. It has been reported that DNA methylation is involved in pathogenesis of a number of diseases. In cerebral ischemia, infarct volume is decreased by inhibition of DNMTs. However, it is not fully elucidated about changes in DNA methylation and expressions of DNMTs at the early stage after cerebral ischemia. In this study, we first used a rat middle cerebral artery occlusion / reperfusion (MCAO/R) model for *in vivo* study. Immunohistological staining revealed that 5mC-positive neurons were increased in the ipsilateral cortex. Based on this result, we thought DNA methylation might be occurred in ischemic neuron. Then, *N*-methyl-D-aspartate (NMDA) - induced neuronal cell death was examined using primary cultured rat cortical neurons. We found that 5mC positive neurons were increased until 1 h after NMDA treatment and then decreased to the same level as NMDA untreated group. DNMT3a, one of the *de novo* DNA methylation enzymes, protein expression was not changed until 1 h after NMDA treatment and significantly decreased thereafter compared with untreated group. These results indicated that DNA methylation was promoted in damaged neurons at the early stage after NMDA treatment. We

furthermore determined effects of DNMTs inhibitor RG108 on NMDA-induced neuronal cell death. We demonstrated that the inhibitor protected neurons markedly from NMDA-induced cell death. Consequently, DNA methylation at the early stage of ischemic status may contribute to neuronal cell death.

Title: Deficiency of the Fn14 receptor enhances synaptic plasticity after acute ischemic stroke and promotes functional recovery without affecting infarct volume

Authors: K. ENNIS[1], D. NAGY[2], S. SU[1], A. THOMAS[1], J. MAHONEY[1], A. NELSON[1], D. MURPHY[3], G. MARSH[2], T. REYNOLDS[2], S. HAMANN[2], C. EHRENFELS[3], R. MASSOL[3], M. ARNOLD[3], M. HAJOS[2], ***L. C. BURKLY**[1];
[1]Acute Neurol. Res. Unit, [2]Biomarkers, [3]Translational Biol., Biogen, Cambridge, MA

Abstract: Synaptic remodeling is thought to underlie functional recovery following acute ischemic stroke (AIS). We postulated that signaling by the microglia-enriched cytokine, TWEAK, through its neuronally-expressed receptor, Fn14, may play a role in synaptic remodeling after AIS based on the identification of Fn14 as a key molecular regulator of synaptic refinement in sensory-dependent visual development in the mouse dorsal lateral geniculate nucleus[1]. It has also been shown that TWEAK and Fn14 mRNA and protein levels are elevated in mouse models of AIS. Here we used a distal middle cerebral artery occlusion + hypoxia (DH-MCAO) mouse model of ischemic stroke that produces somatosensory cortical infarcts and impairments in sensorimotor function, assessed by Erasmus ladder, and hippocampal (HC) basal neurotransmission and long-term potentiation (LTP). Using genetic Fn14 knockout (Fn14KO) mice as a tool to inhibit Fn14 signaling, we assessed the effect of Fn14 deficiency on acute neuronal death and functional recovery in 16-week old male Fn14KO and wildtype (WT) littermate mice after stroke or sham-injury. We first established that naïve Fn14KO mice do not exhibit differences in brain anatomy, histology, cortical and HC dendritic spine density, basal synaptic neurotransmission or synaptic plasticity in HC LTP compared to WT mice. After AIS, Fn14 deletion did not affect infarct size at 24 hours post-stroke, suggesting Fn14 did not mediate acute neuroprotection in this model. However, Fn14KO mice were completely protected against the stroke-induced HC deficits in basal neurotransmission and LTP observed in WT littermates at 12 weeks post-stroke. Notably, the deficits observed in HC slices from WT stroke mice were

normalized by ex vivo addition of an antibody that blocks TWEAK signaling through the Fn14 receptor, consistent with a post-stroke benefit of Fn14 deficiency in vivo. Fn14KO mice were also protected against stroke-induced functional impairment, as shown by a reduced frequency of missteps with the contralateral paws, compared to WT mice as early as 2 weeks following stroke. There was no differential performance between Fn14KO and WT sham-injured animals. We conclude that the Fn14 receptor plays an essential role in synaptic plasticity in both physiological and pathophysiological contexts. Inhibition of the Fn14 receptor following AIS may enhance synaptic plasticity and thereby provide therapeutic benefit to augment functional recovery.

Title: Therapeutic angiogenesis: Nogo-A targeted therapy promotes vascular and functional recovery following stroke

Authors: *R. RUST[1], L. GRÖNNERT[2], R. Z. WEBER[2], G. MULDERS[2], A. M. SARTORI[1], A.-S. HOFER[1], M. E. SCHWAB[3];
[1]Inst. for Regenerative Med., Univ. and ETH Zurich, Schlieren, Switzerland; [2]Univ. of Zurich, Schlieren, Zurich, Switzerland; [3]Inst. of Regenerative Med., Univ. of Zurich, Schlieren, Switzerland

Abstract: Therapeutic angiogenesis is a promising regenerative strategy to promote functional recovery following stroke. Despite clinical evidence that an increase of angiogenesis in the peri-infarct region is beneficial, no therapeutics promoting vascular growth are currently available. So far, pre-clinical studies almost exclusively focused on supplementation of vascular growth factors, which have been shown to be not safe due to the large hemorrhagic risk. We pursued a different strategy by targeting Nogo-A, a potent inhibitor of neurite outgrowth. More recently, Nogo-A has been shown to be a negative regulator of developmental CNS angiogenesis; its respective function in the ischemic CNS is unknown. We demonstrate that genetic deletion of Nogo-A or one of its corresponding receptors, S1PR2, improves vascular sprouting and repair and reduces neurological deficits after focal cerebral ischemia. These findings were reproduced in a therapeutic approach using intrathecal anti-Nogo-A antibodies; such a therapy is currently in clinical testing for spinal cord injury. These results provide a basis for a therapeutic blockage of inhibitory molecules to improve vascular repair and thus may represent a novel therapeutic option for cerebral ischemia.

Title: Neuroprotective role of protein arginine methyltransferases in cerebral ischemia

Authors: *A. COUTO E SILVA[1], C. Y.-C. WU[2], H. POSSOIT[2], G. A. CLEMONS[1], R. H.-C. LEE[2], H. W. LIN[2];
[1]Cell. Biol. and Anat., [2]Neurol., LSU Hlth. Sci. Ctr. Shreveport, Shreveport, LA

Abstract: Cardiopulmonary arrest (CA) is a leading cause of mortality in the USA. CA-induced hypoperfusion contributes to neuronal cell death leading to cognitive impairment. We aim to identify novel neuroprotective therapies which can modulate CBF and provide neuroprotection. We discovered that palmitic acid methyl ester (PAME) is a vasodilator/neuroprotective agent that is released in the presence of arginine derivatives (i.e. L-arginine, N^{ω}-Nitro-L-Arginine). Arginine derivatives are a substrate for protein arginine methyltransferases (PRMTs) that can methylate various biological targets causing pre/post-transcriptional/translational modifications. Because PAME's release is enhanced in the presence of arginine derivatives, our hypothesis is that methylation of palmitic acid (PA) to form PAME via PRMTs is essential to enable PAME's beneficial actions against ischemia, to provide enhancements in CBF, neuroprotection, and functional recovery. We measured CBF via laser speckle flowmetry before and 24 hours after asphyxial CA (ACA, 6 min), a global model of cerebral ischemia. Post-treatment of PAME, but not PA, increased cortical CBF *in vivo* (21.0%±1.0%) to alleviate ACA-induced hypoperfusion. We assessed cell morphology and neurodegenerative stress in the CA1 region of the hippocampus via hematoxylin and eosin, and Fluoro-Jade C (FJC) staining. Our results suggest that the number of normal neurons in ACA rats (492.3±95.6) was significantly reduced as compared to control (909.6±20.1) and ACA+PAME post-treated rats (804.7±27.2). ACA caused an increase in FJC-positive neurons (564.1±75.3), while ACA+PAME alleviated neurodegeneration (170.7±10.2). Moreover, PAME treatment improved working memory function after ACA [alternation ratio ACA (0.26±0.05), ACA+PAME (0.48±0.03)]. We measured mRNA/protein expression of PRMT enzymes to investigate their role in the methylation of PA. Our results suggest that PRMT8 expression is enhanced in the presence of arginine derivatives. PRMT8 is present solely in the central nervous system with no known

function. PRMT8KO mice presented with reduced endogenous regional CBF as compared to wild-type, to suggest a possible role in the methylation of PA. We also measured mitochondrial oxygen consumption rate of hippocampal slices from wild-type and PRMT8KO mice. PRMT8KO hippocampal slices presented with reduced reserve capacity, to suggest that the knockout of PRMT8 results in mitochondrial dysfunction. Overall, our results suggest that PRMT8 plays an important role to maintain CBF and mitochondrial function, and could methylate PA to form PAME, to enhance CBF, neuroprotection, and functional outcomes after CA.

Title: MicroRNA (mir)20a-3p preserves astrocyte mitochondrial function in ischemic conditions

Authors: *T. BRANYAN[1,2], R. SRINIVASAN[2,1], F. SOHRABJI[2,1];
[1]Inst. for Neurosci., Texas A&M Univ., College Station, TX; [2]Dept. of Neurosci. and Exptl. Therapeut., Texas A&M Hlth. Sci. Ctr. Col. of Med., Bryan, TX

Abstract: Previous work from our lab has shown that astrocytes from middle-aged reproductively senescent (acyclic) rats, who typically sustain larger infarct volumes after stroke, have a reduced functional capacity for glutamate clearance and production of trophic factors as compared to astrocytes from adult (normally-cycling) rats, who typically have smaller infarct volumes. Epigenetic analysis revealed greater H3K4 trimethylation of the promoter region of the mir17-92 cluster in adult astrocytes, and qRT-PCR analysis confirmed increased expression of all members of this cluster including a 240-fold elevation of mir20a-3p. Intravenous injection of mir20a-3p mimics, delivered 4h after induction of ischemia, improved stroke outcomes in middle-aged female rats. *In silico* analysis indicates that mir20a-3p modulates mitochondrial genes. The present study tested the effect of mir20-3p on mitochondrial function in astrocytes under normoxic and ischemic conditions. Cultures of male and female human astrocytes were grown until confluent and assigned to normoxic (21% O_2, 25 mM glucose) or ischemic (1% O_2, 0 mM glucose) conditions for 6 hours. Cells were treated with 50 nM mir20a-3p, 50 nM scrambled control miR or vehicle. Additionally, astrocyte cultures were treated with FAM-labeled mir20a-3p oligos, and imaging of these cells indicates that the miRNA is readily taken up

by astrocytes. We assessed mitochondrial function through Fluorescent Recovery After Photobleaching (FRAP) using Mitotracker deep red as a stain for living mitochondria. Astrocytes subject to OGD or normoxia achieved maximal recovery after photobleaching by ~30 seconds and displayed stable fluorescent signal thereafter. Pretreatment with mir20a-3p significantly accelerated recovery after photobleaching compared to cells pre-treated with scrambled miR or vehicle in normoxia and OGD for both sexes. A significant sex difference was observed in recovery after photobleaching, with the male cells experiencing a dampened effect on recovery in response to mir20a-3p or scrambled treatments. Since the rate of fluorescent recovery measures the continuity of the mitochondrial membranes, these data suggest that mir20a-3p likely promotes mitochondrial fusion or inhibits mitochondrial fission. If greater continuity of the mitochondrial membrane compensates for the greater energy demand required after ischemic injury, these data may also explain why stroke recovery is better in young females as compared to males.

Title: Kv1.3 as a pharmacological target for reducing neuroinflammation in the wake of ischemic stroke in both sexes

Authors: Y.-J. CHEN, H. M. NGUYEN, Y. CUI, ***H. WULFF**;
Pharmacol., Univ. of California Davis, Davis, CA

Abstract: The voltage-gated potassium channel Kv1.3 was first discovered in human T cells in 1984 and has since then been pursued as a target for T-cell mediated autoimmune diseases. Kv1.3 is further expressed on pro-inflammatory M1-like microglia and our laboratory therefore more recently evaluated the small molecule Kv1.3 blocker PAP-1 in models of ischemic stroke and Alzheimer's disease. In both male C57BL/6J mice and male Wistar rats, treatment with PAP-1 started 12 hours after reperfusion reduced infarction and inflammatory brain cytokine levels and improved neurological deficit on day-8 after reperfusion MCAO (Y.-J. Chen et al. 2018). We are now testing the therapeutic hypothesis that Kv1.3 inhibition is equally effective in both sexes. As a first step we established 60-min MCAO with reperfusion in female C57BL/6J mice and found that females have smaller infarcts, but that 16-week old animals of both sexes have qualitatively similar pathologies with similar IBA^{+}-microglia/macrophage and T cell

densities in the infarct and a $GFAP^+$ glial scar surrounding the infarct. Based on patch-clamp recordings performed on acutely isolated $CD11^+$ cells $Cx3cr1^{GFP/+}$ male and female mice exhibit similar Kv1.3 current amplitudes and densities on microglia/macrophages from the infarcted area. Immunofluorescent staining revealed that in both male and female $Cx3cr1^{GFP/+}$ mice Kv1.3 expression increases with time after MCAO, peaks between day-7 and day-15 and is localized to GFP^+ microglia/macrophages and $CD3^+$ T cells in the infarcted area. Since these findings suggest that both males and females would equally benefit from Kv1.3 inhibition following ischemic stroke, we compared 16-week old male and female WT C57BL/6J and $Kv1.3^{-/-}$ mice following 60 min-MCAO with reperfusion. T2-weigthed MRI revealed that Kv1.3-deletion produces a similar improvement in neurological deficit and a reduction in infarct volume in both males (WT: 20.5 ± 1.3%, n = 10; $Kv1.3^{-/-}$: 13.3 ± 1.3%, n = 14; $p < 0.01$) and females (WT: 11.4 ± 1.4%, n = 11; $Kv1.3^{-/-}$: 7.4 ± 1.3%; n = 14, p = 0.03). While we of course still need to test the effect of pharmacological Kv1.3 inhibition in aged animals of both sexes, we believe that our results allow us to hypothesize that Kv1.3 inhibition will be equally beneficial in both males and females by reducing microglia/macrophage and T-cell mediated neuroinflammation.

Title: Elevation of extracellular glycine levels attenuates deficits following ischemic stroke *in vivo*

Authors: *J. D. CAPPELLI[1], P. KHACHO[2], A. SOKOLOVSKI[3], B. WANG[1], S. RAYMOND[1], P. CHUDALAYANDI[1], A. Y. WONG[4], R. BERGERON[1];
[2]Cell. and Mol. Med., [3]Neurosci., [1]Ottawa Hosp. Res. Inst., Ottawa, ON, Canada; [4]Univ. of Ottawa, Ottawa, ON, Canada

Abstract: Background: *Ischemic strokes* are the 2nd leading cause of death worldwide and the 1st leading cause of disability, yet there are limited viable treatment options for the at-risk population. Triggered by an arterial obstruction, ischemics strokes cut off the vital supply of oxygen and glucose in the brain. This induces a breakdown of basic neuronal and glial functions, resulting in an increase in the extracellular level of the excitatory amino acid glutamate and overactivation of calcium-permeable *N*-methyl-d-aspartate receptors (NMDARs), inducing cell death. While molecular pathways of stroke have been known for some time, promising NMDAR

antagonists have failed to improve stroke outcome in clinical trials. Thus, alternatives to the direct antagonism of NMDARs are needed. **Rationale:** NMDARs are tetrameric ion channels activated by the simultaneous binding of glutamate and glycine to the GluN2 and GluN1 subunits, respectively. Preliminary *in vitro* data suggests that increasing extracellular glycine levels (>1mM) reduces the NMDAR current amplitude through a process termed glycine-induced NMDAR internalization (GINI). **Objective**: To characterize how elevating glycine levels modulates NMDAR behaviour *in vitro,* and how it can be neuroprotective *in vivo*, following ischemic stroke paradigms. To examine the mechanism through which the pharmacological elevation of brain glycine levels is neuroprotective *in vivo*.**Results:** Our data show that pharmacologically increasing endogenous glycine with the glycine transporter (GlyT1) blocker, *N[3-(4'-fluorophenyl)-3-(4'-phenylphenoxy) propyl] sarcosine* (NFPS), results in a reduction in stroke volumes and cell death in two models of focal ischemia: photothrombosis (PT) and endothelin-1 (ET-1). In addition, animals treated with NFPS had a significant attenuation in behavioural deficits post stroke compared to saline treated animals, in the adhesive removal task and the horizontal ladder task. In order to show that this effect was the result of GINI during stroke, we stereotaxically injected animals with a non-internalizing GluN1 (A714L) Adeno Associated Virus (AAV). The injection of mutant GluN1 did indeed abolish the therapeutic effect of NFPS. Interestingly, our preliminary data suggest that NFPS also attenuates reduction in blood-flow during PT stroke through the COX1/EP4 mediated pathway, using Laser Doppler Flow (LDF) recordings.**Conclusion:** Taken together, our data demonstrate that blockade of GlyT1's is neuroprotective following ischemic stroke. Therefore, this may be a novel means of pharmacologically attenuating stroke symptoms.

Title: Post-treatment of sumanirole provide neuroprotection against ischemic stroke injury in rat model

Authors: *P. KAUSHIK[1], H. TABASSUM[2], S. PARVEZ[1];
[1]Toxicology, Jamia Hamdard, New Delhi, India; [2]Div. of Biomed. Sci., Indian Council of Med. Res., New Delhi, India

Abstract: Background and Purpose: Regardless of the rapid increase of the global burden of ischemic stroke, currently, there are few therapeutic option available to lessen tissue death

following a stroke. Recent studies have shown that mitochondria have a decisive role in response to cerebral ischemia and are an effective target for stroke therapy in rodent models. We investigated whether mitochondrial dysfunction and neurocognition is regulated by dopamine D2 agonist, Sumanirole (SUM). **Materials and Methods**: Male Wistar rats (220-250g) were divided into four groups (n=6), and pre-trained for neurobehavioural assessment. After training, Group 2, Group 3 and Group 4 rats underwent transient middle cerebral artery occlusion (tMCAO) for 1 h followed by reperfusion for 23 h. Group 2 rats were received normal saline while Group 3 rats received SUM with the dose of 1 mg/k.g b.wt (s.c.) and Group 4 rats received SUM with the dose of 3 mg/k.g b.wt (s.c.) after 1, 6, 12, and 18 h of occlusion, respectively. The neurobehavioral assessment was done after 24 h to evaluate behavioural deficits. Subsequently, all animals were sacrificed and brain tissue was collected for analysis of oxidative stress parameters and mitochondrial ROS. **Results:** Behavioural deficits like motor in-coordination and loss of grip strength as well as mitochondrial ROS were enhanced in the ischemic injury. However, treatment with SUM significantly attenuated these impairments, depicts reduction in infarct volume, oxidative stress and improvement in mitochondrial oxidative stress. **Conclusion:** The results of our study revealed that SUM ameliorates neurobehavioral deficits, oxidative imbalance and mitochondrial impairments. **Keywords:** Ischemic stroke, Sumanirole, Mitochondria, oxidative stress and Neuroprotection

Title: N-formyl peptide receptor 2 activation via annexin A1 up-regulates hematoma resolution after germinal matrix hemorrhage

Authors: *J. FLORES[1], Y. DING[2], D. MCBRIDE[3], J. TANG[2], J. ZHANG[2];
[1]Physiol., Loma Linda Univ. Sch. of Med., Loma Linda, CA; [2]Loma Linda Univ., Loma Linda, CA; [3]UTHealth Med. Sch., Houston, TX

Abstract: Germinal matrix hemorrhage (GMH) is one of the leading causes of morbidity and mortality in preterm infants in the United States with little progress made in its clinical management. Survivors are often afflicted with long-term neurological sequelae, which include cerebral palsy, mental retardation, and post-hemorrhagic hydrocephalus. Blood clots disrupting normal cerebrospinal fluid circulation and absorption after germinal matrix hemorrhage are key

contributors towards post-hemorrhagic hydrocephalus development. n-formyl peptide receptor 2 (FPR2), a G-protein-coupled receptor, has been associated with the activation of scavenger receptor CD36. CD36, a transmembrane glycoprotein, plays an essential role in microglia phagocytic blood clot clearance after GMH and its upregulation has been shown to enhance hematoma resolution and attenuate post-hemorrhagic hydrocephalus. Currently, FPR2's role in blood clot clearance after hemorrhagic stroke is unknown. We hypothesize that FPR2 activation by Annexin A1 will enhance hematoma resolution via upregulation of the CD36 signaling pathway, thereby improving short- and long-term neurological outcomes. Bacterial collagenase (0.3 U) was infused intraparenchymally into the right hemispheric ganglionic eminence in male and female P7 rat pups to induce GMH. Annexin A1 and FPR2 Inhibitor (Boc2) were given at 1-hour post-GMH via intranasal administration. Short-term neurobehavior were assessed using negative geotaxis test. Hematoma volume was assessed using hemoglobin assay. Protein expression was assessed using western blots. Long-term neurocognitive deficits and motor coordination were assessed using Morris water maze, rotarod, and foot fault tests. Nissl staining was conducted on long-term samples to calculate ventricular dilation. We randomly assigned each rat pup to groups and time points without bias 24 hours prior to GMH induction. All investigators responsible for neurobehavior, western blots, hemoglobin assay, ventricular dilation, and data analysis were blinded to experimental groups. Sample size was determined by using a minimum detectable difference in means of 10, a standard deviation of 4, a power of 0.80, and an alpha of 0.05 to determine that 6 animals per experimental group were necessary to gain statistical significance. We have demonstrated that Annexin A1 treatment decreased hemoglobin content and improved neurobehavior at 72 hours post-ictus. Annexin A1 attenuated post-hemorrhagic hydrocephalus and neurological deficits 4 weeks post-ictus. Lastly, treatment increased FPR2 and CD36 expression, FPR2's role in hematoma resolution after GMH.

Title: The role of 12/15 lipoxygenase inhibition on stroke induced neuroinflammation

Authors: C. CAKIR-AKTAS[1], M. YEMISCI[1], E. EREN-KOCAK[1], T. DALKARA[2], E. BODUR[3], K. VAN LEYEN[4], *H. KARATAS-KURSUN[1];

[1]Hacettepe University, Inst. Neurolog. Sciences&Psychiatry, Ankara, Turkey; [2]Hacettepe Univ. Fac. of Med., Ankara, Turkey; [3]Dept. of Biochem., Hacettepe Univ., Ankara, Turkey; [4]Massachusetts Gen. Hosp., Charlestown, MA

Abstract: Lipoxygenases (LOX) have important roles in stroke, atherosclerosis, diabetes and hypertension. 12/15-LOX inhibition reduces infarct size and brain edema in the acute phase of experimental stroke (1,2). Neuroinflammation has an essential role in the pathophysiology of stroke, however the effect of 12/15-LOX on this process has not been clarified yet. The aim of this study was to investigate the role of 12/15-LOX inhibition by a novel potent 12/15-LOX inhibitor on the neuroinflammation of acute and subacute phases of stroke.

In this study, ischemia/recanalization was performed by Middle Cerebral Artery occlusion (MCAo) with intraluminal filament model in male Swiss albino mice. Either ML351 (50 mg/kg), newly synthesized 12/15-LOX inhibitor (3) or its solvent, DMSO, was injected intraperitoneally at recanalization after 1 hr of occlusion. Mice were sacrificed at 6, 24 and 72 hrs after ischemia induction. Ischemic regions of brain tissue were isolated. Inflammatory cytokines (IL-6, IL-10 and TGF-beta) were quantified by ELISA. We compared the level of cytokines in treatment, control and naïve brain samples (n=3/group). For the detection of microglial activation, mice were sacrificed by cardiac perfusion at each time point. Immunohistochemical staining protocols were performed for a microglia marker, Iba-1.

IL-6, a proinflammatory cytokine, level was increased in the control ischemic brains compared to naïve and significantly reduced (closed to naïve level) by ML351 for each time point of MCAo ($p<0.001$). The anti-inflammatory cytokine IL-10 was decreased in control and significantly increased in the treatment groups ($p<0.001$). However, TGF-beta another anti-inflammatory cytokine was decreased in controls and induced only in subacute phase of ischemia, 72 hrs in the treatment group ($p<0.001$). 12/15-LOX inhibition also diminished microglial activation in the acute phase, in contrast microglia were activated in the sub-acute phase of ischemia. While the proinflammatory cytokine levels were decreased, anti-inflammatory cytokines were increased after ischemia with ML351 treatment. In accordance with this data, the microglial phenotype was switched from M1 to M2 phase at 72 hrs of ischemia according to immunohistochemical Iba-1 signal.

These results suggest that one of the possible mechanisms of 12/15-LOX inhibition involves the suppression of neuroinflammation in both the acute and the subacute phase of cerebral ischemia by decreasing the pro-inflammatory cytokine and increasing the anti-inflammatory cytokine levels. These findings support the earlier studies recommending 12/15-LOX inhibitors as a treatment option for stroke therapy.

Title: Intranasal insulin treatment improves functional stroke outcomes in mice

Authors: C. J. SMITH, S. NGUYEN, L. S. WATSON, *C. S. ROBINSON;
Med. Univ. of South Carolina, Charleston, SC

Abstract: Strokes pose both a physical and financial burden on patients, it has been estimated by the CDC that strokes cost the United States $34 billion dollars due to treatment and inability to work. The road to rehabilitation after stroke can be a long strenuous process many recovering stroke patients require physical and cognitive rehabilitation. Often times rehabilitation focus is placed on trying to restore physical abilities while the cognitive deficits are not addressed with the same urgency. Many stroke patients not only require rehabilitation but are also diagnosed with hyperinsulinemia; characterized as elevated levels of insulin circulating in the blood resulting from reduced insulin transport from the periphery to the brain, causing an insulin deficiency. Brian insulin promotes neuroplasticity, synaptogenesis, has anti-inflammatory, anti-thrombotic, vasodilatory, anti-apoptotic properties, and is involved in cognition. The benefits of brain insulin give way to numerous research avenues that promote stroke recovery. We hypothesize that intranasal insulin treatment will improve functional recovery following an ischemic stroke in a mouse model of hyperinsulinemia. To explore our current hypothesis ischemic stroke is induced using a 30-minute middle cerebral artery occlusion (MCAO) in a high-fat diet induced and standard diet induced male mouse model (n>11). The animals are assessed on the following criteria; survival, weight, neurological severity score, motor and cognitive function after receiving either intranasal saline (0.9%) or intranasal insulin (1.75U). Preliminary results indicate high-fat diet-induced hyperinsulinemia leads increased adverse neurological deficits and functional recovery following ischemic stroke. Furthermore, our preliminary studies indicate that intranasal insulin may have advantageous benefits improving functional recovery from stroke in the high-fat mice.

Title: Activation of Jak2/Stat1 pathway by IFN gamma induces CXCR3 signaling and inflammatory response by mouse cerebral endothelial cells and astrocytes

Authors: *E. D. WINFORD[1], S. M. DAVIS[2], K. R. PENNYPACKER[2];
[1]Neurosci., [2]Neurol., Univ. of Kentucky, Lexington, KY

Abstract: Emergent large vessel occlusion (ELVO) is the deadliest form of stroke and is caused by a blockage within a major a cerebral artery, usually the middle cerebral artery. This condition triggers edema, which occurs due to the movement of water into the brain. Cerebral edema can produce massive brain damage which can result in disability and death. Leukemia inhibitory factor (LIF), a neuroprotective and anti-inflammatory cytokine, decreases neurodegeneration and increases survival after intraluminal middle cerebral artery occlusion (MCAO) model, a rat model of ELVO. Previously we have reported that IFNγ is the primary inflammatory mediator in the MCAO model. Treatment with LIF decreases its expression and prevents the upregulation of CXCL10, an IFNγ-inducible chemokine. This study examined the presence of IFNγ on mouse endothelial cells and astrocytes by measuring the expression of CXCL9, another IFNγ-inducible chemokine, and determined the ability of LIF to block IFNγ signaling. Exposing cerebral microvascular endothelial cells to 1 ng/ml IFNγ significantly induced expression of CXCL9 under both normoxic conditions and oxygen-glucose deprivation (OGD). Cells exposed to normoxic conditions were plated and allowed to mature for 7 days, then stimulated with 1 ng/ml IFNγ. At 6, 24, 48 and 72 hours after stimulation, supernatants were collected, and ELISA was used to measure the amount of CXCL9 released. Cells subjected to OGD were allowed to mature for 7 days. On day 7, glucose-free DMEM was added to cells, and they were placed in an oxygen-free chamber for 6 h. After 6 h, the glucose-free DMEM was replaced with glucose-containing DMEM containing 1 ng/ml IFNγ. Supernatants were collected at the previously mentioned time points d, and the concentration of CXCL9 was determined via ELISA. To determine whether IFNγ upregulates CXCL9 via the JAK2/STAT1 pathway, cells were treated with 1 ng/ml IFNγ, 50uM fludarabine (STAT1i) and 100uM AG490 (JAK2i). Treatment with JAK2 and STAT1 inhibitors significantly blocked the induction of CXCL9. Also, these cells were treated with LIF (200 ng/ml) and IFNγ under normoxic conditions and OGD. Surprisingly, LIF + IFNγ significantly increased the release of CXCL9 by endothelial cells exposed to OGD.

One potential explanation for these results is that LIF induces CXCL9 expression to open the BBB. LIF is known to promote an anti-inflammatory phenotype in $CD4^+$ T cells and macrophages. Thus, the opening of the BBB could be to allow anti-inflammatory leukocytes to enter the ischemic brain and promote repair after stroke

Title: Temporal evaluation of heme oxygenase-1 expression in peri-infarct neurons and astrocytes after ischemic reperfusion injury

Authors: *D. SINGH[1], H. WASAN[2], U. SHARMA[3], A. DINDA[4], R. KH[5];
[1]Dept. of Pharmacol., All India Inst. of Med. Sci. (AIIMS), New Delhi, India; [2]Dept. of Pharmacol., All India Inst. of Med. Sci., New Delhi Delhi, India; [3]Dept. of NMR, [4]Dept. of Pathology, [5]Dept. of Pharmacol., All india Inst. of Med. Sci., New Delhi, India

Abstract: Heme oxygenase-1 (HO1) is a redox-sensitive, inducible and rate limiting enzyme of heme metabolism. HO1 catalyzes heme to Fe^{2+}, carbon monoxide and biliverdin. After ischemia reperfusion, HO1 has demonstrated neuro-protective effects via its anti-inflammatory, anti-apoptotic and anti-oxidant properties. Here, we evaluate the expression pattern of HO1 in peri-infarct neurons and astrocytes at various time points after ischemia reperfusion injury in rats. Middle cerebral artery occlusion model was established in male Wistar rats (260-290 g) after ethical approval. After 60 min of ischemia, doccol suture was removed to produce reperfusion injury. In sham, all procedures were performed except insertion of suture. Rats were sacrificed after 2 h, 8 h, 24 h, 72 h and 7 days of reperfusion. At each time point, MRI was done. HO-1 expression was studied by western blot. For cell specific expression, HO1 was co-localized with neurons and astrocytes using dual immunofluorescence. MR images showed infarct damage after ischemia reperfusion injury at all-time points. Western blot data revealed HO1 expression in peri-infarct region to be significantly increased at all-time points with maximum expression at 24 h ($p<0.01$) of reperfusion when compared with sham. Dual immunofluorescence revealed that HO1 expression in peri-infarct area starts in few neurons and astrocytes at 2 h with slight increase at 8 h of reperfusion. At 24 h after reperfusion, HO1 was expressed significantly high, more in astrocytes than neurons. Though the expression of HO1 was less at 72 h and 7 days as compared to 24 h, it was expressed in astrocytes predominantly. The results showed that HO1 expression was significantly increased mainly in atrocytes as early as 2 h after MCAo with

maximum at 24 h followed by a gradual decrease. Since, increasing HO1 has been neuro-protective; stimulating HO1 at later time points may be a good therapeutic strategy.

Title: Ascorbate protects against secondary brain damage after focal ischemia via modulation of TET3

Authors: *K. MORRIS-BLANCO[1], M. J. BERTOGLIAT[2], B. CHELLUBOINA[1], R. VEMUGANTI[3];
[1]Univ. of Wisconsin-Madison, Madison, WI; [2]Univ. of Wisconsin - Madison, Madison, WI; [3]Neurolog. Surgery, Univ. of Wisconsin, Madison, WI

Abstract: Ascorbate is an antioxidant and an enzyme cofactor known for its importance in the maintenance of brain function as well as a neuroprotective agent in response to oxidative stress. Recently ascorbate has been identified as a modulator of the ten-eleven translocase (TET) enzymes that produce 5-hydroxymethylcytosine (5-hmC), a CNS-enriched epigenetic modification that is associated with transcriptional activation and neuroprotection. In the current study, we evaluated the role of ascorbate on 5-hmC and its therapeutic potential against ischemic brain injury. Adult mice were subjected to transient middle cerebral artery occlusion (MCAO) and ascorbate was injected intraperitoneally (i.p.) at 5 min, 30 min or 2h of reperfusion. Ascorbate led to robust induction of TET3 activity and 5hmC in the peri-infarct region of the cortex and reduced infarct size at both early and delayed treatment. Knockdown of TET3 by intracerebral injection using siRNA blocked the ascorbate-induced increases in 5hmC and led to increased brain degeneration and mortality. Ascorbate treatment also significantly reduced infarct size and enhanced the expression of several genes involved in neuroprotection in a TET3-dependent manner. We further showed that delayed treatment of ascorbate was also effective at reducing infarct and promoted functional recovery in aged male and female mice and diabetic

male mice. Collectively, these results indicate that ascorbate regulates the 5hmC epigenetic modification in a therapeutic manner.

Title: Changes in the expression of gene associated with retinoid-interferon induced mortality-19 in the dentate gyrus of Camk2α-hetero knockout mice

Authors: *S.-N. HWANG, J.-C. KIM, S. KIM;
The Catholic Univ. of Korea, Seoul, Korea, Republic of

Abstract: Gene associated with retinoid-interferon-induced mortality-19 (GRIM-19) is a subunit of the mitochondrial respiratory chain complex I, required for mitochondrial ATP production. In our previous study, we found that GRIM-19 immunoreactivity was barely detectable in the subgranular zone, but strongly in the granule cell layer that is densely filled with mature granule cells. It was reported that in mice heterozygous for the alpha-isoform of calcium/calmodulin-dependent protein kinase II (Camk2α), most of the hippocampal granule cells fail to mature and remain in an immature state. Therefore, this study was performed to determine cell types of GRIM-19-positive cells in the dentate gyrus of the Camk2α-heterozygous knockout mice (Camk2α-hKO, 12-week-old). Our immunofluorescence study showed that Calbindin (a mature granule cell marker) immunoreactivity was profoundly decreased while Calretinin (an immature granule cell marker) immunoreactivity was significantly increased in the granule cell layer of Camk2α-hKO mice compared with wild-type mice. In addition, GRIM-19 immunoreactivity was profoundly reduced in the granule cell layer of Camk2α-hKO mice as compared to one of the wild-type. In Camk2α-hKO mice, the degree of reduction of Calbindin immunoreactivity was greater than that of GRIM-19. In wild-type mice, double immunofluorescence staining revealed that GRIM-19 was co-labeled in Calbindin-positive cells, but weakly expressed in Calretinin-positive cells in the hippocampal dentate gyrus. In Camk2α-hKO mice, the number of GRIM-19-positive cells co-localized with Calbindin was significantly decreased. Unexpectedly, there was no difference in the number of GRIM-19-positive cells co-localized with Calretinin between wild-type- and Camk2α-hKO mice. Taken together, our data suggest that Camk2α deficiency affects GRIM-19-positive granule neuron maturation in the adult mouse dentate gyrus.

Title: Differential expression of GRIM-19 (gene associated with retinoid-interferon induced mortality-19) in the dentate gyrus of mouse hippocampus following pilocarpine-induced SE

Authors: *J.-C. KIM, S.-N. HWANG, S. KIM;
The Catholic Univ. of Korea, Seoul, Korea, Republic of

Abstract: Gene associated with retinoid-interferon-induced mortality-19 (GRIM-19), which was previously identified as a tumor suppressor associated with cell proliferation and apoptosis, contributes to the switch between oxidative and glycolytic pathways. Meanwhile, a metabolic switch from glycolysis to oxidative phosphorylation has arisen as key actors of neurogenesis. Recent studies showed that neuronal differentiation is accompanied by a metabolic switch from glycolysis in neural progenitor cell to neuronal oxidative phosphorylation. Thus, the present study investigated the GRIM-19 expression of the mice dentate gyrus in the pilocarpine-induced SE model, leading to increased neurogenesis. Male C57BL/6 mice (10-week-old) were treated with pilocarpine (280 mg/kg, intraperitoneally) and monitored to evaluate seizure stage based on Racine scale. After 2 hours of SE, which was defined as a continuous motor seizure of stage 5 (rearing and falling), diazepam was administered to terminate seizure. The mice which received saline instead of pilocarpine served as control. In our previous study, we found that GRIM-19 was expressed mainly in mature granule cells and in some immature cells, but barely expressed in proliferating cells in the dentate gyrus under normal condition. In the present study, we performed immunohistochemistry and immunofluorescence staining to examine GRIM-19 expression pattern in the dentate gyrus. In addition, double immunofluorescence staining was performed using various cellular markers representing distinct stages of adult neurogenesis: Ki-67 (a cell proliferation marker), Calretinin (an immature granule cell marker) and Calbindin (a mature granule cell marker). After SE, compared with control animals, immunoreactivity of Ki-67 and Calretinin was significantly increased, while Calbindin was dramatically reduced in the dentate gyrus. At that time, GRIM-19 immunoreactivity was markedly decreased in the dentate gyrus following SE. Taken together, these results indicate that GRIM-19 immunoreactivity was correlated with granule cell maturation. From these results, we can raise the possibility that the decreased expression of GRIM-19 affects maturation of granule cells in the adult hippocampus,

probably through inhibiting the metabolic switching from glycolysis to oxidative phosphorylation.

Abstract: Traumatic brain injury (TBI) is a progressive disease, characteristic of disability amongst its survivors due to loss of neural tissue. Transplantation of neural stem cells (NSCs) is an option to potentially mitigate progressive neural damage and restore function following severe TBI. Recently we established a protocol for robust durable engraftment of human fetal neural stem cells (hNSC; Neuralstem Inc.) that have been approved by the FDA-approved for use in Phase I/II clinical trials for other central nervous system injury indications (i.e. amyotrophic sclerosis & spinal cord injury). However, safety/tumorigenicity studies are needed in order to obtain FDA approval for a TBI clinical indication. For this purpose, the goal of the current study was to evaluate the potential tumorigenicity of the transplanted cells in immune-compromised rats subjected to penetrating ballistic-like brain injury (PBBI).
Adult male athymic Sprague Dawley rats were subjected to unilateral PTBI via rapid inflation of an elastic balloon attached to a perforated probe that was stereotactically inserted through the right frontal cortex. Animals were randomized to two groups (n=20 per group). At one-week post-injury, animals received perilesional stereotactic microinjection of vehicle (Group A) or 3 million green fluorescent protein (GFP) expressing hNSCs (Group B). Animals were euthanized at 6 months post-transplantation and tumorigenecity potential was assessed by examining brain and peripheral organ sections for oncogenic features such as abnormal mitoses, nuclear atypia,

and necrosis in hematoxylin eosin (HE) stained section as well as quantitation of Ki67 positive mitotic figures in brains and spinal cords.
The transplanted cells within brain sections showed pleomorphic density with seamless boundaries and no signs of tumorigenicity. Neither morphological nor immunohistochemical indicators indicative of preneoplastic or neoplastic growth were evident in transplanted cells. No abnormal masses were detected in peripheral tissues. While some peripheral tissue masses were detected, these were found to be benign neoplasms common to this species of rodents.
In summary, the current data supports the notion that hNSC can be considered a safe cell therapy option for TBI patients.

Title: Elevating microRNA-122 in blood for treatment of ischemic stroke, traumatic brain injury, and intracerebral hemorrhage in rats

Authors: *D. LIU[1], X. CHENG[2], B. P. ANDER[4], H. HULL[4], X. ZHAN[5], F. R. SHARP[6], B. STAMOVA[7], G. JICKLING[8], B. G. LYETH[3];

Surgery, UC Davis, Davis, CA; [4]Dept Neurol., UC Davis, MIND Inst., Sacramento, CA; [5]Neurol., MIND Inst/UC Davis, Sacramento, CA; [6]UC Davis Dept Neurol. and MIND Inst., Univ. of California At Davis, Sacramento, CA; [7]Neurol., Univ. of California, Davis Sch. of Med., Sacramento, CA; [8]Neurol., Univ. of California Davis, Sacramento, CA

Abstract: MicroRNAs (miRs) are very promising new generation drug targets due to their unique miR-target binding that is different from the traditional ligand-receptor. A single miR binds to complementary bases in the 3' untranslated regions (3'UTR) of hundreds of target genes and down-regulates these genes.
Our previous studies showed that intravenous (i.v.) miR-122 mimic (2.4mg/kg, wrapped in PEG-liposomes) improves outcomes after suture middle cerebral artery occlusion (MCAO)-induced ischemic stroke (IS) with a 6 hour time window. In pilot whole genome miR expression studies,

we demonstrated that microRNA-122 (miR-122) is the most significantly decreased miR in blood after both lateral fluid percussion -induced traumatic brain injury (TBI) and intraventricular autologous fresh blood-induced intracerebral hemorrhage (ICH) in rats. As compared to sham operation controls, miR-122 decreased 7 fold at 3 hrs, 39 fold at 24 hrs, 21 fold at 7 days and 24 fold at 14 days in blood after TBI in rats. In comparison, miR-122 decreased 28 fold at 3 hrs, 34 fold at 24 hrs, 31 fold at 7 days and 19 fold at 14 days in blood after ICH in rats. These miR-122 expression data suggest that elevating miR-122 in blood has great potential to treat TBI and ICH.
Therefore, we hypothesized that i.v. miR-122 mimic improves outcomes after TBI and ICH, in addition to IS. Using experimental TBI and ICH models, our data show that miR-122 mimic (2.4 mg/kg, i.v.) decreases BBB disruption at 24 hours after ICH and reduces cognitive deficits at 11-15 days after TBI. Our miR-122 targetome studies show that a set of miR-122 target genes (Pla2g2a, Vcam1, Nos2, Rhbdf1, Olig1, Nrep) are responsible for the therapeutic efficacy of miR-122 mimic on ischemic stroke, while another set (Pla2g5, Ywhaq, Grm1) account for efficacy in ICH. Using 3'UTR luciferase reporter assays and anti-sense Morpholino Oligos (MOs), we show that miR-122 binds to 3'UTR of its target genes Pla2g2a and Vcam1, rather than Nos2. In addition, *in vivo* MO-miR-122-Pla2g2a blocks miR-122 mimic treatment-induced decrease of Pla2g2a in blood cells after ischemic stroke. Although the targetome study of miR-122 on TBI is still ongoing, we predict that a different set of miR-122 target genes are responsible for the efficacy of miR-122 mimic to improve TBI outcomes.
In summary, our data suggest miR-122 mimic can treat IS, TBI and ICH. Therefore, the miR-122 mimic treatment for these acute brain injuries could likely be performed without brain imaging (e.g. in the ambulance, on the battlefield) since it is equally efficacious for IS, TBI, ICH.

Title: Intranasal insulin improves cognitive function and reduces anxiety-like behavior after repeated mild brain injury

Authors: *K. R. BYRNES[1], **N. HOCKENBURY**[1], D. ACS[1], M. C. TSUDA[2], W. H. FREY, II[3]; [1]Uniformed Services Univ., Bethesda, MD; [2]Rat Behavior Core, HJF/Uniformed Services Univ., Bethesda, MD; [3]Healthpartners Neurosci. Ctr., Saint Paul, MN

Abstract: Following a mild traumatic brain injury (mTBI) there is a period of vulnerability to repeated injury, during which a second impact may have worsened outcomes. Our previous research shows that a second impact at 24 hours after an initial mTBI will significantly worsen function and histopathological measures of injury, and that this may be due to a period of depressed cerebral glucose uptake. We have also shown that intranasal insulin can significantly improve outcome after moderate TBI. In order to determine if insulin delivery during the period of vulnerability can improve outcome after a repeated mTBI (rmTBI), we performed a mild lateral fluid percussion (LFP) injury in adult male Sprague Dawley rats followed by intranasal saline (vehicle) or insulin at 4 hours and 24 hours post-injury. A second mild LFP was then performed and behavioral tests assessed. Cognitive function was assessed with the Morris Water Maze task at days 11 - 14 post-injury. While a rmTBI did not significantly affect latency to find a hidden platform, it did significantly alter search strategy in the probe trial test in comparison to naïve rats. This altered search strategy was returned to naïve levels with insulin administration between the 2 mTBI impacts. To assess post-injury anxiety-like function, Open Field, Light-Dark Box and Elevated Zero Maze tests were performed. Rats exposed to rmTBI and saline administration showed a significant increase in anxiety-like behavior, with less time in the center of the open field and more grooming behavior in the periphery of the test. Insulin administration between mTBI impacts significantly increased time in the center of the open field and reduced grooming behavior. While rmTBI rats showed significant reductions in entries into the light area with the Light-Dark box in comparison to naïve rats, insulin did not alter this behavior. No significant effect of injury was noted in the Elevated Zero Maze test. These data demonstrate that rmTBI can negatively affect aspects of memory and anxiety, and that insulin administration during the vulnerable period can reverse these effects. Additional assessment is needed to fully understand the pathophysiology of this response and of insulin's mechanism. However, these data show the promise of intranasal insulin in the treatment of rmTBI.

Title: Chemokine receptors CCR5 & CXCR4: Potential targets for enhancing recovery after traumatic brain injury

Authors: *Y. FRIEDMAN-LEVI[1], S. LIRAZ-ZALTSMAN[2,1], G. GINCBERG[1], E. L. KESNER[1], A. J. SILVA[3], E. SHOHAMI[1];
[1]Hebrew Univ., Jerusalem, Israel; [2]The Joseph Sagol Neurosci. Ctr., Sheba Med. Ctr., Ramat-Gan, Israel; [3]Dept Neurobiol, UCLA Med. Ctr., Los Angeles, CA

Abstract: **Background**: In recent years, chemokine receptors CCR5 and CXCR4, have been investigated in the context of cognitive deficits, neuropathic pain, HIV-associate neurocognitive disorders and stroke-related learning and memory dysfunction in human and rodents. CCR5 was shown to negatively regulate CREB activation, and inhibition of CCR5 signaling enhanced learning, memory and plasticity processes in hippocampal and cortical circuits (Zhou et al. eLife 2016). Moreover, mice with CCR5 knockdown and patients with a naturally occurring CCR5Δ32 loss of function mutation were found to have enhanced motor recovery and reduced cognitive deficits after stroke and traumatic brain injury (TBI) (Joy et al. Cell 2019). In the present study we investigated changes in the expression of CCR5 and CXCR4 after TBI in mice. To this effect we used flow cytometry analysis to measure the expression and co-expression of these receptors in several different time points post closed head injury (CHI) on cortical and hippocampal neurons, astrocytes and microglia. Additionally, we examined the effect of pharmacological blockers Maraviroc (for CCR5) and Plerixafor (for CXCR4), both FDA-approved drugs, on expression levels of these receptors, on motor and cognitive functions and on biochemical and pathological features in the brain. Finally, we investigated the immune response of the treated mice post CHI. **Results:** Cortical and hippocampal CCR5 and CXCR4 levels increased after CHI and the most significant changes in all 3 cell types were found on days 3 and 11. We found that Maraviroc and Plerixafor lead to significant improvement in post-CHI cognitive functions, and Plerixafor also improved motor function. Moreover, we demonstrated a significant increase in the number of hippocampal neurons and hippocampal area, reduced lesion volume and ventricular size, and increased phosphorylation level of the NR1 subunit of NMDAR. Changes in levels of CCR5 and CXCR4 expression on neurons, astrocytes and microglia were also noted along with reduction in the levels of infiltrating cells into the cortex. **Conclusions:** In this study we have elucidated the negative effect CCR5 and CXCR4 chemokine receptors exert on recovery after CHI and recognized these receptors as new potential targets for enhancing recovery following TBI. We identified the time points post CHI in which the expression of these receptors is maximal, and were able to design effective treatments based on FDA - approved drugs, that block these receptors and may serve as potential treatment for individuals suffering from functional decline after TBI.

Title: Mesenchymal stem cell-derived exosomes improve functional recovery in female rats after traumatic brain injury

Authors: *Y. ZHANG[1], Y. ZHANG[2], M. CHOPP[2,4], M. LU[3], Z. ZHANG[2], A. MAHMOOD[1], Y. XIONG[1];
[1]Neurosurg., [2]Neurol., [3]Publ. Hlth. Sci., Henry Ford Hosp., Detroit, MI; [4]Physics, Oakland Univ., Rochester, MI

Abstract: Background: Our previous study has demonstrated that exosomes derived from bone marrow mesenchymal stem cells improve functional recovery in male rats subjected to traumatic brain injury (TBI). The aim of this study was to determine the therapeutic effects of exosomes on functional recovery in female rats subjected to TBI. **Methods:** Anesthetized female age-matched young rats (2-3 months) subjected to moderate TBI induced by controlled cortical impact over the left parietal cortex were randomly divided into the following treatment groups (n=8/group): 1) phosphate-buffered saline (PBS as Vehicle group); and 2) exosomes administered at 1 day (Exo group) post TBI. PBS or exosomes at a dose of 100 μg/rat were injected via a tail vein in 0.5 ml PBS for 5 min starting at 1 day after TBI. Sham female animals with surgery without treatment were included as TBI controls (Sham, n=8). We performed the functional tests 1 day and then weekly post-injury including footfault, adhesive removal, modified neurological severity score (mNSS) and Morris water maze tests (MWM). Animals were sacrificed at day 35 after TBI for future histology study of the brains. **Results:** We found that female TBI rats exhibited spontaneous functional recovery specifically for forelimb footfault and adhesive removal tests and these functions were fully recovered at 28 days post injury, and there was no difference in footfault and adhesive removal functions between Vehicle and Exo groups. However, treatment with exosomes at a dose of 100 μg/rat starting 1 day post TBI significantly reduced mNSS score at 28 days and 35 days compared to Vehicle group ($p<0.05$). Importantly, exosome treatment significantly improved cognitive function (reduced the latency and increased % time spent in the correct quadrant in the MWM test) in female TBI rats compared to Vehicle-treated TBI rats ($p<0.05$). **Conclusion**s: Our data demonstrate that exosome treatment initiated at 1 day post-injury at a dose of 100 μg/rat provides a significant therapeutic effect on functional and cognitive recovery in female rats after TBI.

Title: Unrepaired open craniectomy worsens motor skill impairment in a rat traumatic brain injury model

Authors: *S. BARBAY[1], S. TSAU[1], B. T. ANDREWS[2], R. J. NUDO[1,3];
[1]Rehabil. Med., [2]Dept. of Plastic Surgery, [3]Landon Ctr. on Aging, Univ. Kansas Med. Ctr., Kansas City, KS

Abstract: Decompressive craniectomy (DC) is often required to manage intracranial pressure (ICP) after traumatic brain injury (TBI). Traditionally it involves cranial bone removal at the time of TBI followed by cranioplasty in a delayed fashion. In humans, this can lead to neurological morbidities called syndrome of the trephined. Our long-term goal is to evaluate the use of novel expansile materials that allow for a single stage DC and cranioplasty in the hopes of averting two operations and complications of syndrome of the trephined. In our initial studies, we are utilizing a rodent model of traumatic brain injury (TBI) to test these new materials. The purpose of the present study was to characterize neurological impairment following TBI in rats with an unrepaired craniectomy (DC group) and rats with a closed cranium using a standard non-expansive acrylic following TBI (Cranioplasty group). Long Evans male rats received a controlled cortical impact (CCI) over the caudal forelimb area (CFA) of the motor cortex using a commercial impact device with a 3mm dia. rod with a 1.5 m/s impact velocity delivered at a 2 mm depth from the dura with an impact time of 100 milliseconds. The CFA was exposed with intact dura using a 5 mm cranial trephination. Immediately after CCI rats received either a larger 1 cm craniectomy over the damaged hemisphere (DC group) or an acrylic cranioplasty sealing the cranial vault immediately after impact (Cranioplasty group). Motor performance was assessed on a skilled reaching task on post-CCI weeks 1 - 4, 8, 12 and 16. Three weeks after the CCI injury, the cranioplasty group showed more improvement in motor skill than the DC group. The cranioplasty group continued to perform better than the DC group throughout weeks 4, 8, 12 and 16. Post-mortem assessment of the dorsal surface of the brains from each group 4 mos. after the CCI revealed cortical swelling. The DC group showed more extensive swelling then the cranioplasty group with brain parenchyma protruding through the open cranial vault. The

protracted recovery of motor skills seen after the large craniectomy suggests this model may be beneficial for testing the efficacy of new materials for cranioplasty in rodent TBI models.

Abstract: Mesenchymal stem cells (MSCs) are emerging as a potential therapeutic intervention for brain injury due to their neuroprotective effects and safe profile. However, the homing ability of MSCs to injury sites still needs to be improved. Fibroblast Growth Factor 21 was recently reported to enhance cells migration in different cells type. In this study, we investigated whether MSCs that overexpressing FGF21 (MSC-FGF21) could exhibit enhanced homing efficacy in brain injury. We used novel Molday IONEverGreen™ (MIEG) as cell labeling probe that enables a non-invasive, high-sensitive and real-time MRI tracking. Using a mouse model of traumatic brain injury (TBI), MIEG labeled MSCs were transplanted into the contralateral lateral ventricle followed by real-time MRI tracking. FGF21 retained MSC abilities of proliferation and morphology. MSC-FGF21 showed significantly greater migration in transwell assay compared to control MSC. MIEG labelling showed no effects on MSCs' viability, proliferation and

differentiation. MRI revealed that FGF21 significantly enhances the homing of MSC toward injury site. Histological analysis further confirmed the MRI findings. Taken together, these results show that FGF21 overexpression and MIEG labelling of MSC enhances their homing abilities and enables non-invasive real time tracking of the transplanted cells, provides a promising approach for MSC based therapy and tracking in TBI.

Title: Dual allosteric modulator reverses traumatic brain injury induced cognitive impairments

Authors: *D. J. TITUS[1], T. JOHNSTONE[2], D. HOGENKAMP[2], K. W. GEE[2], C. M. ATKINS[1];
[1]Dept. of Neurosurg., Univ. of Miami Miller Sch. of Med., Miami, FL; [2]Dept. of Pharmacol., Sch. of Medicine, Univ. of California, Irvine, Irvine, CA

Abstract: Traumatic brain injury (TBI) causes long-term neurocognitive disabilities in a significant number of chronic survivors. Thus, effective therapeutic strategies to ameliorate chronic learning and memory deficits after TBI are greatly needed. α5 subunit-containing $GABA_A$ receptors ($GABA_ARs$) and α7 nicotinic acetylcholine receptors (nAChRs) are key regulators of hippocampal network activity and mediate hippocampal dependent learning and memory. Simultaneous allosteric modulation of both the α7 nAChR and α5 $GABA_AR$ with the drug 522-054 induces long-term potentiation (LTP) and enhances cognitive functioning in normal animals. In the present study, we tested the effects of 522-054 on the reversal of deficits in hippocampal synaptic plasticity, and learning and memory in the chronic recovery period of TBI. Adult male Sprague Dawley rats received moderate parasagittal fluid-percussion brain injury or sham surgery. At 3 months after recovery, basal synaptic transmission and LTP at the Schaffer collateral-CA1 synapse was assessed in acute hippocampal slices. TBI caused a significant reduction in basal synaptic transmission and expression of LTP. Bath application of 522-054 (0.1 μM) reduced deficits in basal synaptic transmission and reversed the impairments in LTP expression. Given the reversal of LTP deficits with 522-054 treatment, we tested whether hippocampal dependent learning and memory after TBI could be restored. At 3 months after

recovery, animals received vehicle or drug 522-054 (0.03 mg/kg, intraperitoneally) at 30 minutes prior to training on contextual and cue fear conditioning and the water maze task. TBI significantly impaired cue and contextual fear conditioning as well as water maze acquisition and retention. Treatment with 522-054 during training on both of these tasks reduced deficits in cue and contextual fear memory and water maze acquisition and retention. These results suggest that dual allosteric modulation of cholinergic and GABAergic signaling may be a potential therapeutic to reverse the deficits in hippocampal synaptic plasticity and restore cognitive functioning after TBI.

Title: A ketone mono-ester, 3-hydroxybutyl-3-hydroxybutyrate, attenuates sensory and motor deficits in a CCI model of TBI in male Sprague-Dawley rats

Authors: *C. P. ALMEIDA-SUHETT[1,3], A. NAMBOODIRI[2], K. CLARKE[4], P. DEUSTER[1]; [1]Consortium for Hlth. and Military Performance, Dept. of Military Emergency Med., [2]Dept. of Anatomy, Physiology, and Genet., Uniformed Services Univ. of the Hlth. Scienc, Bethesda, MD; [3]Henry M. Jackson Fndn. for the Advancement of Military Med., Bethesda, MD; [4]Dept. of Physiology, Anat. & Genet. (DPAG), Univ. of Oxford, Oxford, United Kingdom

Abstract: Introduction: Traumatic brain injury (TBI) is a leading cause of death and disability and can lead to long-term morphological and functional deficits. There is no effective therapy to control the progression of injury and prevent the development of neurological deficits after TBI. Ketone-ester supplementation has been shown to be neuroprotective in animal models of neurodegenerative disorders. However, its efficacy in reducing TBI pathophysiology is yet to be determined. **Methods:** A 2x2 factorial design was used to assess the neuroprotective effect of the ketone ester, 3-hydroxybutyl-3-hydroxybutyrate (ΔG®), in male Sprague-Dawley rats (n=32; 8 rats/group) submitted to a controlled cortical impact (CCI) model of TBI. Sham animals were exposed to the CCI surgical procedure but did not receive the brain impact. The rat diet was supplemented with either water or ΔG® by oral gavage (0.5 mL/kg/day) and in water at 0.3% concentration ad libitum. At 28 days post injury, the Neurological Severity Scale-Revised (NSS-R) test was used to assess neurological motor and sensory damage in all rats. Animals were then

perfused, their brains removed, frozen and sliced at 40 μm. A 1-in-5 series of brain sections were stained in cresyl violet and used for stereological quantification of the lesion volume. Data were analyzed using analysis of variance (ANOVA) and analysis of covariance (ANCOVA). **Results:** NSS-R test scores in the CCI group with ΔG® supplementation were 1.16 (SD=0.44), significantly ($p<0.05$) lower than the CCI group with a control vehicle (water) at 4.43 (SD=0.46). There were no significant differences found between the CCI + ΔG®, Sham + ΔG®, and Sham + Control Vehicle (water) groups. Similarly, NSS-R motor scores in the CCI + ΔG® group (0.62+/-0.74) were significantly lower ($p<0.05$) compared to CCI group scores (2.87+/-1.45). There were no significant differences found between the CCI + ΔG®, Sham + ΔG®, and Sham + Control Vehicle (water) groups for both NSS-R total and motor scores. The mean volume of the lesion reduced from 17.32 mm^3 (SEM=10.6) in the CCI group with a control vehicle (water) to 10.1 mm^3 (SEM=3.1) in the CCI group with ΔG® supplementation ($p < 0.001$). **Conclusion:** Ketone ester supplementation improved sensory and motor reflexive behavior in the NSS-R assessment and reduced the lesion volume. Our data suggest that ΔG® supplementation is neuroprotective against TBI-induced morphological and functional deficits. **Disclaimer:** The views expressed are those of the authors and do not reflect an official position of the Uniformed Services University or the United States Department of Defense. Title: Human non-hematopoietic umbilical cord blood stem cell treatment reduces inflammation following traumatic brain injury in rats

Authors: *M. R. CHROSTEK[1], A. T. CRANE[1], V. D. KRISHNA[2], N. L. EMMITT[2], N. G. TOMAN[3], W. J. SWANSON[4], E. G. FELLOWS[3], M. L. SHIAO[1], M. C. CHEERAN[2], W. C. LOW[1], A. W. GRANDE[1];

Abstract: There are an estimated 2.9 million traumatic brain injuries (TBI) reported in the United States each year. Many patients who suffer TBI develop long-term motor and cognitive deficits but have few available treatment options. Following trauma to the brain, a neuroinflammatory response is generated which can exacerbate the initial injury and cause further damage. Chronic neuroinflammation following TBI is associated with neurological decline and offers a target for therapeutic intervention. By modulating the immune response following TBI, neuroinflammation may be reduced leading to improved neurological function and recovery. Here we tested the immunomodulatory effects of human non-hematopoietic umbilical cord blood stem cell (nh-UCBSC) therapy in a rat TBI model. Female Sprague-Dawley rats received a unilateral, controlled cortical impact injury to the primary and secondary motor cortices. Two days after injury rats received either 1 million nh-UCBSC or a vehicle administered through the femoral artery. Different groups of rats were sacrificed at two, seven, and thirty days post-treatment, and assessed using flow cytometry and immunohistochemistry to examine immune system response. Additionally, behavioral testing was conducted to evaluate functional recovery. Following TBI, compared to naïve uninjured controls, there were increased numbers of inflammatory immune cells, primarily neutrophils, in the injured, ipsilateral region of the brain. In the periphery higher neutrophil counts were also noted in the blood. nh-UCBSC treatment of rats with TBI returned neutrophil counts in the brain and blood to the levels similar to the naïve uninjured controls. TBI rats with nh-UCBSC treatment also had increased lymphocyte and NK cell levels in the brain. These results indicate that nh-UCBSC treatment can modulate the immune system following TBI and reduce neuroinflammation which may lead to improved recovery. Of additional interest, the changes in neutrophil numbers in the blood may offer a biomarker which could be useful for monitoring neuroinflammation and evaluating anti-inflammatory treatments.

Title: Daily contextual manipulations are critical for success in a hippocampal dependent rehabilitation task following experimental traumatic brain injury

Authors: *L. M. LAW[1], D. R. GRIFFITHS[1], J. LIFSHITZ[2];
[1]Child Hlth., [2]Child Hlth. - Phoenix, Univ. of Arizona/Phoenix Children's Hosp., Phoenix, AZ

Abstract: Traumatic brain injury (TBI) is not a transient event from which all people recover; the resulting damage can evolve into neurological disease. As with patients, experimental TBI disrupts rodent memory circuits, evident as impaired cognitive performance. Experimental rehabilitation strategies, such as enriched environment and exercise, have partial success in alleviating symptoms. New rehabilitation strategies are necessary to demonstrate therapeutic efficacy and explore cellular mechanisms that promote recovery. Diffuse brain injury by midline fluid percussion leads to cognitive impairments by 1-month post-injury, permitting a timeframe to implement and investigate delayed interventions. Rehabilitation occurs in a box with a peg-board floor that allows for 10cm plastic pegs to be inserted at 2.5cm intervals in designated layouts; termed Peg Forest Rehabilitation (PFR). Brain-injured rats were exposed to PFR (15 min/day), allowing free navigation through either random daily layouts or the same layout daily in the peg-filled arena for 10 days over 2 weeks. The current study compared random daily PFR (dynamic) layouts versus the same PFR (static) layout for two weeks in male and female brain injured rats. We hypothesized that dynamic daily arrangements, not static, are necessary to prevent the onset of injury-induced memory impairments by challenging the limbic memory circuit. Previous results show that 2 weeks of PFR prevents the onset of cognitive deficits in injured rats for short-term, long-term, and working memory. Preliminary data revealed no differences between males and females, so they were combined for analyses. As previously shown, brain injured rats exposed to the dynamic PFR did not exhibit any deficits on 3 cognitive assessments. Interestingly, rats exposed to the static PFR were impaired when compared to the dynamic condition rats. Thus, passive, dynamic, intermittent rehabilitation targeting specific circuitry can prevent cognitive symptomatology. The Peg Forest is a viable rehabilitation strategy to explore cellular and molecular mechanisms to preserve neurological function.

Title: Reversing cognitive decline in chronic traumatic brain injury with targeted complement modulation

Authors: *K. MALLAH[1], A. ALAWIEH[1], R. CHALHOUB[2], F. LANGLEY[1], M. YORK[1], H. BROOME[1], S. TOMLINSON[1];
[1]Microbiology and Immunol., [2]Neurosci., Med. Univ. of South Carolina, Charleston, SC

Abstract: Introduction: Cognitive decline is a major chronic complication of traumatic brain injury (TBI). There are no therapeutic interventions for post-TBI dementia due to poor understanding of the pathophysiological mechanisms linking TBI to cognitive decline. We investigated the role of complement-driven neuroinflammation in neurodegeneration post-TBI, and investigated the effect of complement inhibition in cognitive recovery post-TBI. **Methods:** TBI was induced in adult mice using controlled cortical impact (CCI). Animals were housed for 1 or 2 months before administration of CR2-Crry, an injury-site targeted complement inhibitor, administered by a single or repeated intraperitoneal injections. Animals were then housed in enriched environments (to model rehabilitation therapy) and monitored for 2-6 months after CCI. Cognitive (Barnes maze) and motor testing (neurological deficit, ladder task) were performed. Brains were extracted for histological analyses. **Results:** Following CCI, cognitive performance on spatial learning task continued to deteriorate over 6 months of recovery. There was continued perilesional complement C3d deposition for 6 months after CCI, and significant microgliosis and astrogliosis that involved bilateral brain hemispheres. We observed a significant increase in size of astrogliotic scar at 90d compared to 7d and 30d after CCI. Repeat dosing with CR2-Crry starting either 1 or 2 months after CCI resulted in reversal of cognitive decline compared to vehicle treated animals. Treatment with CR2-Crry did not reduce lesion size after CCI, but significantly reduced the extent of microgliosis in the brain at 2-6 months after CCI. Declining cognitive performance in vehicle treated animals was associated with complement-dependent synaptic loss, which was inhibited by CR2-Crry treatment. **Conclusion:** Cognitive decline after TBI is dependent on ongoing neuroinflammation that can be inhibited with targeted complement inhibition as late as 2 months after injury. Complement inhibition may be a potential treatment for patients with chronic TBI who start to demonstrate signs of cognitive decline.

Title: Nmda receptor modulation with NYX-458 rescues cognitive impairment and peripheral growth hormone levels in a clinically relevant rat model of repeat concussion

Authors: *L. P. CACHEAUX[1], K. LEADERBRAND[1], R. J. WILSON[1], J. S. BURGDORF[1,2], M. E. SCHMIDT[1], S. U. SAHU[2], J. R. MOSKAL[1,2];

Abstract: N-Methyl-D-Aspartate receptors (NMDARs) are a family of ligand-gated ionotropic glutamate receptors that are highly expressed in the central nervous system (CNS). NMDAR-mediated excitotoxicity, and later NMDAR hypofunction, have been implicated in the neurobehavioral sequelae of traumatic brain injury (TBI). NYX-458 is a synthetic, small-molecule, orally bioavailable NMDAR modulator that facilitates hippocampal long-term potentiation and enhances performance in several learning and memory tasks in rodents. Here, a model of repeat closed head injury in adult rats was first characterized and then employed to evaluate the therapeutic potential of NYX-458 in TBI. Compared to sham treatment, repeat TBI resulted in glial activation and altered central cytokine and chemokine expression profiles, as well as reduced NMDAR expression and phosphorylation. Relative phosphorylation of several NMDAR-associated intracellular signaling molecules, including CaMKII and ERK1/2, was also reduced in this model. Behaviorally, TBI rats demonstrated deficits in the forced alternation Y-maze and positive emotional learning tasks. Pituitary dysfunction, and in particular growth hormone deficiency, is often seen in humans with TBI and is associated with cognitive deficits in these patients. Serum growth hormone was significantly reduced in TBI *versus* sham-treated rats, and this effect, as well as performance in both behavioral assays, were rescued by systemic administration of NYX-458. Finally, there was a trend towards elevated serum corticosterone in TBI rats compared to sham-treated rats, and in TBI rats, NYX-458 treatment significantly reduced corticosterone compared to vehicle treatment. Together, these data support the further investigation of NYX-458 in ameliorating cognitive and pituitary dysfunction as a result of head trauma. NYX-458 is in clinical development for the treatment of Parkinson's disease cognitive impairment and demonstrated a favorable safety, tolerability, and pharmacokinetic profile in a Phase 1 study in healthy volunteers.

Title: Neural protection and regeneration by inhibition of cholinesterase in TBI animals

Authors: *Y.-H. CHIANG[1], S.-C. HSUEH[2], W.-C. CHANG[3], C.-C. WU[1], K.-Y. CHEN[2]; [1]Dept. of Surgery, Sch. of Medicine, Col. of Med., [2]The Ph.D. Program For Neural Regenerative Med., [3]Grad. Inst. of Med. Sciences, Col. of Med., Taipei Med. Univ., Taipei, Taiwan

Abstract: Traumatic brain injury (TBI) is a leading cause of death and long-term physical or mental condition disability in the developed world. By 2020 TBI will comprise the third largest portion of the global disease. Within the first year after injury, 70-90% of patients continue to manifest prolonged and constantly permanent neurocognitive dysfunctions. Recently, the emerging evidence indicates that this process of TBI can lead to early onset of dementia. TBI is a strong environmental risk factor for development of Alzheimer's disease (AD). Our previous data have shown that (-)-phenserine (Phen), an acetylcholinesterase inhibitor originally designed and tested in clinical Phase III trials for Alzheimer's disease (AD), can reduce neurodegeneration after mild TBI. In addition, Phen can also inhibit neuronal apoptosis following ischemia/reperfusion injury. Here, we used a mouse model of moderate to severe TBI by controlled cortical impact (CCI) to assess the neuroprotective effects of Phen. Animals were treated with Phen (2.5 mg/kg, IP, BID) for 5 days and the effects were evaluated by behavioral histological and western blot examinations at 1 and 2 weeks after injury. Phen significantly attenuated TBI-induced contusion volume, enlargement of the lateral ventricle, and behavioral impairments in motor asymmetry, sensorimotor functions, motor coordination and balance functions. After injury, the morphology of microglia was shifted to an active from a resting form, and Phen dramatically reduced the ratio of activated to resting microglia, suggesting that Phen can diminishes neuroinflammation after TBI. While Phen has potent anti-acetylcholinesterase activity, its (+) isomer Posiphen shares many neuroprotective properties but is almost completely devoid of anti-acetylcholinesterase activity. We evaluated Posiphen at a similar dose to Phen and found similar mitigation in lateral ventricular size increase, motor asymmetry, motor coordination, and balance function, suggesting the improvement of these histological and behavioral tests by Phen treatment occur via pathways other than anti-acetylcholinesterase (AChE) inhibition. However, the reduction of lesion size and improvement of sensorimotor

function by Posiphen were much smaller than with equivalent doses of Phen. Taken together, these results show that post-injury treatment with Phen over 5 days significantly reduces the effects of TBI, suggesting Phen might be a potential compound for clinical use in TBI therapy.

Title: Divergent effects of gliptins on the pathological outcomes in a mouse model of traumatic brain injury

Authors: *Y.-W. HUNG, Y. WANG, S.-L. LEE;
Natl. Hlth. Res. Inst., Miaoli, Taiwan

Abstract: Traumatic brain injury (TBI) causes severe disability and mortality. Limited direct therapies are available. Modulation of incretin level seems to offer therapeutic effects against several neurodegenerative disorders. It is, thus, hypothesized that active incretin enhancement by gliptins through inhibiting dipeptidyl peptidase-4 (DPP-4) may also reduce the neuropathological progression caused by mechanical trauma. In the present study, we explored the therapeutic effects of two structurally different gliptins in a controlled cortical impact model of TBI. A moderate TBI was stereotaxically delivered to the right sensorimotor cortex of mice. Gliptins were fed to the animals daily following the injury. Sitagliptin and vildaglptin augmented similar level of active glucagon-like peptide-1 in blood and brain. Only sitagliptin mitigated neurological impairment, brain lesions, and microglial activation. Expression of the anti-inflammatory cytokine IL-10 was elevated by sitagliptin in damaged cortex and striatum. In contrast, a structurally-different DPP-4 inhibitor vildagliptin did not produce similar neuroprotective or anti-inflammatory effects. Our data support a favorable protective effect of sitagliptin against TBI.

Title: Rolipram loaded polymeric micelle nanocarrier reduces inflammatory response and apoptosis after traumatic brain injury

Authors: ***C. MACKS**[1], D. JEONG[1], M. LYNN[2], J. LEE[1];
[1]Clemson Univ., Clemson, SC; [2]Greenville Hosp. Syst., Greenville, SC

Abstract: Traumatic brain injury (TBI) is a leading cause of hospitalization and death with many patients living with long-term disability. Following injury to the CNS, the level of cyclic adenosine monophosphate (cAMP) drops due to increased degradation by phosphodiesterase 4 (PDE4). The cAMP level in the CNS is linked with neural growth cone development, regenerative capacity of adult neurons, and reduced levels of pro-inflammatory cytokines. Additionally, many extracellular inhibitors of neuroplasticity, including chondroitin sulfate proteoglycans and myelin associated inhibitors, act through the RhoA and Rho kinase (ROCK) pathway. Rolipram (Rm), a hydrophobic drug, restores cAMP level by inhibiting PDE4 and can improve functional recovery, reduce cell apoptosis, and reduce inflammatory cell infiltration. The goal of our work is to develop a nanotherapeutic for combinatorial delivery of Rm and siRNA targeting RhoA. To accompl ish this goal, we synthesized a cationic, amphiphilic, copolymer (poly(lactide-co-glycolide)-graft-polyethylenimine: PgP) capable of loading hydrophobic drugs and complexing nucleic acids. In this study we investigate the effect of cAMP restoration by Rm-PgP on secondary injury in a rat controlled cortical impact injury (CCI) model for TBI. The Rm was loaded to the hydrophobic core of PgP through solvent evaporation method and the amount of Rm loading was determined by HPLC. A craniotomy (5 mm diameter) centered at 3.5mm posterior and 3.5mm lateral of the bregma was performed and the injury generated using an Impactor at 3.5m/s and a depth of 2mm using a 3mm tip. Animals were divided into 3 groups: Sham, untreated TBI (20µL, Saline), and Rm-PgP (20µL, 16µg Rm). Immediately after injury, Rm-PgP was administered by intraparenchymal injection in the lesion site. At 7days post-injury, brains were retrieved for cAMP level by ELISA assay. For histological analysis, rats were euthanized at 7days post-injury by caridac perfusion with 4% PFA, brains collected, and cryosectioned (30µm). Sections were stained with cresyl violet for

lesion volume and by IHC for ED1 (macrophages/microglia) and GFAP (astrocytes). To assess apoptosis, TUNEL assay was performed. We demonstrated that Rm-PgP treatment restores cAMP to a level not significantly different from sham level for up to 3days post-injury. Additionally, we demonstrated that cAMP restoration by Rm-PgP significantly decreased lesion volume, improved neuronal survival, reduced inflammatory cell infiltration, and reduced astrogliosis compared to untreated TBI. In the future, we will evaluate the synergistic effect of Rm-PgP and PgP/siRhoA treatment on secondary injury in a rat CCI TBI model.

Title: Intravitreal injection of mesenchymal stem cells expressing hIGF-1 increases mouse retinal ganglion cells survival and axonal regeneration in a model of optic nerve crush

Authors: *J. F. VASQUES[1], C. A. ABREU[1], L. CHIMELI-ORMONDE[1], B. S. F. SOUZA[3], M. B. P. SOARES[3], R. MENDEZ-OTERO[2];

Abstract: Introduction and objectives: Retinal ganglion cells (RGCs) are the output neurons of vertebrate retina, and their axons form the optic nerve. RGCs present poor regenerative capacity and their axons do not regenerate at long distances after damaged. Also, axonal damage leads to death by apoptosis of most of RGCs. There are actually no clinically applicable therapies to protect RGCs and restore axonal integrity in an efficient and sustainable way. Therefore, cell therapy emerges as a promising approach that can be easily translated to clinical practice. Recently, bone marrow-derived cells have been used to promote cell survival and regeneration in several preclinical models. In rat model of optic nerve crush, our group recently demonstrated that mesenchymal stem cells (MSC) intravitreally injected remained in eye at least for 18 weeks, leading to sustained protection of RGCs and robust axonal regeneration. However, no visual function recovery was detected. In the present work our goal is to potentiate the protective and regenerative effect of MSC therapy. Considering that many effects evoked by MSC therapy were associated with the trophic factor, cytokines and other molecules secreted by those cells, a novel

promising tool is the genetic modification of cells in order to overexpress specific molecules of interest. Regarding SNC lesions, the insulin-like growth factor-1 (IGF-1) is a potential candidate, due to its neuroprotective and neuroregenerative actions. Therefore, we used mouse transgenic MSC line expressing the human trophic factor IGF-1 (mMSC-hIGF1). Methodology: SvEv129 adult mice were submitted to optic nerve crush and simultaneous intravitreal injection of vehicle, 200.000 mMSC-hIGF1 or control-mMSC. 14 days after surgery eyes and nerves were removed. Retinas were dissected and immunohistochemistry for TUJ1, marker of RGCs, was performed. Axonal regeneration was measured by CTB incorporation, injected intravitreally. Results and discussion: Injection of 200.000 mMSC-IGF1 cells lead to a significant increase (90% higher than vehicle) in RGC survival after optic nerve crush. This neuroprotective effect was more robust than the evoked by control-mMSC, which was already significant in relation to non-treated animals Moreover, axonal regeneration was also increased in mMSC-IGF1 animals, in relation to control-mMSC and vehicle groups. Also, axons from mMSC-IGF1 animals reached further distances in optic nerve. Our data suggests that IGF-1 is capable to potentiate neuroprotective and proregenerative actions of MSCs. It remains to be determined whether this effect is sustained and if it also results in functional recovery.

Title: Viral reprogramming of reactive astrocytes to neurons as a therapy for cerebral injury

Authors: *E. G. FELLOWS, A. T. CRANE, N. G. TOMAN, A. R. STEEVENS, M. R. CHROSTEK, A. W. GRANDE;
Neurosurg., Univ. of Minnesota Med. Sch., Minneapolis, MN

Abstract: Cerebral injury is a leading cause of long-term disability and death worldwide. Common neurological hallmarks of cerebral injury include neuronal loss and reactive astrocytosis. However, current treatments fail to target cellular disruption and improve functional recovery. A novel approach to address neuronal loss is direct reprogramming of reactive astrocytes to neurons following injury. In this method, viral vectors designed to transduce astrocytes force the expression of proneural genes, thereby promoting direct transdifferentiation

into a neuronal lineage. We hypothesize that astrocytes can be reprogrammed to neurons using adeno-associated virus (AAV) and that the penumbra of the lesion can be targeted using stereotactic surgical injections to induce reprogramming and promote functional recovery. We have seen successful reprogramming *in vitro* and *in vivo*. Specifically, we observed canine astrocytes expressing immature neuronal markers following transduction with AAVrh10 expressing either Ascl1 or Ngn2 under the Gfap or Ng2 promoters. In preliminary *in vivo* studies, AAVrh10 expressing Ascl1 and an mKate2 fluorescent reporter under the Gfap promoter was injected into the cortex of rats 7 days following ischemic injury. At 7- and 14- days post AAV injection, we observed mKate2-expressing cells in the cortex and striatum. Importantly, a subset of mKate2-expressing cells also expressed mature neuronal marker NeuN, but not GFAP, indicating a reprogrammed state. These results support the feasibility and efficacy of AAV in stroke models. We are also investigating the mechanisms of reprogramming in traumatic brain injury using the cre-lox system in transgenic mice. After traumatic brain injury, behavior tests were performed at 24hrs, 7 days, and 21 days post-reprogramming to evaluate functional outcome. Immunostaining will be used evaluate infection efficiency and the presence of neuronal markers post-infection. *In vitro* studies using cell cultures isolated from the transgenic mice will be performed for further analysis. In conclusion, AAV has great potential to promote brain repair following cerebral injury.

Title: CMX-2043 improves neurological outcomes after moderate focal traumatic brain injury

Authors: *T. HALLOWELL[1], N. DELSO[1], K. BROWNE[2], M. STOLOW[1], J. STARR[1], M. J. MCMANUS[3], D. CULLEN[2], T. KILBAUGH[1];
[1]Children's Hosp. of Philadelphia, Philadelphia, PA; [2]Ctr. for Brain Injury and Repair, Dept of Neurosurg., Univ. of Pennsylvania, Philadelphia, PA; [3]Ctr. for Mitochondrial and Epigenomic Med. (CMEM), CHOP/UPENN, Philadelphia, PA

Abstract: Traumatic brain injury (TBI) is a leading cause of death and acquired disability in children in the United States. Despite breakthroughs in rodent TBI models, there has been little translational therapeutic success. Although TBI is a multi-faceted injury model, reactive oxygen

species (ROS) have been identified as causing significant secondary injury following TBI. Alpha lipoic acid (ALA) is a naturally occurring compound that has been shown to act as a neuroprotective therapeutic by reducing ROS. This study aimed to identify the efficacy of the drug CMX-2043 (Ischemix Pharmaceuticals), an analog of ALA, in an immature swine model with a five day survival period. Delivery of CMX-2043 was randomized and blinded. A tunneled central venous catheter was placed in immature piglets between 26 and 28 days old to allow for drug delivery and blood collection for biomarker analysis. A moderate focal TBI was delivered using an engineered, piston-driven controlled cortical impact (CCI) device attached directly to the skull. The drug was delivered at designated time points during the five day survival period. MRI scans were taken at the completion of the survival period to allow for quantification of neurological damage. Mitochondrial respirometry was conducted to identify ROS in brain tissue following treatment. Piglets were also outfitted with accelerometers which were used to measure actigraphy characteristics. Animals treated with CMX-2043 demonstrated a 55% decrease in ROS 24 hours post-TBI ($p<0.05$), a 40% decrease in volume of injury ($p<0.1$), a 30% improvement in microstructural tissue integrity ($p<0.05$), a 55% decrease in lactate levels as measured by magnetic resonance spectroscopic imaging ($p<0.05$), improved rest efficiency, and decreased periods of nighttime activity when compared to placebo animals. Lipid peroxidation and protein carbonyl levels confirmed that attenuation of excess mitochondrial ROS (mtROS) production by CMX-2043 was sufficient to protect the brain tissue. Mitochondrial control ratio (RCR), a measure of overall mitochondrial function, also demonstrated a 40% improvement compared to placebo animals ($p<0.05$). Differences in dosing schedules allowed for the distinction of mitochondrial bioenergetic effects (processes?) due to TBI and identified changes in these mechanisms due to treatment. The outcomes of this study provide clinicians with a potential novel avenue for treatment of TBI and shed new light on tissue energetics following TBI. These results suggest that treatment of moderate focal TBI with CMX-2043 significantly improves neurological outcomes in an immature swine model with identifiable translational applications.

Abstract: Traumatic brain injury (TBI) is a major cause of disability, with approximately 1.7 million incidents reported annually. Following a TBI, patients are likely to sustain cognitive and sensorimotor impairments and are at an increased risk of developing neurodegenerative diseases later in life. Despite TBI's prevalence and enduring effects, robust therapies that treat TBI neuropathology are not available in the clinic. One emerging approach is to target epigenetic mediators that modulate a variety of molecular regulatory events acutely following injury. Specifically, previous studies demonstrated that histone deacetylase inhibitor (HDACi) administration following TBI enhanced functional outcomes, reduced inflammation, and was neuroprotective. Here, we evaluated a novel quisinostat-loaded poly(D,L-lactide)-b-methoxy poly(ethylene glycol) (PLA-PEG) nanoparticle (QNP) therapy. This nanoparticle system was previously developed for glioblastoma; QNP administration slowed tumor growth and prolonged animal survival more effectively than free quisinostat. To assess QNP intervention in the context of TBI, a controlled cortical impact (CCI) model was used on adult C57BL/6 mice (2 mm tip diameter, 6.0 m/s over the frontoparietal cortex); all experiments were approved by ASU IACUC. Briefly, we evaluated initial pharmacodynamics via cortical histone acetylation levels following CCI and administration of QNPs. A second cohort of mice underwent a battery of behavioral assessment over the course of a month following injury and QNP intervention (rotarod, open field, gridwalk, and Morris water maze). We observed that QNP administration acutely following CCI increased histone acetylation specifically within the injury penumbra, as detected by Western blot analysis. Initial behavioral results indicate that QNP treatment dampened motor deficits as measured by increased rotarod latency to fall relative to blank nanoparticle- and saline-treated injured controls. Additionally, open field data show that QNP intervention altered locomotion following injury. These results suggest that HDACi therapies are a beneficial therapeutic strategy following neural injury and demonstrate the utility for nanoparticle formulations as a mode for HDACi delivery following TBI.

Title: Cognitive improvement by deep cerebellar stimulation in a traumatic brain injury model of rodents

Authors: N. D. MATHEWS[1], H. H. CHAN[2], O. HOGUE[1], C. WYANT[1], R. CHIOMINTO[1], A. MCCREERY[1], R. KUNDALIA[1], D. P. FLODEN[3], A. G. MACHADO[4], *K. B. BAKER[5]; [1]Cleveland Clin. Fndn., Cleveland, OH; [2]Neurosciences, [3]Ctr. for Neurolog. Restoration, [4]Ctr. Neurolog. Restoration, [5]Cleveland Clin., Cleveland, OH

Abstract: Many traumatic brain injury (TBI) survivors live with persistent chronic cognitive deficits despite contemporary rehabilitation services, underscoring the need for novel treatment. We have previously shown that deep brain stimulation (DBS) of the lateral cerebellar nucleus (LCN) can enhance post-fluid percussion injury motor recovery and increase the expression of markers of long-term potentiation in perilesional cerebral cortex. We hypothesize that a similar beneficial effect will be for cognitive deficits induced by controlled cortical impact (CCI) in rodents through long-term potentiation-based mechanisms. Twenty male Long Evans rats with a DBS macroelectrode in the LCN underwent CCI over the medial frontal cortex. After 8 weeks of spontaneous recovery, DBS treatment was applied for 4 weeks, with the Barnes maze and baited Y maze used to evaluate cognitive performance. All animals were euthanized and tissue harvested for further analysis by histology and immunohistochemistry. All animals in both cohorts, with or without LCN DBS generally had the performance on Barnes maze improved. However, by analyzing the variance of performance, only the treated group demonstrated a steady performance while the untreated group displayed a fluctuated performance ($p<0.01$). There is also a better performance on the baited Y-maze in the treated group when compared to that in untreated. The LCN DBS reversed the loss of BDNF+ cells at the perilesional area induced by the CCI lesion in the treated group, accompanying with the reversal of loss of p75NTR+ signal in the same area. Finally, CCI induced the proliferation of c-fos+ cells at the perilesional area which was further increased by the LCN DBS. The current study supports the hypothesis that LCN DBS improves the cognitive deficits by maintaining the health of perilesional neurons and their excitability.

Title: Effects of exercise as a pre-treatment for TBI in juvenile rats

Authors: *R. C. HOLDEN[1], M. J. HYLIN[2];
[1]Psychology, Southern Illinois Univ. Carbondale, Carbondale, IL; [2]Psychology, Southern Illinois Univ. Carbondale Dept. of Psychology, Carbondale, IL

Abstract: Traumatic brain injury (TBI) is the leading cause of death and disability in the juvenile population. As of yet, there is no clear "gold standard" rehabilitative therapy that maximizes long-term, functional recovery. In fact, most TBI interventions focus on secondary injury mechanisms as targets of treatment and have neglected an important avenue of therapy research: pre-treatment. While other injury models such as stroke have thoroughly investigated various pre-treatment interventions, the TBI model remains relatively unexplored. Exercise has been well-established as a beneficial strategy for brain injury rehabilitation due to its positive impact on neurogenesis, angiogenesis, and synaptic plasticity. Moreover, stroke research has indicated that pre-injury exercise reduces infarct size and benefits overall functional recovery. Therefore, the current study investigated the effects of exercise as a pre-treatment for juvenile TBI. To test this, male Sprague-Dawley rats were divided into three groups: injury+exercise pre-treatment, injury+no treatment, and shams. After being weaned on post-natal day 17, rats in the exercise group were pair-housed in running wheel cages until the injury. On post-natal day 28, rats were anesthetized and received either a controlled cortical impact (CCI) or a sham surgery. Following surgery, rats in the running wheel cages were returned to standard housing. In order to assess the effects of the pre-treatment exercise on recovery, rats underwent cognitive testing on the Morris Water Maze two weeks following injury. Results revealed that the pre-treatment group performed significantly better in the water maze compared to the no treatment group, such that the rats that received exercise showed significantly lower latencies to the hidden platform. These findings indicate that exercise before TBI may help to mitigate the cognitive effects of the damage and that it needs to be further explored as a pre-treatment intervention. Lesion verification to assess the impact of pre-treatment exercise on contusion size is currently underway.

Title: Investigating effects of transcutaneous spinal stimulation in restoring upper extremity function in people with spinal cord injury

Authors: *F. ZHANG, A. RAMANUJAM, K. MOMENI, M. RAVI, R. PILKAR, J. CARNAHAN, G. F. FORREST;
Kessler Fndn., West Orange, NJ

Abstract: Recovery of hand and arm functions is a high priority for individuals with spinal cord injury (SCI), because upper extremity function closely integrates with activities of daily living and determines the quality of their life. It is hypothesized that transcutaneous spinal stimulation (TSS), as an innovative and non-invasive technique, can change the excitability of spinal circuitry and neuro-modulate the spinal networks into physiological states that facilitate the restoration of paralyzed limb functions. Recently, the idea of applying stimulation to cervical spinal network to facilitate restoration of upper extremity function has gained increasing interest, but related research is limited so far. Therefore, this study aims to investigate the effects of TSS for restoring upper extremity and hand function in people with SCI. Individuals with a chronic cervical SCI received TSS intervention combined with hand function training for a 2-month period. Sub-threshold, tonic stimulation (monophasic, 1ms rectangular pulses at 30Hz, and 10kHz carrier frequency) was delivered using a pair of self-adhesive electrodes placed over cervical spinous processes and a pair of reference electrodes at anterior iliac crests. Hand training was supervised by physical therapists and focused on functional tasks aiming to address bilateral hand grasp and dexterity. Functional outcome measures and neuromuscular synergies (calculated from surface EMG signals) of upper extremities and hands were quantified at pre and post training points to determine the effects of TSS-based intervention. Pilot results from one motor complete SCI individual showed that TSS yielded immediate enhancement in grip strength (increased by 122.2±39.3% and 150.0±82.0%, bilaterally), as compared to baseline without stimulation. Voluntary motor control also improved where the participant was able to successfully lift water bottle and grasp tennis ball with stimulation enabled, which were not possible without stimulation. More importantly, the participant demonstrated progressive improvements in a series of hand outcome measures (i.e. grip and pinch strength test, and box and blocks test) over the course of intervention. These data suggest that TSS has the therapeutic potential of promoting neuroplasticity in upper extremity for SCI individuals.

Title: Transcutaneous spinal stimulation augments excitability of spinal circuitry during maximal voluntary contraction

Authors: *K. MOMENI[1,2], M. RAVI[1,2], A. RAMANUJAM[1,2], R. PILKAR[2], F. ZHANG[1,2], E. GARBARINI[1,2], G. F. FORREST[1,2];
[1]Ctr. for Spinal Stimulation, [2]Ctr. for Mobility and Rehabil. Engin. Res., Kessler Fndn., West Orange, NJ

Abstract: Transcutaneous spinal stimulation (TSS) for modulation of the neural networks has increased volitional control for motor complete and incomplete spinal cord injury. The objective of this study was to determine: i) the optimal spinal sites of stimulation and ii) optimal parameters of stimulation to modulate spinal networks for an isometric maximum voluntary contraction. A series of trials were performed with and without stimulation, including: i) maximal isometric knee extension (MVC) and ii) multiple repetitions within each trial. Monophasic pulses were delivered at varying frequencies for different amplitudes to spinal sites between C4/5 and S1/2 (as cathodes), concomitant with isometric knee extension task. Anodes were placed on anterior iliac crests, bilaterally. During spatiotemporal spinal mapping sessions, stimulation amplitudes corresponding to peak EMG responses were identified (A_P). Knee extensor torque values were recorded. At peak amplitude parameters (A_P), peak knee extensor torque increased by 16%, compared to baseline torque without stimulation. At sub-peak amplitude parameters (A_S, lower than A_P), peak torque increased by 36%, compared to baseline. Regardless of stimulation sites, peak torque increased for sub-peak amplitude parameters (A_S), compared to peak amplitude parameters (A_P). Peak knee extensor torque values with and without stimulation increased continually throughout the testing sessions. No neuromuscular fatigue was observed. TSS, with the presence of intent, can significantly augment human spinal motor-neuron excitability and motor pools recruitment rate during task-specific training. Improvements were evident in volitional production of greater isometric torque. These findings support that TSS could facilitate acute plastic changes in the spinal circuitry and, possibly, lead to improvements in functional motor performance.

Title: Spinal mapping identifies optimal parameters to target specific motor pools through existing spinal networks after SCI

Authors: *M. RAVI[1,2], K. MOMENI[1,2], A. RAMANUJAM[1,2], R. PILKAR[2], F. ZHANG[1,2], E. GARBARINI[1,2], G. F. FORREST[1,2];
[1]Ctr. for Spinal Stimulation, [2]Ctr. for Mobility and Rehabil. Engin. Res., Kessler Fndn., West Orange, NJ

Abstract: Spinal cord injury (SCI) affects the nervous system in various ways including causing affected individuals to suffer loss of mobility and sensation below the level of lesion. Activity based training therapies have long been the only therapeutic choice available to SCI individuals. However, more recently, researchers have shown that combining electrical stimulation with the aforementioned training therapies can lead to significant functional recovery for tasks such as standing, walking etc. The hypothesis is that even after SCI, the spinal sensorimotor networks that are non-functional can be activated or enabled when stimulation is used on the corresponding spinal roots. One of the challenges of using stimulation is finding optimal parameters for an individual. We systematically applied non-invasive transcutaneous spinal stimulation (TSS) on the spinal cord at roots between C4/5 and S1/2 with the anodes placed on the anterior iliac crests, and EMG was recorded on lower limb muscles. The stimulation waveforms (pulse width of 1ms) were either 'monophasic,' which consisted of a 10KHz pulse acting as a carrier wave or 'rectified,' which did not have the carrier wave. Systematic modulations of amplitude and frequency induced specific EMG responses for different spinal roots. Post processing involved a specialized, novel algorithm based on empirical mode decomposition to remove the artifact of stimulation pulses from the EMGs . Analysis of the muscle activity showed that the flexor muscles such as the Tibialis Anterior had a directly proportional relationship to stimulation frequency whereas the extensor muscles such as Vastus Lateralis and Gastrocnemius had an inversely proportional relationship with stimulation frequency. Researchers when using epidural stimulation found similar results. For the majority of muscles tested, muscle activity peaked at a given amplitude precipitating a decrease in muscle activity at increased amplitudes indicating that there exists an optimal stimulation amplitude or maximum motor threshold for different muscles. Our results show that spatiotemporal spinal cord mapping could be an essential step in finding optimal TSS parameters to target specific motor pools through the existing spinal networks after SCI.

Abstract: Tonic transcutaneous spinal stimulation (TSS) applied to afferent fibers within L2-S2 posterior (30Hz), below motor threshold have shown immediate positive effects on the leg EMG and reproducibly modified gait kinematics during voluntary treadmill stepping for individuals with incomplete spinal cord injury. Our laboratory has been piloting the intervention of TSS with overground training and exoskeleton training to show that the modulation of spinal networks leads to an increase in excitability of the spinal cord and afferent input during training. Participants completed a series of training sessions with and without stimulation. TSS was delivered between the spinous processes of C4-C5 and L1-L2 vertebrae as cathodes. Anodes were placed on anterior iliac crests. Before training, spatiotemporal spinal mapping sessions were performed by systematically modulating frequency, amplitude, and pulse-width at various spinal sites. Muscle activation data, obtained simultaneously during spinal mapping, provided targeted configurations to enable voluntary motor outputs for training. The stimulation waveform consisted of monophasic rectangular pulse with 10 kHz carrier frequency. Immediate effect of stimulation illustrated an increase in reciprocal and appropriate inter- and intra-limb leg muscle activation and symmetry of bilateral loading. During independent gait, without stimulation, bilateral lower limb motor pools fired simultaneously for an impaired gait pattern. With stimulation, there was a greater inter-limb reciprocal muscle activation for these lower limb pools; Intra-limb coefficient of variation for hip and knee kinematics decreased by 60% and 23%, respectively. Overall gait speed increased by 24%. Data suggested overground training enhanced with TSS and combined with high dosage of stepping can potentially lead to improved gait function.

Title: Neuromuscular responses to electrical stimulation profiles of varying amplitudes and frequency

Authors: *R. PILKAR, K. MOMENI, A. RAMANUJAM, E. GARBARINI, G. FORREST; Ctr. for Mobility & Rehabil. Engin., Kessler Fndn., West Orange, NJ

Abstract: During neuromuscular electrical stimulation (NMES), electrical current is applied to a nerve to elicit action potentials in denervated, peripheral muscles. NMES has been used to assist or restore neuromuscular function to paralyzed muscle after spinal cord injury (SCI). Further, chronic application of electrical stimulation (ES) has been shown to have a therapeutic effect on tissue health and voluntary function. Surface electromyography (EMG) provides an effective way to analyze underlying muscle activity. However, the overpowering presence of electrical stimulus artifact limits the assessment of the direct effect of ES on a muscle or nerve. Recent advances in biomedical signal processing have yielded algorithms that show significant success in removing ES artifacts from EMG signals recorded from the electrically stimulated muscle. Previously, we showed the effectiveness of a custom-developed computational algorithm, utilizing empirical mode decomposition (EMD) and notch filtering, to remove the ES artifact from EMG recordings of the electrically stimulated (35 Hz, 300μs) rectus femoris muscle (RF). We showed distinguishable, artifact-free muscle activations during two conditions of "ES-alone" and "ES+VOL," which is ES combined with the volitional effort to contract the muscle, in SCI (n=5) and able-bodied (n=5) participants. In this investigation, we extend our analysis to examine the neuromuscular responses to ES with ramping profiles at 35 Hz, and ES of 35 Hz, 55 Hz, and 75 Hz at constant amplitudes by studying the novel outcomes derived from artifact-free EMG activities in SCI (n=5) and able-bodied (n=5) participants. We confirm our findings by assessing concurrent torque profiles, measured using an isokinetic dynamometer. This investigation will help with the development of novel neuromuscular mapping techniques to elicit ES thresholds for specific motor pool activation. This could be significant as such relationships have only been established using mechanical outputs such as torque which could be the result of contributions from multiple muscle groups.

Title: Contribution of trunk muscles to upright sitting with segmental support in children with spinal cord injury

Authors: *G. SINGH, L. MENDEZ, B. UGILIWENEZA, A. BEHRMAN;
Univ. of Louisville, Louisville, KY

Abstract: Objective: Trunk muscles innervated by the thoracic and lumbar spine are critical for mobility as they are involved in virtually all movements requiring an upright posture whether seated, standing, or walking. Spinal cord injury (SCI) at cervical and upper thoracic levels results in paralysis or paresis of trunk muscles, as well as the upper and lower extremities, resulting in an inability to maintain upright balance during sitting and standing. Understanding the effects of SCI on trunk muscles should be one of the primary focuses in rehabilitation research to change the trajectory of outcomes in children with SCI. The aim of this study was to examine and compare trunk motor control and patterns of trunk muscle activation during sitting with segmental support in children with SCI to typically developing (TD) children. We selected to test children during the static control component of the Segmental Assessment of Trunk Control (SATCo) test while recording trunk muscle activity. We hypothesized that children with SCI would show significant differences in patterns of trunk muscle activation at the same segmental level of static control when compared to age-matched TD children. **Methods:** Twenty TD children (11f & 9m, age 7±2 years) were recruited from the community. Twenty-six children with chronic SCI (9f & 17m, age 5 ± 2 years) were recruited for this study. Surface electromyography (normalized amplitude) was collected from various trunk muscles. **Results:** Thoracic paraspinal muscle activation was significantly higher ($p < 0.05$) in SCI group from over lower ribs static control (OLRSC) to no support static control (NSSC) level. Lumbar paraspinal muscle was significantly higher in SCI group at pelvis and NSSC level. Rectus abdominus muscle was significantly higher in SCI group at from OLRSC to NSSC pelvis. External oblique was significantly higher in SCI group at pelvis static control (PSC) and NSSC levels. Intercostal muscle was significantly higher in TD group at OLRSC and below ribs static control (BRSC) level. Pectoralis major was significantly higher in SCI group at BRSC level. **Conclusion:**

Children with SCI produced unexpected activation of trunk muscles below injury level. Also, this activation was higher in SCI group than produced by TD group. However, TD children sustained low level of trunk muscle activation (tonic) at each static SATCo level. This information is useful to clinicians and therapist to plan therapies that target activation of truck muscles below the injury level.

Title: Unexpected recovery in a 3 year old with chronic, cervical spinal cord injury and ventilator dependent during activity-based therapy program

Authors: *M. ROBERTS[1], D. STOUT[1], S. BICKEL[2], M. CALVERY[2], K. BROTHERS[2], K. MCNAMARA[1], G. SINGH[3], A. BEHRMAN[3];
[1]Frazier Rehabil. Inst., Louisville, KY; [2]Pediatrics, [3]Neurolog. Surgery and Kentucky Spinal Cord Injury Res. Ctr., Univ. of Louisville, Louisville, KY

Abstract: Background
Paralysis after high, cervical pediatric spinal cord injury (SCI) may include predicted life-long ventilator dependence. Those injured <5 years old are at greater health risk. Activity-based therapies (ABT) may promote activation of the neuromuscular system and recovery post-SCI even in the most severely impaired children.
Case presentation
A premature infant with SCI at 18 days from epidural abscess/compression from C4-sacrum received a tracheostomy at 3 months. At 2 years 7 months an inquiry of the impact of ABT on this child's health and function began.
Evaluative tests/assessments included respiration, number of suctions/capping during therapy, trunk control (Segmental Assessment of Trunk Control, SATCo), upper extremity (UE) capacity observation, development (Bayley-III), parent interviews.
Intervention
Child entered daily ABT program (IRB approval for data collection) including AB-Locomotor Training 1.5 hours/day (144 sessions) and UE/trunk neuromuscular electrical stimulation for 1 hour/day (90 sessions). Ventilator weaning initiated.

Outcomes:
Suctioning rate in therapy decreased, tracheostomy capping during sessions initiated and progressed. Concurrent decrease in respiratory rate over 4 months, 60 to 30 breaths/min. Sleep study confirmed gains and decannulation planned within 3 months. SATCo score increased (0/20-5/20) with head and upper thoracic control. UE use improved from none to volitional intent for reach and targeting. Parent report briefly summarized: "We can have a normal life; he can have a normal life now" further substantiated by significant social-emotional and non-verbal cognitive gains per Bayley-III assessments.
Discussion:
In a child with chronic SCI, predicted to be life-long ventilator-dependent, and described as 'just present', ABTs facilitated plasticity of the neuromuscular/respiratory systems resulting in an engaged, purposeful child, breathing independently with head/trunk control, able to sit on his parent's lap and play.

Title: Differences in resting state functional connectivity between low and high levels of physical activity in healthy school-aged children

Authors: *L. R. ALVARADO[1], A. L. BEHRMAN[2], B. E. DEPUE[3];
[1]Anatom. Sci. and Neurobio., [2]Neurosurg., [3]Psychological and Brain Sci., Univ. of Louisville, Louisville, KY

Abstract: Regular physical activity has been associated with changes in the structure, function, and connectivity of the adult brain. However, fewer studies have explored the effects of physical activity on the pediatric brain; moreover, they have generally focused on pediatric populations with neurological disorders. The present study aimed to test the hypothesis that levels of physical activity affect resting-state functional connectivity (rsFC) of cortical and subcortical sensorimotor centers of healthy school-aged children. Here we compare rsFC in a sample of healthy school-aged children with low levels of physical activity and a group with high levels of physical activity. This cross-sectional study used data from the Child Mind Institute Healthy Brain Network (HBN) biobank, available through the 1,000 Functional Connectomes Project. The HBN biobank houses phenotypical and multimodal brain imaging data from 1151 children and adolescents who consented to the distribution of their anonymized data. Sixty-two children (29 males and 33 females, 10.5 ± 1.7 years) who fulfilled the following criteria were included in the current analysis: 1) ages 8-14 years; 2) available data for the Physical Activity Questionnaire for Older Children (PAQ-C), FitnessGram assessment, age, sex, height, and body mass index; 3) available T1-weighted MRI and resting-state fMRI scans; and 4) no recorded diagnoses. Images were processed using the CONN functional connectivity toolbox v18.b default pipeline for volume-based analyses. Several potentially confounding sources of signal variation were removed by linear regression before undertaking ROI-to-ROI rsFC analysis by seeding the motor cortex, supplementary motor cortex, somatosensory cortex, thalamus, and basal ganglia nuclei. Higher levels of physical activity were associated with higher rsFC among the supplementary motor cortex, precentral gyri, and postcentral gyri. In addition, higher physical activity was associated with higher rsFC between these cortical sensorimotor centers and the thalamus, caudate, putamen, and pallidum. In sum, the rsFC strength of cortical and subcortical sensorimotor centers correlate with levels of physical activities among healthy school-aged children. These findings highlight the robust sensitivity of rsFC analysis in detecting the impact of inactivity on the healthy pediatric brain.

Title: The impact of an activity-based therapy program on pediatric patients with SCI and families

Authors: *K. C. MCNAMARA[1], K. BROTHERS[2], M. L. CALVERY[2], A. L. BEHRMAN[3]; [1]Frazier Rehabil. Inst., Louisville, KY; [2]Dept. of Pediatrics, [3]Dept. of Neurosurg., Univ. of Louisville, Louisville, KY

Abstract: Introduction: When asked "What has participation in this research study meant to your child and your family?" a parent responded, "*You let me out of prison*". This impromptu conversation with a parent catalyzed our exploration of the parent and patient experience in the Pediatric NeuroRecovery Program through a qualitative approach. **Methods**: Participants were the caregivers of patients (1-12 years of age) with acquired SCI who were enrolled in the Pediatric Neurorecovery Program at Frazier Rehab Institute. Patients received Activity Based Therapy for trunk and lower limb capacity and neuromuscular electrical stimulation for upper limb capacity, each 5x/wk for 1.5 hrs/day. In this IRB approved study, semi-structured interviews of caregivers were conducted by PI or trained staff at initial evaluation, after 60-90 sessions of ABT, at discharge and follow-up evaluation time points. Interviews were transcribed, de-identified and uploaded into Dedoose for analysis. An Open Coding Strategy was used to analyze the data. **Results** Temes centered on chid physical and physiological outcomes, psychological impact on the caregiver and developmental changes for the child. **Conclusion:** The developmental trajectory for children and the parent-child relationship is altered after spinal cord injury. Per parent report, gains in child capacity via ABT altered the caregiver role, shifting it from caregiver to parent. The resultant model illustrates a new perspective with regards to the readjustment in the developmental trajectory for child and parent.

Title: Continuous beat-by-beat blood pressure and heart rate recording to assess autonomic regulation of the cardiovascular system in typically developing and in children with spinal cord injury

Authors: *A. KELLER, G. SINGH, A. BEHRMAN;
Univ. of Louisville, Louisville, KY

Abstract: Individuals with spinal cord injury (SCI) have a four-time increased risk for developing cardiovascular disease (CVD) above that of general population. Like adults, children with SCI have higher risk for developing CVD. The risk is potentially magnified by a relatively earlier onset of sedentary lifestyle and longer life expectancy. Lack of high quality prospective empirical studies assessing cardiovascular (CV) function in children with SCI hinders our understanding of the extent and severity that the SCI and paralysis-induced immobility holds for the CV health of this “at-high-risk” group. The goal of this study, as a first step, is to establish a protocol for the assessment of autonomic regulation of the CV system in children with SCI. Previously, 5 second maximal expiratory maneuver (MEP) in sitting has been validated as a method for the assessment of autonomic CV function in adults with SCI. Specifically, continuous beat-by-beat blood pressure (BP) and heart rate (HR) recorded via electrocardiogram (ECG) during this respiratory maneuver can be used to calculate baroreflex sensitivity (BRS) index to measure baroreflex function. Baroreflex is key for maintaining BP homeostasis and represents a critical point of integration of the vascular and neural components. Furthermore, BRS holds predictive value for the CV-related morbidity and mortality. Therefore, the goal of this study was to establish a protocol for the assessment of baroreflex function during 5-s MEP maneuver performed by children with SCI and compare them to typically developing age-matched children. Continuous beat-by-beat BP was recorded using finger cuff (Finapres, Netherlands). HR was recorded with 3-lead ECG (AD instruments) during 5-s MEP maneuver in

TD and children with SCI. At least 3 attempts of maximal expiration for the duration of 5 seconds through three-way valve system with tube mouthpiece and 1.5 mm diameter leak to prevent glottis closure were performed to ensure the quality of the signal. BRS was calculated as a slope and correlation coefficient between BP and R-R peak interval. We demonstrate the feasibility of the non-invasive method of the continuous blood pressure and heart rate monitoring during a maximal expiratory pressure maneuver to be used for the assessment of baroreflex function in children with spinal cord injury.

Title: Functional contribution of the mesencephalic locomotor region to locomotor recovery after spinal cord injury

Authors: ***M. ROUSSEL**[1], H. GODET[1], G. CLAIN[1], D. LAFRANCE-ZOUBGA[2], M. LEMIEUX[1], F. BRETZNER[1];
[1]Axe Neurosciences, Ctr. de recherche CHU de Québec-Université Laval, Québec, QC, Canada; [2]Univ. Laval, Québec, QC, Canada

Abstract: Recently, electrical stimulation of the mesencephalic locomotor region has been shown to improve locomotor recovery after spinal cord injury (SCI). The cuneiform nucleus (CnF), a cluster of glutamatergic neurons, and the pedunculopontine nucleus (PPN), a cluster of glutamatergic and cholinergic neurons, are part of this functional region. It has been shown that these three neuronal populations provide distinct contributions to locomotor control: glutamatergic neurons of the CnF can initiate and accelerate locomotion, whereas cholinergic and glutamatergic neurons of the PPN decelerate and stop locomotion. Here, we propose to identify and characterize the functional contribution of these distinct neuronal populations to locomotor recovery after SCI. Using transgenic mice expressing ChR2 in glutamatergic (VGluT2) neurons, we photostimulated VGluT2+CnF or PPN neurons before and after a thoracic lateral hemisection. Seven weeks after SCI, the ipsilesional limb still showed functional deficits including a slower locomotor rhythm, a decrease in the amplitude of intralimb coordination, and episodes of dorsal stepping. During treadmill locomotion, long photostimulation (10 ms pulses at 20 Hz for 1 s) of VGluT2+CnF neurons accelerated locomotor rhythm, increased postural tone,

and improved plantar stepping, whereas photostimulation of VGluT2+PPN neurons evoked deceleration and locomotor arrest. During swimming, long photostimulation of VGluT2+CnF neurons also accelerated locomotor rhythm and increased the maximal angular excursion of the hip, knee, and ankle, resulting in functional locomotor improvement of the ipsilesional limb. In summary, our results suggest that VGluT2+CnF neurons could be a neurological target for improving functional locomotor recovery following SCI.

Title: Central control of speed-dependent gait expression in intact rats and following spinal cord injury

Authors: *S. M. DANNER[1], C. T. SHEPARD[2,3], I. A. RYBAK[1], D. S. K. MAGNUSON[2,3]; [1]Dept. of Neurobio. and Anat., Drexel Univ. Col. of Med., Philadelphia, PA; [2]Dept. of Anatom. Sci. and Neurobio., [3]Kentucky Spinal Cord Injury Res. Ctr., Univ. of Louisville, Louisville, KY

Abstract: Animals express different locomotor gaits in a speed-dependent manner. As speed increases intact rats exhibit sequential gait transitions that can be described by the phase-relationships between the limbs. The underlying neural control involves rhythm generating circuits for each limb (RGs) interacting through a variety of at-level commissural interneurons (CINs) and both ascending and descending long-propriospinal neurons (LPNs) providing communication between the enlargements. The objective of this study was to investigate and characterize the specific changes in over-ground speed-dependent gait expression in intact rats and following two different spinal cord injuries, a mid-line T9 contusion and a T9 lateral hemisection. To help us understand the specific changes in neural circuity interactions underlying gait expression, we developed a computational model with four RGs, CINs and LPNs. Locomotor speed in the model is defined by brainstem drive to the RGs.
Intact rats sequentially expressed lateral-sequence walk, trot, gallop, half-bound and bound in a speed-dependent manner. In addition, canter occurred during the transition between trot and

gallop. The asymmetric gaits (gallop, canter and half-bound) occurred with either limb as the lead, although there was a preference for the left. After either the contusion or hemisection injury the maximal and average speeds and stepping frequency were lower. Hemisected animals did not express bound or half-bound gaits, and gallop became more prevalent, but only with the limb ipsilateral to the injury (right) as the lead. Contused animals expressed only alternating gaits (gallop, bound and half-bound were lost), while the variability in phase between the homolateral and diagonal limbs increased. Interestingly, this resulted in the expression of gaits not observed in intact rats: diagonal-sequence walk and pace.
By varying both brainstem and LPN drive to/from the lumbar circuitry to simulate the contusion and hemisection injuries, our computational model was able to reproduce the experimentally observed changes in speed-dependent gait expression for both intact and injured rats, including gait transitions and the loss/appearance of specific gaits. Thus, model analysis allowed us to identify potential neural mechanisms underlying the observed gait changes and to propose mechanistic explanations for the experimental results.

Title: Optogeneticially mediated neuromodulation of trunk motor cortex paired with exercise based rehabilitation and viral BDNF leads to axial reflex changes below a complete T9/T10 spinal cord injury

Authors: *K. A. SCHMIDT[1], S. F. GISZTER[2];
[1]Drexel Univ., Philadelphia, PA; [2]Dept Neurobiol & Anat, Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: After a complete T9/T10 spinal cord injury (SCI) in adult rats, trunk control becomes very important for postural stability, and crucial for function if stepping of hindlimbs is enabled. We have developed a neuromodulatory technique aimed at promoting plasticity and motor learning in the trunk motor cortex after SCI, by using subthreshold optogenetic stimulation of cortex via virally delivered Channelrhodopsin (ChR2). Virally delivered enhanced yellow

fluorescent protein (EYFP) is used as a control. When optogenetically mediated neuromodulation is paired with a 25 day robot assisted rehabilitation paradigm, motor mapping studies reveal a significant increase in cortical representation of trunk muscle segments below the injury (1-way ANOVA with Tukey-Kramer post-hoc comparisons, $p<0.05$) in the ChR2+robot rats, both with BDNF induced spinal stepping (N=8) and without (N=8), but not in EYFP+robot rats with (N=8) or without (N=8) spinal stepping enabled by BDNF. Activation of caudal trunk enabled by these representational changes likely also causes plastic changes in spinal circuitry below the injury by influencing sensory input and motor output from the spinal cord caudal to injury.
Monosynaptic reflex testing and Frequency Dependent Depression (FDD) is used widely to test spinal excitability. To understand chronic spinal circuit-level changes mediating trunk reflexes below injury in external oblique and longissimus, we implant a stimulating cuff around the T13 spinal nerve, and monitor trunk muscle responses through 13 paired trunk electromyogram electrodes, spaced both above and below injury, over the course of robot rehabilitation. Due to the proximity of the stimulating cuff to the spinal cord, in ipsilateral muscle segments caudal to injury, the motor response and the reflex response overlap. Artificial neural networks can be used to separate the two signals. However, we have also discovered a contralateral reflex of comparable latency, believed to be monosynaptic, which is also readily analyzed. Effects of neuromodulation of trunk motor cortex on the exhibited chronic spinal excitability and FDD below the injury are observed.

Abstract: Central pattern generators (CPGs) are neuronal networks that generate motor output associated with rhythmic behaviors, such as breathing and locomotion. The functional roles of discrete pathways associated with known locomotor CPGs after spinal cord injury (SCI) are poorly understood. Further, the specific anatomical characteristics of these pathways are largely unknown. In the mammalian spinal cord, long ascending propriospinal neurons (LAPNs) are part of an inter-enlargement pathway that anatomically connects the lumbar and cervical enlargements. The dendritic trees of these neurons are relatively simple with minimal branching and their axons ascend through the outermost layers of lateral and ventral white matter, which is often spared following injury. Previously, we found that LAPNs play a pivotal role in interlimb, but not intralimb, coordination of the hindlimbs and forelimbs during overground stepping in uninjured animals. We hypothesized that conditional silencing of LAPNs after mild/moderate SCI would further impair recovered locomotor function. Contrary to our hypothesis, silencing LAPNs after SCI resulted in improved hindlimb stepping precision and interlimb coordination of the hindlimb pair with no change in coordination between the hindlimb-forelimb pairs. Intralimb coordination showed modest improvements. Together, these data suggest that LAPNs cannot reliably distribute appropriate temporal information between the lumbar and cervical CPGs after incomplete SCI. However, removal of LAPNs from the inter-enlargement CPG circuitry leads to increased independence of the hindlimb and forelimb CPGs, such that they are able to achieve improved coordination of their respective limb pairs. Studies to explore the anatomical plasticity of LAPNs and their inputs after injury are ongoing and will contribute to our understanding of the altered role of LAPNs after SCI. These findings may be critical to understanding the therapeutic efficacy of various forms of spinal stimulation and rehabilitation in SCI patients. Supported by GM103507, NS089324, The Kentucky Spinal Cord and Head Injury Research Trust, and the Commonwealth of Kentucky Challenge for Excellence.

Title: A hybrid neuroprosthesis for standing and walking balance in people with spinal cord injuries

Authors: *M. J. NANDOR[1], R. D. QUINN[2], M. AUDU[1];
[2]Mechanical and Aerospace Engin., [1]Case Western Reserve Univ., Cleveland, OH

Abstract: Gait restoration in people with spinal cord injuries has been an important area of research for many years. Two approaches have been traditionally been utilized – Functional Electrical Stimulation of the users own muscles has been shown to provide health benefits, but is difficult to control, as stimulated muscle is non-linear, time varying (due to muscle fatigue), and slow to respond. By contrast, in the recent years, commercial exoskeletons have been developed that move the users joints through a proscribed trajectory in a much more predictable manner. We have developed a system that aims to combine the best of both worlds, with a mechanical exoskeleton specifically designed with low friction joints to integrated joint torque provided by stimulation. Additionally, while current exoskeleton systems require the user to provide balance through their upper extremities, our system aims to provide hands free balance during gait through the integration ankle torques (both robotic and stimulation). To prove the feasibility of such a system, a control system for bipedal walking in the sagittal plan was developed in simulation. A deep deterministic policy gradient (DDPG) neural network was trained in GAZEBO to predict the ideal foot placement to maintain stable walking despite external disturbances. The simulated biped was able to achieve 1 m/s gait speed, and able to maintain stability while a 30 kg*m/sec. impulse disturbance was applied to the torso. While the controller was trained on a 1.8 meter tall model, it was also able to successfully stabilized models from 1.4 meter to 2.3 meters tall. This simulation work shows controller viability and robustness, and future work will look to integrate and test with human subjects.

Title: Interaction of peripheral-nerve electrical stimulation with central pattern generators in dogs with naturally-occurring complete spinal cord injury

Authors: M. YEO[1], N. JEFFERY[2], *H. PARK[1];
[1]Electrical and Computer Engin., [2]Dept. of Small Animal Clin. Sci., Texas A&M Univ., College Station, TX

Abstract: It is well established concept that the central pattern generator (CPG) in the spinal cord can generate walking rhythm without supraspinal input. Indeed, spinalized animals can recover functional walking rhythms or even ambulate unaided. However, perhaps for evolutionary reasons, the human spinal cord is more severely affected by the loss of supraspinal input and there is limited ability to generate a walking rhythm. To compensate for the lack of supraspinal input after spinal cord injury (SCI) and better activate the CPG, either direct spinal cord excitation by epidural or intraspinal stimulation or indirect spinal cord excitation by sensory augmentation is needed. Of these, sensory augmentation for spinal cord excitation has been underexplored and often consists of mechanical interventions which can constrain motor output. Instead, we propose peripheral-nerve electrical stimulation to activate the dormant CPG after SCI. The objective of this study is to determine whether the peripherally-generated walking rhythm evoked by peripheral-nerve electrical stimulation will coordinate with the inherent rhythmicity of the CPG, depending upon specific stimulation amplitude/frequency parameters. Our preliminary work in dogs with naturally-occurring complete SCI showed that transcutaneous electrical stimulation over a range of 0.3 to 3 Hz, alternately applied onto the left and right leg, could generate a walking rhythm. The stimulation site was selected as the skin below the caudal aspect of the medial malleolus, to target distal-tibial nerve. As stimulation parameters, bi-phasic electrical stimulus were used with 2.5 mA current amplitude and 100 Hz carrier frequency. Also, tail pinch, which induced air stepping at ~2 Hz in the hindlegs without peripheral-nerve electrical stimulation, inhibited the walking rhythm induced by peripheral stimulation at 0.3 Hz. We believe that tail pinch excited the CPG and peripheral stimulation at 0.3 Hz was out of the range required to entrain the self-generated CPG rhythm. Using this canine model with peripheral-nerve electrical stimulation, we will further investigate the interaction between the spinal cord excitation and peripheral intervention using electrical stimulation.

Abstract: The contribution of sensory feedback from the leg for walking has been well established with the two-level half-center central pattern generator (CPG) model. Several gait therapies have also been introduced to evaluate the efficacy of motion-dependent sensory feedback from the leg on gait rehabilitation after spinal cord injury (SCI). For example, robotic devices or motorized belts move paralyzed lower limbs, in turn generating motion-dependent feedback. These body-weight supported treadmill training (BWSTT) interventions show positive effects on gait rehabilitation in both rats and humans after SCI. However, the efficacy of BWSTT on human gait rehabilitation is limited. Recent studies suggest that this may be due to insufficient peripheral sensory feedback. The fact that gait rehabilitation with BWSTT becomes more effective with sensory augmentation, produced with epidural stimulation or vibration on leg muscles, supports the notion. Indeed, the reduced loading of the legs with body-weight support reduces the force-dependent feedback. To compensate for this reduced leg loading, which might be the clearest sensory deficit for BWSTT, the current study aimed to augment tactile feedback from the foot sole, by stimulating the distal-tibial nerve as seen in human and cat studies, and ultimately to test whether the plantar cutaneous augmentation could compensate for reduced leg loading and promote gait rehabilitation. First, we developed a fully-implantable stance detection and plantar cutaneous augmentation system. As a proof of concept, we conducted experiments with two intact rats. We tested that the implantable system could record electromyography from the Soleus muscle, which was used for stance phase detection. Second, we measured compound action potentials from the proximal-tibial nerve while applying electrical stimulation to the distal-tibial nerve. Based on the propagation speed of the measured action potential and the plantar innervation of distal-tibial nerve, we believe that the electrical stimulation on distal-tibial nerve could augment plantar cutaneous feedback.

Abstract: Epidural Electrical Stimulation (EES) applied over the lumbosacral spinal cord enables supraspinal control over the activity of leg motor neuron pools in individuals with spinal cord injury (SCI). EES recruits large-diameter afferent fibers within the posterior roots, which leads to the modulation of motor neuron pools through the activation of proprioceptive feedback circuits. In turn, targeting individual posterior roots enables the specific modulation of motor neuron pools located in the spinal segment innervated by each root. However, inter-subject variability, limited specificity and time-consuming optimization procedures hinder large-scale clinical deployment of this technology. Here, we present new hardware and software to optimize stimulation protocols. First, we exploited anatomical analyses and computational modeling to design a new electrode array with electrode configurations that are optimized to target the individual posterior roots in a broad range of human spinal cords. Second, we established a computational platform that supports the semi-automated creation of hybrid computational models from high-resolution 3-T MRI datasets of individual patients. These models combine personalized, geometrically realistic 3D finite element models of the lumbosacral spinal cord with realistic compartmental cable models and network models of proprioceptive feedback circuits. We established a computational pipeline to obtain anisotropic tissue property maps, discretize the model, perform simulations using an electro-quasi-static solver and couple these simulations with NEURON-based electrophysiology models. This computational pipeline can determine the optimal site of electrode array implantation, predict the specificity of the stimulation, and discover effective configurations of electrodes. The infrastructure is also in place to use the pipeline for automatized implant design optimization. The safety and efficacy of

the newly designed spinal implant and the computational treatment optimization is under evaluation in patients with SCI.

Abstract: Recent studies from independent research teams have shown that epidural electrical stimulation applied to the lumbar spinal cord during intensive motor rehabilitation could restore leg motor control in several individuals with chronic spinal cord injury (SCI). Preclinical studies showed that this intervention is markedly more efficient when initiated in the subacute phase after injury. Here, we present the preparation of a multi-center clinical trial to test the safety, feasibility and preliminary efficacy of this intervention for the recovery of leg motor control in individuals with subacute SCI (less than 6 months after injury). Specifically, we present the development of a single-system multi-purpose software platform that is intuitive and easy to use by the patient and for the optimization of electrical stimulation protocols in clinical settings, while integrating the necessary flexibility to support technological and therapeutic innovations. The software includes user interfaces adapted to the needs of patients, therapists and scientists. It allows to intuitively set up, individualize and execute spatial and temporal stimulation programs for different motor tasks ranging from single-joint movements to cycling-like exercises and walking with real-time closed-loop control based on body-worn sensors. The system receives electromyographic and kinematic data streams that are synchronized with the stimulation. While the option of online visualization provides real-time feedback on the effect of the stimulation during the optimization process, multimodal recordings allow the quantified evaluations of motor performance throughout the rehabilitation program. Furthermore, the software platform integrates units that can support the rapid prototyping of novel automated stimulation optimization and closed-loop control algorithms. For example, the software can integrate electroencephalographic signals to perform brain-actuated spinal cord stimulation. These developments will play a key role for the smooth execution of a multi-center clinical trial in the complex period that follows a SCI.

Abstract: Robot-assisted technologies are increasingly integrated in neurorehabilitation programs. Nevertheless, the relationships between specific robot-assisted training protocols and the augmentation of neuroplasticity remain unclear. Rat models provide a suitable solution to investigate the mechanisms underlying the therapeutic impact of robotic rehabilitation. Here, we present a robotic platform able to provide different levels of assistance during an upper limb reaching task. The device gently clamps the wrist of the rat and guides the movement of the forelimb, providing assistance-as-needed, in order to receive a reward. The system has four degrees-of-freedom (DOF), three translational DOF and one rotational DOF to allow the pronation/supination movement of the forelimb of the animal. The workspace of the robot has been calculated to overlap with the kinematics of rat reaching behaviour, corresponding approximately to an area of 56 x 40 x 20 mm^3. In the vertical plane the movement is driven by a parallel cinematic chain, the design is based on the Pantograph. Horizontal movement and pronation/supination are guided by a linear slide and a parallel shift gear mechanism, respectively. The robot is actuated by three brushed rotary DC motors and one brushless motor coupled with a spindle drive. Two different restrainers allow the rat in a bipedal or quadrupedal position. The first one restrains the rat within a trunk jacket. The other is a head-mounted restrainer. The position of the restrainer is regulated by two micrometric translational stages. Moreover, this platform allows the quantitative assessment of reaching movements. Specifically, a 6-axis load cell records the force signal. The platform is embedded in a system enabling recordings of forelimb kinematic, muscle activity and calcium imaging of brain signals. We are

using this platform to monitor how the brain responds to different training paradigms, both in healthy rats and in rats with severe contusion of the cervical spinal cord.

Abstract: The advent of whole organ clearing techniques has made it possible to visualize whole brains and spinal cords en bloc in three-dimensions. Questions specific to spinal cord injury (SCI) present unique challenges related to clearing, and clearing techniques related to SCI have not been well established. To address this gap, we optimized a number of clearing techniques utilized on the rodent central nervous system to answer specific questions related to SCI. We identified the challenges and found reproducible solutions to clear the rodent spinal cord, visualize regenerating fibres through the hostile environment of complete lesions, preserve the integrity and image more delicate tridimensional structures such as spinal dorsal root ganglia, and achieve *in situ* hybridization on whole spinal cord segments. These clearing methods provide reliable solutions to study SCI pathology, mechanisms of recovery and spinal cord repair interventions.

Title: The role of proprioceptive afferents in activity-dependent, spatiotemporal epidural stimulation of the cervical spinal cord

Authors: *N. D. JAMES[1], I. DEWANY[1], L. BAUD[1], S. SHERMAN[1], B. BARRA[2], N. GREINER[2], N. CHO[1], M. CAPOGROSSO[2], G. COURTINE[1];

Abstract: Contusion of the cervical segments is the most common form of spinal cord injury (SCI). Patients surveys have identified improvements in upper limb function as a top priority for individuals that have suffered this type of injury, but no clinical solution is available for improving the recovery of skilled arm movements. Electrical neuromodulation therapies of the spinal cord have enhanced lower limb function in numerous preclinical models, from rodents to primates, as well as a number of clinical case studies. Despite this success, and the high priority of improved upper limb function for the SCI patient community, efforts to translate this promising technique to the cervical spinal cord and upper limbs have so far been limited. Given the complex patterns of muscle activation required for the execution of skilled arm movements, adaptation of epidural electrical stimulation (EES) to the cervical spinal cord necessitates a thorough understanding of the functional specificity that can be achieved using this technique, as well as the neuronal circuitry that underlies its effect. Here we present functional and anatomical data indicating that lateralised epidural stimulation of the rodent cervical spinal cord effectively targets specific upper limb motor pools, dependent on the rostrocaudal location of the stimulation site. Based on these findings, we have developed and assessed the efficacy of a stimulation paradigm in which cervical EES is delivered in a spatially selective manner and is temporally patterned in accordance with the real time activity of selected upper limb muscles. Furthermore, to gain a greater understanding of key neuronal circuitry we have utilised targeted pharmacological and genetic manipulations, allowing us to demonstrate the pivotal role of proprioceptive feedback circuits in the generation and modulation of motor responses during cervical EES. Taken together, these results establish a conceptual framework for the design and optimisation of targeted cervical implants to facilitate upper limb movements after spinal cord injury.

Abstract: A recent study has shown that spatially and temporally patterned epidural electrical stimulation (EES) delivered to the lumbar spinal cord through a multisite electrode array immediately enables walking in individuals with severe spinal cord injury. These spatiotemporal stimulation protocols require the fine-tuning of numerous parameters such as electrode configurations, timing and duration of stimulation bursts, and amplitude / frequency of multiple stimulation waveforms. Hence, determining such complex stimulation protocols requires an optimization process of several days of manual adjustments involving a large multidisciplinary team of engineers, neurophysiologists and therapists. This time- and resource-intensive approach is not practical for large-scale clinical studies, and even less for a broad clinical deployment. Consequently, it is imperative to gain a robust understanding of the effects of each EES parameter, and to leverage this knowledge to build automated methods that render the optimization process time- and cost-efficient. For this purpose, we investigated the effects of bursts of stimulation pulses at increasing frequencies and amplitudes on the recruitment of leg muscle groups. We tested the ability of multiple sets of electrode configurations to target each posterior spinal root specifically while subjects were lying in supine position. We recorded electromyographic activity and kinematics, enabling us to quantify the muscle specificity and functional effects, respectively. All participants exhibited strong posterior root-specific and frequency-dependent properties in the recruitment of the tested muscle groups. These findings immediately translated from supine position to functional use during walking. Subsequently, we

developed a fully automated online machine learning algorithm able to find, in a short time period, electrode configurations and stimulation parameters targeting specific functional muscle groups. This process relies on Bayesian optimization based on Gaussian processes, and embeds the effects observed during previous trials as prior knowledge. These results establish the first steps towards an in-depth understanding of the effects of different stimulation parameters and the development of efficient automated optimization algorithms.

Title: Role of nociceptive afferent input on forelimb reaching and grasping behaviors in the spinal cord injured rat

Authors: *J. R. WALKER, A. ONG, M. R. DETLOFF;
Neurobio. & Anat., Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: Individuals with spinal cord injury (SCI) suffer a loss of motor and sensory function. The current standard of care to recover fine motor control is rehabilitation focused on a combination of range of motion, aerobic, and strength training (ST). However, limited research has been conducted to determine the role of nociceptive afferent inputs from muscle on spinal plasticity and/or recovery of function. Using a rodent model of SCI strength training rehabilitation, we determined that motor training not only improves forelimb strength and fine motor function but also can modulate the development of neuropathic pain, suggesting that improvements in reaching and grasping may be due, in part, to plasticity of nociceptive afferents. To further explore this, Sprague-Dawley rats received injections of rIB4-conjugated saporin, mu p75-conjugated saporin or unconjugated (vehicle) into the cervical dorsal root ganglia unilaterally to eliminate non-peptidergic and peptidergic nociceptors. There is an uninjured cohort and a group with unilateral C5 SCI. Von Frey and Hargreaves' tests were performed at

baseline and several time points post-injection to assess the efficacy of the nociceptive elimination. Several measures of forelimb strength were recorded over time including the isometric pull task, a single pellet retrieval task and the Montoya staircase test. To confirm the depletion of peptidergic and non-peptidergic nociceptors following saporin injection and/or SCI, cervical DRGs and spinal cords were stained with antibodies against CGRP and isolectin-B4. An understanding of the role of nociceptors in spinal plasticity and functional motor and sensory recovery of SCI patients will guide future research and refine rehabilitation strategies to further improve their quality of life.

Title: Rehabilitative strength training induces anatomical and functional plasticity of primary nociceptive neurons after cervical spinal cord injury

Authors: *M. R. DETLOFF, A. ONG, J. R. WALKER, V. ROVIRA ZAMBRANA, T. THAWEERATTANASINP;
Neurobio. & Anat., Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: More than two-thirds of individuals with spinal cord injury (SCI) develop chronic neuropathic pain. SCI-induced neuropathic pain is associated with both nociceptor hyperexcitability as well as sprouting of primary afferent c fibers that transmit pain information to the spinal cord. We have previously shown that early, aerobic exercise prevents development of neuropathic pain but does not ameliorate it once established. While locomotor training is used in the clinic, the standard of care in post-SCI rehabilitation focuses on improving muscle strength. This project will determine whether early or delayed strength training after SCI can affect nociceptor plasticity and pain development after cervical SCI. Female Sprague-Dawley rats received a C5 unilateral spinal cord contusion corresponding to handedness. A subset of SCI rats underwent isometric forelimb strength training 5 days/week starting at 5 or 42 days post-injury (dpi) for 5 weeks. Briefly, rats complete 50 successful repetitions of at least 50g force in an isometric forelimb pull task to receive a food reward. Mean pulling force returned to near normal after 10 strength training sessions regardless of early or delayed initiation of exercise ($p>.05$ vs baseline). The recovery of forelimb strength corresponded to improvements in reach-

to-grasp behavior as assessed using a single pellet-retrieval task. Delayed strength training reduced paw hypersensitivity and pain behavior as measured by von Frey and mechanical conflict avoidance operant tests compared to unexercised and acute strength training SCI groups ($p<.05$). Preliminary whole cell patch electrophysiology of isolated nociceptors from rats in each group suggest that strength training reduces nociceptor excitability. Another cohort from each group received microinjection of cholera toxin-B into the ulnar nerve to identify large diameter afferents 3 days prior to sacrifice. We are currently completing immunocytochemical experiments assessing the degree of primary afferent sprouting that is associated with forepaw dermatomes. With the results, we hope to better understand the mechanisms underlying SCI-induced pain, allowing for possible refinement of rehabilitation protocols to reduce chronic pain after SCI.

Abstract: The ependymal cell layer surrounding the central canal is an endogenous adult neural stem cell niche. Enhancing this endogenous proliferation could be a lucrative treatment strategy following spinal cord injury. This study investigates the effects of exercise training and of the cholinergic α7 nicotinic receptor positive allosteric modulator PNU 120596, which is known to upregulate cell proliferation of ependymal cells. 4 weeks following moderate spinal cord contusion injury rats were treated with either PNU 120596 or vehicle and either given 24hrs free access to running wheels or not, for 6 weeks. Exercise training revealed vehicle treated rats had a higher mean velocity and increased bouts of activity but no differences were seen in the total distance ran, percentage time spent active or maximum activity durations. At the end of the training period animals in exercise groups displayed significantly higher average BBB sub-scores. The Randall-Selitto paw pressure test revealed that running animals had an increased pain

threshold and had fewer missed steps in the modified step ladder test although the Von Frey hairs test showed no differences between groups. Rats were then transcardially perfused and fixed for immunohistochemical analysis. PNU 120596 treated animals displayed higher numbers of new born cells around the central canal of cervical spinal cord sections in comparison to vehicle treated. Below the lesion this proliferation was attenuated and the exercise trained groups displayed the highest number of new born cells around the central canal region. However, exercise trained animals had fewer new born cells at the lesion site in comparison to non-trained animals. New born cells appear to have migrated well into the white matter in all groups and most of these became GFAP positive astrocytes followed by, APC CC1 positive oligodendrocytes, SoX2 positive neuronal stem cells and only very few were NeuN positive. These results indicate that PNU 120596 is able to augment the proliferative capacity of ependymal cells and that exercise training plays a fundamental role in modulating the spatial proliferation of these cells to enhance recovery of function after chronic spinal cord injury.

Abstract: Combinatorial therapies for the treatment of spinal cord injury (SCI) are vital if a significant amount of locomotor recovery is to be achieved. Parsing out the behavioral and anatomical changes each treatment is having will allow us to effectively combine therapies needed for SCI recovery. Alone, anti-Nogo-A antibody (11C7), locomotor training, or epidural stimulation of the lumbar spinal cord have been shown to improve locomotor outcomes in animal models of SCI. However combining therapies has not always been successful, with certain treatments, such as training alongside anti-Nogo-A therapy, proving to have negative

combinatorial effects. The current study shows the additive effects of sequential anti-Nogo-A antibody treatment followed by epidural stimulation (ES) and daily locomotor training with body weight support. Adult Sprague-Dawley rats received a severe contusion injury at T9/T10, epidural electrodes implantation at L2 and S1, and intrathecal delivery of either 11C7 or control IgG (osmotic pumps). Animals were randomly assigned to one of cage control, locomotor training, ES (40Hz sub threshold), or combined ES and locomotor training. Pumps and catheters were removed after 2 weeks and training began 3 weeks following injury in order to minimize negative outcomes seen with concurrent combined treatments. Rats in the trained groups stepped bipedally-to-quadrupedally with varying amounts of body weight support at speeds of 7-21cm/s (5 days/week, 20 mins/day) for 8 weeks. 11 weeks after injury kinematic recordings were made and motor cortex BDA injections were completed before terminal electrophysiology. Surprisingly, there were no significant differences in BBB scores between groups throughout the treatment period. However, in the last four weeks there was an increase in weight-supported stepping (BBB≥10) in the training and combination group with 11C7, however 11C7 was found to actually decrease weight supported stepping in the ES alone group. Immunohistochemistry data showed that increases in Ia afferent synapses onto motoneurons with 11C7 treatment were modulated by locomotor training under ES, with fewer direct contacts observed in this group. The varied behavioral results underline the importance of understanding the mechanisms of different treatments in order to be able to combine them in the most effective way.

Title: Neuron intrinsic growth program activation in response to electrical stimulation of the primary motor cortex

Authors: *N. ZAREEN, H. ALEXANDER, J. H. MARTIN;
The City Col. of the City Univ. of NY, New York, NY

Abstract: Repairing the corticospinal tract (CST) after spinal cord injury (SCI) is difficult due to many factors. SCI is often incomplete, leaving some intact axons that can sprout in injury-dependent manner below injury site, synapsing with denervated spinal motor circuits. Though insufficiently robust to repair the damaged CST, the CST neurons' innate ability to sprout axons can be augmented via chronic electrical stimulation of the primary motor cortex (MCX), resulting in repair and recovery of motor function. We have shown this in rat models of pyramidal tract lesion (PTx) and cervical SCI, making MCX electrical stimulation (MES) an effective repair strategy. The molecular mechanisms of sprouting, unlocked by MES, are not understood well but are beginning to emerge. We have shown that mTOR and the Jak/Stat pathways are needed for CST sprouting resulting from chronic (10 days) MES. The pathways play distinct roles in CST remodeling: mTOR is needed for CST axonal sprouting while Jak/Stat for pre-synaptic boutons formation. The expression level of the mTOR antagonist PTEN is not altered, but level of the inactive phosphorylated PTEN (pPTEN) peaks along with mTOR activity. Thus, chronic MES activates an axon growth-promoting program in the CST neurons. We ask when during chronic MES period does the growth program switches on and if it persists when MES is discontinued. We used MES at various lengths and examined the levels of mTOR and Jak/Stat activaty and inactive pPTEN. mTOR and Jak/Stat activities increase after 1 day of MES. mTOR, but not Jak/Stat, activity remain high for an additional day after MES and drops after 3 days, showing low persistence after short-term MES. Activities of both pathways remain high after 5 days of MES, increasing further after 10 days of MES. PTEN deactivation proceeds gradually from 1 to 10 days of MES. When checked after 20 days after the end of chronic MES, activity levels were found to be comparable to 10 days MES, showing long-term persistence. This may explain data from our published study, showing increased CST sprouting 20 days beyond the chronic MES period. We conclude that short-term MES results in significantly high mTOR activity independent of PTEN activity and the insufficient PTEN deactivation may not activate axon growth-promoting environment. Functional CST remodeling may result from the concurrent increase in mTOR activity and decrease in active PTEN following chronic therapeutic MES. Long-term persistence indicates that a certain length of MES period is sufficient to activate and preserve axon growth program in CST neurons. This may be convenient in clinical settings, eliminating need for SCI patients to undergo MES for indefinite period.

Title: Combined cortical and spinal neuromodulation strengthens the effectiveness of motor rehabilitation in incomplete cervical spinal cord injury

Authors: *H. SHARIF[1], H. ALEXANDER[1], J. H. MARTIN[2];
[1]Molecular, Cell. and Biomed. Sci., City Col. of New York, New York, NY; [2]Molecular, Cell. and Biomed. Sci., CUNY Sch. of Med., New York, NY

Abstract: Physical rehabilitation is the most widely used form of therapy for motor recovery in individuals with spinal cord injury (SCI). However, most forms of rehabilitation only result in modest degrees of functional improvements. This is primarily because after SCI, axons that transmit descending motor commands are too few and weak to produce effective movements. Therefore, in order to enhance the efficacy of rehabilitation, the few spared corticospinal connections must be strengthened to improve functional neural connectivity. We previously showed that intermittent theta burst stimulation (iTBS) of the motor cortex (M1) combined with cathodal trans-spinal direct current stimulation (tsDCS) improved forelimb function and increased corticospinal tract (CST) sprouting following SCI. The purpose of this experiment is to use the same combined neuromodulatory approach to strengthen the effectiveness of rehabilitation following cervical SCI. Female Sprague Dawley rats (n=8 at the time of abstract submission) were trained to run along a horizontal ladder until forelimb error rate was less than 15%. Rats were given a bilateral C4 moderate contusion (200kdyn), damaging the CST and impairing forelimb function. Following 2 weeks of recovery, rats were randomized to receive 10 days of bilateral M1 iTBS+tsDCS followed by rehabilitation (n=4), or rehabilitation alone (n=4). Rehabilitation consisted of 6 weeks, 5 days a week of 24 runs on the horizontal ladder with alternating gaps. Forelimb performance on the same task was tested once a week throughout the 6-week training protocol, and 2 weeks after. The CST was anterogradely traced using BDA (n=8) injections in the M1 forelimb area. Forelimb motor function was impaired in all animals following SCI. Both groups showed improved forelimb performance by the end of the 6-week training period, and improvements were sustained 2 weeks after cessation of training. However, the stimulation+rehab group improved by 67%, whereas the rehabilitation only group improved by 33%. Histology showed complete ablation of the CST in the dorsal column caudal to the lesion. Spared CST axons in the gray matter caudal to the lesion were derived from lateral CST fibers projecting to the intermediate zone. Stimulation increased spared CST axon length in the gray matter caudal to the injury compared to no stimulation. These results suggest that neuromodulation-assisted rehabilitation is more effective than rehabilitation alone in improving motor recovery and activity-dependent axonal growth after incomplete cervical SCI.

Title: Phasic and tonic stimulation of M1 produces morphological and electrophysiological changes in the corticospinal system

Authors: *L. YANG[1], J. H. MARTIN[2];
[2]Molecular, Cell. and Biomed. Sci., [1]CUNY Sch. of Med., New York, NY

Abstract: Neural activity plays an important role in promoting axon growth and synapse formation in activated neurons and pruning connections in non-activated neurons. The potential of neural activity to trigger axon growth becomes especially important for spinal cord injury (SCI) and repair. Studies in our lab show that patterned electrical stimulation(stim) of primary motor cortex (M1) (i.e., iTBS; (intermittent theta burst stimulation)) facilitates motor evoked potentials (MEPs) during and up to 20 minutes post stim. Previously, we used an optogenetic approach to selectively activate ChR2+ neurons in M1 of adult uninjured rats. CST neurons that received 10 days of optical iTBS had increased axon length and axons projected farther into the motor neuron pools compared to non-stimulated neurons. M1 MEPs showed reduced threshold and latency at the optically stimulated site compared to nearby non-stimulated sites. In the current studies, we determined if a tonic increase in M1 neural activity can also promote CST axon outgrowth and targeting with SC neurons. We microinjected AAV- hM3Dq (excitatory DREADD) and AAV-EYFP (for anterograde CST tracing) into forelimb M1. Subjects were tonically stimulated for 10 days via IP injection of the DREADD agonist clozapine n-oxide (CNO). Post stim, tonically-stimulated M1 had lower MEP thresholds than unstimulated M1. Stimulated axons in the contralateral cervical gray matter were longer and extended farther into the motor nuclei. We next determined if phasic and tonic activation promoted establishment of more synapses with spinal interneurons (INs) in a competitive, activity-dependent manner. We examined Chx10+ INs, an abundant excitatory neuron class in the intermediate zone. Optically stimulated axons made significantly more putative synaptic contacts with Chx10+ INs than non-stimulated axons in stimulated animals. Importantly, non-stimulated axons in ChR2+ animals had significantly fewer contacts compared to non-stimulated axons in controls, suggesting that active axons out compete quiescent axons for synaptic contacts. Synaptic contact analysis is in progress for DREADD activated axons. In summary, phasic and tonic stim of M1 produce

similar increases in contralateral CST axon length and decreases in MEP thresholds. Importantly, phasic stim enhances putative connections with a major class of excitatory IN. Analyses are in progress to determine if tonic activation has a similar effect on targeting of CST connections with spinal excitatory INs and M1-to-muscle connection strength. An important question for future experiments is if patterned or tonic stim is more effective in promoting function after injury.

Title: Downslope locomotor training - A rehabilitative strategy targeting eccentric components of gait

Authors: *L. R. MONTGOMERY[1,2,4], J. M. NANNEY[2,3], S. F. MCMURTRY[5], A. M. DE BOEF[5], E. KAJTAZ[1,2,5], T. NICHOLS[5], D. R. HOWLAND[1,2,3,4];

Abstract: Spinal cord injury (SCI) disrupts the intermuscular coordination required for control of knee and ankle flexion during weight acceptance in early stance. This leads to inefficient weight shift and instability, that maybe exacerbated by changes in inhibitory force feedback (iFFB) as seen in our feline SCI model. Currently there are few rehabilitative strategies focused on eccentric activity to restore intermuscular coordination during stance. Downslope walking increases iFFB activity in a decerebrate preparation (Nichols et al 2014), consistent with the prolonged period during stance when the knee and ankle are held in a stable flexed position as the decline angle increases. As a result, our training strategy uses different declining, walking surfaces to target eccentric control of the knee and ankle through iFFB. The goal of this training paradigm is to enhance recovery of weight acceptance and controlled flexion during stance, thereby improving stability and efficiency of gait. In the current work, adult, spayed felines are trained to perform hind limb stepping on a treadmill (TM) and voluntary overground (OG)

locomotion. Slope on each is varied (0º to -26º) and two speeds (0.5 and 0.8 m/s) assessed on TM. After collection of baseline performance data, each receives a low, lateral T9/10 hemisection (LHX) and is placed in trained (TR) or non-trained (NT) groups. Training occurs 5x/wk out to 12 wks. After LHX, yield on flat surfaces and the normal adaptations to slope are disrupted during TM & OG tasks. Impairments are present bilaterally despite SCI asymmetry. Ipsi- and contra-lesional hind limb kinematics however, are not symmetrical suggesting different combinations of functional loss, recovery and compensation across limbs. The TR group adopts a more consistent yield strategy relative to the NT group which displays excessive flexion of distal joints compared to intact animals. Overall step cycle consistency also increases with TR and particularly on TM. Other step cycle features of the TR also more closely resembled intact animals including the stance-swing transition, extent of hip extension at toe off and step cycle duration. These changes were most evident during OG tasks and slower TM speed (0.5 m/s). The iFFB profiles of the TR and NT groups are presented in a companion poster (McMurtry et al.). This work will help guide development of more effective rehabilitative strategies for recovery of effective eccentric control critical for the coordinated weight acceptance and support phases of gait. Title: Evidence for modulation of force-dependent feedback in cat hindlimb using eccentric training -- A potential mechanism for locomotor recovery

Authors: *S. MCMURTRY[1], A. DE BOEF[1], E. KAJTAZ[1], L. MONTGOMERY[2], J. NANNEY[2,3], D. R. HOWLAND[4,5,3], T. R. NICHOLS[1];

Abstract: Recent evidence from our lab shows gait deficits, including exaggerated yield, following incomplete spinal cord injury is in part due to the dysregulation of inhibitory force feedback (iFFB) from Golgi tendon organs (GTO). GTO pathways form an intermuscular feedback network in the spinal cord that helps regulate mechanical properties of the limb. Regulation of these properties occurs in a task-dependent manner. Specifically, iFFB is a major control variable for modulation of limb stiffness. In conditions mimicking downhill walking iFFB has been shown to be amplified (Nichols et al., 2014). This upregulation of inhibition increases compliance associated with the braking action during downslope walking. Previous results in our lab utilizing a standing decerebrate prep shows flexible configurations of iFFB patterns in the spinally intact cat (SIC), while cats with chronic lateral hemisection (LHX) show one pattern that indicates amplified inhibition onto ankle extensor muscles. We hypothesize that entraining this iFFB network will reestablish feedback patterns as seen in controls and improve gait. Using the decerebrate cat we measure the strength and distribution of inhibitory feedback between extensor muscles spanning one or more joints of the feline hind limb. The muscles include members of the quadriceps and triceps surae groups, a long toe flexor, and plantaris. The animals received a chronic LHX and a subgroup underwent eccentric training prior to the terminal experiments. Following the decerebration and removal of anesthesia, muscles in pairs, denoted as recipient and donor, were stretched in different combinations and intermuscular inhibition assessed as a decrease in the stretch reflex of the recipient muscle. Blinded analysis involved categorizing 9 cats based on their patterns and magnitude of iFFB. Out of 9 LHX cats so far, we have accurately categorized 8 based on iFFB patterns. Specifically, the trained animals showed iFFB patterns resembling SIC, a more moderate amount of inhibition and less convergence onto the ankle musculature. This return to SIC iFFB patterns in the eccentric training group may restore limb stiffness during gait and be a viable rehabilitation approach to recover gait. We are also looking at the kinematic features of locomotion throughout recovery see SfN companion poster Montgomery et al.

Title: Uncovering the spatial representation of taste identity in the human brain

Authors: *J. AVERY, A. G. LIU, C. D. RIDDELL, S. J. GOTTS, J. E. INGEHOLM, A. MARTIN;
Lab. of Brain and Cognition, Natl. Inst. of Mental Hlth., Bethesda, MD

Abstract: In the mammalian brain, the insula is the primary cortical substrate involved in the perception of taste. Recent imaging studies in rodents have identified a 'gustotopic' organization in the insula, whereby distinct insula regions are selectively responsive to one of the five basic tastes. However, numerous studies in monkeys have reported that gustatory cortical neurons are broadly-tuned to multiple tastes, and tastes are not represented in discrete spatial locations. Neuroimaging studies in humans have thus far been unable to discern between these two models, though this may due to the relatively low spatial resolution employed in taste studies to date. In the present study, we examined the spatial representation of taste within the human brain using ultra-high resolution functional magnetic resonance imaging (MRI) at high magnetic field strength (7-Tesla). During scanning, participants tasted sweet, salty, sour and tasteless liquids, delivered via a custom-built MRI-compatible tastant-delivery system. Our univariate analyses revealed that all tastes (vs. tasteless) activated primary taste cortex within the bilateral dorsal mid-insula (cluster-level p-values << 0.01, corrected via whole-brain permutation test), but no brain region exhibited a consistent preference for any individual taste. However, our multivariate searchlight analyses were able to reliably decode the identity of distinct tastes within those mid-insula regions, as well as brain regions involved in affect and reward, such as the striatum, orbitofrontal cortex, and bilateral amygdala (corrected cluster p-values < 0.05). These results suggest that taste identity is not represented topographically, but by a distributed spatial code, both within primary taste cortex as well as regions involved in processing the hedonic and aversive properties of taste.

Title: Generalization of conditioned avoidance of 10% ethanol to sucrose, quinine and sucrose-quinine mixtures in male and female rats

Authors: S. R. HESSEL, ***Y. TREESUKOSOL**;
California State Univ. Long Beach, Long Beach, CA

Abstract: Individual variability in taste responsivity contributes to food and fluid acceptance and rejection. Like humans, female rats have a higher propensity to consume ethanol (EtOH), relative to body weight, compared to males. Though humans and rats innately avoid bitter-tasting stimuli, like EtOH, individual variability in orosensory responsivity to ethanol may explain differences in ethanol intake. Previous findings in the literature suggest conditioned avoidance to alcohols generalize to compounds that humans describe as bitter and sweet. The current study was designed to test the hypothesis that the taste qualities of ethanol differ in female and male rats. Here, male [n=16] and female rats [n=16] were presented 10% EtOH followed by administration (i.p.) of either LiCl [n=12] to induce visceral malaise, or saline [n=20], control. Both females ($p = .002$) and males ($p < .001$) demonstrated avoidance of the 10% ethanol across the 4 conditioning trials. After conditioning, generalization was assessed in a brief-access taste test (10-s trials; 30-min sessions). The test array included water, 0.3 M sucrose, 0.03 M sucrose (representing “sweet” compounds), 0.3 mM quinine, 0.03 mM quinine, (representing “bitter” compounds) and mixtures 0.3 M sucrose - 0.03 mM quinine, and 0.03 M sucrose - 0.3 mM quinine, presented in randomized blocks without replacement. Animals could initiate as many trials as possible during the test session. Average number of licks to each test stimulus was used to calculate suppression scores, indicating the degree to which rats generalized the conditioned avoidance of EtOH to each test stimulus. Both male and female LiCl-injected rats showed higher suppression scores to sucrose than quinine. There was more variability in lick responses to mixtures across all rats independent of sex highlighting the importance of further investigating other potential attributing factors. The brief access feature of this procedure provides behavioral measures in which the contribution of postoral factors are minimized. These findings support a role for oral cues in the responses to ethanol.

Title: Sucrose detection and decision-making coding in the rat anterior insular and orbitofrontal cortex

Authors: *E. FONSECA[1], V. SANDOVAL-HERNÁNDEZ[2], S. MEJÍA-ORTIZ[1], F. ZEPEDA-RUIZ[1], S. A. SIMON[3], R. GUTIERREZ[4];

Abstract: Sweet taste quality, which predicts immediate energy presence, is suggested to be primarily encoded in the anterior insular cortex (aIC). In contrast, intensity/concentration is known to be encoded throughout the gustatory pathway, including the primary and secondary gustatory cortices: aIC and Orbitofrontal Cortex (OFC). Representation of both attributes is essential to shape a taste percept which will lead the subjects to the most convenient food selection. Studies exploring neural representation of these attributes have been mainly achieved in anesthetized animals, in tasks where subjects only decide whether to ingest or not the gustatory stimuli, or that does not allow a dissection between quality and intensity components. Therefore, we designed a sucrose detection task (Water 0% vs. sucrose 0.5, 1.3, 3.2, 7.9, 20%) that allowed the animal to actively report the presence or absence of sucrose while recording single-unit activity. We found that more than half of neurons recorded, in both cortices, were responsive to cue delivery. Although, at the population level, different modulatory patterns were displayed: aIC responded earlier and with a strong phasic component, whereas OFC neurons exhibited a late tonic response. Only a small (~16.6%) subpopulation of Quality-selective (QS) neurons responded differentially to sucrose in comparison to water. This group contained more information -in the firing rate and spike timing- about the intensity in comparison to Non-selective. Furthermore, QS could respond differently to at least two of sucrose intensities (Intensity-Variant, Var) or very similar to all sucrose intensities (Intensity-Invariant, Inv). The proportion of the Inv neurons was higher in the aIC in comparison to OFC, while Var neurons prevailed in the OFC. We propose that Inv neurons could be important to detect sucrose regardless of its sweetness. In both cortices, a subset of Var neurons linearly modulated their firing rate as a function of intensities. These data confirm that both regions represented sucrose quality and intensity physical dimension: responses covaried with stimulus. On the other hand, we confirmed that the psychological dimension of the sweet taste detection can be encoded in both regions: responses covaried with the animal choice. Finally, other decision-variables such as movement direction and outcome omission were encoded by these two regions. Thus, the taste system uses a compact and distributed code to detect and represent the perceived quality and intensity of sucrose. Moreover, the decision variables, as opposed to other sensory systems, are encoded by both cortices demonstrating they served as multimodal areas.

Title: Testing basic principles of gustatory neural coding

Authors: *Y.-S. HUNG, M. A. STOPFER;
NICHD, NIH, Bethesda, MD

Abstract: The sensation of taste (gustation) provides critical information about nutrient content and toxicity of food sources. It is essential for the survival of animals, and in the case of humans, it also enhances our enjoyment of flavoursome foods, the quality of our lives, and our good health. However, the neural mechanisms for encoding and processing taste information are still unclear and controversial within the gustation field. Two major but contradictory hypotheses for taste information coding are widely accepted. The “labeled line” model states that there are a small number of basic taste categories (e.g. sweet, sour, salty, bitter, umami), and that these tastes are encoded, from receptors to brain, via segregated pathways. The other view, the “across fibre pattern” model, asserts that a tastant and its intensity are encoded by interacting ensembles of broadly tuned neurons. Controversy also surrounds the fundamental question of whether the gustatory system senses only basic taste categories, or rather each individual tastant. To understand how taste information is processed in the nervous system, we use fruit flies (Drosophila) to test these fundamental ideas. Taking advantage of genetic tools, we will examine the basic coding hypotheses using both anatomical and physiological approaches. We will identify and characterise the connectivity of gustatory secondary neurons (G2Ns) to different gustatory receptor (GR) expressing neurons, and their responses to a wide variety of tastants. Our preliminary results show that G2Ns connect to more than one type of GR-expressing neuron. The physiological measurements from these cells (by patch clamp and calcium imaging) in flies exposed to various tastants will provide valuable insights into the gustatory coding scheme employed by fruit flies.

Title: Functional division of *Drosophila melanogaster* sweet taste neurons underlying behavioral flexibility towards sugars

Authors: *H.-L. CHEN[1], U. STERN[2], R. YANG[2];
[1]Biol., [2]Neurobio., Duke Univ., Durham, NC

Abstract: While *Drosophila* consistently show appetitive responses toward sugars during food searching, their responses towards sugars during egg-laying site selection is context dependent. For example, they readily accept a sucrose substrate for egg-laying when it is the sole option but robustly reject it when a sucrose-free substrate is available. The mechanism by which *Drosophila* sweet taste circuit ensures consistent response towards sugar during one behavior while promotes flexible sugar responses during another is not known. Here, we report that sweet taste neurons on flies' proboscis are divided into two distinct groups that convey opposing values in the context of egg-laying but promote identical values in the context of feeding. First, we found that a specific subset of sweet taste neurons - that is molecularly distinct from the rest - acts specifically to promote rejection of sucrose during egg-laying. Inhibiting this subset of sweet neurons switched females from robustly rejecting to preferring sucrose for egg-laying. Second, both the sensitivity and the functional output of the rejection-promoting sweet neurons are regulated differently from the rest of the sweet neurons. Removing a specific ionotropic receptor (IR) from these neurons but not the rest reduced sucrose rejection. Moreover, reducing two GABA receptors from these neurons did not impact sucrose appraisal whereas reducing the receptors from the rest enhanced sucrose preference for egg-laying. Third, the rejection-promoting group still promotes appetitive response during feeding. Optogenetic activation of these neurons drove robust proboscis extension, a feeding acceptance, as did optogenetic activation of the rest. Finally, the rejection-promoting group and the rest have shared as well as distinct synaptic targets in the brain. Using Trans-Tango, a newly developed synaptic-tracing technique in flies, we found that both groups synapsed with 2nd order neurons that arborize locally in the subesophageal zone (SEZ), a taste center in the brain where motor neurons controlling proboscis extension extend their dendrites, but the rejection-promoting group did not synapse with 2nd order neurons that showed long range projections to several higher brain areas. Together, our collective results revealed the existence of a specific group of sweet taste neurons that is molecularly, cellularly, and anatomically distinct from the rest of sweet taste neurons and its existence enables consistent

appetitive responses during feeding but context-dependent responses during egg-laying site selection.

Title: Human taste buds are more densely innervated than those of mice and tree shrews

Authors: *B. HIGH, C. E. WILSON, R. YANG, M. E. JETTÉ, T. E. FINGER;
Dept. Cell & Devel. Biol., Univ. of Colorado, Aurora, CO

Abstract: Gustatory nerve fibers innervate mammalian taste buds and express P2X receptors, reflecting the obligate purinergic nature of gustatory transmission. These fibers arise from the facial nerve to innervate the fungiform papillae and from the glossopharyngeal nerve to innervate the circumvallate and foliate papillae. We utilized immunohistochemistry to visualize P2X3, which labels gustatory fibers as well as subset of mucosal nerve fibers, and electron microscopy to compare the patterns of innervation of fungiform and circumvallate papillae of mice, humans and tree shrews (*Tupaia belangeri*), a member of the Euarchontoglires superorder of mammals. Immunofluorescent images were quantified using trinarization then binarization of P2X3-positive nerve fibers to calculate the density of innervation of taste buds. As another means of assessing innervation density, nerve fiber profiles were counted in randomly selected electron microscopic images of taste buds across species. Although the general pattern of innervation is conserved across all three species, initial measurements show that human taste buds have 2-5 times the density of innervation compared to corresponding taste buds in mice and tree shrews. Further ultrastructural analysis is necessary to determine whether the details of connectivity, such as the number of synaptic contacts, in humans differ from those in mice and tree shrews.

Title: Memories are coming: Tracking the neural activity underlying taste aversion learning

Authors: *E. ARIELI[1], N. YOUNES[1], A. MORAN[1,2];
[1]Tel Aviv Univ., Tel Aviv, Israel; [2]Sagol Sch. of Neurosci., Tel Aviv, Israel

Abstract: Neuronal activity in sensory cortices changes following learning, such as in the gustatory cortex (GC) after conditioned taste aversion (CTA) wherein a novel palatable taste becomes aversive following pairing with malaise. These changes, however, have been found using "snapshots" taken 24 hours apart, and thus do not allow a fine temporal description of the response changes over time. Insights about the time course of these changes come from molecular studies showing different molecular cascades that span over hours following the CTA induction. To reveal the neuronal activity changes over time we implanted rats with electrodes in the GC and intraoral cannula for precise taste deliveries, and tracked ensembles of neurons for 48 hours; before, during and after CTA. Our results show that changes in neuronal response dynamics start approximately 1h after CTA induction and end about 8h post CTA, with the main changes occurring 3-6h post CTA. This timing is similar to the time frame of the reported molecular processes. Interestingly, these changes were uncorrelated with changes in their baseline (BL) activity over time. In contrast, high correlations were observed in BL and taste response activity between different neurons, supporting the idea of global changes that govern neuronal activity following learning. Additional analyses of network level synchrony and delta-gamma modulation show similar increases 3 hours post CTA. Together, our results show that long-term electrophysiological changes that occur following taste aversion learning occur at the same time scales of the molecular processes. Moreover, these changes seem to be mainly governed by a network level organization and to a lesser extent by the state of the single neuron.

Title: The effects of sleeve gastrectomy on oral and post-oral sucrose preferences in a high fat diet-induced obese rat model of spinal cord injury

Authors: T. TANG, L. B. WILLING, E. N. BLANKE, N. HORVATH, G. M. HOLMES, ***A. HAJNAL**;
Neural and Behavioral Sci., Penn State Univ. Coll Med., Hershey, PA

Abstract: Approximately two-thirds of spinal cord injured (SCI) individuals become overweight or obese. Weight loss/metabolic surgery, including sleeve gastrectomy (SG) is regarded as highly effective in the long-term treatment of obesity and remission of type 2 diabetes. It is, however, unknown if obese individuals with SCI respond to obesogenic diets and SG similarly to the able-bodied. This study used a rat model of SCI to assess sucrose preferences in the context of dietary obesity, and the efficacy of SG. Male Wistar rats received either contusion injuries of the spinal cord (T3-T4) or spinal sham operation (SP-SHAM). After full recovery, all rats were fed a high energy, high fat diet (HFD, 60%kcal from fat) for 6 weeks prior to sleeve gastrectomy (SG) or abdominal sham surgery (AB-SHAM). Taste preferences based on oral and post-oral effects were assessed using automated gustometers for brief-access (10-s) lick rate analysis and two-bottle choice (2BC) tests for sucrose, respectively, at various time points. Pre-HFD, SCI compared to SP-SHAM significantly reduced sweet taste preferences for sucrose (0.6-1.5M) but did not alter 2BC preference. HFD resulted in greater weight gain in SCI rats, an overall blunting of lick responses to low (0.1-0.3M) and increased responses for high sucrose concentrations (0.9-1.5M). Furthermore, SCI rats on HFD showed avoidance to 0.3M sucrose in the 2BC tests. Lastly, SG compared to AB-SHAM reduced sucrose preferences across all concentrations in both SCI and SP-SHAM cohorts with the SCI rats being more sensitive to this effect. SG also restored 2BC sucrose preference in SCI rats. In summary, SCI, compared to sham-surgery, reduced sweet-taste preferences based on brief-access oral stimulation both prior and post HFD, and also abolished preferences for sucrose based on its post-ingestive effects following HFD exposure. Furthermore, SCI rats were more sensitive to the effects of SG on either oral or post-oral sucrose preferences. Remarkably, SG restored diminished post-oral preferences for sucrose in the SCI rats. These findings collectively support the hypothesis that SCI may result in altered taste and gut-brain nutrient/reward sensing, and in turn, may increase the risk for development of diet-induced obesity. Furthermore, these findings represent the first evidence suggesting that SG may restore normal sensing in SCI more efficiently than non-SCI subjects. Future mechanistic studies are warranted to reveal the underlying neural and hormonal mechanisms.

Title: High fat diet's influence on body composition and peripheral taste organs persists even after switching to a low fat diet

Authors: F. HARNISCHFEGER[1], M. S. WEISS[3], *P. M. DI LORENZO[4], R. DANDO[2]; [1]Food Sci., [2]Cornell Univ., Ithaca, NY; [3]Psychology, [4]Binghamton Univ., Binghamton, NY

Abstract: Recent studies have shown that weight gain arising from consumption of a high fat diet (HFD) in mice is accompanied by a loss of taste buds (Kaufman et al. PLoS Biol. 16(3):e2001959, 2018). Here, we studied whether a HFD in rats would also result in a loss of taste buds and whether this deficiency would persist after rats were returned to a normal chow diet for a prolonged period. Two groups of adult male rats were fed standard chow (CON) or a HFD (45% fat) for 8 wks. The HFD group was then divided into two groups that were weight matched: the HFD-chow group was switched to standard chow and the HFD-pair fed group was given the same number of calories as their HFD-chow counterparts, but in the form of a HFD. Rats were maintained on this diet regime for an additional 12 wks. All rats were scanned with dual-energy X-ray absorptiometry to assess body composition every 4 wks. At the end of the experiment, rats were sacrificed and perfused with saline and paraformaldehyde. Tongues were removed. The fungiform region was stained with methyl blue and imaged to count fungiform papillae. Circumvallate papillae were processed histologically to allow analyis of taste buds. Groups were compared using independent Kruskal-Wallis ANOVA, with statistical significance assumed at $P < 0.05$. Results showed that all rats on a HFD gained weight and showed an increase in the proportion of body fat compared to CON rats during the 8 wks prior to the dietary switch. After the HFD group was divided, rats in both groups continued to gain weight, with the percent body fat in the HFD-pair fed group continuing to increase despite caloric restriction. Percent body fat in the HFD-chow group decreased but remained elevated compared to CON group. Analyses of taste buds showed a clear and significant decrease in the number of taste buds and in the number of fungiform papillae (Ps < 0.05) in both the HFD-chow and HFD-pair fed groups compared with lean CON rats. Additionally, number of Type II cells, as measured by gustducin, were lower in the HFD-chow and HFD-pair fed groups compared with CON rats ($P < 0.05$). Although not significant, the HFD-pair fed group had slightly increased neutrophil invasion into the circumvallate papillae. These data suggest that consumption of a HFD

compromises the peripheral gustatory apparatus and that this effect persists despite a long-term resumption of a standard diet.

Title: State-dependent coding: LiCl-induced sickness alters gustatory oscillatory rhythms and coordinated spiking during taste processing

Authors: *B. T. STONE[1], A. MAHMOOD[1], J.-Y. LIN[1], D. B. KATZ[2];
[1]Neurosci., [2]Dept Psychol, Brandeis Univ., Waltham, MA

Abstract: A large literature addresses how toxicity by way of drug injection (commonly lithium chloride; LiCl) shapes aversive behavior, but few studies have delved into the nature of this powerful state itself. Such states influence an animal's interactions with its environment, potentially affecting its feeding behavior through modifications of taste perception: an animal that is ill, for instance, is less likely to find food appetitive (a fact that can potentially prolong infirmity by demotivating the animal to ingest nutrients). Here, we report the beginning of an investigation into how the spontaneous network state induced by LiCl specifically impacts taste processing, and how the activity underlying this internal state might support learning. Using extracellular (single-neuron and local field potentials; LFPs) recordings during a passive taste delivery task under two (LiCl-induced sickness and Neutral) conditions, I demonstrate evidence that network state changes induced by internal state manipulations are represented in the gustatory cortex (GC). I show that in comparison to a neutral ("healthy") state, rhythmic activity during taste presentation is quenched within 7-12Hz which has previously been reported as reflective of attentiveness to external stimuli. Furthermore, the data show that coordinated spiking activity following taste delivery, as characterized through spike-phase locking within the GC, increases within 4-7Hz while decreases within 7-12Hz; providing evidence that sickness alters the orchestrated communication among neural populations differentially with respect to rhythmic patterns. These results provide powerful evidence towards the function that an animal's welfare has on the establishment and maintenance of natural reward valuation and associative effects of stimuli.

Title: Neonatal chorda tympani transection enhances gustatory responses from uninjured nerves in the adult rat parabrachial nucleus of the pons

Authors: *L. J. MARTIN, S. I. SOLLARS;
Univ. of Nebraska At Omaha, Omaha, NE

Abstract: The gustatory chorda tympani nerve (CT) does not regenerate when it is cut in rats at postnatal day 10 (P10) or younger, resulting in a permanent loss of taste input from the anterior tongue. Early CT transection (CTX) alters the organization of intact gustatory nerve terminal fields in the nucleus of the solitary tract (Martin et al., 2019) and stunts the typical developmental shift from preference to avoidance for ammonium chloride (NH_4Cl) solutions (Sollars & Bernstein, 1996). The importance of CT input for the development of central gustatory function is largely unknown. Here, we recorded gustatory responses from single neurons in the third-order gustatory nucleus, the parabrachial nucleus of the pons (PbN), in adult male and female rats following neonatal CTX. At P5, the CT was accessed via a neck incision and was either transected (CTX) or left intact following visualization (Sham). At least 100 days after surgery, rats were anesthetized with urethane and prepared for extracellular electrophysiology. The CT proximal to the site of surgery was then cut in the middle ear in Sham and CTX rats to ensure that all sampled neurons responded to input from taste nerves other than the CT and that neurons were as similar as possible between experimental groups. Glass-insulated tungsten microelectrodes (1-3 MΩ) were lowered into the brain until gustatory PbN neurons were identified. Firing rates to the following stimuli were recorded: 0.1 and 0.5 M NH_4Cl, 0.1 and 0.5 M NaCl, 0.5 M sucrose, 0.01 M citric acid, and 0.01 M quinine. Neural activity and entropy (breadth of tuning to five stimuli) were compared between groups with ANOVAs and Welch's *t*-tests. Responses were recorded for 25 CTX neurons and 25 Sham neurons. Overall, CTX rats had significant higher responses to taste stimuli ($p = .005$), and differences in taste responses between surgical groups dependent on the solution examined ($p = .001$). Specifically, CTX rats had significantly higher responses to 0.1 M NH_4Cl ($p = .021$), 0.5 M NH_4Cl ($p = .001$), 0.1 M NaCl ($p = .013$), 0.5 M NaCl ($p = .005$) M citric acid ($p = .042$). There was a non-significant tendency for CTX rats to have higher activity to 0.5 M sucrose stimulation ($p = .062$), but responses to 0.01 M quinine were not significantly different between groups ($p = .427$). Neurons from CTX rats also had significantly higher spontaneous activity ($p = .032$) and

entropy (p = .044). These findings suggest that the early loss of CT input leads to compensatory amplification of remaining inputs in a stimulus-specific manner. Higher spontaneous activity, elicited responses, and tuning breadth in CTX rats may reflect an increased convergence of inputs onto PbN neurons.

Title: Do rat brains discriminate Spanish and English languuages?

Authors: *M. SATO, N. MATSUMOTO, Y. IKEGAYA;
Grad. Sch. of Pharmaceut. Sci., The Univ. of Tokyo, Tokyo, Japan

Abstract: There are difficult tasks that humans are not able to solve even after they are repeatedly trained. For example, many Japanese people have difficulty in discriminating between sounds of L and R although the two types of sounds are represented in distinct cell ensembles in the auditory cortices. Thus, since sensory information is conveyed from sensory organs to each sensory cortex as long as humans are exposed to sensory stimuli, we hypothesized that sensory cortices contain the information required to solve a sensory discrimination task. In the process of sensory information transmission from the sensory organs to the sensory cortices, there is little information loss at least in the primary sensory cortex. Therefore, sensory information in a sensory-relevant task may be decoded from neuronal activity in the primary sensory cortex. We hypothesized that when the human language is presented to rats in an auditory discrimination task, the auditory information (*e.g.*, Spanish or English) can be decoded from neural activity, although rats do not basically discriminate between the phonetic features of spoken English and Spanish languages. To test this hypothesis, we developed a new behavioral task, where we extracellularly recorded neuronal activity (*i.e.*, local field potentials (LFPs)) from the rat primary auditory cortex while a rat was given short phrases of Spanish or English sentences. Then, we tried to decode the language given to the rat from the neural activity. Before we presented voices of human languages to rats, as pilot study, we recorded LFPs from the primary auditory cortex while rats were given pure tones (1500 - 7000 Hz, 3 sec) intervened between silent periods, and found the differences in LFPs between the onsets of the silent and tone periods. We examined

whether deep learning can decode the difference of the pitches and silent periods from LFPs. We found deep learning model with a structure that performs one-dimensional convolution in the time axis direction and the electrode channel direction independently, improved decoding performance partially because the spatiotemporal information of LFPs was efficiently used. We tried to feedback the decoded information to the brain and to enhance what the animals are able to do, which would enhance animals' intelligence.

Title: Direct comparison of nonlinear sensory encoding models in ferret primary auditory cortex

Authors: *J. R. PENNINGTON[1], S. V. DAVID[2];
[1]OHRC, Oregon Hlth. & Sci. Univ., Portland, OR; [2]OHRC, Oregon Hlth. and Sci. Univ., Portland, OR

Abstract: A common framework for describing the function of auditory neurons is the linear-nonlinear spectro-temporal receptive field (LN STRF). This model casts a neuron's sound-evoked activity at each moment in time as the linear weighted sum of the immediately preceding sound spectrogram, followed by nonlinear rectification. However, the LN STRF is an incomplete model since it cannot account for context-dependent encoding or other nonlinear aspects of auditory processing. Two alternative models have improved on the predictive power of the LN STRF by accounting for experimentally observed biological mechanisms: short-term plasticity (STP) and contrast-dependent gain control (GC). While both models improve performance over the LN model, they have never been compared directly. Thus, it is unclear whether they account for separate processes or simply describe the same phenomenon in different ways. To address this question, we recorded the activity of single primary auditory cortical neurons (n = 423) in awake ferrets (n = 7) during the presentation of natural sound stimuli. We then fit STRFs incorporating one nonlinear contextual mechanism (GC or STP) or both mechanisms (STP+GC) on this single dataset. We compared model performance using the correlation coefficient (Pearson's R) between predicted and observed time-varying firing rate for each neuron. Our results indicate that there is no significant performance difference between the STP and GC models, but that the STP+GC model performs significantly better than either individual model. This finding indicates that the STP and GC models contain distinct explanatory power. Further,

the success of the combined model hints that auditory cortical neurons utilize at least two independent mechanisms to adapt encoding properties to different sensory contexts. Future neuromorphic sound processing technologies may therefore improve their performance by incorporating both STP- and GC-based strategies.

Title: The properties of neural activities by acoustic factors in higher auditory region to sound stimuli in awake and anesthetized finches

Authors: *A. YOSHIDA, M. INDA, K. HOTTA, K. OKA;
Keio-Univ. Biophysics and Neuroinformatics Lab., Yokohama, Japan

Abstract: Zebra finches (*Taeniopygia guttata*) sing songs to communicate each other. Songs enable the birds to discriminate species and individuals, and the previous study suggested that female finches have high selectivity to individual male songs (Terpstra *et al.*, 2006). In the avian brain, caudomedial nidopallium (NCM), one of higher auditory regions, might play the important roles for memorization and discrimination of songs. In this study, we recorded neural activities to several songs from single NCM neurons in awake finches to investigate the difference between responses to each song. In our experiment, three songs were presented as sound stimuli: direct song (sing for courtship), undirect song (sing in daily life) and hetero-specific song (Bengalese finches' song).We detected the significant differences in awake birds only between the responses to undirect song and those to hetero-specific song. To investigate why there was no significant difference between responses to direct song and those to hetero-specific song, we examined the difference of the several acoustic factors of songs: amplitude, fundamental frequency, mean frequency, frequency modulation and entropy. The comparisons of the effects of these acoustic factors in songs on neural activities indicated that neurons in NCM encode these factors. This result suggests that the difference of acoustic factors could cause the difference of responses.Furthermore, recent studies showed that anesthesia has a great effect on the neural activity (Ruijssevelt *et al*., 2017). We, therefore, recorded the neural activities from single NCM neurons under urethane anesthesia and awaking. In this comparison, there was no significant differences in responses to the whole songs. However, we found the significant differences in the timing and the duration of the responses by syllable base analysis. This suggests the possibility that urethane triggers the response delay of NCM neurons. We approached the influence of anesthesia on the neurons.

Title: Representation of behavioral integration time downstream of auditory cortex

Authors: ***J. YAO**, J. GIMOTO, D. SANES;
New York Univ., New York, NY

Abstract: The central representations of environmental signals are transformed at each locus of an ascending sensory pathway. One characteristic of this hierarchical processing is that the time required to fully encode a sensory cue (i.e., integration time) increases at ascending levels of the nervous system. Here, we sought to determine how auditory information is transformed downstream from core auditory cortex (ACx), at a location thought to support sensory decisions, the parietal cortex (PC). Gerbils were trained and tested on an appetitive alternative forced-choice (AFC) auditory temporal integration task. Specifically, gerbils were required to discriminate between amplitude modulated (AM) noise at 4 versus 10 Hz across a range AM durations (100-1000 ms). Behavioral integration times were measured by examining how AM discrimination scales with stimulus duration. Task performance was poor at very short AM durations (100-200 ms), improved with longer durations, and reached an optimum at ~600 ms. To determine the downstream projections from gerbil ACx to PC, viral tracing experiments were performed. The data revealed a disynaptic pathway from ACx to dorsal auditory cortex to PC. Thus, we hypothesized that the integration times for AM cues are transformed downstream from ACx, in PC, thereby creating the representation that supports integration time on the AM task. To test this idea, muscimol was bilaterally injected in PC to attenuate activity during task performance. While animals continued to perform the task following muscimol infusion, integration times were increased. To determine whether a PC encoding mechanism could account for these behavioral results, we conducted wireless recordings of single-unit activity from neurons in ACx and PC while gerbils simultaneously performed the auditory temporal integration task. Neural integration times are calculated from discharge patterns obtained during psychometric performance. We predict that ACx integration times for AM signals will be significantly shorter than those displayed behaviorally, whereas the neural representation in PC will yield integration times that match psychometric performance. Collectively, these

experiments will reveal whether the neural representation downstream of ACx, in PC, is necessary and supports the observed behavioral temporal integration times.

Title: Characterization of modularity in the lateral cortex of the mouse inferior colliculus using a combination of optogenetic circuit mapping and *in vivo* two-photon imaging

Authors: *B. A. IBRAHIM[1,2], Y. SHINAGAWA[1,2], A. R. ASILADOR[2,3,4], D. A. LLANO[1,2,3]; [1]Mol. & Integrative Physl, [2]Beckman Inst. for Advanced Sci. and Technol., [3]Neurosci. Program, [4]Sch. of Mol. & Cell Bio, Univ. of Illinois at Urbana-Champaign, Urbana, IL

Abstract: The inferior colliculus (IC) is a critical midbrain structure for the processing of auditory stimuli. The IC is a hub that permits widespread convergence of both bottom-up and top-down projections involving auditory, somatosensory, visual, motor and arousal-related brain regions. One of the non-lemniscal divisions of the IC, the lateral cortex (LC), contains periodic modules of GABAergic cells and terminals which stain strongly for a range of metabolic markers. Anatomically, auditory inputs from the auditory cortex or central nucleus of the IC strongly avoid these inhibitory modules and instead form dense projections to the matrix areas that surround the modules. In addition, these modules receive direct inputs from the somatosensory brain regions. On cell type, GABAergic cells in the modules appear to integrate information between the modules and matrix and therefore may be critical to multisensory integration. However, there is no clear mechanism about the function of these inhibitory modules in sensory processing. Here we show using laser-assisted mapping that AC terminals in the LC made monosynaptic connections with all LC neurons with the exception of GABAergic cells in the modules, which we previously have shown to be the only cell type in the LC to receive substantial intrinsic cross-module inputs. In addition, two-photon imaging was used here to characterize the functional activity of the GABAergic and nonGABAergic cells inside and outside the modules. We observed strong tone-responsiveness in the LC, with a broad array of tuning widths. These data suggest that the module/matrix organization of the lateral cortex has the capacity to process auditory stimuli while being modulated by auditory cortical projections.

Title: Neuronal dynamics of non-classically responsive cortical neurons

Authors: *M. INSANALLY[1], B. DEPASQUALE[2], B. F. ALBANNA[3], K. RAJAN[4], R. C. FROEMKE[1];
[1]New York Univ. Sch. of Med., New York, NY; [2]Princeton Neurosci. Institute, Princeton Univ., Princeton, NJ; [3]Natural Sci. Dept., Fordham Univ., New York, NY; [4]Dept. of Neuroscience, Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract: Spike trains recorded from the cortex of behaving animals can be complex, highly variable from trial-to-trial and therefore challenging to interpret. A fraction of recorded cells typically exhibit trial-averaged responses with obvious task-related features and can be considered ‘classically-responsive’, such as pure tone frequency tuning in the auditory cortex. However, a substantial number of cells (including cells in primary sensory cortex) do not appear to fire in a task-related manner and are often neglected from analysis (Olshausen & Field 2006). Even classically-responsive cells lose their stimulus representation during task-engagement without impairing behavioral performance (Otazu et al., 2009). These results suggest that non-classically responsive cells may play an underappreciated role in sensory processing and cognition. Using multielectrode arrays we recorded from 103 single-units in the auditory cortex (AC) and 74 single-units in the frontal cortex (FR2) while animals performed a frequency recognition task. While the trial-averaged responses of some cells exhibited obvious and statistically significant task-related features, many cells were non-classically responsive (64/103 AC cells and 43/74 FR2 cells from 15 animals had neither significant tone-modulated activity nor ramping activity; $p < 0.05$, 5,000 bootstraps). Recently, we showed that non-classically responsive cells contained hidden task-relevant information at levels comparable to responsive cells using a novel single-trial spike-timing-based analysis (Insanally et al., 2019). Here we expand our investigation to explore the potential utility and necessity of non-classically

responsive cells and demonstrate: 1) Non-classically responsive cells are better predictors of single-trial behavioral errors. Historically, the capacity to predict behavioral errors on single trials using responsive cells has been limited. Using our novel decoder, we demonstrate that including non-responsive cells significantly improved predictions of behavioral errors in both auditory and frontal cortex indicating that these neglected cells can provide missing insights into behavioral variability. 2) Non-classically responsive activity is necessary for task performance and interacts synergistically with the activity of responsive cells. Using a recurrent neural network model trained to perform our frequency recognition task, we establish that non-classically responsive activity is necessary for successful task performance. Furthermore, we demonstrate that responsive and non-classically responsive subpopulations have a synergistic effect on network behavior.

Title: Data-driven auditory field mapping for mice using naturalistic sounds

Authors: *H. TERASHIMA[1], H. TSUKANO[2,3], S. FURUKAWA[1];
[1]NTT Communication Sci. Labs., Atsugi, Japan; [2]Dept. of Neurophysiol., Brain Res. Institute, Niigata Univ., Niigata, Japan; [3]Univ. of North Carolina at Chapel Hill, Chapel Hill, NC

Abstract: Studies on hierarchical cortical processing of auditory information require a precise map of functional fields that constitute the auditory cortex. For the mouse auditory cortex, advances of imaging techniques have resulted in a variety of researcher-dependent field maps (Guo et al., 2012; Issa et al., 2014; Tsukano et al., 2015). These mapping studies were biased in two ways: stimuli were only simple synthetic sounds and analyses of responses were hypothesis-driven. To address the issue, here we drew a new areal map of the mouse auditory cortex using naturalistic complex sounds and data-driven analyses. First, we recorded trans-cranial Ca^{2+} responses to a set of naturalistic sounds from the entire auditory cortex of anaesthetized Emx1-GCaMP8 mice. Considering the hearing range of mice, the naturalistic sound set was constructed by pitch-shifting a set of 165 natural sounds for humans (Norman-Haignere et al., 2015) by four octaves. We decomposed the responses into five components using matrix decomposition technique that maximizes non-Gaussianity of spatial components, which was originally developed for human BOLD signals (Norman-Haignere et al., 2015). Comparison with responses to pure tones reconfirmed the previously known tonotopic fields such as A1, AAF, DM, and A2.

Using regularized linear regression, we characterized each component by acoustic features that can predict its coefficient and found that some components are selective to FM sounds, which correspond to fields known as DA and DP. Moreover, we found a new auditory field on the rostro-dorsal side of the classical auditory cortex, which might be related to high-frequency FM sounds like mice vocalizations. Overall, our findings reconfirmed most of the field map drawn by Tsukano et al. (2015) and extended it with a new field. The results demonstrate how naturalistic sounds combined with machine learning techniques can reveal functional organization of the mouse auditory cortex.

Title: Response properties of the bat primary auditory cortex to frequency-modulated stimuli

Authors: *K. BAKSHI[1,2], S. MACIAS HERRERA[2], M. S. SMOTHERMAN[1,2];
[1]Texas A&M Univ. Inst. For Neurosci., College Station, TX; [2]Texas A&M Univ. Dept. of Biol., College Station, TX

Abstract: Neural selectivity to the direction and rate of sensory stimuli is a common feature across sensory modalities. In the auditory system, frequency-modulated (FM) sweeps are essential elements of vocal communication in animals and for human speech. Echolocating bats provide an ideal model for studying the neural circuits underpinning FM sweep selectivity due to their reliance on FM sweeps for biosonar. We used multichannel microelectrode arrays in anesthetized Mexican free-tailed bats (*Tadarida brasiliensis*) to evaluate how FM sweeps were encoded in the primary auditory cortex (A1). Pure tone stimuli were presented to determine the response properties of principal cells and their surrounding local field potentials (LFP), including characteristic frequency (CF), best frequency (BF), minimum threshold (MT), best level (BL) at CF, and frequency response area bandwidth (BW). We used these parameters to map the topographical organization of response properties throughout A1, and then investigated how FM sweep selectivity was represented within this map.
Spiking neurons responding to pure tone stimuli were tonotopically organized rostrocaudally with lower CFs represented caudally. Frequency response areas were significantly lower and broader for LFPs than for spikes, indicating that local interneurons receive convergent inputs

from an asymmetrical frequency range to produce a feedforward inhibition that may bias spiking neuron response properties in favor of downward sweeps. The majority of A1 neurons responded preferentially to downward FM sweeps, with more neurons tuned to slower sweep rates. These results are consistent with hypotheses that intracortical inhibitory processes, such as sideband inhibition, shape FM tuning and suggest that in the free-tailed bat, A1 is preferentially sensitized to sounds occuring within the context of downward FM sweeps.

Title: Auditory neurofeedback for noise suppression and speech enhancement

Authors: Y. DONG, ***Y. G. GAI**;
St. Louis Univ., Saint Louis, MO

Abstract: Cortical entrainment refers to the synchronization of brain activity to external sensory stimuli. For speech input, electroencephalography (EEG) signals may be linearly related to the sound envelope (in the frequency range of 2 to 8 Hz) or other linguistic features. When speech is presented in background noise, our previous study found that brain signals obtained with certain electrodes can suppress response to noise and more or less maintain correlations to the speech component. Here we developed a neurofeedback system to explore if the human subject can actively enhance speech response and suppress noise response. A 64-channel EEG system was used to record brain signals while the subject was presented with speech sentences presented alone in noise. In contrast to conventional neurofeedback systems that mostly measure neural oscillations to monitor the brain's internal states, our system provided the subject with real-time correlations of ongoing EEG signals evoked by speech in noise to a target. This target was either the envelope of the speech alone or pre-recorded EEG evoked by speech alone. Subjects were asked to increase this correlation value by changing their attention or whatever technique they found effective. We observed diverse abilities of subjects in suppressing responses to the background noise. The EEG electrodes that provide the best correlations also differed. The next step of the study is to find out if the auditory neurofeedback training can increase speech intelligibility assessed with behavioral tasks.

Title: Dynamics of primate inferior colliculus neurons during the localization of simultaneous sounds

Authors: *S. M. WILLETT[1], S. T. TOKDAR[2], J. M. GROH[3];
[1]Dept. of Neurobiology, Ctr. for Cognitive Neurosci., [2]Dept. of Statistics, [3]Psychology and Neuroscience, Neurobiology, Ctr. for Cognitive Neurosci., Duke Univ., Durham, NC

Abstract: It is unclear how neurons and populations of neurons encode more than one stimulus. Canonically, a possible solution is to have sufficiently selective neurons so stimuli representations could be encoded by specific neural subpopulations. However, this proposed solution ignores the multi-selectivity of many neural populations, the surprisingly broad tuning of neurons, and the complex content of natural stimuli. For example, neurons in the monkey inferior colliculus encode sound location by monotonically increasing their firing rate with sound eccentricity, while they encode sound frequency with circumscribed, but broad, receptive fields. Recent work (Caruso et. al., *Nature Communications,* 2018) proposed an alternative to the selective subpopulation hypothesis and showed that some inferior colliculus neurons alternate between firing rates corresponding to two simultaneously presented sounds within single trials. However, this study only presented sounds of similar frequencies. It remains unclear if these dynamics exist when sounds of dissimilar frequencies are presented, where neural tuning for frequency may potentially carry a larger coding burden. The current study presented simultaneous sounds with variable separation of frequency to investigate the impact of frequency selectivity on the dynamics of single trials neural responses. To determine the response functions of IC neurons, spiking activity from isolated, sound responsive, neurons were recorded while two rhesus macaques (*Macaca mulatta*) performed a dual sound localization task. The task required monkeys to make either a single saccade to the location of one sound or a sequence of saccades to the location of each simultaneously presented sound. Traditional time and trial pooled analyses found many of the neurons average their responses in the presence of two sounds. Upon closer inspection by an analysis using spike count distributions from single trials (whole trial, i.e. 1 bin) revealed some neurons alternate across trials. That is on some trials neurons responded to one sound and on other trials they responded to the other sound. Analyses at finer time scales in

neurons that exhibited intermediate whole trial spike counts but did not show such fluctuations at the single trial level are currently pending.

Title: Modeling nonlinear dendritic integration in space-specific auditory neurons of barn owls

Authors: J. C. GORMAN[1], A. V. R. MILLER[1], J. L. PENA[2], *B. J. FISCHER[1];
[1]Seattle Univ., Seattle, WA; [2]Albert Einstein Col. of Med., Bronx, NY

Abstract: Dendritic integration can take different functional forms depending on the morphology of the neuron and the active properties of the dendrites and spines. The barn owl's external nucleus of the inferior colliculus (ICx) contains spatially selective neurons (SSN) that form a map of auditory space, where nonlinear input integration has been described. Recent anatomical work identified the existence of large diverse spines in SSNs that may integrate many inputs. The anatomical finding of diverse spines in ICx suggests that ICx may consist of neurons with different functional forms of dendritic integration. Here we use a model to investigate the functional implications of different dendritic nonlinearities in SSNs.
Neurons in ICx become tuned to sound location through selectivity for combinations of sound localization cues. The barn owl uses the interaural time difference (ITD) as a cue for the horizontal direction. ITD is detected by neurons that are narrowly tuned to frequency, and thus unable to uniquely represent auditory space. ICx neurons resolve this ambiguity integrating inputs across frequency. As a result, SSNs display ITD tuning curves with a large peak for a single ITD, surrounded by reduced side peaks, termed side peak suppression (SPS).
We used a two-stage model of ICx neurons to study the relationship between frequency integration bandwidth and SPS, consisting of neurons with dendritic subunits with nonlinear integrative properties. The input to ICx originates in the lateral shell of the central nucleus of the inferior colliculus (ICcl). ICcl neurons respond to ITD and are narrowly tuned to frequency. An established model of ICcl as the source of ICx inputs was used. Plausible SPS values were obtained from intracellular *in-vivo* recordings of ICx neurons to constrain the model. We used the model to predict the frequency integration bandwidth that would produce experimentally observed ranges of SPS for ICx neurons with different dendritic subunit nonlinearities.
We found that different model configurations are possible, but there is a predictable relationship

between the bandwidth of frequency integration and the form of subunit nonlinearity required to achieve experimentally observed ITD tuning curve shapes. Specifically, larger frequency integration bandwidth requires a more suppressive dendritic subunit nonlinearity and vice versa. A sigmoid nonlinearity was able to capture both of these requirements since it is expansive for small numbers of inputs and suppressive for large numbers of inputs. This suggests that ICx neurons may integrate inputs over larger frequency ranges than currently predicted by linear models and frequency tuning curves.

Title: Causal relationship between right auditory cortex and speech-evoked frequency following responses: Evidence from tDCS and EEG

Authors: *G. MAI, P. HOWELL;
Dept. of Exptl. Psychology, Univ. Col. London, London, United Kingdom

Abstract: Speech-evoked frequency following responses (FFR) reflect neural fidelity of speech periodicity and act as a clinical biomarker for speech processing disorders. While FFRs are considered to originate mainly from the brainstem, interest in contributions of auditory cortex (AC) to FFRs has increased. Recent research has shown that FFRs are associated with right-asymmetric AC activity (Coffey et al., 2016, 2017), but a causal relationship between AC and FFRs has not been established. This study combined transcranial direct current stimulation (tDCS) and electroencephalography (EEG) to test for such causality. 90 right-handed normal-hearing young adults were assigned at random to 5 groups (18 participants each group; single-blinded) and received 25-min 1-mA tDCS on AC (reference placed above the contralateral eyebrow) during a frequency discrimination task. Groups were (1) anodal on left AC; (2) cathodal on left AC; (3) anodal on right AC; (4) cathodal on right AC; and (5) sham (30-s ramping-up-and-down). An /i/ syllable was repeated monaurally on the left and right ear before and after tDCS and FFRs were obtained via EEG at the vertex. After-effects of tDCS on FFR spectral magnitudes and inter-trial phase-locking values at the fundamental frequency (F_0) were measured. After-effects showed main effects of group in the left but not right ear listening condition. Posthoc t-tests found that anodal and cathodal tDCS on right, but not left, AC resulted in significant after-effects (reduced FFR magnitudes and phase-locking) compared to sham in the left ear condition. In the right ear condition, no significant after-effects were found for tDCS on left or right AC compared to sham. Changes in neural excitability of the right, but not left, AC

altered FFR strengths along the contralateral pathway, hence providing direct evidence for a causal relationship between right AC and speech-evoked FFRs. Current results thus support the right-asymmetric auditory cortical contribution to processing of speech periodicity and facilitate our understanding of how speech is encoded in human auditory systems.

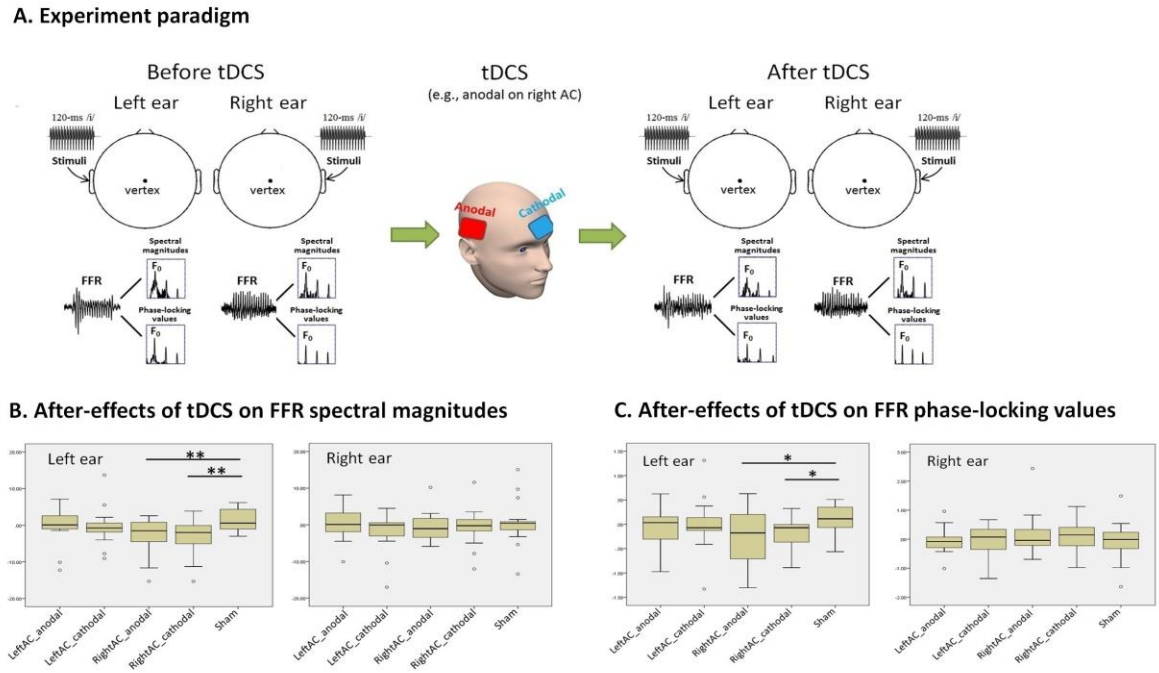

Figure 1. **(A).** Experiment paradigm. Participants listened to a repeated syllable monaurally from the left and right ear while FFRs were obtained from the vertex before and after tDCS. A frequency discrimination task was completed during tDCS. **(B) and (C).** After-effects of tDCS on FFR (B) spectral magnitudes (in *dB*) and (C) phase-locking values (logit-transformed). Significant main effects were found in the left but not right ear condition. Results showed significant after-effects of anodal and cathodal on the right AC compared to sham in the left ear condition. *p < 0.03; **p < 0.01

Title: Phonological feature and pitch classification with a branched convolutional neural network

Authors: *I. M. GRIFFITH[1], A. LEBEL[2], S. JAIN[3], A. G. HUTH[2,3], L. S. HAMILTON[1,4]; [1]Dept. of Communication Sci. and Disorders, Univ. of Texas At Austin, Austin, TX; [2]Dept. of Neurosci., [3]Dept. of Computer Sci., [4]Dept. of Neurology, Dell Med. Sch., Univ. of Texas at Austin, Austin, TX

Abstract: While processing natural speech, the human brain is able to take a complex acoustic signal and transform it into linguistically meaningful content. This includes encoding of simple acoustic features such as frequency or spectrotemporal modulation content, as well as phonological and prosodic representations. Previous research using invasive intracranial recordings has shown that distinct regions of the superior temporal gyrus encode prosodic and phonetic content (Tang et al. 2017). These regions are sensitive to intonational pitch (both absolute and relative) or phonological features, while being invariant to other stimulus features. However, it is not known how such invariance arises from auditory neural networks. To address this, we used a branched convolutional network trained on several hours of natural speech. Our network architecture consists of separate absolute pitch and phonological feature branches, each receiving input from shared earlier network layers. The network was optimized to simultaneously perform both absolute pitch and phonological feature classification, allowing earlier shared feature maps to inform individual task-specific outputs. Confusion matrices generated during model evaluation on a separate dataset indicate a high degree of accuracy and precision in both absolute pitch and phonological feature classification tasks. We next tested whether the representations learned by the network were able to predict brain responses. Using fMRI data collected from participants as they listened to the same natural speech stimuli, we fit encoding models that predict BOLD signals in each voxel using the activation weights from each layer of the convolutional neural network as stimulus features. Both pitch- and phonological feature-trained branches of the network strongly predicted activity in early auditory cortex in both the left and right hemispheres. We compare the spatial distributions of model performance to find regions of auditory cortex that differentially encode these intermediate to late layer representations. These results have implications for how invariance to complex attributes of speech and other natural sounds arise from earlier acoustic representations.

Univ. Hosp., Seoul, Korea, Republic of

Abstract: Human can successfully parse different sound streams and focus on a specific target sound in a cocktail party condition. Recently, several studies have shown that estimating attended sound is feasible with linearly trained neural decoders. In this study, we took the similar approach to build an auditory attention decoder based on human EEG signal recorded during dichotic listening experiment (64 channels, Neuroscan SynAmps RT). Nineteen participants are instructed to attend a speech on the one side of the ear and ignore another speech presented to the opposite side of the ear (order of stimuli presentation is randomly selected). Length of the stimuli was 1 min long and excerpted from a Korean listening comprehension audio samples for college entrance test (Female voice only). Since it has been reported that low-frequency of speech envelope is linearly related to the low-band of EEG, 2-8 Hz band-pass filter was applied to extract low-frequency component of EEG data and 8 Hz low-pass filter was used for extracting speech envelope after applying Hilbert transform. Auditory attention decoder was trained using linear regression method and was validated by leave-one-out validation method. Attended sound stream was selected based on the correlation between envelope of reconstructed speech and that of the original speech. First, we tried to build a subject-specific attention decoder with EEG recordings of all channels. However, most of the trained decoder shows lower performance on auditory attention decoding (mean accuracy of attended decoder: 54.4%, mean accuracy of unattended decoder: 51.4%, 5% of significance level: 67.9%). To increase the accuracy of the trained decoder, we tried forward feature selection method which incrementally searches the feature space and adds effective channels that could give better performance. As a result, we were able to successfully decode auditory attention of each subject (mean best accuracy of attended and unattended decoder: 86.3%). Also, for attended decoder model, channels around temporal region are mostly selected, which could reflect the auditory processing of current auditory attention task. In summary, we have shown that auditory attention can be successfully decoded with neural signals from selected EEG channels. In the future, we are going to try building single decoder model that could be generally applied to different participants without user specific optimization process and also try real-time decoding for applications such as human-robot interaction and hearing aid technology.

Abstract: Frequency modulated (FM) signals are building blocks of complex sounds including those present in vocalization. The auditory cortex (AC) and midbrain inferior colliculus (IC) are two key neural centers for FM coding and they are known to be plastic during the early postnatal period, with some response characteristics shaped by acoustic experiences. Whether or not, and how FM sensitivities are specifically altered at the AC and IC by the acoustic experience remains unclear. The aim of this study is to study and compare the effects of neonatal sound exposure on the neural responses to FM stimuli recorded at the AC and IC later in adulthood. Young pups were randomly divided into two groups: control and experimental. The experimental group received a month-long tone exposure (4 kHz, 65 dB SPL) starting right after birth. The control group was raised in the same environment but without tone exposure. At postnatal week-10, the rat was urethane-anesthetized, and the 2 electrodes were acutely placed on the left AC and a depth electrode into the ipsilateral IC to record simultaneously FM-evoked potentials (EPs). The stimuli were exponential frequency sweeps with 4 different durations. EPs were processed in the spatiotemporal domain to detect FM-related changes within the gamma-band frequency range. In control, FM stimuli produced a rather strong gamma-band response at both the AC and IC: first to the onset of the stimulus and then over certain parts during the time-course of modulation. Gamma activity was time-locked to the low-frequency region of the modulation envelope (250-800Hz). In experimental, gamma-activities showed basically little time-locked response to the same low FM frequency region. But, an unexpected strong gamma response emerged around

300-350 Hz. In addition, this new gamma band activity occurred throughout the entire time-course of the FM sweep. Such gamma band response that was present at both AC and IC, appeared stronger and more robust at the IC. Results showed that long-term neonatal sound exposure had altered FM sensitivities at both the AC and IC, but not in the same fashion. The new 300-350 Hz gamma band response to FM sweeps, reflecting the complex neural plasticity induced by the acoustic experience, was found here for the first time.

Title: Reliable envelope coding from unreliable single neurons

Authors: *K. B. PENIKIS, D. H. SANES;
Ctr. for Neural Sci., NYU, New York, NY

Abstract: While natural acoustic signals, including speech and music, often contain rhythmic elements, the amplitude modulations (AM) composing them are temporally irregular. However, our understanding of AM coding is largely based on periodic stimuli, with responses typically measured from activity averaged over many iterations of each period. Since auditory response properties are sensitive to stimulus history and vary from trial-to-trial, we first asked how temporal regularity impacts coding by individual neurons. Single unit recordings were obtained wirelessly from gerbil auditory cortex (NeuroNexus 16 and 64 channel arrays) as gerbils performed an aversive Go-Nogo detection task in which all modulated stimuli were safe (signaling the availability of a water reward), while unmodulated noise served as the warn signal that predicted a brief electrical shock. Modulated stimuli were either periodically sinusoidally modulated at rates of 2-32 Hz, or aperiodically modulated (i.e., quasi-random sequences of individual periods drawn from the same set of rates). In addition, we characterized responses to vocoded speech stimuli. We found that responses of individual neurons to a given AM period could be modulated by stimulus history, but high trial-to-trial variability led to low discriminability across stimulus history contexts. High response variability raises the question of how neurons can provide a robust representation of the envelope of a complex signal in real time. Our recordings suggest that cortical responses tile the complex envelope. Therefore, our

current analyses focus on assessment of how larger pools of units enhance the representation of irregular AM sequences, including vocoded speech.

Abstract: Sound stimuli are encoded by populations of neurons in the primary auditory cortex (A1). Sound information arrives at its input layer 4 from where activity propagates to associative layer 2/3. Given the hierarchical structure of A1, the encoding of sound information is thought to be transformed between layers, but the nature of this transformation is unclear. Since stimulus information is represented in populations of neurons, we investigated the spatiotemporal organization of neuronal population activity across layers. Mice on the C57BL/6 background are commonly used to study cortical processing, yet these mice develop high frequency hearing loss with age making them a less optimal choice for auditory research. In contrast, mice on the CBA background retain better hearing sensitivity in old age. Therefore, we performed comparative analysis of neuronal populations from both adult (~10 weeks) C57BL/6 mice and CBA mice. We used *in vivo* 2-photon imaging of pyramidal neurons in cortical layers L4 and L2/3 of awake mouse A1 to characterize the populations of neurons that were active both during tonal stimuli and in the absence of any stimulus. Pure tones recruited neurons of widely ranging frequency selectivity in both layers and strains, with CBA mice exhibiting a higher proportion of selectively tuned neurons. We next characterized the spatiotemporal population activity via neuronal ensembles, defined as neurons being active within or during successive temporal windows at the temporal resolution of our imaging sampling rate. For both layers neuronal ensembles were highly variable in size during both spontaneous activity and during sound presentation. Ensemble sizes distributed according to power laws, the hallmark of neuronal avalanches, and were similar across sound levels. Avalanches evoked by sound were composed

of neurons with diverse tuning preference, yet with selectivity independent of avalanche size. Spontaneous and evoked activity in both L4 and L2/3 of A1 in both strains of mice are composed of neuronal avalanches with similar power law relationships. To further probe the temporal correlations at the population level seen in neuronal ensembles, we utilized functional connectivity measures to quantify network structure in both layers and strains. Our results demonstrate that single cell and ensemble activity is largely similar in A1 of adult C57BL/6 and CBA mice with CBA mice showing more sound-level sensitivity in responses. Moreover, our work shows that these neuronal ensembles exhibit network principles linked to maximal dynamic range, optimal information transfer and matching complexity between L4 and L2/3 to shape population activity in A1.

Title: Decision tree based phonetic selectivity using high density µECoG-recordings

Authors: *S. DURAIVEL[1], C.-H. CHIANG[1], K. BARTH[1], I. RACHINSKIY[1], M. HAGLUND[2], D. G. SOUTHWELL[3], S. SINHA[4], J. VIVENTI[1], G. B. COGAN[5];

Abstract: Previous work has demonstrated that the human auditory cortex encodes the spectrotemporal properties of phonetic information during speech perception. The cortical mapping of these phonetic features can be used to develop effective speech prosthesis using ECoG (Mesgarani et al. 2014), however the micro-scale spatial specificity of these features is unknown. Decision tree analysis is an underutilized and interpretable modeling technique that can characterize the spatial importance of electrodes for spectrotemporal and phonetic feature selectivity (Buitinck et al. 2013). We therefore sought to employ this method to elucidate the phonetic feature selectivity of human µECoG recordings. Firstly, to validate this technique, we use a decision tree model to predict neural responses to auditory tones in the rat auditory cortex, since the tonotopy is well established (Insanally et al. 2016). We recorded cortical signals from an anesthetized rat's auditory cortex using a 60 channel (406 um pitch) µECoG electrode array (Trumpis et al. 2017). We played 60 sets of randomly shuffled 13 tones ranging between 0.5 and

32 kHz during the recording session. The broadband neural response (2 – 100 Hz) was used to build a 5-fold cross-validated classification and regression tree (CART) model, and the decision weight of each electrode is interpreted as a selectivity metric in predicting a particular tone. Our preliminary results reveal an above chance decoding accuracy in tone prediction (63.8%; chance – 7.7%, ROC-AUC: 0.958 ± 0.015), and we observed spatial clustering of decision weights for each tone. We then recorded human cortical signals using a 244 channel (762 um pitch) high-density μECoG electrode array implanted on the superior temporal gyrus (STG) of a single patient undergoing treatment for pharmacologically resistant epilepsy during an anesthetized craniotomy. The subject was presented with a set of bisyllabic words and non-words. To build a CART model for phonetic feature prediction, we used high gamma power (70-150 Hz) as a predictor feature for each phonetic class. The decision weights of the electrodes were translated as the selectivity metrics for a particular cluster of phonetic features. Results demonstrated clustering of decision weights in the spatial domain for certain classes of phonetic features. These findings indicate that phonetic information is spatially selective at the micro-scale in human STG. Furthermore, this suggests that decision tree modeling is a useful technique to interpret the spectrotemporal selectivity of each channel and can be a reliable tool for cortical phonetic feature mapping specifically, and auditory processing in general.

Title: Effects of arousal on population coding of natural sounds in primary auditory cortex

Authors: *C. R. HELLER, D. SADERI, Z. P. SCHWARTZ, S. V. DAVID;
Oregon Hlth. and Sci. Univ., Portland, OR

Abstract: Behavioral state variables such as arousal, task-engagement, and attention have been shown to decrease shared variability, i.e., stimulus-independent, pairwise correlations between neurons, in primary sensory cortices. This change may reflect state-dependent processing that removes noise and enhances faithful sensory encoding. However, many questions remain regarding the origin of shared variability and how, or if, it impacts sensory encoding accuracy.

Here, we investigated the origin of shared cortical variability and its dependence on arousal state in the primary auditory cortex of awake, passively listening ferrets. The simultaneous activity of multiple single units was recorded during the presentation of natural sounds and arousal levels were monitored via pupillometry. We found that that arousal influences correlated variability on multiple, distinct timescales. Consistent with the time course of fluctuations in arousal itself, we observed strong covariation in spike rate from trial to trial, on the order of seconds. This result was expected, given previous work showing that arousal modulates the excitability of cortical neurons. At these slow timescales, we saw no change in the amount of shared variability between high and low arousal states. On timescales faster than one second, however, heightened levels of arousal suppressed shared variability. Notably, the degree of suppression for a given pair was not predicted by tuning similarity. Given previous theoretical work showing that shared variability impairs sensory encoding only when present in co-tuned neurons, our results suggest that arousal dependent reductions in shared variability do not necessarily improve sensory encoding. To test this prediction, ongoing experiments are comparing decoding accuracy of neural populations recorded during high and low arousal states.

Title: Differential roles of somatostatin and parvalbumin-positive interneurons in contrast gain control

Authors: *C. F. ANGELONI, X. DING, M. N. GEFFEN;
Univ. of Pennsylvania, Philadelphia, PA

Abstract: Sensory systems are composed of neurons with limited dynamic range, but are required to accurately represent a world in which the dynamic range of incoming stimuli can vary wildly. To efficiently encode environments with different dynamic ranges (referred to here

as contrast), sensory neurons adapt the gain of their response function to effectively match their dynamic range to that of the environment. However, it is not known how this gain control arises in the auditory system. Prior work in the visual system shows that modulating inhibitory synaptic currents can induce changes in gain. Here, we expand on this previous work using a multi-compartment circuit model which simulates populations of somatostatin-positive (SOM) and parvalbumin-positive (PV) interneurons, and their synapses onto the dendrites and somas, respectively, of a population of pyramidal neurons. When increasing either SOM or PV inhibition in the model, we observe that gain-like changes occur primarily when modulating SOM neurons, while an overall subtractive effect is observed when modulating PVs. We then validate our model experimentally, by optogenetically activating these two interneuron populations in the auditory cortex of awake mice as they listen to acoustic stimuli of varying contrast. We found that SOMs have a larger effect on the gain of neural responses, while PVs have a smaller effect on gain, and exhibit subtractive inhibition, in agreement with our model predictions. These findings suggest that inhibitory neurons control the sensitivity of cortical neurons in a predictable manner. Our results lay the groundwork for further exploration of the role of circuits in auditory cortex in regulating psycho-acoustical behaviors.

Title: Characterizing the nonlinear encoding of speech in the human auditory cortex

Authors: *M. KESHISHIAN[1,2], H. AKBARI[1,2], B. KHALIGHINEJAD[1,2], J. L. HERRERO[3], A. D. MEHTA[4], N. MESGARANI[1,2];

Abstract: There is a growing interest in characterizing the response properties of sensory neurons under natural stimulus conditions. The majority of previous studies have used linear models to relate the acoustic features of sound to neural responses. Linear models, however, cannot capture the inherent non-linearity of the processes in the brain. Recent advancements in machine learning and computational power have allowed us to utilize deep learning methods in a large variety of tasks. We investigate the utility of deep neural network models to predict neural

responses to speech in human auditory cortex, with the goal of analyzing the learned networks to gain insight into the nonlinear mechanisms of the brain. The neural responses were recorded from the transverse and the superior temporal gyrus of five patients undergoing surgery for the treatment of epilepsy, as they listened to continuous speech. As deep neural networks (DNNs) have shown great promise in capturing non-linear relationships, we trained a convolutional neural network (CNN) with a non-linearity in each layer using the time-frequency representation of the stimulus as the input and the envelope of the high-gamma activity of the neural responses as the output of the model, to study the effect of artificial neural networks.
In comparison to the STRFs, the predicted responses from the neural networks had a higher correlation with the original responses. On average, using CNNs improved performance by 25%. To interpret the nonlinear function that the network applies to the stimulus, we analyze the linear equivalent of the function, at each time point. As a result, we observe three general classes of nonlinear behavior implemented by the network: gain change, feature memory, and shape diversity. The feature memory or "hold" can be interpreted as the network holding on to a response captured by the STRF. Finally, we quantify these properties for all electrodes and try to explain the prediction improvement gained from using the CNN model, through these simple parameters. Furthermore, we studied the relation between these parameters and the electrodes' anatomical locations and other encoding properties.

Title: Multi voxel pattern analysis of auditory oddball as a tool for investigating locus coeruleus modulation of perceptual circuits

Authors: *K. C. YAGHOUBI[1], M. ALIZADEH SHALCHY[1], X. CHEN[2], J. LANGLEY[2], I. J. BENNETT[1], X. P. HU[3], A. R. SEITZ[1], M. A. K. PETERS[3];

Abstract: The locus coeruleus noradrenergic (LC-NE) system is implicated in many cognitive processes including perception, attention, and decision making. In this study, we aimed to develop and optimize an empirical approach for investigating the relationship among LC activity, neural representations of sensory stimuli, and perceptual performance in humans using multivariate fMRI. We focused on auditory perception, selecting the primary auditory cortex

(A1) as a target region of interest and developing a novel psychometric auditory oddball paradigm; we then evaluated the sensitivity of this paradigm and our computational neuroimaging approach for characterizing the role of the LC-NE circuit in auditory perception. Compared to the standard oddball paradigm that consists of a frequent stimulus and one type of oddball stimulus, our paradigm consists of six different auditory oddball stimuli (1004 Hz - 1128Hz) to facilitate estimation of signal-response functions in behavior and in auditory cortical representations. The resulting psychometric function revealed a fine characterization of behavioral performance. We next used a multi-voxel pattern analysis (MVPA) approach (sparse logistic regression classification) to examine decodability of our psychometric oddball versus frequent stimuli in A1. We showed that we can successfully decode distinct oddball versus frequent neural representations in this area, demonstrating the sensitivity and appropriateness of our behavioral and analytic approach as a tool for characterizing the influence of LC activity on behavioral performance via modulation of neural representations.

Title: Vivarium and laboratory noise, ultrasonic noise, and vibration as unrecognized experimental confounds in neuroscience research

Authors: *J. G. TURNER[1,2];
[1]Illinois Col., Jacksonville, IL; [2]Turner Scientific, Jacksonville, IL

Abstract: Neuroscience research using laboratory animals is purportedly conducted in highly controlled housing and testing environments. The intention of such control is to limit sources of confounding variability that might negatively impact the research animals themselves or interfere with the tests being conducted. We report here on the noise, ultrasonic noise, and vibration levels sampled from a wide variety of research animal vivarium and laboratory spaces (both between institutions and from room-to-room within an institution) in order to help investigators appreciate the role that such noise and vibration might have on introducing confounding variability into their neuroscience research. We also suggest mechanisms for controlling or minimizing the impact of such noise and vibration.

Title: Mismatch responses at the scalp and primary auditory cortex of the rhesus macaque: Mismatch negativity, mismatch positivity, stimulus specific adaptation and deviance detection

Authors: *T. TEICHERT;
Psychiatry and Bioengineering, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Background. Mismatch negativity (MMN) has provided important insights into normal brain function. It is also a sensitive and selective marker of altered brain function in schizophrenia. Rhesus macaques are the most established animal model of MMN, and have provided groundbreaking insights into the circuits and pharmacology of MMN. However, several findings have questioned the homology and utility of MMN in the monkey. (1) Recent studies have shown short-latency mismatch responses (MMRs) in humans at latencies around 40 ms after tone onset. MMRs with similarly short latencies have not been identified in monkey EEG. (2) It is unclear whether MMRs in the monkey comprises of two distinct sub-components, stimulus specific adaptation and deviance detection, as is the case in the human. (3) Despite the possibility to record MMRs at the level of EEG and in auditory cortex, MMRs have not been measured in the same animals using both (i) high-density EEG montages and (ii) intracranial depth recordings in auditory cortex. This has limited our understanding of how macroscopic signals that can be readily observed in the human inform our understanding of the microscopic events in auditory cortex that can only be measured in animal models. Methods. To address these questions we recorded MMRs in four rhesus macaques using 32 channel cranial EEG while the animals passively listened to a modified roving standard paradigm. In a subset of two animals, we also recorded MMRs in primary auditory cortex using 24 and 32 channel laminar depth electrodes. Results. We found mismatch responses at the level of EEG in all four animals. A fronto-central mismatch positivity lasted from 20 ms to 60 ms after stimulus onset. A subsequent fronto-central mismatch negativity was observed between 65 and 110 ms after onset. Using the many-standards control condition, we identify both stimulus specific adaptation and deviance detection. Stimulus-specific adaptation emerged earlier and peaked around 30 ms after onset; deviance detection emerged later and peaked around 55 ms after onset. Laminar recordings in A1 confirmed stimulus-specific adaptation and deviance detection at the level of neural firing and post-synaptic potentials. Deviance detection was present in the first wave of cortical activity (20-

45 ms), but was most pronounced in a later period from 70 to 125 ms. This is the first report of mismatch positivity and deviance detection in this species.

Title: Laminar origin of evoked ECoG high-gamma activity

Authors: *M. DOUGHERTY[1], A. P. Q. NGUYEN[2], V. BARATHAM[3,1], K. E. BOUCHARD[1]; [1]Biol. Systems & Engin., Lawrence Berkeley Natl. Lab., Berkeley, CA; [2]Dept. of Mathematics, Univ. of Iowa, Iowa City, IA; [3]UC Berkeley, Berkeley, CA

Abstract: The high spatiotemporal resolution and broad coverage of electro-corticography (ECoG) makes it a critical methodology for basic human neuroscience and shows promise for brain machine interfaces. The High-gamma (Hγ) component of cortical surface electrical potentials (CSEPs) from ECoG is a commonly used signal for understanding the human brain, but its interpretation is impeded by a lack of spatial localization. To address this, we develop a novel recording setup combining a micro-ECoG (μECoG) array with laminar polytrodes to record both CSEPs and laminar multi-unit activity (MUA) in rats. Recordings were collected from the auditory cortex of four anesthetized female rats presented with forty millisecond tone-pips of varying frequency and amplitude. These stimuli were used to simultaneously estimate the tuning properties of the cortical surface and each lamina within a cortical column. We demonstrate that stimulus evoked CSEPs carry a multi-modal frequency response, peaking in the Hγ range. Laminar MUA responses exhibited similar tuning to CSEP Hγ directly over the intracortical recording site, suggesting a functional relationship. We fit CSEP Hγ to the simultaneously-recorded laminar MUA using a state-of-the-art sparse multi-linear regression model, UoI_{Lasso} to identify laminar contributions to cortical surface Hγ. Our results indicate that CSEP Hγ recorded by ECoG reflects spiking activity from neurons in layer 3. These results provide initial insight into localizing the sources of CSEPs, which will guide clinical and BMI device decisions.

Title: Evoking potentials without events: Intrinsic response identification in neural recordings using higher-order spectra

Authors: *C. K. KOVACH, K. V. NOURSKI, P. E. GANDER, H. OYA, H. KAWASAKI, M. A. HOWARD, III;
Neurosurg., Univ. of Iowa Hosp. and Clinics, Iowa City, IA

Abstract: In contrast to micro-scale unit recordings, field potential data typically lack any obvious, well-defined and discrete neural response, akin to the action potential. The absence of such an event-like response makes it relatively difficult to apply and interpret the kinds of reverse-correlation analyses that have been crucial for revealing receptive fields in unit recordings. Instead, conventional analyses of field potentials have been limited to asking, "what kind of response, if any, follows a given event" rather than "what kind of stimulus, if any, evokes a given response?" Here we demonstrate how this limitation may be overcome with a novel decomposition of the bispectrum (Kovach and Howard, 2019). This technique allows a non-Gaussian time series to be explained by the emission of one or more transient waveforms at discrete times. It yields the respective waveforms, times at which the waveforms are emitted, and reconstructed component signals explained by the emitting processes.
We applied the technique to human intracranial data from 59 epilepsy patients, demonstrating its ability to blindly identify the form and timing of auditory event-related potential (ERP) waveforms recorded from Heschl's gyrus with no prior information about the stimulus. Stimuli were repeated acoustic transients (50 Hz click trains) presented at regular intervals. Averaged responses in posteromedial Heschl's gyrus were generated by the post-stimulus emission of the ERP waveform. In contrast, those in anterolateral Heschl's arose predominantly through the transient suppression of waveforms from the background signal, resulting in a negative image of the suppressed waveform within ensemble averages. The latter finding was confirmed in two separate ways: (1) by the inversion of the generating waveform in the average, and (2) by a transient decrease in average power coincident with the averaged waveform. Thus, the bispectrum decomposition approach enabled us to identify a novel mechanism of auditory ERP generation. We consider implications of these findings for the interpretation of averaged evoked responses and their relationship to background activity. In particular, we examine the potential

for the newly identified contribution of waveform suppression in the average to be mischaracterized as phase resetting under conventional techniques of phase analysis.

Title: Neurons in auditory cortex integrate statistical regularities on different time scales

Authors: *L. GARAMI[1], C. F. ANGELONI[2], X. DING[1], M. N. GEFFEN[1];
[2]Dept. of Psychology, [1]Univ. of Pennsylvania, Philadelphia, PA

Abstract: Auditory objects are often detected through regularities in their acoustical structure. Depending on the complexity, these regularities emerge at various timescales. Our goal is to identify the neuronal circuitry in auditory cortex (AC) that enables the auditory system to detect temporal patterns in sounds with different complexities. On a large scale, human data shows that in both the AC and the pre-frontal brain regions differential brain activity correlates with the predictability (random vs regular) of auditory stimuli. On a smaller scale, responses of individual neurons in AC exhibit sensitivity to temporal regularities in sounds: neurons exhibit stimulus-specific adaptation, a reduction in their response selective to frequently presented inputs. This adaptation may underlie the population sensitivity to more complex spectro-temporal acoustic

regularities, and the rapid perception of such regularities. Here, we adapted a human change-detection paradigm used to test sensitivity to transitions between regular and random acoustic stimuli to test whether and how neurons in mouse AC encode predictable temporal structure. We presented chord pairs and either repeated them (predictable scenes) or distributed them randomly (random scenes). Each trial had a transition, ie. consisted of two scenes picked randomly, while single and multi-unit activity was recorded in AC. Neurons exhibited stimulus-specific adaptation to the spectral content of the chords, as expected. However, this adaptation was enhanced in the regular scenes, indicating that the adaptation on the single neuron level in the auditory cortex can evolve at multiple time scales. In line with the human data, this enhanced adaptation was present as soon as from the second chord pair repetition in regular scenes. The predictability of the preceding scene had a differential effect on firing rate in the first half of the new scene. These results show that while environmental predictability is encoded in AC, the integration time window might be limited at this level, removing information about previous acoustical contexts relatively rapidly as new stimulus statistics are presented.

Title: Role of interneurons in populations' neural coding in auditory cortex

Authors: *M. TOBIN, K. WOOD, X. DING, M. N. GEFFEN;
Dept. of Otolaryngology, Univ. of Pennsylvania, Philadelphia, PA

Abstract: Cortical neuronal networks are comprised of multiple types of excitatory and inhibitory neurons, which perform specific computations. In the auditory cortex (AC), excitatory neurons receive the sound input and transmit the processed signal to other areas, whereas the inhibitory neurons dynamically help shape the response of the excitatory neurons. In the last decade, we have learned specific functions of distinct inhibitory neurons, yet how different interneuron subpopulations affect network dynamics remains unexplored. To establish the role of

different interneuron subpopulations within the cortical network, we stimulated specific interneuron subpopulations, while imaging the network responses to sounds in the AC. We monitored the activity of populations of hundreds of neurons using two-photon calcium imaging and simultaneously increased the activity of a subpopulation of interneurons using optogenetic stimulation. We focused on VIP and SOM inhibitory neurons, which have previously been found to shape cortical responses in a context-dependent fashion (Natan et al, 2015; Pi et al, 2013). Response of neurons activated by sound were enhanced when VIPs were activated, but reduced upon activation of SOMs. The population of cells increasing their activity in response to sound is distinct from the VIP interneuron population, but includes a subset of SOM interneurons. Finally, we observed that sound stimulation reduced the activity of VIP interneurons and increased the activity of SOM interneurons. We conclude that the activation of VIP or SOM interneurons leads to opposite effects on the response of the neural network to sounds in AC.

Title: Reorganization of cortical population neuronal activity following differential auditory fear conditioning

Authors: *K. WOOD[1], R. BETZEL[3], D. S. BASSETT[2], M. N. GEFFEN[1];
[2]Dept. of Bioengineering, [1]Univ. of Pennsylvania, Philadelphia, PA; [3]Dept. of Psychological and Brain Sci., Indiana Univ., Bloomington, IN

Abstract: Auditory perception relies on learning-driven neuronal plasticity within the auditory pathway. Here, we investigated how associative learning, differential auditory fear conditioning (DAFC), affects neuronal population responses to sounds in auditory cortex (AC). In DAFC, the subject is presented with two different frequency tones, one of which is paired with a foot-shock.

Previously, we found that AC is required for expression of DAFC-driven changes in sound-frequency discrimination acuity (Aizenberg and Geffen, 2013) and that modulating inhibitory neuronal activity in AC leads to similar bi-directional changes in discrimination acuity (Aizenberg, 2015). However, how DAFC affects tone-evoked population neuronal activity remained unknown. We hypothesized that DAFC would drive changes in population tone-evoked neuronal activity corresponding to either and increase or a decrease in neurometric frequency discrimination acuity, as a function of fear learning specificity.To understand the transformation of sound representation in AC before and after DAFC we imaged calcium activity in hundreds of neurons simultaneously in AC of awake, head-fixed mice, tracking the same neurons over days under a two-photon microscope before and after two DAFC sessions. We quantified changes in frequency-dependent responses of individual neurons, as well as in population functional connectivity using network analysis. DAFC drove heterogeneous changes in individual neuronal responses for either shock-paired or unpaired tone frequencies. We used population Fisher Information to calculate the discriminability between the conditioned and control stimulus using frequency tuning curves before and after fear conditioning. We found that discriminability before fear conditioning predicted how well the mouse would learn to discriminate after fear conditioning. Neural discriminability after fear conditioning only showed a weak correlation with behavioral discriminability. Neuronal populations formed clusters driven by correlated activity. The neuronal cluster structure changed between days in the absence of DAFC, but the network structure became more consistent over days following DAFC. These findings suggest that DAFC drives cortical population activity into more stable states.

Title: Transformation of sound representations between inferior colliculus and auditory cortex

Authors: *J. BOURG[1], A. KEMPF[1], T. TARPIN[3], B. BATHELLIER[2];
[1]UNIC, CNRS, Gif-sur-Yvette, France; [2]UNIC, CNRS, Gif sur Yvette, France; [3]ENS, Paris, France

Abstract: The auditory system, as other sensory systems, is thought to be hierarchically organized encoding increasingly complex features from peripheral to more central stages. Yet the precise transformations of auditory representations across stages of the most central auditory system are not fully characterized. To start addressing this question in a systematic manner, we used two-photon calcium imaging in awake mice to extensively record auditory responses in the auditory cortex (AC, at depths ranging from 0-600 μm) and the superficial layers of the inferior colliculus (IC, 0-200 μm). To capture both spectral and temporal aspects in auditory coding, we used a wide range of laboratory sounds including pure tones, chords, intensity ramps, amplitude modulated sounds and various frequency chirps. We thereby collected a dataset of 59590 neurons (7 mice, 60 sessions) in the AC, fully sampling the horizontal extent of AC, as assessed with global tonotopic mapping. We also obtained activity from 15311 neurons in the IC (31 mice,101 sessions).
Using model-free clustering to organize this rich dataset, we observed at both levels of the auditory system a large number of complex sound response types, combining specificity for frequency, intensity and their temporal variations. However, particular coding features are markedly enhanced in AC, with the most evident difference appearing in the coding of intensity variations (e.g. onset and offset). While in IC neurons either rapidly reach a response plateau or monotonically increase their response with intensity, in AC it is possible to identify three large neuronal populations non-monotonically tuned to different levels of intensity variations (typically 60,70, 80dB). This tuning allows constructing a rich and divergent representations of the sound envelope, a crucial parameter in sound recognition. In addition, we observe that the two opposite directions of sound frequency modulations (up or down) are represented by less correlated population activity patterns in AC than in IC.
Together these results point towards the progressive emergence of a coding scheme in auditory cortex which captures different temporal features of the sounds into distinct neuronal activity patterns, possibly contributing to perceptual segregation of these features.

Title: Antibodies against lysophosphatidic acid protected against blast-induced ocular dysfunctions

Authors: *P. ARUN[1], A. BATUURE[1], F. ROSSETTI[1], D. WILDER[1], J. DEMAR[1], Y. WANG[1], I. GIST[1], A. MORRIS[2], R. SABBADINI[3], J. LONG[1];
[1]Blast-Induced Neurotrauma, Walter Reed Army Inst. of Res., Silver Spring, MD; [2]Col. of Med., Univ. of Kentucky, Lexington, KY; [3]Dept. of Biol., San Diego State Univ., San Diego, CA

Abstract: Exposure to blast waves has been implicated as the major cause of ocular injuries and resultant visual dysfunctions in veterans involved in recent combat operations. Between 2006 and 2009, 43% of veterans with blast-induced traumatic brain injury (TBI) also had significant closed-eye injuries. While improvised explosive devices have greatly increased the incidence of ocular injuries, no effective countermeasure has been developed thus far. Lysophosphatidic acid (LPA) is a bioactive lysophospholipid released from activated platelets, astrocytes, choroidal plexus cells and microglia and is reported to play major roles in activating inflammatory processes. Acute increase in LPA levels was observed in the cerebrospinal fluid (CSF) of patients after TBI and use of monoclonal antibodies against LPA has been found to be protective against TBI and neuropathic pain in animal models. Since in preliminary studies we observed acute increases in LPA levels in the CSF and plasma of rats after a single blast exposure, we have evaluated the efficacy of anti-LPA monoclonal antibodies for protection against blast-induced ocular injuries. Anesthetized rats were exposed to single blast (19 psi peak total pressure, 4-5 msec duration) using an advanced blast simulator. A single intravenous injection of anti-LPA antibodies (25 mg/kg) was given to rats at 1 hr after blast exposure and ocular functions and retinal pathology were evaluated at different intervals. Visual acuity tests by optokinetics were carried out post-blast on days 2 & 6, electroretinography (ERG) was conducted on days 3 & 7 and retinal pathological evaluations were performed on tissue collected on day 8. H&E staining revealed significant protection against neuronal cell deformation in the retinal photoreceptor and outer nuclear layers after treatment. Immunohistochemical evaluations indicated that the antibody treatment decreased the presence of both activated astrocytes and microglia in the retina. Antibody treatment also significantly improved visual acuity in both eyes on days 2 & 6 post-blast. ERG, as a measure of retinal signaling response to light, showed significant improvements in both A & B waveform amplitudes of the left eyes and B wave of the right eyes on day 7. Our data reveals that LPA plays an important role in ocular injuries following blast and that early intervention with anti-LPA antibodies can provide significant protection against damages to the retina.

Title: The role of microRNA-150 in the pathogenesis of diabetic retinopathy

Authors: *F. YU[1], S. CHAPMAN[2], M. L. KO[2], G. Y.-P. KO[3];
[1]Vet. Integrative Biosci., [3]Vet Integrative Biosci., [2]Texas A&M Univ., College Station, TX

Abstract: Diabetic retinopathy (DR) is a leading cause of vision impairment in the US. Retinal photoreceptors are suggested to have an important role in the pathogenesis of DR in recent studies, but it is not clear as to how photoreceptors contribute to DR under diabetic insults. MicroRNAs (miRs) represent a set of regulators that impact metabolism, angiogenesis, and inflammation and may link to the development of DR. Among them, decreased miR-150 is observed in diabetic patients. MiR-150 is a powerful regulator of inflammation and angiogenesis. Retinal miR-150 is decreased in eyes with ischemic insults. However, it is not known whether retinal miR-150 plays a role in the pathogenesis of DR. We used 661W cells (a mouse photoreceptor cell line) and miR-150 null (miR-150 KO) mice to test our hypothesis that decreased miR-150 in the retina contributes to obesity-induced type 2 DR. We found that 661W cells treated with palmitic acid (100 μM) had decreased miR-150 by qPCR and increased phosphorylated NFκB (pNFκB) and ERK (pERK) using Western blots. Compared to mice fed with a normal chow, mice fed with a high-fat-diet (HFD) for 3 months developed hyperglycemia, insulin-resistance and glucose-intolerance, and had significantly decreased miR-150 in the serum and retina. Using electroretinogram (ERG) recordings, the miR-150 KO mice under HFD for 1 month showed dampened retinal light responses compared to the WT mice. After six months of HFD, the retinas of miR-150 KO mice had a higher level of pNFκB and pERK (immunofluorescent staining) compared to the WT mice fed with a HFD. After 6-7 months of HFD, we observed degenerated retinal micro-vessels in both WT and miR-150KO mice. Our results indicate that decreased miR-150 in the early diabetic retina aggravates inflammation, which may further exacerbate the pathogenesis of DR.

Title: A retinal photoreceptor distribution model based on an algorithm of the Voronoi diagram

Authors: *K. MIYATAKE, T. KOHAMA;
Kindai Univ., Kinokawa-Shi, Japan

Abstract: Recently, simulation studies on human visual information processing using mathematical models have been actively conducted. When simulating visual perception using mathematical models, a simple image information is often used as the input. As the visual information captured by the photoreceptors is processed in the retinal neuron network composed of horizontal, bipolar, amacrine, and ganglion cells, the output from the retina differs from the input image data. To elucidate the mechanism of visual perception using a mathematical model of the visual system, the outputs of the retinal neuron network should be reproduced as the inputs in the model. A more realistic model of retinal neural mechanism has been developed using a honeycomb model of photoreceptor distribution fabricated using an algorithm of the Voronoi diagram (Kubo & Kohama 2018). However, this model limited the distribution of photoreceptors in the central fovea, which is a narrow region containing only cones. Since the characteristics of retinal response are different in the foveal and peripheral visual fields, the Kubo & Kohama model could not be used for the simulation of large visual angles. In this study, we proposed a wide-scale photoreceptor model that reproduces the distribution of the cone and rod cells as a function of retinal eccentricity to simulate the behavior of the visual nervous system to natural scenes. The cone and rod cells differ in density and size depending on the retinal eccentricity. The cone cells are dense and small around the fovea and coarse and large in the peripheral retina. The rod cells have a remarkably low density around the fovea and high density in the peripheral retina. The cone cell density was calculated using a modified Deering model (Kubo et al. 2016), and the size was approximated using a two-dimensional Gaussian distribution as a function of retinal eccentricity. The result of the simulation was consistent with the anatomical evidence of the retina. This indicated that the proposed model could reproduce the visual information received by the retina.

Title: Crx is posttranscriptional regulated by daylight stimulation in postnatal rat retinal neurocytes

Authors: *J. ZHUANG, K. YU, Y. WU, J. QIU, Z. LAI, S. CHEN, M. TANG;
Zhongshan Ophthalmic Center, Sun Yat-Sen Univ., Guangzhou, China

Abstract: Purpose: Crx plays a key role in the center of regulatory network in retina. Abnormal expression induces retinal disorders. This study focuses on elucidation the underlying mechanism of Crx expression in retina neurocytes with light stimulation.
Method: Primary rat retinal neurocytes from postnatal 1day SD rats were incubated in darkness (D-D) or 12 hours daylight and 12 hours darkness cycle (L-D). The level of mRNA and protein of Crx and its downstream genes in retina neurocytes was assayed by qPCR and Western blot. The inducibility of Crx promoter is measured by transfecting a construct with rat Crx promoter luciferase reporter assay. The expressing of exogenous Crx is assayed by transfecting pcDNA3.1-Crx plasmid. The results are confirmed in 15 days and adult SD rats. The data shown are representative of three independent experiments. Statistical significance was analyzed by the Student's t-test.
Result: The mRNA of Crx keeps stable in retinal neurocytes cultured in daylight or darkness (Light (L), 1; Dark (D), 0.863±0.101; P>0.05). However, Crx protein is increased in neurocytes cultured in darkness compared with the control (daylight) by 2.85-fold (**P<0.01). Moreover, Crx protein shows a light intensity-related decrease in retinal neurocytes (Dark, 1; 200luc, 0.742±0.231; 400luc, 0.648±0.104; 600luc, 0.574±0.0.152; 800luc, 0.538±0.0.042; ** p<0.01), without mRNA changed. Downstream genes of Crx, Arrestin and Rhodopsin, are increased in retinal neurocytes cultured in darkness, compared with that cultured in daylight too. The inducibility assay of Crx promoter doesn't change in retinal neurocytes cultured in daylight or darkness (L, 1; D, 1.044±0.227; P>0.1). Thus, posttranscriptional regulatory mechanism might be involved in Crx expression in retinal neurocytes due to light stimulation. However, the expressing level of exogenous Crx in primary retinal neurocytes cultured in daylight or darkness is not changed (L, pcDNA3.1-Crx, 1.433 ± 0.360; D, pcDNA3.1-Crx, 1.569±0.221. P>0.1), which indicates that the posttranscriptional regulatory mechanism might be specific to endogenous Crx gene. Consistent with the results in vitro, mRNA of Crx is not changed, protein

is increased in P15 rat retina in covered eyes (L, 0.439±0.242; D, 0.990±0.129, **P<0.01). However, the Crx mRNA and protein is not affected in adult rat retina by light stimulation. Thus, this mechanism might be involved in immature retina.
Conclusion: This study not only provides new insights into the mechanism of Crx expression in retina. Moreover, daylight condition should be taken into consideration in the strategy of retinal experiment of in vitro.

Title: Adenosine reduces photoreceptor damage in a zebrafish light-induced damage model of age-related macular degeneration

Authors: *A. KHAN, S. L. STELLA, Jr.;
Neural and Behavioral Sci., Penn State Univ. Col. of Med., Hershey, PA

Abstract: Purpose: Adenosine has been shown to be neuroprotective in the CNS and in retinal ganglion cells in the inner retina. However, the neuroprotective effects of adenosine on outer retinal neurons, in particular photoreceptors, is not known. Age-related macular degeneration (AMD) is a multifactorial disease characterized by the impairment or loss of central vision due to macular dropout and loss of photoreceptors. Adenosine has been shown to inhibit photoreceptor excitability by suppressing Ca^{2+} influx through voltage-gated Ca^{2+} channels, which could lead to cell death. The purpose of this study was to see if adenosine would reduce photoreceptor damage in a light-induced retinal degeneration (LIRD) model in pigmented zebrafish.
Methods: Adult wild-type and *Tg(NeuroD:GFP)* zebrafish (used to GFP label rod photoreceptors) were dark-adapted for 24 hours, followed by intravitreal injections of ~ 0.5 µl (1.67 to 167 µM) of adenosine in both eyes. Controls were injected with saline in both eyes. All zebrafish were exposed to full spectrum high intensity light (8000 lumens) for four days and collected at 0 and 96 hours post dark-adaptation. Immunohistochemical analysis was performed on vertical retinal sections in order to visualize cones, rods, and the outer nuclear layer of the retina. Retinal damage was assessed using confocal microscopy with a TUNEL assay and cell specific markers.
Results: Photoreceptors in control retinas collected at 96 hours exhibited severe truncation or

loss of the outer segments, and swelling of the cell body. Additionally, there was an increase in TUNEL positive cells and a significant decrease in rod and cone photoreceptors in the control retinas. In adenosine-treated retinas collected at 96 hours, photoreceptors exhibited less cell death, reduced truncation of the outer segments, lacked swelling, and had cell morphology similar to retinas collected prior to light exposure.
Conclusion: These findings show that adenosine can prevent light damage to the cell bodies and outer segments of rods and cones, and provide evidence of a potential novel therapeutic target for the treatment of the "dry" form of AMD.

Title: Melanopsin (Opn4) regulates retinal neuron diversity during fetal development

Authors: *S. DSOUZA, M.-T. NGUYEN, R. LANG;
Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH

Abstract: The atypical opsin, Melanopsin or Opn4, is expressed within retinal ganglion cells in the mammalian retina where it serves as an input for the circadian clock and regulates scheduled vascular regression of the hyaloid vessel. Although its roles in the adult retina have been well characterized, little is known about the mechanism by which Opn4 signaling functions to regulate the vascular status of the retina. Here, we show that Opn4 regulates retinal diversity as its loss evokes changes in the proportions of various neurons including amacrine cells, bipolar cells, and S-cones in the adult retina. These changes are evident as early as P8 (before eye opening in mice) and depend on gestational light, as dark rearing C57BL/6J mice leads to similar increases in amacrine cells. Additionally, Opn4 appears to drive retinal progenitor cell-fate decisions during development as evident from Ptf1a lineage tracing experiments at E16. These results highlight the importance of fetal light-responsive pathways in driving development and appropriate retinal architecture necessary for visual function.

Title: The GABAergic phenotype of horizontal cells in the mouse retina

Authors: *Z. URESTI, M. MIRANDA-ARANGO;
The Univ. of Texas At El Paso, El Paso, TX

Abstract: The inner nuclear layer of the mammalian retina contains the cell bodies of the amacrine, bipolar and horizontal neurons. About 90% of the amacrine neurons are glycinergic and GABAergic and marked by the expression of the vesicular inhibitory amino acid transporter, VIAAT. By contrast, the phenotype in horizontal inhibitory neurons vary among different mammals. In the primate retina, experimental evidence suggests the absence of VIAAT and GABA has been proposed to be released through the GABA transporters. On the other hand, in rodents, the horizontal cells express the VIAAT and carry out vesicle-dependent GABA release. Although the retina cells have been extensively studied, the precise inhibitory repertoire of horizontal cells is not yet fully elucidated. In this study, we provide additional evidence of the GABAergic phenotype of horizontal cells in the mouse retina by using transgenic technology. Immunostaining of retinal sections from a transgenic line that expresses EGFP under the GAD67 promoter suggest that adult horizontal cells are devoid of GAD67 but contain GAD65. In addition, analysis of sections from a mouse expressing ChR2-EYFP under the VIAAT promoter clearly label horizontal and amacrine cells. Undergoing work will better define a GABAergic character of mouse horizontal cells and contribute to the understanding the basic chemo-architecture of the rodent retina.

Title: Novel roles for encephalopsin (OPN3) within the mammalian central nervous system

Authors: *B. A. UPTON, G. NAYAK, K. ZHANG, R. A. LANG;
Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH

Abstract: Opsins are light-sensitive proteins used for the detection of coherent (i.e. vision-forming) and ambient light. Changes in ambient light occur with regular daily and seasonal patterns and can be used to predict changes in temperature, food and water availability, and as a synchronization cue for behavior, such as migration or reproduction. Atypical (i.e. non-visual) opsins are used to detect these changes in ambient lighting and despite expression in a variety of organ tissue, most mammalian studies have been limited to atypical opsin expression within the eye. Interestingly, opsin-mediated deep brain photoreception has been described in every non-mammalian class of the chordate phylum and there is evidence of atypical opsin expression in the brains of rodents and primates, including human, suggesting that opsin function within the central nervous system is a widespread and evolutionarily conserved process.
Encephalopsin (OPN3) is a highly conserved blue light-sensitive atypical opsin found in a variety of mammalian brain regions, including the cortex, striatum, cerebellum, and hypothalamus. In particular within the hypothalamus, OPN3 is expressed in the paraventricular nucleus, supraoptic nucleus, median preoptic nucleus, and subfornical organ. Despite its broad expression, no functions of OPN3 have been identified to date. Here, we examine the functions of OPN3 in the developing as well as adult mouse brains via gene analysis, behavioral assays, and hemodynamic monitoring. Together, these findings will provide new insight into how blue light and OPN3 shape the development and function of the central nervous system and provide direct evidence for mammalian deep brain photoreception.

Title: GABA release by intrinsically photosensitive retinal ganglion cells influences non-image forming vision

Authors: *T. SONODA, T. M. SCHMIDT;
Neurobio., Northwestern Univ., Evanston, IL

Abstract: Retinal ganglion cells (RGCs) are the output cells of the retina and innervate over 30 brain areas to influence a wide range of physiological processes. Current evidence points to RGCs executing these functions by primarily releasing the excitatory neurotransmitter glutamate with some RGCs also being able to co-release peptide transmitters. However, previous immunocytochemical and electrophysiological experiments have suggested the presence of GABAergic RGCs in multiple mammalian species including rodents and humans. The purpose of this study was to determine the identity and function of these putative GABAergic RGCs using a combination of mouse genetics, viral circuit tracing and optogenetics. Here, we report that a subpopulation of intrinsically photosensitive retinal ganglion cells (ipRGCs) that project to the suprachiasmatic nucleus (SCN), the intergeniculate leaflet (IGL) and the olivary pretectal nucleus (OPN) are GABAergic. Our preliminary data suggest that GABA release by ipRGCs function to dampen the sensitivity of non-image forming visual functions, especially at low light levels. These results identify a novel inhibitory circuit in the mouse visual system.

Title: Light regulates gut microbiome composition and rhythmicity through ipRGCs

Authors: *T. LU[1], C.-C. LEE[2];
[1]Natl. Taiwan Universiy, Taipei, Taiwan; [2]Dept. of Life Sci., Natl. Taiwan Univ., Taipei, Taiwan

Abstract: Environmental light dark cycle is an important external cue to modulate many physiological functions of animals including circadian photo-entrainment. Recent studies indicated that aberrant light dark cycle such as dim light at night affects or chronic jet lag can influence the gut microbiome and metabolic status or mice. However, how does light modulate the gut microbiota remain unclear. We collected fecal samples from WT and ipRGC eliminated mice housed under different light dark cycle, and compare the microbiota between different mice and light dark cycle using 16S rRNA Next Generation Sequencing. Our data suggests light influences gut microbiome composition, diversity and rhythmicity. Furthermore, intrinsically

photosensitive retinal ganglion cells (ipRGCs), a group of photoreceptors, act as key role to provide daily light dark cycle input for gut microbiome modulation. External light dark can regulate gut microbiome composition and rhythmicity through ipRGCs.

Title: Light modulates oxytocin release and sociosexual behavior in mice through ipRGCs

Authors: *J.-H. YU, P.-Y. LIAO, S.-K. CHEN;
Natl. Taiwan Univ., Taipei, Taiwan

Abstract: Over the past decades, oxytocin has been extensively studied for its complex role as a neurohormone that modulates wide aspects of social behavior and conventional physiological functions. In addition to its correlation with stress, how and whether environmental stimulation influence oxytocin release in the plasma and cerebrospinal fluid remain unclear. In the present study, we investigate if light stimuli could influence oxytocin and regulate the downstream sociosexual behavior with mice. We confirmed that a one-hour light pulse can reduce the concentration of oxytocin in the blood. Furthermore, light exposure could also reduce the sociosexual behavior in WT mice, but not in ipRGC genetically eliminated mice. Although the circuit which relays the light signal to regulate the oxytocin release is still under investigation, our results suggest that light can influence the oxytocin level and potentially modulate social behaviors.

Keywords
ipRGC, oxytocin, sociosexual behavior.

Title: A mouse training protocol for time perception test

Authors: *F. LIANG, S.-K. CHEN;
Natl. Taiwan Univ., Taipei, Taiwan

Abstract: Light has a strong effect on our lives and physiological functions. In addition to image-forming visual function for animal to perceive our environment, ambient light could also influence many non-imaging-forming functions such as resetting the circadian clock, controlling the pupil size and modulating emotion and cognition functions. It has been shown that intrinsically photosensitive retinal ganglion cells (ipRGCs) play an important role in non-imaging-forming functions. These ipRGC express melanopsin, a special photopigment with principal absorption wavelength around 470 nm (blue light). Recent evidence also indicates that ipRGCs innervate the SCN and deep layer of the superior colliculus, which is involved in the regulation of circadian and the multisensory integration respectively. It has been showed that human exposed to different melanopsin contrast have slightly different perception of time. However, how light could influence the time perception remain unclear. To setup an animal model for further test, we generate a training protocol for mice to perform time perception test using two-alternative forced choice task. Mice first learned to poke the middle hole to start the trial and hold the position under two beeping sounds plays with interview ranging from 0.6 to 2.4 sec. They then next learn to approach the specific choice point to obtain water reward. After 3 weeks of training, we can test the time perception of mice under different background of light. This training protocol showed that we can used two -alternative forced choice task to study time perception of mice model.

Title: Mouse rod photoreceptor ribbons are essential for the formation of a large pool of primed vesicles

Authors: *C. P. GRABNER[1], T. MOSER[2];
[1]Synaptic Nanophysiology Group, Max Planck Inst. For Biophysical Chem., Goettingen, Germany; [2]Inst. for Auditory Neurosci., Univ. Med. Ctr. Goettingen, Goettingen, Germany

Abstract: Dark adapted animals can perceive very small doses of light. The detection threshold may be set by the activation 0of a few rhodopsin molecules in a single rod. The rod's single synaptic terminal converts the small amplitude photo-currents into synaptic signals. A mouse rod forms a single synaptic ribbon active zone. It is believed that only a subset of ribbon-associated synaptic vesicles (SVs) are available for release onto post-synaptic targets. Whole-cell membrane capacitance (C_m) measurements performed on mature mouse rods made with a high concentration of intracellular Ca^{2+} buffer (10mM EGTA) have reported that ~80 SVs fuse within a 1sec depolarization (Grabner et al., 2015 J. Neurosci.). This result was interpreted to represent release from the ribbon active zone; however, the time course of release and its dependence on intracellular Ca^{2+} buffering were not probed. In the current study, similar recordings were performed using shorter duration stimulations with 0.5 or 10mM EGTA in the pipette. Brief 1 and 3ms steps to -18mV evoked 0.59 and 1.35fF C_m jumps with 10mM EGTA (3 cells), and 1.65 and 3.25fF with 0.5mM EGTA (4 cells). Longer steps to 30ms produced a dC_m of 3.41fF with 0.5mM intracellular EGTA, similar to 3ms step responses, and suggestive of a depleted pool of SVs. Using a C_m value of 40aF for each SV (Grabner and Moser; 2018 PNAS), a total of 85 SVs were estimated to fuse within 30ms. SVs fusing within 3ms (regardless of EGTA conc.) are generally assumed as primed for release (Neher and Brose; Neuron 2018), and those released in 10mM EGTA are within a small Ca^{2+}-nanodomain (< 50nm from Ca_v channels; Burrone et al., 2002 Neuron). To assess the role of the ribbon itself in SV priming, the ribbonless RIBEYE knockout mice were examined (Maxeiner et al., 2016 EMBO J.). In the more permissive release condition of 0.5mM EGTA, 1 and 3ms steps elicited dC_m values of 0.38 and 1.03fF (5 cells), respectively, which were reduced to less than 30% of control values (p values: 0.003 and 0.019 for 1ms steps). This reduction occurred despite similar peak Ca^{2+} currents in rods of RIBEYE ko and wild type mice. The results argue that the synaptic ribbon is critically needed for SV priming, and the findings are congruent with published EM data that revealed the density of SVs

is reduced at the synaptic juncture (Maxeiner et al., 2016 EMBO J.). In summary, the rod's ribbon creates a large pool of ~80 primed SVs, which is equivalent to, or slightly more than, what is commonly viewed as docked at the ribbon's base.

Title: Cannabinoid receptors as modulators of cell migration in retinoblastoma

Authors: *C. M. VECCHINI-RODRIGUEZ[1,2,3], Y. OQUENDO-ALVARADO[4], F. BIAGGI-HUYKE[5], M. PORTELA-VÁZQUEZ[3], J. FLORES-OTERO[1];

Abstract: Retinoblastoma (RB) is an intraocular tumor that develops during childhood. Current therapeutic approaches for RB target DNA synthesis with the goal of decreasing tumor size. However, these therapies fail to control the migration of RB via the optic nerve, which is the primary risk factor for brain metastasis. The survival rate for RB patients with brain metastasis is less than 8%. Recent studies have shown that the cannabinoid receptors (CBRs) and their ligands display anti-cancer roles including the prevention of metastasis by targeting cell migration. Moreover, the expression of the CBRs has been described in the retina of different animal models. Our main objective is to define how we can interfere with RB cell migration to prevent brain metastasis via modulation of the CBRs. Preliminary data from our lab using Western blot assays demonstrate than in contrast to the upregulation of CB2Rs, CB1Rs are downregulated in RB human tumors when compared to fetal retina (Two-way ANOVA, control; $p<0.001$ and $p<0.01$, respectively). Immunohistochemistry results validate the expression of CB1Rs and CB2Rs in murine retina. We hypothesize that RB migration can be modulated by targeting CBRs. To determine if CBRs play a role in the migration of the most invasive RB cells, Y79, we conducted Wound Healing assays. We observe a significant delay in migration (Dunnett's test,

$p<0.05$) in the Y79 cells upon the activation of CBRs with CP55,940 and 2-AG, which activate both CBRs, when compared to the untreated cells. To determine if CB2R is responsible for the delay of migration we used a specific antagonist for CB1R (SR 141716A) and a specific agonist of CB2R (JWH-133). We observe that cells exposed to the combination of SR 141716A and JWH-133 display a delay in migration. In contrast to the migration effect, CBR ligands CP55,940 and 2-AG did not affect Y79 cell proliferation. Overall, our results suggest a potential role of CBRs in the migration of RB cells. We propose that CB2R play a role in the migration rate of Y79 cells, however, ongoing studies are evaluating the role of CB1R. Successful outcomes will contribute to identify novel targets that prevent the migration of RB cells to the brain, and hence increase these patient population survival rate.

Title: Light at night influences intestine transcriptome profile in mice

Authors: *I.-C. LEE, S.-K. CHEN;
NTU, Taipei City, Taiwan

Abstract: Environmental light affects mammalian circadian clock through ipRGCs in retina, and may also influence peripheral circadian oscillation and regulate several physiological hormone homeostasis. Previous studies showed that abnormal light at night time might cause obesity, insulin resistance and gut microbiota oscillation abnormality in mouse. However, the mechanism through which environmental light influences the gut microbiota and host metabolic mechanism remains unknown. In this study, we analyzed the transcriptome expression in small intestine from mice housed under dim light at night (dLAN) or normal light-dark cycle. We found that many genes which influence protein and fat absorption are enriched in dLAN group mice and different expression profile of immune-related genes between dLAN and normal group. Therefore, light exposure during the night time could modulate small intestine gene expression profile which may influence metabolic status of the host or gut microbiota.

Title: LKB1 is required for cone photoreceptor nuclear positioning and function

Authors: *C. BURGER[1], F. LI[1], N. ALBRECHT[2], D. JIANG[1], M. A. SAMUEL[3]; [2]Neurosci., [3]Dept. of Neuroscience, Huffington Ctr. on Aging, [1]Baylor Col. of Med., Houston, TX

Abstract: Cone photoreceptors detect light and are responsible for color vision. These cells are unique in that they have a distinct polarized morphology where their nuclei are precisely aligned at the apical surface of the retina. However, little is known about the mechanisms involved in proper nuclear positioning or the impact of this organization on retina function. LKB1 is a serine/threonine kinase involved in cellular polarity. By deleting LKB1 specifically in cones ($LKB1^{Cones}$), we show that LKB1 is required for proper nuclear localization, while no changes to other cell types are observed. Electroretinography in one-month-old $LKB1^{Cones}$ mice reveal that altered cone nuclear localization reduces photopic but not scotopic retinal responses, indicating that visual processing in cones is reduced. However, by two months of age, scotopic vision also declines, suggesting that changes to cone structure and function progressively impact rod photoreceptor signaling. Together, these data suggest that LKB1 is a regulator of cone nuclear translocation and indicate that nuclear alignment is required for proper signaling in cones and for the preservation of both cone and rod function.

Title: Gene delivery to cone photoreceptors by subretinal injection of rAAV2/6 in the mouse retina

Authors: M. FUKUTOME[1], T. HORI[1], C. MAEJIMA[1], H. MATSUSHIMA[1], K. KOBAYASHI[1], S. KITAZAWA[1], R. KITAHARA[1], K. KITANO[1], K. KOBAYASHI[3], S. MORITOH[1], *C. KOIKE[2];

Abstract: Adeno-associated virus (AAV) has been studied as a safe delivery tool for gene therapy of retinal blinding diseases such as Leber's congenital amaurosis (LCA). The tropism of recombinant AAV (rAAV) including its specificity and efficiency in targeting retinal cell types has been studied with native or engineered capsids, along with specific promoters. However, one of the rAAV serotypes, rAAV2/6, has not been well-studied based on a report of low infection efficiency in the retina. We investigated the tropism of several rAAVs by subretinal injection in the adult mouse and found that rAAV2/6 predominantly infected cone photoreceptors including the main spectral type. Our data suggest that subretinal injection with rAAV2/6 may provide both an efficacious and specific means of gene delivery to cone photoreceptors in murine retinas.

Title: Using cell atlases to investigate the evolution and development of retinal cell types in multiple vertebrate species

Authors: *Y.-R. PENG[1], W. YAN[1], K. SHEKHAR[2], M. LABOULAYE[1], M. YAMAGATA[1], Q. ZHANG[4], G. FENG[4], A. REGEV[3,5], J. R. SANES[1];

Abstract: The vertebrate retina exhibits profound species-specific specializations superimposed on a conserved retinal plan comprising six cell classes: horizontal, bipolar, amacrine and retinal ganglion cells, photoreceptors and Müller glia. Species-specific regional specializations (e.g., area centralis or fovea) and functional capabilities (e.g., high acuity or chromatic vision) stem from the diversification of cell types within shared classes. We have used large-scale high throughput single-cell RNA-sequencing (scRNA-seq) to generate comprehensive cell atlases in two model systems, mice (Macosko et al., Cell, 2015; Shekhar et al., Cell, 2016) and macaques (Peng et al., Cell 2019). These cell atlases enabled us to examine cell types that are specific to the fovea, a high-acuity retinal region in primates, and to identify the degree to which cell types are common to the two species. With these results as a foundation, we are now generating retinal cell atlases from eight additional vertebrate species—human (*Homo sapiens*), marmoset (*Callithrix jacchus*), chicken (*Gallus gallus domesticus*), deer mouse (*Peromyscus maniculatus*), ferret (*Mustela putorius furo*), pig (*Sus scrofa domesticus*), zebrafish (*Danio rerio*), and sheep (*Ovis aries*). Analysis of these atlases is allowing us to tackle the largely unexplored issue of how cell types within classes evolve. In parallel, we are asking when regional specializations arise. To this end, we generated cell atlases of fovea and peripheral retina from neonatal marmosets. Comparison with the adult atlases showed that the majority of cell types are present in neonates, but there are significant differences in foveal gene expression between neonates and adults. Some of these differentially expressed genes may play a role in mediating the formation of structural and functional foveal specializations.

Title: Transcriptomic classification of retina cells from human and non-human primate

Authors: *W. YAN[1], Y.-R. PENG[1], T. VAN ZYL[2], Q. ZHANG[3], G. FENG[3], J. R. SANES[1]; [1]Dept. of Mol. and Cell. Biol., Harvard Univ., Cambridge, MA; [2]Glaucoma Service, Dept. of Ophthalmology, Massachusetts Eye and Ear Infirmary, Harvard Med. Sch., Cambridge, MA; [3]Brain and Cognitive Sci., MIT, Cambridge, MA

Abstract: The retina has been studied intensively in a variety of model organisms, leading to a growing understanding of the cells and circuits that underlie the initial steps in vision. Among mammals, however, only primates have a central specialized retinal region called the fovea, embedded in a slightly larger macula. The fovea underlies most high acuity and much chromatic vision, and is most vulnerable in age-related macular degeneration and other macular diseases. As a first step in understanding the molecular and cellular bases of structural and functional foveal specializations, we recently generated cell atlases of macaque fovea and peripheral retina (Peng, Shekhar *et al*., *Cell*, 2019). Here, we extended this work by generating atlases of human fovea and peripheral retina from over 75k single cell RNA-seq profiles collected from 5 human donors. Among the >50 neuronal types and 6 non-neuronal types in the human retina, most are shared between fovea and periphery, but some genes are enriched in one or the other region. For example, *FBXO15* and *FXYD6* are selectively expressed by foveal *DB4* bipolars and peripheral *DB3a* bipolars respectively. We then generated an atlas from a third commonly used primate model, marmoset. With >45k single cells collected from 2 adult marmosets, we identified >50 neuronal types and 5 non-neuronal types. Finally, we used these data sets to compare retinal cell types among the three primates and between primates and mice. We found that photoreceptor and bipolar types were largely conserved across species, but found species-specific differences among horizontal, amacrine and retinal ganglion cell types. Together these results reveal the specializations of primate fovea compared to the lower acuity peripheral retina and the differences between primate and rodent retina. More generally, the transcriptomic resources we provide establish molecular foundations for studies of human retinal disease and shed light on the evolution of retina.

Title: Alterations in photoreceptor signals due to thyroid hormone receptor beta mutations are present in larval and adult zebrafish

Authors: *C. DEVEAU[1], J. XIAODONG[2], T. YOSHIMATSU[3], S. SUZUKI[4], J. HEJTMANCIK[2], R. NELSON[1];
[1]NIH NINDS, Rockville, MD; [2]NIH NEI, Rockville, MD; [3]Univ. of Sussex, Sussex, United Kingdom; [4]Univ. of Washington, Seattle, WA

Abstract: Thyroid hormone receptor beta (thrb, trB2), the gene responsible for vertebrate red cone development, diminishes and eliminates responses to red cone wavelengths in larval zebrafish (5-12 days post fertilization). We hypothesize that this loss of functional thrb will extend through the retinal circuit, development and into behavior, specifically the optomotor response (OMR) and optokinetic response (OKR). We investigated this hypothesis with two thrb Crisper mutant strains: c. 184_188delTATGGinsGTTCCC (6BP+1) frameshift indel and an in frame c. 184_186delTAT single codon deletion (3BP).
Zebrafish at the larval stage (5-12 dpf) and adult stage (> 3 months dpf) spawning from two breeding pairs, mutant/het-mutant and two het-mutants, were the subjects of this study. Spectral PIII cone signals and ON-bipolar cell signals were recorded using ERG with a light stimulus protocol that ranged from 650nm to 330nm. Eyes were perfused with L-aspartic acid and CNQX to isolate the respective signals. For behavior, the PsychoPy stimulus was presented on a monitor with the larval fish placed directly on top. Antibodies labeling red cone opsin and were imaged with DAPI using a confocal microscope.
The loss of red response in the larval ON-bipolar cells was maintained as seen in cones in larvae. There is a significant loss of red response in the cones with additional significant alterations to the green, blue, and UV cones for the 6BP+1 mutated adult. Larval 6BP+1 mutants OMR and OKR tests showed a loss of red perception. Antibody stains showed no fluorescent red opsin labeled in the mutant while it was present in the heterozygotes and wild types, confirming the thrb:td Tomato transgene confocal images that showed no thrb activity and no presence of red cones.
After finding the eliminations and alterations of red cone ERG signals in larval zebrafish, we continued to find the same lack of long-wavelength cone response in the ON-bipolar cells and adult zebrafish. This shows that the altered signal is maintained through the next step of the circuit and there are no changes throughout development that compensate for the lack of thrb into adulthood. OMR and OKR behavior showed that the red light is not being perceived in the brain so the fish are red colorblind. The antibody stains confirmed that the red opsin is not formed when functional thrb is lost, as seen in additional vertebrates such as mice. Without functional thrb, zebrafish cannot form red cones, red opsin, or perceive red light.

Title: Neural mechanisms of contextual modulation in the retinal direction selective circuit

Authors: *X. HUANG[1], M. RANGEL[2], K. L. BRIGGMAN[2], W. WEI[3];
[1]Dept. of Neurobio., The Univ. of Chicago, Chicago, IL; [2]Computat. Neuroethology, Ctr. of Advanced European Studies and Res., Bonn, Germany; [3]Univ. of Chicago, Chicago, IL

Abstract: Contextual modulation of neuronal responses by surrounding environments is a fundamental attribute of sensory processing. In the mammalian retina, On-Off direction selective ganglion cells (DSGCs) are maximally activated by bright or dark contours moving in the preferred direction across their receptive field (RF) center. Contextual tuning of DSGCs has been previously reported in the rabbit retina (Chiao and Masland, 2003). However, this phenomenon is yet to be studied in the mouse, which is currently the prevalent model organism for retinal circuit analysis. Importantly, how synaptic circuits are engaged to modulate DSGC responses during more complex motion contexts is poorly understood.
Using two-photon targeted patch-clamp recording of genetically labeled posterior-preferring On-Off DSGCs (pDSGCs), we found that pDSGCs are sensitive to discontinuities of moving contours owing to contextually modulated cholinergic excitation from starburst amacrine cells (SACs). Using a combination of synapse-specific genetic manipulations, patch clamp electrophysiology and connectomic analysis, we identified distinct circuit motifs upstream of On and Off SACs that are required for the contextual modulation of pDSGC activity for bright and dark contrasts. The contextual tuning of DSGC Off responses requires GABAergic inputs from wide-field amacrine cells (WACs) onto SACs. By contrast, the weak contextual modulation of DSGC On responses is mediated by a "SAC - WAC - bipolar cell" circuit motif. Furthermore, our results reveal a class of WACs with straight, unbranching dendrites that function as "continuity detectors" of moving contours.
Together, these results demonstrate that divergent amacrine cell circuits implement contextual modulation of DSGC response in the On and Off pathways. Therefore, the extensive retinal network impinging on SACs and DSGCs shapes the information encoding by On-Off DSGCs beyond their direction selectivity during complex motion stimuli.

Title: Enhancement of information transfer on mouse retina by the addition of external noise

Authors: *A. HUNG[1], J. J.-S. WU[1], C.-K. CHAN[2], C.-C. CHIAO[1];
[1]Inst. of Systems Neurosci., Natl. Tsing-Hua Univ., Hsinchu, Taiwan; [2]Inst. of Physics, Academia Sinica, Taipei, Taiwan

Abstract: The addition of noise usually corrupts a system's sensitivity and reliability. However, the phenomenon stochastic resonance [1] (SR) indicates otherwise: adding noise to a certain degree improves visual sensitivity when the cue is obscure [2,3]. However, SR's underlying neural mechanisms remain elusive. Here we report our experimental results on the effects of noise on the encoding process of mouse retinal ganglion cells in a multi-electrode array system under whole field light stimulation. To have a more naturalistic stimulus, the stimulation is generated by a hidden Markov model while the added noises are zero-mean with uniform distribution. Mutual information (MI) between the stimulation and the response is measured at different noise levels to determine whether SR occurs in the retina. Our results suggest that some of the cell types indeed demonstrate stochastic facilitation - mutual information attains a maximum at intermediate levels of noise. This signifies that noise aids in signal detection at lower values, and corrupts the signal at higher values. Some cell types in the retina show monotonically decreasing trends in measured MI, which may correspond to the stimulation being supra-threshold for them. Others show irregular trends in measured MI, which might indicate even more complicated dynamics at work. Moreover, our results indicate that not only does the mutual information increases with noise but the information per spike as well! This means that stochastic facilitation is also energy efficient when improving the encoding process.

Title: Neonatal retinal waves revisited: Evidence for a novel, transient population of hyper-connected cholinergic cellular clusters

Authors: ***E. SERNAGOR**, J. DE MONTIGNY, V. KRISHNAMOORTHY;
Inst. of Neurosci., Newcastle Univ., Newcastle upon Tyne, United Kingdom

Abstract: In the developing retina, spontaneous waves sweep across the layer of retinal ganglion cells (RGCs), the output cells of the retina. Experimental evidence indicates that retinal waves play a crucial role in guiding the refinement of visual connectivity. Wave dynamics undergo profound developmental changes. From initial gap junction communication during late gestation (Stage 1), they become controlled by directly interconnected cholinergic starburst amacrine cells (SACs), the only known retinal cholinergic cells (Stage 2 waves). Direct connections between SACs withdraw at P10 (in mouse). Waves become then driven by newly formed glutamatergic connections originating from bipolar cells (Stage 3 waves, P10-eye opening). Recent observations from our group are challenging the hypothesis that Stage 2 waves are driven by SACs. Using wide-field fluorescence microscopy (Zeiss ApoTome) to visualize retinal wholemounts stained with an antibody against Choline Acetyltransferase (ChAT, the enzyme that synthesizes acetylcholine), we found a novel transient population of cholinergic cells present from P2-9. These cells co-exist with SACs, but they are larger, residing only in the RGC layer and not in the inner nuclear layer. They form tight clusters in an annulus pattern around the optic disc at P2-3. Labelling cholinergic terminals with an antibody against Vesicular Acetylcholine Transporter (VAChT) reveals that they are more conspicuous near the cholinergic cell clusters, suggesting cholinergic neurotransmission in their vicinity. The annulus of cell clusters expands towards the periphery with development, until the clusters disappear at P10, coinciding with the disappearance of Stage 2 waves, which suggests that they may be involved in their generation. In support, using large-scale multielectrode array recordings from the entire retina, we found that wave origins follow a centrifugal pattern between P2-P10 as well, with gradually more waves

becoming initiated in the peripheral retina. Once waves become driven by glutamate, this center-to-periphery pattern disappears and wave origins tile the entire retina. We propose that these cells represent transient hubs of hyper-excitable neurons responsible for the generation of cholinergic waves, somewhat reminiscent of transient subplate neurons in the developing cortex, and super-connected GABAergic hub neurons in the developing hippocampus, suggesting a universal mechanism mediating hyper-excitability in developing CNS networks during the critical period for brain wiring.

Title: Development of direction selectivity maps in the mouse retina

Authors: *A. TIRIAC, M. B. FELLER;
Univ. of California Berkeley, Berkeley, CA

Abstract: Detecting the directions in which objects move is critical for everyday behavior. In mice, directional motion detection begins in the retina where a subset of direction selective retinal ganglion cells (DSGCs) fire more action potentials in response to visual stimuli moving in one direction, called the preferred direction, than visual stimuli moving in the opposite direction, called the null direction. In adult mice, the preferred directions cluster along four directions that align along two optic flow axes—paths that visual stimuli trace across the retina as the animal moves through space (Sabbah et al., Nature 2017). We aim to determine whether visual experience plays a role in the clustering of preferred direction along the optic flow axes. Here, we used two-photon microscopy to image from large populations of RGCs and assess the direction selectivity map in multiple regions of the retina in normal- (12-hour light/dark cycle) and dark-reared mice. We also assessed the direction selectivity map of transgenic mice that express GFP under the Hb9 promoter, which labels DSGCs that prefer ventral motion (Hb9-DSGCs). Our results show that in normal-reared mice, the preferred directions of DSGCs changed as a function of their location on the retina, with the axes of preferred directions of DSGCs skewed in the more ventral parts of the retina, consistent with their alignment along the axes of optic flow. For example, the Hb9-DSGCs close to the optic nerve preferred ventral

motion whereas Hb9-DSGCs in peripheral ventronasal retina preferred ventral and temporal motion. Hb9-DSGCs from dark-reared mice exhibited similar direction selectivity maps as normal-reared mice, suggesting that the development of direction selectivity maps in this cell type does not depend on visual experience. We will present data assessing the impact of dark-rearing on the direction selectivity maps of other DSGCs to determine whether different DSGC subtypes are differentially impacted by visual experience. Title: Temporal dynamics of inhibitory circuits shape the directional code of the retina

Authors: *L. ANKRI[1], E. EZRA-TSUR[1], M. RIVLIN-ETZION[2];
[1]Neurobio., [2]Dept. of Neurobio., Weizmann Inst. of Sci., Rehovot, Israel

Abstract: Direction selective retinal ganglion cells (DSGCs) fire robustly in response to motion in one (preferred) direction, and poorly to motion in the opposite (null) direction. Starburst amacrine cells (SACs) underlie this computation via two mechanisms - they form asymmetric inhibitory connections onto DSGCs; and each of their processes is direction selective. Surprisingly, it has been shown that DSGCs can reverse their directional preference upon a short repetitive stimulation of drifting gratings. This reversal cannot be explained within the scope of the known mechanisms for retinal DS, which heavily rely on the circuit's anatomy. Here we used this reversal to shed new light on the mechanisms underlying the computation of motion. Using patch-clamp recordings, we found that processes of SACs lose their direction selectivity following repetitive stimulation. Instead, SACs' response phase changed, a shift that is reflected in the timing of inhibition to DSGCs, supporting the reversed computation by pulling the excitation-inhibition balance towards the null-direction. We determined SACs' center-surround organization and found that it changed following repetitive visual stimulation. Using a morphology-based simulation we demonstrated that this reorganization underlies the observed

shift in SACs' responses. Taken together, we revealed a novel way to dissect the retinal computation of motion direction to its elementary parts and thereby determine their role in the beautiful complexity hiding in this seemingly simple neural network.

Title: Saccadic suppression in the retina and its underlying mechanisms

Authors: *S. IDREES[1], F. FRANKE[2], M. BAUMANN[1,3], Z. M. HAFED[1,3], T. A. MÜNCH[1,4]; [1]Werner Reichardt Ctr. for Integrative Neurosci., Tuebingen, Germany; [2]ETH Zürich, Basel, Switzerland; [3]Hertie Inst. for Clin. Brain Res., Tuebingen, Germany; [4]Inst. for Ophthalmic Res., Tuebingen, Germany

Abstract: Purpose: During natural viewing, image flow on the retina is determined primarily by the behavior of the observer. Eye movements during active visual exploration, such as saccades, are particularly dominating in this regard. Despite this, retinal image processing has in the past often been studied with isolated stimuli, ignoring the highly dynamic aspects of natural viewing. We recently showed that saccade-like image shifts suppress the responses to subsequent stimuli in the retina, and in a manner that is directly congruent with human perceptual effects of saccadic suppression (Idrees et. al., 2019). Here, we add detailed characterization of retinal ganglion cell (RGC) responses in the context of saccade-induced image shifts, and we also probe the mechanisms underlying these effects.
Methods: We used ex-vivo retinal electrophysiology and recorded from more than 1,000 retina ganglion cells (RGC's) in isolated mouse and pig retinae. We showed test visual stimuli at different times after background image translations mimicking saccade-induced retinal image shifts (Idrees et al., 2019). We varied background image statistics and test stimulus luminance, and we also investigated center-surround interactions and amacrine cell contributions to retinal saccadic suppression.
Results: Retinal responses to test stimuli, when presented in the context of saccades, were strongly suppressed in comparison to responses to the same stimuli presented in isolation. Such saccade-related retinal suppression occurred robustly across many different RGC cell types.

Suppression properties critically depended on the delay between saccade and test stimulus, as well as on the statistical properties of the background scene presented during the saccades. In ON RGCs the suppression lasted for up to 1s, whereas OFF RGCs tended to recover much faster. The suppression did not critically depend on particular saccade-like profile speeds, but was a result of general stimulus-stimulus interaction effects triggered by image displacements. A component of this suppression originated from wide-field amacrine cell mediated inhibition. Another component originated from the cell's receptive field center and might originate in the outer retina.
Conclusion: Saccadic suppression does occur robustly across many different RGC cell types and is a result of specific spatio-temporal retinal-circuit image processing, in which the saccade stimulus elicits activity in both local and global retinal circuits to suppress responses to the test stimulus.

Title: Intrinsic properties shape a feature selectivity computation in a novel RGC

Authors: *S. WIENBAR, G. SCHWARTZ;
Northwestern Univ., Chicago, IL

Abstract: Neural computations arise through the integration of synaptic inputs and intrinsic cell properties. The purpose of this project was identify mechanisms by which intrinsic properties influence cell-type-specific computations in the retina. We identified a new retinal ganglion cell (RGC) type called the Bursty Suppressed-By-Contrast (bSbC) RGC. The bSbC is a morphologically and physiologically distinct cell type. Its key feature selectivity is that its tonic firing rate is decreased by both positive and negative contrast light stimuli. We measured synaptic currents and action potential waveforms in bSbC RGCs though whole-cell voltage, current, and dynamic clamp recordings in whole mount retinas. While the bSbC RGC receives similar synaptic inputs to those in the well-known OFF Sustained Alpha RGC, its feature selectivity is driven by its different intrinsic properties; bSbCs undergo depolarization block more readily than OFF Sustained Alphas. We have investigated the channel mechanisms underlying this key difference. While synaptic inputs in different retinal circuits are frequently

studied for their role in retinal computation, our work highlights the importance of intrinsic properties in RGCs.

Title: Gap junction coupling shapes the encoding of light in the newborn retina

Authors: *F. CAVAL-HOLME, C. VOUFO, Y. ZHANG, M. B. FELLER;
Univ. of California Berkeley, Berkeley, CA

Abstract: Intrinsically photosensitive retinal ganglion cells (ipRGCs) are present early in development and mediate reflexive and behavioral light responses before conventional photoreceptors mature. During development, ipRGCS are extensively gap junction coupled both to other ipRGCs and to non-intrinsically photosensitive neurons. However, the role this gap junction coupling plays in mediating the light sensitivity of developing retinas is not known. Here we use two-photon calcium imaging in a mouse expressing GFP under the melanopsin promoter (Opn4::eGFP) to characterize the irradiance-response and temporal response functions of ipRGCs from postnatal day 6-9 mice. By combining unsupervised clustering algorithms with anatomical approaches, we identify at least 6 distinct functional groupings that mostly but not exclusively map onto the ipRGC subtypes identified in the adult. By pharmacologically uncoupling gap junction circuits, we show that gap junction coupling is required to generate light responses in M2-M6 ipRGCs. Conversely, enhancement of gap junction coupling increases the gain of light-responses in all ipRGCs. We find that the different subtypes of ipRGCs have distinct tracer-coupling patterns, with M1 ipRGCs exhibiting the least coupling and M4s exhibiting the most. Together these data indicate that, even though ipRGCs have a cell-autonomous intrinsic light response, gap junction coupling among these cells significantly contributes to the encoding of light intensity in the neonatal retina.

Title: Visual evoked magnetic fields to 8Hz repetitive pattern-reversal stimulation

Authors: *Y. GOTO[1], S. TOBIMATSU[2];
[1]Physiol., Sch. of Medicine, Intl. Univ. of Helth and Welfare, Narita, Japan; [2]Kyushu Univ, Grad Sch. Med. Sci., Fukuoka, Japan

Abstract: PURPOSE: P100m of transient (TR) visual evoked magnetic fields (VEFs) is originated in the primary visual cortex (V1). However, neural generator(s) of steady-state (SS) VEFs has not been fully elucidated. We investigated the sources of equivalent current dipoles (ECDs) in each response using 8Hz repetitive pattern-reversal stimulation with a whole-head 306-channel magnetoencephalography. METHODS: Ten healthy young adults were subjected to this study. A black and white checkerboard pattern (check size, 50 min; mean luminance, 30 cd/m^2; contrast, 97 %) was phase-reversed at a rate of 8 Hz (duration, 1 s; interstimulus interval, 1.5 s) to stimulate each right and left visual half-field (field size, 8 deg). A total of 100 responses were averaged. RESULTS: In this stimulus condition, TR-VEFs and SS-VEFs were simultaneously obtained in all subjects. In TR-VEFs, N75m and P100m were clearly evoked whereas N145m was not identified because of overlapping with SS-VEFs. The mean peak latency of P100m was 97.3 ms and its ECD was located in V1 around the calcarine fissure contralateral to the stimulated visual field. SS-VEFs were higher amplitude and quasi-sinusoidal responses compared with TR-VEFs and they were continuously observed from 150 ms after the stimulus onset to the end of stimulus offset. Fast Fourier analysis showed that second harmonic response (16 Hz) was the major component. In 8 of 10 subjects, the ECDs of SS-VEFs were widely spread in V1 contralateral to the stimulated visual field. Interestingly, sustained (SU)-VEF was observed in this stimulus condition. CONCLUSIONS: These results suggest that neural generators between TR- and SS-VEFs are differently located in V1. In addition, 8 Hz repetitive pattern-reversal stimulation can be a unique method to obtain TR-, SS- and SU-VEFs, simultaneously.

Title: Functional characteristics of stimulus driven resting state fMRI signals

Authors: *Y.-W. SUNG[1], S. OGAWA[2];
[1]Tohoku Fukushi Univ., Sendai, Japan; [2]Kansei Fukushi Res. Inst., Touhoku Fukushi Univ., Sendai-shi, Japan

Abstract: In the brain mapping study task-fMRI has been used to localize brain regions specifically reflecting a task-related function. On the other hand, resting-state fMRI (rsfMRI) is known to reflect some intrinsic brain function such as the default mode network rather than to reflect specific function. In previous studies, we measured typical rsfMRI signals with no stimulus or task, and stimulus-driven rsfMRI signals, and showed that the primary motor and visual areas could be localized by the comparison of typical rsfMRI and stimulus-driven rsfMRI signals but the locations were off the focal sites by task-fMRI. We, in this study, aimed to further examine characteristics in stimulus-driven rsfMRI signals evoked while participants were solving a puzzle and compared with the previous studies.
MRI measurements were conducted by a 3-Tesla MRI scanner (Skyra-fit; Siemens). From eight subjects, structural images (T1) and functional images were measured. In the resting-state fMRI session, subjects were asked to lie on the bed and not to wander their mind with their eyes open and to gently focus their eyes on the center of the visual field. The resting-state fMRI session was followed by task-fMRI session. In the task-fMRI session, a picture with nine dots were presented on the screen during an 8-min scan and subjects were asked to solve a puzzle, the solution of the nine dot puzzle.
We could find a brain region in BA4/6 that tended to have larger fractional amplitude of low frequency fluctuation (fALFF) for task-fMRI than for rsfMRI ($p = 0.053$, FWE corrected). However, we could not find any brain areas showing larger fALFF for rsfMRI. We also performed regional homogeneity (ReHo) analyses for the present data in addition to the previous studies of motor and visual tasks. ReHo values were larger in the primary motor and visual areas for rsfMRI signals ($p = 0.05$, FEW corrected). The brain areas shown larger ReHo values for task-fMRI during puzzle solving were parietal and middle occipital cortices.
Our results suggest that coherent neuronal activities result in the low frequency band signals at a resting state fMRI and the coherent neuronal activities are disturbed by the external stimulation input. Our results also indicate that the disturbance of the low frequency signals in a functional area by external stimulation is specific to its functional role. On the other hand, coherent neuronal activities observed for internal stimulation of solving a puzzle are different. The

differences in rsfMRI signals for those external and internal stimuli observed through fALFF and ReHo values can be clues for further elucidation of characteristics of rsfMRI signals.

Title: Contrast dependent spatial frequency tuning dynamics in the cat primary visual cortex

Authors: *H. TANAKA;
Kyoto Sangyo Univ., Kyoto, Japan

Abstract: Previous studies on single cells in the primary visual cortex (V1) reported little effect of stimulus contrast on spatial tuning properties inside the receptive field. With regard to spatial frequency (SF) tuning, they showed that the preferred SF of cells hardly changed with stimulus contrast. These studies measured tuning properties using the cell's steady state responses. However, as it is well known, the preferred SF of V1 cells often changes with time. A proposed mechanism of these dynamics is the convergence of two separate thalamocortical pathways with different SF tuning and temporal characteristics. These pathways may also have different contrast dependence. Therefore, if we study SF tunings with high temporal precision, the preferred SFs may highly depend on stimulus contrast. To address this issue, we measured the time course of SF tunings of cat V1 cells under different contrast conditions. We recorded the activities of V1 cells in response to random sequences of flashed sinusoidal gratings of various orientations, SFs, and phases. Stimulus contrast of each sequence was constant and sequences of different contrasts were interleaved. The time courses of the SF tunings for each contrast were computed by applying a subspace reverse correlation technique. We obtained reliable SF tuning time courses for contrast 50%, 12.5%, and 6.25% from 117, 88, and 52 cells, respectively. We first examined whether the total amount of temporal change of the preferred SF during response time depended on contrast. We found that the shifts of preferred SF during response time became larger as the stimulus contrast increased (mean SF shift: 0.20, 0.30, and 0.39 octaves for contrast 6.25%, 12.5%, and 50%, respectively). Next, we compared the preferred SFs between different contrast conditions at three temporal phases. At response onset, preferred SF of the cells does not differ with stimulus contrast. On the other hand, at response peak and offset, the preferred SF is often higher when the stimulus contrast is higher. The present results show that the preferred SF

of cells in V1 highly depends on stimulus contrast, and this dependence dynamically develops during response time.

Title: Visual oddball paradigm reveals feature non-specific prediction errors in V1 of a mouse model of fragile X syndrome

Authors: *A. PAK, S. T. KISSINGER, A. A. CHUBYKIN;
Dept. of Biol. Sci., Purdue Univ., West Lafayette, IN

Abstract: Proper functioning in a noisy world requires specific and timely adjustment of the animal's internal world representation in response to dynamically changing sensory inputs. There is an emerging idea that this process might be impaired in autism. Recent findings support this idea by providing evidence for altered information processing in early sensory areas. Given that feature-specific prediction errors (PE) are crucial for effective adjustment of animal's internal model, we investigated the visual feature tuning of prediction errors in Fmr1 KO mouse model of Fragile X syndrome, a leading genetic cause of the autism. We first showed that there are a decreased habituation and surprise adaptation in the oddball paradigm in *Fmr1* KO mice using pupillometry recordings. We then used silicon probe recordings in the primary visual cortex (V1) along with the modified oddball paradigm and revealed differential laminar processing and feature-specificity of prediction errors in *Fmr1* KO animals. Specifically, we observed a feature-specific "tuning" of PE in WT animals but not in mutant mice. Our results suggest that neural populations in Fmr1 KO mice do not report PE in a specific manner, which would undermine effective adjustment of the animal's internal model following sensory experience.

Title: A periorbital pulse current stimulation preceding upcoming visual stimulation causes macroscopic changes in visual information processing in healthy humans - An EEG study

Authors: *P. DZWINIEL[1], M. ŁABĘCKI[2], I. RACIBORSKA[1], M. ŻEBROWSKA[1], W. J. WALESZCZYK[1];
[1]Nencki Inst. of Exptl. Biol. PAS, Warsaw, Poland; [2]Univ. of Warsaw, Warsaw, Poland

Abstract: *Aim:* To explore how a periorbital pulse current stimulation (pPCS) will affect visual information processing in healthy humans.
Methods: Computer simulations of the induced electric field were performed prior to the study for the planned pPCS setting. Next, 32 healthy volunteers (16 females) in age of 25.7 ± 3.7 were divided randomly into two gender- and age-equal groups - placebo and experimental. Participants watched checkerboard pattern reversals (CPRs) presented on the computer screen in a darkened room. CPR was performed alone (placebo group) or preceded directly with pPCS (experimental group) of different duration (12.5, 25, 50 and 100 ms) and amplitude (100 and 200 μA). Inter-CPR interval was 2.25 ± 0.25 s (0.4 - 0.5 Hz). Simultaneously, EEG signal was recorded and analysed in Python. Amplitudes and latencies of the visual evoked potential (VEP) N1, P1 and N2 components were analysed, as well as the scalp potential distribution, power of the chosen frequency bands and Shannon entropy measures.
Results: Computer simulations indicated strongest electric field on the skin around stimulation electrode edges and corners. Induced electric field was around 10 times stronger in the eyeballs, than in the pre-frontal grey and white matter. During the experiment, despite of the current pulse characteristics, pPCS caused uniform decrease of the VEP's N1-P1 and P1-N2 peak-to-peak amplitudes in the posterior scalp regions. Peak-to-peak amplitude changes were related to N1 and N2 component's amplitude modulation rather than affecting P1 component's amplitude which remained unchanged. Described changes were co-morbid with the overall decrease of the potential in the posterior and increase in the anterior scalp regions. Latencies of the components remain intact. Power in all considered frequency bands dropped in response to pPCS, whereas the strongest pPCS effects were observed in participants who had relatively higher power in all considered frequency bands prior the stimulation. Those participants had also highest and most stable entropy dropout persisting few minutes after pPCS ends. In other participants entropy dropout was also present but vanished after pPCS ends.
Conclusions: We presented an electrical stimulation able to induce complex changes in visual information processing in healthy humans.

Title: Cross-orientation suppression in mouse visual cortex

Authors: *D. J. BARBERA, N. J. PRIEBE;
The Univ. of Texas at Austin, Austin, TX

Abstract: Neurons in the primary visual cortex (V1) exhibit a number of nonlinear response properties to sensory stimuli. One example of a nonlinear response in visual cortex is cross-orientation suppression, when an stimulus oriented orthogonally to the preferred orientation (a mask) suppresses the response to the preferred orientation despite failing to evoke a response on its own. The mouse visual cortex has been shown to exhibit many of the same properties seen in other mammals, such as orientation tuning. Certain features, however, appear to be altered in mouse V1 compared to other species. For example in cats and primates orientation selectivity is invariant to the contrast of the stimulus whereas in the mouse orientation selectivity is not invariant to contrast (Ya-tang et al. 2012). We sought to determine whether neurons in mouse visual cortex exhibits the robust cross-orientation suppression seen in primates and carnivores (Morrone et al. 1982, Carandini et al. 1997, Priebe and Ferster, 2006). We performed in-vivo whole cell recordings from simple cells in mouse V1. Drifting sine wave gratings were presented at the preferred and orthogonal orientation at four different contrasts (0%, 16%, 32%, 48%). These stimuli were then presented simultaneously at all contrast combinations as a plaid stimulus. We observe robust cross-orientation suppression, with some cells exhibiting suppression at the magnitude seen in other species (ex. 85% spike reduction, 75% membrane potential reduction). Although most cells exhibited suppressed responses to the two stimuli, a subset of neurons increased their responses when the preferred and orthogonal orientations were presented, but in a sublinear fashion. We quantify the interaction between the preferred and orthogonal stimuli by comparing the sum of responses to each of the stimuli alone to the responses when they are presented simultaneously. Across our population we found that responses to a plaid stimulus are strongly sublinear (mean reduction for 32% test, 48% mask = 26.31%). These data demonstrate that nonlinear cross-orientation interactions are a common feature of the mammalian visual cortex.

Title: Skewed distribution of response reliability in mouse V1 across different types of visual stimuli

Authors: *J. XIA[1], P. O'NEILL[2], M. GOARD[3], R. WESSEL[1];
[1]Physics, Washington Univ. In St. Louis, Saint Louis, MO; [2]New York Univ., New York, NY; [3]Molecular, Cell. and Developmental Biol. / Psychological & Brain Sci., Univ. of California, Santa Barbara, Santa Barbara, CA

Abstract: Neural responses in cortical circuits vary considerably across repeated presentation of identical sensory stimuli. The apparent irreproducibility of stimulus-modulated cortical activity raises the question to what extent the across-trial variability differs among neurons and depends on the statistics of the visual stimuli. To address this question, we performed two-photon Calcium imaging of excitatory neurons in the primary visual cortex of awake, head-fixed mice during visual stimulation with repeated identical natural movie clips or drifting gratings. We quantified the stimulus-modulated neural activity and between-trial variability for a given neuron in terms of the "response reliability", which is defined as the correlation coefficient between the inferred firing rates from pairs of trials of identical stimulus presentation, averaged across all trial pairs. We found that response reliabilities followed a similar skewed distribution among neurons for both natural movies and drifting gratings, with most neurons having a low response reliability. Which network properties mediate the skewed distribution of response reliabilities? To investigate this question, we built a deterministic model network, consisting of 4000 excitatory and 1000 inhibitory point neurons with random sparse connectivity and external inputs of different amplitude to neurons in the network. The external inputs ("stimulus") are Poisson spike trains that were unique for each neuron, but identical ("frozen") across 20 repeated presentations. There is no inter-trial interval between neighboring trials, so the overall network activity was unique at each stimulus onset. This model investigation yields two important results. First, because of the chaotic nature of this deterministic balanced network and the unique initial condition for each stimulus presentation, the responses of individual neurons were highly variable across trials. Second, the distribution of external input amplitudes across neurons, instead of external input rates, affected the skewness of the reliability distribution. In conclusion,

we found that the response reliability of neurons in mouse V1 follows skewed distribution across different types of visual stimuli. Using a parsimonious deterministic model, we proposed that this may arise from chaotic system with different initial conditions even in the absence of noise.

Title: Serotonergic modulation of functional connectivity in V1 of awake macaques

Authors: *L. SEILLIER, K. KAWAGUCHI, H. NIENBORG;
Ctr. For Integrative Neuroscience, Uni Tuebingen, Tuebingen, Germany

Abstract: Neural activity in the sensory cortex is modulated by behavioral state, which can affect the strength of the neuronal response as well as the state of the local network. Such modulation involves - in part - the action of neuromodulators such as noradrenaline, acetylcholine and serotonin. We previously reported that in the primary visual cortex (V1) of awake macaques, serotonin (5HT) reduces the spiking activity by decreasing response gain without changing neuronal selectivity (Seillier, Lorenz et al., 2017). The effect of serotonin on the local network state is however not understood. To gain insights into the role of serotonin in modulating the local network state, we simultaneously recorded single unit activity (70 units) and local field potentials (LFP) in V1 of macaque monkeys performing a standard fixation task while we presented them with briefly flashed grating stimuli inside the neurons' receptive fields. To examine the modulatory effect on the local network state we applied serotonin (10mM; pH=3.5) or pH-matched saline as a control via iontophoresis. We observed that serotonin ($p < 0.001$, $n = 53$), but not saline ($p = 0.94$, $n = 17$), decreased the power of the LFP, especially in the low frequency (<10 Hz) range. To examine the dependence of the spiking activity on the local network activity as measured by the LFP, we used two metrics. First, we quantified the amplitude of the spike-triggered LFP (stLFP), which has previously been used to infer functional connectivity. Since this metric depends on the power of the LFP, we also used a model-based approach to infer functional connectivity. For each unit we quantified how well the spiking activity could be predicted by the simultaneously recorded LFP using a factored spike-triggered Gaussian mixture model (STM, Theis et al., 2016). Applying serotonin decreased the amplitude

of the stLFP ($p<0.001$) and rendered the spikes less predictable from the LFP ($p<0.001$), suggesting that it decreased the local functional connectivity. Such changes did not occur for the pH-matched saline control condition and could not be accounted for by the observed changes in firing rate. Taken together, we found that the serotonergic effects on the local network state were reduced low-frequency power of the LFP as well as decreased local functional connectivity in V1 of awake macaques. Interestingly, these effects on the local network state paralleled those previously reported for spatial attention (Chalk et al., 2010), raising the possibility of a serotonergic involvement in spatial attention at the level of visual processing.

Title: Combined visual and patterned optogenetic stimulation of ferret visual cortex reveals that cortical circuits may work in the supralinear stabilized network regime

Authors: *S. WANG[1], K. D. MILLER[2], S. D. VAN HOOSER[1];
[1]Biol., Brandeis Univ., Waltham, MA; [2]Cntr Theoretical Neurosci, Columbia Univ., New York, NY

Abstract: A recently proposed theory, the *supralinear stabilized network (SSN)*, has shed light on how canonical computations may be implemented in neural circuits. The SSN shows that, given supralinear neuronal input/output functions, network stabilization requires that recurrent input largely cancel or "loosely balance" feedforward input. This leads to sublinear summation of responses to multiple stimuli. However, for weak stimuli, little or no stabilization is needed and response summation becomes linear or supralinear. Across multiple visual cortical areas, responses to presentation of multiple stimuli are typically closer to the average than the sum of the responses to the individual stimuli, that is, response summation is sublinear (except for very weak stimuli). In most cases, it is not clear whether the sublinear summation is created by the local cortical circuit or is already present in the inputs to that circuit. Combining visual and nonspecific optogenetic stimuli, previous studies found sublinear summation in monkey V1 and linear summation in mouse V1. Here we directly test a cortical component to the sublinearity by using patterned optogenetic stimuli to drive different sets of cortical neurons, or combined visual and optogenetic stimuli. Both methods should provide independently driven inputs to cortex and

allow isolation of the cortical circuit's summation properties. Preliminary results showed that simultaneous optogenetic stimulation targeting independent orientation columns produced sublinear response summation. Combined visual and patterned optogenetic stimulation also elicited sublinear responses. We also found that even though optogenetic inputs were local to specific orientation columns, the resulting neural responses did not respect orientation column boundaries. More importantly, the optogenetic stimulation of inhibitory cells revealed inhibition-stabilization-network type of responses, along with other distinct types of responses from inhibitory cells. These results show that the cortex integrated inputs sublinearly and support the hypothesis that sensory cortex operates in the SSN regime, though incorporation of multiple inhibitory cell types into the SSN model is needed to explain the various types of inhibitory cells' responses.

Title: Impact of experience on tuning diversity and natural scene discriminability in primary visual cortex

Authors: P. L. STAN[1], J. E. KAUTTONEN[2], B. JEON[3], T. FUCHS[2], S. M. CHASE[3], T. LEE[4], ***S. J. KUHLMAN**[2];

Abstract: Optimal encoding of visual scenes requires early-life visual experience. One strategy to determine how experience enhances vision is to identify the specific response features that are modulated by experience to improve natural scene encoding. Our goal was to determine whether experience improves encoding of natural scenes by refining Gabor-like response properties versus directly increasing sensitivity to natural scene features in animals reared under different sensory conditions. We performed large field of view calcium imaging of excitatory neurons in primary visual cortex (V1) in awake standard- and dark-reared mice, as well as mice with delayed-visual experience. The ability of functionally defined neurons to discriminate similar

and dissimilar natural scenes was assessed. We found standard rearing experience improves the encoding of natural scenes in V1 by shifting neural preference away from Gabor-like simple edges towards more complex features present in natural scenes. The net impact of standard experience was a counter-intuitive decrease in neural responses to simple edges. Animals exposed to light after being deprived of vision during postnatal development failed to accurately encode similar natural scenes. Rather than refining the Gabor-like distribution of tuning in V1, our results indicate that early experience improves scene discrimination by enhancing sensitivity to features specifically present in natural scenes.
Examination of the Gabor-like distribution revealed that experience re-shaped the population distribution of orientation preferences such that cardinal axes were over-represented, as expected. We also detected a modest net sharpening of orientation tuning across the population. However, in contrast to the shift towards complex natural scene features, refinement of the Gabor-like distribution was not predictive of discrimination performance on an animal-by-animal basis. Our results support a model in which experience-dependent development of natural scene encoding in V1 is dissociable from that of refining the representation of simple edges and does not rely on increased sensitivity to gratings of high spatial frequencies.

Title: Synaptic mechanisms underlying rapid adaptation in mouse visual cortex

Authors: *J. Y. LI, L. L. GLICKFELD;
Neurobio., Duke Univ., Durham, NC

Abstract: Adaptation is a fundamental feature of visual processing that enables the nervous system to adjust to features of our surrounding environment. Previous studies have largely used stimuli presented for tens of seconds to identify mechanisms underlying adaptation in V1. However, the statistics of natural scenes and the time scale of saccadic eye movements suggest that in most animals, visual input is constantly changing at much higher rates. Indeed, in previously published work, our lab has shown that neurons in V1 can adapt to a stimulus presented for 100 ms (Jin et al., 2019). Thus, we sought to identify mechanisms contributing to adaptation in V1 at naturalistic time scales. To do this, we performed *in vivo* whole-cell

recordings in primary visual cortex of awake mice and measured stimulus-evoked EPSCs and IPSCs in putative layer 2/3 pyramidal neurons. We compared currents evoked by pairs of brief 100 ms static gratings separated by inter-stimulus intervals ranging from 250 ms to 4 s. Consistent with studies of rapid adaptation in somatosensory and auditory cortices, we find that brief stimulus presentation leads to a reduction in stimulus-evoked excitatory and inhibitory inputs (n=11 cells). Interestingly, we observe slightly less adaptation of inhibition than excitation, opposite from what is seen in those other cortical areas, potentially prolonging the time course of adaptation. Generally, these inputs recover on a similar time course to the spike output of these neurons, which suggests that the lasting suppression of responses in V1 is primarily influenced by the suppression of the inputs that cells receive. This is in contrast to a previously identified mechanism of slow contrast adaptation in V1 where suppression of spike output is largely mediated by a tonic hyperpolarization. Our data indicate that suppression of stimulus-evoked excitation and inhibition is conserved across sensory cortical areas for similar time scales of adaptation and that within a single sensory area, different time scales of adaptation could engage distinct mechanisms to suppress spike output. Future experiments will assess the degree to which synaptic depression or network mechanisms could contribute to these changes in synaptic input.

Title: Cellular representation of visual recognition memory in the mouse primary visual cortex

Authors: ***T. KIM**[1], M. T. HARNETT[2], M. F. BEAR[1];
[1]Picower Inst. for Learning and Memory, [2]Mcgovern Inst. for Brain Res., MIT, Cambridge, MA

Abstract: Brief daily exposure to a phase-reversing grating stimulus increases the magnitude of associated visual-evoked potentials (VEPs) in mouse V1 layer 4, a phenomenon termed stimulus-selective response potentiation (SRP). SRP is induced in V1 by mechanisms shared with canonical long-term potentiation (LTP) and is accompanied by behavioral habituation to the familiar stimulus. Both SRP and the behavioral readout of visual recognition memory are sensitive to molecular manipulations restricted to V1. In the present study, we investigated the cellular activity changes associated with the induction and expression of SRP using longitudinal calcium imaging of layer 4 excitatory neurons in V1. Using two-photon microscopic calcium

imaging, we found no significant net change in the population of active neurons during the familiar (learned) stimulus presentation. However, endoscopic calcium imaging revealed a robust reduction of calcium responses elicited by phase-reversals of the familiar visual stimulus and a strong within-session habituation. Despite this dramatic plasticity of responses to phase-reversing gratings, we found no changes in the response to unfamiliar drifting grating stimuli of the same orientation, underscoring the exquisite selectivity of SRP. Combined with previous work, our findings suggest that potentiation of short-latency visually evoked potentials (VEPs) to familiar visual stimuli reflects increased feed-forward activation of V1 but likely recruits feedback inhibition to suppress sustained cellular responses in layer 4 neurons.

Title: Cross-species analysis of mismatch negativity responses in primary visual cortex of mice and ferrets

Authors: *T. SIKKENS, L. M. F. KLAVER, M. A. MULLER, C. M. A. PENNARTZ, C. A. BOSMAN, U. OLCESE;
Cognitive and Systems Neurosci. Group, Univ. of Amsterdam, Amsterdam, Netherlands

Abstract: Mismatch negativity (MMN) is a brain's response to violations of a rule, which is established by regularities in the sensory environment. Following the predictive coding framework, these regularities allow the brain to construct predictions on sensory inputs, where unpredicted sensory changes elicit error or mismatch signals. MMN is typically studied in humans using an oddball paradigm, in which a specific stimulus is being presented repeatedly (standard) but is sometimes changed for a different stimulus (deviant). The MMN response consists of two components: 1) one that can be explained purely by stimulus specific adaptation (SSA), a process caused by the repeated presentation of the same input to the (sensory) system, and 2) a true deviance detection (DD). Previous studies in mice have shown that SSA and DD operate in different time windows and may involve distinct cortical networks. Although mice are

an increasingly common animal model in visual neuroscience, their visual system is distinct from other mammals such as carnivores and primates. It is unknown whether responses to visual mismatch stimuli differ between mice and other mammals. To address this issue we compared mismatch responses in mice and ferrets, whose visual system more closely resembles that of humans.
We performed electrophysiological recordings in primary visual cortex (V1) of head-fixed mice and ferrets using 32 channel laminar probes. During recordings, passively viewing animals were presented with a visual oddball paradigm where the orientation of a presented stimulus changes from standard to deviant. We identified how local fields potentials and single units respond to the different stimuli. We also examined how these responses adapt to stimulus change or stimulus repetition and how these responses compare between mice and ferrets.
We find clear MMN responses in both mouse (n = 8 animals) and ferret (n = 3 animals) visual cortex. Moreover, response parameters such as the timing and amplitude of event related potentials are similar between mice and ferrets. Both species show distinct epochs in which SSA and DD occur, with SSA occurring in earlier (35-120 ms) and DD in later (120-240 ms) time windows. This is consistent with previous reports in mice. Ongoing analysis focuses on similarity of laminar activity profiles and neuronal firing patterns in the two species. These results provide novel insight into the (dis)similarities of cortical mismatch responses in different mammalian species.

Title: Contribution of receptive field center and surround to repetition suppression in macaque visual area V2

Authors: *N. P. WILLIAMS, C. R. OLSON;
Ctr. for the Neural Basis of Cognition, Biol. Sci. Dept., Carnegie Mellon Univ., Pittsburgh, PA

Abstract: Monkey inferotemporal cortex (ITC) neurons respond with declining strength to repeated presentations of a large and complex natural image. This phenomenon - repetition suppression - has often been assumed to arise at the level of ITC because ITC neurons possess

the large receptive fields and sophisticated stimulus selectivity necessary for recognizing the image as a repetition. However, we recently discovered that neurons in V2 exhibit repetition suppression under conditions identical to those employed in studies of ITC (Williams and Olson, 2018, Neuroscience Meeting Planner, Program No. 397.08). This raises the question: How do V2 neurons, with classical receptive fields encompassing only a small fraction of the image, recognize it as a repetition? One possibility is that they are sensitive to repetition of image content not only in the classical receptive field but also in the receptive field surround. To assess this possibility, we monitored neuronal responses to sequential displays in which we controlled independently the repetition of elements in the classical receptive field and in the surround. Each stimulus consisted of a disk scaled to and centered on the classical receptive field and an adjoining annulus with an outer diameter of 8°. The disks and annuli were taken from different natural scenes. The typical receptive field had a diameter of 2° and was located at 5° eccentricity in the lower contralateral visual field. The display on each trial consisted of a prime, a delay and a probe, each 300 ms in duration. Across trials, we independently varied the relation of the probe to the prime with respect to identity of the center component (same or different) and the surround component (same or different). Upon analyzing data from 46 neurons (23 in monkey O and 23 in monkey R), we found that repetition of the central disk was sufficient to produce repetition suppression but that suppression was enhanced by simultaneous repetition of the annulus. Suppression arising from repetition of the annulus occurred in a relatively late phase of the response, beginning around 100 ms after stimulus onset, in accordance with the idea that it might have been mediated by horizontal connections in V2 and/or feedback from downstream areas of higher order. The contribution of the surround to repetition suppression cannot be explained in terms of adaptation as characterized in classical grating-based experiments. Repetition of surround content in the current paradigm leads to reduced response strength whereas repetition of surround content in grating-based adaptation experiments leads to enhanced response strength (Wissig and Kohn, 2012, J.Neurophysiol. 107: 3370-3384).

Title: Cholinergic enhancement of visual conditioning on cortical activity mapping

Authors: *G. LALIBERTÉ, E. VAUCHER;
Univ. of Montreal, Montreal, QC, Canada

Abstract: Visual conditioning can refine the response and connectivity of neurons in the visual cortex and higher associative areas. The cholinergic system could play a role in this tuning, given its important modulatory influence in attention. Our goal is to determine the effect of the cholinergic potentiation on a one-week daily visual conditioning. This was assessed by studying changes on cortical visual responses using wide-field calcium imaging in awake adult (P60-90) transgenic mice. C57BL6 Thy1-GCaMP6s mice were used to assess the neuronal activity in the superficial layers of the primary visual cortex (V1), some secondaries visual areas (PM, RL, AM, A, AL, LM) and the retrosplenial cortex (RS). Cortical activity, latency of the peak response, and size of cortical activation were measured at rest and in response to conditioned or non-conditioned stimuli. The conditioning consisted of drifting gratings, oriented at 30° with 100% contrast (0.03 cpd, 1 Hz), presented daily to head-fixed mice for 10 minutes for a week. The response to monocular stimulation at 3 different contrasts (50, 75 and 100%) and 2 different orientations (30° and 90°, 0.03 cpd) were compared before and after visual conditioning. To evaluate the influence of the cholinergic system, donepezil (0,3mg/kg), a cholinesterase inhibitor, or saline was injected prior to each conditioning session. Naive animals elicited similar cortical responses in terms of strength and contrast sensitivity for the 2 orientations presented (30° and 90°). In the V1 of the DPZ group, results showed a significant decrease in evoked neuronal activity (43%) and latency of peak response (18%) for the conditioned stimulus. Inversely, the latency of peak response was increased for the non-conditioned orientation at lower contrast (50 and 75%). The PM region of the DPZ group showed a decrease of 46% in neuronal activity for the trained orientation compared to the pre-conditioning values. Similarly, the DPZ group showed a decrease in contrast sensitivity for multiple areas of the cortical visual pathway (V1, RS, A, A, and AL). Although we expected a DPZ-induced potentiation of the conditioned responses, based on previous studies in layer 4 of V1, the effect measured here in layer 2-3 rather shows a reduced amplitude and spread of the responses. This could be explained by the interactions of the cholinergic system with local microcircuits, particularly GABAergic neurons, that differ across layers.

Title: Spatiotemporal dynamics of brightness coding in human visual cortex revealed by the temporal context effect

Authors: *H. ZHOU[1], M. DAVIDSON[2], P. KOK[3], L. MCCURDY[4], F. P. DE LANGE[5], H. LAU[6], K. SANDBERG[7];

Physiol., Yale Univ., New Haven, CT; [5]Radboud Univ. Nijmegen, Nijmegen, Netherlands; [6]Dept. of Psychology, Los Angeles, CA; [7]Aarhus Univ. Hosp., Aarhus C, Denmark

Abstract: Human visual perception is modulated by both temporal and spatial contexts. One type of modulation is apparent in the temporal context effect (TCE): In the presence of a constant luminance patch (a long flash), the perceived brightness of a short flash increases monotonically with onset asynchrony. The aim of current study was to delineate the neural correlates of this illusory effect, particularly focusing on its dynamic neural representation among visual cortical areas. We reconstructed sources of magnetoencephalographic (MEG) data recorded from observers (6 male and 9 female human adults) experiencing the TCE. Together with retinotopic mapping, signals from different occipital lobe areas were extracted to investigate whether different visual areas have differential representation of the onset vs. offset synchronized short flashes. From the data, TCE related responses were observed in LO and V4 in the time window of 200-300 ms, while neuronal responses to physical luminances were observed in the early time window of 100-150 ms across early visual cortex, such as V1 and V2, also in V4 and VO. Based on these findings, we suggest that two distinct processes might be involved in brightness coding: one bottom-up process which is energy driven and responds fast, and another process which may be broadly characterized as top-down or lateral, is context driven, and responds slower. For both processes, we found that V4 might play a critical role in dynamically integrating luminances into brightness perception, a finding that is consistent with the view of V4 as a bottom-up and top-down integration complex.

Title: Following neural response against 15Hz blinking light stimuli in goldfish's optic-tectum

Authors: *A. FUNASE[1], Y. SUZUKI[1], S.-E. FUJIWARA[2], S. MIKI[3], I. TAKUMI[1], Y. HIRATA[4];
[1]Nagoya Inst. of Technol., Nagoya, Japan; [2]Dept. Physiol. St. Marianna Univ. Sch. Med., Kawasaki, Japan; [3]Chubu Univ., Kasugai, Aichi, Japan; [4]Chubu Univ. Col. of Engin., Aichi, Japan

Abstract: [Purpose] Our final goal is to the brain function of the Steady-state visual evoked potential (SSVEP). In this study, we focus on the relationship between neural activities and a visual stimulus for the SSVEP. We describe neural activity in the optic-tectum when we show a blinking light stimulus (blinking frequency: 15 [Hz] and 1 [Hz]) to goldfishes. We discuss the following neural response against blinking light stimuli.[Method] We set a white LED in front of the eye so that the eye presented the blinking stimulus. The action potential is recorded in the dark room. the blinking white LED is presented to a goldfish for 60[sec]. The blinking frequency is 1 [Hz] and 15 [Hz]. Action potentials of two goldfishes are recorded in the optic-tectum and action potentials are obtained on 16 positions. 46 units are obtained by the spike sorting. We make a histogram of firing rate (Bin size: 5 [msec]). Separated units are categorized into three categories (on-response unit, off-response unit, and on- and off-response unit). The on-response unit is the unit which has firing rate over 2 SD(standard deviation) only during the lighted time. The off-response unit is the unit which has a firing rate over 2 SD only during the non-lighted time. The on/off-response unit is the unit which has firing rate over 2 SD during the lighted time and during the non-light time. The NULL-response unit is the unit which does not have a firing rate over 2 SD during the lighted time and during the non-light time.[Results and Discussion] We obtained units related to presenting a blinking light stimulus. In 1 [Hz] blinking stimulus, 5 on-response units are obtained, 10 off-response units are obtained, and 31 on/off-response units are obtained. In 15 [Hz] blinking stimulus, 8 on-response units are obtained, 20 off-response units are obtained, and 18 NULL-response units are obtained. 31 on/off-response units in 1 [Hz] blinking stimulus changed into 6 on-response units, 17 off-response units, and 8 NULL-response units in 15 [Hz] blinking stimulus. From these results, neurons in optic-tectum have the following neural response against 15 [Hz] blinking light stimuli and most on/off-response units in 1 [Hz] blinking stimulus change into off-response units in 15 [Hz] blinking stimulus.

Title: Monocular and binocular components of contrast gain control in primate V1

Authors: L. PALMIERI, *B. G. C. CUMMING;
Natl. Eye Institute, NIH, Bethesda, MD

Abstract: We studied the effect of interocular contrast differences on the disparity selectivity of neurons recorded extracellularly from V1 of awake fixating monkeys. We presented random dot stereograms at different disparities under four contrast conditions: 1) High contrast (>99%) in both eyes (HH) 2) Low Contrast (20%) in both eyes (LL) 3) High contrast in the dominant eye, low contrast in the non-dominant eye (HL) 4) the reverse (LH). In the binocular energy model with no contrast gain control, conditions LH and HL reduce the extent of disparity modulation by a factor of 5 (proportional to the contrast). However, the response to binocularly uncorrelated patterns (baseline) is only halved, so the signal to noise ratio becomes poorer. If the monocular gain is increased by a factor of 5 (exactly compensating for the contrast reduction), the disparity tuning curve is identical to that for HH. Changes in gain control after binocular summation affect baseline and modulation equally. We exploit the fact that monocular and binocular gain changes have different effects on baseline and modulation depth to estimate changes in monocular and binocular gains. We estimate the slope and offset the relationship between the HH and LH tuning curves (type II regression) and find the values of monocular and binocular gains in the model that reproduce these. As already reported in the cat (Truchard et al, 2000), we find that increases in monocular gain are larger than binocular gain (paired t-test, $p < 0.01$, $n = 34$ samples from 17 cells). We also find a correlation between monocular gain changes for the dominant and nondominant eye (Pearson correlation = 0.54, $p < 0.05$). There is considerable heterogeneity in the strength of monocular contrast gain control between neurons. The correlation of gain modulation strength between the two eyes identifies a new property that appears to be matched across eyes in binocular neurons. Although correlated, monocular contrast gain changes were significantly larger in the non-dominant eye that the dominant eye. This result raises that intriguing possibility that ocularity measures reflect not just the relative strength of excitatory drive from the two eyes, but also reflect the strength of contrast normalization driven from each eye, with the ‘non-dominant’ eye characterized by a stronger contrast normalization. In human observers, contrast differences (HL or LH) reduce stereoacuity relative to LL. Two features or our data can explain this. First, changes in monocular gain only partially compensate for the contrast changes. Secondly, there is often a significant increase in binocular gain. Therefore, a simple mechanism may explain this paradoxical phenomenon.

Title: A model of efficient coding for motion without ambiguity in cortical area MT

Authors: N. A. LINGAREDDY[1], B. LIU[3], L. C. OSBORNE[4], *S. E. PALMER[2];
[1]Computer Sci., [2]Univ. of Chicago, Chicago, IL; [3]Neurosci. Dept., Duke Universtiy, Durham, NC; [4]Neurobio., Duke Univ., Durham, NC

Abstract: Sensory adaptation can shift the response properties of neurons so that efficient coding for the full range of inputs is maintained. Adaptive changes have been observed in the firing rates and the gain of neurons in response to changes in stimulus properties such as the mean and variance. These adaptation mechanisms in visual areas like the retina operate over a range of timescales. Recent experiments from Liu and Osborne have shown that neurons in the middle temporal visual area of the primate cortex (area MT) respond to fast and slow input fluctuations by independent mechanisms - they modulate their firing rate without changing their response gain (the change in firing rate per change in direction) and vice versa. We use a conductance-based integrate-and-fire model to explore the mechanistic underpinnings of these results. By adding stimulus-dependent firing-rate adaptation to a network model, we can show that the response gain rescales without changing the mean response rate. Adding spike-rate adaptation to the model can help set the mean input noise levels that are required to attain such rescaling of the gain without fine-tuning. This simple model also reproduces observed asymmetric changes in MT responses when the input signal changes from high to low variance versus low to high. Tuning curve shapes also change in response to constant stimulation as a function of motion direction. Our model may also help explain these tuning shift, which have also been observed in other visual areas, such as V1.

Title: Efficiency without ambiguity: An adaptive sensory code in cortical area MT

Authors: B. LIU, ***L. C. OSBORNE**;
Neurobio., Duke Univ., Durham, NC

Abstract: A sensory neuron's response to its inputs depends on recent history. Adaptive changes in input-output functions increase coding efficiency, but they also appear to create an ambiguous mapping between stimulus and response. Here we show that cortical sensory neurons maintain both an efficient and unambiguous stimulus representation by encoding fast and slow timescale stimulus changes via independent information channels. We recorded visual motion selective neurons in area MT responding to coherent optic flow. Dot patterns had a constant speed, and direction that fluctuated stochastically at a timescale shorter than the neural integration time (20ms) around a mean direction that changed on a longer timescale (>100ms). We configured the stimuli such that the mean drive to the neuron did not change as a function of variance level in order to disambiguate the responses to different stimulus features. We find that the variance of fast stimulus fluctuations is encoded efficiently through rapid multiplicative rescaling of response gain, without changes in firing rate. In contrast, firing rate dynamics are insensitive to short time scale motion fluctuations (stimulus variance), but do encode information about the mean stimulus value. Fast and slow adaptation processes add linearly to determine the instantaneous neural response. Independent information channels allow neurons to optimize sensitivity to fast stimulus fluctuations without creating ambiguity about the mean over longer periods. We present a mechanistic model of spiking probability based on feed-forward excitatory drive and balanced excitatory and inhibitory recurrent inputs to account for the data, demonstrating how the brain can encode, and decode, sensory information efficiently and unambiguously.

Title: Pulvinar mediates the oscillatory transmission across low to high hierarchical cortical areas

Authors: *N. CORTES[1], B. SOUZA[2], C. F. CASANOVA[1];
[1]Univ. de Montréal, Montréal, QC, Canada; [2]Anatomie, Univ. du Québec à Trois Rivières, Québec, QC, Canada

Abstract: Cortical activity across the visual hierarchy has different oscillatory ranges. While 25-90 Hz gamma band from supragranular layers influences the feedforward processing, 6-13 Hz alpha band from infragranular layers travels in the feedback direction. However, we have limited understanding of how this cortical communication depends on transthalamic pathways, in particular from the primary visual cortex (V1) to other levels of the visual cortical hierarchy. Here, we investigated how the cortical oscillatory coupling across V1 and area 21a depends on transthalamic pathways by inactivating pharmacologically the pulvinar in cats. Extracellular responses to full-field 100% contrast gratings were recorded in cortical areas 17 and 21a, from anesthetized cats using linear probes before, during and after GABA injection in the pulvinar. Local field potentials, from low-pass filtering of raw recordings, were analyzed with Wavelet and Granger causality tools to determine the oscillatory coupling between cortical layers. Cortical oscillatory activity was enhanced during pulvinar inactivation. In area 17, alpha and gamma bands significantly increased in layers IV, V, and IV. In area 21a, all layers, except layer I, enhanced their oscillatory activity, especially in layer IV with gamma oscillations. Granger causality showed that the pulvinar inactivation caused an enhancement of feedforward gamma waves from area 17 (layer III) to area 21a (layer IV). For the feedback coupling, alpha waves rose from area 21a (layer V) to area 17 (layers III, V, and VI). Our findings suggest that, during visual stimulation, the pulvinar mediates the feedforward gamma band from areas 17 (layer III) to 21a (layer IV). Furthermore, the pulvinar regulates the feedback alpha band from layer V in area 21a to layers II, V, and VI in area 17. Together, these findings provide a possible mechanism underlying feedforward and feedback oscillatory processing throughout the visual cortical hierarchy.

Title: Dynamic functional influence of corticothalamic pathways on first- and higher-order visual thalamus

Authors: *M. A. KIRCHGESSNER[1,2], A. D. FRANKLIN[3,1], E. M. CALLAWAY[1,2];
[1]Salk Inst. for Biol. Studies, La Jolla, CA; [2]Neurosciences Grad. Program, [3]UC San Diego, La Jolla, CA

Abstract: The nature of corticothalamic feedback is a topic of significant interest but little consensus. While previous optogenetic studies in mice have shown that layer 6 corticothalamic (L6CT) neurons in V1 have a net-inhibitory influence over first-order visual thalamus dLGN (Olsen et al., 2012; Denman & Contreras, 2015), slice experiments in the somatosensory system have demonstrated that this can switch to net-facilitation when driven by a 10Hz train (Crandall et al., 2015). Whether these frequency-dependent effects are also discernible in the visual system *in vivo* has not been tested. Moreover, how L6CTs influence higher-order thalamic nuclei, such as the rodent lateral posterior (LP) nucleus, *in vivo* is completely unexplored. Here, we utilize optogenetics in Ntsr1-Cre transgenic mice to selectively manipulate L6CTs in V1 while recording single-unit activity with microelectrode arrays in LP and dLGN as well as the inhibitory thalamic reticular nucleus (TRN) of awake mice viewing drifting gratings. First, we find that sustained L6CT photostimulation with channelrhodopsin largely suppresses visually-evoked and spontaneous activity in dLGN (as has been shown before), and similar inhibition is also observed in LP. However, optogenetic activation of L6CT neurons at 10Hz facilitates activity in both dLGN and LP; this provides the first demonstration of dynamic, frequency-dependent L6CT pathways *in vivo.* Additional experiments probing the mechanism of these effects support the interpretation that L6CTs' influences over their visual thalamic targets are mediated by a balance of direct, facilitating excitation and indirect, depressing inhibition from TRN. Optogenetic inactivation experiments further indicate that these dynamically opposing pathways subserve a fundamentally "modulatory" role for L6CTs in both dLGN and LP. Ongoing studies are probing how layer 5 corticothalamic (L5CT) projections influence LP and whether they exhibit similar or complementary frequency-dependent characteristics. Overall, this work illustrates the dynamic nature of corticothalamic pathways *in vivo* and how their circuitry

allows for tremendous flexibility and a wide range of influence that may promote adaptability to different contextual and behavioral constraints.

Title: Morphology of the projection of the visual cortex to the claustrum in the mouse: A single axon study

Authors: *E.-M. FRIGON, J. ROY, D. BOIRE;
Univ. Du Quebec A Trois-Rivieres, Dept. d'anatomie, Trois-Rivieres, QC, Canada

Abstract: The claustrum is a subcortical telencephalic structure present in all mammals. It is widely and reciprocally interconnected with the entire cerebral cortex. Stimuli from all sensory modalities elicits responses in claustrum neurons and some studies report multimodal responses in the claustrum. It has been proposed that the claustrum is a site of multisensory integration and involved in the generation of conscious percepts. This led to the proposal that sensory representations would overlap. The claustrum in mice exhibits a clear dorsoventral organisation of sensory cortical projections. There is also a significant overlap of sensory domains. Presently, there are no study of the cortical projections to the claustrum at the single axon level. Iontophoretic injections of *Phaseolus vulgaris* leucoagglutinin were performed in the primary visual cortex of adult C57BL/6J mice. A triple immunohistochemistry of Phaseolus, myelin binding protein and neuronal specific NeuN has been done to reconstruct individual axons of the projections from the primary visual cortex to the claustrum using Neurolucida 360 (MBF Biosciences).
These projections were shown in the ipsi- and contralateral claustrum. They were found in the central region along the dorsoventral axis of the claustrum. Individual axons entered the claustrum from caudal levels and traveled for significant distances within the claustrum. Axons were poorly branched along this trajectory expect in some areas where more significant branching was observed. Some collaterals of the main axon branched out, traveled more ventrally and returned to a linear rostral directed trajectory. This suggests that axonal branches of the visual projection to the claustrum leave the visual domain to branch out into parallel domains of other sensory modalities. The local arborisations might suggest smaller modules within the

longitudinal organization of the claustrum. Moreover, the absence of myelin throughout the structure is observed.

Title: On-afferent inhibition underlies stronger V1 responses to dark

Authors: *D. ST-AMAND[1], *C. L. BAKER[2];
[1]McGill Vision Res., McGill Univ., Montreal, QC, Canada; [2]Ophthalmology, McGill Vision Res. Unit, Montreal, QC, Canada

Abstract: The primary visual cortex (V1) receives excitation and inhibition from two distinct retinogeniculate pathways, processing lightness (ON) and darkness (OFF). V1 neurons are more strongly driven by dark than by light stimuli (Jin et al, 2008; Yeh et al, 2010; Kremkov et al, 2013), but it has been unclear to what extent this is due to excitation from the OFF pathway or inhibition from the ON pathway. The goal of this study is to disambiguate excitation and inhibition from both pathways on a large sample of single neurons, by training customized machine learning algorithms to predict their responses to complex stimuli. We record single-unit responses of V1 neurons to natural images, in anesthetized and paralyzed cats, using spike-sorting (Swindale & Spacek, 2014) of signals from multi-channel polytrodes. We then employ a biologically inspired convolutional neural network which separately processes stimuli that are locally above (ON) and below (OFF) the mean luminance. Rectified responses of parameterized 2D Gaussian filters are utilized to mimic lateral geniculate nucleus (LGN) neurons. Excitatory and inhibitory inputs from these ON and OFF pathways combine in a weighted summation, to generate the predicted cortical neuron response. Parameters of this model are optimized in TensorFlow, to best predict a training dataset, with separate holdback datasets for validation (early-stopping) and testing performance. Analysis of 74 simple-type cells shows responses are more strongly driven by dark than by light stimuli, consistent with previous studies (Yeh et al, 2010; Kremkov et al, 2013). Since layer 4 of primary visual cortex receives more input from the OFF than from the ON pathway (Jin et al., 2008), one might have expected this “dark-dominance” to arise from excitation via the OFF pathway. Surprisingly, we instead find the dark-dominance to be driven by relatively greater inhibition from the ON pathway. In addition, we find excitation and inhibition from the OFF pathway to be, on average, approximately balanced.

Inferring the inputs from ON and OFF pathways to primary visual neurons using machine learning provides an opportunity to ask new questions about excitatory and inhibitory integration in cortical neurons.

Title: Spatiochromatic processing in adults who had childhood unilateral amblyopia

Authors: M. A. KLASSEN[1], H. D. J. HATHARASINGHAGE[2], A. R. CRAIG[1], C. S. CHISHOLM[1], C. BEADLE[1], ***M. F. WESNER**[3];
[1]Psychology, [2]Biol., [3]Lakehead Univ., Thunder Bay, ON, Canada

Abstract: Unilateral amblyopia is a visual developmental disorder characterized by a monocular decrease in visual performance usually associated with signal processing miscorrelations between the affected and the non-affected, fellow eye. Generally, it is believed that higher-ordered visual pathway operations in the CNS suppress the less effective ocular signals in favour of the better functioning fellow eye. The extent of dysregulation as it relates to the pathway hierarchy, however, is poorly understood (e.g., Wong, 2014). For example, studies have identified impairments in visual acuity, perimetry, form, face, color, and motion perception, yet these specific functional investigations often overlook a more extensive, global dysregulation that can include cortical compensation for lower-level pathway deterioration (Hamm et al., 2014). To examine possible hierarchical changes in adult amblyopes, we psychophysically measured perimetric thresholds of the retinal cones and the spatiochromatic, post-retinal contrast sensitivities (CS) of the parvocellular (PC) and the koniocellular (KC) streams for both the dominant (DE) and non-dominant (NDE) eye. Traditional automated perimetry assessed the sensitivities of the long- (L) and middle- (M) wavelength cones; Short-wavelength automated perimetry assessed the more disease vulnerable short-wavelength (S) cone sensitivities. Spatiochromatic CS was determined using isoluminant, heterochromatic gabors of varying spatial frequencies along "red-green" (R/G) or "blue-yellow" (B/Y) opponent CIE axes to achieve maximal PC or KC responsivities, respectively. Of the 30 participants (age 18-42; M = 23.7, SD = 6.2), 20 were Controls (14 female) and 10 were child-diagnosed unilateral amblyopes (8 female). Participants were screened for acute or chronic vision disorders, near visual acuity and color vision deficits. DE and NDE sensitivity differences across central (0-6°) and peripheral

(10-22°) zones were found. Most notable were with the Amblyopes who showed substantially higher L- and M-cone DE sensitivities, but higher S-cone NDE sensitivities, particularly at the temporal retinal zones. Interestingly, post-retinal CS showed the largest shifts with presentations of the B/Y gabors where the amblyopic DE showed a >1 log unit gain over the NDE and over both eyes of the Controls. Finally, the DE of Amblyopes had higher CS than Control DEs. We discuss these findings in terms of retinal circulation patterns, KC gain compensations and interocular transfer effects. Our findings support a more global, feedforward and feedback dysregulatory influence in adults who have experienced pediatric unilateral amblyopia.

Title: Late dark rearing disrupts axis selectivity in the mouse thalamus and primary visual cortex

Authors: *C.-E. STEPHANY[1], J. D. REGGIANI[2], N. PICARD[1], M. FAGIOLINI[1], C. CHEN[1]; [1]Neurol., F.M. Kirby Neurobio. Center, Boston Children's Hosp., Boston, MA; [2]Harvard University, Program in Neurosci., Boston, MA

Abstract: Critical periods are brief windows during development when circuits in the brain can be altered by experience. In the visual system, monocular deprivation during the critical period in primary visual cortex (V1) alters the circuitry underlying ocular dominance. Recently, the Chen lab has defined a thalamic critical period when visual deprivation by dark rearing between postnatal day (P) 20-P30 (Late Dark Rearing; LDR) triggers a recruitment of weak retinal inputs onto neurons in the dorsal lateral geniculate nucleus (dLGN). The timing of cortical and thalamic critical periods overlaps, but how LDR affects visual feature selectivity in these structures is unknown. Here, we employed extracellular electrophysiology to measure changes in receptive field properties in both the dLGN and V1 in response to LDR.
In the dLGN, we found that increased retinal convergence by LDR did not affect receptive field size, but was associated with a decrease in axis selectivity and linearity. This supports the idea

that the refinement of retinal inputs enhances feature selectivity in post-synaptic dLGN neurons. In V1, both the spontaneous and evoked firing rates of putative inhibitory neurons were higher in response to LDR compared to normally reared (NR) controls, but remained unchanged in putative pyramidal neurons (Pyr). Thus, paradoxically, the median axis selectivity of Pyr across V1 increased with LDR and a laminar analysis revealed that the largest increase was in the subgranular layers (L5/6). We next tested whether disrupted feature selectivity in V1 in response to LDR is transient or persistent by returning mice to normal housing for 4-6 weeks after LDR (LDR+recovery) and subsequently recording at P60-P70. While firing rates in LDR+recovery mice returned to baseline, the median axis selectivity in Pyr was significantly lower when compared to NR controls. These data demonstrate that the dLGN and V1 respond differently to LDR and are consistent with our working hypothesis that changes in cortical activity feeds back to the dLGN to disrupt retinogeniculate convergence, ultimately reducing axis selectivity in both dLGN and V1. Future work will test this hypothesis by examining the temporal sequence of circuit changes in the two structures in response to LDR.

Title: Perceptual similarity arises from center-surround interactions

Authors: E. F. W. BOWEN, E. CHILDERS, A. RODRIGUEZ, ***R. GRANGER**;
Dartmouth, Hanover, NH

Abstract: When do two things look alike? Below are closeups of three adjacent pixels. The intensity changes from top to bottom images in a) are identical to those in b); i.e., the Euclidean vector distance from a to a' is the same as from b to b'. Yet human perceivers universally report that a and a'are more similar to each other than b and b'. What measure, other than Euclidean distance, corresponds to these reported perceptual distances?
Evidence from our lab and others shows that Euclidean distance between two comparable images is consistently a poor estimator of human similarity judgments. Widely-used "image quality assessment" methods such as "structural similarity" (SSIM) outperform Euclidean measures, but it is not entirely clear which characteristics of these measures confer their predictive power.

We formulate a model directly from the size and dendritic projection patterns of center and surround neurons in the early visual path, generating a simple difference-of-Gaussian computation. We provide new empirical evidence that this center-surround organization underlies these psychophysical judgments. Forty-nine subjects (35F, ages 18-22) compared original and degraded versions of images, scoring them from 0 (least similar) to 100 (identical to original). Surprisingly, the biological center-surround model predicts human similarity evaluations as well as SSIM, despite being simpler and directly derived from dendritic architectures. Ongoing studies suggest further prominent roles for center-surround formulations in several psychophysical phenomena.

Title: Identifying neural circuits underlying visually evoked entrainment

Authors: ***C. ADAIKKAN**[1], K. ABDELAAL[1], M. MURDOCK[1], A. J. HUANG[3], H. A. SULLIVAN[2], I. WICKERSHAM[2], T. J. MCHUGH[3], L.-H. TSAI[1];
[1]Picower Inst. for Learning and Memory, [2]McGovern Inst. for Brain Res., MIT, Cambridge, MA; [3]RIKEN Ctr. for Brain Sci., Wako, Japan

Abstract: Entrainment is an established neural response phenomenon in which patterned sensory stimuli generate neural oscillations with an evoked frequency equal to the frequency of the stimulation. Visually evoked entrainment has been documented in humans and cats, highlighting

the evolutionary conservation of entrainment, but the underlying mechanism of entrainment remain poorly understood. We recently described gamma entrainment in mice, and found profound neuroprotective effects of gamma entrainment on molecular and behavioral phenotypes in mouse models of neurodegeneration. In this study, we examine the cellular and circuit mechanisms of entrainment. Using high-density electrophysiological recordings with silicon linear probes in awake freely moving mice, we find that visual flicker up to 50 Hz faithfully generates entrainment of multiunit activity and local field potential (LFP) in the lateral geniculate nucleus (LGN) and in primary visual cortex (V1). Current source density (CSD) analyses reveal stimulus frequency and layer specific modulation of entrainment with prominent and weaker LGN recipient layers in V1 showing well-delineated sink-source relationship. Selectively decoupling parvalbumin (PV) expressing interneurons in V1 using viral mediated expression of tetanus toxin light chain abolished sensory evoked entrainment at the level of multiunit spiking, spiking of putative excitatory neurons, local filed potential, and CSD in V1. By exploiting rabies virus tracing and simultaneous linear probe recording in V1 and LGN, we are now examining monosynaptic inputs of LGN to PV interneurons in V1 during visually evoked entrainment. Together, our data suggest that synaptic contributions of PV interneurons in V1 is indispensable for sensory evoked entrainment of range frequencies including theta (5 Hz, 8 Hz and 10 Hz) and gamma (30 Hz, 34 Hz, 36 Hz, 38 Hz, 40 Hz, 42 Hz, 44 Hz and 50 Hz). Our data also suggest that harmonic LFP and spiking responses in the V1 is governed by the synaptic activities of PV interneurons locally in the V1.

Title: Mapping functional thalamocortical connections in the mouse visual system

Authors: *J. ZHUANG, S. CHATTERJEE, R. LARSEN, K. TAKASAKI, N. OUELLETTE, B. MACLENNAN, J. WATERS, C. REID;
Allen Inst. for Brain Sci., Seattle, WA

Abstract: A prominent feature of visual information processing in mammalian brains is a hierarchical representation. In the early stage of this hierarchical system, the retina, the lateral geniculate nucleus (LGN) and primary visual cortex (V1) represent progressively more complex

and abstract features of the visual environment. Previous work in carnivores has shown that the projections from LGN to V1 are highly organized with precise functional specificity. In recent years, the mouse visual system is becoming a powerful model for functional studies due to the experimental tractability and availability of genetic tools. Despite some similarities, the visual system of the mouse has multiple structural and functional features that are distinct from what is found in carnivores and primates. For example, in mice, a large proportion of V1-projecting LGN axons are direction selective (DS) and LGN axons project to not only layer 4 but also all superficial layers in V1. It has been proposed that DS LGN axons preferentially project to superficial layers (similar to W pathway in cats and koniocellular pathway in primates) while those with concentric receptive fields mainly project to layer 4 (similar to X/Y pathways in cats and parvocellular/magnocellular pathways in primates). However, attempts to test this hypothesis have showed contradictory results partly due to the lack of LGN labeling specificity. Here by combining the genetic and stereotaxic targeting, we have achieved expression of calcium indicator in LGN neurons with unprecedented specificity. Using volumetric axon calcium imaging, we systematically mapped the response properties of LGN axons/boutons in V1 from layer 1 through layer 4. Our preliminary results show similar levels of DS afferent input across these layers, in contradiction to the hypothesis of strict functional segregation.

Title: Encoding models of visual and electrical stimuli in rat lateral geniculate nucleus: A deep learning approach

Authors: E. MOUNIR[1], B. ABDULLAH[1], H. M. K. MAHDI[1], ***S. ELDAWLATLY**[1,2];
[1]Computer and Systems Engin., Ain Shams Univ., Cairo, Egypt; [2]German Univ. in Cairo, Cairo, Egypt

Abstract: Visual prostheses hold hope of vision restoration for millions with retinal degenerative diseases. The main principal of visual prosthesis is to integrate an electrical stimulation system into functional sites of the visual system, bypassing the damaged site, hence restoring vision. One promising type of visual prostheses targets the thalamic Lateral Geniculate Nucleus (LGN).

Such prosthesis is useful when the retina is completely damaged or when the optic nerve is not functional. One challenge in developing thalamic visual prostheses as well as other prostheses is understanding how stimulus information is encoded in the underlying neuronal population. In this work, we introduce a deep learning approach to model the encoding of both visual and electrical stimuli in rat LGN. We recorded the activity of right LGN neurons in 15 anesthetized female Albino rats *in vivo* using multi-electrode arrays during visual and electrical stimulations. For visual stimulation, a screen was placed tangent to the left eye divided into 4 x 8 pixels. We examined two types of visual stimulation patterns: single-pixel and checkerboard patterns. In both cases, each pattern is repeated for 100 trials. For electrical stimulation, we used a pulse train pattern consisting of 5 biphasic pulses applied 50 times per stimulation channel. An average of 13 and 8.6 neurons per rat were identified for visual and electrical stimulations, respectively. Firing rates of recorded neurons were computed with bins of size 10ms and 50ms. Extracted firing rates and the corresponding stimulation patterns were used to train a deep Convolutional Neural Network (CNN) model using 80% of the data. In this CNN, the stimulus at any time instant in addition to the stimulus history are provided to the network along with the firing history of the recorded neurons. We then used the model to predict the firing rates of the recorded neurons in the remaining 20% of the data. Our results demonstrate significant similarity between actual and predicted firing rates in both visual and electrical stimulation paradigms. The mean correlation between the predicted and actual firing rates across all rats for the visual encoding was 0.63 (maximum was 0.9) and 0.75 (maximum was 0.93) for 10ms and 50ms firing rate windows, respectively. For the electrical encoding, the mean correlation was 0.22 (maximum was 0.42) and 0.59 (maximum was 0.69) for 10ms and 50ms firing rate windows, respectively. Our results demonstrate the efficacy of using deep CNNs in predicting the response of LGN neurons to visual and electrical stimulation. These models could be further integrated to tune electrical stimulation patterns for thalamic visual prostheses.

Title: Using macromolecular tissue volume mapping to parcellate magno and parvo subdivisions in the human lateral geniculate nucleus

Authors: *H. OISHI[1,2], H. TAKEMURA[1,2], K. AMANO[1,2];
[1]Ctr. for Information and Neural Networks (CiNet), Natl. Inst. of Information and Communication, Suita City, Japan; [2]Osaka Univ., Suita City, Japan

Abstract: Lateral geniculate nucleus (LGN) consists of magnocellular (M) and parvocellular (P) subdivisions, which are known to have different response selectivity for visual stimuli. More specifically, M cells are more sensitive to luminance contrast while P cells are more sensitive to color contrast. Identification of these subdivisions using non-invasive neuroimaging is essential for establishing a method to assess functions, developments and impairments of the LGN subdivisions and subsequent visual streams in living humans. However, it has been difficult to identify LGN subdivision using structural neuroimaging partly due to inhomogeneity in conventional T1-weighted image.
Based on the fact that the subdivisions have different anatomical properties, here we tested to utilize macromolecular tissue volume (MTV) mapping (Mezer et al., 2013), which provides quantitative maps corrected for image inhomogeneities, to identify human LGN subdivisions. We first identified the location of the entire LGN using high-resolution proton density-weighted (PD) image ($0.75 \times 0.75 \times 1$ mm^3) from four healthy participants. We then collected MTV data (0.8 mm^3 isotropic voxels) and registered to the PD image. We classified 20% of voxels with the lowest MTV to the putative M-group and the remaining 80% of voxels to putative P-group. This classification is based on a previous study showing that the area size of P-group is roughly four times larger than that of M-group (Andrews et al., 1997). As a result, we found that estimated M- and P-group voxels are clearly separated and are located ventromedially and dorsolaterally, respectively, in all participants. These patterns were consistent with LGN anatomy for human and primates (Selemon and Begovic, 2007). This result suggests that MTV mapping provides a stable parcellation for LGN subdivisions.
MTV separation has some advantages as compared with fMRI-based mapping (Denison et al., 2014) because fMRI experiment requires precise visual stimulation with repeated number of measurements, which may not be suitable for the clinical population with retinal disorders. Since MTV-based parcellation does not require any visual stimulation, this method will be useful to study human LGN subdivisions with respect to retinal disorders, developments or visual functions.

Abstract: The specificity of thalamocortical (TC) connectivity differs for different classes of sensory cortical neurons. TC connectivity onto simple cells of V1, for example, is highly specific, and is governed by multiple rules of connectivity, based largely on congruity of pre- and postsynaptic spatiotemporal receptive field properties (Alonso et al., 2000; Sedigh-Sarvestani et al., 2017, Lien and Scanziani, 2018). Such specificity results in a relatively small proportion of retinotopically aligned LGN neurons synapsing onto each simple cell. By contrast, the connection probability between a sensory TC neuron and an aligned cortical fast-spike interneuron is much higher. Thus, connection probabilities of ~ 2/3 are observed between ventrobasal TC neurons and putative fast-spike interneurons (SINs) in the aligned S1 barrel of rabbits and rats (Swadlow and Gusev, 2002; Bruno and Simons, 2002). Here we examined synaptic connectivity between LGN concentric neurons (by far, the most numerous cell type in rabbit LGN) and retinotopically aligned fast-spike interneurons in layer 4, and we explore reasons for the small proportion of exceptions to the rule of full promiscuity between these populations. We used extracellular cross-correlation methods, combined with spike-triggered LFP/CSD analysis to examine connectivity. We found (a) connection probabilities of ~ 75% between aligned LGN/SIN pairs, and (b) that the remaining (~25%) aligned but unconnected cases could not be explained by a mismatching of receptive field properties. These unconnected cases could, however, be accounted for by one of two factors. The first concerns differences among LGN neurons in the “strength” of the synaptic impact that they generated near the V1 SIN under study. This strength is measured by the amplitude of the spike-triggered LFP elicited by spikes of the LGN neuron. Thus, even when alignment is perfect, an LGN axon can generate no spike-triggered LFPs in the aligned column. Also, an LGN axon may generate a strong impact at some depths, but a weak impact near the L4 SIN under study. In all such cases, we found no connectivity between LGN neuron and L4 SIN. The second factor concerns the postsynaptic L4 SIN, and differences in the extent to which these cells respond to any monosynaptic drive from the LGN. This measure is gained by their responses to electrical stimulation of the thalamus. Notably, the effects of these two (pre- and postsynaptic) measurable factors account for ~ 90% of the exceptions from complete promiscuity in the connectivity between LGN concentric neurons and retinotopically aligned L4 SINs of V1.

Title: Activation of a visual cortical column by a directionally selective thalamocortical neuron

Authors: *Y. I. BERESHPOLOVA[1], C. R. STOELZEL[1], C. SU[1], J. ALONSO[2], H. A. SWADLOW[1];
[1]Dept. of Psychology, Univ. of Connecticut, Storrs, CT; [2]Biol. and Visual Sci., SUNY Optometry, New York, NY

Abstract: The retina of rabbits and rodents has neurons that signal the motion direction of a visual stimulus. These direction selective signals are transferred to the visual cortex (V1) via directionally selective (DS) neurons in the lateral geniculate nucleus (LGN). Notably, the function and synaptic impact in V1 of these LGN DS signals are unknown. Using the method of single-axon spike-triggered LFP/current source-density analysis, we measured the synaptic impact generated by individual LGN DS neurons in area V1 of awake rabbits, and compared them to the impact generated by individual LGN concentric neurons. We show that LGN DS neurons make fast and strong connections in layers 4 and 6, and that their postsynaptic effects are similar to those made by LGN concentric neurons, the main thalamic drivers of V1. By contrast, the synaptic impact of LGN DS neurons on superficial cortical layers was not detectable. We also found that both LGN DS neurons and concentric neurons powerfully (and similarly) drive putative fast-spiking neurons of layers 4 and 6. This powerful DS thalamic input could provide a mechanism for fast and strong feed-forward inhibition to sharpen cortical sensory tuning around the four cardinal directions of motion signaled by LGN DS cells. These results suggest that LGN DS neurons activate a cortical column primarily by targeting the main input layers of the cortex and that the role of DS input to superficial cortical layers is likely to be modulatory.

Title: Primary visual cortex representing central, near peripheral, and far peripheral vision are differentially functionally connected, and these differences follow patterns of known brain networks

Authors: *P. DEMIRAYAK, S. SIMS, U. PANDEY, K. VISSCHER;
Univ. of Alabama At Birmingham, Birmingham, AL

Abstract: In primary visual cortex (V1) central and peripheral vision are specialized for different functions. Due to this specialization, interactions between central, near peripheral and far peripheral regions of V1 and other cortical areas are expected to be different. Previous work from our lab found differential functional connection profiles for different eccentricities of vision, and these patterns followed patterns of known brain networks (Griffis et al., 2017). This earlier work had showed strongly significant effects in only 20 participants, and participants were fixating during minute-long breaks between tasks. We sought to replicate this previous work in a larger sample, and also extend the findings to free viewing during rest. Our resting state analyses were done on 3T preprocessed MRI data from the Human Connectome Project (HCP) database. Data used for the primary analyses were acquired from 782 healthy right-handed participants (22-36; M/F=335/447). Additional preprocessing analyses were performed on the residual BOLD data to reduce spurious variance not associated with neural activity. Regions of interests (ROIs) on central, near and far periphery of V1 were defined for seed-to-voxel analyses based on Freesurfer's retinotopy template developed by Benson et al. (2014) within Freesurfer 6.0 segmented gray matter boundaries. Cingulo-opercular, fronto-parietal and default mode networks were identified as seed ROI for seed-to-seed analyses based on Yeo et al. (2011) reference resting state networks. For both seed-to-voxel and seed-to-seed analyses time series from each seed ROI was extracted and its correlations with either all voxels or other seed ROIs were calculated in Matlab. Our results showed that central, near peripheral and far peripheral sectors of primary visual cortex have different connectivity patterns with non-visual areas. Components of the fronto-parietal control network are tightly functionally connected with central and near peripheral sectors of V1, components of cingulo-opercular control network are tightly connected with near peripheral sectors of V1, components of default mode network are connected with central and far sectors of V1. These results replicated and extended to a broader context, our previous data (Griffis et al., 2017) by suggesting that visual input that is processed by different sectors of primary visual cortex are prioritized by different large-scale resting state networks. Overall, our findings contribute to the understanding of functional processing of visual

information in the healthy young brain and they might serve as a template to compare with abnormal brain functioning.

Title: Retinotopic patterns of structural connectivity between V1 and functional networks

Authors: *S. A. SIMS[1], U. PANDEY[1], S. CEDOTAL[1], J. L. ROBINSON[2], K. M. VISSCHER[3]; [1]Univ. of Alabama At Birmingham, Birmingham, AL; [2]Psychology, Auburn Univ., Auburn University, AL; [3]Neurobio., Univ. of Alabama at Birmingham, Birmingham, AL

Abstract: Vision is important for our everyday life, but we use our central vision differently than our peripheral vision. For example, we use central vision to read and peripheral vision when surveying a landscape. Different functions of central and peripheral vision suggest that information from central vision may be processed differently from that in peripheral vision. A previous functional connectivity study from our lab suggested reliable differences in connections between centrally- and peripherally-representing visual cortex, and those differences follow well-established networks. Central-representing cortex was preferentially connected to the fronto-parietal (FP) network, mid-peripheral was generally more connected to the cingulo-opercular (CO) network, and far-peripheral was more connected to the default mode network (DMN). This led to the question of whether these connections reflect differing structural tracts or if they reflect multisynaptic connections. In this study, we used diffusion MRI of 786 subjects from the Human Connectome Project (ages=22-36; M/F=335/451). We performed probabilistic tractography on anatomically defined target regions of interest in V1, corresponding to central, mid-peripheral, and far-peripheral visual eccentricities and seed regions of the FP network, CO network, and DMN. Differences in cortical termination track probabilities were then analyzed on the surface. Difference maps comparing tract probability for far-peripheral vs. central V1 regions showed the FP network and the DMN were more connected to far-peripheral V1 than central V1. The CO network was more connected to mid than central V1 and in comparison of mid to far V1, the network subdivided so that portions were more connected to mid and others more connected to far V1. These results suggest eccentricity-based regions are differentially structurally connected to cortical, functional networks. In the comparison of eccentricity based regions we found resemblance of structural connectivity to functional connectivity network patterns found in previous work. Results imply that some of the differences in functional connectivity previously observed and recently replicated derive from direct connections

observable through diffusion imaging, but some of these connections cannot be observed through diffusion imaging and may derive from multisynaptic connections. Studying the differential structural connections of portions of V1 contributes to our understanding of the way the human brain processes visual information and forms a baseline for understanding any modifications in processing that might occur with training or experience.

Title: Distinct cellular and network responses to thalamo-cortical versus cortico-cortical L1 inputs in non-primary neocortex

Authors: *C. MURPHY, B. M. KRAUSE, M. I. BANKS;
Dept. of Anesthesiol., Univ. of Wisconsin, Madison, WI

Abstract: Processing of sensory information occurs in cortical networks via the integration of feedforward and feedback signals. Because both matrix thalamocortical (TC) and feedback corticocortical (CC) afferents terminate in cortical layer 1, post-synaptic targets in layer 1 are particularly relevant for integration of these signals and propagation of information through the cortical hierarchy. However, characterization of the synaptic and network response properties of distinct inputs to layer 1 has been limited, especially in non-primary areas. Here, we use murine brain slices to describe cellular and network responses to independent activation of feedback CC and matrix TC inputs to layer 1 of non-primary neocortex. We injected channelrhodopsin into either posterior thalamus or cingulate cortex to isolate TC or CC projections to posterior parietal cortex and extrastriate visual cortex, respectively. We optogenetically activated axon terminals in layer 1. We recorded evoked extracellular responses across the cortical column to measure induced network activity (bursts). We also performed intracellular recordings to measure responses of post-synaptic pyramidal cells, somatostatin-positive inhibitory cells, and parvalbumin-positive inhibitory cells to activation of CC and TC inputs to layer 1. Despite overlap of their terminal fields in layer 1, TC and CC inputs induced unique activation profiles in non-primary cortex. Bursts of coordinated spiking activity, most often restricted to the deep layers, were evoked by activation of TC inputs to layer 1; however, bursts were very rarely observed following activation of CC inputs to layer 1. Whole-cell recordings suggest that this

result may be subserved by differences in response properties of post-synaptic targets between each pathway. For example, pyramidal cells were more strongly activated by TC inputs than CC inputs. Conversely, dendrite-targeting somatostatin-positive inhibitory cells were rarely activated by TC inputs, but exhibited strong, short latency activation by feedback CC inputs. These data support a model in which TC projections enable network activation and information propagation, while feedback CC projections serve a regulatory role.

Title: Structural measures of magno- and parvocellular projections in visual cortex using ultra-high field fMRI

Authors: *K. T. NAVARRO[1], K. B. WELDON[2], M. J. SANCHEZ[3], K. E. M. TREGILLUS[1], S. A. ENGEL[4], C. A. OLMAN[1];

Abstract: Magnocellular and parvocellular streams are important features of the primate visual system. These streams project from the retina to V1 and have been shown to process different aspects of visual stimuli. Recent access to high-resolution neuroimaging has facilitated the exploration at mesoscopic scales in human visual cortex. Here, we investigate potential differences in the structure of magnocellular and parvocellular responses within and across layers of V1 and V2. We used 7T fMRI to observe selective activation of these streams in seven subjects across two scanning sessions. Achromatic, low spatial and high temporal frequency checkerboards targeted the magnocellular stream. Chromatic, high spatial and low temporal frequency checkerboards targeted the parvocellular stream. These stimuli were displayed dichoptically for further analysis of eye selectivity, ocular dominance columns, and presence of the blind spot. This work resulted in four findings: First, responses driven by parvocellular-targeted stimuli resulted in a laminar profile biased towards superficial layers of V1, as compared to magnocellular responses. Second, we found selective activation of the parvocellular stream in foveal V1 when compared to peripheral V1, corroborating data from nonhuman primates (NHP). Third, we found thick, repeating color-selective bands of activation stemming

from the V1 border into V2 and V3 (Fig 1). These bands are analogous to color-selective stripes found in both NHP and human extrastriate cortex, although our data suggest notable differences in the size of these bands across V2. Our bands are on a larger scale compared to NHP findings. Lastly, the depth profile of ocular dominance, computed by comparing left vs right eye responses, differed from the profile of parvocellular vs magnocellular response. Ocular dominance signals were weakest in superficial layers of the cortex (Fig 1). Together, our findings provide insight into how the magnocellular and parvocellular streams are structured in human cortex and how eye selectivity varies depending on the depth of cortical layers.

Title: What degree of global synchrony exists in noradrenergic and cholinergic axons across mouse cortex?

Authors: *L. N. COLLINS, E. D. VICKERS, D. A. MCCORMICK;
Inst. of Neurosci., Univ. of Oregon, Eugene, OR

Abstract: The neuromodulators acetylcholine (ACh) and norepinephrine (NE) regulate excitation and inhibition of cortical circuits via long-range projections from nuclei in the basal forebrain and locus coeruleus, respectively, to broad regions of cortex. Both are strongly implicated in modulation of arousal state based on electrophysiological, pharmacological, and, more recently, calcium imaging experiments which demonstrate that activity of these systems correlates strongly with changes in behavioral state. However, it is unknown whether neuromodulation by NE and ACh is synchronized across wide areas of cortex. Therefore, it is unclear whether NE and ACh signalling differentially modulate cortical excitability across cortical regions. Moreover, it is not known whether any such synchronization that exists across cortical regions is maintained both during spontaneous and sensory stimulus-evoked activity. To begin to answer these questions, the present work examines activity of large numbers of individual cholinergic and noradrenergic axons across multiple regions of cortex simultaneously. Using a combination of viral tracers and transgenic GCaMP6s mouse lines we have been able to replicate previous demonstrations that activity of these axons strongly correlates with arousal measures, such as pupil diameter, whisking activity, and locomotion. We have expanded upon this body of knowledge by exploring the synchronization of activity between axons in disparate cortical regions using mesoscopic 2-photon imaging, allowing investigation of the activity of individual axons over a large field of view at high spatial and temporal resolution. Current results suggest a strong correlation between both noradrenergic and cholinergic axons up to at least 3 mm apart and distributed throughout motor, somatosensory, and visual cortices. In addition, preliminary analyses suggest that NE provides a global neuromodulatory signal throughout the cortex that is tied closely with arousal state of the animal. Ongoing work is focused on recording from regions as far as 5 mm apart in noradrenergic and cholinergic fibers in the cortex and relating their activity to behavior to determine the extent to which NE and ACh provide global, synchronized neuromodulation throughout the mouse neocortex during both spontaneous firing and visual stimulus presentation.

Title: An electroencephalography investigation of the effects of attention on crossmodal temporal acuity

Authors: *C. BABARINSA, Z. KEELEY, K. HIRABAYASHI, S. PAPADAKIS, Z. BARNES-SCOTT, R. JAFFE, L. D. KWAKYE;

Abstract: The ability to accurately integrate sensory information from our environment, a concept known as multisensory integration, is an integral mechanism in information processing that allows us to create a coherent perception of the world around us. The accuracy of this integration is heavily reliant on our ability to precisely distinguish timing differences between unisensory stimuli (crossmodal temporal acuity). Our previous research investigated whether attention alters crossmodal temporal acuity using a crossmodal temporal order judgment (CTOJ) task in which participants were asked to report if a flash or beep occurring at different time intervals appeared first while concurrently completing a visual or auditory distractor task. We found that increasing the perceptual load of the distractor task led to sharp declines in participants' crossmodal temporal acuity. The current study uses electroencephalography (EEG) to understand the neural mechanisms that lead to decreased crossmodal temporal acuity. Participants completed a CTOJ task as described above while EEG activity was recorded 64 scalp electrodes. We found that increasing auditory load led to differences in ERP amplitude approximately 300-1000 ms post onset of the first CTOJ stimulus. In contrast, when increasing visual load, differences in ERP amplitude were found 100-200 ms after the onset of the visual stimulus regardless of which stimulus was presented first. These results indicate that visual and auditory distractors may influence crossmodal temporal acuity through differing mechanisms although the behavioral effects of the two distractor tasks were highly similar.

Title: Bayesian causal inference modeling of attentional effects on the temporal binding window of multisensory integration

Authors: *V. L. FISHER[1], M. JACKSON[2], C. NAVE[2], O. JUNG-BEEMAN[2], L. D. KWAKYE[2];
[2]Neurosci., [1]Oberlin Col., Oberlin, OH

Abstract: In order to understand the world around us, we combine information across the different senses, deficits in this integration have been implicated in various neurological

disorders. This multisensory integration is highly dependent on the temporal relationship between unisensory events and our brain's ability to discern small timing differences between stimuli (crossmodal temporal acuity). Our previous research found that increasing both visual and auditory perceptual load led to sharp declines in participants' crossmodal temporal acuity. Previous research in other labs has demonstrated that the brain integrates multisensory information in a Bayes' optimal way and that the integration of temporally disparate audiovisual stimuli can be modeled using Bayesian causal inference modeling. The present study investigates the influence of visual and auditory perceptual load on the integration of simple stimuli using Bayesian modeling. Participants completed a simultaneity judgment (SJ) task during which they determined whether temporally offset flash-beep stimuli occurred (a)synchronously. Participants completed the SJ task alone (distractor free; DF), in the presence of task-irrelevant visual or auditory distractors (no load; NL), and while completing a concurrent visual or auditory distractor task (high load; HL). Data was modeled using the causal inference model derived in Magnotti et al. 2013, which is based on Bayesian statistics. Our preliminary data show an increase in the temporal binding window with increasing visual and auditory load, confirming our previous studies. Sensory noise consistently increased with increasing visual and auditory load; however, increasing perceptual load led to increases in prior for auditory distractors but decreases in prior for visual distractors. These preliminary findings indicate that attention alters both low-level (sensory noise) and high-level (priors) processing of simple multisensory stimuli and are distractor modality dependent. This supports our previously observed effects of attention on multisensory temporal processing and their applicability to the more general population.

Title: Visual modulation of neuronal firing in the macaque auditory core

Authors: J. J. ORCZYK[1], C. E. SCHROEDER[2], *Y. KAJIKAWA[1];
[1]Nathan Kline Inst., Orangeburg, NY; [2]Nathan Kline Inst. - Translational Neurosci. Div., Columbia Univ. Col. of Physicians and Surgeons, Orangeburg, NY

Abstract: Previous studies have identified modulation of auditory cortical activity by visual inputs using fMRI, scalp EEG, and intracortical electrophysiological recordings in several mammalian species. Intracortical electrophysiological measures include single unit or multiunit activity (MUA) as well as local field potentials. However, most findings regarding modulation of auditory cortical activity by visual stimuli are based on local field potentials. We have also found strong field potential responses to conspecific faces in the auditory cortex of macaque monkeys performing an audiovisual task. However, the generators of visual field potentials in auditory cortex were localized to face recognition areas located in the inferior temporal cortex several millimeters away from auditory cortex. It would thus appear that visual-evoked changes in auditory cortical field potentials are mostly attributable to far-field effects. However, the existence of far-field effects does not necessarily preclude the possibility of local effects of visual inputs on auditory cortical activity even if the local effect on field potentials is masked by the far-field effect. In the current study, we addressed local responses in MUA in the macaque auditory cortex. Visual stimuli were ineffective in driving neuronal firing in the majority of sites. However, brief MUA responses occurring ~100 ms after visual onset were observed at depths below granular layer in a small subset of auditory cortical loci. Additionally, weak inhibition of MUA was observed after 100 ms at many sites. The visual field potentials did not differ between those expressing deep brief MUA responses and/or weak MUA inhibition. These results suggest that one type of visual modulation of auditory cortical responses occurs through a weak suppression of auditory cortical responses, consistent with findings from prior intracortical recordings in human surgical epilepsy patients.

Title: Audiovisual integration in anterior fundus face patch of macaque monkeys

Authors: *A. P. KHANDHADIA[1], A. P. MURPHY[1], L. M. ROMANSKI[2], J. K. BIZLEY[3], D. A. LEOPOLD[1];
[1]NIMH, Bethesda, MD; [2]Dept Neurosci., Univ. of Rochester Sch. of Med. and Dent., Rochester, NY; [3]UCL Ear Institute, 332 Grays Inn Road, London, United Kingdom

Abstract: The macaque superior temporal sulcus (STS) is a major area of convergence of socially relevant stimuli, for example integrating visual and auditory signals. In the visual domain, the STS contains several face patches, which are defined as brain regions more responsive to images of faces than non-face objects. Within these patches, the influence of

auditory information on neural responses is largely unknown, for example during the issuance of an acoustic vocalization. In this experiment, we assessed the responses of single neurons of the anterior fundus face patch (AF) to audiovisual clips of macaque vocalizations, focusing on the spatial sensitivity of AF neurons to the acoustic and visual components. The results indicate a high proportion of visual responses in AF cells to dynamic facial expressions are modulated by the accompanying auditory vocalizations. Such modulation often showed strong stimulus specificity and could be expressed as either enhancement or suppression of the spike rate for different stimuli. A relatively small subset of cells responded to the auditory vocal stimuli alone. We further explored the selectivity of these cells to the spatial properties of audiovisual integration. In one experiment, we presented the same audiovisual clips to the macaques while spatially separating the audio component of the stimuli from the visual shifting it 45 degrees to the left or right but maintaining central visual presentation. Under these conditions, the extent of visual enhancement or suppression depended on both the spatial position and spatial congruence of the visual and auditory components, with suppression most common when the audio stimulus was presented to the contralateral hemifield of the recorded hemisphere. In a second preliminary experiment, we altered head- and eye-centered coordinate systems by turning the animal's head +-45 degrees so it faced the position of the sound sources and requiring the animal to view the centrally presented face with eccentric gaze. Under these conditions, the response suppression was largely abolished. Overall, these results indicate that AF neurons incorporate auditory signals to shape spiking responses to observed socially relevant facial behaviors and these responses depend on the spatial position and congruence of auditory and visual components.

Title: Neural basis of stereognosis in somatosensory system

Authors: *E. V. OKOROKOVA[1], C. M. GREENSPON[2], Q. HE[3], S. J. BENSMAIA[3]; [2]Dept. of Organismal Biol. & Anat., [3]Dept. of Organismal Biol. and Anat., [1]Univ. of Chicago, Chicago, IL

Abstract: When we grasp an object, we acquire information about its three-dimensional structure, which relies on integration of proprioceptive and tactile signals. Cutaneous cues

provide information about the local spatial features of the object - the curvature and texture of a surface, the orientation of edges - whereas proprioceptive signals about the conformation of the hand and the relative positions of these features in space. These two streams of information are then combined to yield a three-dimensional percept of the object, a phenomenon called stereognosis. However, little is known about how signals from these two disparate sensory modalities are integrated to give rise to stereognosis and support our ability to effortlessly identify objects and dexterously manipulate them. To address this question, we have developed an experimental apparatus that allows us to generate objects varying in size and shape for the monkey to grasp while we track its hand movements and measure the forces it exerts on the object at each point of contact. We will simultaneously record neural activity in somatosensory cortex of macaques and seek to characterize the response properties of neurons during active interactions with objects. In particular, we are interested in later stages of processing (including areas 2 and S2), where proprioceptive and cutaneous information is integrated and, as such, are likely to mediate stereognosis.

Title: Vision automatically exerts online and offline influences on tactile spatial perception

Authors: Y. R. WANI, S. CONVENTO, ***J. M. YAU**;
Baylor Col. of Med., Houston, TX

Abstract: Vision and touch interact in spatial perception. How vision exerts online influences on tactile spatial perception is well-appreciated, but far less is known about how vision modulates tactile perception offline. Here, we investigated how visual cues exert both online and offline biases in tactile spatial perception. In a series of experiments, participants performed a 4-alternative forced-choice tactile detection task in which they reported the perception of taps on the left hand, right hand, both hands, or no touch (LRBN task). Participants initially performed the LRBN task in the absence of visual cues. Subsequently, participants performed the LRBN task in blocks comprising non-informative visual cues that were presented near the left and right hands. To explore the effect of distractor salience on the visuotactile spatial interactions, we varied the brightness of the visual cues such that visual stimuli associated with one hand were consistently brighter than visual stimuli associated with the other hand. We found that participants performed the tactile detection task in an unbiased manner in the absence of visual

distractors. Visual cues biased online tactile performance in a brightness-dependent manner, despite an instruction to ignore vision. Moreover, during task blocks comprising visual cues, tactile performance was biased toward the side of the brighter visual cues even on trials in which no visual cues were presented. Using a modeling framework based on signal detection theory, we compared a number of alternative models to recapitulate the behavioral results and to link the visual influences on touch to sensitivity and criterion changes. Our collective results reveal the obligatory and systematic influences of vision on both online and offline tactile spatial perception. Thus, the nervous system appears to automatically leverage multiple sensory modalities to build and calibrate representations for tactile spatial perception.

Title: Olfacto-tactile interactions in mice whisker somatosensory areas S1 and S2

Authors: *A. RENARD, E. HARRELL, B. BATHELLIER;
CNRS, Gif sur Yvette, France

Abstract: Perception is a multisensory phenomenon, however, the mechanisms allowing the integration of information coming from different senses remain poorly understood. A few recent studies in mice showed that multimodal interactions are ubiquitous even at the level of the primary sensory areas. Yet, there is still no report precisely describing the impact of cross-modal interactions on the representations of combinations of stimuli occurring in a passive context or during associative learning. In this study, we establish the existence of multimodal olfacto-tactile interactions in the mouse primary and secondary whisker cortical areas (wS1 and wS2). We performed 2-photon calcium imaging in layer 2/3 complemented with extracellular electrophysiological recordings in layer 5, in awake mice during the synchronized presentation of texture gratings and odors. Whiskers were tracked using high-speed videography and movements were precisely quantified.
We find that 28% of the wS1 responsive cells and 20% of the wS2 responsive cells are significantly modulated when an odor is paired with the grating presentation or presented alone, with a variety of enhanced and suppressed response types. These modulations were found to be non-additive for 15% of them and are not attributable to differences in whisking behavior. This result was confirmed with a close to maximal performance of SVM classifiers in separating the

bimodal from the unimodal trials, with a better prediction in area wS2.
This result shows the existence of an olfactory modulation in the whisker somatosensory cortex of awake mice in a passive stimulation context.

Title: Alpha and beta band brain activity tracks the temporal correlation between auditory and visual stimuli

Authors: *A. R. NIDIFFER[1], E. C. LALOR[1,3,4,2];
[1]Biomed. Engin., [2]Del Monte Inst. for Neurosci., Univ. of Rochester, Rochester, NY; [3]Trinity Ctr. for Bioengineering, [4]Trinity Col. Inst. of Neurosci., Trinity Col. Dublin, Dublin, Ireland

Abstract: Stimulus features that correspond to a common event in the environment are correlated over time and space. For example, mouth movements of a speaker are correlated with the amplitude envelope of the accompanying speech. The brain uses these correlations to bind these features within and across sensory systems which, in the case of multisensory binding, results in enhancements in speech comprehension and selective attention in multi-speaker situations. Though this much is known, little is known about the underlying mechanism by which the brain generates its representation of that correlation. In the current experiment, we recorded high-density electroencephalography (EEG) while presenting participants with continuous streams of auditory and visual stimuli which were amplitude modulated at frequencies from 3-8 Hz. Consistent with previous research, we found that the envelopes of the two streams were simultaneously tracked in EEG phase, and to a lesser extent EEG power. The audiovisual streams were generated independently such that the long-term correlation between their envelopes was zero but across smaller time scales (0.1 to 1 s), correlation fluctuated uniquely across time for each time scale. We first asked at what time scale EEG activity follows stimulus correlation. For most participants, EEG power (but not phase) best reflected correlation computed over the previous 500-800 ms. When examining activity across frequency bands, we found peaks in two bands, alpha and beta, where EEG power tracked stimulus correlation. Scalp topography of this activity revealed decreasing alpha power in parietal electrodes - consistent with the role of attentional suppression - and increasing beta power in frontal electrodes with increasing correlation. The relationship between attention and multisensory integration has been

a topic of interest, especially in the context of temporally dynamic stimuli. Further analysis will shed light on the influence of attentional engagement with the stimuli and the neural tracking of their correlation. These results begin to unravel how brain networks interact to compute and utilize the correlational structure of our environment to give rise to coherent perception.

Title: Crossing the hands in cross-modal contexts affects the spatial cognition: Evidence from EEG

Authors: *A. BOLLINI, C. CAMPUS, M. GORI;
Unit for Visually Impaired People (U-VIP), Inst. Italiano Di Tecnologia (IIT), Genoa, Italy

Abstract: In daily life, to interact with the environment surrounding us, we have to combine information coming from different sensory modalities considering the spatial locations of events. The location of the stimulus can affect task performance even it has no relevance for the task, as in the case of the Simon effect. Indeed, in the Simon task, the participants are faster and more accurate when the position of the target and the response match than when their locations are in two opposite positions. A large body of the literature showed that each sensorial modality encodes spatial information according to a specific frame of reference, e.g. hearing and vision are based on external coordinates while touching on internal coordinates. One way to induce a conflict between the two reference frames is to cross the hands over the body midline. In this case, there is an incongruence between the internal (body-referred) and the external coordinates. Here, to investigate the frame of reference across different sensory modalities, we tested participants with unimodal and cross-modal versions of auditory-tactile Simon task, manipulating the hand's posture. We recorded EEG activity during the task in order to determinate the neural activity representing the direction of spatial cognition in the various scenario and therefore the dominant reference frame. We then focus on behavioral outcome, combining accuracy and reaction times in the Inverse Efficiency Score (IES), and EEG activity, measuring both ERPs and Time-Frequency representations.
Results show both behavioral and neurophysiological differences between the cross-modal and unimodal scenarios, both in the auditory and tactile version of Simon task. In particular, it seems that while in the unisensory auditory task participants followed the external, in the alternating cross-modal modality task, the Simon effect disappears in the auditory modality. Moreover, there was a great drop in performance in the cross-modal tasks, due to sensory-switch costs. This

resulted in greater IES and in a general increase of amplitude in the neural activity compared with performance and activity in unimodal tasks, probably reflecting a greater cognitive load. We also found modulations related to the hand's posture, which affected the behavioral performance and the EEG activity, in particular in the domain of N1 component, known as related also with spatial cognition processes.
These results show how in cross-modal contexts the weights associated with a spatial frame and a sensory modality change dynamically to adapt to the demands of the task.

Title: Decoding anticipatory action plans using EEG event-related potentials

Authors: ***T. C. CHEUNG**, L. L. GUO, A. FROST, C. PEREIRA, M. NIEMEIER; Psychology, Univ. of Toronto Scarborough, Toronto, ON, Canada

Abstract: Feedforward models allow for precise sensorimotor control by anticipating action outcomes. For example, hand movements may be anticipated in the dynamic crossed-hand illusion where the temporal order of tactile stimulations of the left and right hand are more likely to be confused when the hands are crossed as opposed to uncrossed as well as when hands are about to cross (Hermosillo et al., 2011). Study 1, conducted among psychology undergraduates (age: mean=19.26 years old, S.D.=1.29; male: 41.9%), consisted of two stimulus onset asynchronies (SOAs: 0ms and 150ms) between the auditory start-to-move signal and the first of two vibrotactile stimulations (100ms apart) on one of the two index fingers. Results suggested that stationary uncrossed and crossed conditions had the lowest and highest error rates respectively. In addition, planning to move the hands from uncrossed to crossed position increased the former error rate, and planning the otherwise decreased the latter. Two-way ANOVAs showed significant hand position (crossed/uncrossed) and movement planning (stationary/movement) interaction, with $F(1,28) = 7.62$, $p = .01$, partial eta sq. = .214. The results confirmed that anticipated arm movements influenced perceived hand positions.
Study 2 used EEG to map the influence of anticipated arm movements in time by using the spatial and temporal features of ERPs of aligned SOAs (0ms, 125ms, 250ms) after the start-to-move signal. Instead of using the TOJ task, a flashing light located adjacent to either middle finger was used for the SOA manipulations. Support Vector Machine (SVM) were trained

comparing the ERPs between the crossing versus uncrossing conditions at 3 different SOAs. We predicted that comparing with the ready-to-move signal time point, influence of the anticipated movement would become more salient in the time windows closer to the movement onset (i.e., SOA = 250ms), thus boosting the classification accuracy between the two movement conditions. In support to the hypothesis we observed that for SOA=250ms classification accuracies were over 75%, whereas they declined for SOAs of 125ms and were at chance level for SOA=0ms. Our data reveal electrophysiological correlates of forward models in action planning.

Title: Relationship between saccade-related eardrum oscillations and clinical measures of middle ear impedance

Authors: *C. KING[1], R. LANDRUM[1], D. MURPHY[1], S. SCHLEBUSCH[1], D. KAYLIE[1], C. A. SHERA[2], J. GROH[1];
[1]Duke Univ., Durham, NC; [2]USC, Los Angeles, CA

Abstract: Integration of auditory and visual information is necessary in order to make sense of the world around us. How and where this integration occurs within the brain is not known. Our laboratory has identified a phenomenon where, in the absence of auditory stimuli, both eardrums begin synchronous, low-frequency oscillations just prior to saccadic eye movements. These eye movement-related eardrum oscillations (EMREO) change in amplitude and phase with changes in saccade magnitude and direction. This discovery suggests that connections between the visual and auditory systems likely begin as early as the auditory periphery (Gruters, Murphy et al, PNAS 2018). Ongoing work in non-human primates can provide insights into potential anatomical mechanisms (Schlebusch et al, Advances and Perspectives in Auditory Neuroscience conference 2018; Schlebusch et al, Society for Neuroscience conference, 2019) and examining the response in different human clinical populations can also further our understanding of the underlying mechanisms and potential utility of these oscillations.
To further characterize this phenomenon in humans and assess the feasibility for use in future clinical research, we examine the relationship between traditional measures of middle-ear function (e.g., compliance) and characteristic features of the EMREO. Normal hearing subjects

participated in visual tracking tasks, divided into one-hour sessions across several days. Subjects were seated, facing a monitor, and stable head position was maintained using a chinrest. Microphones placed in both ear canals recorded the oscillations. Eye movements were tracked with a video eye tracker. Analysis shows a reliably recorded EMREO in approximately 5 minutes of recording time, suggesting potential value in future clinical research. Middle-ear tympanometric measurements were obtained prior to each recording session, allowing the investigation of the relationship between variations in middle-ear measurements and the structure of the EMREO. The impact of altered visual or auditory input on the response is examined.

Title: Eye movement is linearly encoded by eardrum motion: The decipherable EMREO

Authors: *D. L. K. MURPHY[1], C. D. KING[1], R. LANDRUM[1], S. SCHLEBUSCH[1], C. A. SHERA[2], J. M. GROH[1];
[1]Duke Univ., Durham, NC; [2]USC, Los Angeles, CA

Abstract: After every eye movement, the brain must realign the visual and auditory reference frames in order to co-locate sights and sounds. Exactly where, when, and how such visual-auditory spatial integrations occur is not fully understood. We recently discovered that the eardrum oscillates beginning a few milliseconds before saccades and continuing until well into ensuing periods of fixation (Gruters, Murphy et al PNAS 2018). Information about at least the horizontal direction and length of saccades appear to be reflected in the phase and magnitude of these eye movement-related eardrum oscillations (EMREO).
Here, we sought to assess the full spatial characteristics of this signal for saccade parameters in both vertical and horizontal dimensions. Concurrently we sought to validate that independent estimations of vertical and horizontal saccade parameter contributions can be linearly combined to predict EMREO waveforms for saccades in all directions – a fundamental assumption of current analyses.
We found that EMREOs depend on both horizontal and vertical saccade components, varying predominantly with eye displacement, but modulated by absolute (initial or final) position as well. In toto, EMREO appear to represent combinations of these saccade parameters such that any saccade corresponds to a specific eardrum oscillation that contains a linear combination of the vertical and horizontal saccade parameters. Regressions in both the time and frequency

domain create a fuller picture of the spatial information contained in EMREO. These results demonstrate that detailed information about the relationship between visual and auditory reference frames is present in the earliest stage of the auditory pathway. They also demonstrate that this information is mapped linearly and can therefore be recovered with a small set of basis components.
Future work delving into the relationship between EMREO and the transduction of incoming sounds will be needed to ascertain their effects on the processing of auditory spatial locations in relation to the visual scene. While the frequency and magnitude of EMREO suggest that they may be related to middle ear muscle contractions, the underlying mechanisms that generate them are unknown.

Title: Changes in saccade-related eardrum oscillations after surgical denervation of the stapedius muscle

Authors: *S. N. SCHLEBUSCH[1], M. W. COOPER[1], D. M. KAYLIE[1], D. L. K. MURPHY[1], C. D. KING[1], C. A. SHERA[2], J. M. GROH[1];
[1]Duke Univ., Durham, NC; [2]USC, Los Angeles, CA

Abstract: The connection between the visual and auditory systems plays an important, integrative role in perceiving surrounding stimuli correctly. We have recently reported an oscillation of the eardrum time-locked with the onset of a saccade and in the absence of incoming sound that suggests this connection may begin as early as the auditory periphery. These eye movement-related eardrum oscillations (EMREOs) covary in phase and amplitude with the direction and magnitude of a synchronous saccade (Gruters, Murphy et al. PNAS 2018). However, the acting anatomical features and their joint contributions to this eardrum oscillation-possibly including the stapedius, tensor tympani, and outer hair cells - are still unknown. We first sought to determine the interactions between the stapedius muscle and the eardrum during saccade activity, an important initial step towards understanding both the mechanisms within the middle and inner ear that cause the EMREO and the function of the EMREO.
We recorded EMREOs in one rhesus monkey during a spontaneous saccade task before and after

denervating and transsecting the stapedius muscle of one ear. The monkey was head-restrained in a dark room, and eye movements were tracked with a video eye tracker (1000 Hz sampling rate) while eardrum oscillations were recorded using microphones placed in the ear canals of both ears. We report pre-surgery that we can see a well-characterized, highly reproducible EMREO in both the left and right ear, and that the horizontal component of a saccade has significant input to an accompanying EMREO, as expected from previous work. We then performed surgical transsections of the facial nerve and stapedius muscle on the right side, thus completely denervating the stapedius as well as disconnecting it from the stapes bone of the middle ear. We retested the monkey during and after a four-month recovery period with the same pre-surgery recording methods. After surgical intervention of the stapedius muscle, characteristic EMREOs are not immediately apparent in the operated ear and regression analyses show that the input of the horizontal component of a saccade to an accompanying EMREO is significantly diminished (by about 30%), but not absent. The control ear maintains its pre-surgery, highly reproducible EMREO. Trial-wise analysis in the frequency domain suggests post-surgery changes in the frequency of oscillations of the eardrum in the operated ear and/or phase synchronization with respect to eye movement. Together, these findings suggest that there may be multiple contributors to the EMREO in a complex mechanism within the ear, and that the stapedius muscle is one of these contributors.

Title: Stimulus salience and spatial correspondence determine enhancement or depression of multisensory integration in fish

Authors: N. MARTORELL[1,2], M. PERARA[1,2], ***V. MEDAN**[1,2];
[1]Univ. of Buenos Aires, Buenos Aires, Argentina; [2]IFIBYNE-CONICET, Buenos Aires, Argentina

Abstract: Most animals combine multiple sources of information to form a coherent percept of the world for adaptive behavioral decisions. The underlying mechanisms of such interactions are

far from clear. Here we ask: (i) What are the parameters of a combination of stimuli which determine if integration occurs, and (ii) How is response latency modified by multisensory integration? We answer these questions analyzing the C-start escapes of goldfish (Carassius auratus) in response to auditory pips and visual looming stimuli.
We first described the response probability and response latency to 6 levels of unimodal auditory or visual stimuli of increasing strength. Varying the volume of auditory stimuli and the contrast of visual looms allowed us to obtain unimodal stimuli ranging from low to high salience (<10% to >70% response probability). To determine which combinations produced multisensory integration, we created a multimodal stimuli matrix combining these 6 auditory and 6 visual stimuli. Experiments in 60 animals showed that the strongest multisensory enhancement occurs when both stimuli have minimum salience while it disappears as salience increases.
We next described how integration changes when spatial correspondence between the auditory and visual components is altered. For low salience combinations, we observed multisensory enhancement when both components came from the same direction, multisensory depression when they were 90° apart and no integration at 180° separation. For higher salience combinations, integration was non-significant regardless of spatial separation.
Finally, we analyzed C-start response latency for auditory or visual stimuli with respect to the auditory pip onset or the end of the looming expansion respectively. As expected, brief (5 ms) auditory pips evoked responses with a narrow latency distribution (median = 12.5 ms, 25-75th percentile = 8 to 17 ms, N = 56) compared to longer lasting (4000 ms) visual looms (median = -29 ms, 25-75th percentile = -166 to 30 ms, N = 67). Interestingly, when we presented an auditory pip 116 ms before the end of the loom expansion, the multimodal responses were centered around the auditory latency distribution and showed the same range (median = 12.5 ms, 25 to 75th percentile = 8 to 17 ms, N = 215).Overall we found multisensory enhancement of weak but spatially congruent audio-visual stimuli whose response latency was determined by the auditory stimulus. Ongoing experiments are testing the temporal dependence of these audio-visual stimuli to determine to which extent the auditory stimulus dictates response latency.

Title: Auditory-visual multisensory enhancement in a vertebrate command neuron

Authors: *S. OTERO CORONEL[1,3], V. MEDAN[2,3];
[1]Sch. of Med., [2]Sch. of Exact and Natural Sci., Univ. of Buenos Aires, Buenos Aires, Argentina; [3]Inst. of Physiology, Mol. Biol. and Neurosci., CONICET - Univ. of Buenos Aires, Buenos Aires, Argentina

Abstract: Different sensory systems provide animals with valuable information that allows them to identify possible threats and react accordingly. In fish, the Mauthner cell receives inputs from the visual and auditory systems and commands the C-start escape response. By combining optic tectum and auditory stimulation with in vivo intracellular recordings of the Mauthner cell in goldfish (*Carassius auratus*), here we show that multimodal stimuli produce higher responses than their unimodal counterparts. We also address how the linearity of the multisensory enhancement depends on the temporal order of the unimodal stimuli, as well as the duration and frequency of the tectal stimulus.

Multimodal responses to a sound pip before (-50 ms), simultaneously or after (50 ms) a single 1 ms-tectal pulse are higher than those evoked by the best unimodal stimulus. To obtain a multisensory linearity index (MLI) we divided the peak multimodal response by the sum of the peak unimodal responses. We found that when presenting a sound pip 50 ms before a single tectal pulse, the mean (± SEM) MLI was 0.84 ± 0.02, N=23 and significantly lower than when presenting the sound pip simultaneously (0.91 ± 0.02, N=23, p=0.04) or 50 ms after tectal stimulation (0.92 ± 0.02, N=12, p=0.04).

Increasing the duration (1 to 200 ms) of a 60 Hz tectal train produced higher unimodal responses. However, a sound pip presented at the end of the tectal train produces multimodal responses that are equally effective for all train durations. Accordingly, the MLI for a pip after a single 1 ms-tectal pulse was significantly higher (0.91 ± 0.02, N=23) than for the longest tectal train (200 ms: 0.67 ± 0.05, N=13, $p<0.001$).

Similarly, increasing the frequency of a 100 ms tectal train yielded higher unimodal peaks but failed to improve the multimodal response when combined with a sound pip at the end of the train. As a result, a multimodal stimulus with a tectal train of 30 Hz rendered a higher MLI (0.79 ± 0.03, N=15) than with a 200 Hz train (0.67 ± 0.04, N=12, p=0.04).

Altogether, we found that multisensory enhancement in the Mauthner cell represents a unique example of the inverse effectiveness principle implemented at the single cell level. The linearity of the multimodal enhancement is maximal when a low intensity (i.e. brief or low frequency) tectal stimulus is presented with or shortly after a sound. Behavioral experiments from our lab further support the importance of multisensory integration of low-intensity audio-visual stimuli in the context of the escape response.

Title: Functional magnetic resonance response shape and the inhibitory system

Authors: D. AKSENOV, L. LI, M. MILLER, ***A. M. WYRWICZ**;
Northshore Univ. Healthsystem, Evanston, IL

Abstract: Functional magnetic resonance imaging (fMRI) relies upon blood oxygenation level dependent (BOLD) signal changes for mapping brain activation in humans and animals. The shape of the BOLD fMRI signal can vary considerably even across structures of the same sensory pathway. To explore the relationship between BOLD signal shape and the local level of inhibition, we compared the temporal behavior of the stimulus-evoked BOLD response in the primary cortical and subcortical regions of the visual and somatosensory whisker systems. In order to test the hypothesis that region specific changes were driven by local differences in GABAergic inhibition, BOLD and electrophysiological data were acquired under normal and pharmacologically-modulated levels of neuronal spontaneous activity in the awake rabbit. Functional MR imaging experiments were performed on a 9.4T Bruker BioSpec imaging spectrometer. Imaging data were acquired from four consecutive slices using single-shot gradient-echo EPI pulse sequence (TR=2s and TE=11ms). The stimulus consisted of a 50 Hz vibration delivered to the whiskers on the left side by means of a nylon band coupled to an oscillating magnetic coil and monitored in real time by an infrared sensor to ensure consistent amplitude and frequency of the vibration. The visual stimulation consisted of a 2x2 array of green LEDs flashing at 8 Hz delivered to the left eye. Neuronal activity, including single units and local field potentials, was recorded with non-ferrous wires attached to a chronically implanted microdrive. Data were analyzed after removal of blocks of gradient interference. Data were acquired before and after localized injection of the GABA-agonist muscimol in the whisker barrel cortex (WBC). Our results show that during sensory visual or whisker stimulation, the BOLD responses in the thalamic lateral geniculate nucleus and ventral posteromedial nucleus correlated well with one another, whereas the responses in WBC and visual cortex (V1) showed significant differences in shape and duration. Our electrophysiological data showed that the stimulus-evoked neuronal responses more closely resembled the BOLD response in V1 than in WBC. Moreover, analysis of the average baseline neuronal activity revealed a much lower level of activity in V1 than in WBC. Based on these findings, we sought to test the dependence of the BOLD signal shape on the level of baseline inhibition, as opposed to evoked neuronal response.

Title: Transcriptional analysis of circadian correlations among dopamine, dopaminergic receptors and clocks genes in spinal cord of rat

Authors: *C. PIÑA LEYVA[1,2], B. FLORÁN GARDUÑO[1], L. RODRÍGUEZ SOSA[3], I. JIMÉNEZ ESTRADA[1], J. GONZÁLEZ BARRIOS[2];
[1]Fisiología, Biofísica y Neurociencias, CINVESTAV, México, Mexico; [2]Lab. de Medicina Genómica, Hosp. Regional "1° de Octubre", ISSSTE, México, Mexico; [3]Dept. de Fisiología, Facultad de Medicina, UNAM, México, Mexico

Abstract: In the spinal cord the dopaminergic receptors control locomotor activity and nociceptive functions. Some brain experiments have shown the clock genes are controlled by the dopamine receptors, but in the spinal cord remained unknown what components are present and how are controlled the circadian functions. We examined the circadian behavior and the transcriptional correlation of the dopamine receptors with the clock genes along the spinal cord. We evaluated the mRNA of the dopamine receptors and clock genes by using RT-qPCR (TaqMan assay) and HPLC to evaluate the concentrations of dopamine content in the rat spinal cord. The dopamine circadian behavior was highest in the lumbar and least in the thoracic region. DR3 and DR4 had the greatest circadian expression while DR2 and DR5 showed the least circadian expression in each region evaluated. The clock genes Bmal, Per1 and Cry2 exhibited the mayor expression in cervical, thoracic and lumbar. The positive correlations were: DR1 with Per2 and Per3, DR2 with Rev-erbα, DR4 with Rorα and Cry1, DR5 with Rev-erbα and Per2 and the negative correlations were: DR1 with Clock and Cry2, DR2 with Per1, Clock and Cry2, DR3 with Per1, Clock and Cry2, DR4 with Cry2 and DR5 with Per1, Clock and Cry2. Our results show that dopamine, dopaminergic receptors and the clock genes are organized throughout the spinal cord. All dopaminergic receptors expressed in the spinal cord are involucrate with the transcriptional regulation of the clock genes in order to keep the rhythmicity control of spinal cord functions.

Rhythmic parameters of dopaminergic receptors and clock genes in spinal cord

Gene name	Parameter	Cervical	Thoracic	Lumbar
DR1	Mesor	1.06	1.2	0.61

Title: Implications of firing rate changes in the claustrum during classical conditioning

Authors: *M. REUS-GARCIA[1], N. PERETZ-RIVLIN[2], G. ATLAN[2], A. CITRI[2], A. GRUART[1], J. DELGADO-GARCIA[1];
[1]Div. of Neurosci., Pablo de Olavide Univ., Seville, Spain; [2]The Hebrew Univ., Jerusalem, Israel

Abstract: The claustrum (CL) has been the subject of different theoretical studies addressing its putative role in integrative neural functions, including consciousness. Anatomical studies have revealed that the CL is a sheet-like neural structure located between the putamen and the insular cortex. CL neurons are originated from the insula. The CL sends projections and receive afferents from all cortical regions. Although it is assumed that CL neurons could be involved in cognitive processes and in the integration of different sensory-motor modalities, CL functions studied in alert behaving animals remain unknown. In a previous work, it was shown that associative learning modifies the activity of CL neurons. Here, we have recorded in behaving rabbits claustral single units during the acquisition of a classical eyeblink conditioning task. For conditioning, we used a delay paradigm: a tone as conditioned stimulus (CS) followed by an air puff as unconditioned stimulus (US) that co-terminated with it. Conditioned (CRs) and unconditioned (URs) responses were determined from the rectified electromyographic (rEMG) activity of the orbicularis oculi muscle. Neurons were recorded across habituation and conditioning sessions using 16 channels proves with the aim of reaching the whole length of the CL. Recorded cells were identified by their synaptic and/or antidromic activation from medial prefrontal (mPFC) or motor (M1C) cortices of both sides. Preliminary results obtained using the software Kilosort showed that CL neurons were activated during sessions of paired CS-US presentations in early stages of the learning task. In contrast, CL neurons decreased their firing rates during the last conditioning sessions, i.e., when CRs reached asymptotic values.

Title: Atypical afferents of the thalamic reticular nucleus

Authors: *B. D. RICHARDSON[1,2], E. J. HANSEN[1];
[1]WWAMI Med. Educ., [2]Biol. Engin., Univ. of Idaho, Moscow, ID

Abstract: Accurate coding and filtering of sensory information depends on the sensory thalamocortical circuit where the thalamic reticular nucleus influences thalamocortical neuron coding and activity. However, an understanding of afferents that may be regulating the thalamic reticular nucleus is incomplete. Brain regions that integrate multi-modal sensory information to form internal predictions or determine emotional state may impact sensory thalamic neuron regulation of information flow to cortex. To identify potential atypical afferents to the thalamic reticular nucleus that may modulate their activity, a retrograde adeno-associated virus (AAVrg-Chronos-GFP) was injected into the thalamic reticular nucleus of male and female C57bl/6 mice. After 20 days of recovery, mice were euthanized and coronal tissue sections were immunohistochemically stained for GFP and markers for specific cell types. Using fluorescence microscopy, retrograde-labeled neurons that have been well established as presynaptic to thalamic reticular neurons were identified, including neurons in the sensory cortices and thalamus. In addition, anatomical data from these retrograde viral tract-tracing studies suggest that cerebellar nuclei and amygdala also directly project to the thalamic reticular nucleus. Specifically, neuronal cell bodies in the ventral dentate, dorsolateral interpositus, and basolateral amygdala expressed GFP following AAVrg injections into thalamic reticular nucleus. These connections between cerebellum/amygdala and thalamic reticular nucleus may be important conduits for the relay of multi-modal sensory information or emotional context in regulating selection of and attention to specific stimuli and their features. While there is clear anatomical evidence for these connections, the function of cerebellar and amygdala projections to thalamic reticular nucleus and subsequent influence on auditory thalamic neurons is widely unknown. These data provide a foundation for identifying the functional impact of cerebellar and/or amygdalar projections to the thalamic reticular nucleus in a mouse model. Efforts to further develop the anatomical distribution and identify the functional impact of afferent projections from cerebellar nuclei and basolateral amygdala are ongoing.

Title: Multisensory integration related to dentition in the neocortex of the naked mole-rat (Heterocephalus glaber)

Authors: *N. J. M. HITE[1], J. NIE[2], D. K. SARKO[3];
[1]Physiol., [3]Dept. of Anat., [2]Southern Illinois University, Sch. of Med., Carbondale, IL

Abstract: Multisensory studies focused on (or simply including) dentition are nearly absent, despite the fact that multisensory integration is essential to critical daily functions such as chewing and speech that rely on dental and craniofacial structures. In the current study, we assessed how tactile inputs from the teeth are combined with inputs from additional sensory modalities in the naked mole-rat, a species with highly specialized and well-developed dentition. Single-unit, *in vivo* electrophysiological mapping of the neocortex was performed in anesthetized naked mole-rats. Electrophysiological recordings examined multisensory neuronal responses, particularly targeting border zones between modality-specific cortical areas based on previous studies in laboratory rats. This cortical mapping compared neuronal responses to single-modality (e.g., somatosensory) stimuli alone vs. neuronal responses to multisensory stimulus combinations (i.e., more than one sensory modality, such as somatosensory + auditory). We presented auditory (A), visual (V), and tactile (T) stimuli in the following combinations to study multisensory integration regarding tactile stimulation of the incisor: A, V, T, AV, AT, VT, AVT. We hypothesized that auditory and visual stimuli would modulate the dominant mechanoreceptive inputs from the naked mole-rat's well-innervated and specialized dentition. We expected that multisensory stimulus conditions would generate stronger neuronal responses (i.e., increased firing rates and shorter latencies to response) compared to responses to unisensory stimuli alone. Altogether, these studies provide insight into the neural substrates facilitating dental sensory perception, and the critical role that additional sensory modalities might play.

Title: *In vivo* recordings of opto-tagged S1-projecting claustrocortical neurons in a cross-modal detection task

Authors: *M. CHEVÉE, E. F. FINKEL, D. H. O'CONNOR, S. P. BROWN;
The Solomon H. Snyder Dept. of Neurosci., Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: The claustrum, a, thin, elongated subcortical nucleus located between the cortex and the striatum, forms extensive reciprocal connections with cortex. Claustrocortical (ClaC) neurons have been proposed to suppress cortical responses to distracting stimuli by modulating the gain of specific target regions (Jackson et al. 2018, Atlan et al. 2018, Narikiyo et al. 2018), which suggests that the claustrum integrates top-down information with sensory signals. *In vivo* recordings have revealed sensory responses in claustrum neurons. However, both *in vivo* and *in vitro* studies provide little evidence for multisensory integration (Olson and Graybiel 1980, Sherk and LeVay 1981, Remedios et al. 2010, 2014, Kim et al. 2016). How top-down signals and sensory information interact to influence the activity of ClaC neurons is poorly understood.
To address this question, we hypothesized that ClaC neurons respond to sensory stimuli differently based on context and on the cortical region they target. We trained mice to perform a cross-modal detection task and recorded from ClaC neurons that specifically project to the whisker associated somatosensory cortex. Mice were presented with interleaved whisker and visual stimuli and were trained to respond to one modality while ignoring the other. The modality rewarded alternated in blocks of trials multiple times within an experimental session. This approach allowed us to observe the response of ClaC neurons to sensory stimuli in distinct contexts defined by the task rules, motor signals and reward.
We found that ClaC neurons were strongly modulated by the task. Responses lasted up to 3 seconds, spanning the sensory, motor and reward phases of a trial. The neurons integrated the rules, as responses were stronger for the rewarded modality than for the unrewarded modality. Furthermore, we found that the response triggered in a trial was suppressed during licking. These findings provide new insights into how sensorimotor signals are represented in claustrocortical circuits and how these patterns of activity may influence cortical sensory processing.

Title: Multisensory responses in primary auditory cortex of the cat

Authors: *C. BOUCHER[1], X. BAO[1], Y. MERRIKHI[1], M. MEREDITH[2], S. G. LOMBER[1]; [1]Dept. of Physiol., McGill Univ., Montreal, QC, Canada; [2]Dept. of Anat. and Neurobio., Virginia Commonwealth Univ., Richmond, VA

Abstract: Core auditory cortex of the cat is comprised of primary auditory cortex (A1) and the anterior auditory field (AAF). Neurons in both fields respond strongly to acoustic stimuli and are tonotopically organized. In hearing animals, a small number of cells in AAF respond to tactile stimulation. Following early-onset hearing loss, a much larger proportion of neurons in AAF become responsive to tactile and/or visual stimulation, indicating that crossmodal sensory reorganization is robust in this core auditory area. Unfortunately, results from similar studies conducted in A1 of the cat are not as clear. In hearing cats, most studies do not show multisensory responses in A1 (Stewart & Starr, 1970; Rebillard et al., 1977; Kral et al., 2003). Furthermore, only one study has documented crossmodal plasticity in A1 following perinatal hearing loss (Rebillard et al., 1977), while others have not (Stewart & Starr, 1970; Kral et al., 2003). A methodological consideration of these studies involves the type of anesthetic used. In this study, hearing animals were lightly anesthetized with ketamine. We recorded audiovisual responses from A1 (i.e., unisensory auditory, unisensory visual, subthreshold multisensory or bimodal) and we examined the visual characteristics to which A1 maximally responds. Multisensory stimuli were developed by pairing a pure tone stimulus with a flash stimulus at various stimulus onset asynchronies, and the visual stimuli presented include gratings, flashes, dots, and checkerboards. A linear multielectrode array recorded multi-unit activity and local field potentials across cortical layers. Contrary to previous work using other anesthetics, we identified unisensory auditory, unisensory visual, bimodal, and subthreshold multisensory multi-unit activity in A1. We also found neurons where auditory-visual interactions either suppressed or enhanced neuronal activity. Additionally, visual stimulation can modulate the neural response to auditory inputs depending on the stimulus onset asynchrony. Taken together, it is possible to identify visually responsive neurons in A1 of the cat. These results will serve as baseline data for a future study, examining the degree to which this cortical area undergoes crossmodal plasticity following early-onset hearing loss.

Title: Cortico-cortical representation induced by conditioning in primary of auditory, visual, somatosensory cortices

Authors: *G. TASAKA[1], Y. IDE[1], M. TAKAHASHI[1], N. NAKAJIMA[2], T. AIHARA[3]; [1]Tamagawa Univ., Machida,Tokyo, Japan; [2]Tamagawa Univ., Machida, Japan; [3]Tamagawa Univ., Tokyo, Japan

Abstract: Recently, many studies for plastic changes of cortico-cortical network were reported. Some of them were induced by association of sensory information. Sensory cortices are defined by responses to physical stimuli in specific modalities. Recently, however, human neuroimaging studies have shown auditory cortex activation without sound. In our previous study, plastic changes induced a fear conditioning by pairing a pure tone with an electric foot-shock (US) were measured in the auditory cortex and somatosensory cortex of a guinea pig, using optical recording with voltage sensitive dye. As the result, auditory information could be retrieved on the basis of an electric foot-shock alone. It showed that somatosensory and auditory cortices were associatively activated by a single modality of sensory information. However, the association mechanism of cortical signals elicited with the conditioning is still unclear. In this study, to investigate the influence of conditioning on cortical activity, the second-order conditioning with three sensory stimuli (light, tone, foot-shock) was additionally performed to first order conditioning paradigm in previous study. On the first day, blood flow was monitored during the tone-shock or light-shock conditioning; as a result, conditioning responses was observed. On the second day, paring of light and tone was repeated so that conditional responses to both light and tone were observed after the conditioning. Next, three cortical activities, in auditory cortex (ACx), visual cortex (V1), and somatosensory cortex (S1, S2), for each sensory stimuli were simultaneously measured using the optical imaging with voltage sensitive dye. As a result, we found that each stimulus (light, sound, foot-shock) alone, through second-order conditioning, could activate three cortices in absence of the others stimuli. These results suggest that two different modalities could be retrieved across each sensory cortex by one modality of sensory information after the conditioning. It is considered as a formation mechanism of cortico-cortical representation for some information modalities.

Title: Brain miniaturization: Comparisons of the neuroarchitectures of brains in the honey bee and stingless bees

Authors: *I. T. SINAKEVITCH, S. NIVERTY, N. CHAWLA, B. H. SMITH;
Arizona State Univ., Tempe, AZ

Abstract: *Apis mellifera* is a model insect for the study of olfactory and spatial learning. A honey bee must navigate and orient over large distances for feeding and reproduction, which is critical for survival. It has highly structured visual and olfactory neuropils that send input to an elaborate area of the brain called the 'mushroom body', which integrates different sensory modalities and is vital for learning and memory. The architecture of the honey bee mushroom body has been well established, and it consists of two cup-like calyces each composed of two identical halves. Calyces receive inputs related to olfactory, visual, mechanosensory and reward processing, and it is thought that the mushroom body is important for spatial learning. Stingless bees have the smallest brains but perform similar behavioral tasks as a honey bee. We have investigated the structural differences in the honey bee and stingless bees mushroom bodies. We used immunocytochemistry with a synaptic neuropil marker (anti-synapsin), a mushroom body marker, anti-DC0, and a nucleus marker DAPI to compare the olfactory neuropils in honey bee and stingless bees. Images were collected from sections under a confocal laser scanning microscope. Digitized images were analyzed using a 3D visualization software AMIRA to produce a 3D model of the antennal lobes and mushroom bodies. We found that the stingless bee mushroom body has a similar general structure as the honey bee: a large mushroom body with two cup-like calyces and medial and vertical lobes located in the protocerebrum. However we also found differences in the synaptic neuropilar structure in the calyx and lobe. The stingless bee has a less columnar structure in the area where pedunculus subdivides in the vertical and medial lobes. Specifically, the smallest stingless bees have two columns of Kenyon cell axons in each mushroom body. This ranges to three columns in the biggest stingless bees compared to six in the honey bee. The difference in the Kenyon cell composition in the columns might reflect a difference in the organization of visual and olfactory inputs in the calyx, and thus they reflect the spatial/olfactory integration of the mushroom body in these bees. The honey bee has a large collar (visual input) and smaller olfactory input. The stingless bee with three columns in pedunculus has more substantial lip (olfactory) volume in the calyx compared with the volume of the collar (visual). We speculate that the number of the columnar Kenyon cells are reduced in the smallest stingless bee, which also has a sizeable antennal lobe and relatively smaller compound eyes.

Title: Plasticity of ponto-cerebellar circuits generates a prospective error signal in climbing fibers

Authors: *S. OHMAE, J. F. MEDINA;
Dept. of Neurosci., Baylor Col. of Med., Houston, TX

Abstract: Climbing fibers play the role of teachers during motor learning, by sending two types of error signals to the cerebellum: a retrospective error signal driven by sensory feedback after an unexpected event occurs, and a prospective error signal of unknown origin that provides the cerebellum with a prediction of the upcoming sensory event before it occurs. Here, we use eyeblink conditioning in mice to demonstrate that the prospective signal of climbing fibers has a motor-related component (motor-CF), which is causally linked to the predictive defensive action generated by the mouse in anticipation of an aversive airpuff stimulus to the eye. Furthermore, we used simultaneous recording and targeted electrical and optogenetic stimulation to identify a ponto-cerebellar pathway that is sufficient and necessary for generating the prospective motor-CF signal. Altogether, our results reveal a hardwired recurrent circuit that allows the cerebellum to activate its own climbing fiber input and essentially become its own teacher.

Title: The cerebellum and prefrontal cortex cooperate to perform a cognitive timing task in mice

Authors: *G. J. WOJACZYNSKI, J. J. SIEGEL, J. F. MEDINA;
Dept. of Neurosci., Baylor Col. of Med., Houston, TX

Abstract: Decades of research have firmly established the cerebellum as critical for associating external stimuli with adaptive motor responses, i.e. sensorimotor adaptation. Whether the cerebellum plays a similar role for cognitively driven motor behavior is currently unknown. In a novel task, we trained mice to produce an adaptive motor response to an internally generated representation of an omitted stimulus within a sequence. Here, we demonstrate through recording and optogenetic experiments that the medial prefrontal cortex encodes a cognitive signal representing the omitted stimulus, while the cerebellum mediates the adaptive motor response. Our results reveal a functional link between the prefrontal cortex and cerebellum during cognitively driven behavior, providing the foundation for further research into understanding how this link may be impaired in a variety of neurological and neuropsychiatric disorders.

Title: Evidence that the cerebellum coordinates movement on the mental number line

Authors: *J. S. TSAY, M. KING, S. D. MCDOUGLE, R. IVRY;
Psychology, Univ. of California Berkeley, Berkeley, CA

Abstract: Neuropsychological and neuroimaging studies point to the involvement of the cerebellum in working memory tasks, although the nature of this contribution is poorly understood. McDougle et al., (in preparation) recently tested individuals with spinocerebellar atrophy (SCA) on two tasks that tap into working memory, mental rotation and memory search, with the SCA group only impaired on the former. They hypothesized that mental rotation involves the manipulation of a mental representation in a continuous manner, whereas memory search requires a sequential operation applied to distinct representations. To test this hypothesis in a new context, we compared SCA (n = 15) and control (n= 13) participants on an arithmetic task requiring the verification (true or false) of single-digit addition problems (e.g., 7 + 5 = 13). For problems such as these, RT becomes longer as the magnitude of the sum increases. This has

been attributed to the time required to traverse a mental number-line. In contrast, the RT function is relatively flat for addition problems involving the same number, or what are called “ties” (e.g., 4 + 4 = 9), presumably because the answer to these problems can be retrieved from an over-learned look-up table. The RT data for the SCA group showed a larger slope on the non-ties compared to the control group, but no slope difference was observed between the groups on the ties. These results provide further evidence that the cerebellum is recruited for “cognitive” tasks that required the continuous manipulation of a representation, perhaps reflecting an embodied form of internal simulation and a generalization of a functional role for this structure in coordinating movements.

Title: Cerebellar modulation of attention to distractor stimuli in a sensory conflict task: A transcranial magnetic stimulation study

Authors: *D. R. ANDREW, M. S. ADAMS, S. R. MUIR, W. R. STAINES;
Kinesiology, Univ. of Waterloo, Waterloo, ON, Canada

Abstract: Although the cerebellum has long been considered a motor structure, emerging evidence has highlighted the role of the cerebellum in higher order functions. Coordination of movement and cognition within multisensory environments requires the ability to orient ourselves to relevant stimuli, which is often described as attention. Studies have identified changes in connectivity in prefrontal and associative cortices, implicated in diverse attentional networks, following non-invasive stimulation of hypothesized attentional nodes within the right cerebellar hemisphere, although its specific modulatory role is not well discerned. This study sought to further specify the cerebellum's role in attention by assessing changes to the processing of sensory conflict following its transient inhibition. It was hypothesized that following transient inhibition of the cerebellum using continuous theta burst stimulation (cTBS), participants' ability to ignore a distractor stimulus would be attenuated; resulting in larger event related potentials (ERPs) in response to distractors and decreased accuracy on the task. Participants made a graded motor response to the amplitude of visual or tactile stimuli that were presented either individually or simultaneously and varied in amplitude. Attention was altered by having participants respond only to tactile or visual stimuli as instructed, prior to the start of each block; resulting in conditions in which participants received a relevant, an irrelevant, or a relevant stimulus with a distractor in the other modality. Somatosensory ERPs and performance were measured using electroencephalography (EEG) and grading accuracy respectively. These measures were collected pre and post cTBS to the right (Group 1) and left lateral (Group 2) cerebellum (centre of coil placed 1 cm below and 3 cm to the right or left of the inion). Results demonstrate that the somatosensory N70 decreased in response to unattended tactile stimuli versus when they were attended to. Prior to cTBS, the presence of a visual distractor during a tactile attended block demonstrated a smaller N70. Post right-cTBS, the presence of a distractor resulted in an increased N70 amplitude, suggesting an affected ability to ignore a distractor. Behavioural data demonstrates that after cTBS, grading of both visual and tactile stimuli is less accurate. These changes are not as pronounced for the left-cTBS group, suggesting that there is a localized attention node within the cerebellum. Understanding the cerebellum's role in these processes is critical as it may prove to be a clinically significant target for the treatment of the symptoms observed in behavioural disorders.

Title: The cerebellar dentate nucleus in autism: Are neurons and their perineuronal nets preserved despite missing purkinje cells?

Authors: *C. BRANDENBURG[1], B. WHITE[2], C. ENSOR[2], G. J. BLATT[1];
[1]Hussman Inst. For Autism, Baltimore, MD; [2]Hussman Inst. for Autism, Baltimore, MD

Abstract: Purkinje cell (PC) dysfunction is the most consistent neuropathological finding in autism, with as many as 75% of cases showing reduced numbers. Human postmortem studies have also reported differences in PC size and gene expression in the autism brain. The lateral hemisphere displays the greatest PC decrease reported. However, the dentate nucleus (DN), which normally receives projections from the lateral hemisphere, did not seem to be affected in preliminary studies of total neuron numbers in autism, although very few postmortem cases have been analyzed. The DN harbors the greatest percentage of neurons in the brain surrounded by a perineuronal net (PNN). Genes involved in PNN formation and function have been implicated in autism. Given the known PC reductions in autism, we aimed to determine whether there are further deficits in neuronal numbers within the cerebellar circuitry, as DN neurons are likely to be impacted by PC deficits. PNNs around the DN neurons were also quantified and western blots for expression are underway. Immunohistochemistry was performed on human postmortem brain tissue from 19 control and 18 autism cases. From each case, five 40µm sections at every sixth interval through the DN were immunostained with nickel DAB anti-HPLN1, a link protein in the PNN. Neutral red was used as a counterstain to identify all neurons. A Zeiss Microbrightfield Stereoinvestigator system was used to quantify neuronal densities within the DN contour. Neurons falling within the software's dissector were quantified then divided by the total area counted. The density of neurons with PNNs, based on HPLN1 expression, was not different between control (mean= 1,682.27±417.51) and autism (mean= 1,658.57±228.93 neurons/mm^3). The density of neurons without a PNN also showed no differences (control mean= 1,487.74±386.44 and autism mean= 1,462.14±384.31 neurons/mm^3) and therefore total neuron numbers were similar (control mean= 3,170.01±632.64 and autism mean= 3,120.71±520.12 neurons/mm^3). Despite reports of significant reductions in the number of PCs in the lateral hemisphere of the cerebellum, similar reductions are not evident in the DN. Thus the targets of PC output within the DN appear to be preserved by the remaining PCs and inferior olive input. Furthermore, the proportion of neurons surrounded by PNNs compared to those without appear

to be unaltered. Further work is underway to determine whether activity-dependent components of the PNN, such as aggrecan, are affected while total PNN numbers remain unchanged.

Title: The influence of cerebellar transcranial direct current stimulation applied over multiple days on motor learning in an overhand throwing task

Authors: *L. LIMA DE ALBUQUERQUE, D. LIDSTONE, M. PANTOVIC, I. MUNOZ, M. K. ZUROWSKI, E. W. WILKINS, J. S. DUFEK, B. J. POSTON;
Kinesiology, Univ. of Nevada, Las Vegas, Las Vegas, NV

Abstract: Cerebellar transcranial direct current stimulation (c-tDCS) has been shown to enhance motor skill and motor learning in relatively simple motor tasks involving the hand and arm. However, it is unknown if c-tDCS can enhance motor performance in complex, multi-joint tasks that involve coordination of the whole body. The purpose was to examine the influence of c-tDCS applied over multiple days on motor learning in an overhand throwing task. The study was a randomized, SHAM-controlled, between-subjects, double-blind experimental design. A total of 21 young adults (12 males, 9 females) were allocated to either a c-tDCS group or a SHAM group. Each subject completed three experimental sessions on consecutive days at the same time each day. In each session, subjects practiced overhand throwing trials to a small target located on a wall 6 meters away. A total of 7 trial blocks (10 trials per block) were performed each day and consisted of a baseline-test block, 5 practice blocks, and a post-test block. Anodal c-tDCS was applied to the cerebellum ipsilateral to the right hand during the practice blocks for 20 minutes. c-tDCS was delivered using previously determined effective parameters (current strength: 2 mA; anode: 3 cm right of the inion; cathode: right buccinator muscle) with a NeuroConn Stimulator that was placed in a small, tight-fitting backpack which did not restrict performance. Motor performance was quantified as the endpoint error (absolute distance of the ball's final endpoint relative to the target center). Endpoint error declined with practice for both groups over the 3 days. However, there were no significant interactions (all p values > 0.2). Thus, there were no significant differences for endpoint error between the 2 groups. These preliminary findings indicate that the application of c-tDCS during practice over 3 consecutive days does not improve motor learning in a complex overhand throwing task in young adults.

Title: Cerebellar high gamma activation during performance of a reaching task in MEG

Authors: F. W. CARVER[1], L. SEPE-FORREST[1], R. QUENTIN[2], T. HOLROYD[1], *R. COPPOLA[1], A. C. NUGENT[1];
[1]NIMH, Bethesda, MD; [2]NINDS, Bethesda, MD

Abstract: High-frequency electrophysiological activity is known to arise from cerebellar cortex during performance of sensorimotor tasks. However, observation of cerebellar activation at high frequencies is rare in non-invasive recordings with human subjects. Recently we have shown the ability to resolve task-dependent changes in high gamma power from the cerebral cortex using magnetoencephalography (MEG). In the current investigation, we seek to determine if high gamma can also be recorded from the cerebellar cortex with MEG. To do so, we employed a center-out reaching task known to elicit cerebellar high gamma activity in animal research. Ten right-handed healthy volunteers participated in the study in which they were asked to center a circular cursor using a joystick and then quickly reach for a target presented randomly at one of eight locations equidistant from the center. Subjects had to reach the target within 1.5 seconds during 80 trials. Linearly constrained minimum variance beamformers were used to localize neuromagnetic sources during the reach portion of successful trials. We calculated whole brain contrasts of power between reach and rest in a high-gamma frequency band (65-115Hz). Group T-tests of the resulting brain volumes revealed significant increases in high-gamma during reaching ($p<.001$, $q<.05$) in two connected clusters - one in the bilateral posterior cerebral cortex, and the other in the right lateral cerebellum. The cerebral cluster was centered on the bilateral superior parietal lobules and neighboring areas, with the majority of voxels in the precuneus. The cerebellar cluster was in the right lateral posterior lobe, with most voxels in lobules VI and VII. Both precuneus and lateral posterior cerebellum are expected to be active during a visuomotor task. What's unique here is the observation of high gamma activation in these regions with MEG. In the cerebral cortex the form and function of high-frequency activity is still under debate, although there is evidence that it is not oscillatory in nature, but instead results from asynchronous spiking in local cortical networks. There is more evidence of oscillatory activity at high frequencies in the cerebellum, but more research is needed to understand the exact

mechanisms involved. Our demonstration that high gamma can be recorded from cerebral and cerebellar cortices non-invasively with MEG opens up new avenues for investigating this activity in humans.

Title: Neural connections between oculomotor neural integrators and vestibulo-cerebellum

Authors: T. SUGIMURA, *Y. SAITO;
Nara Med. Univ., Kashihara, Japan

Abstract: Gaze holding is primarily controlled by the oculomotor neural integrators, which are separated into the prepositus hypoglossi nucleus (PHN) for horizontal gaze and the interstitial nucleus of Cajal (INC) for vertical gaze. Although it has been argued that the neural connections from the integrators to the vestibulo-cerebellar cortex are significant in gaze holding, the properties of the integrator neurons that project to the cortex have not been well defined. In the present study, we examined the proportion of cholinergic PHN and INC neurons that were retrogradely labeled by injecting a dextran-conjugated Alexa 488 tracer into the cerebellar flocculus (FL) or uvula/nodulus (UN) using choline acetyltransferase (ChAT)-tdTomato transgenic rats, in which cholinergic neurons exhibit tdTomato fluorescence. When the tracer was injected into the FL unilaterally or the center of the UN, the retrogradely labeled neurons were observed in the PHN but not in the INC. The proportion of cholinergic PHN neurons that projected to the UN (21.7 ± 0.8 % in 6 rats) was significantly larger than the proportion of the neurons that projected to the FL (9.1 ± 1.5 % in 6 rats, $p < 0.0001$). The proportion of cholinergic PHN neurons that projected to the UN differed depending on the caudal (9.1 ± 1.3%), intermediate (23.3 ± 2.1%) and rostral (32.6 ± 2.0%) regions of PHN. To examine PHN neurons projecting to other cerebellar cortices than vestibulo-cerebellum, we injected the tracer into the anterior vermis [spino-cerebellar (SC) cortex] and the posterior hemisphere [cerebro-cerebellar (CC) cortex]. The proportions of cholinergic PHN neurons projecting to the SC and CC cortices were 23.3 ± 2.7 % and 19.1 ± 1.9 %, respectively, which were comparable to that of cholinergic PHN neurons projecting to the UN. INC neurons projecting to the SC and CC cortices were not found. These results suggest that the neural connections to the cerebellum from the oculomotor

neural integrator are limited to the PHN. In addition, cholinergic neurons that project to the FL are fewer than the neurons that project to the UN, SC, and CC cortices.

Title: Spike sorting for multichannel recordings in floccular complex of the primate cerebellum

Authors: ***N. J. HALL**, D. J. HERZFELD, S. G. LISBERGER;
Dept. of Neurobio., Duke Univ., Durham, NC

Abstract: Multichannel, multi-neuron recordings in the cerebellar flocculus exacerbate two central problems of spike sorting. 1) Nearby neurons may exhibit firing rates that are very different from one another, resulting in asymmetric cluster densities. 2) Many neurons have extremely high firing rates: for example, Purkinje cells frequently have baseline firing rates > 80 Hz. High firing rates cause a very large number of spike overlaps, both within single channels and across multiple channels in the recorded voltage traces. Overlap can cause false separation of spikes within a single unit. We attacked these problems with a “divide and conquer” approach by modifying and combining two existing spike sorting methods. First, we find and cluster individual spike waveforms using the iso-cut method described by Chung et al. 2017. Iso-cut finds a non-parametric minimum density point in high dimensional space over the combined distribution of two clusters. If this density is sufficiently deviant from the expectation of a unimodal distribution, the two clusters are separated; otherwise they are combined. We included modifications that increase the ability of iso-cut to separate clusters that have a very different number of spikes. Second, we identify overlapping spike waveforms that may have been missed using the binary pursuit strategy introduced by Pillow et al. 2013. Binary pursuit involves minimizing the residuals of the fit between all known spike waveforms and the raw voltage recording that is being sorted. At every point in the voltage trace, a spike’s waveform is iteratively subtracted if the subtraction reduces the residual voltage. Third, we use all discovered waveform shapes and spike times to produce a set of adjusted spike clips - snippets of the voltage trace centered on a given spike time that have all other known spikes removed. These adjusted clips are then passed through the iso-cut algorithm anew for final spike clustering. Finally, we consolidate spikes across channels into single units and discard noise clusters. These

four steps typically result in ~99% spike detection and 96-99% correct sorting in simulated datasets with high firing rates. It resolves multichannel recordings of the spikes of neighboring Purkinje cells, which can include overlaps of greater than 10% of spikes even within a small, ~2 ms time window.

Title: Responses of mouse cerebellar Purkinje cells to omissions in regular trains of sensory stimuli

Authors: *G. W. ZEMPOLICH, S. T. BROWN, I. M. RAMAN;
Neurobio., Northwestern Univ., Evanston, IL

Abstract: The perception of time in the brain is likely to emerge from computations in neuronal circuits. The cerebellum, a major sensorimotor integrating region, is a good candidate to encode aspects of temporal perception, as it orchestrates movements with precise timing and allows animals to adapt to stimuli at specific intervals. Because the cerebellum appears specialized to detect sub-second intervals (200-1000 ms), we tested whether neurons in the cerebellum may in fact "count", similar to a metronome. Extracellular recordings were made from Purkinje cells in crus I/II of the cerebellum in ketamine-xylazine anesthetized and awake head-fixed mice. Mice were stimulated by 2-Hz trains of stimuli consisting of either a 50-psi, 10-ms air puff to the ipsilateral whisker pad (tactile) or an 80-dB, 60-ms whistle (auditory). The 26th stimulus of each train was omitted, and the trains with the omission were applied 40 times. Simple and complex spike firing rates from Purkinje neurons were analyzed to assess their responses to the stimuli in the train and to the 26th omission. The results demonstrate that different Purkinje cell responses in anesthetized mice could be categorized based upon the simple spike pattern evoked by each stimulus. In anesthetized mice, no cells responded to whistles, but all cells responded to air puffs, displaying either a suppression of firing, an elevation of firing, an elevation preceding a suppression phase, or multiple periods of suppression. In awake mice, cells responded with firing rate increases to both tactile and auditory stimuli. In both anesthetized and awake mice, cells fired complex spikes to tactile stimuli with high probability, but none fired to omitted stimuli, suggesting that complex spikes were linked to the sensory stimulus rather than the "error" of a

missed stimulus. While local field potentials and/or simple spikes in some cells showed a well-timed response just preceding the omitted air puff in anesthetized recordings, these omission-related responses were undetectable in awake mice. The results suggest that under some circumstances, cerebellar neurons may count on a sub-second time scale in that they can respond to violations in periodicity, but that arousal masks or alters these responses.

Title: Sensory experience remodels genome architecture in a neural circuit to drive motor learning

Authors: *P. VALNEGRI[1,2], T. YAMADA[3], Y. YANG[1,2], A. BONNI[2];
[1]Neurobio., Northwestern Univ., Evanston, IL; [2]Neurosci., Washington Univ. Sch. of Med., St Louis, MO; [3]Univ. of Tsukuba, Tsukuba, Japan

Abstract: Neuronal activity-dependent transcription couples sensory experience to adaptive responses of the brain including learning and memory. Mechanisms of activity-dependent gene expression including alterations of the epigenome have been characterized. However, the fundamental question of whether and how sensory experience remodels chromatin architecture in the adult brain *in vivo* to induce neural code transformations and learning and memory remains to be addressed. Here, *in vivo* calcium imaging, optogenetics, and pharmacological approaches reveal that granule neuron activation in the anterior dorsal cerebellar vermis (ADCV) plays a crucial role in a novel delay tactile startle learning paradigm in mice. Strikingly, using large-scale transcriptome and chromatin profiling, we have discovered that activation of the motor learning-linked granule neuron circuit reorganizes neuronal chromatin including through long-distance enhancer-promoter and transcriptionally active compartment interactions to orchestrate distinct granule neuron gene expression modules. Conditional CRISPR knockout of the chromatin architecture regulator Cohesin in ADCV granule neurons in adult mice disrupts enhancer-promoter interactions, activity-dependent transcription, and motor learning. These

findings define how sensory experience patterns chromatin architecture and neural circuit coding in the brain to drive motor learning.

Title: Cerebellar output pathways for spatial and temporal locomotor calibration

Authors: D. M. DARMOHRAY[1], M. R. MACIEL[3], J. JACOBS[3], *M. R. CAREY[2];
[1]Champalimaud Ctr. For the Unknown, Lisboa, Portugal; [2]Champalimaud Ctr. For the Unknown, Lisbon, Portugal; [3]Champalimaud Fndn., Lisboa, Portugal

Abstract: Locomotor adaptation on a split-belt treadmill is a highly conserved form of motor learning in which externally-imposed gait asymmetries are reduced through recalibration of interlimb coordination. This form of learning requires the interposed cerebellar nucleus and has distinct spatial and temporal components that are adapted at different rates and are differentially lateralized in the cerebellum. Here, we investigate whether distinct cerebellar efferent pathways mediate learning in space and time. Axonal tracing from the cerebellar nuclei reveals many candidate premotor nuclei in the midbrain and brainstem that could underlie this form of learning. Dual color retrograde tracing from these premotor areas further demonstrates that interposed neurons projecting to specific downstream sites are spatially segregated and partially distinct. Finally, genetic manipulations of neural activity in specific cerebellar output pathways have differential effects on spatial and temporal learning, suggesting that these components of adaptation involve distinct neural circuits.

Title: Selective modular expansion of the cortico-cerebellar system explains variation in brain size among primates and humans

Authors: *J. SMAERS, D. VANIER;
Stony Brook Univ., Stony Brook, NY

Abstract: Ascertaining to what degree the brains of model species are representative of human brains is crucial to neuroscientists. This is particularly true with regard to primate species, whose evolution is typified by extensive variation in brain size. An enduring question in this context is whether certain brain regions can be identified that vary in size more than others, and whether such highly variable regions explain variation in brain size across primates. We investigate the tempo and mode of evolution of brain organization using the largest combination of brain regions analyzed to date (36 brain regions representing over 90% of the brain, across 17 primate species, including humans). Results indicate that the constituent brain regions of the cortico-cerebellar system show the highest rates of evolution, demonstrate a modular pattern of evolution, and closely align with changes in overall brain size. These results indicate that primate brain evolution is primarily characterized by a conserved evolutionary trajectory towards an expansion of the cortico-cerebellar system. This suggests that a stable genetic and developmental structure underpins primate and human brain evolution. Our results thereby have important implications not only for the suitability of primates as models for humans, but for understanding the nature of primate and human cognition.

Title: Focal adhesion proteins and Calpain are involved in the reorganization of the actin cytoskeleton of Bergmann fibers

Authors: Y. BASTIAN[1], ***J. A. MENDEZ**[2];
[1]Unidad de Investigación Biomédica IMSS-Zacatecas, IMSS, Zacatecas, Mexico; [2]Inst. of Physics, Biophysics, Univ. Autonoma De San Luis Potosi, San Luis Potosí, Mexico

Abstract: In the cerebellum, the lamellar processes of Bergmann glia cells (BGC) interact very closely with the incoming synapses of Purkinje cells. Disturbance of BGCs AMPA receptors (AMPAr) induces the retraction of the lamellar processes and impairs the fine motor coordination of mice. Recent evidence shows that activation of AMPAr in BGC leads to the reorganization of the actin cytoskeleton through two processes: changes in the intensity of F-actin staining of Bergmann fibers and changes in the number of Bergmann fibers stained. Whereas the first process depends on the activation of RhoA in a signal pathway involving PI3-K, FAK and PKC, the second process depends on external calcium in a Rho-independent manner. Using F-actin staining as well as immunoprecipitation assays together with western blots, we found in coronal cerebelar slices that the change in the number of Bergmann fibers stained with fluorescent-Phalloidin is prevented by the inhibition of Calpain with both calpeptin and ALLN. We also found that in response to AMPAr activation, Spectrin and Actinin, proteins of the focal adhesion complex, are cleaved. Furthermore, cleavage of Spectrin and Actinin is prevented by the treatment with Calpain inhibitors and chelators of calcium. Our results suggest that remodeling of proteins of the focal adhesion in response to calcium influx is required for the reorganization of the actin cytoskeleton in BGC.

Title: Dopaminergic modulation of cerebellar UBCs

Authors: *E. CANTON, V. DUMRONGPRECHACHAN, Y. KOZOROVITSKIY;
Northwestern Univ., Evanston, IL

Abstract: The cerebellum is influenced by a wide range of neuromodulatory circuits. These circuits are likely to mediate significant effects on activity and plasticity within the cerebellum, thereby modulating motor control. Our previous work has focused on characterizing the functional expression of Drd1R (Dopamine receptor type 1) within lobules IX (Uvula) and X (Nodulus) of the cerebellar vermis, in transgenic Drd1a-Cre; Ai14 mouse line we find expression in unipolar brush cells, an excitatory granular layer interneuron. Using *ex vivo* electrophysiological recordings we have found that selective pharmacological activation of Drd1Rs leads to an increase in tonic firing rates and increases in NMDAR mediated excitatory inputs. We hypothesize that the source of dopamine onto UBCs are nodular purkinje cells which are known to express Tyrosine Hydroxylase. Purkinje cells are classically known to send their main projections to the cerebellar nuclei, recent work has shown Purkinje cells within lobules IX (Uvula) and X (Nodulus) in the vermis also make monosynaptic inhibitory connections with nearby Golgi and granule cells. By selectively expressing ChR2 in Purkinje cells we can evoke short latency inhibitory postsynaptic currents (IPSC) in UBCs. Cre dependent transynaptic retrograde modified rabies virus infection shows that nodular Purkinje cells send direct projections to UBCs. Future work will use a combination of optogenetic activation with dopamine sensor Dlight1.1 as well as fast scan cyclic voltammetry (FSCV) to directly find the source of dopamine on UBCs.

Title: Training of marmoset monkey for head-fixed electrophysiological recordings from the cerebellum

Authors: *P. HAGE[1], E. SEDAGHAT-NEJAD[3], K. KARBASI[2], T. PALIN[4], R. SHADMEHR[5];
[1]Biomed. Engin., [2]Johns Hopkins Sch. of Med., Baltimore, MD; [4]Biomed. Engin., [3]Johns Hopkins Univ., Baltimore, MD; [5]Dept Biomed. Eng, Johns Hopkins Univ. Dept. of Biomed. Engin., Baltimore, MD

Abstract: The New Age Callithrix Jacchus, the common marmoset monkey, is a promising new animal model due to the species' socially-oriented behavior and potential for breeding transgenic generations. However, to date there have been little published work on behavioral training in the head-fixed protocol. Indeed, there is some doubt as to whether the animals can be trained to produce robust goal-directed behavior over hundreds or thousands of trials. Here, we report our results of a year-long protocol to train one animal to consistently achieve over 1000 successful reward-driven trials, while recording with high density electrodes from multiple simultaneously isolated Purkinje cells from the lobules 6 and 7 of the midline cerebellum. Our head-fixed procedure included use of CT imaging, computer aided design (CAD), and 3D printing of a titanium headpost. We then used an MRI to map the targeted cerebellar recording region and designed an electrode alignment apparatus for daily acute recording. Following surgery, we implemented a protocol for safely food restricting the monkey and then used the head-fixed protocol as the only means for feeding the animal. We present data from the system's implementation with 1 adult female marmoset monkey (4 years old), consisting of simple and complex spike recordings acquired from multiple simultaneously recorded Purkinje cells in lobules 7CbA(a), 6Cb(a-c), and 6Cb(e). Additionally, we demonstrate the efficacy and safety of the food-restricted behavioral training protocol, supported by a healthy maintenance of the monkey's weight paired with performance capabilities of up to 1500 successful trials per session. While acute and semi-chronic systems have recently been developed for targeted recording of locations in the cerebral cortex, the brain stem, and a variety of deep brain structures, our work allows for high resolution targeting of specific lobules of the cerebellum during eye movement tasks. Additionally, there exists no literature that establishes a safe and effective food-restricted behavioral training protocol that demonstrates the maintenance of health and promising task performance, as shown in this work. Our system and training methodologies provide useful tools to conduct a wide range of cerebellar neurophysiological studies, as well as a general system development pipeline which could be customized and implemented for the study of other neural processes.

Title: Cerebellar and cerebral cortical responses to transcranial alternating current stimulation using an *in vivo* approach

Authors: *R. A. HEFFNER, R. DAVIS, F. ANDERSON, T. COFER, H. LU;
Philadelphia Col. of Osteo. Med. GA, Suwanee, GA

Abstract: Recent studies have suggested that transcranial electric stimulation could potentially be an effective therapy for cerebellar movement disorders. Our previous studies have explored the effects of anodal and cathodal transcranial direct current stimulation on cerebellar and cerebral cortices. The effect of transcranial alternating current stimulation (tACS) is included in this study to better our understanding of transcranial electrical stimulation. Local field potentials (LFPs) of the cerebellar and cerebral cortices were recorded with tACS (200 μA, 20 Hz). Power spectrum analysis was used to investigate cerebellar cortical activity in response to tACS. The results of the power spectrum analysis revealed that tACS decreases the peak amplitude at low-frequency (2 Hz) while the motor cortex remains unchanged. This decrease was observed in 8/10 recordings. In order to study the response of individual PCs to tACS, we successfully isolated 9 PCs from the cerebellar cortex. Six of these cells demonstrated a decrease in the average firing rate between pre- and post-stimulation (11.6 Hz), while 3 cells demonstrated a slight increase (1.6 Hz). The cross correlation level between cerebellum and cerebral LFPs demonstrated an increase in 4/8 recordings (0.02-0.045). Two of the recordings showed an decrease (0.005-0.02) and 2 recordings were unchanged. Nine recordings showed coherence between the two brain regions at 10 Hz, 5/9 displayed either an increase or decrease. Eight out of 9 recordings showed additional coherence from 85 to 95 Hz. This coherence change and it's meaning at high frequency will be further investigated.

Title: Convergence of sensory-evoked signals via multiple pathways in the cerebellum

Authors: *T. ISHIKAWA[1], I. SUGIHARA[2], M. SHIMUTA[1];
[1]Dept Pharmacol, Jikei Univ. Sch. of Med., Tokyo, Japan; [2]Neurophysiol., Tokyo Med. & Dent. Univ., Tokyo, Japan

Abstract: The cerebellum receives various types of inputs via mossy fibers and climbing fibers, both of which convey signals from peripheral sensory organs and from the cerebral cortex. It is

not well-understood how those multiple types of signals are integrated in the cerebellar cortical circuit. To address this issue, we investigated somatosensory signals from the facial area of mice (VGAT-ChR2 mice) whose cortico-ponto-cerebellar pathway could be blocked by light illumination onto the somatosensory cortex. When we gave tactile stimulation to the upper lip, excitatory synaptic currents in granule cells appeared in two distinct timings in the in vivo whole-cell recordings in anesthetized mice (ketamine/xylazine). The early response (9.1 ± 0.5 ms latency, average ± s.e.m, n = 17) was not affected but the late response (31.0 ± 0.7 ms latency, n = 20) was suppressed by the light illumination, suggesting that they were direct trigeminal and indirect cortico-pontine responses, respectively. More than a half of the granule cells (15/27 cells) in our recording had both the early and the late excitatory synaptic response, while other cells (10/27 cells) had either the early or the late response. In current-clamp recording, action potentials were generated either in the early or in the late timing. Such two-phase responses were obtained in a wide area in crus II of the cerebellar cortex, from 5a- to 7+ aldolase C compartments. Consistent results were obtained in field potential recordings in the granule cell layer of awake mice. In Purkinje cells, the early simple spikes were not affected but the late simple spikes were suppressed by cortical photoinhibition. Interestingly, the complex spikes were also suppressed in the same manner. These results demonstrate that cerebellar granule cells relay diverse types of inputs from the trigeminal nuclei and the somatosensory cortex to Purkinje cells, which integrates those signals with ones from the somatosensory cortex via climbing fibers.

Title: Effect of cerebellar theta burst stimulation on plasticity of interconnected parietal and motor areas

Authors: E. GOLDENKOFF[1], T. G. LEE[2], *M. VESIA[1];
[1]Sch. of Kinesiology, [2]Dept. of Psychology, Univ. of Michigan, Ann Arbor, MI

Abstract: Voluntary movement control and motor learning depend on plasticity in a number of spatially distributed but interconnected brain regions. Transcranial magnetic stimulation (TMS) has become a popular clinical tool for noninvasively modifying plasticity in brain networks.

TMS is not only capable of modulating activity in the targeted region beyond the duration of the stimulation itself, but also interconnected brain circuits. Yet, the mechanisms driving cortical plasticity in response to brain stimulation are not well understood. The cerebellum is an important structure involved in movement control and cognitive processing. Notably, cerebellar output projects to different interconnected cortical areas in the human motor system such as premotor, motor and parietal areas to support cognitive-motor function. Therefore, developing strategies to modulate plasticity processes between the cerebellum and cortex may provide a more mechanistic understanding at the brain circuit level of the effects of TMS underlying plasticity of neural networks and advance treatment of movement disorders. Previous work shows stimulation to the cerebellum can modulate cerebellar excitability and influence motor and cognitive behavior. However, the impact of cerebellar stimulation on neural activity of interconnected parietal and motor areas remains largely unknown. We address this gap in knowledge by evaluating whether spike timing-dependent plasticity (STDP) aftereffects in the human parieto-motor circuit change after cerebellar stimulation. We used theta burst stimulation to modulate cerebellar excitability. We used a cortico-cortical paired associative protocol (ccPAS) by means of TMS to induce STDP by repeatedly applying paired pulses over the posterior parietal cortex (PPC) and primary motor cortex (M1). We measured M1 excitability and PPC-M1 connectivity at baseline, immediately after cerebellar TBS and immediately, 15, 30, 45, 60 min after ccPAS. Preliminary results reveal that cerebellar inhibition modulates parieto-motor connectivity, which leads to an increase in motor excitability by ccPAS. Our ongoing work will test whether the plastic change is anatomically and temporally specific. These findings indicate that cerebellar TBS can noninvasively trigger a targeted change of plasticity in a parieto-motor circuit.

Title: Neuronal signals regulating and monitoring of synchronized saccade timing in the primate deep cerebellar nuclei

Authors: *R. TAKEYA, M. TANAKA;
Hokkaido Univ. Sch. Med., Sapporo, Japan

Abstract: Several lines of evidence shows that the cerebellum is essential for synchronized movements. To explore the underlying mechanism, we examined neuronal activity in the cerebellar dentate nucleus in monkeys performing the synchronized saccade task (Takeya et al., 2017), in which the animals made sequential saccades to alternately presented visual stimuli. The target appeared periodically at a fixed interval of 400, 550 or 700 ms (selected randomly for each trial), and every synchronized saccade (± 20% interval) was reinforced with a liquid reward. In the control condition, the target interval was randomized within each trial, and every reactive saccade (> 150 ms following the target onset) was reinforced.
So far, we have recorded from 70 task-related neurons which can be classified into four clusters: Ipsilateral (n = 19), Contralateral (5), Bilateral (24), and Postsaccade (22) neurons. The Bilateral neurons appeared to be more involved in synchronized than reactive saccades because 47% of them exhibited > 20% increase in firing modulation for synchronized saccades, while this proportion was small for the other types of neurons (21, 0, 32% for Ipsi, Contra and Postsac neurons, respectively). Many neurons exhibited ramping preparatory activity with slopes proportional to the inter-saccadic interval, and showed a significant partial correlation between the preparatory activity (150-300 ms before saccades) and inter-saccadic interval (26, 40, 79 and 14% for Ipsi, Contra, Bilateral and Postsac neurons, respectively). For the 19 Bilateral neurons, significant correlation was found for ipsilateral (n = 5), contralateral (6), or bilateral saccades (8). Since each saccade timing may alter depending on the temporal error of previous saccades, we examined partial correlation between saccade latency and postsaccade neuronal activity (50-200 ms). Again, the proportion of neurons with a significant correlation was greatest for the Bilateral neurons (79%; 5, 5 and 9 neurons for ipsi, contra and both directions, respectively) compared to the other types of neurons (32, 40 and 50% for Ipsi, Contra and Postsac neurons, respectively). Among 14 Bilateral neurons with a significant correlation for ipsilateral postsaccadic activity, 12 neurons also showed a significant partial correlation for contralateral preparatory activity, suggesting that they might regulate contraversive saccade timing using the error signals for ipsiversive saccades. Thus, our results show that the output node of the lateral cerebellum carries relevant signals to motor control and error monitoring for synchronized saccades. In particular, the Bilateral neurons might play a prominent role.

Title: Regulatory control of microglial phagocytosis by estradiol and prostaglandin E2 in the developing rat cerebellum

Authors: *M. PEREZ-POUCHOULEN, S. J. YU, C. R. ROBY, N. BONSAVAGE, M. M. MCCARTHY;
Pharmacol., Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract: Microglia are essential to sculpting the developing brain and they achieve this in part through the process of phagocytosis which is regulated by microenvironmental signals associated with cell death and synaptic connectivity. We have shown that in the cerebellum, microglial phagocytosis reaches its highest activity during the third postnatal week of development but the factors regulating this activity are unknown. Here, we explored the relationship between the PGE_2-estradiol pathway and microglia in the maturing cerebellum since the signaling pathway involving prostaglandin E_2 (PGE_2) stimulation of the estrogen synthetic enzyme aromatase, peaks during the 2^{nd} postnatal week and is a critical regulator of Purkinje cell maturation. Thus, we treated developing rat pups, from postnatal day (PN) 8 to 12, with pharmacological inhibitors of estradiol (formestane, 5 µg / 0.05 ml s.c.) and PGE_2 (nimesulide and indomethacin, 5 µg / 0.05 ml s.c.) synthesis and then stained microglia with the universal marker Iba1 to count microglia engaged in phagocytosis as well as phagocytic cups in the vermis and cerebellar hemispheres at PN17. Formestane reduced the number of phagocytic cups in the vermis, but not in the cerebellar hemisphere at PN17. Similar results were found after treatment with nimesulide and indomethacin. In contrast, treatment with estradiol or PGE_2 had little effect on microglial phagocytosis in the developing cerebellum. We also treated more rat pups with estradiol (5 µg/0.05 ml dissolved in sesame oil), PGE_2 (2.5 µg/µl) or vehicle and found they had little effect on microglial phagocytosis in the developing cerebellum. We conclude that endogenous estrogens and prostaglandins upregulate the phagocytic activity of microglia during a select window of postnatal cerebellar development, but exogenous treatment with these same signaling molecules does not further increase the already high levels of phagocytosis. This may be due to an upper threshold or evidence of resistance to exogenous perturbation. NIH Grant R01-MH091424 to M.M.M.

Engin., Univ. of North Carolina-Chapel Hill/NCSU, Chape Hill, NC

Abstract: The cerebellum is the brain area that enables agility in motor, sensory and cognitive domains. It provides fast-forward computing modules that support other brain regions in complex tasks, like the movements of a tennis champion or the articulation of complex sentences. Despite its critical role in motor and cognitive functions, basic questions underlying cerebellar function, such as neural population dynamics and plasticity mechanisms, are still highly debated. The difficulties lie in sampling populations of cerebellar neurons during complex yet quantifiable behavioral conditions. Investigations that can achieve this critical requirement offer mechanistic insights into cerebellar function and aid in the development of therapies to restore and treat ailments of the cerebellum, including motor dyspraxia.
Eyeblink conditioning (EBC) is a tractable, quantifiable behavioral paradigm that allows for probing of cerebellar activity during the different phases of motor learning. In EBC, animals gradually learn to close the eyelid in the presence of a neutral stimulus (light flash), after such stimulus has been repeatedly paired with an air-puff to the cornea. While electrophysiology of EBC-controlling areas has been performed in multiple species during learning (mice, rabbits, and rats), calcium imaging has so far been impossible because of their location deep in the brain, which hinders their optical accessibility. Therefore, the population dynamics of cerebellar neurons during this task are unexplored. Here we propose to employ the ferret preparation as an animal model to study neuronal subpopulations dynamics during EBC learning. Unlike rodent models, ferrets present a superficial and optically accessible EBC-controlling area.
As a first step, we probed the viability of this preparation by training awake intact ferrets in EBC. By pairing a mild air puff to the whisker with a blink-eliciting air puff to the cornea, we have, for the first time to our knowledge, successfully trained ferrets in EBC in a head-fixed manner. Conditioned responses (CRs) were detectable after a few sessions and continued to increase throughout the training. With this behavioral preparation in place, we aim to answer population coding questions, like error signal encoding and the role of different neuronal subpopulations in the production of CRs.

Title: A novel basal ganglia thalamocortical normal and pathological motor circuitry model

Authors: *D. KUMBHARE[1,4], G. WEISTROFFER[2,4], M. S. BARON[3,5];
[1]Neurosurg., [2]Biomed. Engin., [3]Neurol., Virginia Commonwealth Univ., Richmond, VA; [4]Res., [5]SE Parkinson's Dis. Research, Education, and Clin. Centers, Hunter Holmes McGuire Res. Inst., Richmond, VA

Abstract: Although the rate-based classical basal ganglia (BG) circuitry model provides an invaluable framework for conceptualizing BG-thalamocortical (BGTC) connections, the model has major limitations. As part of our investigations of the pathophysiology of movement disorders, we have performed multi-nuclei multi-neuronal recordings from the globus pallidus (GP; rodent equivalent of GP externa (GPe), entopeduncular nucleus (EP; equivalent of GP internus (GPi)), subthalamic nucleus (STN), pallidal receiving thalamus, and motor cortex in head restrained awake rats under resting and movement conditions. We have investigated these key nuclear regions in normal and different rat models of dystonia and parkinsonism using various optogenetic and pharmacological manipulations. From these studies, we propose a novel BGTC model, which accounts for observed pathophysiological features of dystonia, an illustrative common movement disorder.
Per our modeling, under dystonic *resting* conditions, GPe, STN, and GPi neurons are altered from normally tonic and fast to pathologically slow and highly irregular and bursty. The suppressed BG output signaling from EP causes insufficient hyperpolarizing input to ventrolateral (VL) thalamus. This, in turn, causes VL neurons to fire tonically, rather than in the intended burst baseline 'ready' mode.
With movement, due to different overlapping mechanisms, GABAergic inhibitory striatal neurons projecting to GPe are excessively burst activated, which produces excessive silencing of GPe neurons. Also, failure of GPe-STN auto-stabilizing prevents highly specific BG output signaling and instead induces pathological synchrony. Non-discriminate, excessively suppressed GABAergic inhibitory GPe signaling, in turn, causes GPi neurons to non-discriminately burst activate. The prominent hyperpolarizing GABAergic input from GPi non-discriminately switches VL neurons to a 'movement', albeit pathological, burst mode. Moreover, the indiscriminate and temporally inaccurate GPi motor output produces non-select and highly erroneous

thalamocortical burst signaling. This ultimately induces pathological corticospinal motor signals which lead to the characteristic sustained co-contractions and overflow muscle activation features of dystonia.
This novel BGTC model is anticipated to advance our understanding of the underlying pathophysiology of different movement disorders.

Title: Parkinsonism and dystonia originate differentially along highly discrete cortical basal ganglia motor subcircuits

Authors: *G. WEISTROFFER[1,3], D. KUMBHARE[2,3], M. S. BARON[5,4];
[1]Biomed. Engin., [2]Dept. of Neurosurg., Virginia Commonwealth Univ., Richmond, VA; [3]Res., [4]Southeast Padrecc, Hunter Holmes McGuire VA Med. Ctr., Richmond, VA; [5]Neurol., VCUMC/VCUHS, Richmond, VA

Abstract: *Background*. The basal ganglia-thalamocortical (BGTC) motor network is organized into segregated re-entrant subcircuits originating from distinct primary and premotor motor territories. We previously reported that a precise neurotoxic ibotenate lesion in the ventral motor territory of the globus pallidus (GP; rodent equivalent to GP externa (GPe)) induces dystonia, while a discrete dorsal lesion induces parkinsonism. To delineate these two subcircuits, we injected multi-synaptic anterograde and retrograde neuronal viral tracers into the two identified GP hotspots and the associated cortical hotspots.
Methods. Under the guidance of microelectrode recording, florescent tagged vesicular stomatitis virus (rVSV) was locally administered (7.56E+10 TU/ml, 0.4-1.4 μl) into the previously defined parkinsonian or dystonia hotspot in GP (n=18 rats). After 2-4 days, the rats were perfused, and the brains were processed. Successful discrete targeting of injections into the GP hotspots was affirmed by induction of the anticipated motor condition upon delayed local viral induced neuronal degeneration.
Results. Dense, circumscribed anterograde labeling of neurons was observed in the thalamus and motor cortex. Initial rats (n= 5) injected with a higher viral dose (>1.2 μl) and maintained for 4 days post-injection consistently developed unilateral dystonia indistinguishable from that

induced by ibotenate lesions. Based on computational modeling of the observed histological labeling, the GP dystonia hotspot projected primarily to primary motor cortex (L2.2, A2.1, D2.5) and the parkinsonian hotspot to secondary motor cortex (L1.5, A2.4, D2).
Significance. This study provides compelling evidence that two representative movement disorders, dystonia and parkinsonism, originate along separate and largely segregated primary and secondary motor BGTC subcircuits, respectively. This has important implications for developing new approaches to treating various movement conditions in humans.

Title: Distinct striatal population dynamics during voluntary movement under healthy and disease conditions

Authors: *D. ZEMEL, H. J. GRITTON, M. F. ROMANO, X. HAN;
Boston Univ., Boston, MA

Abstract: The dorsal striatum, a major structure of the basal ganglia circuit, guides voluntary movement by coordinating various cortical and sub-cortical neural activities. Disruption of striatal function can lead to movement disorders such as Parkinson's disease (PD). However, striatal neural population dynamics during voluntary movement in healthy and disease conditions are not fully characterized. Recently, we found that in healthy mice activation of pavalbumin positive cells (PV) facilitates movement while activation of cholinergic interneurons synchronize activity within medium spiny neurons (MSN) networks to signal the end of a movement bouts. Here, we performed simultaneous local field potential (LFP) recording and Ca^{2+} imaging in the dorsal striatum of mice during voluntary movement under healthy conditions, as well as 6-hydroxydopamine (6-OHDA) induced low dopamine Parkinsonian conditions. Under healthy conditions, we found that high-speed movement periods and low-speed movement periods correspond to distinct network states with unique neural population dynamics and different predominant LFP oscillations. High-speed movement periods are characterized by higher correlation between the activity of MSN pairs, higher firing rates of PV interneurons, and reduced LFP beta (12-20Hz) oscillation power compared to low-speed movement periods. Upon dopamine depletion, striatal network gradually transitioned towards a state with elevated beta oscillation power. These results provide new insights into neural population dynamics and bulk

LFP patterns in the striatum under healthy conditions, as well as provide informative description of the changes in population activity upon dopamine depletion in a PD model.

Title: Regulation of Parkinsonian motor behaviors by a diencephalon-midbrain circuitry

Authors: *L. LI, Y. LI, X. LI;
Zhejiang Univ., Zhejiang, China

Abstract: Parkinson`s disease is a debilitating neurodegenerative disorder with classical parkinsonian motor symptoms including bradykinesia, rigidity, rest tremor, postural and gait impairment. Despite Lewy bodies and loss of dopaminergic neurons in the substantia nigra, the disease pathology remains poorly understood. In our study, we discovered a diencephalon-midbrain circuitry that when optogentically activated promptly induced Parkinsonian motor impairments such as rotations, increased freezing, bradykinesia and decreased motor coordination on rotarod in mice. While optogenetic inhibition of this circuitry had no observable impact on motor performance of normal mice. Either optogenetic activation or inhibition of the circuitry affected level of anxiety as revealed by open field test. Intriguingly, in 6-OHDA established parkinsonian mice model, optogenetic inhibition of this circuitry ameliorated motor performance of modeled mice. Our study revealed a novel circuitry involved in parkinsonian motor symptoms and provided potential therapeutic targets for PD.

Title: Deep brain stimulation of the Tourette Syndrome target (centromedian-parafascicular complex) results in striatal dopamine efflux in the rat

Authors: *A. E. RUSHEEN[1,2], A. S. BARATH[2], H. SHIN[2], J. ROJAS CABRERA[2], K. E. BENNET[3,2], C. D. BLAHA[2], Y. OH[2,4], K. H. LEE[2,4];
[1]Med. Scientist Training Program, [2]Dept. of Neurologic Surgery, [3]Div. of Engin., [4]Dept. of Physiol. and Biomed. Engin., Mayo Clin., Rochester, MN

Abstract: Background: Tourette syndrome (TS) is a neurodevelopmental disorder characterized by the chronic presence of both motor and vocal tics. Epidemiologic studies show that over 100,000 children are affected with TS and often exhibit behavioral comorbidities that interfere with scholastic performance and social development. For severely affected subjects, deep brain stimulation (DBS) has emerged as a treatment option. While many targets for DBS therapy have been identified, an effective target is the centromedian-parafascicular complex (CMPf) of the thalamus. Despite the clinical benefit of DBS, the neurobiological mechanism by which DBS of the CMPf alleviates symptoms of TS is not understood. Based on previous studies, we hypothesize that DBS alters striatal extracellular dopamine concentrations resulting in a reduction in motor tics. **Methods**: In urethane anesthetized rats, the parafascicular nucleus (Pf) (ML:+1.2, AP:-4.6, DV:-6.1) was electrically stimulated using a concentric bipolar electrode and dopamine concentrations recorded in the striatum with a carbon fiber microelectrode (ML:+2, AP:+1.2, DV:-4.1). Fast scan cyclic voltammetry was used to measure stimulation-evoked phasic changes in dopamine concentrations. In addition, multiple cyclic square wave voltammetry, a novel technique developed in our laboratory, was used to measure stimulation-evoked basal changes in dopamine concentrations. Pharmacological confirmation of the dopamine responses was performed with nomifensine (20 mg/kg i.p.), a dopamine reuptake inhibitor. **Results**: Electrical stimulation of the Pf (0.3-0.5 mA amplitude, 60-90 Hz frequency, 2 ms biphasic pulse width) elicited a stimulation time-locked phasic 2.2±.9 nA increase in oxidation current at 0.6 V, indicating extracellular dopamine release in the striatum (n=3 rats). This increase in dopamine release was directly correlated with both stimulation frequency and intensity. Basal dopamine levels were recorded over 5 hrs in response to 4 s, 5 min, and 20 min stimulation, with time-locked fluctuations in extracellular dopamine concentrations. Finally, nomifensine administration enhanced the phasic stimulation-evoked response by ~150%, confirming the recorded responses were due to dopamine. **Conclusions**: These findings suggest that DBS of the CMPf alters extracellular striatal dopamine concentrations which may be important in the mechanism by which DBS alleviates motor symptoms of TS. Precisely how DBS alters extracellular dopamine concentrations, and if stimulation-evoked changes in striatal dopamine concentrations are correlated with motor tic amelioration, are the subjects of future studies.

Title: Phase-dependent electrical stimulation modulates phase-amplitude coupling in Parkinson's disease

Authors: *Y. SALIMPOUR[1], K. A. MILLS[2], W. S. ANDERSON[1];
[1]Neurosurg., Johns Hopkins Sch. of Med., Baltimore, MD; [2]Neurol., Johns Hopkins Univ., Baltimore, MD

Abstract: Cross-frequency coupling (CFC) is a neural mechanism for large scale information transmission across the cortical and subcortical network in the brain. Phase-amplitude coupling (PAC) in which the amplitude of the faster oscillation is coupled to the phase of slow rhythm, is one of the most common quantitative representations of CFC. PAC has been suggested to be the potential mechanism for regional and cross-network integration of distributed information processing in the cortical and subcortical structures. In a healthy brain, PAC accompanies learning and memory. and changes in PAC have been associated with neurological diseases such as Parkinson's disease (PD). It has recently been reported in PD patients that the level of PAC is abnormally larger than the control group. Additionally, effective treatment such as medication and deep brain stimulation are associated with normalization of PAC. Among different brain neuromodulation techniques, phase-dependent stimulation has a strong potential to modulate PAC levels. With only limited evidence from animal studies, there has been no direct observation of PAC modulation as a result of phase-dependent stimulation of the human cortex. In this study, phase-dependent stimulation was directly applied to the motor cortex and superior temporal cortex of human subjects intraoperatively. Stimulation locked to the peak of beta oscillations increased beta-gamma coupling in the motor cortex and trough stimulation reduced the coupling level. Similarly, stimulation at the theta band peak intensified the theta-gamma coupling over the superior temporal cortex. These results taken together imply the capacity of phase-dependent stimulation for modulating PAC level and demonstrate possible applications in neurological disorders associated with abnormal PAC.

Title: Diverse mechanisms lead to common dysfunction of striatal cholinergic interneurons in distinct genetic mouse models of dystonia

Authors: *M. SCARDUZIO[1], K. ESKOW JAUNARAJS[1], M. E. EHRLICH[3], L. L. MCMAHON[2], D. STANDAERT[1];
[1]Neurol., [2]Cell, Developmental, and Integrative Biol., UAB, Birmingham, AL;
[3]Neurology/Pediatrics, Mt. Sinai Sch. Med., New York, NY

Abstract: Dystonia is a movement disorder typically resulting in twisted postures via abnormal muscle contraction. Three common forms of isolated human dystonia result from mutations in the *TOR1A* (DYT1), *THAP1* (DYT6), and *GNAL* (DYT25) genes. Experimental models carrying these mutations facilitate identification of possible shared cellular mechanisms of pathophysiology. Clinical and experimental data indicate striatal cholinergic dysfunction in dystonia. Recently, in male *Dyt1*$^{\Delta GAG/+}$ mice (model of DYT1) we reported elevated extracellular striatal acetylcholine by *in vivo* microdialysis and "paradoxical excitation" of cholinergic interneurons (ChIs) in response to dopamine D2 receptor (D2R) agonism by *ex vivo* slice electrophysiology. The paradoxical excitation involved muscarinic receptors (mAChRs) and was caused by a switch in D2R coupling from canonical $G_{i/o}$ to non-canonical β-arrestin signaling. We sought to determine whether these mechanisms in *Dyt1*$^{\Delta GAG/+}$ mice are shared with *Thap1*$^{C54Y/+}$ knock-in and *Gnal*$^{+/-}$ knock-out, respectively DYT1 and DYT6 dystonia mouse models. We found *Thap1*$^{C54Y/+}$ mice of both sexes have elevated extracellular striatal acetylcholine and D2R-induced paradoxical ChI excitation, which was reversed by mAChR inhibition. In contrast, elevated extracellular acetylcholine was absent in male and female *Gnal*$^{+/-}$ mice, but the paradoxical D2R-mediated ChI excitation was retained and only reversed by inhibition of adenosine A_{2A} receptors, not by mAChR inhibition. The $G_{i/o}$-biased D2R agonist failed to increase ChI excitability, suggesting a possible switch in coupling of D2Rs to β-arrestin, as previously seen in *Dyt1*$^{\Delta GAG/+}$. These data show that while elevated extracellular acetylcholine levels are not common across these genetic models of human dystonia, the D2R-mediated paradoxical excitation of ChIs is shared and is caused by altered function of distinct G-protein coupled receptors.

Title: Striatal cholinergic interneurons and fetal alcohol exposure-induced behavioral flexibility

Authors: ***J. WANG**, A. BINETTE, X. XIE, X. WANG, L. SMITH, R. MIRANDA; Neurosci. and Exptl. Therapeut., Texas A&M Hlth. Sci. Ctr., Bryan, TX

Abstract: Numerous studies suggest that prenatal alcohol exposure (PAE) alters cognitive flexibility. Behavioral flexibility is mediated in part by cholinergic interneurons (CINs) in the striatum. However, it is not clear whether CINs contribute to PAE-induced changes in behavioral flexibility. To assess this possibility, we trained female Ai14 mice to consume high levels of alcohol for 6 weeks using the intermittent access to 20% alcohol two-bottle choice procedure, and the Ai14 mice were mated with alcohol-naïve male ChATCre mice. We found that both male and female PAE offspring exhibited elevated locomotor activity, suggesting that PAE causes hyperactivity. To investigate the contribution of CINs to alcohol intake of these PAE offspring, we infused AAV-DIO-hM3Dq into the dorsomedial striatum (DMS) and found that chemogenetic excitation of DMS CINs via hM3Dq increased home-cage alcohol intake. CIN excitation is known to increase striatal dopamine release via acetylcholine that acts on nicotinic receptors on dopaminergic terminals in this area. We thus tested the effect of a nicotinic receptor antagonist, DHβE, on the CIN-mediated increase in alcohol intake, and observed that DHβE completely abolished the increase. Lastly, we tested behavioral flexibility of PAE offspring and found that male mice exhibited a deficit in reversal learning of operant self-administration using sucrose and food pellets. Our data suggests that PAE-induced inflexible behavior may be associated with alterations in striatal CINs.

Title: Difference in pallidal single unit activity in cervical dystonia with jerky and sinusoidal head tremor

Authors: *A. SEDOV[1], S. USOVA[1], U. SEMENOVA[1], A. GAMALEYA[2], A. TOMSKIY[2], S. B. BEYLERGIL[3], H. A. JINNAH[4], A. G. SHAIKH[3];

Abstract: Two common movement disorders, dystonia and tremor, frequently overlap. Their biological relationships remain unclear. One hypothesis is that tremor and dystonia are due to the same fundamental biological process. A second hypothesis is that tremor and dystonia are due to distinct biological processes which frequently co-occur. Here we test these hypotheses by measuring the physiological activity of the globus pallidus in the most common form of dystonia, cervical dystonia, which frequently combines with tremor of the head. We compared three groups of patients, those with no tremor at all (pure dystonia), those with jerky head oscillations (dystonic tremor), and those with sinusoidal tremor. We used microelectrode recording from 13 CD subjects undergoing deep brain stimulation (DBS) surgery under local anesthesia. We analyzed the spontaneous activity of 727 pallidal neurons (398 GPi and 329 GPe). Clustering of spike-train recordings allowed classification of pallidal activity according to burst, pause, and tonic neurons - the types of neurons expected in dystonia patients. We found the differences in cells distribution between analyzed groups of patients. Burst GPi neurons were more common in pure dystonia or dystonic tremor groups compared to the sinusoidal tremor group. Pause GPi and GPe neurons were more common in the sinusoidal tremor group compared to the pure dystonia or dystonic tremor groups. In addition to their frequent prevalence, the pause neurons in sinusoidal tremor group had lower firing rate and were more irregular. The number of spikes within the burst were higher and inter-burst intervals were longer in sinusoidal tremor group. Neurons of patients with pure dystonia and dystonic tremor had similar parameters. We also found bihemispheric asymmetry in the dystonic tremor and pure dystonia groups, while such asymmetry was not present in the sinusoidal oscillation group. These results revealing

differences in the physiology of pallidal neurons of dystonic and sinusoidal tremor patients, suggest their distinct mechanistic underpinings.

Title: Reversal of subthalamic nucleus dysfunction in Q175 Huntington's disease mice through viral vector mediated lowering of mutant Huntingtin

Authors: *J. F. ATHERTON, J. KONDAPALLI, D. WOKOSIN, M. D. BEVAN;
Physiol., Northwestern Univ., Chicago, IL

Abstract: The subthalamic nucleus (STN) is an element of cortico-basal ganglia-thalamo-cortical circuitry critical for action suppression. Huntington's disease (HD) is a progressive neurodegenerative disorder that results from an expanded CAG repeat in the gene encoding huntingtin (Htt) protein. In the initial stages of HD, action suppression is impaired, resembling the effects of STN lesioning or inactivation. The Q175 knock-in mouse model of HD, which expresses full length human mutant htt with ~179 CAG repeats, is associated with abnormal intrinsic and synaptic properties in cortical and striatal neurons together with neuronal degeneration and behavioral abnormalities. We previously found that the intrinsic activity of STN neurons from Q175 het mice is diminished at 6 months of age compared to wild type littermates (WT). Firing disruption is due to increased activation of NMDA receptors leading to activation of K_{ATP} channels. The aim of this project is to further characterize STN abnormalities in HD using the Q175 mouse model and to explore potential strategies for correcting STN dysfunction.
To assess mitochondrial redox state mice were injected in the STN with AAV to express redox-sensitive GFP (roGFP) in neuronal mitochondria. 2-photon imaging of roGFP showed increased oxidation of STN neuronal mitochondria in Q175 het mice relative to WT. Disrupted firing in Q175 was rescued to WT levels by decomposition of H_2O_2 by catalase and alleviated by expression of the antioxidant regulator NRF2. Proteomic and RNAseq analysis of the STN revealed changes in the levels of proteins related to cell excitability, mitochondrial function,

redox pathways, and cell signaling. Viral expression of a zinc finger protein (ZFP) targeting mutant Htt reduced transcription of mutant Htt in the STN by 58% (measured with qPCR). Viral reduction of mutant Htt for 2 months rescued autonomous STN activity. Together, these data argue that dysfunction of firing in the STN is a consequence of mitochondrial oxidant stress. Rescue of intrinsic activity through mutant Htt reduction suggests that STN dysfunction is in large part cell autonomous and may represent a target for symptomatic and/or disease-modifying therapies.

Title: Basal ganglia output in the Q175 model of Huntington's disease

Authors: *A. TIRAN-CAPPELLO, M. D. BEVAN;
Dept. of Physiol., Northwestern Univ., Chicago, IL

Abstract: Huntington disease (HD) is caused by expansion of trinucleotide repeats in exon 1 of the huntingtin gene and is associated with the progressive dysfunction and/or degeneration of neurons, astrocytes, and oligodendrocytes in the cortico-basal ganglia thalamo-cortical circuit and the emergence of debilitating psychomotor symptoms. The mechanisms underlying the pattern and sequence of HD dysfunction and degeneration are poorly understood but are thought to arise from toxic-gains-of-function, which impair neuronal and glial physiomes both directly through cell-autonomous effects and indirectly through the derangement of the circuits in which these cells are embedded. Interestingly, BAC-transgenic and knock-in (KI) HD murine models have revealed that profound, complex alterations in the properties of neurons and glial cells impair the cortico-basal-ganglia-thalamo-cortical circuit long before overt cell loss. For example, cortical, striatal, pallidal, and subthalamic nucleus cells exhibit highly abnormal physiological properties that compromise energetics, redox balance, proteostasis, intracellular signaling, ionic gradient regulation, action potential propagation, cellular excitability, and synaptic transmission and integration. These data argue that aberrant basal ganglia processing and output are likely to contribute to the psychomotor symptoms of HD. However, the properties of basal ganglia output neurons in HD models have not been characterized. To address this deficit, we have embarked on a series of *in vitro* and *in vivo* electrophysiological, anatomical, and molecular studies to

investigate the cellular and synaptic properties of substantia nigra pars reticulata (SNr) neurons in the Q175 KI model of HD. Our initial studies suggest that the autonomous firing of SNr neurons is not altered in HD mice. We are now studying the synaptic patterning of these cells using electrophysiological recording in conjunction with optogenetic identification and manipulation approaches.

Title: Altered synaptic connectivity onto a distinct subset of striatal neurons in levodopa-induced dyskinesia

Authors: *A. E. GIRASOLE[1], M. RYAN[3], M. M. MCGREGOR[2], R. PALETZKI[4], R. BRAKAJ[2], C. R. GERFEN[5], A. B. NELSON[1];

Abstract: Action selection requires coordinated function of the striatal direct and indirect pathways. In Parkinson's disease, loss of dopaminergic inputs alters this balance, leading to motor deficits. While dopamine replacement therapy with levodopa alleviates parkinsonian symptoms, treatment is limited by the development of drug-induced abnormal involuntary movements, termed levodopa-induced dyskinesia (LID). Recently, a unique and stable subpopulation of predominantly direct pathway striatal neurons, captured using an activity-dependent mouse line (FosTRAP), was found to contribute to dyskinesia. Understanding the distinct cellular and synaptic features of this population could inform our understanding of heterogeneity within the direct pathway, as well as the cellular and circuit mechanisms of LID. Here we used optogenetically identified single-unit recordings, monosynaptic retrograde rabies tracing, and slice electrophysiology to identify the unique cellular and circuit properties of this novel subpopulation compared to striatal direct pathway neurons more generally. *In vivo*, we found FosTRAP neurons fired at exceptionally high rates in response to levodopa, which in turn correlated with dyskinesia severity on a fine timescale. Further, we see that FosTRAP neurons

receive increased excitatory synaptic input at the functional level, with little alteration in the anatomical distribution of synaptic input, compared to direct pathway neurons more generally. These findings describe physiological and functional heterogeneity within the striatal direct pathway in the context of LID, and identify a potential underlying cellular mechanism. These results highlight the need for cell-type specific strategies for treating LID, and point the way to new therapeutic targets.

Title: Chronic L-DOPA induces activation of SRF in the striatum of a dyskinetic rat model

Authors: *I. D. LIMÓN PÉREZ DE LEÓN[1], D. L. RODRÍGUEZ-REYES[1], V. PALAFOX-SÁNCHEZ[2], I. MARTÍNEZ-GARCÍA[3];
[1]Lab. de Neurofarmacología-FCQ, Benemerita Univ. Autonoma De Puebla, Puebla, Mexico; [2]Dept. of Integrative Biol. and Physiol., UCLA, Los Angeles, CA; [3]Lab. de Neuroquímica-FCQ, Benemérita Univ. Autónoma de Puebla, Puebla, Mexico

Abstract: According to several studies about the molecular mechanism underlying L-DOPA induce-dyskinesia has been found that overexpression of the delta FosB protein could be as a molecular mediator of persistent adaptations in the striatum allowing the dyskinesia. However remains to be elucidated how the *fosB* gene is overactivated during a dyskinetic process. The serum response factor (SRF) has been involved in the synaptic plasticity, the activation of SRF is mediated by the phosphorylation at serine 103 and it could bind in the *fosB* promoter region to promote its expression, but is still unknown if chronic levodopa induced the activation of SRF in striatum of dyskinetic rats. The objective of the present study was to evaluate if L-DOPA induce the activation of SRF in medium spiny neurons (MSN) in the striatum of dyskinetic rats. Male Wistar rats received unilateral 6-OHDA-injection in the medial forebrain bundle by stereotaxic surgery. Fifteen days post-surgery, the rats were evaluated in the cylinder test to determinate the dopaminergic lesion. The rats received a daily intraperitoneal injection of 10 mg/Kg of L-DOPA during 16 days to develop *abnormal involuntary movements* (AIMs). We study the SRF and p-SRF^{Ser103} in MSN of direct and indirect pathway in dorsolateral striatum. The results showed that the dyskinetic group showed an exacerbated p-SRF^{Ser103} immunorreactivity in MSN of direct and

indirect pathway in dorsolateral striatum respect to control group administrated with L-DOPA. Therefore, this data suggest that L-DOPA induce the activation of SRF in the direct and indirect pathway of basal ganglia. Also phospho-SRF^{Ser103} could be an important striatal biomarker of dyskinesia induced by L-DOPA.

Title: Parkinsonian beta power during rest and movement in the globus pallidus internus and subthalamic nucleus

Authors: *R. S. EISINGER[1], J. CAGLE[2], E. OPRI[3], J. ALCANTARA[3], S. CERNERA[2], K. FOOTE[4], M. S. OKUN[5], A. GUNDUZ[3];
[1]Neurosci., [3]Biomed. Engin., [4]Neurosurg., [5]Neurol., [2]Univ. of Florida, Gainesville, FL

Abstract: Background: Over the years, an expansive body of literature has linked beta-frequency (12-30Hz) power to movement initiation and suppression throughout the basal ganglia and motor cortex. In Parkinson's disease (PD), pathologically high levels of beta activity reflect specific symptomology and normalize with pharmacologic or surgical intervention. Although beta characterization in the subthalamic nucleus (STN) of PD patients undergoing deep brain stimulation (DBS) patients has now been translated into novel adaptive DBS paradigms, limited studies have characterized beta power in the globus pallidus internus (GPi), another popular DBS target.
Methods: To address this shortcoming, for the first time, we set out to directly compare beta power in the STN and GPi during rest and movement in people with PD. A total of 33 subjects completed a simple behavioral experiment - consisting of periods of rest and button presses - leading to LFP recordings from 13 (11 participants) STN and 26 (22 participants) GPi nuclei. We examined overall beta power as well as beta power dynamics (i.e., beta bursts).
Results: We found higher beta power during both rest and movement in the GPi, which also showed greater beta desynchronization during movement. Beta power is positively associated with bradykinesia and rigidity severity, however in our data these relationships were present only in the GPi cohort. With regards to beta dynamics, bursts were similar in duration and frequency between the GPi and STN, but the GPi showed stronger bursts, which were also correlated to

bradykinesia-rigidity severity.
Conclusions: These results overall suggest that relative to the STN, beta in the GPi may be readily detected, modulates more with movement, and may relate more to clinical impairment. Taken together, this could point to the GPi as a potentially effective target for beta-based closed loop DBS.

Title: Learning contributes to Parkinsonian motor impairment and requires activation of indirect pathway spiny projection neurons

Authors: *T. H. C. CHEUNG[1], Y. DING[1], X. ZHUANG[2], U. J. KANG[1];
[1]Fresco Inst. for Parkinson's and Movement Disorders, Dept of Neurol., NYU Langone Med. Ctr., New York, NY; [2]Dept Neurobiol, Univ. of Chicago Dept. of Neurobio., Chicago, IL

Abstract: In Parkinson's disease (PD), dopamine (DA) neuron loss leads to profound motor impairment. Surprisingly, the beneficial effects of the DA precursor L-DOPA can persist long after its plasma level has returned to baseline. This long-duration response (LDR) of L-DOPA is observed both clinically and in animal models, but its neural mechanism is unknown. Here, we use unilateral 6-hydroxydopamine lesion and two distinct motor tasks to show that motor performance of tasks learned before DA depletion worsened gradually despite full depletion. This worsening is driven by learning, as it is experience-dependent and task-specific, caused by pairing specific task exposure with a DA-depleted state. In addition, both the induction of L-DOPA's LDR and its subsequent decay after L-DOPA withdrawal are also experience-dependent and task-specific. c-Fos staining shows that gradual decay of motor performance is associated with both reduced activation of direct-pathway spiny projection neurons (dSPNs) and increased activation of indirect-pathway SPNs (iSPNs), consistent with dSPNs' role in promoting movements and iPSNs' role in inhibiting movements. However, iSPN activation (by D2R antagonist) is sufficient to cause gradual motor impairment in DA-intact mice, whereas blocking iSPN activation (D2R-knockdown, chemogenetics, or A2A receptor antagonist) prevented gradual motor impairment, and this occurred despite reduced dSPN activation. Targeted ablation of cholinergic interneurons show that they are uninvolved in gradual Parkinsonian motor

impairment. We further show that LDR induction require CB1 receptors, consistent with iSPN long-term depression; whereas LDR decay require NMDA receptors, consistent with iSPN long-term potentiation. Surprisingly, we found that D1R agonist was able to both induce LDR and prevent LDR decay; however, unlike D2R agonist or L-DOPA, the effect of D1R agonist requires intra-striatal GABA-A receptors, suggesting an indirect D1R effect that requires intra-striatal microcircuitry. In summary, DA depletion causes gradual Parkinsonism mediated by task-specific learning and iSPN activation. D2R and D1R play dissociable roles: D2R activation directly blocks gradual Parkinsonism, whereas D1R activation blocks it indirectly via intra-striatal GABA signaling.

Title: Real time monitoring of circuit plasticity reveals a role for orbitofrontal-striatal pathway in cocaine-induced hyperlocomotion

Authors: *S. BARISELLI[1], N. MIYAZAKI[1], A. V. KRAVITZ[2];
[1]NIH, Bethesda, MD; [2]NIDDK, Natl. Inst. of Hlth., Bethesda, MD

Abstract: The dorsal striatum integrates glutamatergic and dopaminergic inputs. Although several studies clarified the roles of dopamine in regulating neuronal firing and cortical excitatory synaptic transmission *in vitro*, its role *in vivo* remains largerly unexplored. Here, we studied the effects of hyperdopaminergic states on neuronal firing and cortical input efficacy in the dorso-medial striatum (DMS) of awake mice. We found that cocaine increased overall striatal activity, at both direct and indirect pathways, and increased input efficacy of orbitofrontal cortex (OFC) projections. Moreover, by monitoring the OFC-DMS inputs in real-time, we found that high-frequency stimulation (HFS) in awake mice weakened striatal excitatory inputs and attenuated cocaine-induced hyperlocomotion. Thus, the real-time monitoring of striatal inputs allowed us to identify circuit adaptations underlying hyperdopaminergic states, to develop an evidence-based approach to manipulate relevant circuits and rescue aberrant behavioral traits.

Title: Phase-dependent closed-loop modulation of beta-frequency network oscillations in Parkinsonian rats

Authors: *M. ROTHWELL, C. MCNAMARA, A. SHAROTT;
MRC Brain Network Dynamics Unit, Dept. of Pharmacol., Univ. of Oxford, Oxford, United Kingdom

Abstract: Abnormally sustained oscillations in the beta frequency band (15-40Hz) are a consistent feature of the cortico-basal ganglia circuits of the parkinsonian brain. Effective pharmacological and surgical treatments reduce the power and network synchronization of these oscillations. Such manipulations, however, also modulate many other neuronal processes unrelated to the disease. Post-hoc analysis of beta-frequency stimulation of the subthalamic area in Parkinson's disease patients has demonstrated that oscillation amplitude is modulated by the phase at which stimulation is delivered. Computational studies suggest such phase-dependent modulation of neuronal oscillators could result from shifting the relative timing of neuronal activity. Applying such phase-dependent stimulation in a closed-loop manner, whereby pulsatile stimulation is consistently delivered to a specific phase of the ongoing oscillation, could lead to a more selective modulation of symptoms and reduced side effects. To test this hypothesis, we performed closed-loop phase-dependent stimulation in 6-OHDA hemi-lesioned rats, which display robust power increases in the high-beta band (28-40Hz) across the cortex and basal ganglia. We utilized a digital circuit-based system to produce a continuous online phase-estimate, which enabled the speed and accuracy required to perform accurate online phase-locked stimulation despite the transient, burst-like nature of the oscillations. Such phase-estimates were calculated from an electrocorticogram recorded above the motor cortex and used to control the timing of electrical stimulation of the globus pallidus external segment (GPe). Within individual animals, stimulation of GPe on some cortical phases led to amplification of the amplitude of the cortical beta oscillation, while others led to suppression, demonstrating network-level modulation. Motor performance during stimulation at the suppressing and amplifying phases was compared to no stimulation and continuous high-frequency stimulation using the Catwalk system, which provides various measures of locomotor performance while animals run on a linear track. Overall, these results suggest that phase-dependent closed-loop

modulation could provide a viable method to modulate pathological beta oscillations in Parkinson's disease.

Title: Dorsal striatum volume increase after electroconvulsive therapy correlates with improvement of psychomotor symptoms in late life depression

Authors: M. G. A. VAN CAUWENBERGE[1], L. EMSELL[1], F. BOUCKAERT[1], K. VANSTEELANDT[1], F.-L. DE WINTER[1], M. LAROY[1], C. C. ADAMSON[2], A. DOLS[3], M. L. STEK[4], *J. VAN DEN STOCK[1], M. VANDENBULCKE[1];
[1]KU Leuven, Leuven, Belgium; [2]Murdoch Childrens Res. Inst., Melbourne, Australia; [3]GGZ inGeest Amsterdam, Amsterdam, Netherlands; [4]VUmc Amsterdam, Amsterdam, Netherlands

Abstract: Depression is among the top ten causes of impaired health worldwide. Primarily a mood disorder, depression is also associated with cognitive and motor dysfunction. The term psychomotor dysfunction (PMD) covers both decrease (retardation) and increase (agitation) of gross and fine movement, facial expression and gait in psychiatric illness. Clinical PMD has a prevalence of 20% in depression and is more common in the elderly. The presence of PMD predicts chronicity and better response to electroconvulsive therapy (ECT). Previous research on the neurobiology of PMD revealed white matter lesions and atrophy in the fronto-striato-pallido-thalamic circuit, but the pathophysiology and contribution to motor symptoms has not been clarified.
The present study aimed to identify whether PMD in late life depression (LLD) correlates with gray matter volume of the basal ganglia and whether volumetric changes following ECT relate to PMD improvement. A two-center (VU-GGZ Amsterdam, KU Leuven) prospective cohort study was conducted between January 2011 and December 2013, including 110 patients with LLD (> 65 yr.), eligible for ECT and with no other major neurological or psychiatric illness. Participants were clinically evaluated 1 week before, 1 week and 6 months after an averaged 6-week ECT course using outcome measures of mood (MADRS), cognition (MMSE) and psychomotor function (CORE). Brain MRI was available for 67 patients on the first two time points and 24 patients at six months. Automated volumetric analysis was conducted bilaterally on four regions

of interest: the caudate nucleus, putamen, globus pallidum and nucleus accumbens. Statistical analysis included GLM at baseline, Wilcoxon signed rank test and linear mixed models for longitudinal comparison. A p-value <0.05 was defined significant, Bonferroni correction was applied. Volumetric outcome was analyzed in a linear regression model with CORE, sex, age, number of ECT sessions, psychosis and site of scanning as predictors.
At baseline, psychomotor retardation (CORE retardation) correlated inversely with left and right caudate nucleus volume. One week after ECT, all clinical outcome measures improved and volume increases occurred bilaterally in the caudate nucleus, the putamen and the right accumbens nucleus. Improved psychomotor functioning correlated with volume increase of the left caudate nucleus and left putamen. Number of ECT sessions and psychosis predicted this volume increase. Six months after ECT, clinical improvement persisted, but volumetric differences could not be detected. This data suggests that dorsal striatum volume is a predictor of PMD in LLD and a possible target for intervention.

Title: Optogenetic silencing of cholinergic neurons of the basal forebrain evokes falls and impairs cued turning in rats with striatal dopamine loss

Authors: *A. KUCINSKI, K. B. PHILLIPS, M. SARTER;
Univ. of Michigan, ANN ARBOR, MI

Abstract: Falls, gait and balancing deficits, and attentional impairments are common symptoms in about half of the patients with Parkinson's Disease (PD) and are associated, in addition to striatal dopamine (DA) losses, with loss of cortical and thalamic acetylcholine (ACh). We previously established a rat model (dual, ‘DL’ rats) of PD falls which result from dorsomedial striatal DA and cortical ACh losses, and which reflect the loss of compensatory attentional supervision of complex movements. DL rats exhibit a high propensity for falls on a beam traversal task that taxes attentional control of gait, balance and movement sequencing. Here we hypothesized that optogenetic silencing of BF cholinergic neurons in rats with striatal DA losses would also evoke falls, thereby allowing a precise temporal determination of risk factors for

falls. ChAT-Cre rats received bilateral infusions of the Cre-dependent light-activated chloride channels (AAV-8-Ef1a-DIO iC++-EYFP) into the BF and were implanted with fiber optic cannulae to inhibit BF cholinergic neurons. Rats were previously familiarized with the traversal of a 3-m stationary or rotating (8 RPM) squared rod. In half of the runs, rats expressing the opsin or a EYFP control received two 1-s, 4-6 mW pulses per run, the first right after rats initiated traversals and the second halfway along the beam. Optogenetic stimulation increased the rate of falls significantly, by 64% on the stationary rod and by 65% on the rotating rod. Falls in rats without DA losses, or which expressed the control construct in the presence of striatal DA losses, were not affected by the laser pulses. As we previously demonstrated that DL rats also exhibit deficits in cued turning while walking on a treadmill the effects of optogenetic inhibition of BF cholinergic neurons were also assessed in this secondary task. Laser stimulation during the 2-s turn cue in rats with DA losses reduced the rate of successful turns, but not of cue-evoked successful stops. These results further validate that inhibition of BF cholinergic neurons unmasks the impact of striatal DA loss for gait, balance and movement sequencing and selection. Future experiments will determine whether optogenetic enhancement of cholinergic signaling can prevent falls and improve cued turning in DL rats, and thus potentially serve as a therapeutic approach to improve movement control and prevent falls.

Title: A diencephalic pathway for movement initiation and rescue of Parkinsonian symptoms

Authors: *G. D. R. WATSON[1], R. N. HUGHES[2], E. PETTER[3], H. H. YIN[4];
[1]Psychology & Neurosci., [2]Psychology and Neurosci., [4]Dept. of Psychology and Neurosci., [3]Duke Univ., Durham, NC

Abstract: The parafascicular nucleus (Pf) of the thalamus projects to the subthalamic nucleus (STN), a major target for deep brain stimulation (DBS) in Parkinson's disease (PD), but the function of this projection remains unknown. Here, we used optogenetics, 3D motion capture, *in vivo* electrophysiology and 1-photon calcium imaging, unsupervised behavioral classification,

and viral-based neuroanatomical tracing to examine the contribution of Pf efferents to movement generation in mice. We discovered that Pf neurons are highly correlated with movement velocity and excitation of Pf neurons generates turning and orienting movements. Movement initiation was not due to Pf projections to the striatum, but rather its projections to the STN. Optogenetic excitation of the Pf-STN pathway restores movement in a common mouse model of PD with complete akinesia. Collectively, our results reveal a thalamo-subthalamic pathway regulating movement initiation, and demonstrate a circuit mechanism that could potentially explain the clinical efficacy of DBS for relief of PD motor symptoms.

Title: Forelimb motor learning results in specific refinements in intertrial motor variability, is associated with striatal plasticity and is impaired in mouse models of Huntington's disease

Authors: *C. L. WOODARD[1], M. D. SEPERS[1], J. D. BOYD[1], A. L. SOUTHWELL[2], M. R. HAYDEN[1], T. MURPHY[1], L. A. RAYMOND[1];

Abstract: In order to assess motor learning over long time scales in mice and mouse models of disease, we have designed an automated, self-directed behavioural testing system which is accessible to group-housed mice from their home-cage and can be accessed at will, 24 hours per day. This design eliminates the need for the animal to be exposed to novel environments, and minimizes experimenter interaction, significantly reducing two of the largest stressors associated with animal behaviour. Additionally, mice can be passively trained on a difficult task over weeks or months of testing with comparatively little effort, allowing us to more easily study longitudinal changes in motor skill. In this system, mice use their forelimb to pull a small lever either to a specific position or with a specific velocity in order to receive water drops. Group-housed mice can be individually tracked using subcutaneously implanted RFID capsules, and

high-resolution lever position analysis as well as video recording allows for assessment of learning and quantification of motor kinematic parameters. Mice assessed using this system can successfully use trial-and-error learning to improve their performance of the task over several weeks. Animals reduce intertrial variability specifically on the task-relevant parameter (either maximum lever position or lever velocity), while the intertrial variability of other parameters does not change. Acute slices taken from the brains of mice trained on this task show hemisphere-specific electrophysiological changes in dorsolateral striatum medium spiny neurons (MSNs). Specifically, the amplitude of spontaneous excitatory post-synaptic currents (sEPSCs) is lower, and the presynaptic probability of release is higher, in the hemisphere contralateral to the trained forelimb as compared to the ipsilateral hemisphere. We are currently using this system to assess motor learning and forelimb kinematics in the YAC128 and Q175-FDN models of Huntington's disease, and have found deficits in the ability of these mice to reduce intertrial variability of kinematic parameters with training. This platform should prove useful for both the study of neurophysiological mechanisms of motor learning, and for preclinical drug trials toward improved treatments in HD and other neurodegenerative disorders.

Title: Dystonic-like movements in a mouse model of task-specific dystonia are stereotyped and distinct from innate behaviors

Authors: *K. KERNODLE[1], W. T. DAUER[2], D. K. LEVENTHAL[3];
[1]Neurosci. Grad. Program, [2]Univ. of Michigan, Ann Arbor, MI; [3]Neurol., Univ. of Michigan, Ann Arbor, Ann Arbor, MI

Abstract: We previously established a mouse model of task-specific dystonia that develops dystonic-like movements after repeated training on the single pellet skilled reaching task. These mice carry a human dystonia mutation and have no dystonic-like movements during natural behaviors. However, dystonic-like movements emerge during training on the skilled reaching task. This scenario is broadly similar to humans with task-specific dystonia, which typically develops following extensive training on a highly dexterous motor task. The movements that

develop in the mice are visually similar to innate grooming behaviors. We used a deep learning algorithm to generate 3-dimensional trajectories of the dystonic-like movements as well as visually similar movements. Although both movement types are highly stereotyped, dystonic-like movements are asymmetric between forepaws whereas grooming is symmetric. Additionally, the frequency of dystonic-like movements is higher than visually similar grooming movements, with paws appearing out of phase with each other more frequently. These results support the use of learning algorithms for movement classification and allow unique studies of dystonic-like movements in a mouse model of task-specific dystonia.

Title: Spatiotemporal dynamics of striatal circuits during repetitive behaviors in autism spectrum disorder

Authors: *A. M. VICENTE[1], G. J. MARTINS[1], V. B. PAIXAO[2], R. M. COSTA[1];
[1]Columbia Univ., New York, NY; [2]Champalimaud Fndn., Lisbon, Portugal

Abstract: Autism Spectrum Disorder (ASD) is a developmental disorder characterized by a set of symptoms including repetitive behaviors. Repetitive motor patterns have long been considered to be inflexible actions dependent on habitual circuitry. Striatal direct and indirect pathway projection neurons (dSPN and iSPN) are essential for action initiation and performance as well as habit formation. While dSPNs appear to support continuation of ongoing actions, iSPNs seem to regulate switching from current actions. Furthermore, corticostriatal plasticity is critical for decreases in behavioral variability during learning. Since regulation of the coordinated activity of dSPN and iSPN is likely essential in controlling repetitive actions, we decided to investigate their role during natural and learned behaviors in a genetic mouse model of ASD (*Del16p11.2* heterozygous mice). To achieve this goal, we first imaged dSPNs and iSPNs in freely moving *Del16p11.2* mice and littermate controls, while using an unbiased behavior classification to extract their movement patterns. We observed that behavioral cluster similarity in *Del16p11.2* heterozygous mice is increased compared to their littermate controls, suggesting a greater degree of stereotypy for these animals. Previous results have shown stronger correlations between local SPN activity, suggesting the existence of functional domains within striatal circuitry. We observed an increase in cross-correlations between SPNs in *Del16p11.2* mice compared to

controls, which can denote changes in corticostriatal connectivity. To study stereotypy in learned behavior, we have used a task newly developed in the lab to investigate learning and performance of heterogeneous sequences, where animals have to learn to perform a specific sequence of nose pokes to receive a water reward. *Del16p11.2* mice performed a higher number of nose pokes and presented increased stereotypy in learned sequences. However, when the rewarded sequence was changed, *Del16p11.2* mice showed no impairment, and even a faster transition to the new sequence, and therefore no signs of behavior and cognitive inflexibility. These experiments reveal the changes in striatal organization in ASD, with spatial and temporal resolution, and how those affect behavior.

Title: Inhibition of signaling and metabolic pathways in the Pink1-/- rat model of early-onset Parkinsonism

Authors: *C. A. KELM-NELSON, M. R. CIUCCI;
Univ. of Wisconsin Madison Dept. of Surgery, Madison, WI

Abstract: Parkinson disease (PD) is a progressive, neurodegenerative disease with early-stage pathology hypothesized to manifest in the brainstem. Loss of function in the PTEN induced kinase 1 (*Pink1*) causes autosomal recessive PD, an early-onset form of the disease. At 8 months, the *Pink1*-/- rat model of PD exhibits detectable limb and cranial sensorimotor deficits as well as brainstem pathology including reduced catecholamine concentrations and abnormal, aggregated alpha-synuclein. The aim of the present study was to identify differentially expressed genes (DEGs) using high throughput RNA-seq in the brainstems of *Pink1-/-* male and female rats as compared to their respective age-matched wildtype (WT) controls and determine their relationship to the *Pink1* gene. A set of significant, annotated DEGs were identified in both males and females. KEGG pathway enrichment analysis was used to compare the gene set to existing network datasets. Briefly, in males, pathways (*genes*) of interest include pentose and glucuronate interconversions (*AKR1B10, UGT1A9*), and glycine, serine and threonine metabolism (*PSAT1, MAOB*). In females, glutathione metabolism (*GSTM3, SMS*), PPAR signaling (*UBC, SLC27A6*), and metabolism (*TPMT, GSTm3*) pathways were identified.

WGCNA was used to identify significant biological networks of interest; *Pink1* was a central module with many interconnecting genes of interest. Separate analysis of male and female modules that included *Pink1* also had different genes suggesting a sex-specific difference. In general, the data suggest that loss of *Pink1* influences signaling and oxidative stress pathways within the brainstem. The next step in this work is to link specific neurobiological change with limb and cranial sensorimotor behavior.

Title: Behavioral sensitization to methylphenidate is modulated by glutaminergic signaling in the caudate nucleus

Authors: *N. KING, S. FLOREN, N. KHARAS, M. THOMAS, N. DAFNY;
Univ. of Texas McGovern Med. Sch., Houston, TX

Abstract: Methylphenidate (MPD) is the most widely prescribed psychostimulant for the treatment of attention deficit hyperactivity disorder, and is growing in use as a recreational drug and academic enhancer. MPD acts on the reward/motive and motor circuits of the CNS to produce its effects on behavior. The caudate nucleus (CN) is known to be a part of these circuits, so a lesion study was designed to elucidate the role of the CN in response to acute and chronic MPD exposure. Five groups of n=8 rats were used: control, sham CN lesions, non-specific electrolytic CN lesions, dopaminergic-specific (6-OHDA toxin) CN lesion, and glutaminergic-specific (ibotenic acid toxin) CN lesions. On experimental day (ED) 1, all groups received saline injections. On ED 2, surgeries took place, followed by a 5-day recovery period (ED 3-7). Groups then received six daily MPD 2.5 mg/kg injections (ED 9-14), then three days of washout with no injection (ED 15-17), followed by a re-challenge with the previous 2.5 mg/kg MPD dose (ED 18). Locomotive activity was recorded for 60 minutes immediately after each injection by a computerized animal activity monitor. The electrolytic CN lesion group responded to the MPD acute and chronic exposures similarly to the control and sham groups, showing an increase in locomotive activity, i.e. sensitization. The dopaminergic-specific CN lesion group failed to respond to MPD exposure both acute and chronically. The glutaminergic-specific CN lesion group responded to MPD exposure acutely but failed to manifest chronic effects. This confirms the dopaminergic system of the CN is necessary for MPD to manifest its acute and chronic

effects on behavior, and demonstrates that the glutaminergic system of the CN is necessary for the chronic effects of MPD such as sensitization. Thus, the CN plays a significant role in the expression of acute and chronic effects of MPD exposure.

Abstract: Somatosensory information is filtered at different levels of the ascending sensory pathway during voluntary movements including grasping. Evidence has shown that the integrity of afferent (sensory) axons projecting through the spinal cord dorsal columns to the brain in humans with spinal cord injury (SCI) is impaired. How sensory input is gated along the ascending sensory pathway during gross and fine grasping in humans with SCI remains largely unknown. To address this question, we assessed somatosensory evoked potentials (SSEPs) from contralateral somatosensory cortex (S1) following the electrical stimulation (intensity 10% of M-max) of the ulnar nerve (600 pulses at 5 Hz, 0.1 ms of duration) at rest and during precision and power grip (at 5 % and 30 % of maximal voluntary contraction (MVC), in humans with and without chronic incomplete SCI. We found in control subjects that sensory gating at subcortical levels and in S1 increased during power grip compared with precision grip with increasing levels of voluntary contraction. In SCI participants, sensory gating occurred at subcortical levels and in S1 during 30 % of MVC to a larger extent during power grip compared with precision grip. These findings indicate that humans with SCI gate sensory input mainly during gross compared with fine grasping behaviors. We argue that this reflects the reorganization of neural pathways following SCI.

Title: Multifinger interaction and coordination in levodopa naive Parkinson's disease patients: An uncontrolled manifold analysis

Authors: *P. B. DE FREITAS, Jr[1], S. M. FREITAS[2], M. M. LEWIS[3], X. HUANG[4], M. L. LATASH[5];
[1]Univ. Cruzeiro Do Sul, Sao Paulo, Brazil; [2]Univ. Cidade De Sao Paulo, Sao Paulo, Brazil; [3]Dept. of Neurol., Pennsylvania State Univ. Dept. of Neurol., Hershey, PA; [4]Dept. of Neurol., The Pennsylvania State Univ., Hershey, PA; [5]Dept. of Kinesiology, Pennsylvania State Univ., University Park, PA

Abstract: According to the uncontrolled manifold (UCM) hypothesis, the total force (F_{TOT}) produced by two or more fingers of a hand is stabilized by co-varied commands to individual fingers. Thus, inter-trial variance in the finger force space is higher in directions that do not affect F_{TOT} (within the UCM) compared to directions that affect F_{TOT} (orthogonal to the UCM), resulting in a signature inequality: $V_{UCM} > V_{ORT}$. This inequality and high action stabilizing synergy are reflected by a high index of synergy ($\Delta V >> 0$). If a person plans to increase F_{TOT} quickly, a high ΔV is clearly ineffective, so the controller reduces ΔV in a predictive manner just before (~200 ms) the change in F_{TOT}. This phenomenon has been addressed as anticipatory synergy adjustments (ASA). Earlier studies reported lower indices of F_{TOT}-stabilizing synergies and smaller and shorter ASAs in individuals with Parkinson's disease (PD). Testing levodopa-naïve PD patients would allow disambiguating the effects of PD from possible effects of long-term exposure to the levodopa. Thirteen levodopa-naïve PD patients and 13 healthy controls performed a variety of four-finger and one-finger tasks including maximal voluntary contraction (MVC). The main task involved four-finger accurate steady F_{TOT} production at 5% MVC, followed by a quick force pulse into the 25%-MVC target, and return to the initial F_{TOT} level. The outcomes used to assess action stability were V_{UCM}, V_{ORT}, and ΔV. The time of ASA initiation (t_{ASA}) and the magnitude of the ΔV_Z drop ($\Delta\Delta V_Z$) provided information about the ASAs. Overall, levodopa-naïve PD patients were weaker (lower MVC) than controls. Also, PD subjects showed a lower synergy index, ΔVz, than controls, due to the high inter-trial variance component affecting F_{TOT} (i.e. V_{ORT}). Moreover, levodopa-naïve PD subjects showed a trend toward shorter and smaller ASAs in preparation for the force pulse, mainly in the non-dominant hand. These

results confirm earlier reports regarding the effects of PD on multi-finger synergy indices. The data show that these differences are due to PD-associated changes in neural circuitry rather than long-term levodopa exposure. Our findings support the idea that changes in indices of multi-finger synergies may be used for early detection of PD-related changes in the basal ganglia, as levodopa-naïve PD patients already show detectable changes in indices of stability.
